DESCRIPTORS Ambiguity; Associative Learning; Data Collection; *Language Research; *Psycholinguistics; *Semantics; *Verbal Learning; *Word Lists

ABSTRACT

Norms of free association to common ambiguous English words are reported. Responses were categorized on the basis of sense relevance. On this basis, the sense dominance of the words was quantified, and the degree of ambiguity associated with each word estimated by the information measure U. This publication will be of interest primarily to researchers in verbal learning and psycholinguistics. (Author)

ASSOCIATION AND UNCERTAINTY:
NORMS OF ASSOCIATION TO AMBIGUOUS WORDS

Charles A. Perfetti, Robert Lindsey, and Blaine Garson

The fact that words have multiple meanings is of interest from a number of points of view. A significant part of a well-known attempt to characterize the formal requirements of lexical representation is devoted to questions of polysemous entries in a dictionary (Katz & Fodor, 1963). On the other hand, multiple meanings can be viewed as theoretically unimportant facts to be dealt with through multiple dictionary entries (Weinreich, 1966). (As a practical matter, lexicographers tend to use single and multiple entries according to etymologies.)

Questions of semantic structure and dictionary making aside, the main purpose for these norms is empirical. Research which relates free associative data to performance has relied on norms of association which take no explicit account of word ambiguity.¹ On the assumption that association data can be analyzed according to meaning, the present work was undertaken to (1) quantify the sense (meaning) dominance of some ambiguous English words, (2) indicate the sense-relevance of free association to these words, and (3) estimate quantitatively the ambiguity associated with each word.

Data Collection

The associations were collected during the 1969-1970 academic year from students at the University of Pittsburgh. A single response was given to each word by 108 subjects. The words were presented on audio tape at an eight-second rate. There were two orders, one being the reverse of the other. Ss were instructed to give the first word that came to mind upon hearing the word, but no mention was made of multiple meanings.

¹Independently, Kausler and Kollasch (1970) and Cramer (1970) have reported norms for homographs. These studies have both used visual presentation of words in contrast to the auditory method of the present study. Cramer's study has the additional difference of restricting all sense judgments to only two categories.

The Words

Associations were given to the 109 words arranged alphabetically on page 7. Words were chosen so as to have at least two distinct meanings. We were not concerned with etymological distinctness, but only with contemporary usage. Thus, while most of the words typically would be found with multiple entries in a dictionary (e. g., bridge, count, rock), some would not (e. g., country, change).

The grammatical form class of the words was of course variable, although only content categories were used. Every word on the list belongs to more than one class, but in no case was ambiguity only a difference in form class.

Frequency of occurrence, as measured by the Kucera and Francis (1967) count for printed English, varied from 1 per million (perch, mug) to 897 per million (well). There were 31 words within the range 0-25; 21 within the range 26-50; 20 within the range 51-100; 20 within the range 101-200; 12 within the range 201-500; and 5 words with frequency greater than 500.

Semantic Judgments

All responses to a given word were listed together on a single page and judged for sense category by five judges.² The expected senses of a word were indicated at the top of a page by a brief definition. Judges indicated their judgments for each response according to the following rules:

1. Each response was categorized according to the judges' determination of which sense would most likely yield the observed response. In most cases this is quite straightforward. The response river to the word BRIDGE goes unequivocally into the sense (span), not into the sense (cards).
2. If a judge thought a response was appropriate for more than one sense, he could mark it as ambiguous (A). For example, wide in response to YARD was judged A between the two senses (lawn) and (unit of measure). Also, responses which involved stimulus repetition or stimulus pluralization were judged A.
3. A third alternative open to the judge was to decide that a response had no clear part of any sense. Examples

² The five judges were Mr. Keith Bromberg, Miss Pat Franklin, Miss Blaine Garson, Mr. Robert Lindsey, and Mrs. Dianne Quinlan.

of this category (X) were picture to TRAIN, past to ROCK, and imagine to LIGHT.

4. In some cases, a sense of the word not anticipated seemed to be reflected in some responses, and a judge could suggest adding another sense category. In such instances, the final decision of whether to add another sense was made by the senior investigator.³

Some responses were obviously based on misperceptions and homophony. These were discarded for the final analysis, which resulted from combining the independent decisions of the five judges. When the judges were divided between two senses, the word was placed in the A category. When the decision was between a sense category and the X category, it was placed in the sense category, unless a majority of judges had put it in X. Occasionally, we overruled the judges by deciding that a judgment was in error due to lack of information on the part of the judge. Thus, a judge not familiar with ice hockey might have incorrectly categorized the response hockey to CHECK.

