## ABSTRACT

Primarily a longitudinal and quantitative analysis of achievement functioning, this experiment sought to identify factors which promote or impair the learning of individual children. The 683 Junior High students were divided into one of eight groups according to sex, race and whether their seventh grade Iowa Test of Basic skills composite score was above or below that expected from their Kindergarten Metropolitan Readiness Test performance. The incidence of males and females making unexpected gains (Ups) or losses (Downs) was approximately the same, but a significantly greater proportion of black children made greater than expected achievement gains. Thirty-three Up Ss were then matched with 33 Down $5 s$ according to sex, race, and initial MRT score, and compared along a number of achievement and school-related dimensions in order to identify factors which tend to differentiate Ups and Downs within and between sex and race. Recommendations for further research and replication were provided and methods were suggested for implementing some results into classroom teaching techniques. (Author/SK)

## INTRODUCTION

During the last decade, educators have met little success in increasing the intellectual and academic gains of disadvantaged children (Coleman, et.al. 1966; Equal Educational Opportunities, 1969; Hannah Report, 1967). There may be two chief reasons for the apparent failure of compensatory programs: (1) the programs have characteristically implemented group-oriented enrichment, and (2) they have emphasized IQ gains. It is entirely possible that educational intervention may be more successful if emphasis is given to the motivations, values, aspiration and needs of individual children and their families, and if such steps seek to alter achievement patterns rather than Io's (Scott and Sattel, 1971).

Educational intervention might be more successful if the educational enterprise examined the many ways in which individual students' total milieu mav shape learaing. This would require a shift from theory-weak empiricism of the past to better conceptual formulations and increased methodological sophistication. Independent theories which consider only single variables such as teacher-pupil ratio could thus give way to multivariate experimental designs which deal with the complex interactions which occur in home, school and community (Hermann, 1966).

A number of investigators have focused on achievement in terms of what Barnes (1955) identifies as a complex process of "crystallization" of achievement performances after first or second grade (Ahlstrom and Havighurst, 1971; Kerensky, 1967; Cratty, 1970). Shaw and McCuen (1960) found higher and lower achieving males significantly different beginning at grade three; however, with respect to females, those who later were to become low achlevers tended to exceed the high achievers in grade point average through the fifth grade. At grade six the high achieving females attained a higher grade point average for the first time and the differences proportionately increased.

There is reason to believe that students' success-ratio within the classroom may be increased if we focus on the clusters of quasi-unique characteristics which influence achievement. When the child enters first grade at age six, for example, sbout two-thirds of $I Q$, but only one-third of achievement to age seventeen has been determined (Bloom, 1964). The interaction of $I 0$, achievement, and socio-economic circumstances are illustrated in one study which revealed that students from welfare (Aid to Families of Dependent Children: AFDC) homes achieved similar IQ's, but substantilally lower achievement scores, than comparable children from non-AFDC homes (Scott and Damon, n.t.).

If the achievements of AFDC children reflect the impact of basic home conditions to greater extent than do $I Q^{\prime} s$, it seems reasonable to conclude that effective education will have to identify and cope with non-classroom factors upon which much of all children's learning may largely depend. What seems to be needed is a combination of naturalistic and case-study assessments which assess the growth of individual children within the context of various developmental periods and total milieu.

This study focuses on a single question: Why do some children make broad achievement adyances while others make little if any academic gains? If answers can beilfound for this question, the schools should be in a better position to upgrade educational services for vulnerable as well as notentially gifted children. There is no question but that achievement differences of children vary widely. Using the Iowa Test of Rasic Skills, Stewart (1970) found that average educational gains in fourth and fifth grade ranged from seven to sixteen months for students who were achieving tivn or more grades above actual grade placement and gains ranging from a loss of four months to a gain of eight months for students achicving one or more gradsts below their grade placement. We need to better uncierstand why, and in what vadys, some children learn more rapidly than others.

Other investigators have attempted to identify underachfeving and vulnerable children early so as to strengthen conditions which are conducive to learning. When comparing successful with unsuccessful work-study hovs Ahlstrom and Havighurst (1971) found that the unsuccessfal boys had attended several different schools, and noted as have others (Davidson and Greenburg, 1967), that a good attendanc: record was significant for school achievement. Althouph the Coleman study (1966) found that, when socio-economic factors are stat istically contrdiled, differences between schools account for only a small. fraction of pupil achievement differences, Majeske, et.al. (1972), using the same data, note that most school outcome measures become increasingly more predictable the longer the student stays in school.

