## ABSTRACT

This publication contains-a sequence of lectures given to high school mathematics teachers.by the author. Applications. of mathematics emphasized are elementary algebra, geometry, and matrix algebra. Included are: (1) an introduction concerning teaching applications of mathematics; (2) CHapter 1: Mechanićs for the High School Student; (3), Chapter 2: Growth Functions; (4) Chapter 3: The Role of Mathematics in Optics; (5) Chapter 4: Applifation of Matrix Algebra. Included in each chapter are background materials, examples, some 'teaching suggestions, and some.exercises. (RH)
 *: Documents'acqui.red by ERIC include many informal unpublished ". . ** * materials not available from other sources. ERIC makes every effort * * to obłain the best copy available. Nevertheless, items of marginal * * reproducibidity are often encountered and this affects the quali,ty * of the microfiche and hardcopy refroductions ERIC makes available * Via the ERIC Document Reproduction Setvice (EDRS). EDRS is noth ** * responsible for the quality of.the original document. Reproductions * * supplied by EDRS are the best that can be made from the original.

1. Why Should Applied Mathematics be Taught in the High School?

Jacobi (1804451), speaking for the pure mathematician, claimed that the motive for mathematical research is "the honor of the human spirit." The same could be said of playing chess: there is no denying its aesthetic and iṇtellertual yappeal. So why is the youth who takes his chess as serionsly as his math-. ' $\because \quad=$ ematics thought to ke misguided? Is there such a difference between moving pieces of wood about on a board and manipulating ink marks on paper?

- Chess, fъr all its excellence, is merely a game; unlike mathematics; ,it is Without appicications: The miracle of mathematics is that paper work can be re"lated to the world we live in. With pen or pencil' we can hitch a pair of scales to a star and weigh the moon. Such possibilities give applied mathematics its vital fascination. Can any subject give the would ${ }^{*}$-be mathematician - initfally, at least. $-a^{3}$ stronger and more natural fnterest?

Afia what about the non-mathematician? 'Deny"him introduction to this subject, and his appreciation of our cultural heritage must inevitably be inadequate. For mathematics in the broadest sense is instrumental not only to our runderstanding, but also to our changing the world we live in. And are we not a changing socièty-in a,changing world?
2. Difficulties of Teaching Applied Mathematics in the High School.

In our high school systems the teaching of science and the teaching of mathematics have become estranged. To apply mathematics there must be something to apply it to. To appiy it there must be a field of appzication even though there is nothing which you can count as common scientific knowledge among your students. Yet you cannot squeeze many lectures on physics or chemistry or blology intd your mathematics course. This is your first difficulty. There is a second." The bulk of mathematics which does apply to other fields is too advanced for your students; you would be talking above their heads.
3. What is the Way Around This Dilemma?

Go back to the beginnings of science, to Archimedes, to Euclid and Heron, - to Galileo and Stevinus, when things were very obwious, very simple, and could be expilainede in fiew words.. Thus, applied mathematics in the narrow sense of the term, ig., machanics, is the ideal topic with which to begin, and is, accordingly, the sukject of Chapter 1. For the same reasons, in Chapter 3, I take optics to illustrate the role of mathematics in formulating scientific' theories and begin with Euclia's. And although in Chapter 2 (which illustrates important applications of functional and recursive equations to growth problems)
a things are not always so obvious and simple, and so concisely explainable, the same principle is nevertheless adhered, to. Here, its application is slightly less stringent.

5it 4. Rejection af the "Modern" Approach.
Many eyebrows will rise in horror at such a proposal. Modernists will exclairf, "Here we are living in the space age, yet you propose to teach the mathematics of antiquity." Such people never tire of pointing out that whereas today's college courses in the sciences ćover twentieth-century science, to' day's college courses in mathematics deal with eighteenth-century mathematics: They infer that the mathematics currently taught is necessarily out of date.

The emergence of such a conclusion in atechnological society is understandable; the inference is none the less faliacious.

Edison's phonograph, Ford's Model $T$, and the Wright brothers' aeroplane are out of date. But such machines are not oút of date because they are old; they are put of date because of rapid technological progress; they have been superseded by more efficient ones of 'better design. ' The pyramids of Egypt, although old, are not out of date; progress in the pyramid building line is siow these days; the Egyptiap variety, although old, has yet to be superseded. Supersession is not necessarily entailed by newness. Beset by the fad of modernity we must be ever mindful of Aladdin and the cry, "New lamps for old."

Technology and science advanće hend in hand;' each helps the other over obstacles to progress. Likewise, the rudimentary chemistry and biology of the eighteanth century is now, in large measure, out of date. But not, marif you, out of date because, 11ké the pyramids, it is old: 'out of date bêcause inadequate theories Have been superseded by more adequate ones. "So we see the sense In present-day college teaching of the sciences giving eighteenth-century developments scant attention. The difigent reader will now exclaim, "But surely twentieth.century mathematical. developments supersedé those of the eighteenth century, and a fortiori, supersede those, of antiquity." Such an exclamation ind1cates grave misconception.

Mathematics is different. . Old scientific theories, like old automobiles superseded by better ones, are relegated to the scrap heap. Mathematics usually conserves, seldom iscraps., New mathematics is superimposed upon the old rather, than the old superseded by the new. As with the successive cities of. Damascus, the old is the foundation of the newa Mathematics is cumulative: Concepts thousands of years old are still in use today. "Old bricks are used to make new, buildaings.

The mathematics most intnediately applicabli to the sciences, is mechanics Roughzy but.concisely put, mechanics is the alphabet of "science. To spell out new theories we, need new words, not a new alphabet.
5. Mechanics Al Alphabet of Science.
our children, are both the beneficiaries and the victims of a technological áge. pull a switch, ©ress a button, or move a lever, and a complicated mechanism is'set in motion. Iurn a knob, and we see and hear the President making a speech in Washington. How doés the mere turning of"a knob result in, the presentation of distant events? With the tremendous jump from the simplic1ty of primitive machines to the complexity of modern mechanisms, connections are lost sight of. The great illumination of understanding a simple machine', the insight of grasping, say, that the principle of the lever underlies prying
off the lid of a can, id lost to the modern child. His, docile nonunderstanding of science is limited to gecepting the pronouncements of the white-coated, ? bespectacled man on IV, with his solemn, "Science has proved that ...."

Understanding science starts with mechanics. And mechanics, to borrow a phrase from Pólya, starts with the "congenital or inarticulate" physics we all acquire, willy-nilly, in crawling from the crade: the experiential facts of. pusining and pulling, the properties of sticks and stones; our unavoidable introduction to force, mass, weight, rigidity, flexibility, . . . Here is a common background of knowlede for the teacher to exploit. His business is to make this knowledge articuriate.

The brilliant, very simple, very obvious, coneisely explainable mechanics Of Archimedes is the natural articulation. Of Law of the léver can lead in three easy lessons to showing how a TV set works.

- There is no denying the chasm between levers and, electronics. Yet innovators "of both had-common habits of mind -- the beientific attitude. Something of this" attitude can be inculcated by showing how the painstaking application and reapplrication*or a simple, seemingly trivial concept, the lever, can lead to something complex and deep, the theory of mechanics. In teaching mechanics we 5 decisive step toward bridging the gap.

6. A Question of Rigor

Idealization is inevitable in the applications of mathematics. By this सivice the complexity of a physical situation is reduced to manageable proportiońs. A stone bécomes a point, a"lever a line; knots in beams are ignored, and the wood is presumed to be precisely, homogeneous. At this gage justification is practical'rather than logical. And occasionally int teachring we introduce an additional assumption with an "It" is obvious that ........ or a wave of the hand, and meet a stoo fussy objection with e shrig of the shoulders. Partial articulation. Sựch reasoning was good enough, initially, for Archimeges, for Galileo, and for Newton. Surely it' is good enough for your students' high school initiation. Or, do you presune your students abler than Archimedes?

The mechanics of antiquity is not antiquated: its perennial youth is as young as today-and as modern as tomorrow.

Liken applied mathematics to a car. Insight, intuition, imagination are ifts matory its driving force; rigor, its trakes, the logical chec!.s that control it. Of culurse a can without brakes is dangerous; imagination must not be allowed to run riot: We need to control imagination and to direct insight. But a car without a motor is useless. We need to drive a little before we need to brake a little.

But axiomatics are the disc brakes of mathematics --the very latest, up-to-date-ẹsto most rigorous of logical checks. So why contẻnt ourselves by teaching mechanies with only an axiom or two? Why not give a full-blown axiomatkc treatment?

The object of axiomatics is to find explicitly the absolute minimum of assumptions necessary to a theory'. With axiomatics we huy deep enlightenment; the price that muṣt be pald is sophistication beyond the novice. An axiomatist is a man who finally ties a bow tie with the 9 ther hand behind his back. Oh $i$ yes, it. can be done with one hand; on tô, itcacannot be done with less. Beginners beṣt use both hands.
ir . Development of geometry did not patiently wột several centuries for Euclid's axiomatization; nor did it wait more than twenty succeeding centuries after Euclid for Hilbert's final dotting of the logical i's and crossing out of the illogical t.s. Partial articulation of inarticulate experience necessarily preceded campliete articulatibn.

To teach, disastrously, teach with a level of rigor inappropriate to your students or your subject.

I hope to have persuaded you that some' understanding of applied mathematics (especially mechanics), liberaily conceived, ought to be part of the very fabric of educhted common sense, not exclusively the prerogative of the woula be math(1) ics or science specialist.

Being teachers, you know full well that teaching is an art; that to. teach effectively you must have the Greek sense of theater, the ability to tit11, lete or irritate the imagination of your students, to make them articulate their experience, so that they would hitch scales to a star and weigh the moon. :- Allow me to give the material I belleve important to present. Only you can best know how to present it. Teachers are apt to be overawed by university people. While the latter can probabiy decide what material is important, it is the role of the teacher to decide what aspects can be taught in the high school, When it cah be taught, and how best to teach it.

Chapter 1. Mechanics ${ }^{\text {A }}$. the ${ }^{\text {High School Student. }}$

### 1.1. Archimedes ${ }^{\text {a }}$ Law of the Lever.

, We start with the simplest maonine known to mankind, the leger. Supposedly, ever since man developed beyond the level of the ape he has used sticks to lever stones. The Egyptians in building their pyramids used elaborate machines con-

- sitting of a combination of levers;" yet their knowledge of levers appears. to have been largely inarticulate. We all know that in pushing a door shut, the nearer the paint at which we push is to the line of the hinges the harder we need push. Yet how many of us realize that this common experience exemplifies the law of the lever? The hinge is the fulcrum about which the turning moment of Our push counterbalances the opposing. turning moment of friction at the hinge: We have experience but not the articulation;

It seems that Archimedes (287-212 B.C.) was the first in history to ask for the precise mathematical formulation of the conditions of equilibrium of the lever. To ask* this question was itself a tremendous step - - to ask for mathematical laws for the behavior a combination, of sticks and stones; for here is a crucial novelty - that number plays a role in understanding and predicting nature

We now retrace the essential steps by which Archimedes derived his formulation. "He started with the simplest case: a weightless lever with equal arms suspending"equal weights. . See Fig. Yen

${ }^{\circ}$
Question: Which weight sinks? By the law of insufficient reason there is no
more cause for the left-hand weight to sink than the right; by the $1 a w$ of sufficlient reason there is as much reason for the left not to sink as for the right; the figure is symmetrical. That is, the lever does not move at all.

We cannot prove this by mathematics. Resort to the latrof sufficient $s$ (or insufficient) reason is, really an appeal to our common experience. So, with Archimedes, we take it as axiomatic that a lever as illustrated in Fig. 1 is in equilibrium, We shall refer to this as Archimedes ' Axiom.
'At first sight such a beginning seems too trivial to be capable of devil- e opment. And yet ....? Consider Fig. 2. F

Here, a homogeneous beam of constant cross section is suspended by a string at each end $\dot{E}_{1}, E_{2}$ of the lever. If the lever tilts about its fulcrum the beam tilts with it. The same argument is again applicable: by considerations of symmetry there is no reason why the, lever (and with it the beam) shouka tilt, either way. We have equilibrium.
$\therefore$ Next, consider carefưlly Fig. 3, a modification of Fig: 2. .

What changes have been made? The beam is now suspended by strings from $A_{1}$. end $A_{2}$ (where ${ }^{E_{1} A_{1}}=\ell_{1}, A_{2} E_{2}=\ell_{2}^{\prime}$ ), instead of from the ends of the lever - $E_{1}, \mathbb{E}_{2}$. But, despite these changes, equilibrium of lever and beam remain: (3) terdependents if the lever tilts then the beam must tilt with it; if the beam.
does not tilt the lever cannot tilt. The difference is that the modified figure is not symmetrical --unless $A_{1}, A_{2}$ happen to "be symmetrically placed with. respect to $F$ (i.e., not unless $\ell_{I}=\ell_{2}^{\prime}$ ). At this stage we need introduce furthen idealization; suppose the strings by which the beam is supported at $A_{1}, A_{2}$ to be weightless. Thus., conceptually, we regain symmetry, and consequently, -equilibrium. With weightless strings, we have one body, a lever-cum-beam, symmetrically balanced about its fulcrum $F$ with respect to external forces. Whether the tensions in the strings (internal forces) are equal is irrelevant. Next, we introduce an element of specialization. Study Fig. 4 and under-. stand it.

We take any arbitrary point" $E$ on " $\mathrm{E}_{\mathrm{I}} \mathrm{E}_{2}$, and select $\mathrm{A}_{1}, A_{2}$ to be the special $\because$ points such that $A_{1}$ is the midpoint of $E_{1} E$, and $A_{2}$ the midpoint of ER /2. Since $E_{1} A_{1} \neq \ell_{1}, A_{2} E_{2}=\ell_{2}$, it follows that $\mathrm{E}_{2} \mathrm{E}=2 \ell_{1}^{\circ}, \mathrm{EE}_{2} \neq 2 \ell_{2}$, and since $\mathrm{E}_{1} \mathrm{E}+\mathrm{EE}_{2}=\mathrm{E}_{1} \mathrm{E}_{2}=22$ it follows that
ie.,

But,
and $^{-}$
Hence, by (1)
(i)
 Ideaíly, we supgose there to be no loss of material in cutting the beam, and, consequentry' no nloss in weight. This, "proviáed that there is no change in the distribution of material --which poula result in a change in the distribution . Wringt.- equilibriúm will strily obtain. That is, equilibrium still obtains provided that the parts, of cut beam retain the positions they had prior to the cut. Were these trotate in vertical planes about their points of suspen- $\because$. sion, the distrabution. of weight would be changed. But esince $\dot{A}_{1}, A_{2}$ are the midpoints of $E_{1} E$ and $E E_{2}$, we see that these are symmetrically placed with pespect to their suspending strings and will remain in equilibrium. Thus the sevs of lever-cum-two-beams is in equilibrium.
" Since the wood is supposed homogeneous, we may, without loss of generality, suppose it ofr unit dẹnsity. Thus we have a wefight: $2 \ell_{1}$ suspended at , $A_{1}{ }^{\prime \prime}$. counin terbalanceđ by a weight ${ }^{2} \hat{\ell}_{2}$ staspended at $A_{2}$. That is, by (2) a weight $2 \ell_{1}$ actīng $a t_{\text {a }}^{\text {a }}$ distance $\ell_{2}$ from the fuicrum counterbailances a weight $2 \ell_{2}$, acting at a distance $\ell_{1}$ froftit. This situation is illustrdted by Fig. 6.

Fid. 7 .

What are the conditions for equilibrium? Obviously
$: 5$

Let $W_{1}=3 \ell_{2}, W_{2}=2 \ell_{1}$, سnd we have
or
right weight $\times$ length of right arm $=$ left "weight $\times$ length of deft arm. The product of, the weight and the length of the arm is a measure of, the tendency of the weight to turn the arm about the fulcrum. $W_{1} \ell_{1}$ is said to be the moment of $W_{1}$ about $F$. So, alternatively put, for equilibrium
'right hąnd moment $=$ Left hànd mợent.
This is Archimedes' law of the lever.
I have shown you how Archimedes' law is devised from "congenital or inarticulate" physics. Acfually, this original treatment was somethat more dompli$\because$ cated; what I have given you is a modification due to Lagrange (1736-1813) $:$ early" in the last century, when such mathematics was not below the dignity of mathematicians of the first rank.

A colleague, when teaphing advanced applied mathematics at Stanford last quarter, was so. intrigued bythis particular proof of Archimedes' law of the lever that he spent two lecture periods dinscussing just the axiomatic impiications of this kind of proving. This invoives explication of the notion of sym"metry, the distinction between forces external to and internal to a system, thet nothing is changed by cutting the beam, and many other considerations. We could, for example, give an alternative proof by considering the beam to be suspended by four strings, one at 1 , two at', $E$, and one at $E_{2}$, instead of by strings at $A_{1}, A_{2}$. Then a new Fig. 5 would comprise two beams each suspended by ftrings at its end points; one suspended from $E_{1}$ and "E, the other from $E$ and $E_{2}$. The final step would be to replace the suspension of each beam a single string at its midpoint, i.e., strings at $A_{1}, \dot{A}_{2}$ wouid repiace .18
strings at. $E_{1}, E$ and at $E, E_{2}$, respectively. This is an alternative way of ", obtaining the original Fig. 5.

I mention these matters only to show that the mathematics of Archimedes is not trivial, despite its antiquity. Here there is enough food to satisfy the hungriest thinker. (I have already pointed out the unsuitability pf fullblown axiomatic for, the beginner.) This is how, starting from "the obvious," the inarticulate physics about which there is common agreement, we build up our-máthematics in a cumulative way. I shall further. illustrate this cumulative process by making applications of Archimedes! law.

## 1.2 'First Application: The Centroid of a Triangle.

We consider an idealized triangle, made of rigid but weightless material. 'lying in a horizontal plane; with a weight' $W$-suspended from each vertex. our problem is to find the point at which the triangle can be supported without tilting from the horizontal. See Fig.. 7 .

But how are we to contend with three forces all at once? We must use What we know, yet the law of the leven is applicable only to two forces. That this law may be applied, we must, eliminate the effect of the third weight, say considering $A^{\prime \prime}$, the mid point of $B C$, as the fulcrum of $B C$, we have a lever f With equal; weights suspended fromiequal arms. Thus if the triangle is also supported at $A^{\prime \prime}$, the points. $A_{\gamma} A^{\prime}$, "anáconsequently the line $A A^{\prime}$ (a median.
of the" triangle), are fixed, so that the only motion possible is a rotation about $A A^{i}$. But the forces at. B, C counterbalance, sQ that the triangle is $l$.
in equilibrium.
Obvioidsły an upward force of $\mathbb{N}$ at a will counterbalance, that of the
Weight suspended there. What upward force at $A$ ! will counterbalance the downward forces of $W$ ad $A$ and at $B$ ? When standing on the platform of a weighing machine, your weight, as indicated by the machine, is the same no matter whether you stand on one leg or both. The total downward force is 2 W , so we require $2 W$ acting upward at $A^{\prime}$. In short, in so far as equilibrium is concerned, the original forces are equivalent to downward forces of $W$ at $A$ and $2 W$ at $A$ '. We have reduce a problem of three forces, to a problem of two forces. See Fig. 8.

The rest is easy, for the law of the lever is immediately applicable to this pair of force Let $G$ be the point on AA: such that

$$
A G=2 \cdot A^{\prime} A
$$

so that

$$
W \cdot A G=W^{\prime} \cdot\left(2 \cdot A^{\prime} A\right)=: 2 W \cdot A^{i} A^{\bullet}:
$$

Thus the triangle is in equilibrium when suspended at, G. This solves our problem. Additionally, we may, remark that, since the total of the downward forces at $A, A^{\prime}$ is $3 W$, we have that the effect of the three equal forces of $\mathrm{W} /$ at the vertices is equivalent to a force of it at $G$.

Articulation of our common- experience and painstaking application of the law of the leverthas solved our problem; yet we have' by no means exhausted the results inherent in this problem. The argument by which we conclude that $\%$ the point of suspension for equilibrium ${ }^{\prime}$ is $\dot{G}$, two-thirds the way down the median, 'is equally applicable to the other two medians. There are no.grounds for "preference. Yet the forces considered can have only one resultant, consequently three medians must be concurrent at $G$, a point two-thirds the way down each. See Fig. 9.

In this short deduction we see the jinterplay between mechanics and geometry. 'Not only can we use mathematics to deduce laws of nature; we can use laws of nature to deduce more mathematics. Here is" an art of which. Archimedes was a master.

Another result. Now suppose the horizontally placed triamgle of Fig. 9 to be a lamina of hómogeneous material. From a simple application of similar triangles it follows that any line segment $B^{\prime} C^{\prime}$ parallel to $B C$ is bisected by the median $A A^{\prime}$. Consequently the thinner we make a strip with $B_{1} C_{1}$ as one. edge, the more nearly rectangular it will become, and the more nearly its geometrical center lie on the median. And with homogenious ${ }^{\text {mataterial a rectan- }}$ gular lamina would, if, suspended at its geơmetrical cénter, be in equilibrium. Thus we may conceive of the triangle as made up of indefinitely thin ṣtrips, with the equilibrium point of each - and therefore the equilibrium point xf all monjoinedy--Iying on this medián. See Fig: 201

Fig. 10.
But for precisely similar reasons the equilibrium point must also lie on the other two medians, so by the foregoing result this point must be G. Thus the "triangle, horizontally orientated, could be maintained in equilibrium by a * force equal to its weight acting vertically upwards at $G$. In short, the multi; tube of gravitational forces acting on the various.bits of the lamina' act as if they were all concentrated at $G$. For this reason $G$ is know. as the center of gravity, or centroid; of the triangular lamina.

### 1.3 Second Application: The Area Under a Parabola.

Archimedes ${ }^{1 "}$ predecessors and contemporaries had tried, unsuccessfully, to f compute the area of an ellipse and the area under a hyperbola. Charactepistically, Archimedes tackled the other conic section -- the parabola --and was "successful: Wis success caused a sensation,* as well it might, for his method lies at the threshold of the integral calculus. 号

Unlike Archimedes, we have the notational convenience afforded by analytital geometry. The problem is to find the area under the parabola $y=a x^{2}$ between ' $x=0$ and $x=h$, ie., the shaded area' $O A B$ of Fig. 21.: By considerstrons of symmetry it is visibly obvious that this is one-half the area $\mathrm{OBB}_{1}$, one-half that between the given parabola and its mirror image in $0 x, y=-x^{2}$. Carefully compare Figures 11 and 12. To any vertical strip $P Q$ (of length $\left.a x^{2}\right)$ at a distance $x^{x}$ from $\underline{O}^{2}$ in Fig. 11 there is a corresponding vertical
 midpoint of PQ moves from 0 to A , and to use a favorite expression of

Fig. 12
Archimedes, "fills" the area $\mathrm{OBB}_{1}$; the midpoint of $\mathrm{P}^{\prime} \mathrm{Q}_{4}$ moves from $\mathrm{O}^{\prime}$. to A A and "fills" triangle $O^{\prime} B^{\prime} B_{1}{ }^{\prime}$.

Now study the conjunction of these figures in a vertical plane given by Fig. 13.
m
:-
Fig. 13
23

The lever . $O A^{\prime}$ has. fulcrum at, ' $0^{\prime}$, where $00^{\prime}=1$. We suppose the corresponding typical strips. $P Q$, 'P' $^{\prime}$ ' to have the same width $\epsilon$, and the homogeneous material of both bodies to be of unit density. Thus the weight of the strip $P Q$ is $2 a x^{2} \cdot \epsilon \cdot \frac{1}{}$, and the weight of $P!Q^{\prime}$ is $2 a x \cdot \epsilon \cdot l$. But, obviously the center of gravity of: $P Q$ lies vertically below 0 , so that the moment of $P Q$ about $0^{\prime}$ is

$$
\cdot 00^{\prime} \cdot\left(2 a x^{2} \cdot \epsilon \cdot 1\right)=1 \cdot\left(2 a x^{2} \cdot \epsilon \cdot 1\right)=2 a x^{2} \epsilon .
$$

And since $P^{\prime} Q^{\prime}$ is at a distance $x$ From $O^{\prime}$, its moment about $O^{\prime}$ is

Thus,

$$
\begin{gathered}
x \cdot(2 a x \cdot \epsilon \cdot 1)=2 a x^{2} \epsilon \cdot \quad: \quad+\quad,
\end{gathered}
$$

$$
\text { moment of } \mathrm{PQ}, \text { about } O^{\prime}=\text { moment of } P^{\prime} Q^{\prime} \text { about } O^{\prime}, Q
$$

and the corresponding strips counterbalance one another. But this result holds for each and every corresponding pait! We conclude that

Moment of whole body $Q B B_{1}^{\prime}$ about $0^{\prime}=$ foment of $O B^{\prime} B_{1}^{\prime \prime}$ about $0^{\prime \prime}$. Let. $W$ be the weight of ${ }^{\circ} \mathrm{OBB}_{1}, ~ \triangle A^{\prime} B_{1}$ : has height $O A^{\prime}=h$ and base $B^{\prime} B_{1}^{\prime}=2 a h$ and therefore weight $\frac{1}{2} \cdot 2 a h \cdot I_{-}=a h^{2}$. This weight acts as if concentrated at $G$, the centroid of y pe $\triangle$. By a previous result. $G$ is' twothirds the way along $\mathrm{OA}^{2}$, and our last equation becomes ${ }^{2}$

So, remembering that our materid/s are of unit density., wise have

Area od under the parabola $=\frac{1}{3} \mathrm{ah}^{3}$.
We conclude with the elegit result that

Of course this proof is not completely rigorous, since the strips ' $P Q$, $P^{\prime} Q^{\prime}$, of thickness $' \epsilon$, are not precisely rectangular. Yet it is intuitiygly evident that by making $\epsilon$ sufficiently small we make the errors of these approximations as small as we please, so that for sufficiently small $\epsilon$ the difeerence between the moments of $P Q$ and $P^{\prime} Q^{\prime \prime}$ about $0^{\prime}$ - may be made arbitrarily small. Further articulation would necessitate explication of the notion of limit. To say this is not to sneer at Archimedes' proof by his "mechanical method," as he cailed it:" to the contrary, it is to suggest that intuitive proofs are often indispensable stepping stones to bettèr ones'. Archimedes was *too good a mathematician to rest content with this proof; he subsequently gave a completely rigorous one by the "method of exhaustion." "The disçovery (by his mechanical method of what was the right formula was necessarily prior to proving it right To fook; first catich your hare.

