## ABSTRACT

The College of Education of the Cleveland State Oniversity opened its first graduate program in 1968. The purpose of the study reported here is to provide information for reflection about the college's past performance and for planning new directions in its graduate programs. The study uses information from college and university records, organized so that it shows what has happened in the college's graduate programs and to the students who enrolled in them. The findings are organized around four topics: (a) patterns of admissions; (b) student characteristics; (c) student performance and progress; and (d) predicting student performance. It was found that the College of Education, over the eight years reviewed here, admitted a very large, diverse group of sídents to graduate study. It graduated, or is likely to graduate, only a small portion of those students. The reasons for most of the student attrition remain unknown; this study has only shown the magnitude of attrition and that the reasons for it are not academic. (MM)

2
Students' Performance in K. Ed. Programs at The Cleveland State University, 1955-1975

- Shortly after the College of Education at The Cleveland State University opened it.s first graduate degree progrems in 1968 , its faculty was nearly overwhe?med by the sheer numbers of students who souzht admission. At the time, the full-time faculty was small, fewer than twenty, and the number of students and the climate of deference to students demands left no time for reflerition and precious little time for planning. Now there is time, both for careful reflection about the character and direction of the college's graduate programs and for planning new dirsctions. then the collese and university wero both norw hastily conceived programs and stomap admissions policies were acceptable--inceed, they were necessary to meet the needs and demands of clientele. Now they are not.

The purpose of this study is to provide the infomation necessary for mature reflection about the college's past performence and for planning its now directions in graduate programs. The study uses information from college and university recoris, o:ganized so that it shows--so far as it is possible-what has happened in the college's praduate programs and to the students who enrolled in them. The findings are organized around four topics: (a) patterns of admissions, ( $b$ ) students' charactieristics, ( $c$ ) students' performance and progress, and (d) predicting students' performance.

## Hethod

Because this study uses data that are readily available in university records, it offers no methodological novelty in the type of information or in the method of obtaining it. What is original about the study is the
attont to make some sense out of the body of information that is routinoly collecter in the administration of degree programs and to use it critically for evaluatirs those peograms.

The repistrar's computer racords were used to compile a tape that contained the following information for all active or inactive graduate students in education: (a) name, (b) social security numbor, (c) birtindate, (d) race, (e) credits earnec, ( $f$ ) crerlits attempted, ( $(\mathrm{y}$ ) grade averese, (h) number oi incomplote grades pendine, (i) entranos states, (j) enrolluent date, and (k) gracluation date (when applicable). From studonts filos kopt by tho Collese of Education, the following infomation was adred: (a) whother or not the student had earned a grevious graduate degree, (b) íiller Analozies Test score, (c) Graduate Rocore Eranination verbal and quantitative aptitude scores, (d) undergraduate grado average, (o) prosram choice, and (f) sex. The repistrar's records provided initiel data on 3,640 students. . The process of searching Collegg of Dducation recouds turned up another g2á students, the data on whom had somanow been expurged from the registrar's computer tape. (Their data still oxist in the writton records.) Thus, the population studied consists of 4,556 persons who enrolled for eraduate study in the College of Education batween the opening of the first program and the end of the $197^{4}-75$ acadomic year.

The date were processed using the Statistical Package for the Social Sciences (Hie, Hull, Jenleins, Steinbrenner, \&ent, 1975). In the analyses, two new variables were compated, the student's age at entry into the program and the number of quarters elapsed between his entry and graduation or December, 1975, whichever was later. Then, analyses were done, most of

## i. Er. Prosrams

$!$
Which are simple frequercy distributions of the variables for verious subpopalations or crosstabulations of eroups of variables. In addition, I attenoted to develop prediators of acaderic success, using linear regression and discriminant analysis. Where appropriate, the discussions of the results include elaboration on the criteria and techniques usec in analyses.

Results
Adnissions Patterns
In admissions to graduate prognars, the truth is a cliché. College of Education graduate amissicns have grom by leaps and boands. Figure 1 illustrates the grovth of graduate aimissions over the eight years of the prograns existence. The first lean in admissions came in 1959, an increaso from 57 to 402 adrissions. This inereaso marked the opening of the college's first general graduate degree prograns, those in curriculur and instruction and in scbool administration. The programs existing before 1909 were a selactive program for kindergarton and primary teachers and two "internship" programs contracted with the Cloveland Public Schools for uncertified teachers it had employed in elementary and junior high schools. The kindergarten/primary prosram was quickly eclipsed by the sheer numbers of students admitted to the program in elementary curriculum and instruction.