To the writers' knowledge, however, no study has yet formulated sufficiently precise guidelines for operationalizing preventive education on the basis of quasi-unique influences within the total milieu of individual students or small groups of students. In their review of the literature, Mackler and Giddings (1965) concluded that very little is really known about the attainment of academic success among disadvaritaged students excent that it occurs with far more than chance frequency. On the other hand, Davidson and Greenberg (1967) searched the student records of 1,331 non-white students before finding 80 students who were academically successful. Scott (1970) noted that it was Ear more difficult to predict that later achievement of non-white students on the basis of reading readiness or teacher evaluation. He noted, however, that predictive coefficients for deprived children were particularly low if the children secured low readiness scores in kindergarten. From this, he siggested that subsequent research may reveal ways in which potentialities of vulnerable children may depend upon a comprehensive understandinf of students' total environment. At the same time, he confectured that there may be a need for a side variety of strategies, depending upon the circumstances of individual. children.

In sum, important questions are presently unanswerable. Why do some students ashieve far less (or more) than what we would expect on the basis of test results or teacher assessment? In what manner do home, school, and community influence students' learning profiles, and how do those learning nrofiles shift during various developmental periods? This experiment seeks to identify environmental factors which promote or impede the learning of individual children, the development of which may facilitate the estahlishment of more effective action-oriented programs.

## METHODOLOGY

The study which is reported here consists of two separate"parts.
FART I. The cumulative folders of all seventh, eighth and ninth grade students in the Waterloo Community School District's two fully integrated funior high schools were examined. Of these 1,237 students, the files of 638 [ 198 white males (WM), 121 black males (BM), 201 white females ( NF ), and 118 black females (BF)] coitained both the Metropolitan Readiness Test (MRT) percentile score and the Iowa Test of Basic Skills (I'rBS) seventh grade comnosite percentile score.

The 638 Ss were divided into three groups according to whether their ITBS score was higher than, similar to, or lower than that predicted hy their MRT performances. It was felt that comparing the MRT, taken by Ss toward the end of the kindergarten year, with the seventh grade ITBS composite score, administered at midyear, would most accurately reflect patterns of elymentary school ( $K-K$ ) learning.

In order to compare MRT and ITBS scores, ITBS Towa grade equivalents rere converted to natinnal percentile scores, and then both the MRT and ITRS national percentiles were converted to $T$ scores.

In comparing the discrepancies between two achievement scorns it vas neressarv to account for the "regression effect" (Thomdike, ligk3) which refers to the ifkelihood that an extreme, score on the MRT tends to be associated with a less extreme score on the ITBS.

The explanation of this phenomenon rests in the fact that ohserved scores are determined by two factors, the true score and measurement error. Their sum is the obtained score. If we assume that measurement error is random, i.e. that no systematic factor influences the error in a particular direction, then the error component is not likely to influence as Ss achievement score in the same direction on the second measure and the $S$ will consequently tend to be less extreme on the second score.

In order to allow for regression factors in identifying uniquely different within-S performances it was decided that Ss making gains of .7 or more of a s.d. would be identified as "ups;" those with losses of or exceering. . 7 s.i. as "Downs;" and those who neither gained nor lost . 7 or more s.d. as "Holds." The cut-off point of .7 was considered valid insomuch as when the solit-half methods is employed

[^0]a difference of $.5 \mathrm{~s} . d$. in the ITBS Reading subtest, for example suggests that a $S$ is performing at least one grade level above or below that predicted by his kindergarten performances on the MRT.

Ss were further differentiated according to sex (male and female) and race (black and white) which resulted in a total of twelve proups. There are a number of reasons for controlling for sex and race in a study of this nature. In the first place school related varlables, such as ability and school performance may be more highly correlated for one group than another. Further, the absolute level of performance may tend to be higher for one group than another. 'This means that if the groups are not separated in analvsis, the magnitude of significance between observed variables and school performances will not accurately reflect the true level for the rroups separatelv.

It is also felt that variables predicting performance for one group may be different from variables predictive for another. Even if the same variables are involved for different groups, the direction of the relationship might differ. If the groups are not separated, these possibilities are obscured. Finally, past failure to control for sex and race differences in academic performance has greatly contributed to our present ignorance concerning the sources of these differences (Levin, 1965).