Archimedes'rigorous proof for the area under the parabola, together with a dozen or so other proofs, including the wolume of the sphere, were known ty mathematicians of the Renaissance. That he had initiaily used a "mechanical method" was also known, but not the details. His cooking told -nathing of his catching. Cavalieri (1598-1647) devised a way, based on the intuitiveiconsideration that if two figures have equal corresponding strips or cross sections (e.g., $P Q$ and $P^{\prime} Q^{\prime}$ in Fig. 13), then the corresponding total areas (or volumes) axe equal. 'It was not until 1906 that a palimpsest giving . the details of Archimedest mechanical method was discovered in Istanbul, and translated by Heiberg (185刑1928), the great Danish expert on-Greek mathematical
texts. Had this been available to Cavalieri, his development, and consequently that of Fermat, Newton, and Leibnitz, would have been radically different.

Let us recapitulate. We began with the question, "What is the law of the lever?" Geometry, with "inarticulate" mechanics, enabled us to find this law; successive applications of it, reducing a problem. of three forces to two, to one, determined the centroid of the triangle - and gave us, incidentally; a theorem of geometry, The notion oof centroid with yet another reapplication of the law. of the lever gave us the area under a parabola. This is typical of the way mathematics works: beginnings almost too trivial to take seriously, lead, with repeated applications, to new insights and new, discoveries, which, . . with repeated application, yield yet further insight and, discovery;
1.4. Third Application: The Law of the Crooked Lever.
4. . We suppose a homogeneous beam to be freely pivoted in a vertical plane about a (horizontal) nail through its geometrical. center $F$, with weights $\mathrm{W}_{1}, \mathrm{~W}_{2}$ suspended from. it as illustrated by $\dot{F} \pm \dot{\mathrm{g}} .15$ and such that

The homogeneous beam being symmetrically placed about $F$, its weight has no effect" on the equilibrium of " $W_{1}$, $W_{2}$; the whole figure is in equilibrium. What changes may we make in the suspension of $W_{1}$ without disturbing equilibrium? Supposing $\frac{W_{1}}{}$ to be a constant weight, $A_{1} \bar{F}$ must remain unchanged, for otherwise the turning moment of $W_{2}$ about $F$ would be altered. $3^{-i}$ we all know that the vertical pull of a weight on point of suspension
$i$
,
26
is unchanged by shortening or lengthening the string by whinch it is suspended, if the string itself is of negligible welght:- Clearly, $W_{1}^{\prime}$ may be raised of lowered; what matters for equilibrium is that its line of action, its supporting string, passes vertically through $A_{1}$. See Fig. 16.

$\therefore$ Study Fig. 16. Does it matter mat $W_{2}, W_{2}$ are now suspended from $A_{1}^{\prime}, A_{2}^{\prime}$, respectively, instead of from $A_{1} A_{2}$ ? No, for the lines of actons of the two forces (and the forces themselves, of course) are unchanged.

But what is the role of the beam in this seheme of things? - Being 'homogeneous and suspended about its geometrical center, it has no turning moment; itais, in effect, weightless. ‘ Its role is givèn by its rigidity, whereby the turning moments of $W_{1}$, $W_{2}$ with points of application $A_{1}{ }^{\prime}, A_{2}^{\prime \prime}$ ' are just the same as if these points had been $A_{1}, A_{2}$. It remains merely to idealize a little more to reject its substance while retaining its rigidity. In short, equilibrium is

where $A_{1}{ }^{\prime} F A_{2}$ is a crooked, welghtless, rigid lever.

Hence, if $\alpha_{1}, \alpha_{2}$ are the angles which. $A_{1}{ }^{\prime} F, A_{2}{ }^{9} F$ make with-the vertical, we have

$$
\ell_{1}^{\prime} \cdot \sin \alpha_{1}=\ell_{1}, \ell_{2}^{\prime} \cdot \sin \alpha_{2}=\ell_{2}
$$

aind, by (2)

$$
\begin{equation*}
W_{1} \ell_{1} \prime \sin \dot{\alpha}_{1}^{\prime}=w_{2} \ell_{2}^{\prime} \dot{\sin } \alpha_{2}^{\prime}, \tag{3}
\end{equation*}
$$

the law for crooked levers. That is, the turning moment of a force is now the product of the force, the length of the arm, and the sine of the angle between them. The factor. sin $\alpha$ is the-price we pay for.crookedness. ' Note that when $\alpha_{1}, \alpha_{2}$ are each $90^{\circ}$, since $\sin 90^{\circ}=1$, (3) becomes

$$
W_{1}^{\prime} \cdot \ell_{1}^{\prime}=W_{2} \cdot \ell_{2}^{\prime} \cdots
$$

Characteristicalíy; our new result incluades that from which it was deduced. Let us turn to prifther developments.

## 1.5

## Galileo: The Law of the Inclined Plane.

Galileo ( $1564-1642$ ) was interested in the mechanics of the inclined plane. He asked and answered the question: / Given ar weight. W on a frictionless plane inclined at an angle $\alpha$ to the horizontal, what force w acting up the plene is, necessary to prevent. W. from sliding dow? See Fig. 18.

Note that the precise formulation of the problem is itself a step toward solution. The inarticulate physics of "boycling makes it obvious that the steeper , the incline the greater the necessary restraining force, Clearly ${ }^{2}$ H is a maximum when $\alpha=90^{\circ}$, and must then, wíthout any help from the incline, support the full weight of $W$; otherwise $W<W$. Thus it is appropriate to deno e the
restraining fore e by the smaller letter. This consideration suggests the question: Is the designation of the angle of incline by " $\alpha$ " entirely fortuitous? Consider the notation or (3). Can the ceiyed-of as an application of the law of the crooked lever? Yes. --given tho -- Ingenuity

First, since vertical forceps are better understood, Galileo converts w acting up the inclined plane into a/yertical force by introducing, a frictionless pulley wheel and a weightless string, thus:

This stŕrategem may not appear at first sight to advance solution of the problem. But what is the problem? What weight $w$ is needed to counterbalance $W$ ? If these are in equilibrium, there is a certain constraint between them. The connecting string being inextensible, if $W$ moves up or down the incline a distance " $d$, then $w$ moves vertically up or down the same distance.. Galileo had the great insight to see that "this constraint could be realized in a diffferent way -- by the introduction of a crooked lever. See Fig. 20.

Fig. 20 ',
$A_{1} F A_{2}$ is an equal-armed, crooked (and rigid but weightless) lever with furlcram $F . \rightarrow A_{1}$ is the center of gravity of ${ }^{\prime \prime} W$, and $F A$ is perpendicular to the inclined plane; $A_{2}$ is ant: point on the line of action of $w$, and $F A_{2}$ is horizontal. To satisfy ourselves that a point $F$. satisfying these
requirements exists, it is sufficient to note that the bisectors of angle is" the locus of points equidistant from $A_{1} V$ and $A_{2} \dot{V}$.

If the lever is rotated about $F$ in a vertical plane, since the lever is equal-armed, $A_{1}, A_{2}$ trace out arcs of equal circles. The smaller the. rotation the more nearly these arcs approximate to straight lines, ie., for infinitesmal rotations the displacement of A" (the center of gravity of W) along the inclined plane is the same as the vertical displacement of $A_{2}$, and therefore the same as that of $w$. Thus the constraint realized by string and pulley may, alternatively $\overline{\text { a }}$ be realized by the crooked lever $A_{1} F A_{2}$. But we know the conditions for equilibrium with crooked levers, so that the problem" is, in principle, solved.

Now, the details;

Fig. 21

From Fig. 21 it is clear that the angle. between the arm $A_{1} F$ and the vertical line of action of $W$ at $A_{1}$ is $\alpha$. So, by the foregoing considerations, fee see that the conditions for $W$ to maintain $W$ in equilibrium on an inclined plane of angle "a are equivalent to those for equilibrium in the following situation.

Fig. 22

By the law of the crooked lever,

$$
\text { since } \quad \cdot \mathrm{w} \ell \cdot \sin 90^{\circ}=w \ell \cdot 1
$$

$$
\begin{aligned}
\mathrm{W} \ell \cdot \sin 90^{\circ} & =W \ell \cdot 1 \\
W \ell & =W \ell \sin \alpha
\end{aligned}
$$

so that
$\mathrm{w}=\mathrm{W} \sin \alpha$

This is the law of the imclined plane.
1.6 Stevin: The Law of the Inclined Plane:

There is another proof, a most equant proof, due to a Dutch,mathematician Simon Stevin or Stevinus (1548-1620). Although Stang inas one of the most brilliant applied mathemátičians who ever lived, he is less well known than Gålileo; he was not threatened with death by, burning at the stake. He invented the first

* hotseless carriage, a sailing carriage for use on the dunes of the Dutch coast; he constructed famous dikes still in use today; and feeling practical need for the facility of decimal fractions, he invented them. For him, mathematics, to be any good, had to be good for something.

Let us see how he proved the law of the inclined plane, that the force acting down it due to $W$, when the angle of inclination is $\alpha$, is $W$ sin $\alpha$. His proof is based on the following figure.

Fig. 23
Stevin was so pleased with his proof that this diagram graced as vignette, with the inscription, "It looks like a miracle, but it is not a miracle," is the
tithe page of his treatise on mechanics. He had good cause for his pleasure; how the law of the inclined plane follows from the equilibrium of a heavy rope, with joined ends, when suspended over a triangular prism, is dovious only to a man of his geniuser

荷ppose the hetry rope to be in motion initially. This suphosition raises the quéstion, when will stop rotating? Its rotation is caused of the forces acting upon it: But for every particle of rope that goes down, say, at' C, an identical particle moves up at $A$. Thus the configuration of the rope remains unchanged, and consequently the driving forces which initially caused motion still. persist. Therefore, since it is rotating initially, it must continue to rotate forever.. We have a perpetual motion machine and ca use its power to drive a dynamo.

We feel, as Stevin felt, that this conclusion is absurd. But either the heavy rope is in equilibrium or it is not. With him, we have no plternative but to conclude that the rope must be in equilibrium.

Undoubtediy the portion of the rope hanging below the trifugle hangs symmetrically; the downard force at $A$ is counterbalanced by an equal downward force at $C$. Thus, since the rope $A B C$ is in equilibrium before the removal of the portion $A D C$, it must remain in equilibrium affer its, removal. That is, the force acting down the one incline due to the freight of the rope
$B A^{\circ}$ counterbalances the force acting down the other due rope BC. See Fig. 24.
fo the weight of the

A (2n:
The force $F$ necessary to prevent a weight $W$ from siliding dawn en inclined plane of angle $\theta$ depends on $\theta$, $F$ increases as $\theta$. increases, $F$ $\because$ "decreases as $\theta$ decreases; that is, . $F$ is a function of $\theta$, say, $f(\theta)$. Also, 32
of course, $F$ depends on $W$. If for a given incline $W$ is doubled then $F$ is doubled. $F$ varies both as $W$ varies and as $\theta$ varies, that is,

$$
\begin{equation*}
F=W(f(\theta)) \tag{3}
\end{equation*}
$$

The problem is to specify $f(\theta)$. See Fig. 25.

Fig. 25

Let $\rho$ be the density of the rope, i.e., the weight of unit length, so that the weight of the rope $A \dot{B}$ is ap and that of $B C$ 'is $b \rho$. Then, since $A B$ 'is inclined at angle $\alpha$ to the horizontal the force $F_{1}$ to prevent it slipping down is given by

$$
\begin{equation*}
F_{1}=a p \cdot f(\alpha) \tag{4}
\end{equation*}
$$

Likewise, the force $F_{2}$ to prevent $B C$ slipping down its incline of angle $\beta$ is

$$
\begin{equation*}
F_{2}=b \rho \cdot f(\beta) \tag{5}
\end{equation*}
$$

But since the rope. $A B$ counterbalances the rope $B C$.

$$
F_{1}=F_{2}
$$

so, by (3), (4), and (5),

$$
a \rho \cdot f(\alpha)=b \rho \cdot f(\beta)
$$

and from the geometry of Fig. 24 ,

$$
a=\frac{h}{\sin \alpha} \quad, \quad b=\frac{h}{\sin \beta}
$$

giving

$$
\frac{h}{\sin \alpha} \rho \cdot f(\alpha)=\frac{h}{\sin \beta} \rho \cdot f(\beta)
$$

so that

$$
\because \quad \frac{f(\alpha)}{\sin \alpha}=\frac{f(\ddot{\beta})}{\sin -\beta}
$$

But Stevin's argument is applicable to any arbitrary triangle $A B C$. No matter what non-obtuse angle ${ }^{\ell} \dot{\alpha}$ we have selected for the one incline, we are free to select $\beta$ for the other incline independently of our first choice. If $\because$. , we take another case of Fig. 24 with angles $\alpha, \beta^{\prime}$ we similarly deduce

$$
\frac{f(\alpha)}{\sin \alpha}=\frac{f\left(\beta^{\prime}\right)}{\sin \beta^{\prime}}
$$

giving, with our first result,

$$
\frac{f(\dot{\alpha})}{\sin \alpha}=\frac{f(\beta)}{\sin \beta}=\frac{f\left(\beta^{\prime}\right)}{\sin \left(\beta^{\prime}\right)}
$$

i.e., $\frac{f(\theta)}{\sin \theta}=C$, where is a a constant, and any non-obtuse angle $\theta$. Hence, in (3), we have

It remains to determine $C_{i}^{\prime}$, When $\theta=90^{\circ}, \cdot \mathrm{W}$ is as if suspended adjacent to a vertical wall, and clearly $F=\mathrm{F}$, substituting in (6), we have,

$$
W=W \cdot C^{\circ} \cdot \sin 90^{\circ}=W \cdot 4 \mathrm{C} \cdot 1
$$

therefore,
and

$$
\begin{aligned}
& \quad C=1 \\
& \because \quad F=W \sin \theta
\end{aligned}
$$

### 1.7 In conclusion.

Although I have made this derivation much longer than need be, I feel it well' worthwhile to teach. It has the advantage of introducing the notion of a function in a natural way: I know it is "modern" to teach children that a function is an ordered pair, and that a nine-year-old sounds so sweet when he tells you so. "Wouldn't it be nice if the nine-year-old knew what to do with an ordered pair? Mathefaticians evolved the notion of function because they had a need; it enables them to cope with situations in which this depends on that. That this frifs-that deperdence ils up"刑e same logical tree as the son-fathey relationship . comes much later. In teaching, never put logical carts before huristic horses.
 miracle, but it is. not a miracle." The endess rope which does not slide upon the triangle contains; so, to speak, the law of the incined plane. Stevin's àchievement was to make this unanalyzed, inarticulate knowledge, grticulate. What at first sight is apparently miraculous, we see subsequently to be no more, miraculous than other items we. regard as self evident. His work is characteristic of the first rate in applied pathematics.

The law of the lever has many other applications,' but I have no more time. . I hope I have given you some insight into the driving force of mathematics and some diea of how good mathematicians go, initialily, about their business.

What work have we considèrèd? Archimedes' as simplified by, Lagrange, then Gailileo's; then Stevin's. The sequence is not entirely fortuitous. Mankind has found its way by groping, by trial and successive correction, by closer approximation to the truth. oh, yes, there have been tremendous blunders in the, development of mathematics and science, but broadly speaking the work of firstrate men of one era.has been used as a foundathon for their work by the first- $\because$ rate men of the succeeding era. Mechanics, as we have said, is the alphabet of of "science. Thus the sequence in which fruitful concepts"evolved is a first indication of the sequence in which to teach them. "The history of ideas corrcerns itself with all concepts, good, indifferent, and bad. To the contrary, the
their contrast with bad ideas can serve to show what makes better ideas better. Tósconclude this lecture may I remind. you that the initial development of mechanics" was not. a full blown axiomatic treatment. Are your students abler than Ar̀chimédes?

Hंats, therefore hat pegs; growth, therefore growth functions. What could be a-more natural introduction to the concept of function than growth problems?

In the fost section I show how the exponential law of growth is derited from a functionaf "equation that arises naturaily from its context. In the second" section wentensider an application by Maxwell of thís result. Next, iniconsidering population growth we, are led from functional to recursive equations.

Their use is further elegantly exemplified in the fourth section by considering the, "growth" of the number of sides of a regular polygon of "fixed perimeter', thereby giving Cusarus' formula for $\pi$.
2.1 The Exponential Law of Growth.

How much timber is there in a fores Trees grow. The older the forest, the bigger the trees. The.bigger the trees, the greater the amount of wood: Provided thāt there are no forest fires and no trees die, the volume of wood increases with time. The volume of timber depends upon when the forest was Planted; it is a function of the time for which the trees have peen growing.

Doesn't this situation invite introduction of a mathepatical notation?
We introduce one. " $N(t)$ " is to be read as "the volume of timber (in cubic feet, say) in a given forest $t$ years after it was planted." Thus $N(0)$ is the volume of timber in the given forest 0 years after it was planted, i.e., $N(0)$ , is the volume of timber initially.

But the volume of timber in the giveh forest after $t$ years, $N(t)$, does not depend only upon the time for which it has been growing; alsg, it depends -upon the size of the forest originaily, $N(0)$. And how does $N(t)$ depend upon N(0) ? We take it as obvious that if a forest had originally been twice as big then it would now be twice as big as it is; if originally three times., the original size, now three times its present size; if originally four times the orignal size, now four times the present sizę; and so on. More precisely, supposing"
that the gipen forest has:been growing for $t_{1}$ years, its present volume of timber wouls be $N\left(t_{1}\right)$, or $2 N\left(t_{1}\right)$, or $3 N\left(\dot{t}_{1}\right)$, or $4 N\left(t_{1}\right)$, or whatever, according its original volume was $N(0)$, or $2 N(0)$, or, $3 N(0)$, or $4 N(0)$, 'or whatever. it was, respectively. Thus the relation between, $\bar{N}\left(t_{1}\right)$ andry( 0 ) is such that
$\frac{N\left(t_{1}\right)}{N(0)}=\frac{2 N\left(t_{1}\right)}{2 N(0)}=\frac{3 N\left(t_{1}\right)}{3 N(0)}=\frac{4 N\left(t_{1}\right)}{4 N(0)}=\ldots .=k_{1}$, where $k_{1}$ is a constant

$$
\begin{equation*}
N\left(t_{1}\right)=k_{1}^{;} N(0)_{t} . \tag{1}
\end{equation*}
$$

This is the mathematical statement of the assumption that the present (at time $t_{1}$ ) yolume of "timber is directily proportional, to the original amount. © This assumption merely amounts to assuming. non-interference of different trees in the forest, one with another; they grow independently.

If, alternatively, we had supposed the forests to grow for $\dot{t}_{2}$ years, we would have concluded that

$$
\begin{equation*}
N\left(t_{2}\right)=k_{2} N(0) \tag{2}
\end{equation*}
$$

where $k_{2}$ is some constant. This raises the question: Does. $k_{1}=k_{2}$ ? Well, suppose them equai. What follows?

$$
N\left(t_{1}\right)=N\left(t_{2}\right)
$$

i.e, that the volume of timber in the given forest is the same after $t_{2}$ years as it, was after. $t_{1}$ years. The consequence is that there would have been no growth at all for $t_{2}-t_{1}$ years.
.But with forethought we could have foreseen this consequence. (1) or (2) tellsbut half the story; the present size of the forest depends not only on its originap size, but also on the time for which it has been growing; $N(t)$ "depends in $t$. as well as on $N(0)$. So, ton tell the whole story, $k_{1} \ln _{\text {in }}(1)$ must denend on, or be $a$, function of, $t_{1}$, 'and $k_{2}$ in (2) must depend on, or be a function 38.
of, $t_{2}$. That is, (1), (2) must be exemplifications of a $1 / W_{\mathrm{w}}$ of the pattern

$$
N(t)=k N(0)
$$

where $k$ depends on ' $t$.

- Although we know that $k$ depends on $t ;$, me not know how $k$ depends on $t$. So we must leave the nature of the relationship unspecified, and write that $k=-f(t)$, giving

1

$$
\begin{equation*}
N(t)=N(0) \cdot f(t) \tag{-3}
\end{equation*}
$$

Note 'that putting $t=t_{1}, \quad t=t_{2}$, successively, we get

$$
N\left(t_{1}\right)=N(0) \cdot f\left(t_{1}\right), N\left(t_{2}\right)=N(0) \cdot f\left(t_{2}\right)
$$

so that , $k_{1}=f\left(t_{1}\right)$,

so that $k_{1}, k_{2}$ are constants as required by (1), (2); but that $k$ is fixed in value for a given value of $t$ is not to imply that $k$ has the same fixed value for different values of $t$.

With hindsight, we can now see (3) as obvious. If $f(t)$. is the yolume of timber in one tree after t years of growth, then $N(0)$ trees growing for the same period have a total value of timber of $N(0) \cdot f(t)$, the volume of the forest after $t$ years, $N(t)$. $\quad$.

We must use (b) to specify $f(t)$. Suppose for ease of exposition that our . forest was planted at the turn of the century. Then 5 years later, in l\$05, its size $N(5)$ satisfies the equation'

$$
\begin{equation*}
N(5)=\grave{N}(0) \cdot f(5) \tag{4}
\end{equation*}
$$

What is its size in 1911? What, in other words, is the size $(5 f 6)$ years after planting? "Two ways of answering this question now present themselves: the ${ }^{\circ}$ one in terms of its growth since it was planted, in 1900, $(5+6)$ years ago; the nther in terms of its additional growth since 1905, 6 years ago.

By (3) the first answer is -

$$
\begin{equation*}
N(5+6)^{\prime}=N(0) \cdot P(5+6) \tag{5}
\end{equation*}
$$

The second answer is slightly less obvious. We now consider our forest as. if it had been plarred-in 1905 wit* the initial size
$[N(0) \cdot f(5)]$-- see (4) -- and had grown for only 6 years. $\mathrm{By}_{\mathrm{a}}(3)$, we have

$$
\begin{equation*}
\overline{\mathrm{N}}(6)=[\mathrm{N}(0) \cdot f(5)] \cdot f(6) \tag{6}
\end{equation*}
$$

(the bar in " $\bar{N}(6) "$ is used to remind us that " 6 " refers to 6 years after 1905, not 1900).

But thesertwo answers, given by (5) and (6), must be the same, for $N(5+6)$, the volume of wood in our forest $(5+6)$ years after $1900^{\circ}$, is the volume of wood there, " $\bar{N}(6), 6$ years after 1905. Consequently,

$$
N\left(0^{\circ}\right): f(5+6) \fallingdotseq[N(0) \cdot f(5)] \cdot f(6)
$$

:which gives the functional equation
$\therefore \stackrel{\theta}{\circ}$

$$
f(5+6)=f(5) \cdot f(6)
$$

The specific periods; 5 and 6 years, were used for ease of exposition. The argument may bepeated with the unspecified arbitrary periods $t_{1}, t_{2}$, giving

$$
\begin{equation*}
f\left(t_{1}+t_{2}\right)=f\left(t_{1}\right) \cdot f\left(t_{2}\right), \tag{7}
\end{equation*}
$$

the funcuinal equation that the function of the sum is equal to the product of the functions.

Note that to deduce this equation I didmot need any technical knowledge of" biology or forestry. That I merely made articulate what we all know even though we never stopped to think, about it is evidenced by your inmediate acceptance of my premises:

and with $t_{1}=t, t_{2}=2 t, *$

$$
f(3 t)=f(t) \cdot f(2 t)=f(t): f(t)^{2}=f(t)^{3}
$$

These results lead us to suppose that

$$
f(\overline{n-1} \cdot t),=f(t)^{n-1}
$$

$\because$
the consequence of which, since

$$
f(n t)=f(t+\overline{n-1} \cdot t)=f(t) \cdot f(\overline{n-1} \cdot t) \quad \text { by }(3)
$$

is that

$$
\begin{equation*}
\therefore \quad f(n t)=f(t)^{n} \tag{8}
\end{equation*}
$$

But $f(1 \cdot t)=f(t)=f(t)^{1}$
so that (8) holds when. $n=1$, and consequently by; the principle of mathe-
metical induction (8) holds for every positive integer $n$.
Thus, we have

$$
\begin{align*}
f(n t) & =f(t)^{n}  \tag{8}\\
f(m t) & =f(t)^{m} \tag{9}
\end{align*}
$$

where $n$, $m$ are positive integers.
Putting $t=\frac{1}{n}$ in (8)

Taking the $n^{\text {th }}$ root

$$
\begin{aligned}
& \text { ? } \\
& ?
\end{aligned}
$$

$$
\begin{aligned}
& f(1)=f\left(\frac{1}{n}\right) n \\
& f(1)^{\frac{1}{n^{\prime}}}=f\left(\frac{1}{n}\right) \\
& f(1)^{\frac{m}{\vec{n}}}=f\left(\frac{1}{n}\right)^{m} \\
& \frac{4}{t}=\frac{1}{n} \quad \text { in }(9), \\
& 41
\end{aligned}
$$

Raising t $\sigma^{\circ}$ the $m^{\text {th }}$ power,

Fist. putting

$$
\begin{aligned}
& f\left(\frac{m}{n}\right)=f\left(\frac{1}{n}\right)^{m} \\
& f\left(\frac{m}{n}\right)=f(1)^{\frac{m}{n}}
\end{aligned}
$$

Putting $\frac{m}{n}=t$ and $f(1)=2,{ }^{\circ}$. we obtain speciftcation of $f(t)$, namely,

$$
\begin{equation*}
f(t)=a^{t} \tag{10}
\end{equation*}
$$

where $a$ is a constant since $f(1)$ is a constant, and $t$ is any positive rational since $m, n$ are arbitrary positive integers. This is known as the exponential function.

Hence, by (3) the law of growth for our forest becomes

$$
\begin{equation*}
N(t)=N(0) \therefore a^{t} \tag{10}
\end{equation*}
$$

the value of a depending upon the kind of forest considered.
(Strictly speaking $f(t)$ has been defined only for rational yalues of $t$; but if it is conceded that a forest grows continually, then obviously (10) is to be accepted, for all (r'eal) values of $t$. Whether this point should be discussed or not discussed depends upon the maturity of your students.)

We have answered the question: How much timber is there in a forest? Yet it takes but slight reflection to see that the law of growth need not be applicable solely to forests. Of course, it is applicable to any phenomenon whose growth occurs as the growth of trees occur. And how do trees grow? Trees grow in such a way that the amount of growth made. in any period is proportional to the amount of wood growing af the beginning of that period.".

It is important to be clear on this point. Part of our, inarticulate common knowindge, it is readily articulated by the law of groth. $N(t), \dot{N}(t+1)$, $N\left(t^{\circ}+2\right)$ being the volumes of timber in a given forest at the end of $t$, $t+1, t+2$ years, respectively, $N(t+1)-N(t), N(t+2)-N(t+1)$ are the amounts of growth in the $\left(t^{\prime} 1\right)^{\text {th }}$ and $(t+2)^{\text {th }}$ years. By (10),

$$
N(t+1)-N(t)=N(0) \cdot\left(a^{t+1} a^{t}\right)=N(0) \cdot a^{t}(a-1)=(a-1) \cdot N(t)
$$

Similarity,

$$
N(t+2)-N(t+1)=(a-i 1) \cdot N\left(t^{n}+1\right) .
$$

In words: the amount of growth in the $t^{\text {th }}$ year is (a -1 ) times the amount 1 available to growth at the beginning of that year, "and the amount of growth in the $(t+1)^{\text {th }}$ year is $(a-1)$ times the amount available to growth at the beginning of that year. But that $t$ is measured in years is irrelevant; we could have measured $t$ in seconds; we could have 'taken one-million'th of a second to be our unit of time. It follows that, the amount of growth in any instant is proportional to the amount of material available to growth at the -beginning of that instant; ie., that'the instantaneous rate of growth is propertional to the amount of growing material.