The next bound in enrollments came in 1971, and this increase also reflected the expansion of programs into fields for which there was great demand. In this case, the school counselor program attracted large numbers of students and soon surpassed both administration programs in size (Soe Figure 2.).

```
Insort, Figures 1 \& 2. about here
```

As Figure 1 indicates, the colleg's graduate admissions ramained fairly steady, at about 700 to 750 mew admissions per year, for the period following 1971. However, there is a third leap that is not apparent in the graph. The deta for 1975 include admissions for only the first thres quarters of the palendar year because the acadenic yeer ended in lugust, and the end of the acederic year was used as the cut-off date for this study. If new admissions for the Fall guarter, 1975, followed the past pattern of amounting to aboat $45 \%$ of the total. for the rest of the year, then now adnissions for 1975 would exceed 1,000. Again, this can be interpreted as reflecting college changes that were in tune with existins demands. In this instance, the introduction
 plified admissions requirements, may account for mach of the 1975 increase. This interpretation jis corroborated by the data on catezories of admissions giren in Table 1 below.

The profiles of adrissions to the several college programs show another aspact of the nature of demand for graduate programs. Figures 2 through 7 show these profiles, with the programs grouped by department and by size. The larger programs are graphed to show quarterly fluctuations in admissions; the smaller programs are graphed only to show annual totals. The adinissions shom for 1967 antedate the college's programs; evidently three students transfered to the College of Education from programs that opened earlier.

Insert Figures 3 through 7 about here

Cne pattern that shows clearly in the graphs of admissions to indivicual prosrams is the tims dependence of demani for some programs. It is clear that the numbers of new students for the prozrams in elomentary ard seconary school administration reached their peaks in 1971 and fell off singrply thereaftor (figu:s 2). The school counselor progran, which obviously tapped an unet need when it opened in 1971, reachec' its peak in new adnissions in 1973. Its admissions, too, have fallon off noticeably. Similar, though less pronounced patterns appear in the profilas of the tio curriculum and instruction programs and of the learnins disabilities program. The latter program is quity row, and so thore is not sufficient data for a cloar trend in the profile. Hosever, the rigure 3 data show a very sharp rise and a very sharp drop. Such a pattern would be consistent with the expectation one would have Eor students' intorests fueled by federal funding for a limited set of ners positions. Such interest dovelops quickly, as laws and eppropriations ara passed; and it wenes egually starply, as the positions defined by categorical aid are filled.

In contrast to these very large programs, with their sharp rises an? falls in enrollments, several college programs have shown much more rodest enrollments, but also enrollments that show promise of stability, and even modest long-term growth. The programs in higher education (Figure 4), emerging adolesent education (Figure 5), reading (Figures 5\&6), and business education (Figure 6) show fairly stable patterns of admissions.

The gaphs understate growth in 1975 ow indicate false drops in new ad:aissiors. This is the result of not including fall, 1975, acinissions in the clata for this study.

The contrast between the admissions patterns of large scale ard small scale programs spotights a major policy arobien. Prosrams with hish, but short lived demand majgenerate rapid erowth, but the faculty and staff that the prosram growth brings rast be sustained when the dewand wanes. Altornatively, such programs can be stafied heavily with part-tims faculty, a practice which usually dravs censure from accrediting agencies. Modost prosrams do not generate such staffing problens--unless, of course, one mistakes the character of his program. It remains an interesting, unanswered question whether or not one could obtain stable admissions to a high denand prozran by "stretching out" the admissions through selection.