The Uncertainty Measure

We were interested in a measure which could indicate the degree of ambiguity associated with each word, based on (1) the number of different senses and (2) the relative frequency of each sense, based on the percentage of associations. We finally settled on the information measure U as the most useful and interpretable index.

Consider what might be meant by "maximum ambiguity." A word with an indeterminately high number of equi-probable senses would seem

³That such decisions were sometimes difficult reflects a well-known problem in semantics and lexicography: The number of senses of a word depends on the degree of sensitivity required. Our general approach was pragmatic. If an additional sense was clearly indicated, and if it could be used without increasing the number of responses in the A category, it was used. Thus, we distinguished BAR as (physical object) from BAR as (exclude), because the judges could categorize the responses without dumping very many into A. On the other hand, while we distinguished four senses of CHECK, we did not distinguish between the sense (draft drawn on a bank) and the sense (bill)--which are distinguished in the sentence, "I paid the check with a check." To do so not only would have drawn a line finer than usual, it would have forced us to classify about 35 percent of the responses as ambiguous--e. g., money, pay.

to fit the bill. Accordingly, a word with ten equi-probable senses is more ambiguous than a word with five equi-probable senses. But the word with five equi-probable senses is more ambiguous than the word with five senses that are not equi-probable. The information measure reflects both of these factors which contribute to our intuitive idea of ambiguity.

To obtain the measure (U) for our words, all X and A responses were discarded.⁴ That is, the percentages for sense categories alone were adjusted to add up to 100. The new percentages were then used as probability estimates for the information statistic, $U = \sum_{i=1}^n p_i \log_2 \frac{1}{p_i}$, where, for our purposes, n is the number of senses and p is the probability associated with each sense.

The resulting value is the semantic uncertainty (U) associated with a given word. Since the maximum U depends on the number of senses, a word with two senses has a maximum value of 1.00, less than the maximum value for a word with three, four, or five senses. The full range for the words in the norms is from .16 (SOUND) to 2.09 (FAIR), with a median of U=.92.

The validity of U ultimately depends not only on our classification of responses but also on the number of senses we have allowed a word to have. Note that there are no empty senses. A sense was not established unless our subjects' responses indicated it. Conceivably, additional subjects or different samples would result in responses to an additional sense of the word. Moreover, the question of how many senses to represent is sometimes difficult, as mentioned previously (see footnote 3). However,

⁴This has the effect of adding A and X to the senses in proportion to the existing percentages. For example, if S₁ is twice S₂, the As are assigned to S₁ and S₂ at a 2 to 1 rate. An alternative procedure would be to make the assignment equally, i. e., half to S₁ and half to S₂, but our judgment was that, while neither correction would be totally satisfactory, the preferable assumption was proportionality. A third alternative would have been to use the percentages as given for each sense in the norms to compute U. But this is unsatisfactory, because it underestimates U by ignoring legitimate responses. A fourth alternative would have used X and A as separate categories, in effect treating them as additional senses. While this would reflect the judges' uncertainty, it would overestimate U as we have conceptualized it.

while we offer U with some uncertainty, we think it has some empirical potential.⁵

Use of the Norms

The words are arranged alphabetically in two sections. In the first section, each word is listed with its U value, followed by each sense in descending order of frequency. Each sense (Si) is followed by a number which is the percentage of responses categorized under that sense. Next is a brief sense characterization of Si in parentheses. (This characterization is neither definitive, nor theoretical--it is merely a convenience.) Then, opposite Si is a list of responses in descending order of frequency. Only responses of frequency greater than one are listed here. An exception to this is the case of a sense with no responses of frequency greater than one. Here all the single responses (responses with frequency of one) are listed. After all the senses come the X and A categories and the percentages for each. No response is listed unless its frequency is greater than one. For the A category, the ambiguity refers to all senses except where parentheses indicate the senses involved. Finally, the second section lists the singles for each word, beginning on page 33.

⁵To name just two possibilities, it appears to take less time to process an ambiguous word than an unambiguous word (Rubenstein, Garfield, & Millikan, 1970). U may predict this relationship more exactly. Secondly, the recognition of ambiguous words as a function of verbal context (Light & Carter-Sobell, 1970; Perfetti & Goodman, 1970) may be related to U.