What grows in this way, as trees grow? If. in (10) a were less than 1 the trees would grow smaller, i.e., decay. It is known that the rule of decay of radioactive material is proportional to the amount of material available; con-" sequently' the law of growth is applicable. When a ray of light passes through an absorbing medium, the intensity of the light is weakened by the passage; the weakening is proportional to the intensity. Thus the law of growth is also applacable here. Wenhave

$$
I(x)=I(0) a^{x}
$$

where $I(0)$ is the intensity of the incident light ray at the surface of the absorbing medium, $I(\dot{x})$ (the intensity at a depth $x$ within the absorbing medium, and a (less than one) the absorption factor.

Compound, as opposed to simple, interest is another example. With simple interest the rate of growth of the investment (supposing interest to be left on deposit). is "constant and is proportional to the capital invested initially. The amount of interest earned in the thirtieth year is the same, as that earned in the third" year. If, to the contrary, interest payable on capital is "permitted to accrue as additional capital and the total capital to date (ie., initial
'investment plus accrued interest) grows at a rate proportional to the total . capital. to date (not"proportionalily to the capital initially), then interest is said to be compounded.

If interest is permitted to accrue as capital at yearly intervals, the interest is said to be compounded annually. Of course, in this event the amount of interest earned in the thirtieth year vastly exceeds that earned in" the third year, for the capital grows with the interest. The formula is

$$
\begin{equation*}
c_{n}=c_{0} a^{n} \tag{II}
\end{equation*}
$$

where $C_{0}$ is the capital initially, $C_{n}$. the total capital at the end of $n$ * years, and a a constant depending upon the annual rate of ińterest. If interest is compounded at more frequent (or less frequent) regular interyals, then $n$ is to be taken as the number of times interest has been permitted to accrue as capital, $C_{n}$ the total capital after the ${ }_{n}{ }^{\text {th }}$ increment, and a a constant depending upon the rate of interest for the intervals in question, semiannual, quarterly, or whatever it may be. With this application of the law of growth there is merely the difference that $n$ is restricted to integers.

Interest could be compounded daily or at' far.more frequent intervals. : Though your bank manager might. not agree, you could argue that an instant after investing your capithisou should be entitled to an instant interest. of ine course, calculated pro rata with the annual rate this would be small. Nevertheless, with your money growing continually you might be tempted to suppose that you would become infinitely rich in a year or two -- until you tempę̉red your wishful thinking with the somber reminder that this growth would also be governed by the general law of growth. It turns out that if your capieal $C_{0}$ was invested at $100 \%$ per annum compounded instantaneously, then your total capital $C_{n}^{\prime}$ at the end of $n$ years would be given by

$$
c_{n}=c_{0} e^{n}
$$

where é, a number of great importance in mathematics, is the base of Naperian logarithms. This formula was first deduced by Bernoulli. Note that it exemplifies
the general law, with $a=e$. The only difference is that since the increment periods are instantaneous, $n$ is not restricted to integral values. Putting $\mathrm{n}=-1$, we conclude thät in the time C would double itself at $100 \%$ simple interest, withe interest continually compounded it becomes ${ }_{-}^{C}{ }_{0}$ d. Approximately $e=2.718$, so, investors please note, while the one way $\$ 100$ becomes $\$ 200$, the other way it grows to nearly $\$ 272$.

To recapitulate: I have shown how the concept of function and the barest rudiments of functional equation theory may be used to deduce the exponential law of growth, and I have indicated fields of application.

```
2.2 Maxwell's Derivation of the Law of Emrors.
In this section we consider Gauss' law of errors (Gauss 1777-1855). We
``` shall find that Maxwell's (Maxwell 1831-1879) ingenious derivation of it depends. . upon the solution of a functional equation. This solution is an application of the exponential law functional equation considered in the last section.

When at the beginning of the last century astronomers, physicists, and surveyors started to make very precise measurements, it was realized that there is no such thing as an absolutely accurate measurement.

First consider the question of a single observation. Astronomers chart the stars as accurately as they know how, yet two astronomers seldom observe the same star as being in the same position,--though it is in the same posidecimal place or two.

To come nearer home, the spring in your bathroom scale becomes fatigued. and loses a little of its springiness. * With changes in temperature bits of , metal alter in length and so modify its mechanism. If over-conscientious about your weight, you may evade many of these contributions to inaccuracy by resorting to an equal-arm balance of appropriate dimensions. But even the arms of balances become tired and droop a little. Better designed and more careffully constriructed instruments measure more accurately, yet it is always a question of
more or less better; there are no absolutely accurate measuring devices. We include the human eye reading a pointer against a graduated scale.

We suppose you, afflicted by a weight-reducing fad, weighed yourself on three bathroom scales this morning, their' readings being 201, \(207, \stackrel{\circ}{20} 4\) pounds. Your problem: What was my weight this morning? Possibly you would, in the absence of a known weight with which to test the scales, take the arithmetic avierage, 203 pounds, as correct. You would conclude almost with certainty that you did no't weigh 300 prounds, and think it very unlikely that you were as much as 250. Surely the further removed the estimated figure from 203 or 'thereabouts, the more unlikely its correctness.

Uninwited, the notion of probability intrudes upon the scene. Unceartain, ", of the correct figure we cannot be certain of the error of measuredireadring; the most we can ask is such questions as, "What is the qikelirhood that.the observed reading \(n\) does not differ from the actual measure by, say, more than \(\frac{1}{100} n\) "" The general answer to questions of this sort is called the law of errors. With this answer we shal, be presently concerned:

Secondly, consider the question of the combination of observations. Al. though hundreds of physicists have made measurements from which to deduce the velocity off light, no two physcists have obtained exactly. the same result. The deduced number being dependent upon several measurements, each subject to error? the final result necessarily incorporates a combination of these errors. -

Consider, for simplicity, the following example. A square lamina of side 5 units is measured as having sidēs of. 5.1 and 4.9 units. So whereas the actual area is 25 squàre units, the area deduced on the basis of our measurements is 24.99. Although there is a \(2 \%\) error in each of our measurements there is only a \(\frac{1}{25}\); of \(1 \%\) error in the final result. One measurement. was too big, the other too small, so that each error tends to annul the inaccuracy due to the other. " But this oversimplifies; the point being that, we never know with certainty the actualy errors. A more realistic question is: If it is \(95 \%\) certain that the error in each of our measurements does not exceed \(2 \%\), what is the probability"
that the error in the area calculated on the basis of these measurements does , not exceed, say, l\$?

We have briefly indicated the kind of problem this line of thought leads to: now we must return to what it leads from; the probability of squch and such an error in a single measurement. As we have said, the general answer to this latter question is knawn as the law of errors.

The law was first derived by Gauss in the masterly way characteristic of this great mathematician; but his approach to the problem was so abstract that Maxwell, among others, was only partially convinced of the correctness of his derivation. It lacked that down-to-earthness found in, for example, Stevin's deduction of the law of the inclined plane. Maxwell was led to examine Gauss' proof when he needed the law of errors to further develop statistically the kinetic theory of gases. He was concerned with the down-to-earth conception of the behavior of a gas as that of billions of molecules"darting to and fro, pushing against the walls of their enclosure, so it is perhaps not too surprising that he came up with a marvelous, inmediately graspable, proof. . Yet on second thoughts it is most surprising; many contemporary physicists shared 'his dissatisfaction, but none his discovery, suou is the prerogative of genius. From.the problem of molecules impinging on the walls of their enclosure, Maxwell turned to that of bullets hitting a target. Let us consider his derivation of the law of errors.

Consider the marksman who misses the bull's-eye. Typically, the (printable) phrase he uses to describe his shot, is one of the following sort: to the right of center; on center, but too far to the left; on "center, but, too high; to the right of center and too high; "left of center ind low He refers to his bullet's position as a combination of two errors;a horizontal and a vertical deviation from the bull's-eye. Taking our cue from him, we introduce rectangular coordinate axes with origin at the bull's-eye and \(x\)-axis horizontai. " ' \(H(x, y\) ) is the position of his hit.

If a marksman is standing in a fixed position at a certain distance from the target, what is, his probability of hitting the bull's-eye? First, this will depend upon the size of the bull's-eye. Surely we are agreed that, if it is no bigger than the point of a pin, then it is practically impossible to hit; and that if it is conceived of as a mathematical point, then the probability of hitting it is zero. Thus we must reformulate our questions: instead of asking, "What is the probability of hitting ( 0,0 )?" we mast ask, "What is the probability of hitting the target within the neighborhood of ( 0,0 )?" The general question is, "What is the probability (when aiming at ( 0,0 )) of hitting within the neighborhood of ( \(x, y\) )?"

Obviously, the probability will depend upon the size of the neighborhood; take the whole world for the neighborhood of ( 0,0 ), and the marksman cannot miss. The neighborhood must be specified. It is natural to take the rectangle of . W.-. Sides \(\Delta x, \Delta y\), centered on ( \(x, y\) ) as the neighborhood of ( \(x, y\) ). See Fig. 1 .

Yet there remains a question. What, explicitly, do we mean by "probability"? If a marksman in firing his first 1000 requads at the bull:s-eye hits its neighborhood 60 times, does the same thing with his second. \(100^{\circ} 0\) shots, with his third, and fourth thousand, then we would say that his probabjlity of a bulliseye is \(\frac{60}{1000}\). But it is a commonplace that performance varies, even for an enthusiast whose marksmanship does not improve with practice. It would be more realistic to suppose his successive scores \(60,57,62,59, \ldots\).... juage his
expectation of a bull's-eye; we would consider his performance in the long run. More generally, the probability of a shot hitting the neighborhood of ( \(x, y\) ) will be said to be \(p\), if he has hit this neighborhood in times with \(n\) shots, where \(n\) is very large.

Clearer as to what we mean. by "probability," we -readdress to ourselves the \(a\) question: "What is the probability of a hit in the rectangular \(\Delta x \times \Delta y^{\prime \prime}\) neighborhood of \((x, y)\) ?." For brevity, we put this symbolically, \(P(x, y, \Delta x, \Delta y)\) ? But aren't we really asking two questions? Or, to be more precise, are there not two (easier) questions on which the answer to our original question depends?
(1) What is the probability that a hit will lie in the rectangular strip of width \(\Delta x\) centered on \(x\) ? Symbolically, \(P(x, \Delta x)\) ?
(2) What is the probability that a hit will lie in the rectangular strip of width \(\Delta y\) centered on \(y\) ? Symbolically, \(P(y, \Delta y)\) ?
Study the conjunction of Figs; 2(1), 2(2) to give Fig. 1.

Fig. 2(1)

, Does not this make it clear that our original question may be construed as:
What is the probability that a hit will lie in both strips?
How, specifically, does \(P(x, y, \Delta x, \Delta y)\) depend on \(P(x, \Delta x)\) and \(P(y, \Delta y)\) ? The dependence may be illustrated by a problem of throwing dice.

Suppose that the probability of throwing a \(\bar{\beta}\) with a given die is \(\frac{1}{6}\) an that of throwing a 4 with a second die is also \(\frac{1}{6}\), what is the probability of throwing a 3 with the first and a 4 with the. second? In the long run 3 turns up
with a frequency of \(\frac{1}{6}\) ，so that if we consider． \(36 n\) throws，where \(n\) is large， on of these pairs fill have a 3 uppermost on the first die（and the other 30 n pairs will not）．Of these， \(6 n\) pars，since the frequency of a 4 with the second die is．\(\frac{1}{6}\) ，independently of the first result，just \(n\) of them will have a 4. uppermost．Thus，just \(n\) of the \(36 n\) pairs will have a 3 uppermost on the first and a 4 uppermost on the second．In short if two independent events have prob－ abilities，of \(\frac{1}{6}\) and \(\frac{1}{6}\) ，then the conjoint event has a probability of \(\frac{1}{6} \times \frac{1}{6}\) ． More generally，＂if \(p_{1}, p_{2}\) are the probabilities of two．independent events， then the probability of the combined event is \(p_{1} \times p_{2}\) ，the product of the in－ dividual probabilities．It follows that
\[
\begin{equation*}
P(x, y, \Delta x, \Delta y)=P(x, \Delta x) \times \dot{P}(y, \Delta y) \tag{1}
\end{equation*}
\]

It in an men mathematical secret that with two，questions to answer it is best to answer them one at a time．What is \(P(x, \widehat{\Delta x})\) ？If a barn is five times ？ as wide as its door，then surely the chance of hitting the barn is five times that of 雇iting the door．Or，if the door is fixed in position（i．e．g the position \(x_{\text {d }}\) ，its center line is fixed，say \(x=x_{1}\) ）bust its width \(\Delta x\)（varies， then the probability of hitting it varies directly as its width．．So，we take＂．＂ it that for a vertical strip whose center line is \({ }^{\circ}\) ．
where \(\mathrm{k}_{\mathrm{l}}\) ，is a constant with respect to \(\Delta \mathrm{x}\) ．
But，although the＂constant of proportionality＂is independent of the
width \(\Delta x\) of the vertical strip，it is obviously not independent of the pori－ tron of the strip（ice．，the \(x\) value of its center line）．Consider，for example，a barn with two doors of the same size．Surely the chances of hitting the one we aim at，straight in front of us，is greater than that of the otter． The farther to the side the other is，the smaller its chance of being hit．Thus， reminiscent of（1）and（2）of the last＇section we will have
\[
\begin{gathered}
45 \\
P\left(x_{1}, \Delta x\right) \equiv k_{1} \cdot \Delta x \\
P\left(x_{2}, \Delta x\right)=k_{2} \cdot \Delta x
\end{gathered}
\]
exemplifying the pattern,
\[
P\left(x_{n}, \Delta x\right), k_{n} \cdot \Delta x
\]
where \(k_{n}\), although unchanged by changes in \(\Delta x, "\) is dependent upon, i.e., is a function of, \(x_{n}\). In short,
\[
P(x, \Delta x)=\dot{F}(x)^{\prime} \cdot \Delta x
\]

Suppose a barn to have three doors of the same size, the one to the left and the one to the right being equidistant from the one straight ahead of us. Surely': the chance (when aiming at the midale one) of hitting the one on the left is "the same as that of hitting the one on the fight. The chances of a "left" error are the same as .those of an equal "right" error. Mathematicaliy,
\[
P(x, \Delta x)=P(-x, \Delta x)
\]

Hence, by (3),
\[
F(x)^{ \pm}=F(-x) ;
\]
that is, \(F(x)\) is' a symmetrical function.
Since \((x)^{2}=(-x)^{2}\), clearly the simplest unspecified symmetrical function is \(f^{\prime}\left(x^{2}\right)\). There is, for example, no gain in generaity in taking, \(f\left(x^{4}\right)\), or \(f\left(x^{6}\right)\), for these are also of the form. \(f\left(x^{2}\right)\) with \(x=x^{2}, x^{4}=x^{3}\), respectively. Thus (3) becomes of the form
\[
\begin{equation*}
P(x, \cdot \Delta x)=f\left(x^{2}\right) \cdot \Delta x \tag{4}
\end{equation*}
\]
which indicates, for example, that the probability of a hit in the left-side strip of Fig. 3 is the same as that of a hit in the right-side strip.

The next question: \(P(y, \Delta y)\) ? Again compare Fig. \(2(2)\) with Fig. \(2(1)\). What differences are there? If \(x=y, \Delta x=\Delta y\), the strips are of the same size and at the same distance from 0 . The only difference is that of direction;
the one is above; the other to the right of, 0 . And what role does difference play? We are agreed that a hit, (say) 3 inches left of center has the same probability as a hit 3 inches right of center; is a hit 3 inches above center more likely than 3 inches below center? Right of center was given no preference .over left of center; why should above center be given preference over below center? It is natural to consider them -equiprobable. This leads to another question: Is a hit 3 -inches to right of center more likely than, say, 3 inches above, center? Consider the circle of radius 3 inches with center 0 , illuscrated by Fig. 4.

In firing at 0 (the immediate neighborhood, of), which point on this circle

 at any two points on a circle to equiprobable; no direction is supposed to have preference.

Y .

Direction being considered irrelevant, it follows that the strips of Fig. \(2(1), 2(2)\) (with \(x=y, \Delta x=\Delta y\) ) are not only of the same size and at the same distance from 0 , also they acre similarly situated withrrespect to 0 in the probabilistic sense. Thus \(P(y, \Delta y)\) is determined by precisely the same function as \(P(x, \Delta x)\). só, by (4)
\[
\begin{equation*}
P(y, \Delta y)=f\left(y^{2}\right) \cdot \Delta y \tag{5}
\end{equation*}
\]
and hence by (1)
\[
\begin{equation*}
P(x, y, \Delta x, \Delta y)=f\left(x^{2}\right) \cdot f\left(y^{2}\right) \cdot \Delta x \cdot \Delta y \tag{6}
\end{equation*}
\]

At this stage Maxwell displays his ingenuity. He introduces a rotation of. axes. 'See Fig . 5.

Lr: His ingenuity is that the ordinate of \(H\) native to the new axes is zero, for -H lies on the \(\xi\)-axis. \(H(x, y)\) relative to the old axes is \(H(\xi, 0)\) relative to the new. And since the probability of a hit within the neighborhood, of a point is independent of the direction of the axes to which it is referred, the probability of a hit within the immediate neighborhood of \(H\) is given by B
as well as by (6) ' From (6), (7), we have,
\[
f\left(x^{2}\right) \cdot f\left(y^{2}\right) \cdot \Delta x \cdot \Delta y=f\left(\xi^{2}\right) \cdot f(0) \cdot \Delta \xi \cdot \Delta \eta
\]
and since the immediate neighborhood of \(H\) is described both by \(\Delta x\) a \(4 y\) and by \(\Delta \xi \cdot \Delta \eta\), these terms cancel out, and imply that
\[
f\left(x^{2}\right) \cdot f\left(y^{2}\right)=f(0) \cdot f\left(\xi^{2}\right)
\]

By Pythagoras: Theorem, \(\xi^{2}=\dot{x}^{2}+y^{2}\), so
\[
\begin{equation*}
f\left(x^{2}\right) \cdot f\left(y^{2}\right)=f(0) \cdot f\left(x^{2}+\dot{y}^{2}\right) \tag{8}
\end{equation*}
\]
(8) is a functional equation of the form
\[
\begin{equation*}
. f(a) \cdot f(b)=K \cdot f\left(a^{\prime}+b\right) \tag{9}
\end{equation*}
\]
where \(f(0)=K\). Here we may indulge in wishful, thinking, for we recall that the functional equation for the law of growth is of the form
\[
\begin{equation*}
f(a) \cdot f(b)=f(a+b) \tag{10}
\end{equation*}
\]

If \(K\) were equal. to 1 , then the law of errors would have the same form of functional equation as the law of growth, and consequently the solution of (8), would likewise be an exponential function.

It turns out that (8) can be reduced to the form (10). We put
"so that
\[
\frac{f\left(x^{2}\right)}{f(0)}=g\left(x^{2}\right)
\]
\[
\begin{aligned}
f\left(x^{2}\right) & =f(0) \cdot g\left(x^{2}\right) \\
f\left(y^{2}\right) & =f(0) \cdot g\left(y^{2}\right) \\
f\left(x^{2}+y^{2}\right) & =f(0) \cdot g\left(x^{2}+y^{2}\right)
\end{aligned}
\]

Substituting in (8)
\[
\left[f(0) \cdot g\left(x^{2}\right)\right] \cdot\left[f(0) \cdot g\left(y^{2}\right)\right]=f(0) \cdot\left[f(0) \cdot g\left(x^{2}+y^{2}\right)\right]
\]

Dividing by \([\dot{f}(0)]^{2}\), we obtain,
\[
\because \quad-\quad g\left(x^{2}\right): g\left(y^{2}\right) \doteq g\left(x^{2}+y^{2}\right)
\]
the functional equation of the law of growth: Consequently
\[
g\left(x^{2}\right)=a^{x^{2}}
\]
\[
\begin{aligned}
& \frac{f\left(x^{2}\right)}{f(0)}=a^{x^{2}} \\
& f\left(x^{2}\right)=f(0) a^{x^{2}}
\end{aligned}
\]
and, by (4)
\[
P(x, \Delta x)=f(0) \cdot a^{x^{2}} \cdot \Delta x \cdot
\]

And finally, for brevity, putting \(f(0)=A\),

4
This completes Maxwell's derivation of Gauss' famous law of errors.
We discuss this law briefly. Since the chance of a large deflection is obviously smaller than the chance of a small deflection, a<l. Plotting \(a^{2}\) as a function of \(x\), we obtain a bell-shaped curve typical of symmetrically deviated errors. See Fig. 6.

This is the starting point for the development of the whole theory of the error of combinations of observations.

2,3 Differential Versus Functional Equations:
Generally speaking, scientific laws are deduced from differential, rather than functional, equations. Why? Differential equations are easy to set up; they are the mathematical answer to: What is the instantaneous change of a given state?. Functional equations are hard to come by; often, genius is required to find them. \(I\) would prefer to use differential equations; your students cannot. In \({ }^{*}\) consequence, my hands are tied; so, let us see what else we can do with the functional variety.

\subsection*{2.4. The Problem of Predicting Population Growth.}

What is the. Iaw of increase of human population? The simplest, plausible assumption is thatithe number of people ofthe \((\dot{n}+1)^{\text {th }}\) generation, \(x_{n+1}\), will, be directly proportional to the \(n^{\text {th }}, x_{n}\). Symbolically,
\[
\begin{equation*}
x_{n+1}=q \cdot x_{n} \tag{3}
\end{equation*}
\]

On this basis, if \(x_{1}\) is the population of the first generation considered, the population of successive generations will be
\[
\left.\begin{array}{c}
x_{1}, q x_{1}, q_{1}^{2} x_{1}, q^{3} x_{1}, \ldots
\end{array}\right)
\]

If \(q>1\), thempopulation is increasing. Again we hâve ân exponential law. This formula was stated in words by Malthus (1766-1834): populations of countries increase in geometric ratio. It is interesting to note that Malthus was led to his formulation by inspection of the census records of the American people, which showed a-doubling` of population every 50 years. His statement, simple as it is, crude as it is, hali a tremendods, iffluence on the whole of social philosophy in the 19th century:

The social philosophers of the French Revolution argued that it was man-路"
kindts duty, to ease the hardship of the poor, and to abolish pestilence, plague, famine, and war, so that everyōee could live happily till aeath of old age. Malthus thought this view greatly mistaken. What would happen with neither pestilence nor plague, with neither famine nor war? -The population, increasing 'in geometrical ratio, would in a few years, he argued, become s \(\varnothing\) vast, that the" earth could not feed it. The Manchester industrialists used this argument to . pron up their policy of free enterprise, to increase trade while leaving the world at large to sort itself out. There could be no obligation te better the lot of the poor nor attempt to prevent famine or war; for these thethgs, if evils, were evils necessary to prevent overpopulation, Malthusi law became the arithetic of húmán misery.

Darwin also thought about the consequences of a population increasing \(\Gamma^{8}\) geometrically. For him the problem had a wider context. He was as much, if not mare; interested in the increase of a colony, of sea birds as in the Manchestery birth rate. What, he asked, controls population? The dinosaurus has lang been extinct; the whale has furvived: Ultimately, he gave an answeri his theory of natural selection. There followed his theory of evolution of species. What is man's obiligation to man? Is one to succor or to starve one's neighbor? The fall of the Bastille and the dark Satanic mills gave contradictory answers. By the middle of the last century even some industrialists began to question whether the evil of overworked and underpaid factoz hands, living' underfed in overcrowded slums mas a necessary evil. Couldn't.theres be a better arithmetic?
(Ne Belgian sociologist, Verhulst, made an important observation. Catasetrophies, wars, and plagies have occurred from time, to time, not all the time. - Between any two succesive catastrophies there, was a period of tranquility, say, 'typically, that of two or three generations. This period, had. the law of increase been geometrical, would have given the population ample time to regain and, surf pass, before the next catastrophe; its size before' the lást. We illustrate fith Fig. 7.

But mankind has inhabited the earth for thousands af" years, so that although we
 do not know the value of \(n\), where \(x_{n}\) is the present ( \(n{ }^{t h}\) generation) population, we dठ know that' \(n\) is large. With in'large, and "the population before imminent catastrophe greater than that before the previous one, surely the world
would now be qvercrowded. Verhuist concluded that the geometric law does not give a correct account of the facts.

Discontent with the old arithmetic was the first step towards the new. Verhulst replaces
by
\[
\begin{equation*}
x_{n+1}=q \cdot x_{n}-r \cdot x_{n}^{2} . \tag{3}
\end{equation*}
\]

What is the effect of \(-r \cdot x_{n}^{2}\) ? The larger, \(x_{n}\) becomes, the larger \(x_{n}^{2}\) becomes relative to \(x_{n}\), so that the larger the population the greater the braking effect of \(-r \cdot x_{n}^{2}\) on its rate of growth. A vast population canconly increase very slowly. To say that \(-\mathrm{r}: \hat{x}_{n}^{2}\) is a "slowing up" factor is to describe it \({ }_{2}\) in terms of its consequences; Vefhulst did better. His factor is the outcome of a more painstaking analysis of population growth; he described it in terms of what causes the slowing up: competition.

Man's activities are of two kinds, cooperative and competitive. A marriage is the "outcome of successful competition by a man against other men for a woman; a child is the outcome of successful cooperation by a man with a womann. Farmers and biochemists cooperate to produce greater yields of wheat; bankers and bank robbers compete for the customers' deposits. Soldiers cooperate as armies to compete against other soldiers' copperating as armies." Verhulst, took the view that in the main cooperation tends to increase, and competition tends \(\ddagger a\). decrease, the population.

How is the intensity of the struggle for family existence to be measured? Competition occurs when each of two or more people wants exclusively the same thing. When, for example, two married men want homes, and only one hoase "is. available.: What is the probability that two men of a popưdation \(x_{n}\) both want the same house? If \({ }^{*} p\) is the probability of either wanting, it, \(p^{2}\) is the probability of both wanting it. But the larger \(x_{n}\), the greater the chances. n a man wanting it. That to double, \(x_{n}\) would be to double \(p\), is a plausible
supposition. 'Yet, if ' \(p\) is directly proportional to \(x_{n}\), then \(p^{2}\) is directly proportional to. \(x_{n}^{2}\). Thus it is not unreasonable to take \(r \cdot x_{n}^{2}\) as a measure of the competition.