The patterns of admissions of students who don't want graduate degrees contrast sharply with those of the larse scale programs, despite tho similarity of the numbers involved. Thile the large scale programs show heary new admissions in both sumer and fall quarters (figures 2 and 3), tho admissions for workshops and non-degree studies, shown in Figure 7, hava sharp paaks in sumar quarters, followed by sharp drops in fall quarters. Noreover, thera is a steady rise in the numbers of such students, with a curious tio-year cycle between major peaks. The explosion of ner non-degree admissions in the summer of 1975 probably does not signal a major shift in students' academic ambitions. Rather, it likely reflects simple acknowledgement of the limited purpose for study that a large proportion of graduate students in education have. Before the $1974-75$ academic year, the admissions procedures
of the colloge required students who honestly had no deg ere ambitions to pretend that ther did, just to be admitted to take classes. In fact, the categorization of these stulents for this study was done on the basis of the types and number of courses thay completed rather than on the basis of their statements on the adrissions applications. Tho idga that a large proportion of the college's students do not really want graduate degrees is supported by the data on anounts of work competad and prozress rates that is presented below.

One last quantitative aspect of the college's admissions to graduate stiudy that bears some examination is the pattern of admissions by catezories defined by admissions requiremsnts. These catggories, defined by the regulations of the College of Grachate Studie:s, relate either to prosadures or to parporised qualifications for graduate study. The categories aro: (a) regular sraduate student, one "fully qualifisd" fon graduate stugy; (b) special graduate student, one who does not meet adnission criteria-.-chiofly that for a 2.60 undergraduate GPA-obut who is admitted probationally; and (c) provisional gracluate student, one who has not subinitted all materials raquired for admission, but who is admitted for one quarter without them. Table 1 shows the numbers and percentages of students admitted to these categories since 1968. However, the data understate the admissions to special graduate and provisional fraduate categories; when students admittod to these categories qualify for another category (e.g., a special graduate being admittod to degree candidacy or a provisional student subnitting the materials necessary for admission to special graduate status), the registrar changes the studunts' admissions status. Thus, the numbers originally

## X. Esl. Prorarams

admitted to special graduata or provisional graduate standing aro largerbut unkom-athan fors show in Table 1 , and the numbers originally admitiod to regular graduate status are correspondingly smeller.

Insert Table 1 about her:

It is clear from Table 1 , regardless of the changed classifications, that tho provisional acmission, which was croater in 1973, has quictry becore the dominant mode of entry to gracuate study in the Collnge of Dacation. This may be radically changed when data become available on admissions to the new non-dorree status, which became effective in the fall of 1975. It is altozethar possible that the non-degree status will eftectively replace the provisional status, if those who wera adritted to prorisiomal status were so admitted because of theis: lack of interest in degrons. Since the basic difiterence between provisional acmission and special or rezular admission has only to do with the student's sub:ission of transcrints and racommenations, it is probabiy accurate to say that students mo are admitted provisionally aren't very interested in graduate degrees, let alone those who remain provisional students after tinree months.

Table 1 also shows an apparently declinine proportion of students who fail to meet the criterion (2.50 undergraduate GPA) for regular graduate admission. If this is accurate-and not aserely an indication of admissions to degree candidacy, it probably reflects the well-known inflation of undergraduate grades over the past ten years (Ttzioni, 1975; Ferguson \& Vaxey, 1975; Davidson, 1975), rather than indicating increases in the academic abilities of students. To check on this question, I examined distributions
of tho :iller fnalogies Test (Mit) scores by yor of admssion and foun no trend, upurd or othernse. The meen wis soness for various jeers fluctuated whin a few noirts of the overell mon of 43.

## Characteristies of Studont:

 been a diverse grow, no mattor what the banis for comarison. Breakdoms
 Given in Tables 2 and 3. Sinee these data are comile fron recores, thoy Ieave something to be desired. Unknom sex, difficult as it is to understand, is simoly the result of stadents hevine left blanhs on their adrission applications and having rames, like Barion, which aro ased for either sex. Tho racial data wote btained fron votuntary questionairos used by the refistrar sinee $197 ?$ to meet federal rejorting requiremmen. The catogorins, wich are those specified for reporing by the U.S. Department of Health, Edueation, and relfare, are obviousiy suspect scientianically; and the return rate of the questionnaires is not impressive.

Insert Tables 2 \& 3 about here

Since no college progrem has used selective admissions criteria at all, let alone criteria that might discriminate sexully or racially, the distribution of individuals to programs has been solely due to self-selection. With about 60\% of the student group boing vomen, only four programs have majorities of men. These are the two adrinistration programs (predictably) and the two teaching internship programs. The predominance of men in the
lattor prorrans was the result of the hiring policies of the cleveland pubIic Bohools for the terpoway positions from which the students rore dram. If one can assume that thosis tho did not respond to the registrar's race questionnare have the sane racial propontions as those who did (and that the rosponsos were truthiul), then the proparations of Black studonts in the collne:s programs vary batieen about 7 and $32 \hat{A}$, with most prograns harine about $25 \%$ Black statents, a small pereentage of Oriontal students, and the rest wite. Thers are no apparent patterns of racial distributions in the various programs.

