ABSTRACT

Conducted as part of a 5-year longitudinal study of 5,159 young women in the national civilian noninstitutional population who were 14 to 24 years of age at the time of the initial (February 1968) interview, this progress report contains the results of the second interview and describes the magnitude and patterns of changes in personal, educational, and labor market experience that have occurred since the initial interview. Of those originally interviewed in 1968, 96 out of 100 were reinterviewed in 1969, and analysis of this data revealed that: (1) Black girls were more likely than white girls to drop out of school before completing the twelfth grade, (2) Approximately three in ten young women had revised their educational goals with one in eight raising their goals and one in six lowering their goals, (3) Approximately one-third of the young women employed at the time of both surveys made at least one interfirm move during the period, (4) job changes were associated with larger increases in hourly wages and with increased job satisfaction, and (5) White young women have substantially more labor market knowledge than black young women. Results of the initial survey are reported in ED 049 376. (SB)

This report was prepared under a contract with the Manpower Administration, U.S. Department of Labor, under the authority of the Manpower Development and Training Act. Researchers undertaking such projects under Government sponsorship are encouraged to express their own judgment. Interpretations or viewpoints stated in this document do not necessarily represent the official position or policy of the Department of Labor.

FOREWORD

This volume is a brief progress report on a longitudinal study of the educational and labor market experience of young women. In early 1965, the Center for Human Resource Research, under a contract with the U.S. Department of Labor, began the planning of longitudinal studies of the labor market experience of four subsets of the United States population: men 45 to 59 years of age, women 30 to 44 years of age, and young men and women 14 to 24 years of age.

Cost considerations dictated limiting the population covered; given that constraint, these four groups were selected for study because each faces special labor market problems that are challenging to policy makers. In the case of the older male group, these problems are reflected in a tendency for unemployment, when it occurs, to be of longer-than-average duration and in the fact that average annual incomes of males decline continuously with advancing age beyond the mid-forties. In the case of the older of the two groups of women, the special problems are those associated with reentry into the labor force on the part of a great many married women after their children no longer require their continuous presence at home. For the young men and women, of course, the problems are those revolving around the process of occupational choice and include both the preparation for work and the frequently difficult period of accommodation to the labor market.

While the more-or-less unique problems of each of the subject groups to some extent dictate separate orientations for the four studies, there is, nevertheless, a general conceptual framework and a general set of objectives common to all of them. Each of the four studies views the experience and behavior of individuals in the labor market as resulting from an interaction between the characteristics of the environment and a variety of economic, social, demographic, and attitudinal characteristics of the individual. Each study seeks to identify those characteristics that appear to be most important in explaining variations in several important facets of labor market experience: labor force participation, unemployment experience, and various types of labor mobility. Knowledge of this kind may be expected to make an important contribution to our understanding of the way in which labor markets operate and thus to be useful for the development and implementation of appropriate labor market policies.

For each of the four population groups described above, a national probability sample of the noninstitutionalized civilian population has been drawn by the U.S. Bureau of the Census. Members of each sample are being surveyed periodically for five years. This

report is the second in the series of the younger group of women. It summarizes some of the information yielded by the second round of interviews conducted between mid-December 1968 and mid-March 1969. Our focus here is upon changes in educational attainment and educational aspirations, interfirm movement, geographic mobility, and the extent of occupational information possessed by the respondents. We had intended to analyze changes in labor force participation and unemployment rates, but were prevented from doing so by a coding error involving labor force and employment status. This error, of course, is being corrected. Using tabular data, the report is intended primarily as a progress report on the longitudinal study. More intensive multivariate analyses of the data are underway and will be reported elsewhere. The unique nature of some of the tabular data already in hand, however, argues for our presenting it at this time.

John R. Shea
Associate Project Director

ACKNOWLEDGEMENTS

Both the overall study and the present report are products of the joint effort of a great many persons. The research staff of the Center has enjoyed the continuous expert and friendly collaboration of personnel of the Bureau of the Census, which, under a separate contract with the Department of Labor, is responsible for developing the samples, conducting all of the interviews, processing the data, and preparing the tabulations we have requested. We are indebted to Daniel Levine and Earle Gerson who have, in turn, served as Chief of the Demographic Surveys Division; to Carrol Kindel, our principal point of contact with the Bureau; to Marie Argana, the former Chief of the Longitudinal Surveys Branch, and to Robert Mangold, its current Chief. We also wish to acknowledge our indebtedness to James Johnson and the interviewing staff of the Field Division, who were responsible for collecting the data; to Eleanor Brown and David Lipscomb of the Systems Division for editing and coding the interview schedule; and to Betty Dobronski, Benny Sharp, and their associates for the computer work.

The advice and counsel of many persons in the Department of Labor have been very helpful to us both in designing the study and in interpreting its findings. Without in any way implicating them in whatever deficiencies may exist in this report, we wish to acknowledge especially the continuous interest and support of Howard Rosen, Director of the Office of Research and Development of the Manpower Administration, and the valuable advice provided by Stuart Garfinkle and his successor Frank Mott and by Jacob Schiffman, who, as our principal contacts in the Office of Research and Development, have worked closely with us from the outset.

We also wish to acknowledge the contributions of other members of the Center's staff. Herbert Parnes, Director of the Project, provided us with his always valuable insights and reactions. Other colleagues who gave us the benefit of their reactions to an earlier version of the manuscript are Arvil V. Adams, Andrew Kohen, James Murphy, Edward O'Boyle, and John R. Shea. Ellen Mumma and Regina Parks were responsible for checking the manuscript and for maintaining the necessary liaison with the Census Bureau. Finally, we wish to thank Dortha Gilbert and Kandy Bell for typing this and earlier versions of the manuscript.

What changes occur during the course of one year in the educational and labor market status of young women? To what extent do 14- to 24-year-old women leave or return to school, revise their educational and/or occupational goals, change jobs, and alter their labor force and employment status? Moreover, what are the correlates of such changes? This report addresses questions such as these.

In early 1968, interviews were conducted with a national probability sample of 5,159 young women 14 to 24 years of age who were in the civilian, noninstitutional population.¹ The results of that initial survey, which was designed to set the stage for the five-year longitudinal analysis to follow, have been reported in the first volume of this series.² The present volume, based on data from the first and second surveys, is intended merely as a progress report on the longitudinal study. Its principal purpose is to describe the magnitudes and patterns of change that have occurred during the one-year period. The central focus is upon changes in educational and labor market status, but changes in other characteristics of the respondents are examined for their effects upon educational or labor market experiences.

In the remainder of this chapter the extent of attrition from the sample between 1968 and 1969, movement out of the formal school system and between levels within that system, and changes in the educational aspirations of high school students are described. In Chapter 2 we look at movement among employers and among geographic areas. In Chapter

* This chapter was written by Joseph M. Davis.

1 For a description of the sample design, see Appendix B.

2 John R. Shea, Roger D. Roderick, Frederick A. Zeller, Andrew I. Kohen, and Associates, Years for Decision: A Longitudinal Study of the Educational and Labor Market Experience of Young Women, vol. 1, U.S. Department of Labor, Manpower Research Monograph no. 24 (Washington, D.C.: U.S. Government Printing Office, 1971).

3 the extent of occupational information among young women is considered and is related to enrollment status, family background, and labor market variables. Chapter 4 contains a summary of the major findings.

I ATTRITION FROM THE SAMPLE

Of the 5,159 members of the sample interviewed in 1968, only 4.3 percent (226) were not reinterviewed in 1969 (Table 1.1). Two percent of the sample refused to continue their participation, 2.0 percent could not be located by Census interviewers, and an additional 0.3 percent were not interviewed for other reasons such as temporary absence from the home, institutionalization, or death. There was very little intercolor difference in attrition: 4.0 percent of the blacks and 4.3 percent of the whites left the sample.³ School enrollment status in 1968 is strongly associated with attrition from the sample: of those enrolled, 3.0 percent of the whites and 2.1 percent of the blacks left the sample; of those not enrolled in 1968, 5.7 and 5.6 percent of the whites and blacks, respectively, were not reinterviewed in 1969, largely because they could not be located. Tables 1-A-1 and 1-A-2 at the end of the chapter examine attrition from the sample, controlling for selected demographic, social and economic characteristics of the respondents. For those not enrolled in school, attrition rates were highest among white domestic service workers, blacks who were opposed to mothers of pre-school-age children working, and blacks with 13 or more years of education. Highest attrition rates for the enrolled occurred among unemployed blacks and married⁴ whites.

II COMPARATIVE SCHOOL ENROLLMENT STATUS 1968 AND 1969

There is considerable empirical evidence of a strong association between educational attainment and a host of labor market success measures. As well as being a measure of knowledge and skills, it is widely held that educational attainment is a proxy for many other characteristics which influence an individual's performance in the labor market. Consequently, it is important to identify those factors which influence the amount of education a young woman obtains.

3 The term "blacks" refers only to Negroes; "whites" refers to Caucasians. Other races are not considered separately but are included in grand totals.

4 "Married" refers only to those who were married, spouse present. "Nonmarried" refers to those who have never been married or who are widowed, divorced, separated, or married, spouse absent.

Table 1.1 Attrition Rate between 1968 and 1969 Surveys, by Reason, 1968 Enrollment Status, and Color

1968 enrollment status and color	Total number 1968 (thousands)	Percent refused	Percent unable to locate	Total attrition rate ^a
All respondents	18,053	2.0	2.0	4.3
Whites	15,831	2.0	2.0	4.3
Blacks	2,222	1.4	2.3	4.0
Enrolled in school	9,100	1.7	1.0	2.9
Whites	8,067	1.7	1.0	3.0
Blacks	1,033	1.4	0.7	2.1
Not enrolled in school	8,953	2.2	3.1	5.7
Whites	7,764	2.3	3.0	5.7
Blacks	1,189	1.4	3.7	5.6

^a Includes some respondents who were not interviewed for other reasons such as temporary absence from the home, institutionalization, or death.

Two important questions concerning the educational attainment of young women may be addressed with the data in hand: what characteristics are associated with dropping out of high school; and, what are the correlates of attending college immediately upon completion of high school? Analysis in the initial volume on this cohort indicated that, at least among whites, educational attainment is strongly associated with family background variables.⁵ We expect the same kinds of variables to influence dropping out of high school and enrolling in college. Nevertheless, we have reason to believe that some factors are more powerful predictors of dropping out than of transition to college. For example, economic considerations may be especially salient in movement to college, whereas pregnancy and child-bearing may be relatively more important in accounting for premature withdrawal from high school.

Of those respondents who were reinterviewed in 1969 and who had been enrolled in school in 1968, 88 percent of the whites and 76 percent of the blacks were still enrolled in 1969. Of those respondents who were interviewed both years who were not enrolled at the time of the initial survey, 4 percent of each color group had returned to school by the second survey (Table not shown).

Correlates of Dropping Out of High School

Among those respondents who remained in the sample, high school dropout rates for white and black girls for the one-year period were 4 and 11 percent, respectively.⁶ However, because of attrition from the sample, this probably underestimates the actual dropout rate, for if our suspicion is correct that young women who were not reinterviewed had a higher high school dropout rate than did those reinterviewed, the understatement is even greater.

Comparing these rates with the one-year high school dropout rates (unadjusted for attrition) among the young men in the same age category indicates that white young men and women are about equally likely to drop out of high school (5 and 4 percent, respectively) while black young women are somewhat more likely than are young black men to drop

5 Shea et al., Years for Decision, 1:30-32.

6 These rates, unadjusted for attrition from the sample, are based on the number of young women in grades nine through eleven at the time of the first survey.

out (11 versus 7 percent).⁷ Research on the relationships among race, socioeconomic status, and leaving school before graduation typically has found that intercolor differences in dropout rates actually reflect differences in socioeconomic status.⁸ This topic will be more fully examined below; it is worth noting here that black youth also tend to be older than white for any given grade in school, and dropout rates from high school are strongly related to age-grade lags (Table 1.2).⁹

Table 1.2 Mean 1968 Age and High School Dropout Rates between 1968 and 1969 by Grade Level in 1968 and Color: Re-enrolled in 1968 Enrolled in Grades 9 to 11 in 1968

9 See Shea et al., Years for Decision, 1:19; Zeller et al., Career Thresholds, 2:22.

For blacks and whites alike, dropping out of high school seems to be associated with having a father who was not a high school graduate and with having attended a high school in the South (Table 1.3).¹⁰ Among whites, respondents with urban backgrounds are somewhat more prone to drop out of high school than are those from nonurban areas, although this relationship does not prevail for blacks.¹¹

Not surprisingly, high school girls who in 1968 had aspired to a high level of educational attainment, viz., to four or more years of college, had much lower rates of dropping out of high school than did girls with lower aspirations. Only 1 percent of the young white and 4 percent of the black women who aspired to a bachelor's degree left high school before graduation while about 6 percent of the whites and 17 percent of the blacks with lower aspirations dropped out of high school.

Transition from High School to College

White young women who were high school seniors in 1968 were twice as likely as their black counterparts to be enrolled in college in 1969 (52 compared to 26 percent) (Table 1.4). These rates are 12 percentage points lower in each color group than those for a comparable group of young men one and one-half years earlier.¹²

As was true for high school dropout rates, rates of college entrance are related to demographic and socioeconomic background variables, although in a somewhat different manner. College attendance is positively related to father's education, among whites at least, and is much more prevalent among respondents from urban areas. On the other hand, unlike high school dropout rates, there are no systematic South versus non-South differences in rates of college entrance. For both blacks and whites, movement into college is directly related to educational goals in 1968. It is especially noteworthy that fully 85 percent of the white young women who in 1968 reported aspirations for a college degree were enrolled in college in 1969.

¹⁰ South includes the South Atlantic, East South Central, and West South Central Census divisions.

¹¹ The urban-nonurban distinction is based upon the respondent's residence at age 14.

- a Includes a few respondents repeating the twelfth grade in 1969.
b Excludes respondents with father deceased in 1968.
c Percentages not shown where base represents fewer than 25 sample cases.

In summary, the intercolor variation in the probability of attending college immediately following high school is much larger than the intercolor variation in the likelihood of completing high school. Neither difference, however, seems to be much affected by controlling for the variables just considered.

III CHANGES IN EDUCATIONAL ASPIRATIONS OF HIGH SCHOOL YOUTH

As has been demonstrated in the previous section, educational attainment is strongly related to educational goals. In this section, we turn our attention to an examination of changes in the educational aspirations of high school students between the two surveys. Although there has been a great deal of research on the determinants and consequences of the educational aspirations of young men and women, analyses of year-to-year changes in such aspirations have been attempted only infrequently.¹³ In our earlier report based on the first survey of the young women, we noted that, in the aggregate, their educational goals were unrealistically high in light of known trends in educational attainment among women. It appears highly unlikely, then, that all young women in our sample will realize their educational goals. This raises the important question of what determines whether a young woman maintains or changes her educational goals.