If discerning, you' may observe that we have neglected, to add, a competition factor, \(-r_{1} \cdot x_{n}^{3}\), theft for three competitors, and a factor \(-r_{2} \cdot x_{n}^{4}\), that for four competitors, and so qM. True. But it is useless to set up equations which completely fit a situation if this leaves us with mathematics too difficult to handle. In applying mathematics to reality there is always a compromise: by introducing an element of idealization, or by ignoring less important factors, what is too complex lis reduced to what is manageable. Often; the proper question is not, ""Is a given formula dead accurate?" but rather, "Is it a sufficiently good approximation for the present investigation?". Is (3) adequate for population
'investigation? I am anxious to answer this question, for in so doing I shall halve opportunity to exemplify that quite intricate problems can be dealt with by mere high school mathematics.

If \(r=0\), the competition factor \({ }^{\prime}-r \cdot{ }^{3} \cdot \dot{x}_{n}^{2}=0\), and, we find ourselves considering a society with the tranquility of lotus-eaters. With no competition (3) reduces to (1), so that (3) is a better formula. in the sense of including (I) as a limiting case. Turn from the tranquility of everxgne lotus-eating to the desperation of some not elating at all. Se all know what happens if competi tron is so severe that there are more hands than jobs, and more mouths to feed
Than food to feed them: life is nasty, brutal, a nd for many, short. That \(x_{n+1}\) ' could be smaller than \(x_{n}\) is obvious. But, what answer does (3) give? We write it in the form
\[
x_{n+1}=x_{n}^{2}\left(\frac{q}{x_{n}}-r\right)
\]

This form makes it clear that when, for any given \(q, x_{n}\) is specified, we can select \(r\) such that \(\left(\frac{q}{x_{n}}-r\right)\) is arbitrarily small. Consequently \(x_{n+1}^{\text {i }}\) can be"made as small as we please and, 'a fraction, less than \(x_{n}\). But there is no immediate answer to the question: Does (3) also give ' \(x_{n+2}\) correctly?

Unfortinateiy,
\[
\dot{x}_{n+2}=x_{n+1}^{2}\left(\frac{q}{x_{n+1}}-r\right)
\]
 ficulty is that the denominator of \(q\) has been changed. Since \(x_{n+1}<x_{n}\), it follows that the factor \(\left(\frac{q}{x_{n+1}}-r\right)>\left(\frac{q}{x_{n}}-r\right)\), but this is, of itself, insufficient to determine if \(x_{n+2}<x_{n+1}\).

However, that \(7(3)\) can be used to describe correctly the population at least one generation ahead in extreme states \({ }^{\text {i }}\) of society gives us fome expectation that it will serve far ahead in intermediate states, neither completely tranquil nor thoroughly brutal. At \(\widehat{\text { least }}\) it does mérit moré systematic examination.

First we further reconcile the complex with the manageable. .For intermediate states of society the change in population from one generation to the next will be so slow that \(x_{n} \cdot x_{n+1}\) will be sood approximation to \(\dot{x}_{n}^{2}\). Con-. sequently, we may consider
\[
\begin{equation*}
x_{n+1}=q \cdot x_{n}-r \cdot x_{n}^{-} x_{n+1} \tag{4}
\end{equation*}
\]
instead of (3)s without introducing any really significant change. In the populas tion law. (4) is preferable, as this makes for much easier mathematics.
(4) is a mixed equations \(\dot{x}_{n+1}\) occurs on both sides of the equations: Making : \(x_{n+1}\) the subject of the formula, we have
\[
\begin{equation*}
x_{n+1}=\frac{q}{1+r x_{n}} \therefore x_{n} \tag{5}
\end{equation*}
\]
"We observe that whereas with Malthus' law \(x_{n}\) has a.factor \(q\), with (what is essentially) Verhul'st's law the factor is \(\frac{q}{1+r x_{n}}\); the growth factor is no longer a constant, but depends on \(x_{n}\). "The longer \(x_{n}\) "becomes, the mallerit the growth factor. The population self-regulating; ovexpopulation is prevented. Verhulst's law echoes his original observation.

Our problem is to find \(x_{n+1}\). in terms. of \(x_{1}\). With Malthus' Law this
as easy. Indeed, the textbooks are crammed so full with geometrical
\(C^{-}\)
progressions that the student is apt to suppose there are no other yarieties. Real problems, alas, seldom have the neat and obvious form of school exercises; to the contrary, they often come in ugly and hidden forms. How to transform the latter into the former is an essential part of the art of doing mathematics. Although the student cannot reasonably be expected to have the foresight to see that (5) is in essence geometrical, he can reasonably be required to have the hindsight. .
- Taking reciprocals in (5),
\[
\frac{1}{x_{n+1}}=\frac{1+r x_{n}}{q x_{n}}=\frac{1}{q} \cdot \frac{1}{x_{n}}+\frac{r}{q}
\]

That the reciprocals of \(x_{n+1}, x_{n}\) gatisfy a simpler law, invites the substitutions
\[
\xi_{n+1}=i \frac{1}{x_{n+1}}, \quad \xi_{n}=\frac{1}{x_{n}}
\]
which give
\[
\xi_{n+1}=\frac{1}{q} \cdot \xi_{n}+\frac{r}{q}
\]

But for the constant term we would have the formof Malthus' law. The thought is father of the wish. Substituting
\[
\xi_{n+1}=\eta_{n+1}+\alpha, \quad \xi_{n}=\eta_{n}+\alpha
\]
where \(\alpha\) is an arbitrary constant, werhave,
\[
\eta_{n+1}+\alpha=\frac{1}{q} \cdot\left(\eta_{n}+\alpha\right)+\frac{r}{q}
\]
so that,
\[
\eta_{n+1}=\frac{1}{q} \cdot \eta_{n}+\left(\frac{\alpha}{q}+\frac{r}{q}-\alpha\right)
\]

Since \(\alpha\) is an arbitrary constant, we are at liberty to give it whatever spécIfication we please. But we wish the constant term of the equation to be zero; accordingly, it pleases us to define \(\alpha\) by

i.e., such that:
\[
\frac{\alpha}{q}+\frac{r}{q}-\alpha=0
\]

\[
\alpha+\quad \alpha+r=q \alpha
\]
which gives
\[
\alpha=\frac{r}{q-1}, \quad \text { provided } q \neq 1
\]

The condition that \(q>1\) merely implies that when \(r=0\), ie., when there is competition, the population is increasing. This supposition is acceptable and meets the proviso that \(q \neq 1\). Consequently, we take \(\alpha\) to be \(\frac{r}{q-1}\) and infer that
\[
\begin{equation*}
\eta_{n+1}=\frac{1}{q} \cdot \eta_{n} . \tag{Gi}
\end{equation*}
\]

We have transformed the form of Verhulst's law to that of Malthus': the laws themselves are, of course, distinct.

Since (6) is of the same form as (1), we have, as an analogue of \({ }^{\prime}(2)\).
\[
\begin{equation*}
\Leftrightarrow \quad \cdots \eta_{n+1}=\left(\frac{1}{q}\right)^{n} \cdot \eta_{1} \tag{7}
\end{equation*}
\]

It remains merely to reverse our transformations to obtain \(x_{n+1}\) as a function of \(x_{n}\). There is a gain of notational compactness by delaying the substitution for \(\alpha\) until the end

Firsty-we-go. back from the \(\eta^{r}\) s to the.\(\xi^{\prime}\) s. since
\[
\xi_{n+1}=\eta_{n+1}+\alpha
\]
by (7)
\[
\xi_{n+1}^{\prime}=\frac{1}{q^{n}}: \eta_{1}+\alpha
\]
\[
\xi_{1}=\eta_{1}+\dot{\alpha}
\]
so that
\[
\xi_{n+1}=\frac{1}{q^{n}}\left(\xi_{1}-\alpha\right)+\alpha=\frac{1}{q^{n}} \xi_{1}+\left(1-\frac{1}{q^{n}}\right) \alpha=\frac{\xi_{1}+\left(q^{n}-1\right) \alpha}{q^{n}}
\]

Second i, we go back.from' the \(\xi^{\text {'s }}\) ' to the \(x^{\prime}\) s. Since,
\[
\xi_{n+1}=\frac{1}{x_{n+1}} \cdot \xi_{1}=\frac{1}{x_{1}}
\]
we have,
\[
\frac{1}{x_{n+1}}=\frac{\frac{1}{x_{1}}+^{0}\left(q^{n}-1\right) \alpha}{q^{n}}=\frac{1+\left(q^{n}-1\right) \alpha x_{1}}{q^{n} \cdot x_{1}}
\]
and taking reciprocals,
\[
x_{n+1}=\frac{q^{n}}{1+\left(q^{n}-1\right) \alpha x_{1}} \cdot x_{1}
\]

Finally, since
\[
\alpha=\frac{r}{q-1}^{\alpha}
\]
we , have,
\[
\begin{equation*}
x_{n+1}=\frac{\ldots q^{n}}{1+\frac{\left(q^{n}-1\right)}{q_{1}-1} r \cdot x_{1}} \tag{8}
\end{equation*}
\]

Common prudence demands some check on our work. Substituting \(n=1\) in (8), we 'have
\[
x_{2}=\frac{q}{1+r x_{1}} x_{1}
\]

The same substitution in (5) gives the same result. It checks.
By a judicious use of the fact that (2) is a consequence of (1), we have deduced a formula for \(x_{n+1}\) when subject to Verhulst's Law; in terms of \(x_{1}, q\), and \(r\). What is its significance? We suppose \(q\) greater than, but close to, \(r\), and \(r\) very small indeed.

First we investigate the consequences of \(n\) being small also. Since
\[
\frac{q^{n}-1}{q-1}=1+q+q^{2}+\cdots+q-1 \approx \quad(q \approx 1)
\]
\(\frac{q^{n}-1}{q-1} \cdot \mathrm{rx}_{1}\), will be small compared with unity when \(n\) is small. Thus, without chäarge of gross' neglect we can ignore 'the second term of the denominator of (8) when considering the first few generations. We have
\[
x_{n+1} \approx q^{n} \cdot x_{1}
\]
i.e., that Verhulstis law approximates to Malthus'.

Next we : investigate the consequences of large \(n\). "When \(n\) is large and \(\dot{q}>1\), it follows from \(\frac{q^{n}-1}{q^{0}-1} \approx n\).that \(\frac{q^{n}-1}{q-1} r x_{1}\) is. large compared with unity. ' So without gross neglect we may ignore the first'term of the denominator "of (8), giving
\[
x_{n+1} \approx \frac{q_{n} \cdot x_{1}}{\left(q^{n}-1\right) \cdot\left(\frac{r}{q-1}\right) x_{1}}=\frac{q^{n}}{q^{n}-1} \cdot \frac{q-1}{r}
\]

But, with \(\dot{q}>1\), the larger, \(n\) is, the larger \(q^{n}\). and the nearer \(\frac{q^{n}}{q^{n}-1}\) "t 1. Consequentiy, the nearer' \(x_{n+1}\) to \(\frac{q-1}{r}\). Yet in neglecting the first term of the denominatór, we overestimate \(x_{n+1}\), so that no matter for how many generations the poplulation continues it will not exceed \(\frac{q-1}{r}\). ' Observe that this upper limit to the size of \(x_{n}\) is independent of the size of the original population \(x_{1}\) Isn't this astonishing?

The graph of (8), knowh as the togistic on flying \(S\) curve is illustrated by FIg. 8 ,

interval is there between one generation and the next? Every minute several people die and several are born. Who belongs to the present generation? to be precise "the present generation" refers to an overlapping of many generations, those generated in the years 1900, 1901, 1902, 1920, 1921, among others (if still şurviving). As statistics are usually taken on a yearly basis, it is convenient to sonsider the population in successive years as successive generations, to take \(x_{1}\) as the population for the first year consitered and \(x_{n+1}\) that \(n\) years later.

Let us take 1959 as the first year and obtain the actual figures for \(\mathrm{x}_{1}\), \(x_{2}\), and \(x_{3}\), the population of the U.S. in 1959, 1960, and 1961; from the available table of population statistics. Substituting the figures for \(x_{1}\) and \(x_{2}\) in (8), we obtain a first equation relating \(q\) and \(r\); substituting the figures for \(x_{2}\) and \(x_{3}\), we obtain a second. We now have two equations in the two unknowns, \(q\) and \(r\), sufficient to determine them. (8) has been tailored to fit the facts; the growth coefficient \(q\) and the competitive coefficient \(r\) are chosen so as to describe gorrectly the recent population history of the U.S. पf in (8) we write the figures for \(q\), \(r\), and \(x_{1}\), our formula is ready for use. Substituting \(n=3\), we predict the population for 1962; substituting n \(=4\), we predict that for 1963 .
- Would it be rash to take the result of substituting \(n=100\) as more than a very" tentative prediction of the population for the year 2059? Iypically, growth and competition remain steady, so that a formula that has accurately described the last two years may reasonably be expected to describe the next two. But over the span of a'century the growth and competitive factors have more time in which to alter, so that the long term prediction should be moxe. cautiously regarded.

We have seen that three successive years' statistics are sufficient to "determine \(q\) and \(r\). Had we usea all the statistics. of the last decade, the eight periods`1952-54, 195今-55, 1954-56, ..., 1959-61. would háve given us eight " determinations of \(q\) and. eight of \(r\). Had these differed in, the last decimal *
place or two we would have struck the typical figure which would give the best overall description of the decade. What fits the facts for the last ten years is surely more likely to fit the next hundred than that which fitted merely the last two.

Is Verhuist's formula reliable? Around about 1850 he madé: a carefui population study of several European countries •and of the United States. his law to predict their populations as far ahead.as a céntury. Some of his : predictions are famous, and justly so. For example, he calculated that Fraqee would reach a maximum population of 40 million in 12 l ; the event proved him correct. Despite the \(\mathcal{C i v i l}\) War, his prediction for the U.S. population in 1940 was less than a million out, But ironically, his law applied to his own country, Belgium,' did not work. Belgium's population curve for the century is given by Fig: 9.

How did Verhulst's prediction go wrong? Belgium switched from agriculture to industry and Colonized the congo. This distinct sociological change per manently altered the growth and competition coefficients. His application of his law continued to describe the growth of Belgium as agricuitural when it s was in fact industrial. Observe that the Belgian population curve is a combination of the parts of two S-curves, the earlier with arricultural, and the later with industrial, cọnditions obtaining. How then, it may well be asked, 'was his prediction for the United States successful despite the Civil War? of course, Verhulst could not know that the Civil War was going to break out a de- . cade or so after he made his population analysis and so he could not take the * hanged values of the growth and competition coefficients into account. The
point is that these changes of coefficients, unlike those due to switch from agriculture to industry in Belgium, were merely temporary: soon after the Civil War his coefficients wore again accurately descriptive. With people killed in the war his 1865 population estimate was high, but his estimate and the actual population of that time bothmave \(\dot{\circ}\) growths asymptotic to \(\frac{q-1}{r}\). In the long run his prediction would have beenforrect; the run to 1940 was long enough for it to be correct, within 1 million.

As promised, I have shown you that quite intricate results can be obtained Githout using differential equations. Actually formula for \(x_{n+1}\) for any. speciffied \(n\) ' can be obtained from (5) by using only the very simplest of 'algebra. Putting \(n^{\circ}=1,2\), successively, we hàve
\[
x_{2}=\frac{q}{1++r x_{1}} x_{1} ; \quad x_{3}=\frac{q}{1+r x_{2}} x_{2}
\]
so that
\[
x_{3}=\frac{q}{1+r\left(\frac{q x_{1}}{1+r x}\right)} \cdot \frac{q}{1+r x_{1}} x_{1}
\]
gi.
Multiplying numerator and denominator of right side by \(i+r x_{1}\),

Proceeding in this way \(x_{4}, x_{5}, \ldots\), can be obtained from , \(x_{1}\). We, go step by step along \(\mathrm{an}_{\mathrm{z}}\) adventurous path to find where it leads us. Aftex patient travel
- the way the road runs being clearly discerned, the more ambitious student may prove the formula for \(x_{n+1}\) by mathematical induction.
\(2.5 \frac{\text { Cusanus's }}{1} \frac{\text { Recursive }}{\text { Formula }}\) for \(\frac{\pi}{0}\).
- When, as in the last séction, \(x_{n}\), a member of a sequence, is definëd in terms of eaplier members of the sequence, it is said to be defined recursively \({ }_{c}^{*}\) This terminology,acknowledges descriptively that the sequence. refers back to itself; "it 户̄, so to speak, a sra"ke biting its own, tair.

We now consider one of the most elegant recursive formulae in mathematics, namely that given by Cusanus ( \(1401=64\) ) in about 1450 . ' Even though it. was the first to facilitate the calculation of \(\pi\) better than Archimedes: formula, it is not widely known. Already more than five hundred years old, perhaps it is = too modern for the "modernists." With this formula we have a hint that there was, contrary to popular historical misconception, tremendous intellectual activit before the Renaissance. Despite what the history books fail to say without Cusanus and his ilk Galileo and Newton could not have inherited the groundwork they did in fact inherit.

Cusanus', calculation of \(\pi\). It really'is obvious that if a fegular polygin of perimeter \(p\) is circumscribed by a circle of radius \(R\) then the more numerous the sides of the polygon the closer the approximation of \(p\) to \(2 \pi R\) and \(\frac{p}{2 R}\) to \(\pi\). Surely thousands of persons before and since Archimedes must have thought of this yet how many have found a method of effectively exploiting it to calculate \(\pi\) ? Archimedes considered an. unending sequence of regular polygong, each polygon with more sides than its predecessor, each circumscribed by the stine circle; Cusî̉nus considered an unending sequence of regular" polygons, each polygon with more sides than its predecessor, \({ }^{\circ}\) but all of the same perimeter and therefore circumscribed by different circles. Whereas Archimedes found the limit of \(p\) with constant \(R\), CCusanus found the limit of \(R\) with constant. \(p\). Both methods are elegant. Encourage the student who finds Cusanus, elegance - exciting to study archimedes' for himself.

How, specifically; did Cusanus exploit his idea? - He did so in the follow-ing-way. From a given circle \({ }^{\circ} C_{j_{0}}\) of radius \(r_{1}\) circumscribing a regular poly- , : go of \(\leq m\) sides and perimeter \(k\), anoth circle \(c_{2}\). of radius \(r_{2}\) circumscribing a regular polygon of double the number of sides; but with the same perimeter, is constructed. By repetition of the procedure ' \(n\) times there
 \(\ldots, r_{n+1}\), circumscribing regular polygons with \(\frac{\text { constant }}{4} \frac{\text { perimeter }}{v} \mathrm{k}\) of m, \(2 m, 2^{2} m, \ldots, 2^{n} m\) sides, respectively. It is intuitively clear that
\[
\pi=\frac{k}{2 R} \text { where } R=\lim _{n \rightarrow \infty} r_{n+1}
\]
.(Since we are now considering a sequence of circles of constant perimeter we use the letter \(k\) in preference to ' \(p_{n}\) ) The real problem, of course, is to \({ }^{\circ}\) determine \(\stackrel{\vdots}{n}_{\substack{n+1}}\). The way in which \(C_{2}\) is constructed from \(C_{1}\) determines the relation between \(r_{2}\) and \(r_{1}\). But \(L_{3}\) is constructed from \(C_{2}\). as \(C_{2}\) from \(C_{1}\) so that \(r_{3}\) has the same relation to \(\dot{r}_{2}\) as, \(r_{2}\), to \(r_{1}\), and for similar reasons' \(r_{4}\) has the same relation to \(r_{3}\) as \(r_{3}\) has to, \(r_{2}\). Thus \(r_{4}\) "can be determined in terms of \(r_{3}\), while \(r_{3}\) "can be determined in terms of \({ }^{\prime} r_{2}\), and \(r_{2}\) in terms of \(r_{1}\), so that finally \(r_{4}\), can be determined in terms of \(r_{1}\). More generally, \(r_{n+1}\) is determined in terms of \(r_{n}\), which in turn is determined in terms of its sequential predecessor, which in turn ... , so - that finally \(\dot{r}_{n+1}\) is determined in terms of \(r_{1}\). The formula is recursive. Now for the details. What, specifically, is the gelation between \(r_{2}\) and \({ }^{\prime} r_{1}\) ? Fig. 10 illustrates the essentials of what we are given: the m-sided circumscribed polygon being regular, it is sufficient to consider just one of \({ }^{+}\) its sides.

We make the construction illustrated by Fig. il.

1

Since, as Euclid tells us, angle subtended. at circumference is one-half \({ }^{1}\) angle subtended at center,
\[
\bar{\prime} \angle B_{1} A_{2} B_{1}{ }^{\prime}=\frac{1}{2} \angle B_{1} A_{1} B_{1}^{\prime}
\]

Consequently 2 m such triangles as \(\mathrm{B}_{1} \mathrm{~A}_{2} \mathrm{~B}_{1}^{\prime}\) fit together to form a regular polygon with perimeter \(2 \mathrm{~m} \times \widehat{\mathrm{B}_{1} B_{2}{ }^{\prime}}\), which is circumscribible by a circle \(C^{*}\) with center \(A_{2}\) and (say) radius \(r_{2}^{*}\). Fig. 12 illustrates the essentials. Retaining \(A_{2}\). as center we now shrink Fig. 12 to half size. We now have a. circle \(C_{2}\) circumscribing a regular polygon with the same perimeter as, but twice the number of sides of, that circumscribed by \({ }^{\prime} C_{1}\). See Fig. 13. Compare Fig. 13 with Fig. 10 :

Fig. 12

The problem is to find \(r_{2}\) in terms of \(r_{2}\). To do this we first consider the geometry of Fig. 11. Since, as Thales tells us, the angle included in a semicircle is a right angle, \(A_{2} B_{2} E\) is a right angle. (it is subtended at the circumference of \(C_{1}\) by diameter \(\left.A_{2} E\right)\). Thus triangles \(A_{2} B_{2} E, A_{2} B_{1} D_{1}\) are both right triangles (the latter is right angled at \(D_{1}\) ) and additionally have a common angle \(B_{1} A_{2} E\). Therefore these triangles are similar, and consequently their corresponding sides are proportional, so that
\[
\frac{A_{2} B_{1}}{A_{2} D_{1}}=\frac{A_{2} E}{A_{2} B_{1}}
\]
ie.,
\[
\frac{r_{2}^{*}}{h_{2}^{*}}=\frac{2 r_{1}}{r_{2}^{*}} .
\]

Thus
- But \(h_{2}^{*}\) is an uninvited bedfellow and is speedily to be replaced.

72
\[
\begin{align*}
h_{2}^{*}= & \dot{A}_{2} P_{1}=A_{2} A_{1}+A_{1} D_{1} \\
& h_{2}^{*}=r_{1}+h_{1} \tag{2}
\end{align*}
\]

We have related the measurements of Fig. 10 to those of Fig. 12; we wish to relate them to those of Fig. 13. But Fig. 13 was obtained from Fig.. 12 by reducing everything to half size, so that
\[
\begin{aligned}
& r_{2}=\frac{1}{2} r_{2}^{*} \\
& h_{2}=\frac{1}{2} h_{2}^{*}
\end{aligned}
\]

Hence, from (2) we have
\(\because \quad \therefore \quad \therefore \quad h_{2}=\frac{r_{1}+h_{1}}{2}\)
and from (1),
\[
\begin{gather*}
r_{2}^{2}=\frac{1}{4}\left(r_{2}^{*}\right)^{2}=\frac{1}{4} \cdot 2 r_{1} \cdot 2 h_{2} \\
 \tag{4}\\
\quad r_{2}=\sqrt{r_{1} \cdot h_{2}} .
\end{gather*}
\]

This derivation discloses our motive for using a star notation: to emphasize the transitory role of \(r_{2}^{*}\) and \(h_{2}^{*}\). \(\dot{h}_{4}\),
(3) and (4) give \(r_{2}\) in terms of \(r_{1}\) (and \(h_{1}\) ). The intrusion of the \(h^{\prime} s_{\text {_ }}\) is an incidental complexity that must not be permitted to obscure the leading idea; in specifying the relation between. \(r_{2}\) and \(r_{1}\) (and \(h_{1}\) ) we have reached the heart of the matter. In "repeating our procedure to obtain \(C_{3}\) from \(C_{2}\) as \(C_{2}\) was obtained from \(C_{1}, r_{3}\) "will have the same relation to \(r_{2}\) as \(r_{2}\) has to \(r_{1}\), and in obtaining \(C_{4}\) from \(C_{3}, r_{4}\) will have the same relation to \(: r_{3}\) as \(r_{3}\) has to \(r_{2}\) and \(\dot{r}_{2}\) has to \(r_{1}\). Consequently, for \({ }^{C_{n+1}}\) : se have.
\[
\begin{equation*}
h_{n+1}=\frac{r_{n}+h_{n}}{2} \tag{5}
\end{equation*}
\]
\[
\begin{equation*}
\text { - } r_{n+1}=\sqrt{r_{n} \cdot \dot{h_{n+1}}} \text { : } \tag{6}
\end{equation*}
\]

Let us recapitulate. To avoid the verbosity of saying that \(h_{n}\) is the altitude of any triangle whose vertex is the center of \(\dot{C}_{n}\) and whose base is \(\therefore\) one of the sides of the regular polygon circumscribed by \(C_{n}\), let us refer to \(h_{n}\) as the altitude of \(C_{n}\). Then, if, \(C_{1}\) is a circle of radius \(r_{1}\) and altitude \(h_{1}\) circumscribing a regular polygon of \(m\) sides, and perimeter \(k\), by repeating " \(n\) ' times the process considered above we form a' sequence of circles \(C_{1}, C_{2}, C_{3}, \ldots, C_{n+1}\) of radii \(r_{1}, r_{2}, r_{3}, \ldots, r_{n+1}\), (and altitudes \(h_{1} ; h_{2}, h_{3}\), \(\ldots, h_{n+1}\) ) circumscribing regular polygons of \(m, 2 m, 2^{2} m, \ldots, 2^{n_{m}^{\prime}}\) sides, respectively, where \(h_{n+1}, r_{n+1}\) satisfy (5), (6) for \(n=0,1,2, \ldots, n\).

To calculate \(\pi\), i.e., \(\frac{k}{2 R}\), it merely \({ }^{\circ}\) remains to \(^{\prime}\) determine \(R\), where \(R=\lim _{n \rightarrow \infty} r_{n+1}\). It is convenient to take \(C_{1}\) as circumscribing a regular hexagon, ie., to take \(m=6\), and to take \(r_{1}=1\). See. Fig. 14 .