The distribution of stadents' apes at ontry into their graduata prograns is shom in Tigure 8, and the averare ontry age for each of the colege's prorrans is shom in Pabla 4. Fho nost interesting thime about the distribution of students" ares is the very gool nproximation that it makes to a lownthric curve. Sent nay surprise sore sbout this is the rairly hish nambers of young ( 21 to 25 years) despit: tre average ape of 32.2 years. Of much nore interest for interpretive purposes are the difierences arong prorrems.

Insert Figure 8 and Table 4 aboot here

The two teaching internship programs, both now defunct, had far and away the youngest groups of students of all programs. As noted above, these students had been recruited to teach in Cleveland schools and wero enrolled at Clevoland State University to pursue teaching certification at the graduate level. That the students vere mostly men of draft age, at a time when draft
deferments were given to teachers, may explain the low completion rates for these prorwams thet are noted below.

There are no really striking differences among programs in the average entry ages of students. Students in the supervision, learning disabilities, and emerping adoloscent education programs average somewat older than students in other programs, but only by two or thres years. There is a marked disference in age between students in degree prosrams and those undocided about prorram or not seeking deanees; the average age of the latter groups is substantially greater than that of any other student groap. These two grouns also comprise a plurality of the graduato student body, almost a third of the total.

Academic ability. The distributions of students undereraduate grade averages, Jiller Analogies Test scores, and Graduate Record Rxamination scores, on the whole, are what ons would expect for graduate students in education at a state university. The data do not deviate noticeably from national norins. I'he overall distributions of these variables are show in Figures 9, 10, 11, and 12. Breakdoms of averages for each of the college's programs are shown in Table 5. One should note, however, that wat or GRe scores are available for less than half of the students admitted to graduate standing in the college, despite college acmissions policies requiring one test score or the other. Generalizations from these data require the assumption that those who took the tests were representative of all students.

Insert Figures 9 through 12 and Table 5 about here

The college mear and standard deviation on the MAT, 43.0 and 17.0, are comparable to those obtain 'rman . rional norm groups. The mean and standard deviation for edt in mastor's programs are 39.? 15.4, and those for school a. . wion majors at schools granting uxal degrees are 44.5 and 15.7. One should note that the latter norm group includes both doctoral candidates and master's degree candidates (Psychological Corporation, 1970 , pp. 5-5), and one must also be coutious of comparisons because of probable "sample bias" in the data on Cleveland State's students.

The GRA, MAT, and undereraduate GPA data show parallel differences arong the students in tho several college prorrams. Students in supervision, learnina disabilities, readiny, and curriculun and instruction generally had higher scores on these criteria than did students in administration or business education. These differences, while meeting the criteria for statistical significance, are not large enough to yield clear interpretations of therselves. As is noted below, these differences are accompanied by differences in non-completion rates contrary to those one would expect from the predictor data (See Table 8 below.). Students' Performance

The ultimate criteria for judging the worth of a school program are its success rates. There are several such rates that are regularly used: the proportion of entering students who finish programs, the frade performance. of students in programs, and the job placement record of program graduates. The latter criterion, probably the most important, is beyond the scope of: this study. However, from data in the college records, it was possible to

M. Ed. Prorrams

14
oxamine tho two others and, to a lesser extent, the relationship between them.

Progress toward derrees. Table 6 shows the numbers of students admitted to each of the colloge's programs w w least three querters, the numbers of students admitted to degree carcisiecy, the numbers of degrees granted, and the median numbers of quarters that graduates took to complete their degrees. Tho admissions prior to 1975 were used to give a realistic figure for comparing with the numbers admitted to degree candidacy, which requires the student to have comoleted 12 credits. The proportions of students admitted to candidacy are low, less then half overall; and, of course, the proportions of students gradiiatjng are even lower.