Changes in Educational Aspirations

For both color groups, about seven-tenths of the young women enrolled in high school or below both years held the same aspirations in 1969 as in 1968 (Table 1.5). About one in eight had raised their aspirations, and almost one in six had lowered their educational aspirations.¹⁴

¹³ Among the exceptions are the longitudinal study of tenth graders by Jerald G. Bachman and Associates, reported in Youth in Transition, vol. 3 (Ann Arbor, Michigan: University of Michigan Institute for Social Research, Survey Research Center, 1972) and the longitudinal survey of the cohort of young men from the National Longitudinal Surveys, as reported in Zeller et al., Career Thresholds, vol. 2, and in Andrew I. Kohen and Herbert S. Parnes, Career Thresholds, vol. 3, U.S. Department of Labor, Manpower Research Monograph no. 16 (Washington, D.C.: U.S. Government Printing Office, 1971).

¹⁴ The elimination of high school dropouts from the universe under consideration here almost certainly has resulted in understating the proportion of the 1968 sample who revised their goals downward.

Table 1.5 Comparison of Educational Goals, 1968 and 1969, by Grade Attending in 1968, Educational Goal in 1968, and Color: Respondents Enrolled in High School or below Both Years

a Includes a few respondents enrolled in the twelfth grade both years.

b Percentage distribution not shown where base represents fewer than 25 sample cases.

Among the whites, but less clearly so among blacks, the higher the grade in school in 1968, the greater the likelihood of a rise in educational aspirations between 1968 and 1969. Other intercolor differences, however, are slight. Fully one-fourth of the young women in both color groups who aspired to 16 or more years of education in 1968 had revised their aspirations downward by 1969. This result is in line with our expectation of a lowering of unrealistic goals over time. An interesting intercolor difference obtains among those respondents whose educational goal in 1968 was 14 years (i.e., two years of college). While equally likely to revise their aspirations upward, whites are more than twice as likely as blacks to revise downward (22 percent versus 9 percent).

When asked why they had changed their goals, the overwhelming majority of respondents cited "interest" as their reason for having done so, irrespective of the direction of change. Interestingly, "economic" reasons were rarely mentioned in connection with raising goals and only infrequently mentioned (about one in ten responses) as the reason for downward revision.

Correlates of Downward Revision of High Goals

We turn now to an examination of a number of factors that appear to be related to a downward revision in educational aspirations. This examination is restricted to those who were enrolled in high school in both 1968 and 1969 and who had aspired to 16 or more years of education when first interviewed in 1968. The latter restriction was imposed because in most instances there are insufficient sample cases for analysis of young women with lower initial year aspirations.

As might be expected, young women who had aspired to four or more years of college in 1968, but actually expected to receive less, were relatively more likely to revise their aspirations downward (Table 1.6). Whereas less than one-fourth of the whites and blacks who had expected to receive a college degree had revised their goals downward, as many as one in three with lower expectations than aspirations in the base year had revised their aspirations downward by 1969.

A strong positive relationship exists between family income and stability of high educational aspirations (Table 1.7). Among the whites, 31 percent from families with incomes under \$6,000, 25 percent from families with incomes ranging from \$6,000-9,999, and 20 percent with incomes over \$10,000 lowered their aspirations. The relationship is even more striking among blacks: i.e., the corresponding percentages are 32, 22, and 11. This intercolor difference suggests that high-income blacks have more stable educational goals than do high-income whites.

The lowering of high educational aspirations is also largely negatively related to father's education. Since father's education generally bears a strong positive correlation with family income, this

result is to be expected. The relationship appears to hold for both whites and blacks, although among blacks with 12 or more years of education the number of sample cases represented does not allow a confident conclusion.

Among whites, the likelihood of having lowered educational aspirations is negatively associated with age. Thirty percent of the 15-year-old whites lowered their goals as compared to 24 percent of the 16-year olds and 21 percent of the 17-year olds. Among blacks, no clear direction of association can be discerned. We noted in the first volume of this study that, on average, blacks held higher educational aspirations in 1968 than did whites.¹⁵ We also know that whites are more likely to achieve their educational goals. The relatively high rate of downward revision among 15-year-old whites suggests that whites tend to bring unrealistically high aspirations into line with reality earlier than do black girls. The latter seem not to do this until they are older and are confronted directly by the difficulties associated with obtaining higher education.

CHANGES IN JOB STATUS OF OUT-OF-SCHOOL YOUTH

In this chapter we focus principally upon the work records of those who were out of school and employed at the time of the surveys in both 1968 and 1969. In the first section we examine changes in hourly earnings between the two survey dates for those young women employed as wage and salary workers both years. In Section II the nature, extent, and correlates of interfirm movement are considered. The extent and correlates of geographic mobility are dealt with in Section III.

I CHANGE IN RATE OF PAY, 1968-1969

Of those young white women who were out of school and employed as wage and salary workers in both years, mean hourly earnings increased by \$.32, or 16 percent (Table 2.1). For their black counterparts, the absolute increase was only one-half that of the whites (\$.16), and the relative increase was only 9 percent.

1968 Occupation

Increases in hourly rates of pay vary considerably by major occupational category. Among white youth, those in white-collar occupations clearly display the greatest percentage increases in mean rates of pay, ranging between 16 and 20 percent (Table 2.1). Whites who were blue-collar workers in 1968 received the lowest relative increases (5 percent), with those who held nondomestic service jobs gaining only slightly more (8 percent). Among blacks, the variation is even greater. The hourly wage rate of domestic service workers rose by 72 percent, while the wages of nondomestic service workers remained virtually unchanged. The white-collar and blue-collar increases were 10 percent and 15 percent, respectively. A look at the 1969 level of wages shows that wages for whites exceeded those for blacks in all the occupational categories except clerical-sales¹ and blue-collar, where near equality existed.

* This chapter was written by Roger D. Roderick.

¹ The somewhat higher wage rate of black clerical-sales workers vis-a-vis white clerical-sales workers in both 1968 and 1969 is largely a function of the relatively greater concentration of blacks than of whites within clerical rather than sales occupations.

Table 2.1 Selected Measures of Change in Rate of Pay between 1968 and 1969, by 1968 Occupation and Color: Respondents 18 to 25 Years of Age, Out of School and Employed as Wage and Salary Workers in 1968 and 1969

Education

When the young women are classified by educational attainment (Table 2.2), the mean hourly earnings of blacks are below those of whites in every educational category for which the number of sample cases is sufficient for confident estimates. Moreover, the black-white relative differentials are greater in 1969 than in 1968 for all but those at the lowest level of education, for whom the differential remains constant. Thus, the already-disadvantaged position of black young women relative to white deteriorated even further between 1968 and 1969.

High School Curriculum

Our examination of the relationship between the curriculum from which a respondent graduated and her subsequent hourly earnings is limited to those with exactly 12 years of education. This restriction was imposed because other educational categories do not contain sufficient numbers of sample cases to warrant consideration, and educational attainment must be controlled because of the intercorrelation between curriculum and educational attainment on the one hand and between educational attainment and wage rate on the other. In 1969, as in 1968, the hourly rate of pay for respondents from the general curriculum was lower than for graduates of other curricula; furthermore, the relative differentials had increased by 1969 (Table 2.3). These relationships generally prevail within both color groups, although there are too few sample cases of black graduates from college preparatory programs to permit confident wage estimates for them.

It is worth noting here that among those white young women who have some college experience the relative increases in rates of pay for graduates of college preparatory programs exceed those for respondents who were enrolled in the general curriculum while in high school (Table not shown). Certain factors must be taken into account in interpreting this relationship, however. For example, we do not know whether this relationship will hold over a longer period of time. Furthermore, to the extent that it does hold it is still unclear whether this reflects program differentials per se or differences in ability which students bring to the program.

II INTERFIRM MOVEMENT, 1968-1969

Any respondent whose 1969 employer was other than her 1968 employer is said to have made an interfirm move. All others are

classified as not having experienced such movement.² As should be expected of young women in the early stages of their work careers, a substantial volume of interfirm movement was reported for the period. Of the 3.2 million young women out of school and employed in both years,³ approximately one-third changed employers between 1968 and 1969. Where we present interpretations of these data, it is with the qualification that, due to a problem in the original questionnaire, we are unable at this time to distinguish between voluntary and involuntarily separations.⁴

Correlates of Interfirm Movement

Education Interfirm movement is greater for those who have not completed high school and for those who have gone on to college than for those who have exactly 12 years of education (Table 2.4). This is as expected, although the reasons for and the implications of the mobility among the nongraduates clearly differ substantially from those for the young women with college experience. Interestingly, interfirm mobility rates are almost identical for blacks and whites at each of the two higher levels of educational attainment, whereas movement among the blacks with less than a high school diploma is considerably greater than among the white nongraduates. This is probably a reflection of the relatively greater difficulties encountered by the less-educated black (vis-a-vis the less-educated white) in her early labor market activity. Among other things, the average educational attainment of the black nongraduate is less than that of the white nongraduate.

2 Our measure undoubtedly understates the total amount of movement among young women during the year for three reasons. First, it refers to the number of movers and not to the number of moves made over the course of the year. Second, the proportion who were not reinterviewed in 1969 probably contains a disproportionately large number of young women who changed employers during the period. Third, it counts as nonmovers those who left their 1968 employer and then returned to that employer by the time of the 1969 survey.

3 The data in this section generally pertain to respondents who were not enrolled and who were employed at any job during both the 1968 and 1969 survey weeks.

4 The questionnaire has since been redesigned so that later surveys will enable us to differentiate between voluntary and involuntary separations. Furthermore, retrospective data are being gathered in an attempt to rectify this initial oversight.

1968 occupation An examination of mobility rates within major occupational groups supports the above speculation. It is within the domestic services, where the socioeconomic rewards as well as the educational requirements are low, and where more than 10 percent of the blacks were employed in 1968, that changes of employers among blacks are particularly high (Table 2.5). In none of the other occupational categories is interfirm movement noticeably greater among blacks than among whites.

Table 2.4 Proportion Making Interfirm Changes, 1968 to 1969, by Highest Year of School Completed and Color: Respondents 18 to 25 Years of Age, Out of School and Employed in 1968 and 1969

Highest year of school completed	WHITES		BLACKS	
	Total number (thousands)	Percent interfirm changers	Total number (thousands)	Percent interfirm changers
Less than 12	276	34	104	46
12	1,845	28	194	26
More than 12	759	36	74	35
Total or average	2,879	31	372	34

With the exception of the domestic services--for which it admittedly may not be meaningful to talk about employer change in any case--the nondomestic service classification contains the highest frequency of interfirm movement (45 percent for each color group). This identical rate for both blacks and whites is of note, given the intercolor differential in three-digit occupational distribution within the nondomestic services. Within the two remaining major occupation categories, mobility rates are substantially lower for both whites and blacks. Among blacks, white-collar and blue-collar workers are about equally likely to have made at least one employer shift (25 and 24 percent, respectively). On the other hand, white young women in white-collar positions are substantially more likely than are those in the blue-collar group to have moved (30 percent versus 22 percent). Finally, a comparison of these white-collar/blue-collar relationships with those which were found in the second survey of the young men is of interest. There, whites in blue-collar occupations were found to be one-and-one-half times as mobile as those in white-collar jobs, while among blacks the white-collar workers were more

mobile.⁴ This discrepancy may be in part a function of the male-female differential in distribution among the three-digit occupations that comprise the white-collar and blue-collar groups.

Length of service in 1968 job One of the axioms of labor market behavior is that the probability of job separation declines substantially as length of service with an employer increases. In part, this reflects the fact that the early period of service is one of "trial," from the viewpoint of both the employee and the employer. It also reflects the fact that both parties' investment--economic, social, and psychological--increases with the passage of time. Furthermore, the effect of institutional arrangements is in the same direction. For example, layoff rules by and large are such that the probability of layoff decreases with increased tenure. It is not surprising, then, that even though the age of these respondents precludes long tenure, interfirm mobility decreases monotonically with increasing tenure for both the whites and blacks (Table 2.6).

In the case of white women 40 percent of those who had been in their 1968 jobs for less than one year had changed employers by 1969. This proportion is 20 percent for those with from one to four years of service and 10 percent for those with five or more years. For blacks, the corresponding figures for the first two categories of service are essentially the same as for the whites, 41 and 23 percent, respectively. The longest service category contains too few sample cases in the case of blacks to warrant discussion.

Rate of pay, 1968 We had anticipated that respondents whose 1968 hourly rates of pay were relatively low would be more likely to have changed employers by 1969 than would those whose wages in the base year were higher. We expected this relationship in part because we had hypothesized that dissatisfaction with low wages would lead to voluntary quits and in part because of the association between low wages and short tenure. The data generally support the anticipated inverse relationship, both among whites and among blacks (Table 2.7). Black respondents who earned less than \$1.50 per hour in 1968 are nearly twice as likely to have changed firms as are those who had earned \$1.50 to \$1.99 per hour, and four times as likely as those whose wage rate had been \$2.00 to \$2.99 per hour. The pattern among whites, while somewhat less pronounced, generally resembles that among blacks.

Job satisfaction, 1968 One method of assessing job satisfaction is to examine respondents' attitudes toward their jobs. Interfirm movement between 1968 and 1969 was strongly related to 1968 expressions

b Universe restricted to those who were wage and salary workers in 1968.

of job satisfaction (Table 2.8). The data here support our expectations that the dissatisfied would be more likely than the satisfied to change jobs, and that there would be a noticeable difference in mobility between young women who had reported that they liked their jobs "very much" and those who had said they liked their jobs "fairly well." Among whites, the most satisfied were substantially less likely than were the dissatisfied to change jobs, and for both color groups those who had earlier reported that they liked their jobs "very much" were noticeably less likely than those who had said that they liked their jobs only "fairly well" to have made an interfirm move.

Job attachment In the initial (1968) survey, employed respondents were asked the following question: "Suppose someone in this area offered you a job in the same line of work you are in now. What would the wage or salary have to be for you to be willing to take it?" This question was designed to identify propensity to respond to perceived differentials among jobs, and should not be interpreted as merely another measure of job satisfaction. In each of the other cohorts in the National Longitudinal Surveys, this measure of propensity to move has shown a clear positive relationship to job satisfaction.⁵ In contrast, no consistent relationship in either direction was found to exist between degree of satisfaction and job attachment in the case of young women.⁶

If the question involving the hypothetical job offer is in fact a valid measure of propensity to change jobs in response to perceived differentials in "net economic advantage," one would expect this mobility measure to be related to the probability of job change. While considerable ambiguity is doubtless introduced by the inability to separate the voluntary from the involuntary job changers, the predictive power of the mobility measure still may be tested with the available data. To begin to test this model, we show in Table 2.9 the relationship between the mobility propensity measure and the degree of actual interfirm movement between the 1968 and 1969 surveys. Among both white and black young women the relationship is in the expected positive direction. Those whose response to the hypothetical job offer had classified them as highly mobile are most likely to have changed jobs, while those identified as immobile are least likely. Further, the positive relationship appears to be monotonic, although for whites the

differences in actual mobilities that exist between adjacent categories of mobility propensity are very small. The absence of a stronger positive association between 1968 attachment and 1968-69 movement, along with the fact that a sizeable proportion of the "immobile" (25 percent of the whites and 21 percent of the blacks) moved, no doubt reflects such factors as (a) involuntary moves, and (b) nonwage elements of decisions to move voluntarily.