PART II. The second part of the study identified the course of academic change and specific environmental factors which influenced achievement in children who by seventh grade have shown either sharp gains nr precipitious declines relative to their kindergarten achievement scores.

Up and Down Ss were matched according to three variables: race, sex and initial readiness score. The matching of Up and Down Ss according to MRT scores enabled the experimenters to compare $S$ s who begin first grade equall.v "ready;" but because of a combination of factors, hal.f the ss make achievement gains much greater than expected (Ups) while the other half make achievement gains much l.ess than expected (Down).

It was possible to match 33 of the initial 54 Up Ss with an anmronriate Down S, resulting in a total $N$ of 66 ( $33 \mathrm{Ups} ; 33$ Downs). The exnerimenters recognize that these procedure introduced all the limitations which accomnany a study which utilizes only a few Ss. On the other hand, the small N permits consideration of factors which are often lost in an extensive study which emplovs many Ss. It can be noted, for example, that many of Pjaget's contrihutions have come to us as a result of his observations of the behavior of his three children.

The matched pairs were then compared according to a series of items in the school cumulative records. These included: school absences (K-K) ; number of schools attended; incidence of AFDC families; number of sihlings, third or fourth grade IQ on the Califormia Test of Mental Maturity (CTMM): third grade performance on the Metropolitan Achievement Test (MAT); fourth, sixth and seventh grade performance on the ITBS; and fifth and seventh grade performances on the Iowa Silent Reading Test (ISRT).

With the assistance of personnel from the Waterlon Comminitv Schonls, a questionaire was devised (Appendix $\Lambda$ ) which was to be utilized in interviewing
parents of Ups and Dows on a completely voluntary basis. With this auestionaire an attempt would be made to identify variables in schonl achievement which coul.d be understood in light of home background factors (Coleman, 1.?66). However, after approximately one-third of the $S s^{\prime}$ parents had honn intervieved, a complaint was lodged and because of increasing racial unrest in the faterlno Comminity and in spite of numerous and frequent attemnts by administrators of the Waterloo Schools to allow us to resume, permission to continue uas denied. Consenuentiv. a significant portion of this study remains unavailahle. This is particularly distressing in view of the evidence that school programminf for individual differences might best be implemented through our imprnved understanding of home background.

## RESUTTS

PART I. As shown in Table 1 , of the 638 Ss for whom both MRT and seventh frade ITBS composite scores were available, only 8.5 percent scored .7 or more s.d. higher on the ITBS than MRT (Ups); 40.2 percent experienced corresponiling losses (Downs); 51.3 percent of the $S^{\prime}$ ' ITBS scores failed to exceed a difference of . 7 s.d. from their original readiness measure.

When the Chi-square statistic is applied to the data in Table $\frac{1}{2}$, no significant sex differences are revealed but race is highlv significant ( $\mathrm{X}^{2}=16.4$; df=2; $p$ ( . 001 ) as a variable which determines the predictability of whether is tend toward making greater or less achevement gains than expected. In fact, with one degree of freedom, it is noted that black children exnerience proportionately more. Ups (BM and BF percents of 14 and 11.9 , compared to ! M and NF percents of 5.5 and 6.0 respectively, $p<.01$ ) as well as fewer down ( $B M$ and $B F$ percents of 31.4 and 33.0 , compared to $W M$ and $W F$ percents of 47.0 and 43.4 respectively, $p$. 02). However, no significant racial differences emerged with respect to the incidence of "Holds" ( $\mathrm{X}^{2}=.94$; df $=1, \mathrm{NS}$ ).

PART II. Table 2 indicated that Ss in each group began elementary school with almost identical readiness skills but that by the seventh frade two distinct achievement subgroups had been formed: Ups or Downs ( p < . OOl for HM , BM, HF ; P ( . 05 for BF).

In Tables 3 through 6 within-group or between suhgroun achievement pattems reveal the progressive achievement shifts which result in distinctiv different achievement profiles by seventh grade.