Insert iable 6 about here

These indications of low rates of completion are disturbing, but they can be sountered by the argument that the short span of the college's existence would make them misleadingly high. To take this into account, I exam-ined several other related indices: the average number of credits earned, the average progress rate (in credits per quarter), and the distribution of credits earned by individuals. The averages of credits earned and of progress rates are broken down by prozrams in Table 7. The distribution of credits earned for all of the college's students is show in Figure 13.

Insert Table 7 and Figure 13 about here.

As it turns out, the average numbers of credits earnod are misleading becauss of the skewed distribution of credits earned. Wihile the average number of credits earned for the college is something over 17, both the median and the mode of the distribution are below 9. Aoparently, about half of the cr spraduate students either don't intend to complete more than a ( $\quad$ two, or they quit or go elsewhere after completing less than 10 credits. Disturbing as this interpietation may be, it is supported by the data on proaress rates in Table 7. Thare are only two programs in the college in which students on the average take at least one course per quarter; these are the higher education progran and the program for teachers of energing adolescents.

Followine $u$ on the problem hichlizhted by the progress rates for college procrams, I computed non-completion rates for cach prograin, usins, two years, three years, and four years after entry to the program 35 the bases for calculation. Theso non-completion rates are shown in Table 8. The two year rate is an actual non-completion rate for those who had been enrolled for at least two years by the end of 1975; the other tivo rates are estimated from progress rates. If anything, the estimated non-completion rates are overly optimistic, since new, one-time studonts will have high progress rates.

Insert Table 8 about here

The data are disturbing. Only two of the college's programs have expected drop-out rates of less than $50 \%$, the emerging adolescent education
and the elementary administration proframs. The programs in counselor education and curriculum and instruction can oxpect to lose 2/3 or more of the students that they enroll. In this connection, it is pertinent that the prozram for teachers of emerging adolescents is the collegers most structured : "nm in terms of courso minction and sequence, and the cur1 ... uruction programs are twe least structured. Whether or not there is a direct relationship between prosram structure and stidents' commitment is arguable; these data support the contention that there is.

Students prades. There is reason to question the sources of the apparent attrition of students in the college's graduate proerams. Students' grades are usually assumed to be a major factor in attrition, throush the velicla of solection and retention practi ns: To oxmire this issue, it is nocessary to look both at swdents' ? perfomanee and at the seleation/retention cecisions that the collers culty has made at least martixly on the basis of students' prades.

The distribution of students' grade $=$ ages is shom in Figure 1Tistributions are shown for three groups o." students: the entire popution of students, the students who have graduated from the college's procrams, and the students who have been barred froin further registration by the university registar. The reasons far such action by the resistrar are several; they inclade: failure of proxsional graduate students to zakit the materials required for admissior as regular or special students, termal of degree candidacy (or failure to apply for it) to special graduate T.-_dents who have completed at least 12 credits, dismissals of students by faculty action, and mandatory dismissals.

## Insert Figure 14 about hera

In vien of the presumably major differences in these groups, one might expoct their grade average distributions to differ markedly. Such is not the case. The grado averafe distributions for all students and for students barred by refi itrars action are virtually identical in shape, the difference betreen them being the height of the peaks around 3.0 and 4.0. The distrition of grade averages for program graduates differs from the other two in having a sliphtly lower mode ( 3.63 instead o 3.88 ) and in being truncated at 3. 0 . of tra raite distributions is accompanied by similar lack of difference in median - Ir verages of the three groues, wich are 3.4\%, 3.55, and 3.40 for ain ands, graduates, and barred students respectively. Despite the overating Eroportions of students in all caterories who have raceived grade weraras above 3.0, the proportion of students' grade averages below that $1=7$ : overstated. lost of the grade averages of zero are the resula or students leaving the university without bothering to drop courses or of twones failing to make-up inamplete grades within the prescuibed perict. In Gese instances, the resiscear records failing grades as a retter of rou tre procedure.

Insert Table 8 ajout here

Fre: the foregoing discussion, one would not expect there to be differences amaprograms in students' grade averages, and indeed there are not.

The mean srade averages for students in the various proframs are shown in Table 8. Tho only programs whose mean grade averages deviate from the college's noms are the tro internshis programs, both of which have been defunct for several years.