Here \(h_{1}\) is evidently the altitude of an equilateral triangle of unit side. By simple calculation we find \(h_{1}=\sqrt{\frac{3}{2}}\). The reader is, now in a position to
calculate a sequence of successively better approximations to \(R\), and hence, : to \(\pi\). \({ }^{\text {as }}\)

This raises the question of the accuracy of approximations. It really is intuitively obvious that as increases the angle at the vertex of each triangle constituting the regular polygon circumscribed by \(C_{n}\) will get smaller and smaller, and therefore \(r_{n}\) and \(h_{n}\) more and more nearly equal, giving
\[
\lim _{n \rightarrow \infty} r_{n}=\lim _{n \rightarrow \infty} h_{n},
\]
1.e., that \(r_{n}\) and \(h_{n}\) both converge to \(R\). And since the hypotenuse is the greatest side of a right angle, 4

See Fig. 15.
\[
r_{n}>h_{n}
\]

Considering the polygon, \(h_{n}\) is the radius of the circle it inscribes and \(r_{n}\) is the radius of "the circle circumscribing it: ultimately, in the limit surely these circles coincide. Thu's it seems reasonable to suppose that \(r_{n}^{\prime}\) decreases,
\(h_{n}\). increases and
\[
r_{n}>R>h_{n}
\]

The astonishing thing is that we are, able to anticipate that, for example, 'for the hexagon, with \(r_{1}=1\), and so perimeter \(k \xlongequal[=]{=} 6\), the repeated applications. of (5) and (6) will converge to \(\frac{6}{2 \pi}\), i.e., to \(\frac{3}{\pi}\).

We may add that neither Cusanus nor Descartes (1596-1650) (who made externsive use of Cusanus ' formulae) worried \({ }^{\circ}\) overmuch' about convergence: they were . confident of their intuition.

With no more than an elementary knowledge of inequalities we can prove convergence. The crux of the \({ }_{\text {minter }}\) is that the difference between \(r_{n}\) and \(h_{n}\) gets smaller and smaller. But having the abhorrence for square roots that pythagoras had for bean eating, we prefer to consider the difference of \(r_{n}^{2}\) \(\begin{array}{ll}\text { and } h_{n}^{2} \\ \text { By (5), } & \end{array}\)
\[
r_{n+1}^{2}-h_{n+1}^{2}=r_{n} \stackrel{\rightharpoonup}{h}_{n+1}-\left(\frac{r_{n}+h_{n}}{2}\right)
\]
but by (.5)
\[
r_{n}\left(h_{n+1}\right)=r_{n}\left(\frac{r_{n}+h_{n}}{2}\right)
\]
\[
\text { so . . } \left.\quad \because \quad r_{n+1}^{2}-h_{n+1}^{2}=r_{n}\left(\frac{r_{n}+h_{n}}{2^{2}}\right)-\left(\frac{r_{n}+h_{n}}{2}\right)\right)^{2}
\]
\[
\begin{aligned}
& 1 \\
& \cdots
\end{aligned}
\]
\[
=\left(\frac{r_{n}+h_{n}}{2}\right)\left(r_{n}-\frac{r_{n}+h_{n}}{2}\right)
\]
\[
=\left(\frac{r_{n}+h_{n}}{2}\right)\left(\frac{r_{n}-h_{n}}{2}\right)
\]
\[
=\frac{1}{4}\left(r_{n}^{2}-n_{n}^{2}\right)
\]

Thus
and
\[
\begin{aligned}
& r_{3}^{2-m h^{2}}\left(\frac{1}{4}\left(r_{2}^{2}-n_{2}^{2}\right)\right. \\
& \dot{r}_{2}^{2}-n_{2}^{2}=\frac{1}{4}\left(r_{1}^{2}-h_{1}^{2}\right) . \\
& 76
\end{aligned}
\]
so that
\[
r_{3}^{2}-n_{3}^{2}=\frac{1}{4^{2}}\left(n_{1}^{2}-n_{1}^{2}\right) .
\]

Proceeding in this way, after 'n steps, we have.
\[
\begin{equation*}
r_{n+1}^{2}-h_{n+1}^{2}=\frac{1}{4^{n}}\left(r_{1}^{2}-\dot{h}_{1}^{2}\right)^{2} . \tag{7}
\end{equation*}
\]

\section*{(}

But , \(r_{1}\) the hypotenuse of the triangle is greater, than \(h_{1}\) the altitude (see Fig. 10), so that \(r_{l}^{2}-h_{1}^{2}\), is positive and hence

Consequently, \(r_{n}-h_{n}>0\), so by (5)
\[
\begin{gathered}
h_{n+1}-n_{n}=\frac{1}{2}\left(r_{n}-n_{n}\right) \\
.
\end{gathered}
\]
and therefore
\[
\begin{equation*}
\dot{h}_{n+1}>h_{n}, \quad< \tag{9}
\end{equation*}
\]

Squaring (6) and dividing by \(r_{n} \cdot r_{n+1}\)

(8)
so
ide.,
\[
\frac{r_{n+1}}{r_{n}}=\frac{h_{n+1}}{r_{n+1}}
\]
\[
1>\frac{h_{n+1}}{r_{n+1}}
\]
\[
1>\frac{r_{n+1}^{n+1}}{r_{n}}
\]
\[
\begin{equation*}
\Leftrightarrow r_{n+1}<r_{n} \tag{10}
\end{equation*}
\]

Arithmetic confirms intuition. (9) shows that successive values of \(h_{n}\) increase (so that if there, exists an \(R, h_{n}<R\) ), while (10) shows that successive values of \(r_{n}\) decrease (s, that if there exists an \(R, R<\dot{r}_{n}\) ) and
(7) shows that if either \(r_{n}\) or ̈ \(h_{n}\) converges then both converge to the same limit. Conjointly these results imply Shat there is an \(R\) such that for all ' \(n, \quad h_{n}<R<r_{n}\), and that
\[
\lim _{n \rightarrow \infty} h_{n} \geqslant R=\lim _{n \rightarrow \infty} r_{n}
\]

Let's be specific. Taking the hexagon as our initial polygon, with \(r_{1}=1\) and (consequently) \(h_{1}=\frac{3}{2}, \quad 8 y(7)\)
\[
r_{n+1}^{2}-n_{n+1}^{2}=\frac{1}{4^{n}}\left(1^{2}-\frac{3}{4}\right)=\frac{1}{4^{n+1}}
\]
so that
\[
r_{n+1}-h_{n+1}=\frac{1}{4^{n+1}} \cdot \frac{1}{r_{n+1}+h_{n+1}}
\]

But, by (9) \(h_{n+1}>h_{1}=\sqrt{\frac{3}{2}}\), and by (8) \(r_{n+1}>h_{n+1}>\sqrt{\frac{3}{2}}\), so that \(r_{n+1}+\) \(\therefore h_{n+1}>\sqrt{\frac{3}{2}}+\sqrt{\frac{3}{2}}\) and \(\frac{01}{r_{n+1}+h_{n+1}}<\sqrt{\frac{1}{3}}\).

Therefore,
\[
r_{n+1}-n_{n+1}<\frac{1}{4^{n+1}}: \frac{1}{\sqrt{3}}<\frac{1}{4^{n+1}}
\]

That is to say that the difference between the radif of the circumscribing and inscribed circles of the polygon obtained, after \(n\) steps from the initial hexagon is \(<\frac{1}{4^{n+1}}\). Convergence is rapid.

Since \(\sigma R=k\) and in this example the perimeter of the hexagon is 6 (as remarked earlier), \(R=\frac{6}{2 \pi}=\frac{3}{\pi}\), so that the successive values of \(h_{n}\) increase to \(\frac{3}{\pi}\) while the successive values of \(r_{n}\) decrease to it. "That is,
\[
0 ; n_{n}<\frac{3}{\pi}<r_{n}
\]
so that
\[
\therefore \pi<\frac{3}{h_{n}}, \frac{3}{r_{n}}<\pi
\]
1.e.,
\[
\frac{3}{r_{n}}<\pi<\frac{3}{h_{n}}
\]

Even the case \(n=1\) is interesting
\[
\frac{3}{1}<\pi<\frac{3}{\sqrt{\frac{3}{2}}}
\]
i.e.,
\[
3<\pi<2 \sqrt{3} \approx 3.4
\]

Surely the reader will want to work out, \(n=2,3,4\) (and maybe others) for
himself.
Finally, with the suggestion that the reader take a second look at Fig. 15 and the reminder that
\[
\lim _{\theta \rightarrow 0} \frac{\sin \theta}{\theta}=1
\]
he is urged to prove that in the general case the limit of \(r_{n}\) and the limit of \(h_{n}\), i.e., \(R\), is given by

\subsection*{2.6 Arithmetic and Geometric Means}
\(M_{A}\) the arithmetic mean of \(a_{1}, a_{2}, a_{3}, \ldots, a_{n}\) is defined by
\[
M_{A}=\frac{a_{1}+a_{2}+a_{3}+\cdots+a_{n}}{n}
\]
\(M_{G}\) the geometric mean of these quantities is defined by
\[
M_{G}=\sqrt[n_{1}]{a_{1} \cdot a_{2} \cdot a_{3} \cdots, a_{n}}
\]

Thus, for example, (5) of the lastwsection states that \(\dot{h}_{n+1}\), is the arithmetic mean of \(r_{n}\) and \(h_{n}\), while (6) states that \(r_{n+1}\) is the geometric mean of \(r_{n i}\) and \(h_{n+1}\)
"If all, the quantities \(a_{1}, a_{2} ; a_{3}, \ldots\), are
\[
M_{A}=\frac{n a_{1}}{n}=a_{1} \quad \cdots \quad \text { and } \quad M_{G}=n \sqrt{a_{1}^{n}}=a_{1}
\]
so that \(M_{A}=M_{G}\). . If not all the quantities are equal then \(M_{A}^{\prime}>M_{G}\). This is very easily proved in the simple case \(n=2\). For the two quantities \(a, b\) we have
\[
M_{A}=\frac{a \pm b}{2}, M_{G}^{\prime}=\sqrt{a b}
\]
therefore"
\[
\begin{aligned}
M_{A}-M_{G} & =\frac{1}{2}(a+b-2 \sqrt{a b})=\frac{i}{2}\left[(\sqrt{a})^{2}-2 \sqrt{a} \sqrt{b}+(\sqrt{b})^{2}\right] \\
& =\frac{1}{2}(\sqrt{a}-\sqrt{b})^{2}
\end{aligned}
\]
but \(\frac{1}{2}(\sqrt{a}-\sqrt{b})^{2}>0\) unless \(a=b\). This proves the proposition.
What are the uses of these means? "I f"n independent measurements are made of the same quantity, if, for example, \(a_{1}, a_{2}, a_{3}, \ldots, a_{n}\) are the \(n\) numbers indeperronaty obtained for the distance of the sun from the earth, then the arithmetic mean is the most reliable estimate. Gauss' argument to this effect is well known. Less well known is his application of the geometric mean. -This follows.

How is a weight \(W\) to be accurately determined by using badly made scales? How, for example, with scales of which one arm is longer than the other? We suppose that \(W\), when placed in the right and left pans, counterbalances weights \(W_{1}, \dot{W}_{2}\), respectively. What is the actual weight of \(W\) ? study Figs. 16 and' 17 .

For equilibrium in Fig. 16 we have

75
.1

Fig. 17.
and for equilibrium in Fig. 17,
\[
\begin{equation*}
\ell_{1} W=\ell_{2} W_{2} \cdot \tag{2}
\end{equation*}
\]

Now we come to Gauss' important observation. Multiplying (1) by (2)
so that
\[
\lambda \quad W=\sqrt{W_{I} \cdot W_{2}} .
\]

Thus \(W\) is independent of the lengths of the arms. Use of the geometric mean rectifies "this imprecision of the scales.
\(\because\)

\section*{\(3: 1\) Euclid's Optics.}

We begin with' Euclid ( \(\dot{c} .300 \mathrm{BC}\) ). Not unnaturally for a geometer, he Wished, as' doubtlessly had many geometers before him, to apply geometry to optics: Unlike the o others he was successful. Conceiving light as propagated in straight lines enabled him to apply geometry to optics. of second thoughts this state-
ment cannot stand. Until Euclid had applied geometry to optics there was, to use the Irish idiom, no such subject as optics. Nowadays, when using diagrams, is an ingredient of educated common sense, of course it is obviof that light is propagated in straight. lines. If light rays could not be represented by lines, optical phenomena could not be illustrated by' diagrams. We, with the arrogance of hindsight, cannot begin to understand Euclid's foresight in making his basic assertion. that light is.rectilinearily propagated. When the needle in the hay'stack has been pointed out to us, we are prone to suppose that finding it ha's no problem at all.
- Physical objects that more or less crudely approximate to straight lines readily, come to mind, for example, a taut wire. But. surely a shaft, of sunlight : piercing the shutters of a darkened room is singularly aptasisn't this the perfect example? fiEuclid must have been well pleased with his observation. Yet Mote that his basic assertion embraces metaphysical speculation as well as physical observation. We see only the shafts of light at which we look; we do not see the shafts with which we look. We cannot observe the rays with which we observe, yet. Éucliá claims all rays to be propagated in straight mines. Such metaphysicalefassumptions regarding unobservable are acceptable in so far as they facilitate understanding of observables. Is hismpstulate obvious? Your answer depends upon how much or how little you think about it.

Given that ray light are straight lines, hon Euclid asked, is the direction of a raystriking the surface of a plane mirror related to that of the reflected "ray? ' See Fig. 1.

This Figure reduces optics to geometry. The lines \(\ell_{1}, \ell_{2}, n\), represent the incident ray, the reflected ray, and the normal to the surface at the point of incidence, respectívely. The angle \(\alpha\) between incident ray and normal is termed the angle of incidence, while the angle \(\beta\) between, reflected ray and normal is termed the angle of reflection. "What is thé relation between \(\beta\) and \(\alpha\) ? Euclid found by experiment that \(l_{2}\) lies in the plane determined by \(l_{1}\) and \(n\). Thus \(\ell_{1}, n\), and \(\ell_{2}\) in Fig. 1 may be considered to lie in the plane of the paper. To determine \(\ell_{2}\) uniquely, it 'remains to specify. \(\beta\). As the result of many experiments Euciid found that \(\beta==^{\prime} \alpha\), i.e., that angle of reH flection is equal to angle of incidence, 'riths is the famous' law of reflection. as formulated by him in his Optics:
- hathough this law was based on a large number of experiments we mustiremember that Greek technology was rudimentary, their measuring instruments imprecise, and theif plane mirrors fimperfect. What assurance had Euclid that B. was precisely equal to \(\alpha\) ? , He had the comforting security of experiment backea by belief. He held a posisibly only half-articulate, whit certainly deep-seated, belief about the nature of things; that Nature if notifortuitous'- that her laws WiPX have simplicity and elegance. With the courage of conviction he asserted his law to hold exactly for perfectly plane mirrors. But many of Euclid's contemporaries, eyen if equally courage pus, had grave doubts, whether hhs law
 of nature at all.
3.2 Heron: The Shortest Path Principle.

To add grounds for belief we introduce Heron of Alexandria who lived a generation.'or so after Euclid. (His birth and death dates are uncertain.) A. mar who played a far greater role "in the development of science than that usually ascribed in the textbooks, he built the first automaton, made the first attempt at building a steam engine, developed trigonometry and applied it extensively. A man with both feet on the ground, he was forever stressing the possibilities of applying mathematics.

Heron gave a proof of Euclid's law of reflection. His proof consists of showing that -both of Euclid's laws, that
\(\mathrm{F}_{1}\) Light is propagated rectilinearity
\(E_{2}\) Angle of Reflection = Angle of . Incidence
are consequences of the principle proposed by Heron himself, that
H Light. takes the shortest pat \({ }^{H}\) possible. \({ }^{\text {B }}\)
Here we have what is probably the first example of the unifying trend so characteristic of science. Surely either of \(\frac{\mathbb{E}_{2}}{}{ }^{\prime} \cdot E_{2}\) could be true without the other. Is it not perfectly reasonable to conceive of light being propagated ain straight lines without \(\beta=\dot{\alpha}\), and \({ }^{\prime}\), \({ }^{\prime}\) verse dy? But \(H\) could not be true without both being true. Whereas \({ }^{2}\) belief in the truth of both. \(\dot{E}_{1}, E_{2}\) merely affords grounds for believing, \(H\), believing \(H \frac{\text { necessitates believing both }}{E_{1}}, \mathrm{E}_{2} \cdot\) Moreover, the complete formulation of \(E_{2}\) is complicated, while \(H\), like \(E_{1}\) is simple. Is f ot easier to believe one statement of a certain kind than twenty, or two of "the same or a more complicated kind? It is in this sense that Heron "proved" Euclid's'law of reflection.

The proof that. \(E_{1}\) follows from \(H\) is obvious. Since the shortest" dis-" trance between any two points \(A\) and \(B\) (in free space) is the straight line \(g B\) "that joins them, light, in moving from \(A\) to \(B\) by the shortest" path possible, is necessarily propagated rectilinearity. Fig. \({ }^{2}\) iso self-expianatory.

The proof that . T2 follows from \(H\) is, not obvious. We suppose ifght to travel from \(A\) via some point. \(P\) in the mirror surface to \(B\). \(P N\) - is the normal' to the mirror surface at p. See Fig. 3 .

If the light did not become incident to the mirror surface, then the light could not be reflected from it:. Here, in asserting that a ray takes the shortest path possible from A to \(B\), we cannot mean the shortest of all possible paths (the straight line \(A B)\), we must mean the shortest possible path via the surface of the mirror: "Thus to prove that \(E_{2}^{*}\) is a consequence of \(H\) is to prove that, if APB is the shortest path possidle (via the mirror surface), then the angles made by the straight lins, AP, PB With .PN. are equal.

First we show that the Iines \(A P, P B, c^{\circ}\) cannot be wigily. The distance from \(A\) to \(B\) via \(P\) will be a mimimum whent \(A\) and \(P B\) are both minima; for if both were not minima their sum couild bédecreased. But the minimum distance between any two points is the straight line joining them, so that the distance. from. \(A\) to ' \(B\) via \(P\) cán be a minimum only if - \(A P\) and \(F B\) are both straight lines. Accordingly, we exclude \(\overline{=}\) wiggly fines from further consideration.

Thits leadsius to the crux of the proof. What is the position of \(P\) such that the sum of the straight line distances AP, PB is a minimum? At this, stage we avail ourselves of Herqn's Ahgenuity by introducing an auxiliary point \(B^{\prime}\), the mirror image of \(B\). That is to say; * \(B^{\prime}\). is the point on the normal from ' \(B\) to the mirror as far below the surface as \(B\) is above It. See Fig. 4...

Since \(M C\) is perpendicular to \(\mathrm{BB}^{\prime}\) and C is the midpoint of \(\mathrm{BB}^{\prime}, \mathrm{MC}\) is the perpendicular bisector of \(\mathrm{BB}^{\prime}\); i. \({ }^{\text {K., MC }}\) is the locus of points equidisfant from \(B\) and Bi. . Therefore, no matter what point \({ }^{\text {a }} \mathrm{P}\) is on MC ,

and consequently
\[
A P+A B=A P+P B^{\prime} \quad-\quad .
\]

The former will be a minimum only when the latter is a minimum. But the shortest distance between \(A\) ind is the straight line joining them, so that the latter, and consequently the former, will be minima when " \(P\) is collinear with \(A\) and \(B^{\prime}\).

It remains merely to show that when APB' is a straight line, the ingles made by, \(A P\) and \(B P\) with the normal at \(P\) are equal. Study \(F i g .58\)

Since "AFB' is now a straight line, MPA and \(B^{\prime \prime} P\) are verfically opposite angies, so that :

by symmeth (and also, bj congruence of triangles \(P B C\) and \(F^{\prime} C\), from two sides and their included angle, \(\mathrm{PC}=\mathrm{PC}, \quad \angle \mathrm{PCB}=90^{\circ}=\angle \mathrm{PCB}, \quad \mathrm{CB}=\mathrm{CB}\) '), so that
\[
\angle \mathrm{MPA}=\angle \mathrm{BPC}
\]

Therefore the complement of the former is equal to the complement of the latter, í.e., 1
\[
\angle A P N=\angle B P N
\]

This completed the proof that \(\cdot E_{2}\). is implied by \(H\).
The critical reader may well ask, How did Heron hit upon the idea of the auxiliary point. "B'?" But haven't we ail seen swan and reflection flơating double on a placid lake? The, swan's image is the same size as the ofan, but upside dokm. In terms of Fig. 5, mif MC represents the lake surface and \(C B\) the swan, then \(C B^{\prime}\) represent"s the swan's image; in particular \(B^{\prime \prime}\) is the image of \(B\). "To an observing eye at \(A\) looking along' \(A P, B\) appears to be on AP produced at \(B^{\prime}\). To see \(B\) "in" \({ }^{\text {a }}\) reflecting surface is to see it as if it were at \(B^{\prime}\), and-there were no reflecting surface. The concept of mirror image enables us, in effect, to throw away the mirror and reduce the problem of a reflected ray's path to that of a nonreflectedray. By \(=E_{1}\) the path of light from \(A\) shortest path possible. We can but suppose that Heron had such. considerations of these in mind when he pondered the problem; for ponder the problem he did.

\section*{\(3: 3\) Ptolemy and Refraction.}

Me further defelopment of optics leads us to the work of the great. Alexandrian astronomer; Ptolemy, who flourished 12.7 to 141 ac, 151 AD. Shortly after the time of Heron deep interest, if astronomy, rafsed other questions concerning the nature of light. Ptolemy found from his observations of the stars that the propagation of light near the earth's surface is not precisely recti-
- linear, but slightly curved. On the analogy of a"straight stick partially. immersed in water, appearing bent, he ascribed the curvature of light to passage
through layers of air of different density.
Textbook writers would have us believe that the Greeks were interested only in the things that they could see but not touch. To the contrary, a vast amount of experimental work was done in Alexandrian times:. Ptolemy, to better understand the effect of change in density on the bending of light rays by the atmosphere, conaucted experiments to measure the deflection of light rays in passing from air to water. See Fig. 6.

Upon penetriating the surface of the water the incident ray does not continue along AP (produced); but at an angle to it. The deflected ray, is said, to use the commogly accepted term, to be refracted. Possibly the reader is disposed to take \(\angle B P A\) as a measure of the refraction. Ptolemy did not do this. Refractio is sufficiently*similar to reflection to merit analogous terminology: With both phenomena there is a ray incident to a surface, and therefore an angle of incidence: 'The oniy difference is that whereas with reflection the ray after incidence is determined above the surface, with refraction it is deflected below it. Is, it not therefore natural, to measure angles for both phenomena with reference to the normal to the shrface; to lase the sare definition of angle of incidence for both; and"zince a ray deflected upwards is meakured against the upwara normal to measure against the downward normal a ray

Ptolemy found that \(\beta\) depends upon \(\alpha\); a change in the angle of incidence results in a change in the angle of refraction. Mathematically put, \(\beta\) is a function of \(\alpha\), say, \(\beta=f(\alpha) . \because\) As a first. step toward specification \(f(\alpha)\) Ptolemy, made extensive tabulation of the ordered pairs, \(\alpha\) with the corresponding • \(\beta\) :- "Despite more and yet more experiments, with extensiye and, yet more extensive tabulation, the law of ordering continued to elude hịm. Finally he had to "give up.
\(3.4^{\circ}\) Kepler and Refraction.
More than' a thousand years later the problem was tackled by Kepler (1571-' 1630), an astronomer justiy famous, who had genius at finding the functional relation governing, the mqst recalcitrant of ordered pairs. Allow me to illustrate his capacity \({ }^{\prime \prime}\)

Year ofter year he worked away, conjecturing and checking, until finally he hit upon hypotheses that fit his observational"data. He showed that each pianet describes an ellipsé having the sun at' one of its foci, and that the "r air areas described by the radil drawn from a planet to the sun are proportional to ' the time taken by the planet to describe them. Fon each planet he knew \(r\), the maximum distance of its elliptical orbit from the sun, and for each he calcula- of tefithe manetary yeaf \(T\), the time it takes to complete a fulit orpit, He - tabulateds \(T\) and \(r\). He asked himpelf What'is the functionat relation between

That he may have some measure of Kepler's achievement, the reader is asked to seek the relation of \(T\) to \(r\) for the following tabulation.
- ".

Not obvious, eh? Alas, to find is to seek successfully. After hours or \(j\) days of unsuccess we likely concede that such problems demand a Kepler. But these are neat and tidy figures, tailormade for the occasion; devoid of messy decimals, our tabulation has none of the more-or-less-ness of the observational data of Kepler's problem. His was difficult.

A hint. Our \(r\) column contains naught but perfect squares. * Is the relaion of \(T\) to \(r\) now obvious? No, the "obvious" "conjecture is wrong; \(T\) is〈 notialso a perfect square. No, neither is \(T\) the sum of two perfect squares. \(T\), it so happens, is a perfect cube. Advantageously we rewrite our tabulation.

曻 Thus, for example,
\[
\frac{66}{22}=0 \frac{117}{39}=\frac{129}{43}=\cdots \cdot=3
\]
\[
66_{0}=3 \cdot 22
\]

1 with exponent is
\[
66^{3}=3^{3} \cdot\left(22^{3}\right)
\]

What a pity the 22 is cubed instead of squared. Thinking wishfully, wecwrite

\[
\left(66^{3}\right)^{2} \stackrel{n}{=}\left(3^{3}\right)^{2} \cdot\left(22^{2}\right)^{2} \cdot(22)^{2}
\]

It is left to the reader to show that
satisfies our tabulation.
\[
T^{2}=729 \cdot r^{3}
\]
: Kepler's tabulation, though difficult, was, governed by the same. proportionalíty. He found that
\[
\mathbb{T}^{2}=k \cdot r^{3}
\]
where \(k\) is a constant. This is his famous third law that the square of the time of revolution of a planet about the sin is proportional to the cube of that planet's.maximum distance from it. Although our tabulation with nice whole numbers devoid of observational error inadequately illustrates his achievement, it does afford some hint why Kepler's discovery' cost hfm nearly a decade of in-
besant toil.

With.équal enthusiasm Kepler turned to the refraction problem of specifying \(\beta\) in terms of \(\alpha\). Knowing his ability, we anticipate his success. His formule works well for smalt' \(\alpha\), but the greater " \(\alpha\) becomes the greater it \(\phi\) inaccuracy. For " \(\alpha\) greater than \(15^{\circ}\) its inaccuracy is unacceptable. It is a make \(\operatorname{shift}\) affair; even Kepler was unsuccessful.
3.5 Fermat: \(\frac{T}{i}\). The Quickest Path Principle.
- Although the reader is understandably impatient to learn the correct formola, the development of science if not to be" hurried. Solution of long stand-" ing problems is attendant upon the Winds of fresh discovery; the new ideas of a
lively intelligence, stimulated by the intellectual ferment of its day. The (gively intelligence was Fermat'sl (Fermat i601-1665); the intellectual ferment of its day, the question, "Does light have a velocity or.is its propagation instantaneous?"