An examination of mean $r$-scores suggests that a great deal of change has occurred in almost all achievement areas within three of the four prouns prior to the third grade. MAT subtest which discriminate Ups and Derwns within each groun include: WM-Reading ( $p<.01$ ) and Arithmetic ( $p<.01$ ): BM--Vord Recognition ( $p<.01$ ) and Arithmetic ( $p<.05$ ) ; WF-Word Recognition, Kord Discrimination, Spelling, and Arithmetic (all $p<.001$ ) amd Reading ( $n<. n 1$ ); RF-none significant.

With respect to the MAT subtest sensitivity, Word Recopnition differentiates Ups and Downs for BM and WF; Word Discrimination for WF; Readinp for WM and WF: Spelling for NF ; and Arithmetic for $\mathrm{KM}, \mathrm{BM}$ and WF .

By the fourth grade Uns and Downs have become significantly fistinct subsroups within the WM and BM as well as WF Ss (Table 4). Black Female lips and Downs differentiate significantly on the Reading Comprehension, Lanfuage and Arithmetic subtest of the ITBS (all p .05), but not on the Vocabularv and Work Studv skills subtests. By the sixth grade Ups and Dorms of all srouns differ significantiv on all ITBS subtest ('rable 5). For WM, BM, and IUF Ss the strength of djfference has increased and, for the first time, BF lins and Dows differ significantly on all achicvement measures.

T'able 6 illustrates increased differentiation betreek I!ps and Downs in neariv all achievement areas ( $p<.001$ in all except $B F$ Language, Arithmetic, and Nork Study SkillsSubtests). It is noted that RF performances on lork Study Skills does not reach significance at the seventh grade level: this seems to result from the fact that Ups experienced no increase in grade equivalent from the sixth to seventh grades ( 5.8 in both), while Downs made modest gains during this one year period.

Table 7 indicates that ISRT distinguishes Ups and Downs amons PM, NF and RF, but not WM , is at both the fifth and seventh grade levels.

The low $N$ appears to have contributed to the fact that Tahle 8 cites only two differences in attendance patterns of Ups and Downs which reached statistical significance, and it should be noted that hoth these differences appear with respect to black males. However, the possibility that most extensive replicatory experimentation, employing a larger $N$, might yield statistical significance is suggested by the fact that in the 27 comparisons between the four groups of Ups and Downs, 18 revealed Downs to be more frequently absent.

Table 9 shows that black Downs were significantlv more mohfie than hlack lps, but that no significant mobility differences were noted with the other three groups. It is also shown on Table 9 that black male Downs were, to a statistically significant extent, more representative of AFDC families than black male Ups but that this was not the care with $S$ s in the other three groups. Finally Table 9 discloses that white femait: Ups had significantly more siblings than white female Downs.

As illustrated in Table 10, in each group Ups secured higher Ins than Downs by third or fourth grade, but that the differences are significant onlv with males (WM, $\mathrm{P}<.05$; $\mathrm{BM}, \mathrm{p}<.01$ ).

## CONCLUSIONS

Primarily a longitudinal and quantitative analvsis of achievement functioning, this research project sought to identify factors which promote or impair the learning of individual children. The first part of the study categorized seventh, eighth and ninth grade $S$ s in each of four groips (BM, WM, BF, WF). Fach sroup was then divided into three subgroups (Ups, Downs, Holds) according to whether their seventh grade achfevement performances were above, below or relatively equivalent to that predicted by a kindergarten readiness measure.

The incidence of girls and boys in the three subgrouns was annroximately the same. However, and contrary to a number of studies which suggest that schools are particularly negligent in facilitating the learning of minoritv proup children (Coleman, 1966; Rosenfield and Hilton, 1971; Vilson, 1969), a sipnificantly greater proportion of black, and not white, children made greater than expected achievement gains.

There may be several possible explanationa for this findinf. First, the situation may be unique to the Waterloo Community School District which has, for a number of years, at tempted to upgrade minority group education (Stewart, 1972). It would seem that there should have been as many Ups as Downs, and the much p,reater incidence of both black and white Downs suggests the possibility that present compensatory educational procedures in Waterloo, stressing as they do larpely disadvantaged students, may have lowered the general achfevement opportunities for still larger numbers of both less disadvantaged and advantaged hlack and white students.

Secondly, there has deen relatively jittle longitudinal research. Most educational research has been horizontal, with prediction of performance limited to one point in time. Contrasted to this, the lonpitudinal approach permits the exploration of predictor variable stability through time. This may explain why the MRT appears to be unsatisfactory as a long term predictive instrument for almost half (Ups plus Downs) of the sample.