Insert Table 10 avout here

Since the issue of the relationsing between erades and attrition came into question, $I$ examined the grouil of students who were discontinued by refistrar's action for evidence of the working of active selection and retention policies. The results of this scrutiny are siom in Table 10. Encause the college has not keot records of selection/retention decisions so that they could be summarized, it was reoessary to infer tive reasoms for discontinuance. The students counted as having defaulted adiriseions all remained categorized as provisional students more than one quarter after their initial admission. Some of them, pericularly those rith GPA's less than 3.0 , may have been academically dismissed; it is quite unlikely that many of the 502 provisional students witi GPA's greaten than 3.0 were discontinued for reasons other than simply not supplying admissions documerts. The students who are listed as having had degree candidacy denied are special graduate students who have earned more than 12 credits. Again, those with GPA's less than 3.0 were probably denied candidacy. Of those whose GPA's are:greater than 3.0 , a few may have been denied candidacy under the "single C" rule (which states that a special graduate student who earns a $C$ will not be admitted to degree candidacy), but most of these students
$\therefore$ EA. Programs
nrobably simply dic not apply for candidacy. The few students wo were clastly dismissed five evirisnce of the operation of selection and retention procedures on a small scale, but it is indicative of the actual policy operation that the vast majority (over $80 \%$ ) of even those students barred from studes were probably cut off by their om disinterest in continuing.

All this rather clearly indicates that selfoselectaun $1 .$. ine yrary, and one might almost say the only factor in ti.s loss or retention of students. Grades are relosant only in a very nareinal number of cases. In the 197576 aceremic yem, less than $2 \%$ of the over 5,000 raduate grades assirned were below $B$ (lote 1.). Such practice cannot form tho base for an aoadomic selection and retention policy that will have much orfect.

## Prodicting Studerts' Sucesso

The ult mate test zow any admission critorion is how well it predicts the students' saccess. The most conronly user mes.sure of students' success is the grade average (GPA), and a common problem mith attempts to validate admissions critoria by predictin\% GPA is that not all students are adnitted, truncating the range of tire predictor scores. Sincs virtually all students who applied to the college were admitted, that proslem is present in this study; but a companion oroblem is. As noted above, the GPA distribution is sufficiently truncated that it becones questionable as the criterion for prediction studies, particularly in viow oE its marginal effect on attrition.

Be that as it may, I attempted to account for the variance of graduate graie avgrages by linear regression using four predictor variables: IAT scores, undergraduate GPA's, rhether or not the student had earned another
graduate derree, and the student's age at admission. The results of that regression are shom in pables 11 and 12 . It is interesting that in spite oi the very restricted variation of graduate GPA's, there is a fairly anod ovorall correlation between the den $^{7}$ nd r"... . . lation obtained here ( +0.317 ) compares favorably with a number of those obtaired in validity studies of the HAT (Psycholorical Corporation, 1970), particularly so in vie:- of the size of this sample, which is more then twice as large as the largest cited in tre $W$ manual.

Insent Tables 11 \& 12, about hero

Folloring thi = finding, I calculated rerressions separately for each
 putations. The results are sumarized in Tables 13 and 14. In these tables, the multiglo correlation coefficient and the multinle $R^{2}$, which estinates the proportion of GPA variance predicted, are given, together rith tho name of the best predictor variable. The hifhest nultiple correlations are obtained rith small samples ( 0.5 , , the reading programs), and the correlations for large groups are quite modest. There were no data for programs omitted.

Insert Tables 13 \& 14 about here

Eowever interesting the regressions on GPA may be froin a methodological viewpoint, they are essentially moot because of the lack of importance of the GPA nctod above. A much more relevant criterion for admissions stendards would be thoir ability to predict completion of the program, or at least
adequate progress toward that goal. For this $\because \%$, I dofinoc aden.
 quarter, the rate necossany to earn the dorree in three years. Using progran completion or "adsenate" progress as the criterion of success, I attompted to construct : discriminant function to predict it. To do so, a subroutine of the SPSS package (Hye, et al., 1975) that maximizes the statistical criterion krom as Ra's $\underset{\sim}{\underline{Z}}$ was used. The results, show in Table 15, vere not impressive. The college's adnissions criteria, ase, and sex combined permit one to do just a little better ( 59.65 ) at predicting success than he could do with a toss of a coin. Changing the success criterion to include a progress rate of thrae credits per quarter and a GPA o: at least 3.0 only lowened the preliction erfoctiveness to $53.5 \%$.