Comparison of marital status, 1968-1969 It was anticipated that interfirm mobility would be related to changes in marital status. A woman's marriage, for example, may bring about a geographic move and an accompanying employer switch, or it may prompt a change from full-time to part-time work, a shift which may result in an employer change. Thus, we expected that women who were married in both years would be less mobile than would either those who underwent some change in marital status during the period or those who remained nonmarried.⁷ By and large, our expectations were met. Among black young women, 40 percent of those whose marital status changed reported working for a different employer in 1969 than in 1968, as compared to 36 percent of those who remained nonmarried and 24 percent of those who were married in both years (Table 2.10). Similarly, white women who were married in both 1968 and 1969 were substantially less mobile than were those reporting a change in marital status (28 versus 46 percent), although they were no less mobile than were the young whites who were nonmarried at the time of both surveys.

Comparison of residence, 1968-1969 As expected, job changers were overwhelmingly more likely to have changed their place of residence between the surveys than were those who remained with the same employer (Table 2.11). Twenty-six percent of the whites who made interfirm moves had also made geographic moves, while only 2 percent of those who remained with the same employer were living in a county (or SMSA) in 1969 different from that in which they had resided in 1968. The corresponding figures for the blacks are 21 percent and 1 percent.

Consequences of Interfirm Movement

Changes in rate of pay, 1968-1969 In interpreting the relationship between interfirm movement and changes in rate of pay between 1968 and

⁷ The term "married" refers to respondents who are married, spouse present. "Nonmarried" refers to those who have never been married or who are widowed, divorced, separated, or married, spouse absent.

1969, it must again be kept in mind that the interfirm changes under consideration include involuntary as well as voluntary shifts. It is reasonable to expect a greater proportion of those respondents who changed jobs involuntarily than of those who remained with the same employer to suffer a decrease in hourly wages. As for the voluntary movers, some were no doubt motivated by a higher rate of pay, whereas there must have been others who changed for nonpecuniary reasons. Among the former, a positive association between employer mobility and changes in rates of pay should be expected, but we have no reason to anticipate a consistent relationship of any type between job shifts and pay changes among the latter.

Table 2.12 reveals that white young women who made employer changes between 1968 and 1969 received greater relative increases in hourly pay rates than did those who made no moves (a 20 percent increase versus a 14 percent increase). This is also true for the blacks, although the differential is very slight. Interesting intercolor differences appear when we examine the relationship between change in rate of pay and educational attainment. Within the group of whites, the relationship between education and relative wage increases is positive for both job changers and nonchangers. In terms of the magnitude of relative increases, changers, however, hold an 8 percent edge over nonchangers at both levels of educational attainment for which the number of sample cases permits examination. The pattern among blacks differs noticeably from this. Movers again fared better than nonmovers, but the advantage accruing to movers vis-a-vis that going to nonmovers is substantially greater for those who have not completed high school than for those with high school diplomas.

Change in job satisfaction, 1968-1969 An important psychological dimension of interfirm movement is its association with changes in the levels of job satisfaction. It would seem reasonable to hypothesize a positive association between interfirm movement and increased job satisfaction, although our inability to separate the voluntary from the involuntary changers precludes confident interpretations of the association which we discuss below.

Nevertheless, there is some evidence that moves made by the young women over the period led to greater job satisfaction and that movers fared better in terms of increased job satisfaction than did those who did not move. This seems consistent with the finding that interfirm movement and increases in wage rates were positively related. Among whites, the proportions of both changers and nonchangers expressing an increase in job satisfaction are greater than those expressing a decrease (Table 2.13). Job changers, however, are more than twice as likely as nonchangers to have reported increased satisfaction (70 percent versus 32 percent). Among whites who switched firms, the percent for whom there was no change in job attitude and that for whom job satisfaction declined are almost identical: 15 and 14 percent, respectively. As would be expected, the majority (59 percent) of those who remained with the same firm said they liked their jobs the same in 1969 as in 1968. Almost one-third of the immobile whites expressed an increase in job satisfaction, while less than one-tenth reported a decrease. The overall pattern is essentially the same for the blacks. One difference is that relatively fewer blacks--movers or nonmovers--revised their job attitudes in either direction. Another difference is that white young women who changed jobs were somewhat more likely than were black interfirm changers to have said that they were less satisfied with their jobs in 1969 than they had been in 1968.

III GEOGRAPHIC MOVEMENT, 1968-1969

Correlates of Migration

1968 occupation Young women not enrolled in school evidence a considerable amount of geographic movement over the course of a 12-month period.⁸ Thirteen percent of the white women who had been

⁸ It must be noted, however, that the rates to which we refer doubtless understate the rate of geographic movement among the national civilian noninstitutionalized population of women of that age group because of the attrition from the sample between the two surveys and because of the greater likelihood of migration among those who dropped out of the sample.

employed at any job at the time of the 1968 survey had made geographic moves by the time of the 1969 survey (Table 2.14). This is somewhat greater than the 9 percent mobility rates for the comparable group of black young women. The intercolor variation is in this direction for all occupational categories, but is particularly strong in the case of nondomestic service workers, where 23 percent of the white young women as compared to 7 percent of the black changed their places of residence. Whereas mobility rates among blacks vary only slightly by 1968 occupation, among whites those in nondomestic services were clearly most mobile, followed by those in professional, technical, and managerial and those in blue-collar occupations. Clerical and sales workers were least mobile.

Education Rate of migration bears a generally positive relationship with years of school completed, both among whites and among blacks (Table 2.15). Among whites, those with some college experience have the highest rates of migration. Geographic movement does not differ perceptibly between white women with less than 12 and those with exactly 12 years of education, while black high school graduates have a somewhat higher rate of movement than do nongraduates.

Change in marital status It is clear that in the case of both whites and blacks, geographic mobility is related to change in marital status. Young women who were either married both years or nonmarried both years were much less mobile than were those who changed from one of these statuses to the other during the period (Table 2.16). Whites whose marital status changed were more than three times as mobile as were whites in either of the groups for which marital status remained constant. A similar pattern prevailed for blacks. Looking just at those whose marital status changed, the migration rate for whites exceeded that for blacks by one-third (32 versus 24 percent). Within each color group, movement from one area to another occurred with approximately the same frequency for the two subsets whose marital status remained unchanged, with only minimal intercolor variation in rate levels.

Prospective interfirm and geographic mobility, 1968 A hypothetical question relating to a job offer outside the local labor market area that was asked in the 1968 interview performed as expected for whites, but no clear relationship obtained for blacks. Young nonmarried women who were out of school and employed as wage and salary workers in 1968 were asked whether they would accept a job offer which required no occupational change but which necessitated a geographic move. Among whites, the relationship between prospective geographic mobility and actual mobility is positive and monotonic (Table 2.17). The mobility rate for those whose responses classified them as "highly mobile" is one-and-one-half times as great as that for the "moderately mobile" and nearly twice that of the "immobile."

Table 2.14 Migration Rate, 1968 to 1969, by 1968 Occupation and Color: Respondents 18 to 25 Years of Age, Employed in 1968, and Out of School in 1968 and 1969

Consequences of Migration

Changes in labor force and employment status and in rate of pay
Young women who were out of school in 1968 and 1969 and who changed their areas of residence between the survey dates are more likely to have undergone a change in their labor force status than are those who made no interarea moves (Table 2.18). For whites and blacks alike, more nonmigrants than migrants were either in the labor force both years or out of the labor force both years. It is somewhat difficult to assess the effects of moving on labor force and employment status. Movers more frequently left the labor force than did nonmovers, but at the same time they are more likely than nonmovers to have entered the labor force. Among whites, withdrawal is more prevalent than entry, and the migrant-nonmigrant differential is greater in the case of exit. On the other hand, the opposite associations obtain in the case of blacks.

Among white young women who were out of school and employed as wage and salary workers in both 1968 and 1969, the mean increase in hourly rate of pay for those who made geographic moves is \$.12, whereas the mean change for those who did not move was \$.34 per hour (table not shown). Strictly in terms of hourly rates of pay, then, geographic movement seems to have been dysfunctional for those white respondents. (There are too few sample cases of black migrants to permit analysis.)

Change in job satisfaction, 1968-1969 Among whites,⁹ it is clear that geographic movement is directly related to changing one's attitude toward one's job. The proportion of movers who reported that they felt the same about their jobs in 1969 as they had in 1968 is only one-half that for the nonmovers (Table 2.19). One cannot make the generalization that geographic movement was functional in terms of job satisfaction, however, for while migrants are somewhat (51 versus 43 percent) more likely than nonmigrants to have said that they liked their 1969 jobs more than their 1968 jobs, they are also nearly three times as likely to report a decrease in job satisfaction.

⁹ There are too few sample cases of black migrants to permit confident analysis.

CHAPTER THREE*

KNOWLEDGE OF THE WORLD OF WORK

Inasmuch as individuals are relatively free to choose among occupations and employers, it is desirable that their stock of occupational information be such that they are aware of the range of alternatives for which they might qualify so that their choices may be reasonably well informed. This is important both from the standpoint of efficient resource utilization and of the welfare of the individual.

The precise nature and extent of labor market information that is desirable depends, in part, upon the stage of the life cycle. In the case of young women in school it is particularly important that they be aware of the characteristics of the full range of occupations potentially available to them. Only on the basis of such information can rational decisions concerning occupational preparation be made. For those out of school, on the other hand, while such information is not entirely irrelevant, it is somewhat less important, since the range of occupations effectively open is restricted more narrowly as a result both of educational decisions made in the past and of previous work experience. Marriage and child-bearing, of course, serve to increase the number and stringency of such restrictions.

It seems reasonable to hypothesize that a young woman's experiences in the labor market will, to some degree, be associated with the extent of her labor market information. Similarly, her knowledge of the world of work may logically be expected to be related to certain demographic characteristics, to her socioeconomic background, and to her educational experiences. Specifically, we would anticipate labor market information to be positively associated with age and education. Further, a direct relationship would be expected between labor market information and parental education, family income, exposure to reading material in the home, and having lived in an urban community while growing up. Mental ability should also be positively correlated with scores on an occupational information test.

In terms of labor market success, our expectation would be that a respondent's knowledge of the world of work would be directly

* This chapter was written by Roger D. Roderick and Joseph M. Davis.

associated with her being employed, with her position in the occupational hierarchy, and with her hourly rate of pay.¹

I THE OCCUPATIONAL INFORMATION TEST

Our measure of "knowledge of the world of work" is a rather restricted one, consisting of but a single set of questions involving occupational identification. Respondents were asked to select the one of three statements that best describes the duties of each of ten occupations--assembler, keypunch operator, bank teller, department store buyer, dietician, statistical clerk, nurse's aide, social worker, medical illustrator, and quality control girl in a bakery. Each of the occupational identification questions was assigned one point, so that scores on the test could range from 0 to 10. On the basis of their scores on this test, respondents were classified into quintiles, with the top two quintiles considered to be "high" scores, the middle quintile to be "medium," and the lower two to be "low."²

It is clear that our measure taps only one dimension of "labor market information." Although the number of occupations used is exceedingly small, a relatively wide range of the total occupational hierarchy is represented. Moreover, the test includes no index of the respondents' knowledge of the typical educational attainment of incumbents of the ten occupations in question, nor does it provide any indication of the respondents' familiarity with earnings associated with the occupations. Further, no measure of their awareness of employment opportunities is elicited by the test.³ Finally, the time

1 In these cases, the direction of causality is likely to shift as length of time in the labor market increases, i.e., knowledge is more likely to be the cause of early labor market experience, whereas continued tenure in the labor market doubtless increases scores on the occupational information test.

2 These divisions were based upon the scores of all respondents.

3 For a portion of the young women in the sample, an alternative measure of such information exists. In the first (1968) survey, employed respondents were asked what they would do if they lost the jobs they currently held. Those who indicated that they would look for work were asked, "Are there any particular companies in this area where you would apply?" Those who offered a positive response to the latter were then asked, "Why do you mention these particular companies?" Respondents able to mention alternative employers in the area may be presumed to have better labor market information than those who cannot.

constraints on the interview and the fact that the questions had to be applicable to a national sample of young women ranging in age from 15-25 and representing all socioeconomic levels imposed substantial limits upon what was feasible. Nevertheless, our preliminary results, described below, and those for a more detailed test administered to a parallel group of young men in 1966,⁴ provide some basis for optimism that this test not only has predictive value, but actually measures--however crudely--extent of labor market information.

II DETERMINANTS OF OCCUPATIONAL INFORMATION SCORES

Age, Education, and Color

Occupational information bears a strong relationship to education (Table 3.1). Among whites enrolled in school, there is a clear positive monotonic relationship between highest year of school completed and test scores. Moreover, the pattern for those not enrolled in school by and large duplicates that for the enrolled, and in neither case are the associations noticeably affected by the age control. Furthermore, these conditions generally hold for blacks as well. This is particularly interesting in view of the strong influence of age on the extent of occupational information in the case of the boys.⁵

Finally, the size of the intercolor differences is substantial. On average, whites are two to three times as likely as blacks to have high scores and less than one-half as likely to have low scores. While this is clearly affected by intercolor differences in educational attainment, the black-white test score differentials are only somewhat reduced when education is controlled. Finally, age does not explain any additional part of the large differences between the races.

In the two sections immediately following, the association between formative influences experienced as a teenager and test scores and that between school-related experiences and test scores is explored. The analysis is confined to respondents 15 to 18 years of age who were enrolled in school in 1969. The homogeneity of the group generated by these restrictions minimizes the difficulty encountered when working with explanatory variables that are highly correlated with educational attainment. For example, if the universe were more diverse as to age, enrollment status, and educational attainment, a relationship between an explanatory variable and labor market information might simply

⁴ Parnes et al., Career Thresholds, 1:119-38.

reflect the strong association that has been seen to exist between educational attainment and extent of occupational information. This problem, of course, is not completely eliminated by the universe restrictions here imposed, but it is very substantially reduced.