Possibly Calileq '(1564-1642) was the first to tackle this question experimentally. At night on a mountain top he signalled with a lantern to a colleague on an adjacent mountain. His colleague, on seein'g thé light of Galileors lantern, uncovered his own. Galilotried to measure the interval between dispatch of his signal and receipt of his colleague's. As near as. he could tell, light is instäntaneous. \({ }^{\prime}\) To us the experiment is incredibly náive, but Galaileo did not know that the time for say, two 10-mile light journeys, is of the order of one tenthousandth of a second. He experimented to find out.

This live issue captured Fermat's attention. Suppose, he pondered, light \({ }^{4}\) is not instantaneously propagateq, but has a velocity.: Further supposé this velocity to be constant, What then? Time is distance divided by velocity; the shortést path is the quičkest. Thé supposition that light takes the shortest, time has precisely the same consequences as Heron's principle that it takes the shortest path. But alternatively, suppose that the velocity of light whe constant for any given medium, is different for different.media. In particular, suppose that light. in water has'a velocity different from Phit in air. What then? Wifh travel in both air and water the shortest path conceivable is not the quickest. A bent line is fonger than the straight line between the same end point ; simply because a refrated ray is refracted it cannot take the shortest path: does it take the quickest? If so, the consequences of Heronis shortest path principle stillhold, and perhaps refraétion is also explicable.

Further thought gives this conjecture further plausibility. E could be expressed `as a minimum principle. A straight. line bends" neither tp the one side or the other; it has zero curvature. 'So, instead of'saying'that light is propagated rectilinearily, why not say that light takes the path of minimum curvature?" Heron's minimum principle that, light takes the shortest apath is more
embracing and covers reflection as well.as \(E_{1}\) : Why not an even more embracing minimum principle that covers refraction as well as reflection and \(E_{i}\) ?
- 'Fermat's conjecture explains at least as much as Heron's.', Does it explain more? What precisely are the implications for refraction of the minimum: orinciple that flight takes the quickest' path possible? "What is the quickest path? Consider the plight of a golfer who in driving from the fairway at A, hooks , (not slices -the golfer is left-handea) his ball into the box, gt , B. See Fig. 8 .

How best can he retrieve his bally? Not by taking the shortest route APr B; but by taking the route AP "B. Mich minimizes the amount of bog that he, frantically determined as golfers are,"must flounder r through waist deep, Clearly this is the quickest possible route. opine it, for example, with Api. His longer walk AP" across the fairway where the going, ip easy and therefore rapid takes him at a most a minute or two more, but hin shortest bog route baBy Bayes hin an hour or two of floundering. The extra time spent in waving farther ocyoss, the fairway is neglible compared with the time saved from battlintify bog. Similarly AP "B compares favorably against, any other route. It is ina my ely evident. that floundering is so, exasperatingly slow that as increase " floundering distance cannot be compensated for by the corresponding decrease dry farrwain travel. - Therefore the quickest route has the minimum of bog travel, f.eqthat In which \(B P^{\prime \prime}\) is. perpendicular to MP'. We have solved the quickest path proElem in the extreme case where the golfer's fairway: velocity " \(V_{1}\) "is very large 'compared with (since almost zero) \(V_{2}\) 'his bog velocity.

What is the other extreme case？frat inowich bog is replaced by fairway， so that \(V_{2}\) is，increased to \(V_{1}\) ．Then，of course，the quickest path irs the shortest path APi．And what about intermediate cases？Surely the quickest －route from＇\(A\) to \(B\) is．\(A P B\) where \(P\) moves rectilinearly from \(P\) to \(P^{\prime \prime}\) ，／ as \(V_{2}\) decreases from \(V_{1}\) to nearly zero． －／Suppose the bog replaced by bracken and gorse．Off the fairway the going is not so desperately bad as floundering through bog，but more arduous than fair－ way walking；we expect \(P\) to be intermediate between \(P^{r}\) and \(P^{\prime \prime}\) ，Were the going rougher than it is off the fairway，our golfer would go farther out of his way（i．e．，deviate farther from the shortest route \(A P^{\prime} B\) ）to cut down the amount of rough，time－consuming，terrain he need travel across＇；were it less rough he would go less far out of his way．Less time－consuming terrain would necessitate a smaller，more time－consuming terrain a greater，deviation．It is intuitively clear that as \(V_{2}\) decreases from \(V_{1}\) to nearly \(\dot{b}\) zero，the quickest route is＇such that \(P^{\prime}\) moves from \(P^{\prime}\) to \(P^{\prime \prime}\) ．

We suppose \(A F B\) to be，the quickest route from，\(A\) on the fairway to \(B\) ． in the rough．See Fig． 9.

Fig： 9.
Let us＂compare \(A Q^{\prime} B\)＂With the quickest route．In taking＂then Homer，route our golfer has less faitway to stride across；namely AP－AQ＂，so that his time saving on fairway travel is \(\frac{A P^{\prime}-A Q^{\prime}}{V_{1}}\) ．But with less fairway travel he has more＂of＂the＂rough to cross，namely, EQ＇\(-B P\) ，so that his extra time f spent in the

the quickest. That is to say.
\[
\begin{align*}
& \text { to say . }  \tag{1}\\
& =\frac{B Q^{\prime}-\frac{B}{B}}{V_{2}} \cdot-\frac{A P-A Q^{\prime}}{V_{1}}=t^{\prime}
\end{align*}
\]
where \(t^{\prime}\) is the time ,by which route. \(A Q{ }^{\prime} B\) exceeds the quickest. Moreover, the closer-the route \(A Q^{\prime} B\) to the quickest, the quicker it becomes; that is, the closer "Q! apron mates to " \(P\), the more \(t\) ' decreases toward zero. In short,". (1) is such thatzonsitive "t' tends to zero, as \(Q^{1 \cdot}\) tends to \(P\). \(\because\) Next ret us compare \(4 Q^{\prime \prime} B\) with the quickest route \({ }^{4}\) With the former route our golfer, has, \(A Q^{n}-A P\) of extra fairway travel, which loses him \(\frac{A Q^{\prime \prime}-A P}{" V}\), but, , BPP-BQ' less struggling in the rough, which gains him \(\frac{B P-B Q '}{V_{R}} \cdot \frac{1}{\prime}\) But all told he must lose more time than he gains, for otherwise the latter could not be the quickest route. . That is to say
\[
\begin{equation*}
<\quad \therefore \quad \frac{A Q^{\prime \prime}-A P}{V_{1}}-\frac{B P-B Q^{\prime \prime}}{V_{2}}=t^{\prime \prime} \tag{2}
\end{equation*}
\]
where \(t^{\prime \prime}\) is' the time by which route \(A Q^{\prime \prime} B l\) exceeds the quickest. And as with the previous comparison, (a) is such that positive \(t^{\prime \prime}\) tends to zero as \(Q^{\prime \prime}\) tends to. \(R\)

Let us compare the left side comparison \(A Q^{\prime} \dot{B}\) of the quickest route with the riष्टht side comparison" AQ "B. The condition (2) is equivalent to
\[
\begin{align*}
& -\frac{A P-A Q^{\prime \prime}}{V_{1}}-\frac{B Q^{\prime \prime}-B P}{V_{2}}=t^{\prime \prime}, \\
& \text { and consequently, equivalent to } \\
& \frac{B Q^{\prime \prime}, B P}{V_{2}}-\frac{A P-A Q^{\prime \prime}}{V_{1} \cdot q \cdot t^{\prime \prime}} . \tag{3}
\end{align*}
\]

Compare (1) with (3). We observe that the former, when \(Q_{i}^{\prime}=Q\) and \(t^{\prime} t^{\circ}\), - and the latter; when. \(Q^{\prime \prime}=Q\) and \(t^{\prime \prime}=t\), is the condition
\[
\begin{equation*}
\frac{B Q-B P}{V_{2}}-\frac{A P-A Q}{V_{1}}=t \tag{4}
\end{equation*}
\]
where positive 't tends to zero as \(Q\), tends to \(P\). 'That ism to say, the vela: ton between \(A Q B\) and the quickest route is governed by (4) no matter whether

\section*{2}
any other path \(A Q B\), condition (4) is satisfied.
Few mathaticians, even among those of the first rank, could claim invent-" tron of the calculus. Fermat is one of he few. To solve the problem of the if quickest path he invented the method of the calculus of variations. To the basic idea of this method, the reader has, in following the plight of our golfer, been afforded an intuitive introduction. With the fairway replaced by air,"the". rough by water, and our golfer by a ray of light, \(\dot{( })_{(4)}\) is immediately \(\overbrace{0}^{\circ}\) applicable.
to the problem of a refracted ray taking the quickest path possible.
See Fig. 10.

\(1^{\circ}\) Fig. 10.
The circle with center \(A\) ard radius \(A Q\), cuts \(A P\) in \(R\), and its tangent at \(Q\) (perpendicular to. \(A Q\), of course) outs \(A P\).in \(R^{\prime} . \quad \angle P Q R^{\prime}=\gamma_{\cdot}^{\prime}\).

What happens as \({ }^{\dagger} Q\) moves closer and closer to \(P\), ie., as \(Q \rightarrow P\) ? Since楼
\[
\angle Q R^{\prime} P=90^{\circ}+\angle Q A P .
\]

But, as \(Q \rightarrow P\), clearly \(\angle Q A P \rightarrow 0\), so that \(\angle Q R P_{1} \rightarrow 90\) and consequently,

 consequently; \(A P-A Q \rightarrow Q P-\sin ^{\circ} \gamma\). Therefore,

Next, study Fig. Il.

The circtle with center \(B\) and radius \(B Q\) cuts \(B P\) (produced) in \(S\), and its tangent at \(Q\) (perpendicular to " \(B Q\), of course) cuts \(B P\) (produced) in \(S^{\prime}\). \(\angle P S^{\prime}=\delta\),

It is left as an exercise for the reader to show in a precisely similar way that
\[
\frac{B Q-B P}{V_{2}} \rightarrow Q P \cdot \frac{\sin \delta}{V_{2}} \text { as } \begin{gather*}
Q \rightarrow P  \tag{6}\\
\cdot
\end{gather*}
\]

By (4)
\[
\frac{B Q-B P}{V_{2}}-\frac{A P_{4}-A Q}{V_{1}} \rightarrow 0 \text { as } Q \rightarrow P
\]
so that by (5) and (6)
\[
Q P \cdot \frac{\sin \delta}{V_{2}}-Q P \cdot \frac{\sin \delta}{V_{1}} \rightarrow 0^{\circ} \text { es } Q \rightarrow P:
\]

That is to say, that, wen the routes \(A Q B, A P B\) are arbitrarily close, the difference.
\[
Q P\left\{\frac{\sin \delta}{v_{2}}-\frac{\sin \gamma}{v_{1}}\right\}
\]
is arbitrarily small; the closer \(A Q B\) is to the quickéstroute, the more nearly true that

In other word
\[
\begin{equation*}
\frac{\sin . \delta}{\sin \gamma}=\frac{v_{2}}{v_{1}} \tag{7}
\end{equation*}
\]

Since in the limiting position the routes \(A Q B, \overline{A P B}\) are arbitrarily ciose, \(\angle\) QR'P, differs from a right angle by an arbitrarily small amount sa that
the situation of Figs. 12 obtains.

Thus \(\alpha\), the angle of incidence of the light way Ap with the normal \(P N\), and \(\gamma\) are both complements of \(\angle Q P R^{\prime}\). Therefor
\[
\begin{equation*}
\alpha=\gamma . \tag{8}
\end{equation*}
\]

Similarly, in the limiting position. the situation of Fig. 13 obtains.

Consequently, \(\delta\) and ' \(\angle S^{\prime} P N\) are both complements of \(\cdot \angle\) QPS', and the latter is vertically opposite to \(\angle \mathrm{BPN}^{5}\), the angle of refraction \(\beta\). Therefore,
\[
\begin{equation*}
\beta^{0}=\delta \tag{9}
\end{equation*}
\]

Substituting \({ }^{(8)}\) ( 9 ), in (7), we have
\[
\begin{equation*}
\frac{\sin \beta}{\sin \alpha}=\frac{V_{2}}{V_{1}} \ldots \tag{9}
\end{equation*}
\]
\[
\begin{equation*}
\therefore \tag{10}
\end{equation*}
\]

This is Fermat's law of refraction, which may be alternatively expressed
\[
\begin{equation*}
\quad \because \because \sin ^{\circ} \beta=K_{1} \cdot \sin \alpha, \text { where } K_{1}=\frac{V_{2}}{V_{1}} \tag{11}
\end{equation*}
\]
i.e., that \(\sin \beta\) "is atrectly proportional' to \(\sin \alpha\), where the constant of. proportionality is \(\frac{\mathrm{V}_{2}}{\mathrm{~V}_{1}}\).

Fermat is law was later rediscoyered independently by both Snell, and Descartes, and was used by the latter to explain the phenomenon of the rainbow. It won rapidi acceptance with contèmporary scientists. rFrom (10) we have
\[
\beta=\arg _{1} \sin \left(\frac{\mathrm{~V}_{2}}{\mathrm{~V}_{I}} \sin \alpha\right)
\]

That Kepler failéd to conjecture suç a complicated functional relationship between \(\beta\) and \(\alpha\) occasions no surprise. What is surprising is that he was so successful as to find a formula of tolerable accuracy for \(\alpha<15^{\circ}\),
\(3.6 \frac{\text { Newton's }}{1} \frac{\text { Mechanistic }}{\text { Theory }}\) of Light.
With Vewton (1642-172\%) science came of age; Understanding the starry heayens was within man's' grasp. It was'almost as if Newtomith his three laws and few axioms could, as Jesus with his two /hoavels adaine fisines, work miracles. Heexplained the ebby and flow of the waters of the deep and the passage of the fiery bodies in, the firmament above. ,Nature lost her mystery; man his impotence: The solar system is a gigntic piece of clockwork, and Newton had discowered how it ticks. Newton's mechanics is the key to everything, around the surf; must it not be the key to everything under the sun? To the enthusiasm born of his success, his laws and axioms were as clear as day. The minimal path'principles' of Heron and 'Fermat were still darkly mysterious. Surely the optics of Euclid, Heron, and Fermat could be explained mechanistically. . . Newton thought .so.

Newton begins at the beginning. "The first thing to explain is the rectiIinear propagation of light. His first law states that a body moving with unifortn vélocity in a straight line will contine to do so unless acted upon by extermal forges to change that motion. Are not Euclid's ànd. Newton's first lawis remarkably similar? With characteristic ingenuity Newtón makes the former as an immedigte consequence of the latter by introduction of the supposition thait a ray of light consists' of minuté bodies; particles, or corpuscules. Because of this supposition Newton's theory of light is known as the corpuscular

How does Newton account for Euclid's law of reflection? According his his corpuscular theory, an incident ray of init is "fortected because of the colision of its constituent particles with, those oforstituting the surface of the
 particle, for all the others will behave in the same way under similar circumstances.

First let us consider a specigh case, that of an, incident ray normal to the mirror'. See Fig. 14. P? Its attempt to penetrate the surface \(\mathrm{MM}^{\prime}\) perpendicularly downwards is resisted solely by forces acting perpendicularly upwards (due to the constituent partic \({ }^{\text {a }}\) of the mirror surface int the neighborhood of \(P\) ). Consequently the particle returns along the normal.

We now turn to the general case. It is assumed that \(V_{1}\), the velocity of a. light ray, in ai ir, is constant irrespective of its direction relative to the , , mirror. Thus the problem "is the following. A particle travelling with velocity ' \(V_{1}\) along \(A P\) at an angle \(\alpha\) to the normal is reflected with velocity \(V_{1}\) along \(B P\) which makes some angle \(\beta\) with the normal. What/ is the relation: between \(\beta\) and \(\alpha\) ? \({ }^{\text {See Fig. }} 15\).

obliquely, Newton insists that the structure of this surface is such that the s. restitahce to penetration is solely 'by forces actin's perpendicularly upwards Just an the special case considered above. What are the consequences of his insistence? Forces acting in the direction, PN have no components in the direction MM', so that the forces (if any) acting in this direction on the particle at \(P\) "before impact are unchanged by impact. Therefore the velocity of the particle parallel to \(M M\) when part of the reflected ray, is just the same as when part of the incident ray. Motion parallel to the surface remains *
unchanged. Equating, component velocities parallel to MM', we have
\[
v_{1} \sin \beta=v_{1} \sin \alpha
\]

ABut, by hypothesis, the resultant velocity of the particle when reflected is. \(\dot{V}_{1}\) at an angle \(\beta\) to PN. Hence it. is clear from Fig. 16 that, \(\beta=\alpha\).

Next, refraction. What is the difference between reflection and refraction? Whereas in the latter the incident ray is successful in penetrating the surface, in the former it is not. Newton treats, these phenomena similarly, No matter whether or not penetration is successful", Newton continues to insist that the only forces opposing penetration, even if oblique, act perpendicularly, to the surface. Consequently, for refraction as for reflection, motion parallel to the surface remains invariants And whereas the refracted ray differs from the reflected ray by being propagated in water instead of air, so that its component velocity parallel to \(M^{\prime \prime}\) is \(V_{2}{ }^{\prime} \cdot \sin \beta^{\circ} \cdot\) instead of \(V_{F} \cdot \sin \beta\), the incident". ray is the same in both cases. See Fig. 17.

Fig. 17.
Therefore, equating component:velocities parallel to \(\mathrm{MM}^{+}\),
\[
\mathrm{V}_{2} \cdot \sin \beta=\dot{\mathrm{V}}_{1} \cdot \sin \alpha
\]

1 giving

\subsection*{3.7 Fermat \({ }^{\text {N Versus Newton: }}\) - Experimentum Cruces.}

Thus Newton, like Fermat, concludes that sin \(\beta\) is directly proportional to \(\sin ^{\circ} \alpha_{0}\) However, comparison of (11) with (12) also shows that, although their formulae have the same form, Newton's constant of proportionality is the reciprocal of fermat's. And' it is an experimental fact that the refracted ray is bent towards the normal, \(1 . e, \beta \leq \alpha\), so that \({ }^{\circ} \sin ^{\circ} \beta \leq \sin \alpha\). Consequently a formula of the form

\section*{\(\sin \beta K \cdot \sin \alpha\)}
cannot be. coprrest unless the constant of proportionality \(K\). is less than
 Fermat's formulae cannot i be correct unless the velocity of light in water is单ess than the velocity in air, Newton's.cannot be correct unless the precise opposite is the case.

Newton had no difficulty, in finding an argument to vindicate his own

\footnotetext{

}
medium; so that the forces acting upon it are constant; there being no acceleration the net force mast be zerot "Similarly in water. Bu't when a particle is'. passing from one medium to another there is a change from one homogeheity to another', so that the forces acting upon it momentarily are not constant. Water 'has greater density thap ajir, its particies are more tigñty packed. When a particle reackés the neighborhood of the interface, ahead. of it is an accumul'ation of me'tter, befind it, a sparsity. 'Consequently., since the more the mass the greater thefaticraction, the particle has momentarily a terrific accelera tion and speeds up from: \(V_{1}\) to \(V_{Z}\). Having passed through the interface, once again there is no net force and the particle continues with' constant zelocity \(V_{2}\).
1.0 century. And then technological advances made it possiole to show experimentally that light is slower in water than in air. This was the experimentúm crucis.
* The basis of Newton's'axgument, that kight consists of particles, is untenaile. "We must add that Fermat enunciated his quickest' patî principle a quarter of a century before it was know experimentaly. that the propagation of light is not instantaneous.

\subsection*{3.8 Ro Recapitulate:}
háve traced the development of elementary optics over the centuries up to the formulation of Fermat's and Newton's theories. Both explain rectilnear "propagation of light; both account for the law of reflection; both give the same kind. of formula for refraction: yet they are rivals. Rivals, for with regard to refraction they differ in detail. Here is a situation typicar of.
[.- scienge's history; a conflict of theory'only to be resolved by determination
* of fact. 'That is the role of:crucial experiment.

But when a consequence of a theory is in question, the basis of the theory also in question. In rejecting Newton's consequences for refraction as
\% contrary to façt, we must reject the basis of these consequences- the
"corpuspular nature of light. That Fermat's theory-could explain all the facts vindicated his quickest path principlè̀. \(\therefore\) Later this developed into the wave theory of light-at that the constitution of light is not c̣orpuseies, but waves. Alghouth space does not permit consideration of further developments, I hope to have shown you something well worth showing of the role of mathematics in the evolution of science. Mathematics marpens" our seeing of logical consequences and focuses our attention on appropriàte experimentation; an aid to - vision, it is the eyeglass of the mind.
3.9 The Role of Science in Mathematics.

I "íh to end with a curious twist. "From'the role of mathematics in science, we turn to the role of science in mathématics; for despite an abundance of material, how science gives grounds for mathematical theorems dis little known. Convenient to our purpose is the problem of how to construct \(p^{-}\) tangent to the ellipse.
"if two pegs \(F_{1} ; F_{2}\) are hammered \({ }^{\circ}\) into the ground and a. cord tied to both of them is kept taut by a stick \(P\), the movement of \(P\) under this restraint marks out an ellipticaaj. flower bed. See Fig. 18.

This method of construction exhibits the usual, generative, definition of the ellipse. The Zocus. of a point \(\dot{P}\).such that the sum of its distances from two
fixed points \(F_{1}, F_{2}\) (called. the faci) is constant, is said to be an ellipsolid; when ' \(P\) is restricted to one plane through \(F_{1} ; F_{2}\), its locus is said to be an ellipse. Traditionally the constant sum is taken to be Ra, giving the equation, of the ellipse as
\[
F_{1} P=P F_{2}=2 a .
\]

The "circle is a special case of the ellipse, the ellipse a generalization of the circle. When \(F_{1}, F_{2}\) become coincident
\[
\mathrm{F}_{1} \mathrm{P}+\mathrm{PF} \mathrm{~F}_{2}=2 \cdot \mathrm{~F}_{1} \mathrm{P}=2 \mathrm{a}
\]
so that \(F_{1}\) (and \(F_{2}\) ) become the center of a circle of radius \(a\). This quggestsuat that properties of the circle will be limiting cases of properties of the ellipse. What light does this suggestion throw on the problem of constructing \(\overline{\mathrm{a}}\) tangent at • P to the ellipse? See Fig. 19.

The tangent at \(P\) to the circle with center \(F_{1}\) is perpendicular to the radius \(F_{1} P\). How do, we go from this limiting case to the general? Equally well we could say that the tangent is perpendicular to \({ }^{\circ} \mathrm{F}_{2} \mathrm{P}\), or that it is perpendicular to both \(F_{2} P\) and \(F_{2} P\). But obviously the tangent can be perpendicular only to one of these lines', when they are no longer coincident. Which one? Surely they have equal claims. What is an acceptable compromise? That \(F_{1} P, F_{2} P_{i}\) are equally inclined to the tangent, ie., that \(\gamma=\delta\). Sere Fig. 20.

This comjecture has merit, forit. is consistent with the limiting , case; when * \(\mathrm{F}_{1}, \mathrm{~F}_{2}\) become coinaident \(\gamma=\delta=90^{\circ}\). But to syppose that \(\gamma=\delta\) is equivze. lent to supposing. their complements to be equaly, i.e., that \(\alpha=\beta\). See Fig. 21: ."

\(\because \cdot \quad\).

mirror from which an incident ray \(F_{1} Q\) is reflected through ' \(F_{2}\), then \(F_{1} Q F_{2}\) (mist be the shortest path possible (via the mirror) from \(F_{1}\) to \(F_{2}\). It remains to show that the shortest path is such that \(Q\). is coincident with \(P\), the point at which TTM is tangential to the ellipse.

Consider Fig. 22:

It is evident that any point \(Q\left(\mathrm{gn} \mathrm{T}^{\prime \prime} \mathrm{T}^{\prime \prime}\right)^{\prime}\) not, coincident with \(P\) must lie \(\therefore\) outside the ellipse; therefore suppose \(F_{1} Q\) to cut the ellipse at R. Since \(R F_{2}\) is the shortest path from \(R\) to \(F_{2}\),
\[
R Q+Q F_{2}>R F_{2}
\]

Consequently, adding \(F_{1} R\) to both sides of the inequality,
, ie.,
\[
-\left(F_{1} R+R Q\right)+Q F_{2}>F_{1} R+R F_{2}^{*}
\]

But \(R\).is on the ellipse, so that by definition
\[
F_{1}{ }^{\prime}-{ }^{\prime} F_{2^{\prime}}=2 a .
\]

Therefore,
whereas, \(P\) being on the ellipse,
\[
F_{1} P+F_{2}=2 a
\]

Since light takes the shortest, path, it follows that \(Q\) must be coincident with P. That is, a ray of light from one focus, incident to a mirror.
(tangential to the ellipse) at its.point of contact, is reflectedythrough the Qther. This completes the proof of our conjectured construction of a tangent to the ellipse.

Fermat was the man who first raised and substantially aṇswered the wider question of how to find tangents to plane curves in general. To solve this, problem for any curve whose funftion is an algebraic polynomial he invented the differential calculus. Yet-it'ig refreshing with the present density of calculus textbooks to find that a construction for the ellipse can be established without resort to differentiation. The solution by optics, given above, 4 was the earliest.

Thàt in Fig. \({ }^{2} 21 \quad \alpha=\beta\). has several practical applications. The key to \({ }^{\circ}\) fhese applications is that for a silvered ellipse the immediate. (elliptical) neighborhood of \(P\) will reflect light as if it were the sû́rface at \(P\) of the mirror fangentifal to the ellipse at that point. Consequently, no matter what its direction, a ray passing through one focus will be reflected at the ellipse through the other. The heat of a fire at \(F_{1}\) although radiated in all directions will be reconcentrated at \(F_{2}\). If no radiation is dissipated en route and none lost in cortact with the ellipses silvered surface, \(F_{2}\) is as hot as \(F_{1}\). A reflecting ellipse with a fire at, one focal point has á fire at both; Focus is the Latin for fireplace or hearth. Similarly for an auditorium with an ellipsoidal cupola, \(F_{1}, F_{2}\) are known as the whispering points, Since-sound is reffíected in the same way"asalight, a dispersed and therefore weakened \(\frac{d}{\text { whisper from }} F_{1}\) will be inauikie in all other parts of the room except at \(\mathrm{F}_{2}\) where the whisper is reconcentrated'. See Fig. 23.

It is often instructive to go to the limit. We found it profitable to consider the limiting or degenerate case of the ellipse where \(F_{1}\) and \(F_{2} .{ }^{\circ}\) become coincident; we now. go to the other extreme and suppose, them to be as far apart: as possible. With \(F_{1}\) fixed, the farther \(F_{2}\) is moved from it, " the more elongated the ellipse and the more nearly parallel \(\mathrm{PF}_{2}\) to the axis, VF 1 . See Fig. \(2 \dot{4}\).

Fig: 24. ".
Finally, with ' \(F_{2}\) at infinity, the ellipse has degenerated into what is. known as the parabola and \(\mathrm{PF}_{2}\), has become parallel to the axis. See Fig. 25 .