Inseric Table 15 about !ere

Bad as the overall preaiction of successful progress might be, there was considerable variation among programs when the same procedure was applied to them separately. The resulis of the separate discriminant analyses are summarized in Table 16. In these malyses, the success criterion was a progress rate of three or more credits per quarter and a grade average of at least 3.0. Despite the appearances from the figures on prediction effectiveness, only two of the discriminant functions, those for the school nounselon program and the elmmentary curriculum and instruction program, yielded results that were statistically different from the results one could obtain by chance, ヨ.ध., by tossing a coin. Hovever, the variables
that pradicted sucees: in the counselor education propram were sex and enrollnent ase, not reasures of past acadonic performaneo or ability. Only the olementary curriculum and instruction program had a clear relation betiveen ultimate success in the program and one of the university's admission criteria.

What is clear from these prediction studies is that the traditional predictors of success in graduate school work moderately well for predictine variation in graduate rrades, particularly so in view of the low variance of those grades; but they do not predict ultimate success. It would not be realistic to expect admissions criteria, such as undergraduate grades and test scores, to predict program completion with high precision; themost that is expected is that admissions critaria would enabla reduction of the potential attrition. Galy for the profran in elenontary curriculum and instruction would such a reduction of expected attrition be possible by use of admissions standards; and there, the reduction, while statisticelly significant, would be quite modest.

## Discussion

The College of Education, over the eight years reviewed here, has admitted a very large, very diverss group of students to graduats study. It has graduated, is likely to graduate, only a small portion of those students. It is disturoinf that academic criteria have nothing to do with the vast majority of instances in which students have not completed work on degrees. In fact, the reasons for most of the stuEent attrition remain unkno:m; this study has only shown tha magnitude of atrition and that the reasons. for it are not academic.

There can be no question that the college?s academic standards are not a major factor in atirition. The median grade averase the collofats students earned in undergraduate work was 2.66 ; their median graduate grade average was $3.47,8 / 1.0$ of a point hi乡her and certainly no direct ; discourapement. As Table 10 shows, grades are directly involved in less than 150 of the more than 3,300 cases of students who have neither graduated nor are naking sufficient progress to do so. Grades and academic expactations may be indirectly involved in sone attrition. Some students have told me of their disappointment at the ease with which thoy can earm $A^{\prime}$ s and at the difficulty of distinguishire themselves in 2 climate where even modest effort receives high manks. fiow much this kind of discontent contributes to the collese's attrition problem is not known, as are the host of other possible reasons that students have for leaving.

It is clear that the college must berin to find out why its graduato students leave. Aside from the selfoservine reason--which I shall Ieave to others to explore fully--that their leaving ropresents a lot of lost revenue, there is even more loss in human terms. There are ambitions that were simply frustrated, ambitions and potential that were never crystalized, teaching skills that were not improved, and idəas that were not encountered.

If the College of Education is to mature, it must learn whom it serves and decide why. This means learning what students want and what they don't, which can only be done by asking them. It means examining, questioning, and changing its programs to meet the needs of students, the commuity, and the profession at large. If the college undertakes this difficuit task of
self-exanination, it may be able to retrieve sone of the tuman loss that is buried in its prograns' high attrition. If it does rot, it will surely fail its urban rission for not knowing it. What is sad about such a prospect is that with all such institutional failures, the recognition will come so very slowly. io one will assign an $F$ to put a merciful end to the agony.

Classification of Students' Success
by Discriminant Function ${ }^{\text {a }}$

|  | No. of <br> Cases |  | Unsuccessful |
| :---: | :---: | :---: | :---: |
| Mctual Group | Successful |  |  |
| Unsuccessful | 1021 | 651 | 370 |
| Successful | 418 | 212 | 205 |

${ }^{\text {a }}$ Success was arbitrarily defined as either completing the degree or averaging completion of at least four credits per quarter. The discriminant function was generated using the method of maximizing Rao's $V$ with the following variables as predictors of success: MAT, undergraduate GPA, sex, and entry age. Only HT scores did not enter the discriminant function. Fowever, the resulting function classifies group membership correctly only $59.6 \%$ of the time, just under ten per cent better than the chance probability.