Cultural Influences

A teenage girl's knowledge of the world of work is doubtless affected by a variety of formative influences (Table 3.2). To begin with, certain differences are to be seen between those from nonurban and those from urban areas. Among black young women, those from urban communities are three times as likely as are those from nonurban communities to have achieved high scores on the occupational identification test. A similar, but much smaller difference is evident for whites. These relationships are as anticipated. Having grown up in an urban environment should be expected to afford an exposure to a wider range of occupations than having grown up in a nonurban area. Similarly, urban-nonurban differences should be expected to be greater among blacks than among whites.

The level of parental education is another influence which might be expected to be directly related to the extent of a young girl's occupational information. For both blacks and whites there is a positive--though not monotonic--association between high test scores and mother's educational attainment. Also for both color groups, those whose mothers did not complete high school are substantially more likely to have scored low on the test than are those whose mothers completed exactly 12 years of school. Furthermore, among whites the latter are more likely to be low scorers than are daughters of mothers who continued their education beyond high school. Once again, the black-white distinction is as expected, for the variation in maternal influence upon "career versus homemaker" orientations is almost certain to be different among blacks than among whites.

The extent to which the young teenager has access to reading material in her home shows up as strongly related to how much she knows about the world of work. White young women whose families had library cards and regularly got newspapers and magazines have substantially better knowledge about the world of work than do those whose families lacked one or more of these. One-third of those having had all three forms of literary exposure scored high on the occupational information test, as contrasted with one-fifth of those lacking one form of exposure and just one-eighth of those lacking two or more forms. The pattern is basically the same among blacks, although somewhat less regular. That is, those who came from families where all three forms of literary exposure were present are unmistakably more likely than are those from homes where two or more forms were absent to have scored high (16 versus 7 percent). However, the black young women who had lived in households where only one form of exposure was missing are the least likely of all to have scored high (3 percent).

b Excludes respondents whose mothers were deceased at time of interview.

While the intercolor variation in test scores is considerably reduced when exposure to reading material is controlled, it is noteworthy that, even within each category, blacks rank considerably lower on knowledge of the world of work than do whites. For example, whites are twice as likely as blacks to have attained high scores, both among those whose homes provided the highest (32 versus 16 percent) and among those whose homes provided the lowest (13 versus 7 percent) levels of exposure to reading material.

School-Related Influences

Several aspects of a young girl's school-related experiences are associated with her knowledge of the world of work (Table 3.3). Inasmuch as some of the cultural influences referred to above and some of the school-related influences described below are doubtless intercorrelated, we cannot claim that the latter are independent influences.

Among whites, the relationship between high test scores and mental ability is positive and monotonic. Only 11 percent of those in the lower three IQ stanines achieved high scores on the occupational information test, as compared to 45 percent of those in the upper three stanines. Among blacks, the same sort of relationships generally prevail, although the number of sample cases for stanines six through nine is insufficient to permit confident analysis. While the patterns are consistent across color groups, there are, as in the case of the literary exposure variable, distinct intercolor differences within each stanine category for which the number of sample cases allow comparison. Whereas blacks are much more heavily concentrated in the lower stanine categories, it is nevertheless true that in no category are the blacks more than two-thirds as likely as the whites to have scored high on the test; likewise, in every category the blacks are substantially more likely to have scored low. At this point it should be noted that of all the school-related variables, IQ exhibits the strongest relationship with occupational information scores.

The proportion of college preparatory curriculum enrollees who attained high scores on the knowledge of the world of work test exceeds that for young women from the vocational-commercial programs, which in turn is greater than that for those in the general curriculum track. These relationships exist for both whites and blacks.

III THE LABOR MARKET CONSEQUENCES OF OCCUPATIONAL INFORMATION

The data below offer some support for our expectations that labor market information exerts an influence upon a young woman's achievements in the labor market. The universe under consideration in

this section differs from that examined thus far in that, for purposes of homogeneity, it is restricted to 18-to-25-year-olds who have completed exactly 12 years of education and who were not enrolled in regular school at the time of the 1969 survey.

Labor Force and Employment Experience, 1969

Among young women with 12 years of education, those who scored high on the occupational information test are somewhat more likely to have been employed at the time of the 1969 survey than are those whose scores were low (Table 3.4). Conversely, high scorers were less frequently out of the labor force than were low scorers. Unemployment was about equally prevalent within the two groups. These relationships hold for both whites and blacks, but are slightly more pronounced in the case of the blacks. For neither whites nor blacks, however, are these associations particularly strong.

Occupation, 1969

Respondents whose knowledge of the world of work is high, as measured by our occupational information test, were more often found in white-collar occupations than were those exhibiting the lowest amounts of labor market information (Table 3.4). This is clearly the case for both color groups, but is particularly true for the blacks. Low scores, on the other hand, were more heavily concentrated in both blue-collar and the nondomestic services than were high scorers. This also is true for blacks and whites alike, with virtually no intercolor variation in the magnitude of the differential. Occupancy of domestic service positions appears not to have been affected by knowledge of the world of work.

Hourly Rate of Pay, 1969

The hourly rates of pay for young women are clearly related to the extent of their occupational information (Table 3.4). Among whites, lower proportions of those who scored high on their tests fall within the two lower wage categories than do those who scored low. Consistently, the high scorers are more likely to be in the higher wage groupings than are the low scorers. The same pattern prevails among the blacks.

It appears, then, that this index of knowledge of the world of work helps explain a young woman's accommodation to the labor market. The strong correlation between scores on the occupational information test and our measure of mental ability, however, warns us that the association between the former and labor market success, as described above, may largely reflect the fact that occupational information and intelligence are highly intercorrelated. We intend to examine this further when subsequent waves of data are in hand.

a "Occupation" refers to current or last occupation.

b Total also includes respondents in farm occupations not shown separately.

c Includes only those employed as wage and salary workers.

Of the 5,159 respondents originally interviewed in 1968, 96 out of 100 were reinterviewed in 1969 (p. 2). With the 1969 data in hand, we are able to examine longitudinal changes in the personal, educational, and labor market experiences of the young women in the sample. Even over a single year (from February 1968 to February 1969), considerable change occurred in labor market status. Data from the second wave of interviews also afford the initial opportunity to look at the correlates of the extent of knowledge of the world of work.

In the paragraphs below we highlight some of the empirical relationships described in earlier chapters and also take the opportunity to compare the behavior of young women and young men over a one-year period. While both groups were 14 to 24 years of age when initially interviewed, first interviews took place at different times: October 1966 in the case of the men and February 1968 for the women. The fact that economic and social conditions changed to some extent between these two dates doubtless affects some of the comparisons.

I CHANGES IN EDUCATIONAL EXPERIENCES AND EDUCATIONAL ASPIRATIONS

Of the young women enrolled at the time of the 1968 survey, 88 percent of the whites and 76 percent of the blacks were still in school in 1969 (p. 4). Furthermore, among both color groups, 4 percent of those not enrolled in the initial year had returned to school by the time of the second interview. As expected, blacks were more likely than whites to leave school before completing the twelfth grade: between 1968 and 1969, 4 percent of the young white girls and 11 percent of the black dropped out prior to graduation (p. 4). The percentage for whites is approximately the same as that which prevailed among white males in the same age category between 1966 and 1967. However, the dropout rate for the black girls at the high school level exceeds that of their male counterparts.¹

* This chapter was written by Roger D. Roderick.

1 Zeller et al., Career Thresholds, 2:3.

For the most part, the correlates of premature withdrawal from high school are those that would be expected. For example, respondents whose fathers had little education are more likely to have left high school with no diploma than are those with better-educated fathers (p. 6). Respondents who went to high school in the South more frequently failed to graduate than did those who attended high school elsewhere. Those with high educational aspirations were less likely than were those with lower aspirations to drop out of high school.

Turning to movement from high school to college, young white women who were in the twelfth grade in 1969 were twice as likely as their black counterparts to have gone on to college by the time of the 1969 survey (p. 6). For each color group, the fraction continuing its education was 12 percentage points below that for young men of the same race.² The factors associated with the likelihood of entering college are, by and large, merely the inverse of those associated with premature departure from high school. For whites, entry to college is positively related to paternal education, and for both blacks and whites to having come from an urban background and to educational aspirations as stated in 1968 (p. 6).

Respondents who were enrolled in school were asked about their educational goals in both the 1968 and the 1969 interviews. Of those in high school at the time of both surveys, approximately three in ten had revised their goals (p. 9). These results are similar to those found among the young men. One in eight young women had raised their goals, while slightly more (one in six) had lowered them. As in the case of the young men, the reasons most often cited for these changes can be subsumed under the general heading "interest." In contrast to the young men, only a few of the young women reported that economic factors were responsible for the modification of their educational goals.³

To the extent that downward revision of educational goals represents a convergence toward reality over time, it is interesting to note that young white girls appear to make such downward revisions at earlier ages than black girls (p. 14). Overall, those whose aspirations were highest in 1968 were most likely to revise their goals downward (p. 11). Finally, downward revision tends to be more common among girls from families of low socioeconomic status as measured by family income and father's education. Also, girls whose 1968

2 Ibid., p. 7.

3 Ibid., p. 64.

expectations were more modest than their aspirations manifested an above-average tendency to lower their aspirations between 1968 and 1969 (p. 11).

II CHANGES IN RATE OF PAY AND IN JOB STATUS

Examination of labor market behavior has been confined to women who were out of school on both survey dates. Overall, wage changes were more favorable for whites than blacks. The mean rate of pay for whites rose over the one-year period by 16 percent, as compared to only 9 percent for the blacks (p. 21). Among the former, the percentage increase was greatest for white-collar workers and least for blue-collar workers; among the latter, domestic service workers received the largest relative increase, while the wages of nondomestic service workers did not rise at all (p. 21). The association between educational attainment and change in mean rate of pay was generally positive for the whites and negative for the blacks (p. 23). Looking only at respondents who have completed exactly 12 years of school, those who had been enrolled in vocational or commercial programs made the greatest gains in rate of pay (in absolute as well as relative terms), while those from general curricula made the smallest.

Approximately one-third of the young women who were employed at the time of both the 1968 and the 1969 surveys made at least one interfirm move during the period, either voluntarily or involuntarily (p. 26). This represents considerably less mobility than occurred among young men of the same ages in the one-year period 1966-1967.⁴ There were few, if any, surprises in our examination of the correlates of interfirm mobility. The likelihood of a change of employer between 1968 and 1969 is negatively related to length of service (p. 29), rate of pay (p. 29), degree of satisfaction (pp. 29, 32), and "attachment" to the 1968 job (pp. 32, 35). Women whose marital status changed had an above-average tendency to change jobs (p. 35). From the standpoint of occupations, domestic service workers are, of course, the most mobile (p. 27). Excluding that group, the most mobile group is the nondomestic service category, where mobility among blacks is precisely equal to that among whites. Within all other occupational categories, blacks are more likely than whites to change their jobs.

Judging from patterns of wage increments between the two survey dates, changing jobs seems to have been functional for this group of young women. On average, respondents who changed employers enjoyed larger increases in hourly earnings, the difference being particularly

⁴ Zeller et al., Career Thresholds, 2:28.

noticeable among whites (pp. 35, 37). Job changes also appear to have been functional in terms of attitudinal change. Change of employer is associated with increased job satisfaction for both blacks and whites (p. 39). This relationship is consistent with that found over the one-year period 1966-1967 for white young men, but not for the black young men.⁵

Thirteen percent of the white and 11 percent of the black respondents not enrolled in school in either survey year changed their place of residence between 1968 and 1969 (pp. 39, 41). This is a rate of geographic mobility as great as or greater than that found among young men of the same ages in 1966-1967. When the universe is further constrained to include only young women who were employed in both years, the migration rate is somewhat lower, at least in the case of blacks. Generally, geographic movement is positively related to educational attainment and to having experienced a change in marital status (p. 41). In each of those respects, the relationship is consistent with that for white male youth but not with that for young black men.⁶ Among the latter, those whose marital status changed from never-married to married were least likely to have moved and those with less than 12 years of education had higher mobility rates than those in any other educational category. Not unexpectedly, geographic movement is high among the white young women whose propensity to make a geographic move was characterized as "high" in 1968 (p. 41).

The consequences of geographic movement are not clear at this juncture. Nonmigrants are more likely than migrants to have been in the labor force in both 1968 and 1969 (p. 46). Migrants are more likely to have moved out of the labor force; they are also more likely to have moved into it. Among whites, the departure effect is stronger than the entrance effect, whereas among blacks the opposite is true. This suggests that at least some of the geographic movement among blacks is in response to job opportunities elsewhere. In terms of psychological returns, whites who made a geographical move are somewhat more likely than nonmovers to report increased job satisfaction. but they are also substantially more likely to evidence decreased satisfaction (p. 46).

III KNOWLEDGE OF THE WORLD OF WORK

As measured by our simple occupational information test, white young women have substantially more labor market knowledge than black

5 Ibid., pp. 33-35.

6 Ibid., p. 47 ff.

young women (p. 51). While test scores show a strong positive relationship to educational attainment and to scores on mental ability tests, the intercolor variation in occupational information persists even when the latter two variables are controlled (pp. 51, 53). Among young women enrolled in high school in both 1968 and 1969, those in the college preparatory track most frequently had high occupational information scores, while those in general curricula were least likely to have high scores (p. 55). Girls from urban communities attained high scores more often than did those from nonurban areas, although the relationship is more pronounced among blacks than among whites (p. 53). Access to reading materials in the parental home is strongly related to knowledge of the world of work, although the pattern is decidedly clearer for whites than for blacks (p. 53). Consistently, for both color groups, low test scores are disproportionately frequent among respondents whose mothers had little education (p. 53). All of these relationships are substantially similar to those previously found for young men of the same age.⁷

There is some evidence that occupational information may have provided a positive payoff in terms of labor market success, although we have not thus far been able to control statistically for several variables which may be intercorrelated both with occupational information and labor market success. Among girls with exactly 12 years of education, those with high test scores have higher rates of pay, less unemployment, and a greater likelihood of being in white collar jobs than do girls with more limited occupational information (p. 57).

7 Parnes et al., Career Thresholds, 1:119-38.

APPENDIXES

AGE

Age of respondent as of last birthday prior to January 1, 1969.

ATTITUDE TOWARD EMPLOYMENT OF MOTHERS

This attitudinal measure is based on responses to a series of three questions postulating the employment of a married woman with preschool-age children under specified conditions: (1) if it is absolutely necessary to make ends meet; (2) if she prefers to work and her husband agrees; and (3) if she prefers to work, but her husband does not particularly like it. The responses were scored as follows: for each question, "definitely all right" was weighted 5 points; "probably all right," 4 points; no opinion or undecided, 3 points; "probably not all right," 2 points; and "definitely not all right," 1 point. The composite score for each respondent thus had a possible range of 3 to 15. Scores of 3 through 9 were designated "opposed"; 10 and 11, "ambivalent"; and 12 through 15, "permissive."

CLASS OF WORKER

Wage and Salary Worker

A person working for a rate of pay per time-unit, commission, tips, payment in kind, or piece rates for a private employer or any government unit.