As we have seen, Barnes proposes that achievement "crystallization" occurs after Ss were given the MRT and this would appear to explain some of the variance. Moreover, the data from this study suggest that achievement "crystallization" occurs at different developmental periods which mav covarv with sex and race. Replicatory longitudinal studies designed to set at this interaction, appear to be warranted.

Finally, personality variables have been shown to be related to school achievement (Moriarty, 1966; Ahlstrom and Havighurst, 1971; Kerensky, 1967: Tseng and Sonstegard, 1971) and the low predictahilitv of the MR' mav reflect the presence of personality and emotional factors which this study could not fullv consider.

The second phase of the study identified factors which tend to differentiate Ups and Downs within and between race and sex.

WM Ups were differentiated from WM Downs by having: above average as compared to average IQs; higher Reading and Arithmetic achievement from third grade on; and increasingly greater achievement in all areas from fourth grade on.

BM Ups were differentiated from BM Downs by having: average as compared to below average IO; progressively fewer absences which reached significance by sixth grade; less mobility as witnessed by their attending fewer schools; proportionately fewer families receiving, AFDC pavments: higher word Recognition and Arithmetic skills from third grade on; and increasingly greater achfevement in all areas from fourth grade on.

The finding that fourth grade IQ differentiates Uns and Downs among males is consistent with Cotler and Palmer's (1970) conclusion that intercorrelation scores between achievement and IQ data are somewhat hipher for boys than girls (. 84 contrasted with . 73, using IO and Composite ITBS score) for grades four through six.

WF Ups were differentiated from WF Downs by having some siblings, and increasingly greater achievement in all areas from third grade on.

BF Ups were distinguished from BF Downs by having: increasingly higher Reading Comprehension, Language, and Arithmetic skills from fourth grade on; all achievement areas higher in the sixth grade; and al. 1 but Work Study Skills were higher in the seventh grade.

Attempts at identifying home background factors through voluntary parental interviews were stalemated when complaint was issued to Waterloo school administrators who asked that the interviews be terminated. Onlv 22 of the 66 narents had been interviewed and it was thus impossible to assess the interview data.

## RECOMMENDATIONS

This research must be viewed as a pllot study which suggests areas deserving more extensive investigation. The results indicate the significance of both personality and situational variables as they relate to school achievement. Moreover, they indicate that some variables may be specifically related to race and sex. Thus we find some evidence that after fourth grade ahsences of WM and $B M$, but not $W F$ and $B F$, may be suggestive of sex-linked motivational factors. Why are there more absences among male, but not female, nowns? Additional study might also disclose whether BM from AFDC homes are more vulnerable than BF from AFDC homes. Another unanswered question concerns the evidence that mohility impairs the learning of $B M$ to a greater extent than is the case with WM , UF , and BF .

The findings suggest that scores in some academic areas are more effective indicators of later achievement than scores in other areas. For example, arfthmetic skills seem to be a major area of sensitivitv. It is one of the first to discriminate Ups from Downs among all groups. If replication studies should bear this out, it might be feasible to provide children mith first and second grade experiences rich in activities designed to develon arithmetic skills. Subsequent experimentations may disclose that more effective remediation might best be implemented if race and sex is given some consideration. Snecificallv, findings of this study indicate that in addition to arithmetic, word recofnition may be an early priority in plans to individualize instructions.