Fig. 25.
Thus, given a point source of light at \(\hat{F}_{1}\), the reflection from a silvered parabola MVM' is a beam parallel to, the axis ow the parabola VF \({ }_{1}\) : Rotation of the parabolic mirror about, its axis generates what is know as a paraboloid of revolution. This, of course, reflects a solid beam of light from, a point source at \(F_{1}\) parallel to its axis, and is exemplified by the motorcar headlamp. And conversely, since the rays radiated from a distance sources are almost
parallel, they are accumulable within the immediate neighboriood of \(F_{1}\). A. paraboloidal reflection could with equal Justice be termed a paraboloidal accumulator. Radio rayss individuålly weak, can be collectively magnified into a strong signal. As wéll as essential to radar listening devices, the partboloidal reflector is the basis of the radio telescope.

Ghapter 4. Applications off Matrix Algebra.

Although my purpose in this lecture is to show what matrices are good for, not to teach matrix theory as such, I shall assume merely that you recognize a, matrix when you see one and can readily perform matrix, row times column multiplication for very simple matrices.

My aim is two-fold, my lecture has two parts. In Fart 1, Mathematics with Matrices, my principal objective is \({ }^{\circ}\) to convince you that matrices are much more than a kind of mathematigal noughts-and-crosses designed to delight examiners and depress examinces, that matrix technique reaily does facilitate doing mathematics. In Part 2, From Matrix Theorem to Relativity Physics, I aim to show how this facilíty, used with bold imagination, devastates "omiortable, commonplace conceptions of our physical world.

Part 1. Mathematics with Matrices

\subsection*{4.1 Why Use Matrices?}

H Have you ever tried using a lump of rock, to drive a six-inch nail into a four-inch beam? It is easier with a hammer. Easier because the hammer is designed expressly for the j8b," designed to have good balance, to handle weíi,' to effect a neater job with less effort. ' Its design, deceptively simple, is dependent upon giving much thaught to question's of rigidity, distribution of weight, "and center of percussion." Hard thinking goes into its design; hard work is -simplified, by'its use.

Matrices; tod, are deceptively simpie. Some clever fellows gave much thought to devising a notation that handles well and a technique that does a tidier \(x\), more effortless job. Yes, matrices take the slog out of nailing equations. And, as with driving nails, there is no need'to take anyone's word for it; experience is" con'clusive. Presently, you will have the experience. Not to start our mathematical carpentry with rusty nails, we first review:

\subsection*{4.2 Rotation of. Rectangular Axes.}

Given a plane, we introduce a rectangular coordinate system origin 0. If from any arbitrary point \(P(x / y)\) we drop a perpendicular e to the \(x\)-axis, then the length of this perpendicular is \(y\) (the ordinate of \({ }^{\circ}\) ) and the distance from its foot to. 0 is \(x\) (the abscissa of \(P\) ). A difgram makes - it clear that to any given point \(P\) there corresponds just one pair of: coordinates \((x, y)\) and, conversely, that to any, given ( \(x ; y\) ) there gorresponds/júst one point P. See Fig. l.

Next we introduce new rectangular coordinate system \(\bar{x}, \bar{y}\) with the same origin 0 . Although the position of \(P\) remains unchanged, relative to the new coordinate system, it has new, coordinates. \((\bar{x}, \bar{y})\), See Fig. . \(2, \ldots, \ldots, \ldots\), \(\ldots\)

This situation very, naturally raises the question, what is the relation between the old and new coordinates of P? If, we are given P's old coordithates * \((x, y)\) then \(P\) is fixed and so, its new coordinates \((\dot{\bar{x}}, \bar{y})\) must, in principle at least, be determinate. Conversely, given* pis new "coordinates (y, y , what are its old coordinates. \((x, y)\) ? What is the transformation from the poe coopdimple system to the other?
- Easy reasoning shows that the rule for going from/ the coordinates in the one system to those in the other, say from \((x, y)\) to. \((\bar{x}, \bar{y}), "\) must be a linear transformation, 'That is to say, the rule must be a system of linear equations in " \(\bar{x}, \bar{y}^{\prime \prime}\) and \({ }^{\circ} \mathrm{x}, \mathrm{y}^{\circ}\) of the form
: where \(A, B, C\), and \(D\) 'are numbers independent of \(\bar{x}, \bar{y}\) and \(x, y\).
Why is this? Because this is the only sort of system which can be in-
 also determine a unique value for \(\bar{x}\) and for \(y\) when \(\bar{x}\) and " \(\bar{y}\) are given. If \(A, B, C\), and \(D\) were not independent of \(x\) and \(y\), then the formulae would contact quadratic or more complicated' terms in \(x\) or \(y\), so that given values of and \(\bar{y}\) would not necessarily determine \(x\) and \(y\) uniquely.

If the reader will use the explicit formulae for \(\bar{x}\) and \(\bar{y}\) to derive
explicit formulae for \(x\) and \(y\), he will get formulae of the pattern
\[
\begin{aligned}
& x=\bar{A} \bar{x}+\bar{B} y \\
& y=\bar{C} \bar{x}+\bar{D} y
\end{aligned}
\]
where \(\bar{A}, \bar{B}, \bar{C}\), and \(\bar{D}\) axe expressed in terms of \(A, B, C\), and \({ }^{5} D\).
Y You know well how to solve as system of two simultaneous linear equations in the two unknowns \(x\) and \(y\). You will obtain the above two equations if ty bu express.' \(x\) and \(y\) in terms of \(\bar{x}\) and \(\bar{y}\). It is easy to express the new constarts \(\bar{A}, \bar{B}, \dot{C}\), and \(\bar{D}\) by means of \(A, B, C\), and \(D\). It might be a good exercise for you fo can ry out, the calculation. We do not do it here because we are independent of the coordinates of \(P\), they may be found by specializing. A well-chosen point A Al it educe the labor of calculation-

Let us take the point on the x-axis at unit distance from the origin. See Fig. 3.

\section*{7}

What are \(P_{0}\) 's coordinates in the no f system? 'its abscissa; \(\bar{x}\) is, of course, the distance from 0 to \(Q\), where \(Q\) is the foot. of the perpendiculace dropped from \(P_{0}\) to the \(\bar{x}\)-axis. So, faking our first equation A.
\[
\text { with } x=1, y \doteq 0 \text {, }
\]

Figs.
\(Q\) is théfoot.of the
our first equation
\[
\bar{x}=\tau A x+B y
\]

To. go farther we need to know the eng made by the new axis with the old.
Let this, be aroma the obvious geometry of Fig. 3, since \(O P_{0}=1\);
\[
\alpha Q=\cos \alpha
\]
\[
A=c \rho s . \alpha
\]

Next, what is the ordinate \(\bar{y}\) of \(P_{0} ?\) Since. \(P_{0}\) lies below the \(\vec{x}\)-axis; it is the negative of the perpendicular \(P_{0} Q\), that is,

114

So, taking our second equation
\[
\bar{y}=C x+D y
\]
- with \({ }^{\text {: }} \mathrm{x}=1, \mathrm{y}=0\),
\[
-\sin \alpha \doteq C \cdot 1+D \cdot Q=C
\]

Of the four numbers. \(A, B, C\), and \(D\) in the transformation, we have already found two, \(A\) and \(C\). It remains to find, \(B\) and \(\Rightarrow D\). And isn't it obvinous what to do?' The y-axis is just as good as the x-axis; it should be given equal consideration. So, having taken a point one unit along the x-axis, we now take a point one unit along the \(y\)-axis. Let \(P_{1}\), be the point with coordinates \((0,1)\) in the old system. See Fig. 4.

*
What are \(P_{1}\) 's coordinates in the new system? Its abscissa \(\bar{x} \cdot\) is, of course, the distance from 0 to \(R\), where \(R\) is the foot of the perpendicular dropped from \(P_{1}\) to the \(\bar{x}\)-axis. So, substituting \(\bar{x}=O R\) and \(x=0, y=1\), Fin the first equation en the transformation
\(\therefore \underset{\sim}{x}\)
\[
O R=A \cdot O+B \cdot I=B
\]
\(\because\) And since \(\angle O \mathrm{P}_{1} \mathrm{R}\) and the angle \(\alpha\) between OX and \(\overline{\mathrm{X}}\) are both complements of \(\angle P_{1} O \bar{X}, \angle O P_{1} R=\alpha\). Consequential; with \(O P_{1}=1\).
so that
\[
O R=\sin \alpha
\]
\(\therefore\)
\[
\mathrm{B}=\cdot \sin \alpha:^{:_{0}^{\prime}}
\]

Similarly, since \(\dot{\bar{y}}=\cos \alpha\), we obtain \({ }^{\prime}\) from the second equation of the

\section*{transformation that}
\[
\dot{\mathrm{D}}=\cos ^{\dot{\prime}} \alpha \text { : }
\]
!.
We have found \(A, \dot{B}, C\), and \(\dot{D} .\), 'We conclude that the required transfor-
\[
\left.\begin{array}{l}
\therefore \bar{x}_{a}=\left(\cos ^{3} \alpha\right) x+(\sin \alpha) y  \tag{1}\\
\therefore-\bar{y}_{y}=(-\sin \alpha) x+(\cos \alpha) y .
\end{array}\right\}
\]
, Our refresher course is completed; we have scraped the rust off our nails. |'

Transformation wisen smith without Matrices
We now use matrix algebraic write (1) in a slightly simplified form. We
get
 right side gives a column matrix whose terms are

and.
for multiplication of the-sfodratiatrix on the right side by the first on the

\[
\left(-\sin ^{2} \alpha\right) x+\left(\cos ^{2} \alpha\right) y
\]
which equal \(\overline{\mathrm{x}}\) anat- \(\bar{y}\), réspectivefy.'
The first element of this column matrix \({ }^{\text {Gin }} \mathrm{s}\) obtained, as the reader doubt-. lessiy recalls, by multiplying \(x y\) (the first element of the column of the secon matrix) by cos \(\alpha\) (the first element of the first row of the first matrix), by multiplying \(y\) (the second element, of the column of the second matrix) by sin \(\phi\), (the second element \({ }^{\text {a }}\) ' of the first row of the first matrix), and by adding these products together. Yes, it's easier to do than to state. The second element is similarly obtained by using the elements of. the second row of the first matrix instead of its first row elements. "In brie \(\dot{f}\), multiply column \(\overline{\text { by }}\) rows.
 a bracket. less laborious to write than an equality sign? Really, this is splitting hairs.". "What matters is not so much how a tool looks, but how it handles.
_How weal does it handle? Let us do some mathematical carpentry to find but; let uss deduce -- I beg your pardon, let us nail home \(-=\) the basic trigonometric angle sum formulae for \(\cos (\alpha+\beta)\) and \(\sin \left(\alpha^{\prime}+\beta\right)\). For comparison let us do 'the job twice; once driving our nails with a hammer, ie., using matrix transformations such as ( \(1^{*}\) ), and once hitting our nails with a stone, ie., using non-matrix transformations such as (1).

Suppose that the \(\mathrm{x}, \mathrm{x}\) rectangular coordinate system is first rotated through an angle \(\alpha\) 'to give a second \(\bar{x}, \bar{y}\) systêm and then through an adartonal "angle \(\beta\) to give a third \(\overline{\bar{x}}, \overline{\bar{y}}\) system. See Fig. 5 .

Fig. 5

Regarding the second system as the old and the third system as the new, since the latter makes an angle \(\beta\) with the former, by virtue of (1), i.e., substituting \(\beta\) for \(\alpha\), \(\bar{x}\) for \(x, \quad \bar{y}\) for \(y\), and \({ }^{\prime} \overline{\bar{x}}\) for \(\bar{x}\), \(\dot{\overline{\mathrm{y}}}\) for \(y\), we have
\(\#\)
\[
\left.\begin{array}{l}
\overline{\bar{x}}=(\cos \beta) \bar{x}+(\sin (\beta) \bar{y} \\
\overline{\bar{y}}=(-\sin \beta) \bar{x}+(\cos \beta) \bar{y}
\end{array}\right\}
\]
(2)
and, by virtue of ( \(1^{*}\) )
\[
\binom{\overline{\bar{x}}}{\overline{\bar{y}}}=\left(\begin{array}{cc}
\cos \beta & \sin \beta \\
-\sin \beta & \cos \beta
\end{array}\right)\binom{\bar{x}}{\bar{y}}
\]

Next, taking the first system to be the old and the third system to be the new, since the latter makes an angle \(\alpha+\beta\) with the former, by virtue of (1),

\[
\left.\begin{array}{l}
\dot{\bar{x}}=(\cos \overline{\alpha+\beta}) x+(\ddot{\sin \overline{\alpha+\beta}}) y  \tag{3}\\
\overline{\bar{y}}=(-\sin \overline{\alpha+\beta}) x+(\cos \bar{\alpha}+\bar{\alpha}) y .
\end{array}\right\}
\]

Similarly', by virtue of ( \(1^{*}\) )
\[
\binom{\overline{\bar{x}}}{\overline{\bar{y}}}=\left(\begin{array}{l}
\cos \overline{\alpha+\beta}  \tag{*}\\
-\sin \overline{\alpha+\beta} \overline{\sin } \overline{\alpha+\beta} \\
\cos \overline{\alpha+\beta}
\end{array}\right)\left(\begin{array}{l}
x \\
0 \\
y
\end{array}\right)
\]

Note that this far the differences are merely notational, but this is the \(\dot{\gamma}\) 'ing of the ways. From here, on the non-matrix method is more laborious: from (2*), we have
\[
\binom{\bar{x}}{\bar{y}}^{\prime}=\left(\begin{array}{cc}
\dot{\cos \beta} & \sin \beta  \tag{*}\\
-\sin \beta & \cos \beta
\end{array}\right)\left\{\left(\begin{array}{cc}
\cos ^{\alpha} \alpha & \sin \alpha \\
-\sin \alpha & \sin \alpha
\end{array}\right)\binom{x}{y}\right\}
\]

Hence, from (3*) and (4*), we have, in view of the associative law of matrix 1 mul市iplication,
, \(\left(\begin{array}{ll}\cos \overline{\alpha+\beta} & \sin \overline{\alpha+\beta} \\ -\sin \overline{\alpha+\beta} & \cos \overline{\alpha+\beta}\end{array}\right)\binom{x}{y}=\left(\begin{array}{ll}\cos \beta & \sin ^{\prime} \beta \\ -\sin \beta & \cos \beta\end{array}\right)\binom{\cos \alpha \cdots \sin \alpha}{-\sin \alpha \cos \alpha}\left(\begin{array}{l}x \\ \vdots \\ y^{\prime}\end{array}\right) \cdot\left(\begin{array}{c}\left.5^{*}\right)\end{array}\right.\) so that
\[
\left.\left(\begin{array}{cc}
\cos \overline{\alpha+\beta} & \sin \overline{\alpha+\bar{\beta}}  \tag{5**}\\
-\sin \overline{\alpha+\beta}-\cos \overline{\alpha+\beta}
\end{array}\right) \stackrel{(\cos \beta}{\sin \beta} \begin{array}{c}
\sin \beta \\
-\cos \beta
\end{array}\right)\left(\begin{array}{cc}
\cos \alpha & \sin \alpha \\
-\sin \alpha & \sin \alpha
\end{array}\right)
\]

To determine \(\cos \overline{\alpha+\beta}\) it remains merely to multiply the first row of the first matrix (on the right, side) into the first cham of the second. We get
\[
\overline{\cos \alpha+\beta}=\cos \beta \cos \alpha+\sin \beta(-\sin \alpha \alpha)-\alpha
\]
which, to show due respect to the alphabet, we write
\[
\cos \overline{\alpha+\beta}=\cos \alpha \cos \beta-\sin \alpha \sin \beta \ldots
\]

Similarly, multiplying the 'first. row into the second column, we get
ie.,
\[
\sin \overline{\alpha+\beta}=\sin \alpha \cos \beta+\cos ^{\circ} \alpha \sin \beta .
\]

Next, we continue with the non-matrix method. Using, (1) to eliminate \(\bar{x}\). f- and \(\bar{y}\) from (2) is a much more strenuous affair than using ( \(\mathbf{I N}^{*}\) to eliminate \(\binom{\bar{x}}{\bar{y}}\) from (2*). How much more strenuous you can find out only by doing the algerbra for yourself; your mental muscles will not tire by watching me work. I'll wait.

Your labors' correctly completed, we both have
\[
\left.\begin{array}{l}
\overline{\bar{x}}=(\cos \alpha \cos \beta-\sin \alpha \sin \beta) x+(\sin ) \cos \beta+\cos \alpha \sin \beta) y  \tag{4}\\
\overline{\bar{y}}=-(\sin \alpha \cos \dot{\beta}+\cos \alpha \sin \beta) x+(\cos \alpha \cos \beta-\sin \alpha \sin \beta) y
\end{array}\right\} .
\]

Hence, from ( \(\mathrm{y}^{2}\) ) and (4), we. have
\[
\begin{align*}
& \left(\cos _{\mu} \overline{\alpha+\beta}\right) x+(\sin \overline{\alpha+\beta}) y \\
& =(\cos \alpha \cos \beta-\sin \alpha \sin \beta) x+(\sin \alpha \cos \beta+\cos \alpha \sin \beta) y  \tag{5}\\
& (-\sin \overline{\alpha+\beta}) x+(\cos \overline{\alpha+\beta}) y \\
& 0-(\sin \alpha \cos \beta+\cos \alpha \sin \beta) x+(\cos \alpha \cos \beta-\sin \alpha \sin \beta) y)
\end{align*}
\] And sincerest equations hold for arbitrary \(x\) and \(y\), taking \(x=1, \dot{y}=0\), tic first gives us immediately the formula for \(\cos \overline{\alpha+\beta}\), the second the furmule for \(\sin \overline{\alpha+\beta}\).

How much extra work does the non-matrix method entail? Quite allot; we have both done it, we know. But let is see precisely what this extra work is (5) written directly in matrix notation is.

\[
=\left(\begin{array}{ll}
\cos \alpha \cos \beta-\sin \alpha \sin \beta \\
-(\sin \alpha \cos \beta+\cos \alpha \sin \alpha & \cos \beta+\cos \alpha \sin \beta \\
\alpha \cos \beta-\sin \alpha \sin \beta
\end{array}\right)\binom{x}{y}
\]

Notice anything remarkable? Well, compare \({ }^{\prime}{ }^{\prime}\) ) with (5*). We must conclude that
\[
\left(\begin{array}{l}
\cos \alpha \cos \beta-\sin \alpha \sin \beta \quad \sin \alpha \cos \beta+\cos \alpha \sin \beta \\
-(\beta \sin \alpha \cos \beta+\cos \alpha \sin \beta)  \tag{5"}\\
=\left(\begin{array}{ll}
\cos \beta & \sin \beta \\
-\sin \beta & \cos \beta
\end{array}\right)\left(\begin{array}{ll}
\cos \alpha & \sin \alpha \\
-\sin \alpha & \cos \alpha
\end{array}\right)
\end{array}\right.
\]

But, (4) written directly in matrix notation is
\[
\binom{\overline{\bar{x}}}{\overline{\bar{y}}}=\binom{\cos \alpha \cos \beta-\sin \alpha \sin \beta \quad \sin \alpha \cos \beta+\cos \alpha \sin \beta}{-(\sin \alpha \cos \beta+\cos \alpha \sin \beta)^{\prime}, \cos \alpha \cos \beta-\sin \alpha \sin \beta}\binom{x}{y}
\]

Thus* (4) is, in effect, ( \(^{*}\) ( with the first pair of matrices on its right muntiplièd out.
'. What do you conclude?' 'Think about it. . Whereas by using matrices, we obtain. (5*) without having to multiply out the product
\[
\left(\begin{array}{lll}
\cos \beta & \sin \beta \\
-\sin \dot{\beta} & \cos \beta
\end{array}\right)\left(\begin{array}{ll}
\cos \alpha & \sin \alpha \\
-\sin \alpha & \cos \alpha
\end{array}\right)
\]
to obtain (5) without using matrices necessitates multiplying out the non-matrix . equivalent of this' product. Put paradoxically, whereas' the use of matrices. avoids. computation \(\overline{\mathbb{Q}} \mathrm{f}^{\text {w }}\) the matrix product, the avoidance of matrices necessitates it. Isn't it easier to drive nails with a hammer than with a store?
4.4 Orthogonal Matrices.
matricemoty the. form

gives another matrix of the same form; they constitute a group. The performance
 mane of a second and similar operation, namely; \(\left(\begin{array}{ll}\cos \beta & \sin \beta \\ \text { sin } \beta \text { cos } \beta\end{array}\right)\) on the result of the first operation (see (4*) ), is equivalent to the performance of the
single operation \(\left(\begin{array}{ll}\cos \overline{\alpha+\beta} & \sin \overline{\alpha+\beta} \\ -\sin \overline{\alpha+\beta} & \cos \overline{\alpha+\beta}\end{array}\right)\) on \(\binom{x}{y}\left(\operatorname{see}\left(3^{*}\right)\right)\), These operations give the transformations of the coordinates of \(P\) for rotations. of axes through an angle \(\alpha\), an angle \(\beta\) following an angle \(\alpha\), and an angle \(\alpha+\beta\). But, of' course; a rotation 'through' ' \(\dot{\alpha}\) ' followed by a rotation through ' \(\beta\) has the same outcome as a single rotation through \(\alpha+\beta\). This"is the reasoning underlying the deduction of (5*) from ( \(3^{*}\) ) and ( \(4^{*}\) ). Isn't it obvious from the geometrical point of view that rotation transforms must constitute a grouph Of course', the transform for a'rotation \(\theta\) will have \(\theta\) for an ingredient, but why \(\cos \theta\) and \(\sin \theta\) ? Of course, \(\alpha, \beta\), añd \(\alpha+\beta\) will be ingredients of our transforms, but why their cosines and sines?

Feconsider the derivation of (1*). Take another look.at Fig. 3. If \(O R\) is to be the ' \(\bar{x}\) value of \(P_{0}\), by definition \(P_{0}\) ' must be paraliel to \(\overline{\mathrm{Y}} \overline{\mathrm{Y}}\). Yet if \(0 \bar{X}, \bar{X}\) were not perpendicular, the angle at \(Q\) would not be a right angle, \({ }^{2}\) so that \(O Q\) would not. be equal to cqs , \(a\) and \(P_{0} Q\) would not be \(\sin\), Thus;, we come to see that
\[
\left(\begin{array}{ll}
\cos \theta & \sin \theta \\
-\sin \theta & \cos \theta
\end{array}\right)
\]
is necessarily the pattern of'matrices with which we can hande transformations of coordinates induced rotations of rectangular axes. And since mathematicians are disposed to use the word orthogonal rather than rectangular or rightangled, matrices of this pattern are baid to be orthogonal matrices. ,

Right angles are very special angles; right-angled axes very'special axes; \({ }^{\prime}\) we 'must expect orthogonal matrices to have very. special properties. They do. Look at the patterr again. The first row is such that
\[
(\cos \theta)^{2}+(\sin \theta)^{2}=1
\]
the sefond, such that
\[
(-\sin \theta)^{2}+(\cos \theta)^{2}=1
\]
\(\checkmark\)

While adding the product of the elements in each column, we have 4
\[
\cos \theta \cdot(-\sin \theta)+\sin \theta \cdot \cos \theta=0
\]

These properties are characteristic; if a matrix has them it is orthogo-
nal; if it doesn't, it isn't. Formally, a matrix

is said to be orttrogonal if and only if
.4 .5 A MBst Important-Theorem.
Given that.
\[
\binom{x}{y}=\left(\begin{array}{lll}
A & B \\
& \cdots & \\
C & & D
\end{array}\right)\binom{x}{y}
\]
\(\therefore\) is subject toaithe very special condition that \(\left(\begin{array}{ll}A & B \\ C & -D\end{array}\right)\) is orthogonal, ought not we anticipate some very specicial relation between the new and the old coordinates of P? Look at the question geometrically: See Fig. 6.

\[
\begin{aligned}
& \rangle \quad . \quad A^{2}+0, B^{2}=\cdot 1 \\
& C^{2}+D^{2}=1 \\
& \mathrm{AC}+\mathrm{BD}^{2}=0 \text {. }
\end{aligned}
\]

OP remains unchanged, so does its square. And we all remember one of the very , first formulae we learned in coordinate geometry, namely, that the square of the J distance of a point from the origin is the sum of the squares of its, coordinates. Calculating in the old \(x, y\).coordinate system,
\[
(Q P)^{2}=x^{2}+y^{2}
\]
and 'in the new \(\bar{x}, \bar{y}\) system,
\[
(\mathrm{OP})^{2}=\bar{x}^{2}+\bar{y}^{2}
\]
so that
\[
\bar{x}^{2}+\bar{y}^{2}=x^{2}+y^{2}
\]

We have the result:
Given that
\[
\cdot\binom{\bar{x}}{-}=\left(\begin{array}{cc}
A & B \\
C & D
\end{array}\right)\binom{x}{y}
\]
\(-1 f^{*}\left(\begin{array}{cc}A & -B \\ C & D\end{array}\right)\) is orthogonal, then \(\bar{x}^{2}+\bar{y}^{2}=x^{2}+y^{2}\).
Can we say more? Well, we "can at least suspect more:" Suppose that the pairs of axes to be oblique instead of orthogonal. It is no longer true, in general, that
or that
\[
\ldots \quad \ldots(O P)^{2}=-x^{2}+y^{2}
\]
\[
(O P)^{2}=\bar{x}^{2}+\vec{y}^{2}
\]

Of course, it could conceivably still be true that, \(\bar{x}^{2}+\bar{y}^{2}=x^{2}+y^{2}\), but isn't this most unlikely? We conjecture that \(\vec{x}^{2}+\bar{y}^{2}\) cannot (for arbitrary \(x\) gad, y) be equal to \(x^{2}+y^{2}\) unless \(\left(\begin{array}{cc}A & B \\ C & D\end{array}\right)\) is indeed orthogonal: (The reader who has used oblique axes will recall that if the angle between them, is \(\omega\), then in consequence of the Cosine Rule, calculating in the old \(x, y\) system
\[
(O P)^{2}=x^{\dot{2}}+y^{2}+2 x y \cdot \cos \omega
\]
sin nt in the new \(\bar{x}, \bar{y}\) system
\[
(O P)^{2}=\bar{x}^{2}+\bar{y}^{2}+2 \bar{x} \bar{y} \cos \omega
\]

Thus, \(\bar{x}^{2}+\bar{y}^{2}=x^{2}+y^{2}\) if and only if \(x y=\overline{x y}\) ", so that our suspicion is seen to be well foundetu.)