Self-employed Worker

A person working in her own unincorporated business, profession, or trade, or operating a farm for profit or fees.

Unpaid Family Worker

A person working without pay on a farm or in a business operated by a member of the household to whom she is related by blood or marriage.

COLOR

In this report the term "blacks" refers only to Negroes; "whites" refers to Caucasians. Other races are not shown separately.

EDUCATIONAL ASPIRATIONS

Total number of years of regular school that the respondent would like to achieve.

66/67

EDUCATIONAL ATTAINMENT: See HIGHEST YEAR OF SCHOOL COMPLETED

EDUCATIONAL EXPECTATIONS

Total number of years of regular school that the respondent thinks she will actually achieve.

EMPLOYED: See LABOR FORCE AND EMPLOYMENT STATUS

EXPOSURE TO READING MATERIALS AT AGE 14

Whether the respondent had access to a library card, newspapers, or magazines in the home at age 14.

HEALTH LIMITATIONS

Respondent's evaluation of whether her health or physical condition limits her activities or the kind of work she is able to perform.

HIGH SCHOOL CURRICULUM

Orientation and goal of high school courses, usually related to future educational or occupational plans. Categories used are college preparatory, vocational, commercial, and general.

HIGHEST YEAR OF SCHOOL COMPLETED

The highest grade finished by the respondent in "regular" school, where years of school completed are denoted 9-11, 12, 13-15, etc.

HOURLY RATE OF PAY

Hourly compensation in dollars for work performed. Self-employed are excluded because of the problems encountered in attempting to allocate their earnings among wages and other kinds of returns. When a time unit other than hours was reported, hourly rates were computed by first converting the reported figure into a weekly rate and then dividing by the number of hours usually worked per week.

INTERFIRM MOVE

Respondents who were employed in both 1968 and 1969 are considered to have made an interfirm move if their employer in 1969 is different than their employer in 1968. Intervening moves and returns that may have occurred are ignored.

JOB ATTACHMENT (measured in 1968)

Relative increase in rate of pay for which an employed respondent would be willing to accept a hypothetical offer of employment in the same line of work with a different employer in the same local labor market area.

JOB, CURRENT OR LAST

For those respondents who were employed during the survey week: the job held during the survey week. For those respondents who were either unemployed or out of the labor force during the survey week: the most recent job.

JOB SATISFACTION

The degree of satisfaction workers feel toward their current jobs was measured in 1968 by a sample question asked of employed out-of-school youth: "How do you feel about the job you have now? Do you like it very much, like it fairly well, dislike it somewhat, or dislike it very much?" Change in job satisfaction between 1968 and 1969 was measured by asking respondents who were not enrolled in school in 1969 and who were employed in both 1968 and 1969 the following question: "Would you say you like your present job more, less, or about the same as (the job you held) last year?"

LABOR FORCE AND EMPLOYMENT STATUS

In the Labor Force

All respondents who were either employed or unemployed during the survey week:

Employed

All respondents who during the survey week were either (1) "at work"--those who did any work for pay or profit or worked without pay for 15 hours or more on a family farm or business; or (2) "with a job but not at work"--those who did not work and were not looking for work, but had a job or business from which they were temporarily absent because of vacation, illness, industrial dispute, bad weather, or because they were taking time off for various other reasons.

Unemployed

All respondents who did not work at all during the survey week and (1) either were looking or had looked for a job in the four-week period prior to the survey; (2) were waiting to be recalled to a job from which they were laid off; or (3) were waiting to report to a new job within 30 days.

Out of the Labor Force

All respondents who were neither employed nor unemployed during the survey week.

LABOR FORCE PARTICIPATION RATE

The proportion of the total civilian noninstitutional population or of a subgroup of that population classified as "in the labor force."

LENGTH OF SERVICE IN 1968 JOB

The total number of years spent by the respondent in her current job at the time of the 1968 survey.

MARITAL STATUS

Respondents were classified into the following categories: married, husband present; married, husband absent; divorced; separated; widowed; and never married. The term "married" refers only to those who are married with husband present; "nonmarried" is a combination of all other categories.

MIGRATION, 1968 to 1969

This variable is based upon a comparison of county (or SMSA) of residence in the survey weeks of 1968 and 1969. Thus, migration is defined as a situation in which the county (or SMSA) of residence differs between those two periods, and ignores intervening moves and returns that may have occurred.

NONSTUDENT

All respondents not enrolled in regular school at the time of the survey.

OCCUPATION

The major occupation groups are the 10 one-digit classes used by the Bureau of the Census in the 1960 Census, with the addition of breaking the service workers into two groups, domestic and nondomestic. The occupational groupings are: white-collar (professional and technical workers; managers, officials, and proprietors; clerical workers; and sales workers); blue-collar (craftsmen and foremen, operatives, and nonfarm laborers); service (domestic and nondomestic); and farm (farmers, farm managers, and farm laborers).

OCCUPATIONAL INFORMATION TEST

A series of questions designed to measure the extent of the respondent's information about the labor market. For each of 10 occupations, the respondent is asked to select the one of three statements that best describes the duties of that occupation. Each correct response receives one point, so that the range of scores on the test is from 0 to 10.

OUT OF THE LABOR FORCE: See LABOR FORCE AND EMPLOYMENT STATUS

PART-TIME EMPLOYMENT

A maximum employment of 34 hours per week. The two ways in which this measure is used are: (1) actual number of hours worked during the survey week at all jobs; (2) usual number of hours worked per week on current or last job.

PROSPECTIVE GEOGRAPHIC MOBILITY (measured in 1968)

Relative increase in rate of pay for which an employed nonmarried respondent would be willing to accept a hypothetical offer of employment in the same line of work outside the local labor market area in which she resides.

RESIDENCE AT AGE 14

Degree of urbanization of area in which the respondent lived when she was 14 years of age. Categories are: farm or ranch; rural nonfarm; town; suburb of city; small city (25,000- 99,999); and large city (100,000 or more).

SCHOOL ENROLLMENT STATUS

An indication of whether or not the respondent is presently enrolled in regular school.

SELF-EMPLOYED: See CLASS OF WORKER

SURVEY WEEK

For convenience, the term "survey week" is used to denote the calendar week preceding the date of interview. In the conventional parlance of the Bureau of the Census, it means the "reference week."

TOTAL FAMILY INCOME

Income from all sources (including wages and salaries, net income from business or farm, pensions, dividends, interest, rent, royalties, social insurance, and public assistance) received in 1968 by any family member living in the household during the survey week. Income of nonrelatives living in the household is not included.

UNEMPLOYED: See LABOR FORCE AND EMPLOYMENT STATUS

UNEMPLOYMENT EXPERIENCE IN 1968

Cumulative number of weeks in calendar year 1968 that the respondent reported she was not working but was looking for work or on lay off from a job.

UNEMPLOYMENT RATE

The proportion of the labor force classified as unemployed.

UNPAID FAMILY WORKER: See CLASS OF WORKER

WAGE AND SALARY WORKER: See CLASS OF WORKER

SAMPLING, INTERVIEWING AND ESTIMATING PROCEDURES

The Survey of Work Experience of Young Women is one of four longitudinal surveys sponsored by the Manpower Administration of the U.S. Department of Labor. These four surveys constitute the National Longitudinal Surveys.

The Sample Design

The National Longitudinal Surveys are based on a multi-stage probability sample located in 235 sample areas comprising 485 counties and independent cities representing every State and the District of Columbia. The 235 sample areas were selected by grouping all of the nation's counties and independent cities into about 1,900 primary sampling units (PSU's) and further forming 235 strata of one or more PSU's that are relatively homogeneous according to socioeconomic characteristics. Within each of the strata a single PSU was selected to represent the stratum. Within each PSU a probability sample of housing unit was selected to represent the civilian noninstitutionalized population.

Since one of the survey requirements was to provide separate reliable statistics for Negroes and other races, households in predominantly Negro and other race enumeration districts (ED's) were selected at a rate three times that for households in predominantly white ED's. The sample was designed to provide approximately 5,000 interviews for each of the four surveys--about 1,500 Negroes and other races and 3,500 whites. When this requirement was examined in light of the expected number of persons in each age-sex-color group it was found that approximately 42,000 households would be required in order to find the requisite number of Negroes and other races in each age-sex group.

An initial sample of about 42,000 housing units was selected and a screening interview took place in March and April 1966. Of this number about 7,500 units were found to be vacant, occupied by persons whose usual residence was elsewhere, changed from residential use, or demolished. On the other hand, about 900 additional units were found which had been created within existing living space or had been changed from what was previously nonresidential space. Thus, 35,360 housing units were available for interview; of these, usable information was collected for 34,662 households, a completion rate of 98.0 percent.

* This appendix was written by Carrol Kindel, member of the Longitudinal Surveys Branch, Demographic Surveys Division, U.S. Bureau of the Census.

Following the initial interview and screening operation, the sample was rescreened in the fall of 1966, immediately prior to the first Survey of Work Experience of Males 14-24. For the rescreening operation, the sample was stratified by the presence or absence of a 14 to 24 year-old woman in the household. The rescreened sample was used to designate 5,533 young women age 14 to 24 as of January 1, 1968, to be interviewed for the Survey of Work Experience. These were sampled differentially within four strata: whites in white ED's (i.e., ED's which contained predominantly white households), Negroes and other races in white ED's, whites in Negro and other race ED's, and Negroes and other races in Negro and other race ED's.

The Field Work

About 325 interviewers were assigned to the survey. Preference in the selection of interviewers was given to those who had had experience on one of the other longitudinal surveys. However, because many of the procedures and the labor force and socioeconomic concepts used in this survey were the same as those used in the Current Population Survey (CPS), each interviewer was required to have prior CPS experience. In this way the quality of the interviews was increased while the time and costs of training were decreased.

Training for the interviewers consisted of a home study package which included a reference manual explaining the purpose, procedures and concepts used in the survey and the home study exercises, a set of questions emphasizing points explained in the manual. In addition to the home study package there was a day of classroom training in the Data Collection Centers for those interviewers who were not experienced in the longitudinal surveys. This was a small group, about five percent of the total interviewers. Survey supervisors conducted these sessions using a verbatim training guide which contained lecture material plus a number of structured practice interviews designed to familiarize interviewers with the questionnaire. Interviewers experienced in longitudinal surveys were permitted to begin working on their assignments immediately after completing the home study package. The training materials were prepared by the Bureau Staff and reviewed by the Manpower Administration and the Center for Human Resource Research of the Ohio State University. Professional staff members of the participating organizations observed both the training sessions and the actual interviewing.

There were staggered dates for beginning interviewing on this survey. One reason is that experienced interviewers were ready to begin their interviewing assignments as soon as they had completed their home study exercises while inexperienced interviewers had to wait to begin their assignments until after the classroom training session. The Data Collection Centers were not instructed to hold classroom training on a particular day; however, each office scheduled training sessions at its own convenience taking into consideration other survey commitments.

Because the demands of other surveys on the interviewers' time was particularly heavy at this time, Data Collection Centers were instructed to mail assignments to interviewers on a flow basis depending on each interviewer's work load.

Finally, the Christmas holiday interrupted, somewhat, the usual office routine since it is often inconvenient for both respondent and interviewer to conduct an interview during the holidays. Interviewing began during the middle of December 1968 and continued through mid March 1969. This is a longer time period than usually permitted for Census Surveys. Several factors accounted for the length of the interviewing period:

1. Most of the respondents were attending school and/or working. Therefore, they were only available for interviewing during limited times of the day.
2. The requirement that all interviewers have CPS experience caused some delay since the interviewers devoted about one week per month to the CPS.
3. A year had elapsed since our last contact with the respondent so those respondents who had moved in the past year had to be relocated by the interviewer. Also some respondents had married so their last names were different from the name we had listed for them.

The final completion rate for interviews is given in the tables below.

In 1968, of the 5,533 respondents originally selected, 5,477 were found to be eligible for interview and 5,159 were actually interviewed.

Summary of 1968 Interview

	Total eligible for interview	Total interviews	Noninterviews			
			Total	Refusals	Unable to contact	Other
Number of cases	5,477	5,159	318	151	120	47
Percent of workload	100.0	94.2	5.8	2.8	2.2	0.9
Percent of noninterviews			100.0	47.5	37.7	14.8

The 5,159 young women who were interviewed in 1968 constituted the panel for the 1969 survey. The noninterviews were not included because there would be no base year data for them. Of the 5,159 eligible

sample persons, 4,933 were actually interviewed. The table below gives the detailed noninterview information.

Summary of 1969 Interview

	Inter- viewed in 1968	Inter- viewed in 1969	Noninterviews				
			Total	Refused	Unable to contact	Deceased	All other
Number of cases	5,159	4,933	226	96	112	2	16
Percent of workload	100.0	95.6	4.4	1.9	2.3	Less than 0.1	0.2
Percent of noninterviews			100.0	42.5	49.5	0.9	7.1

A full edit to check the quality of the completed questionnaires was done by Data Collection Center staffs. The edit consisted of reviewing each questionnaire from beginning to end to determine if the entries were complete and consistent and whether the skip instructions were being followed. If there were minor problems, the interviewer was contacted by phone, told of her error and asked to contact the respondent for further clarification. For more serious problems, the interviewer was retrained, either totally or in part, and the questionnaire was returned to her for completion.

Estimating Methods

The estimation procedure adopted for this survey was a multi-stage ratio estimate. The first step was the assignment to each sample case of a basic weight which took into account the over-representation of Negro and other race strata, the rescreening procedure and the sampling fraction of the stratum from which it was selected. The sample drawn from the white stratum was selected at an eight out of nine ratio, while the selection for the sample for the Negro and other race stratum was at a seven out of eight ratio. Thus, from the Survey of Work Experience of Females 14 to 24, there were eight different base weights reflecting the differential sampling by color within stratum (i.e., white ED's versus Negro and other race ED's) during both the rescreening and selection operations.

1. Noninterview Adjustment

The weights for all interviewed persons were adjusted to the extent needed to account for persons for whom no information was obtained because of absence, refusals or unavailability for other reasons. This adjustment was made separately for each of twenty-four

groupings: Census region of residence (Northeast, North Central, South, West), by residence (urban, rural farm, rural nonfarm), by color (white, Negro and other races).

2. Ratio Estimates

The distribution of the population selected for the sample may differ somewhat, by chance, from that of the nation as a whole, in such characteristics as age, color, sex, and residence. Since these population characteristics are closely correlated with the principal measurements made from the sample, the latter estimates can be substantially improved when weighted appropriately by the known distribution of these population characteristics.¹ This was accomplished through two stages of ratio estimation, as follows:

a. First-Stage Ratio Estimation

This is a procedure in which the sample proportions were adjusted to the known 1960 Census data on the color-residence distribution of the population. This step took into account the differences existing at the time of the 1960 Census between the color-residence distribution for the nation and for the sample areas.

b. Second-Stage Ratio Estimation

In this final step, the sample proportions were adjusted to independent current estimates of the civilian noninstitutional population by age and color. These estimates were prepared by carrying forward the most recent Census data (1960) to take account of subsequent aging of the population, mortality, and migration between the United States and other countries.² The adjustment was made by color within five age groupings: 14 to 15, 16 to 17, 18 to 19, 20 to 21, and 22 to 24.