1. Is the child obedient to parents?
( ) is very obedient; can be depended on to follow all requests with little or no supervision
( ) fairlv obedient; occasionally puts off or fails to do as told
( ) does not obey well ; often says "I won't" or promises and then does not do as told; requires continual watching and chocking on; slow or resistant about doine things.
( ) verr disobedient; hardly ever does as told; seems to make a point of doine the urone things; defiant, or very undependable; resents all requests to do things.
( ) gets mixod up or confused about directions or requests
If the child obeys one parent but not the other, which one is obeyed? Father () Mothor ( )
2. Hou often is the child usually punished?
( ) never
( ) once a week more or less
( ) once a day more or less
( ) several times each day
3. Who usuallv decides on and carries out the punishment? (If more than one person, put check in more than one box; underline person most responsible)
( ) mother
() father
( ) older brother
( ) older sister
( ) prandparent
( ) maid or housekeeper
( ) other person (who $\qquad$
4. What does vour child do on weekends, and who does he do it with? $\qquad$
$\qquad$
$\qquad$
5. How does the child get alone with other children? (check one that fits rour child)
( ) has practicallv no plavmates at all; explain if so
) plavs well with othor children ow apo enjovs it areatly
( ) dates with opposite sox
( ) plars with other childron orm ape
( ) often piots into trouble with othor children unless watched all the time
If child has tronble with others, how?
( ) hurts them
( ) is heat up or picked on by them
( ) airaid of them; can't hold his own with other children
( ) teased a lot hy plavmates and others own are
( ) influoncod by bad companions to rot into tronble or mi sbehavior
( ) is tho loader in rettino companions into trouble or mischief
( ) umonollar with other childron; not invited to partjes, not accepted br rroup, won't play with the other childron in the neionborhood
( ) 口lavs mostly with bigger childron; prefers then to childron nwn size
( ) nlaws majnlv with smaller childreni profers them to own sizo
( ) plays mainlv with children of opposite sex; prefers them to plavmates of own so
( ) handicapped and has difficulty keepirg up with children owm size (exomple: deaf, blind, crippled, heart condition, cerebral pals,r, rhumatic fever).

Ahnut how manv times per week do other children come to plav with this child in vour house or vard? (ostimate the averare)

About how many times per wook does vour child go to the hopie of other children to plar? (estimate the average)
9. If there are brothers and sisters, how does the child get alone with them?
(Check as manv statements as apply corroctly)
( ) no brothers or sisters, or none livine with child
( ) rets alone vary well; groat friends and companions
( ) fairly well, not much friction, they cooperate, spend some time together pleas.
( ) child quarrels considerably with one or more brothers or sisters (who $\qquad$
() ioalous of brother or sister
( ) seels or savs some other child in the family is the favorite
() competes with other child in family: alwavs trving to keep up with, surpass or belittle other child.
() child picked on or bossod by a brother or sister.
( ) child shares a room with one or more hrothers or sisters (whom $\qquad$
( ) criticizes other child very often, or "tattles" on other child.
( ) tries to boss or dominate a brother or sister.
10. Does the child ever earn any monev br working for it?
( ) regularly ( ) once in a while ( ) practicall.v never
Tf so, how?
11. Speech behavior
( ) doesn't talk enouph, even though able to; too quiet
( ) talks too much; is annoving at times
( ) lisps
( ) stutters or stammers
( ) speech is "Jerky"--not smooth
() talks too fast
( ) talks easilv, but words not distinct and clear
( ) talks in strainer, high-pitched or hoarse voice
( ) talks very loudly--yells a lot
() whines a lot; or complains about many thinfs or people
( ) uses bad lanauage, swear, "cusses"
( ) often interrupts others during conversations
( ) may not Hear woll; ofton asks others to repeat what is said, or seems not to understand what is said to him
() has had hearine checked during past vear (if so, where?
( ) anvthing else ur.asual or peculiar ahout speech
12. ITas rour child any nervous habits?
( ) squintine or blinking
( ) thumb sucking.
( ) chewing on pencils or clothes
( ) biting or picking fingornails
( ) scratchine solf often
( ) gritting teeth during sleep
( ) pulling or tivistinf hair
( ) squirmincr or wricpling about
) tics (jerking of muscles, "making faces")
) unisual gestures or mannerisms
13. Child's interests and use of time:
( ) a few interests; plays some games; amuses self a fer minutes at a time, but not very lons; gets tired of new tors after a few dars; or listens th radin or T.V. many hours a day.
( ) about average number of interests for are; enjors play with other childron; knows some games or onjovs plavine with some other tors for a fair lenoth of time; if adolescent, movies, baseball games, lirht reading, listening to radio, watching $T . V .$, runs about with a ganp of friends or "dates."
( ) manv interests; keeps self busy for several hours everv day withnut much difficultr: hard to pet child away from play to eat or go to sleep, etc.; if in school, rearis nows and current events, etc.
( ) unusual interest development for afe: enpares in one or more active hobbies fnr long periods with considerable skill, plans activities ahead, organizes contructive proup activities, reads important books, studies serinusly subjects besides school assignments, plays with tovs creatively. Child never ras enough time to do all the things likes.
( ) strong interost development, but "lopsided," not well balanced; for examnle: spends too nuch time readinf (a "bool "pangi" interestod in dangerous activiites or peculjar ideas; suends too moh time roing studv with just one girl-friend or boy=friend; fascinated br nlaving with fire, fums, speeding in cars; power, religion, monev, his appearance, clothes, health or diseases, deatr, "crime;" sponds too much time on schnol work.