After this step, each sample person has a weight which remains unchanged throughout the five-year life of the survey. The universe of study was thus fixed at the time of interview for the first cycle. No reweighting of the sample is made after subsequent cycles since the group of interviewed persons is an

1 See U.S. Bureau of the Census, Technical Paper No. 7, "The Current Population Survey--A Report on Methodology," Washington, D.C., 1963, for a more detailed explanation of the preparation of estimates.

2 See U.S. Bureau of the Census, Current Population Reports, Series P-25, No. 352, November 18, 1966, for a description of the methods used in preparing these independent population estimates.

unbiased sample of the population group (in this case, civilian noninstitutionalized females age 14 to 24) in existence at the time of the first cycle only.

Coding and Editing

Most of the data could be punched directly from the questionnaire, since many of the answers were numerical entries or in the form of precoded categories. However, the Bureau's standard occupation and industry codes which are used in the monthly CPS were also used for the job description questions and these codes are assigned clerically. In addition, the answers for all the "open-end" questions had to be clerically coded, using categories which were previously developed in conjunction with the Center from hand tallies of a subsample of completed questionnaires from previous longitudinal surveys which contained the same questions.

The consistency edits for the questionnaire were completed on the computer. A modification of the CPS edit was used for the parts of the questionnaire which were similar to CPS; separate consistency checks were performed for all the other sections. None of the edits included an allocation routine which was dependent on averages or random information from outside sources, since such allocated data could not be expected to be consistent with data from subsequent surveys. However, where the answer to a question was obvious from others in the questionnaire, the missing answer was assigned to the item. For example, item 57a ("Is it necessary for you to make any regular arrangements for the care of your child(ren) while you are working?") was blank, but legitimate entries appeared in items 57b and 75c ("What arrangements have you made?" and "What is the cost of these child care arrangements?"), a "Yes" was inserted in 57a since 57b and c could have been filled only if the answer to 57a was "Yes." Therefore, the assumption was made that either the key punch operator had failed to punch the item or the interviewer had failed to record it.

SAMPLING VARIATION

As in any survey based upon a sample, the data in this report are subject to sampling error, that is, variation attributable solely to the fact that they emerge from a sample rather than from a complete count of the population. Because the probabilities of a given individual's appearing in the sample are known, it is possible to estimate the sampling error, at least roughly. For example, it is possible to specify a "confidence interval" for each absolute figure or percentage, that is, the range within which the true value of the figure is likely to fall. For this purpose, the standard error of the statistic is generally used. One standard error on either side of a given statistic provides the range of values which has a two-thirds probability of including the true value. This probability increases to about 95 percent if a range of two standard errors is used.

Standard Errors of Percentages

In the case of percentages, the size of the standard error depends not only on the magnitude of the percentage, but also on the size of the base on which the percentage is computed. Thus, the standard error of 80 percent may be only 1 percentage point when the base is the total number of white women, but as much as 8 or 9 percentage points when the base is the total number of unemployed white women. Two tables of standard errors, one for whites and one for blacks, are shown below (Tables C-1 and C-2).

The method of ascertaining the appropriate standard error of a percentage¹ may be illustrated by the following example. This sample represents approximately 1,000,000 black young women who were 18 to 25 years of age in 1969 and who were out of school in both 1968 and 1969. Our estimates indicate that 11 percent of these women were living in a different county (or SMSA) in 1969 than in 1968. Entering the table for black women (C-2) with the base of 1,000,000 and the percentage 10, one finds the standard error to be 1.7 percentage points. Thus, the chances are two out of three that a complete enumeration could have resulted in a figure between 12.7 and 9.3 percent (11 ± 1.7) and 19 out of 20 that the figure would have been between 14.4 and 7.6 percent (11 ± 3.4).

1 Because the sample is not random, the conventional formula for the standard error of a percentage cannot be used. The entries in the tables have been computed on the basis of a formula suggested by the Bureau of the Census statisticians. They should be interpreted as providing an indication of the order of magnitude of the standard error, rather than a precise standard error for any specific item.

Table C-1: Standard Errors of Estimated Percentages of Whites
(68 chances out of 100)

Base of percentage (thousands)	Estimated percentage				
	1 or 99	5 or 95	10 or 90	20 or 80	50
100	2.9	6.4	8.8	11.7	14.7
200	2.1	4.5	6.3	8.3	10.4
350	1.6	3.4	4.7	6.3	7.9
500	1.3	2.8	3.9	5.2	6.6
1,000	0.9	2.0	2.8	3.7	4.7
5,000	0.4	0.9	1.2	1.6	2.1
15,830	0.2	0.5	0.7	0.9	1.2

Table C-2: Standard Errors of Estimated Percentages of Blacks
(68 chances out of 100)

Base of percentage (thousands)	Estimated percentage				
	1 or 99	5 or 95	10 or 90	20 or 80	50
50	2.4	5.4	7.5	10.0	12.5
75	2.0	4.4	6.1	8.2	10.5
150	1.4	3.1	4.3	5.8	7.2
300	1.0	2.2	3.0	4.1	5.1
1,000	0.6	1.2	1.7	2.2	2.8
2,374	0.4	0.7	1.1	1.4	1.8

Standard Errors of Differences between Percentages

In analyzing and interpreting the data, interest will perhaps most frequently center on the question whether observed differences in percentages are "real," or whether they result simply from sampling variation. If, for example, one finds on the basis of the survey that 3.3 percent of the whites, as compared with 7 percent of the blacks, are unable to work, the question arises whether this difference actually prevails in the population or whether it might have been produced by sampling variation. The answer to this question, expressed in terms of probabilities, depends on the standard error of the difference between the two percentages, which, in turn, is related to their magnitudes as well as to the size of the base of each. Although a precise answer to the question would require extended calculation, it is possible to construct charts that will indicate roughly, for different ranges of bases and different magnitudes of the percentages themselves, whether a given difference may be considered to be "significant," i.e., is sufficiently large that there is less than a 5 percent chance that it would have been produced by sampling variation alone. Such charts are shown below.

The magnitude of the quotient produced by dividing the difference between any two percentages by the standard error of the difference determines whether that difference is significant. Since the standard error of the difference depends only on the size of the percentages and their bases, for differences centered around a given percentage it is possible to derive a function which relates significant differences to the size of the bases of the percentages. If a difference around the given percentage is specified, the function then identifies those bases which will produce a standard error small enough for the given difference to be significant. The graphs which follow show functions of this type; each curve identifies combinations of bases that will make a given difference around a given percentage significant. For all combinations of bases on or to the northeast of a given curve, the given difference is the maximum difference necessary for significance.

Thus, to determine whether the difference between two percentages is significant, first locate the appropriate graph by selecting the one labeled with the percentage closest to the midpoint between the two percentages in question. When this percentage is under 50, the base of the larger percentage should be read on the horizontal axis of the chart and the base of the smaller percentage on the vertical axis. When the midpoint between the two percentages is greater than 50, the two axes are to be reversed. (When the midpoint is exactly 50 percent, either axis may be used for either base.) The two coordinates identify a point on the graph. The relation between this point and the curves indicates the order of magnitude required for a difference between the two percentages to be statistically significant at the 5 percent confidence level.²

² In another report by the staff of this Center (Belton M. Fleisher and Richard D. Porter, The Labor Supply of Males 45-59, (April 1970),

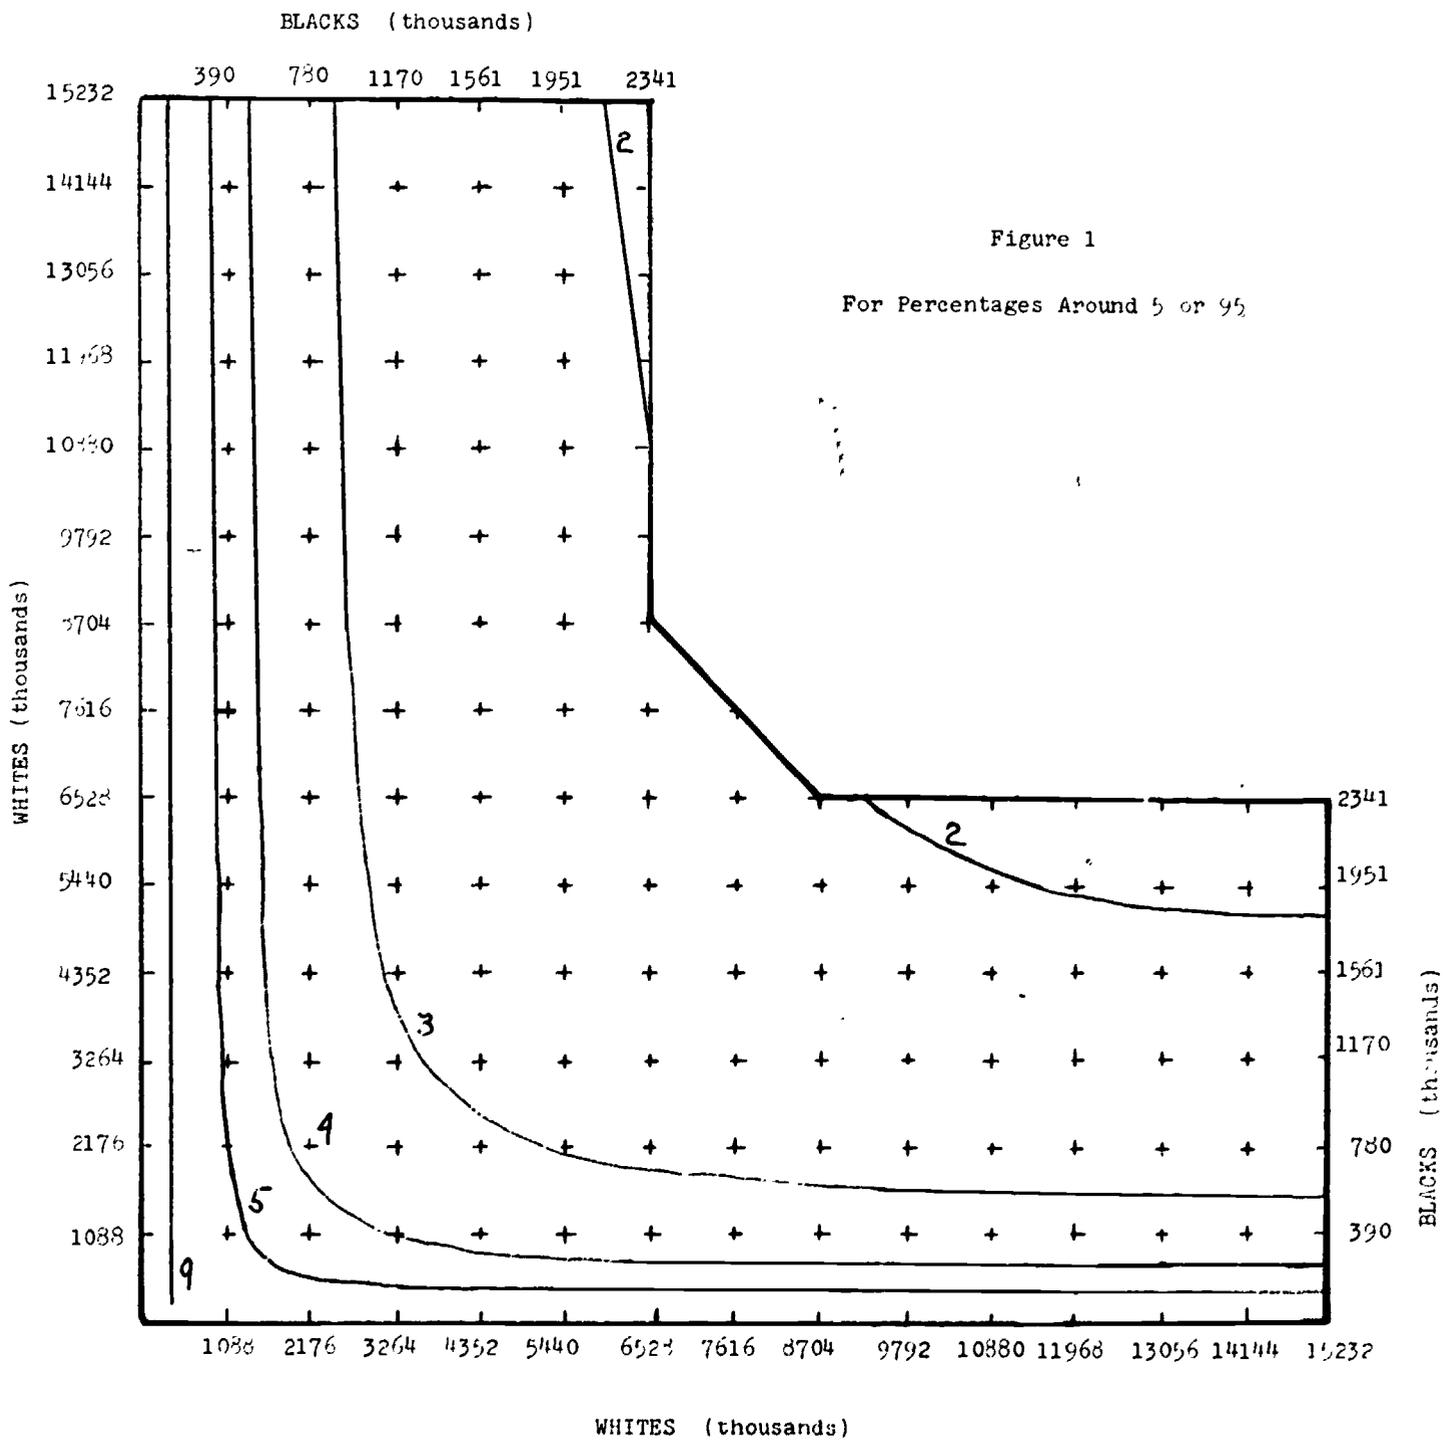

All this may be illustrated as follows. Suppose in the case of white women the question is whether the difference between 27 percent (on a base of 6,000,000³) and 33 percent (on a base of 5,000,000) is significant. Since the percentages center on 30 percent, Figure 4 should be used. Entering the vertical axis of this graph with 6,000,000 and the horizontal axis with 5,000,000 provides a coordinate which lies to the northeast of the curve showing combinations of bases for which a difference of 6 percent is significant. Thus the 6 percentage point difference (between 27 and 33 percent) is significant.

As an example of testing for the significance of a difference between the two color groups consider the following. The data in our study show that for women in the age cohort 18 to 24, 78 percent of the white nonstudents (on a base of 7,394,000) and 83 percent of the black nonstudents (on a base of 1,000,000) were in the labor force at least one week in 1967. To determine whether this intercolor difference is significant Figure 3 is used because the midpoint (81) between the two percentages is closer to 80 than 90.⁴ Entering this graph at 1,000,000 on the vertical axis for blacks (calibrated along the right side of the figure) and at 7,394,000 on the horizontal axis for whites provides a coordinate which lies to the northeast of the 5 percent curve. Thus the 5 percentage point difference in labor force participation rate is significant.

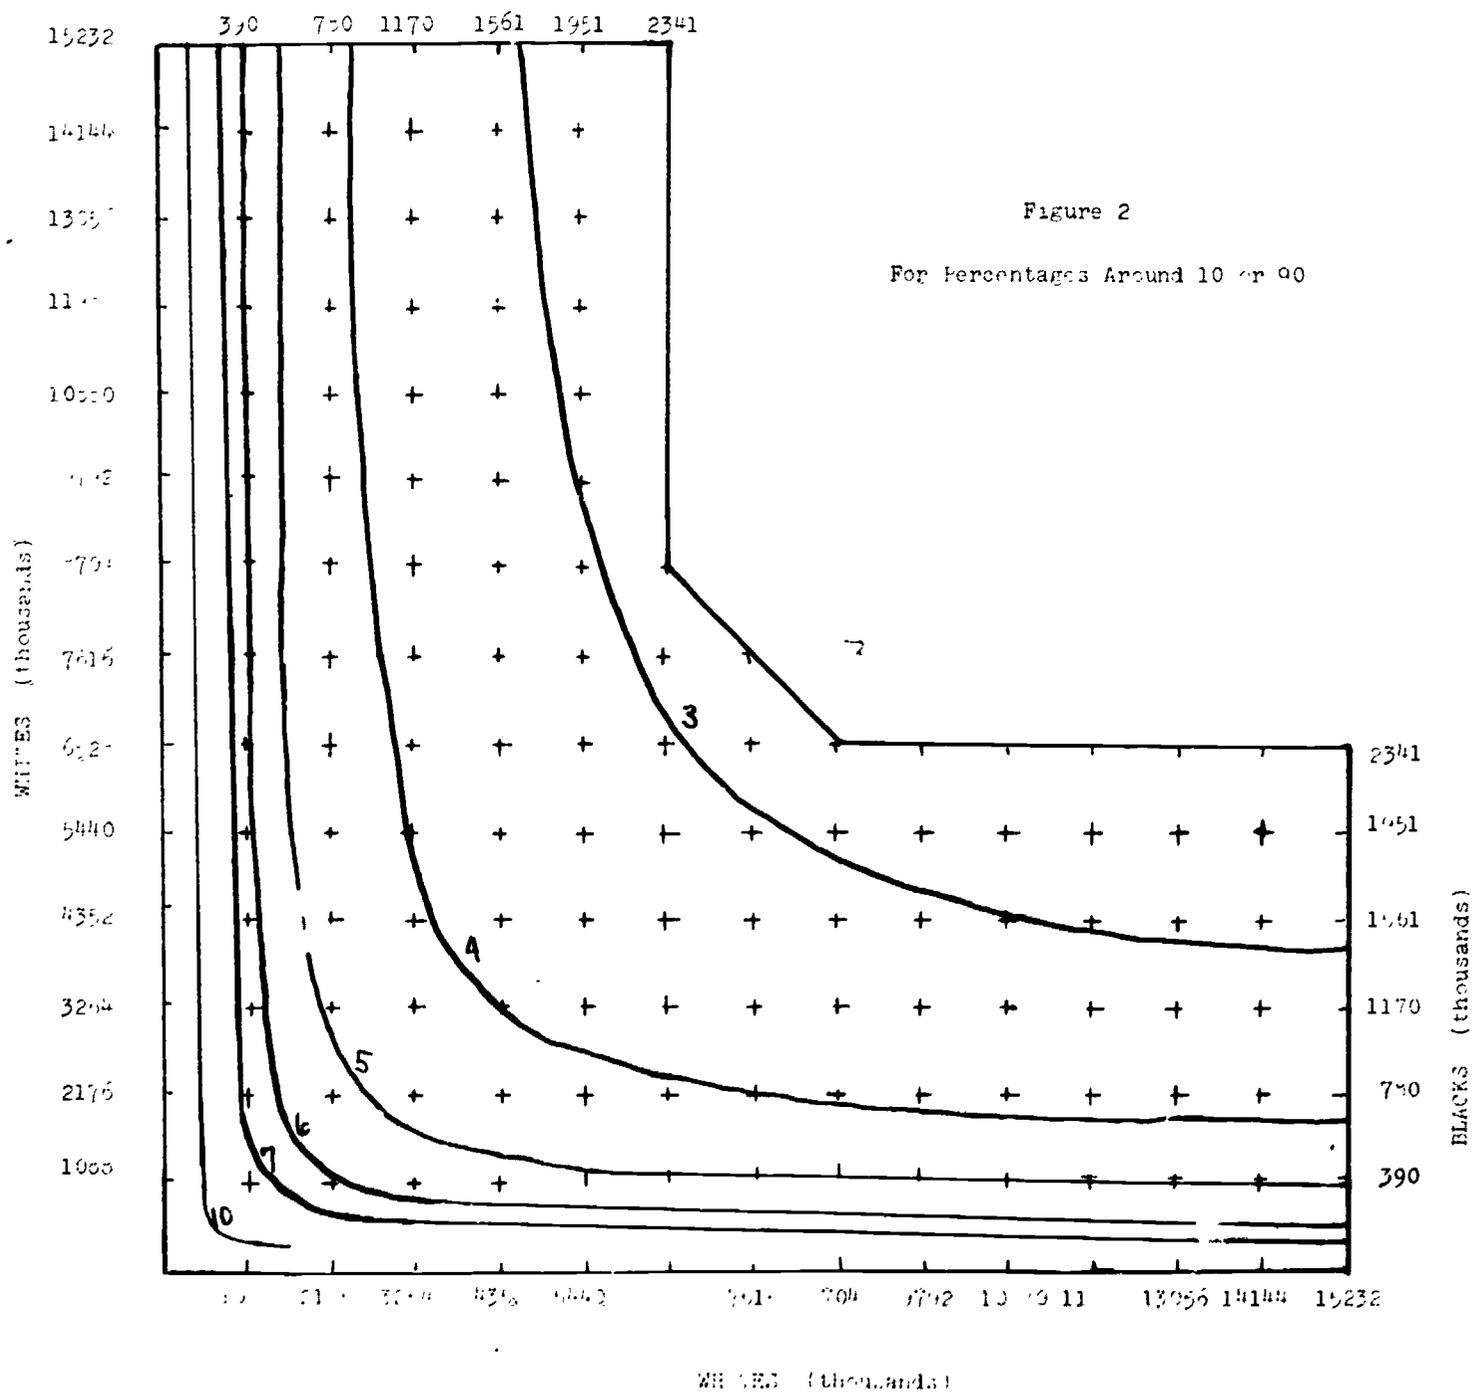

Appendix B, pp. 92-110) it was argued that unadjusted standard errors (as opposed to the adjusted standard errors discussed in footnote 1) could be used to test for the significance of the coefficients in a linear regression. Clearly this argument applies to tests for the significance of the difference between proportions, and, as a result, the techniques used in this report are currently being altered. Thus the graphs should be interpreted as providing only a rough and conservative estimate of the difference required for significance.

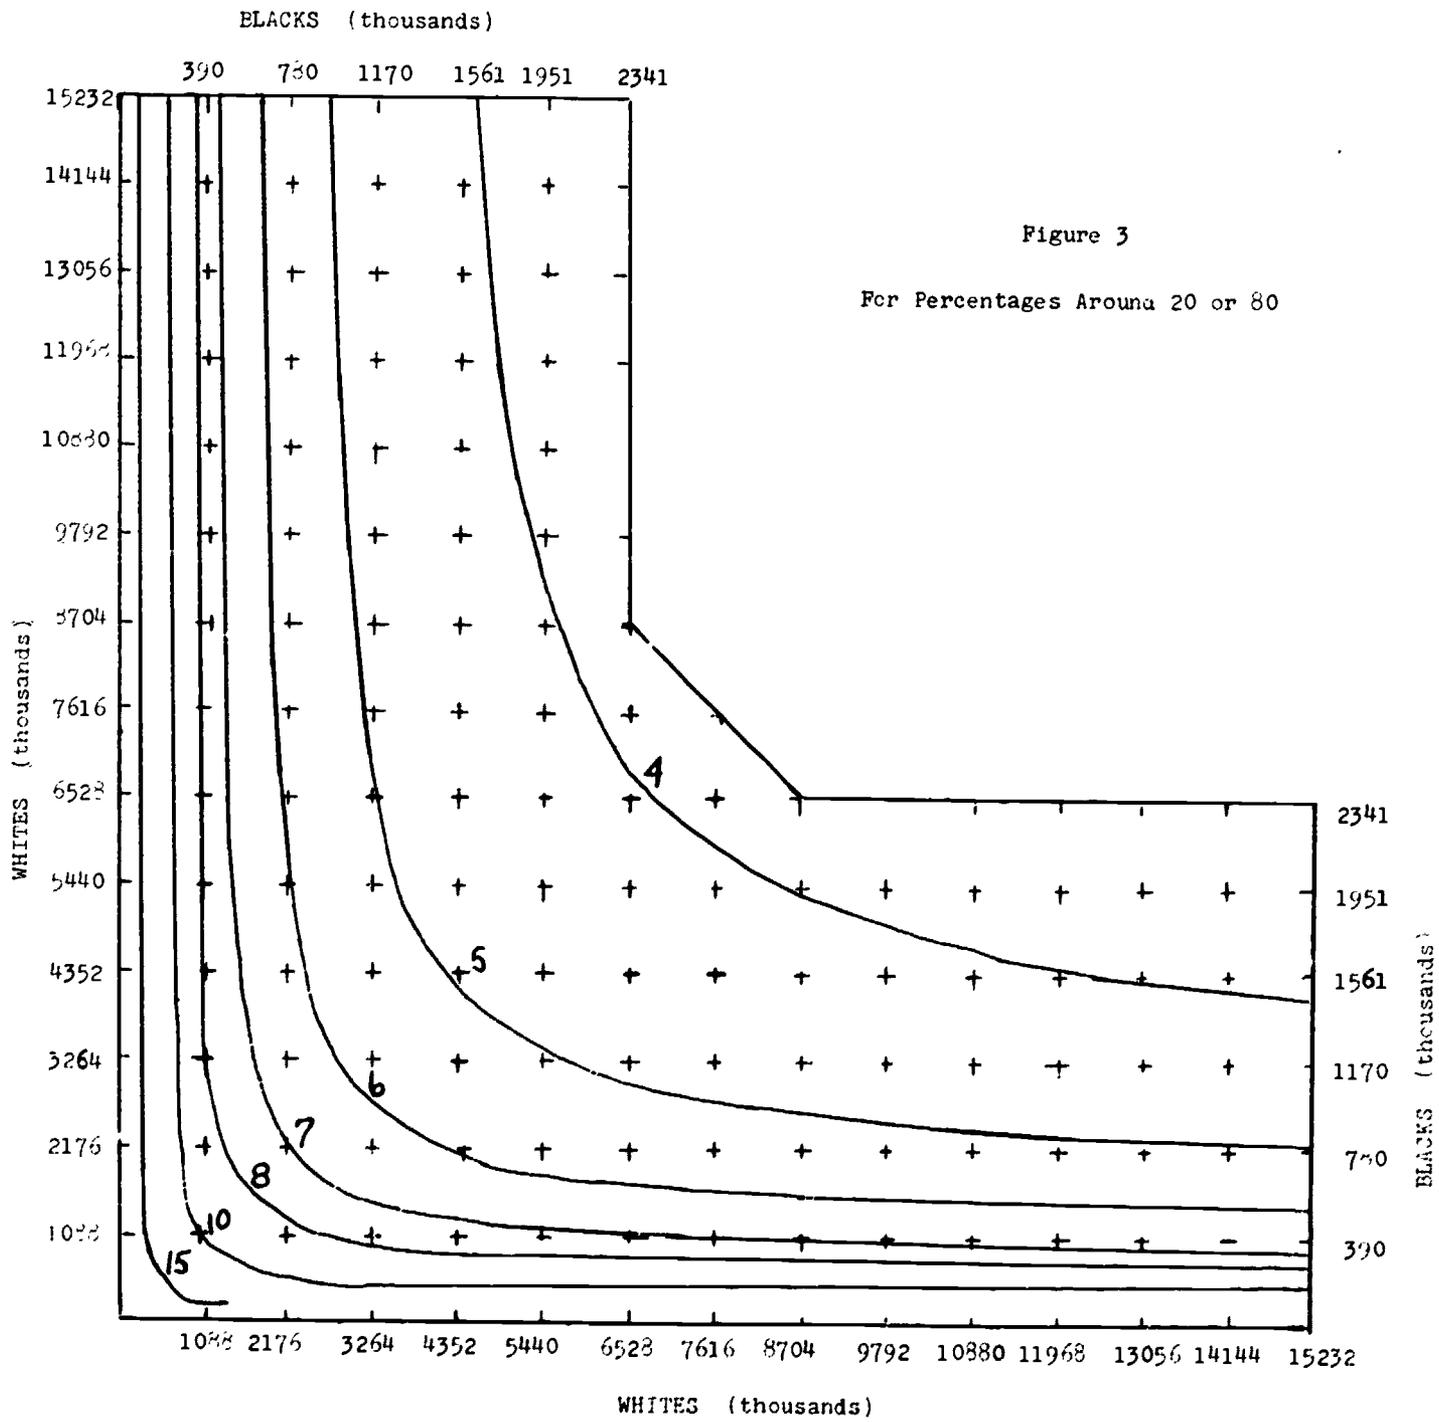

3 Each of the curves in the graphs of this appendix illustrates a functional relationship between bases expressed in terms of actual sample cases. For convenience, however, the axes of the graphs are labeled in terms of blown-up estimates which simply reflect numbers of sample cases multiplied by a weighting factor.