That are the child's favorite activities and interests, if anrr?
14. 'Shat do vou anticipate your ohild will be doinf, ten vears from now?

That does your child expect to be doing ten years from no:s?
15. Child's ar justinent to school:

If child is botweon 5 and 18, oheck all items whioh applv
( ) cht?d is makinp, excollent arademic propross; grades better than averare
( ) is nakine about avorare grintes and profress
( ) Ls makinf slov progross jr. school; poor prades
( ) has failod ( lot boon pr mot.cd)
() onco ( ) trice ( ) 3 times, sinoe berinning school
( ) is excuser from certain classes in school ( example: physical ed.)
( ) is sometimes truant from school (plays hooker)
( ) dislikes school in peneral
( ) behavior or conduct at school a problem
( ) has trouble with other children roins to or from school
( ) worrios a lot ahout failing in school
( ) bored with school bocause it is too easy
( ) child daudreams much of the time
() wary stubhorn, willful; or shows a nerative attitude much of the time.
(!) dislikes schonl in foneral
15. Please comolete the following statements True or False.
1. Ton much nonsense poes on in school
2. School can bo verv borine at times
3. There's too much importance placed on prades
4. Most puppils learn what ther have to learn, oot hecause the"
want to leam
5. Too much of what we have to study does not make sense
$\therefore$ Pupils have to keop reading anc studrine the same old thines
over and over
7. Teachers expect ton much of pupils
8. Most pupils are not interested in learnine
O. Some pubils are alwars makinct fom of other pupils in the
classrnom
10. Teachers aro ton hossy
11. Teachers alwavs seem to like some pupils hetter than others
12. Pupils do not have much freerom in school
13. Teachers reall. do not understand children
14. Pupils are treated fairle in schnol
17. Child seems to dislike to be home:
( ) often is late or missos meals; soldom plays at home; is awar much of the time wi thout lettiner parents know where
( ) child complains a lot or criticizes home
( ) or often finds fault with paronts
18. Does the child imitate or strongly resemeble some other person or persons in behavior or personalitr? :hom, and how?

$\qquad$
19. Do vou sometimes helieve that when your child jis tome from schnol sick he really mav not he sick but not want to fo to school? $\qquad$
20. Famjily hoalth:
A. "ow and past vear.
( ) exceptionally hoalthe, very strong, sturdi, practicall\% never ill
( ) hotter than averape; rarelv ill and then orly one minor illness
( ) averape; occasional colds rurine past vear, or a few minor illnesses
( ) holow averafe; no or more illnesses of twn weeks or loneor; or many severe colds, low vitality
( ) very ponr health, suffors from a sorious illness, or very frail and easilv or nften sick, or neoded two or major operatíns, etc. .
23. Fow effective have these community aroncies been in belping you raise rour child? very
ro need to use not, helpful somewhat moderatelv harmful

D. Mistory of health:

List all ifeeases child has had sinco birth, ircludine measles, whonping couch, etce. and montion if thore was a fevor or rash, or anv striking. chanpo in tho child following the illross.

Trps of unusunl illnoss or accidonts (include all tospitalizatinn)
Tupe
Ago Time Jost from schnol.

Sevoritv of illness

1. $\qquad$

2. $\qquad$
3. $\qquad$
4. $\qquad$
5. 

${ }^{6}$
C. Does the child have any of thoso fairly often or all the time?

21. Fow many timos havo family mombors heon hosvitalized?

Has ant fami ly membor of clnso firiond of the shild djes? If so, who and when?
22. How often do you attonci school functions? talk with school porsonnel?
$\qquad$ attond PrA?
heve parent-tcact or canforences?
opan house?
class plavs?
other?

[^0]:    *We are greatly indebted to Dr. A. N. Hieronymus, nirector of the Iowa Basic Skills Testing Program at the University of Iowa for calling our attention tis the regression effect and also for his personal. and immediate attention to our need for current tables which would allow us to convert JTBS grade equivalents to nacional percentile norms and to national prade equivalents.