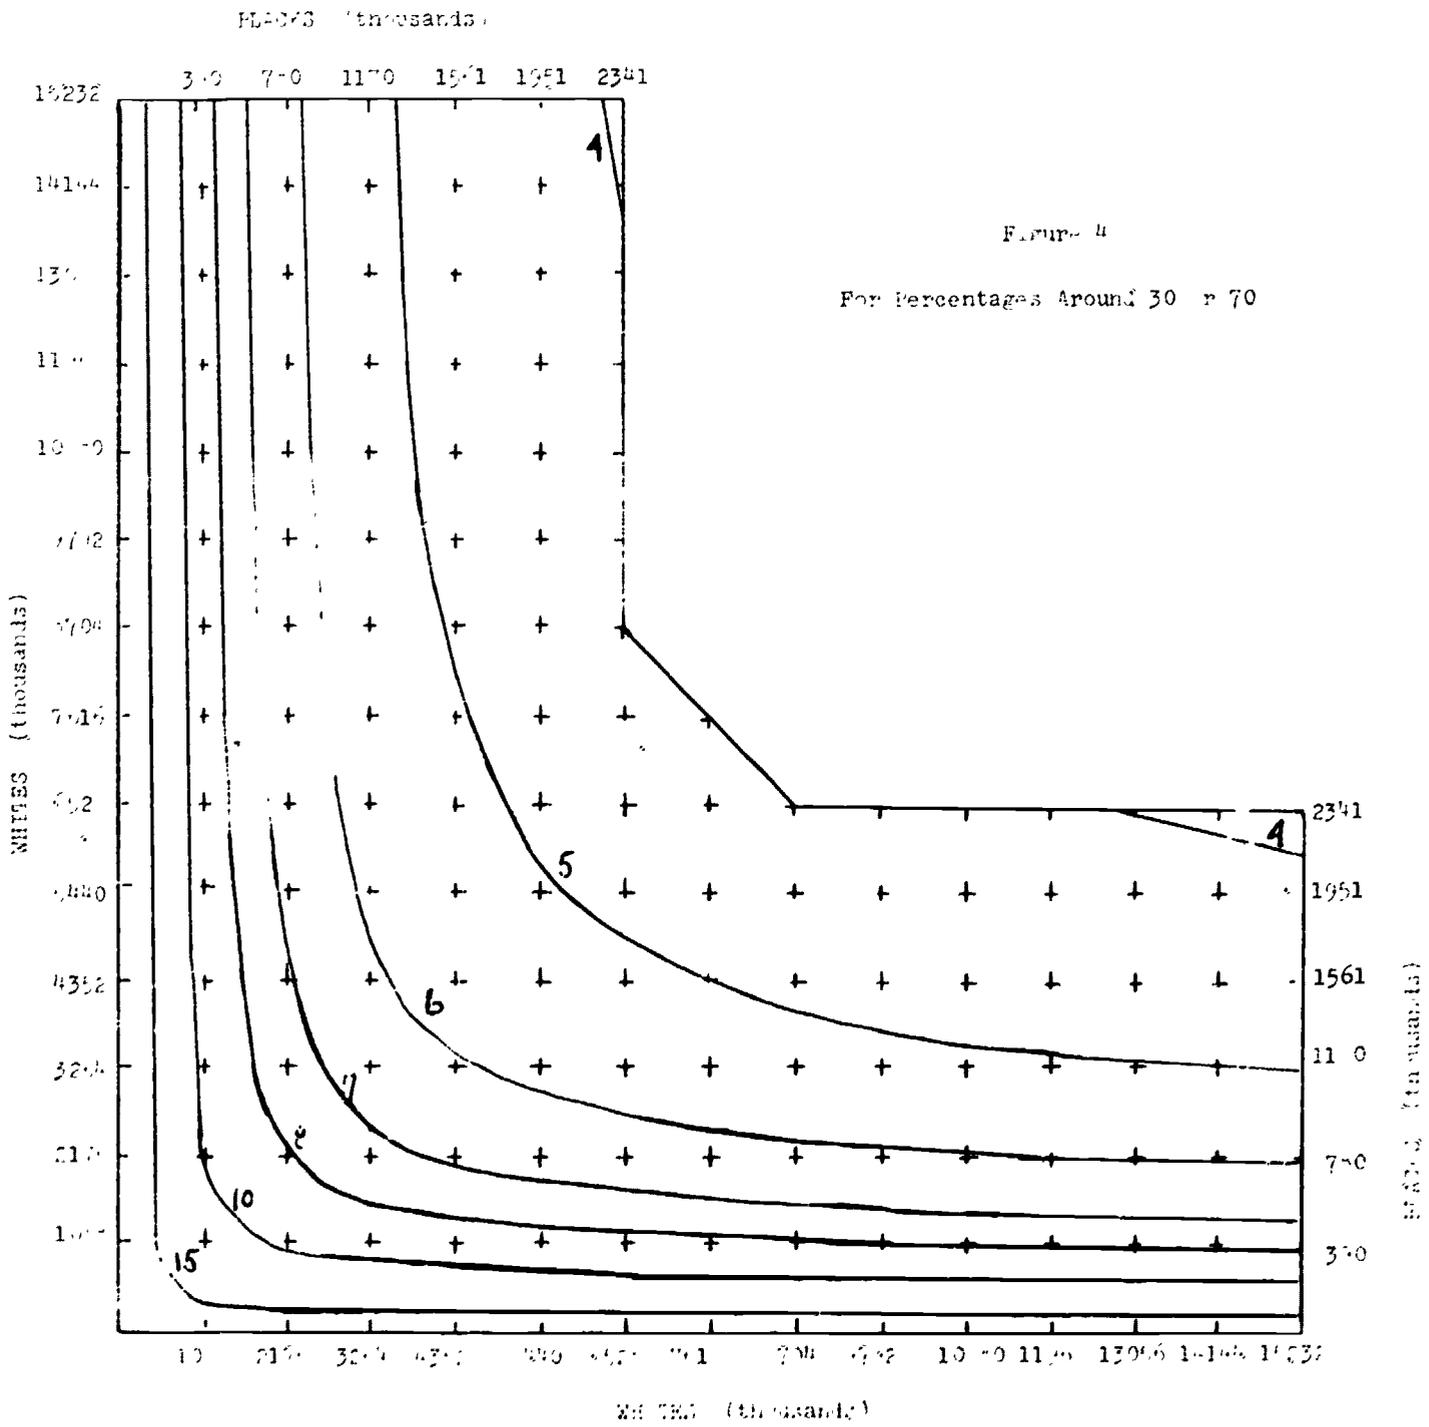

4 If both percentages are less (greater) than 50 and the midpoint between the two percentages is less (greater) than the percentage for which the curves were constructed, the actual differences necessary for significance will be slightly less than those shown on the curve. The required differences shown on the curves understate the actual differences necessary for significance when both percentages are less (greater) than 50 and the midpoint is greater (less) than the percentage for which the curves were constructed.

Notes

XII. FAMILY BACKGROUND

<p>Now I have some questions on your family background. 90. Where were you born?</p>	<p>90. 1 <input type="checkbox"/> U.S. City _____ County _____ State _____ 2 <input type="checkbox"/> Outside U.S. Specify country _____</p>
<p>91. For how long have you been living in this area (city or county of CURRENT residence)?</p>	<p>91. 1 <input type="checkbox"/> Less than 1 year 2 <input type="checkbox"/> 1 year or more – Specify _____ 3 <input type="checkbox"/> All my life – SKIP to 94</p>
<p>92. Where did you live before moving to (name of city or county of CURRENT residence)?</p>	<p>92. 1 <input type="checkbox"/> U.S. City _____ County _____ State _____ 2 <input type="checkbox"/> Outside U.S. Specify country _____</p>
<p>93. Where did you live when you were 18?</p>	<p>93. 0 <input type="checkbox"/> Respondent is 18 or less 1 <input type="checkbox"/> U.S. City _____ County _____ State _____ 2 <input type="checkbox"/> Outside U.S. Specify country _____</p>
<p>94. 0 <input type="checkbox"/> Respondent not married – SKIP to 95 How old were you at the time of your first marriage?</p>	<p>94. Age _____</p>
<p>Now I'd like to ask about your parents. 95. Are your mother and father living?</p>	<p>95. 1 <input type="checkbox"/> BOTH parents alive 2 <input type="checkbox"/> MOTHER alive, Father dead 3 <input type="checkbox"/> FATHER alive, Mother dead 4 <input type="checkbox"/> NEITHER parent alive</p>
<p>0 <input type="checkbox"/> Respondent is not married – SKIP to 97 96. What about your husband's parent's? Are his mother and father living?</p>	<p>96. 1 <input type="checkbox"/> BOTH parents alive 2 <input type="checkbox"/> MOTHER alive, Father dead 3 <input type="checkbox"/> FATHER alive, Mother dead 4 <input type="checkbox"/> NEITHER parent alive</p>
<p>97. Where were your parents born – in the U.S. or some other country?</p>	<p>97a. FATHER 1 <input type="checkbox"/> U.S. 2 <input type="checkbox"/> Other – Specify _____</p> <hr/> <p>b. MOTHER 1 <input type="checkbox"/> U.S. 2 <input type="checkbox"/> Other – Specify _____</p> <p><i>If either parent born outside U.S. – SKIP to 99</i></p>

I have a few questions about the education and work experience of the other family members living here.

Line number	Name <i>List below all persons living here who are related to respondent. Enter the line number from the Household Record Card</i>	Age <i>(As of January 1, 1968)</i>	Relation-ship to respondent <i>(Example: husband, son, daughter-in-law, brother, etc.)</i>	Persons 6 - 24 years old			Persons 25 years old and over		Persons 14 years old and over		
				Is ... attending or enrolled in school? <i>Circle Y - Yes N - No</i>	If "Yes" - what grade (year)? If "No" - What is the highest grade (year) ever attended?	Did ... finish this grade (year)?	What is the highest grade (year) of regular school ... has ever attended?	Did ... finish this grade (year)?	During 1967 how many weeks did ... work either full or part time (not counting work around the house)?	In the weeks that ... worked, how many hours did ... usually work per week?	What kind of work was ... doing in 1967? <i>If more than one, record the longest</i>
110	111	112	113	114	115	116	117	118	119	120	121
			Respondent								
				Y N		Y N		Y N			
				Y N		Y N		Y N			
				Y N		Y N		Y N			
				Y N		Y N		Y N			
				Y N		Y N		Y N			
				Y N		Y N		Y N			
				Y N		Y N		Y N			
				Y N		Y N		Y N			

122. ASK at the completion of the interview. If more than one respondent in the household, ask for each. We would like to contact you again next year at this time to bring this information up to date. Would you please give me the name, address, and telephone number of two relatives or friends who will always know where you can be reached even if you move away? - Enter information below.

	Name	Relationship to respondent	Address	Telephone number
1.				
2.				

CHECK ITEM Y	Notes
1 <input type="checkbox"/> Respondent has completed less than 1 year of high school (Q. 2 or 4) 2 <input type="checkbox"/> Respondent has completed 1 or more years of high school and -- 3 <input type="checkbox"/> Signed release 4 <input type="checkbox"/> Did not sign release

V. KNOWLEDGE OF THE WORLD OF WORK

61. I'd like your opinion about the kind of work that women in certain jobs usually do. For each occupation on this card (*hand card to respondent*) there are three descriptions of job duties. Will you please tell me which description you think best fits each job? Be sure to read all of the possible answers before you decide.

A. ASSEMBLER

- 1 Puts together and fixes machines used on an assembly line
 - 2 Takes broken parts off an assembly line and sends them to scrap area
 - 3 Works on a production line putting parts together
 - 4 Don't know
-

B. KEYPUNCH OPERATOR

- 1 Operates a machine which sends telegrams
 - 2 Operates a machine which punches holes in cards used in computers
 - 3 Operates a cordless telephone switchboard and pushes switch keys to make telephone connections
 - 4 Don't know
-

C. BANK TELLER

- 1 Checks bank records
 - 2 Talks to persons who want to borrow money
 - 3 Receives and pays out money in a bank
 - 4 Don't know
-

D. DEPARTMENT STORE BUYER

- 1 Selects the items to be sold in a section of a department store
 - 2 Checks on the courtesy of sales people by shopping at the store
 - 3 Buys department stores that are about to go out of business
 - 4 Don't know
-

E. DIETICIAN

- 1 Waits on tables in a restaurant
- 2 Suggests exercises for persons who are overweight or sick
- 3 Plans menus for hospitals and schools
- 4 Don't know

V. KNOWLEDGE OF THE WORLD OF WORK - Continued

61. Continued

F. STATISTICAL CLERK →

- 1 Solves business problems using a computer
- 2 Makes calculations with adding machines or a desk calculator
- 3 Prepares bills and statements for customers
- 4 Don't know

G. NURSES' AID

- 1 Teaches nurses how to take care of patients
- 2 Tests blood samples of hospital patients
- 3 Serves food to hospital patients and performs other duties to make patients comfortable
- 4 Don't know

H. SOCIAL WORKER

- 1 Conducts research on life in primitive societies
- 2 Writes newspaper stories on marriages, engagements, births, and similar events
- 3 Works for a welfare agency and helps people with various types of problems they may have
- 4 Don't know

I. MEDICAL ILLUSTRATOR

- 1 Draws pictures of medical uniforms for use in ads
- 2 Teaches medical students correct operating procedures
- 3 Draws pictures that are used to teach anatomy and surgical operating procedure
- 4 Don't know

J. QUALITY CONTROL GIRL IN BAKERY

- 1 Finds out if packages of pastries are the proper weight
- 2 Tells bakers what to do
- 3 Keeps records of how much bread is sold
- 4 Don't know

While answering Section V, was another person present?

- 1 Yes
- 2 No - Go to 62

Would you say this person influenced the respondent's answers?

- 1 Yes
- 2 No

VI. ASSETS AND INCOME

62a. So far as your overall financial position is concerned, would you say you are better off, about the same, or worse off now than you were at this time last year?

- 62a. 1 Same - SKIP to Check Item V
 2 Better off } 1SK b
 3 Worse off }

b. In what ways are you (better, worse) off?

b. _____

CHECK ITEM V

- x Respondent is NOT head of household - SKIP to 64a
 1 Respondent is head of household - 1SK 63a

				Y N		Y N			

80. Last year you mentioned (read names from item 87R on Information Sheet) as persons who will always know where you can be reached even if you move away. Is this still true? (If so, verify the addresses and telephone numbers and enter below. If not, enter information about other persons who will know the respondent's whereabouts.)

	Name	Relationship to respondent	Address (Number, street, city, State, ZIP code)	Telephone number
1.				
2.				

INFORMATION SHEET

Entry on 1968 Questionnaire

81R. Whether respondent was attending or enrolled in school

Yes No

Grade respondent was attending OR highest year of regular school completed:

None 0
 Elem 1 2 3 4 5 6 7 8
 High 1 2 3 4
 College 1 2 3 4 5 6 7+

82R. Respondent's educational goal:

Not asked educational goal
 Less than high school
 High 1 2 3 4
 College 2 4 6 7+

83R. Respondent's labor force status:

Unable to work
 Labor Force Group A
 Labor Force Group B
 Labor Force Group C

84R. (1) Name of employer _____

(2) Kind of work done _____