Combining fact with fancy we anticipate:
Given that
\[
\binom{\bar{x}}{\bar{y}}=\left(\begin{array}{cc}
A & B \\
& { }^{B} \\
C & D
\end{array}\right)\binom{x}{y}
\]
\(\bar{x}^{2}+\bar{y}^{2}=x^{2}+y^{2}\) if and only if \(\left(\begin{array}{ll}A^{\prime \cdot} & B \\ C, & D\end{array}\right)\) is orthogonal. We have committed ourselves to an opinion. Until we know whether we are right or wrong, how can we decently rest?
- We rewrite the given matrix equation thus
\[
\begin{aligned}
& \bar{x}=A x+B y \\
& \bar{y}=C x+D y
\end{aligned}
\]

Squaring both equations and adding, we get
\[
\begin{align*}
\bar{x}^{2}+\bar{y}^{2} & =\left(A^{2} x^{2}+2 A B x y+B^{2} y^{2}\right)+\left(C^{2} x^{2}+2 C D x y+D^{2} y^{2}\right) \\
& =\left(A^{2}+C^{2}\right) x^{2}+\left(B^{2}+D^{2}\right) y^{2}+2\left(A B^{\prime}+C D\right) x y . \tag{6}
\end{align*}
\]

If \(\left(\begin{array}{cc}A & \dot{B} \\ \cdots & ,\end{array}\right)\) is orthogonal, by definition, \(A^{2} \dot{C}^{+} B^{2}=\dot{1}, \quad \dot{C}^{2}+2 D^{2}=1\), and \(A B+C D=1\), whereupon (6) gives
\[
\bar{x}^{-2}+\bar{y}^{2}=x^{2}+y^{2}
\]

Not surprising, but we would have, been surprised at the contrary. The substitulion does serve as some sort of check on our algebra, does' \(£\) it?

If for arbitrary \(x, y\)
\[
\bar{x}^{2}+\bar{y}^{2}=x^{2}
\]
(6) gives
\[
i: x^{2}+i: y^{2}+0 \cdot x y=\left(A^{2}+C^{2}\right) x+\left(B^{2}+D^{2}\right) y+2(A C+B D) \cdot x y
\]

Equating coefficients: of this identity
for \(x^{2}\),
\[
2=A^{?}+C^{2}
\]
for \(y^{2}\),
\[
1_{G}=B_{x_{0}}^{2}+D^{2}
\]
and for \(x y\),
\[
0=?(A B+C D)
\]
so that,
\[
0=A B^{\prime}+C D .
\]

The matrix is orthogonal; our conjecture is, a theorem.

\subsection*{4.6 A Matter of Notation.}

We have seen that some orthogonal matrices are characterised by the pattern
\[
1 \cdot \cdot \cdot\left(\begin{array}{ll}
\cos \theta & \sin \theta \\
-\sin \theta & \cos \theta
\end{array}\right)
\]

To compute the elements of this matrix given \(\cos \theta\), it is, course, natural to use trigonometric tables: If, for example, \(\cos \theta=0.5172\), we use the cosine table to find \(\theta\), the angle where cosine is 0.5172 , and then the sine table to find the sine of this angle. But tables are not always at hand. How can we get along without them? Yes, by -using
\[
\sin \theta=\sqrt[4]{1-\cos ^{2} \theta}
\]

With \(\cos \theta=0.5172\), we have, without using tables
葛:
\[
\sin ^{\prime} \theta=\sqrt{1-0.5172^{2}}
\]

To indicate our dispensation from the need to use tables, we put \(z=\) cos \(\theta\), in consequence of which \(\sin \dot{\theta}=\sqrt{1-\cos ^{2} \theta}=\sqrt{1-z^{2}}\), and write the above' typical orthogonal matrix with the notation

125

We have said the same thing, yet with a!different emphasis.
Has, now, every orthogonal matrix such' a representation by means of one variable \(\quad z\) ? Given an arbitrary orthogon\&l matrix \(\left(\begin{array}{ll}A & B \\ C & D\end{array}\right)\), let us replace the letter \(A\) by. z. Since \(A^{2}+B^{2}=1\), we see that \(B=\sqrt{1-z^{2}}\) where the 'squares root may be taken either positive or negative. Next, the condition \(\therefore A C+B D=0\) now reads \(z C+\sqrt{1-z^{2}} D=0\). Hence, we find \(\frac{C}{D}=-\frac{1}{2} \sqrt{1^{\prime}-z_{d}^{2}}\); this fact can now be stated as follows. There exists a constant \(\alpha\) such that \(C=a \sqrt{1-z^{2}}, \quad D=-\alpha z\). Since; finally, \(C^{2}+D^{2}=1\), we conclude . . \(\alpha^{2}\left(1-z^{2}+z^{2}\right)=1\) and \(\alpha^{2}=1\). This allows us two choices for \(\dot{\dot{\alpha}}\), namely, \(\alpha=+1\) and \(\alpha=-1\). Hence, the most general orthogonal matrix has the form
\[
\left(\begin{array}{ll}
A & B \\
0 & D
\end{array}\right) \doteq\left(\begin{array}{ll}
z & \sqrt{1-z^{2}} \\
-\sqrt{1-z^{2}} & z
\end{array}\right) \circ \dot{ } \quad=\left(\begin{array}{ll}
z & \sqrt{1-z^{2}} \\
\sqrt{1-z^{2}} & -z
\end{array}\right)
\]

Only the first kind of orthogonal matrices occur under rotations of - the-coordinate axes.

What is the meaning of the second kind of orthogonal matrices? Let us . specialize and choose the convenient value \(\dot{z}=1\). Thus, we are led to the matrix \(\left(\begin{array}{ll}1 & 0 \\ 0 & -1\end{array}\right)\) which is of the exceptional form. As a matter of fact, the knowledge of this one particular orthogonal matrix allows us to bridge over from all orthogonal matrices of the first kind to all orthogonal matrices of the secon kind. 'Indeed, the rules of matrix multiplication yield the identity
\[
\left(\begin{array}{cc}
1 & 0 \\
0^{0} & -1
\end{array}\right)\left(\begin{array}{ll}
z & \sqrt{1-z^{2}} \\
-\sqrt{1-z^{2}} & -z
\end{array}\right)=\left(\begin{array}{ll}
z & \sqrt{1-z^{2}} \\
\sqrt{1-z^{2}} & -z
\end{array}\right) .
\]
as you may verify as an exercise in matrix multiplication. *Thus, each orthogonail matrix of the first kind becomes an orthogonal matrix of the second kind by multiplication with this particular matrix.
Let us now interpret the meaning of the transformation
\[
\binom{\dot{x}}{\bar{y}}=\left(\begin{array}{ll}
1 & 0 \\
0 & 0 \\
0
\end{array}\right)\binom{x}{y}
\]
which takes, in non-matrix form, the following shape:
\[
\vec{x}_{1}=x, \quad \bar{y}=-y .
\]

Yo can easily verify that this transformation takes place if we keep four dordinatie axes but direct the positive \(y\) direction in the opposite sense. In' other words, we reflect the \(y_{q}\)-axis on the \(x\)-axis as if the, \(x\)-axis werêa Clearly, under such a coordinate transformation the distance from the orlafigity also preserved." The transformation considered is called a reflection. "We haver thus proved that every orthogonal matrix cantandex fed as a matrix belonging
 the special reflection matrix \(\left(\begin{array}{cc}1 & 0 \\ 0 & -1\end{array}\right)\).

In general, the mathematician bewares of changes of coordinate systems which involve a reflection, One is accustomed to drawing the y-axis a nd x-axis in such a position that the first axis is obtained from the second by a rotation in counterclockwise sense. This is the so-called positive-sense of rotation. If we, make a transition to al new coordinate system by reflection, we change the orientation of the coordinate axes. They go now over into each other by rotating the \(x\)-axis in the clockwise (negative) sense.

We can assemble the insight obtained in. this section in the following theorem:

Theorem A: Given that
\[
\binom{\bar{x}}{\bar{y}}=\left(\begin{array}{ll}
A & B \\
C & D
\end{array}\right)\binom{x}{y}
\]
is a transformation which preserves the orientation of the coordinate areas and preserves. the distance from the origin \(x^{2}+y^{2}=\bar{x}^{2}+\bar{y}^{2}\). This holds if and in only if
\[
\left(\begin{array}{ll}
A & B \\
C & D
\end{array}\right)=\left(\begin{array}{ll}
z & \sqrt{1-22^{2}} \\
-\sqrt{1-z^{2}} & z
\end{array}\right)
\]

\section*{}

And since the fomentation of the coordinate axes is not changed and the distance OP remains, jnváriamt
\[
\vec{x}^{2}+\vec{y}^{2}=x^{2}+y^{2}
\]

We have in consequence "of Theorem A.):
\[
\begin{aligned}
& \text { ne \% Theorem A. }): \\
& y,\binom{\bar{x}}{\bar{y}}=\left(\begin{array}{ll}
z & \sqrt{1-z^{2}} \\
-\sqrt{1-z^{2}} & z
\end{array}\right)\left(\begin{array}{l}
x \\
x \\
y
\end{array}\right)
\end{aligned}
\]
in..,
\[
\begin{aligned}
& \bar{x}=z \dot{x}+\sqrt{1-z^{-2}} \cdot \dot{y} \\
& \dot{y}=-\sqrt{1^{\prime}-z^{2}} \cdot x+z \cdot y
\end{aligned}
\]

To assign geometrical significance to \(z\), it is convenient to take, \(x=1\), .
\[
\begin{aligned}
& \overline{\bar{x}}=z \\
& \bar{y}=-\sqrt{1-z^{2}}
\end{aligned}
\]
"From Fig. 3 it is obvious that \(\bar{x}=\cos ^{2} \alpha, \bar{y}=-\sin \dot{\alpha}\), (the minus sign because \(Q P_{0}\) has the opposite sense to \(\left.\bar{Y}\right)\), so that
\[
\begin{gathered}
8^{\prime 2} 2=\cos \alpha \\
\dot{+} \sqrt{1-z^{2}}=\sin ^{2} \alpha \\
1 /, ~
\end{gathered}
\]

Thus, (1) follows immediately.
Effortless? This is hitting ag nail with a power-driven hammer. 'For us' muscle-driven hammers are a thing of the past. Arid bashing away with stones?

128

Oh, that sort of thing belongs to cave-man mathematice. -
Although (1) could have!been deduced even more succintly, 'I have preferred the present argument because it is echoed-- albeit faintly-- in a subsequent argument.
4.8 To Sum Up.

リ.. :
- By considering orthogonal transformations in some detail; I have tried to typify what matrices are good for matneflutics. And by emphasiang the rough
 without matrices, I have thied to make it easier to appreciate the facility afforded by'matrix technique But do not mistake analogy for mathematical appreciation; in particular, there is no substitute for working out and pondering over the mathematics of Section 4.3 for yourself.

Parte. From Matrix Theonem to Relativity Physics..

Here my main objective, you will recall; is to show how relativity theory arises out of matrix algebra used with bold imagination. This part is more difficult, although not more difficult matrematicqlly. 'More difficult because,
unlike Part 1, it demands that you-- how shall I put it? -- unthink firmly- even if uncritically-held notions.

The basic relativity problem arises out of trying to state with mathematical precision what we dan mean when we use the phrase "at the same'time" or say that two events were simultaneous. And what on earth has this to do with matrix algebra? A good question, a very good question, but let us not get ahead
IV of ourselves. It is better first to appreciate how the problem arose; the strangest motive for the reception of new notions is the failure of old ones.

\section*{4.9, The Michelson-Morley Experiment.}

'126
one of the world's greatest experimental physigists. He is perhap'stbest intro "duce by the following anecdote: Asked by a father if his son should be encouraged to continue his studies to become a physicist, Michelson is said to have replied, "No, advise your son not to study physics. It is a \({ }^{1}\) dead subject. What there is to know, we know-- except that possibly we could measure a few. things, to the sixth decimal place instead of the fourth."

The irony of the story is that Michelson is the man whose ex eriments led to such a revolution that we have learned more about physics in the last sixty years than in all the preceding centuries.
. Put"this story is revealing as well as ironical. Michelson was a man with a pas ken for accuracy, a man who measured everything to the sixth decimal place. He had, in particular, in the late 1870's, by most ingenious experimentation measured the velocity of light with hitherto unheard-of accuracy. The velocity of the earth in its journey round the sun having been determined with fair accuracy from astronomical data, Michelson's next ambition was to remeasure, it - himself -- to the. sixth decimal place. With this objective, in sight, in 1881, assisted by Morley, he made the experiment that was "to make them famous. the Michelson-Morley experiment.

The concept upon which this experiment was based was simple. Suppose that we put a transmitter \(T\) and a receiver \(R\) a certain distance apart on the surface of the earth and measure the time taken for a signal, a flash of light, to go from \(T\) to R. See Fig. 7.

The, signal sent from \(T\) with the enormous velocity of light e has to overtake \(\dot{A}\). which is moving ahead with velocity " x , the velocity of the earth. Therefore it has velocity \(c-v\) relative to \(R\) and in consequence will take little \(\therefore\) more time to reach \(R\) than it would if the earth were at rest, And if a netum signal is sent from \(R\) back to \(T\) it is approached. by \(T\)-as it approaches T, so that its velocity relative to \(T\) is \(\dot{c}+\mathrm{v}\). See Fig. 8.

Fig. 8

Therefore the return signal will take less time than it would if the earth were at rest and still less tine than, the initial, outgoing signal does,
: Let us describe briefly the ingenious experimental arrangement to carry out this observation. See Fig. 9.

Fig. \(9^{\prime}\)

We have a light source, \(L\) which sends a light ray in the direction of the motin of the earth. This ray falls on a mirror \(M\) which is partially transpar'O and stands under an angle of \(45^{\circ}\). against the incoming ray. Thus, a part
\(\therefore\) of the light is reflected under \(90^{\circ}\) to a mirror. \(M_{2}\) and a part goes through to a mirror \(M_{3}\). Observe that the light ray has now been split. up into two rays; one moving along the line \(M_{1} M_{2}\), that is, perpendicular to the earth's * motion, and the other moving along \(M_{1} M_{3}\) parallel to the earth's motion. \#Both. rays are reflected again at the mirrors \(M_{2}\) and \(M_{3}\) and return to the trans-". parent mirror \(M_{1}\). Now, part of the vertical light ray \(M_{2} M_{1}\). passes through.: \(M_{1}\) and goes to the objective of an interferometer J. At the same time a part of the light ray \(M_{3} M_{1}\) is reflected at \(M_{1}\), and also en \({ }^{\text {E }}\) ers into the same. interferometer: Thus, we mix in \(J\) the' light of two different travel histories. The two types of light differ in their part by the difference in time which is necessary to travel from \(M_{1}\) to. \(M_{2}\) and back ag compared to the time which it takes to travel from \(M_{1}\) " to \(M_{3}\). and back. iou do not' need to know the operalion of an interferometer. It is sufficient to know that such an instrument is sensitive enough to compare light rays coming from the same origin but having spent different times in travel. Being mathematicians, we stall rather calculate the expected difference. in travel time which the instrument will measure.

Let \(\dot{\ell}\) be the distance between the mirrors \(M_{1}\), and \(M_{3}\), and \(M_{1}\) and \(M_{3}\) which, as you see, we assume to be equal. The travel time from " \(M_{1}\) to \(M_{3}\) "and back is evidently
\[
T=\frac{\ell}{c-v}+\frac{\ell}{f+v}=\frac{2 \ell c}{c^{2}-v^{2}}
\]
since in the forward motion light should travel with the lesser relative velacity \(c-v\) and in return with the larger velocity \(c+v\), as we discussed before.

It is more difficult to find the travel \({ }^{\circ}\) time from \(M_{1}\) to \(M_{2}\) and back. Let us look at the experiment from a point in outer space, so that we do not participate in the motion of the earth. At' the moment when the ray eave's the
mirror \(M_{1}\), this mirror has the position, \(M_{1}(1)\) in space, and ' \(M_{2}\) sits at the point \(M_{2}^{(1)}\). But, suppose it takes the time \(\frac{1}{2} t\) until the ray hits the 'mirror \({ }^{\prime}\) \(M_{2}\). During this time the mirror \(M_{2}\) has shifted in the direction of the earth's

Fig. 10
motion and sits at the point \(M_{2}^{(2)}\) in space. It reflects the light back to \(\dot{M}_{1} ;\) by reason of symmetry it will take the same time \(\frac{1}{2} t\) to return from, \(M_{2}\) to \(M_{1}\). But when the light reaches \(M_{1}\), its position. in space will be at \(\therefore M_{1}^{(3)}\). We know that the distance \(M_{1}^{(1)}\) to \(M_{1}^{(3)}\) is given by vi since is the total travel time and since the earth moves with the speed 4 . On the other hand, the light which -travels with speed \(c\) had to cover in the time \(\frac{1}{2} t\) the distance \(M_{1}^{(1)}\) to \(M_{2}^{(2)}\). Thus, in the right triangle \(\left.\Delta M_{1}{ }^{(1)} M_{M}(2)_{M_{2}}^{(3)}\right)\) ain three sides are known as indicated in Figure 10. By the Pythagorean therem, we have
\(+\ell^{2}=\frac{1}{4} t^{2}\left(c^{2}-v^{2}\right), t^{2}\) that is, \(t=\frac{2 \ell}{\sqrt{c^{2}-\hat{v}^{2}}}\) \(\qquad\)
"The travel'time \(T\) from \(M_{1}\) to \(M_{3}\) "is not the same as that needed to go from \({ }^{4} M_{1}\) to \(M_{2}\). The ratio of travel times is.
\[
\frac{m}{t}=\sqrt{\frac{1-\frac{v^{2}}{c^{2}}}{}}
\]

This, square root which occurs here in our elementary considerations is cherac teristic for relativity theory and will occur later in quite a different way
* The above reasoning allowed ् Michelson to predict a time difference In travel time ana to adjust his instruments in such a way that the effect could be safely measured.
- Although the idea behind this experiment is so simple, the refinements
necessary to achieve the accuracy that Michelson demanded made the actual experimental set-up a hive of ingenuity. As I have said, Michelson was one of the world's greatest experimental physicists. Indeed, he achieved such accuracy that he would have been able to determine \(v\); the earth's velocity, even if it had been moving only one tenth as fast as it does.
" 'Michelson made the measurement and created a scandal'in physics. What. value for" \(v\) did he get? Zero. Yes, ZERRO. The flash of light takes precisely the same time to go from \(T\) to \(R\) as from, \(R\) to \(T\). But this is preposterous. Even the small boy who steals apples from an "orchard appreciates the importance of relative velocity -- even if he cannot spell the words. He knows perfectly well that to esqape a good hiding he must continue to run away from, not towards, the wrathful farmer hard in his pursuit. But surely there can be no difference in principle between being chased by a farmer and a flash of light? The flash is more fleet of foot, that's all.

Physicists could not believe their eyes. The Michelson-Morley .experiment was. yepeated again and again. Again and again the answer was zero. This was againct-all uriaerstanding of physics. How, for goodness' sake, could the velocity of light relative to a moving object be the same when overtaking the object as when moving towards it? Déspite heated discussion, the cold fact is, that the , velocityi of lightis invarient. :
4.10 What Time is it?

After a discussion of the Michelson-Morley experiment and its conce wable 4
consequences had been prolonged in scientific, journals for some twehty years, Einstein came up with a penetratíng remark. "What," he asked, "do we mean by saying that two events happened at the same time. 'How do we know that efverybody oan agree what the time is at this very instant?"
- In this age of jet trayel it is a commonplace experience (that different longitudes have different times. A telephone call from San Francisco to New York immediately confirms a different clock reading there. This communication;
made by electricity at the speed of light, is so rapid that for all practical purposes the We'st Coast inquirer hears the East Coast answerer's repiy at the same ,time as it is spoken in New York. At the same time the two clocks record different times, yet neither clock is wrong. Somehow or other clock readings . are dependent upon an agreement about how we measure time. This remark is silly or subtle, as yó please. Doesn't it sound peculiar to say that at the same time different clocks can correctly record different times? I am mindful of the visiting philosophy professor who, in concluding his discourse on Time with 'the remark, "So you see, gentlemen, I do not know what Time is," looked at his watch -- and dashed to catch his train.

Even if we dismiss the-different-times-at-the-same-time paradox as merely verbal, it is none the less a fact that winth interplanetary travel a realistic. probability the business of synchronising clocks becomes of practical importance. And cosmic voyaging introduces'a complication not encountered in terrestial travel. Whereas the time lag in hearing in San Francisco what is said in New York is about \(\frac{11}{50}\) th of a second, the time lag in interplanetary communication (by radi" \({ }^{\prime \prime}\) waves with the velocity of light) is a matter of minutes, and that between the earth and"the stars, months.

Suppose, for example, that a radio signal sent by \(E\), an observer on earth, to \(A\), an astronaut in outer space, \(60^{\circ} \times 186,000\) miles away, takes 1 minute. If \(E\) sends his signal when hisi clock records 12 o'clock, then his signal reaches \(A\) when his ( \(E^{\prime}\) s) watch records 12:01. A, in receiving the
 diately signals back. And since the distance between \(A\) and \(E\) remains unchanged, this return signal also takes 1 minute. Therefore \(E\) receives A's acknowledgement at \(\cdot 12: 02\) by his ( \(\mathrm{E}^{\prime} \mathrm{s}\) ) clock.

This, you will say, is all verd simple. Surely there's nó difficulty. At \(12: 01 \mathrm{E}\) says to himself, "A is now receiving my signal sent at \(\frac{1}{3}: 00\). by my clock and setting his clock at le: 01, the same time as mine." And from E's point of view'isn't his conviction established beyond doubt by his clock

\section*{}

The point is that whereas \(E\) knows that he himself sends a signal at 12̈:00 by his clock and knows he receivés \(A^{\prime} s^{\prime}\) conifirmatory signal at 12:02, \(E\) does not know that \(A\) received his ( \(E^{\prime}\) s) signal when his ( \(E^{\prime} s\) ) clock read 12:01. (4yys, he is convinced, but he does not know. He cannot be in both places at once to find out. He has no method of direct verification.

To synchronize clocks by means of light or radio signals, we must know the velocity with which our signals are transmitted, but to determine this velo. \({ }^{4} t y\), we must know how long the transmission takes. To attempt to synchronize. clocks without knowing the velocity of light and to determine the velocity of light without using a clock, is just as futile as to try to produce hens without eggs and eggs withott hens.

It is arguable that if eyewitnesses to \(E\) 's signalling \(A\) are separated by great distances, then they must report vastly different, yet equally reliable, opinians of the time indicated by his (E's) clock when his signal reaches A. All very confusing. To go intio great detail is to invite great confusion. Physicists went into very great detail. Many on-paper experiments were made in which people frantically set their watches as they hastily got on and off trains, trams, boatis, and bicycles, scheduled for immediate departure at velo-, cities near that of light. Scientific journals were full of these wild excursions.

Of course, it is easy to poke, fun. The physicists were able, seriousminded people, trying to fogure out an important problem. Their real difficulty was concefual rather than mathematical; quite literally, they didn"t know what Fithoy were tajking about. Whereas'we all know well' enough how to use the concept of time in everyday conversation, we are at a loss when we come to map its logical geography.

The matter was finally cleared up in 1905 by Einstein. He did two things of the greatest possible importance for physics: (1) He saw more clearly than any of his contemporarles what the basic problem is and gave it precise mathefratical formulation; (2) He, solved it. The first is by far the more difficult achievement.

This section I shall devote to (1), the next to" (2).
" Although Einstein (1879-1955) was an imaginative thinker with his head in the clouds, he had both feet on the ground. He did not spend several years in the Swiss Patents Office for nothing. A professor of metaphysics would have asked: "What is Time?" or, "What is the essence of Time?" or more'recently, "What do we mean by Time?" Einsteir, on the contrary, asked: "If a happening is observed by two persons, how are the one man \({ }^{*} s_{s}\) answers to the questions, '? Where?', 'When? ', related is the other,'s? He looked for an answer in terms of measuring rods and clocks, not essences or semantics. He was a professor of physics, not "metaphysịcs.

Aithougheminstein was primarily interested in observers "astronomical distarices apart;more homèly exposition results from bringing them down to earth.

So is a man' who is standing at a railway track in the darkness, of the night, "and \(T\) is a tree by the side of the track distance \(x\) in the positive direction from \(S_{0}\). See Fig. 11. The notation \(S_{0}\) stands for Standing Still at the \({ }_{0}\) Origin of the Stationary Systęm; " \(\mathrm{I}^{\prime \prime}\) you' can figure out for yourself. mon

\(M_{0}\) is an engine driver or motorman who drives a train along the track in the -positive direction. He measures distances from where he sith in his moving cab, ahead positivg behind negative. And since he moves with his train, the distance \(\bar{x}\) of the tree from him is, of course, changing as his train moves along. The notation \(M_{0}\) stands for Motorman Who is the Origin' of the Moving System'. When \(M_{0}\) in his locomotive thundering along tre track passes \(S_{0}\), they synchronize their watches; each sets his to zero hour. \(S_{0}\) sets his \(t=0\), and \(M_{0}\) sets his (a different, watch, so we must usé a different letter) \(\bar{t}=0\). Also when \(M_{0}\) is passing him (i.e., when \(\left.t=0, \bar{t}=0\right), S_{0}\) flashed a powerful lantern in the positive direction of the track. Almost immediately the tree is made visible to both \(S_{0}\) and " \(M_{0}\) for an instant by the passing flash--just as it would be by a flash of lightning. \(S_{0}\) says that he caught a glimpse of \(T\) at a distancé \(x\) from himself at time \(t ; M_{0}\) says that he. glimpsed the tree at a distance \(\bar{x}\) from himself at time \(\bar{t}\) scribes that the tree was momentarily visible as the event \((x, t), M_{0}\) describes it as the event \((\bar{x}, \bar{t})\).

We put Einstein's question thus: "If a happening is observed by two men, how are the one \({ }^{\text {man's answers to the questions' 'Where?', 'When?' related to the }}\) other's?" It now takes on a more mathematical tone to become: What are \(\overline{\mathrm{x}}\) land \(\bar{t}\) in terms of \(x\) and \(t\) ? Or, mindful of mgtrices: What is the transformation from \(\left(\begin{array}{l}x \\ 0 \\ t\end{array}\right)\) to \(\binom{\bar{x}}{\bar{t}}\) ?

Very possibly you are tempted to say that, whereas \(x\) and \(\bar{x}\) are different because \(M_{0}{ }^{\prime}\) is moving and \(S_{0}\) is stationary, t and \(\bar{t}\) must be the same. Do not be intimidated by practical concern with small scale terrestial experience.

And although not concerned with the color of the engine-driver's soeks, you may be tempted'at this stage to introduce \(v\), the velocity of the train. This would be a mistake; Einstein kept the problem simple. We all know the maxim, "Put first things first"; he knew which things gre the first, things. His thinking was incisive.

What is rélevant? Let us cast our minds back to orthogonal matrix transto go from \(\binom{x}{\dot{t}}\), to \(\binom{\bar{x}}{\frac{t}{t}}\). There is a similarity. The previous transformation is linear because of a one-to-one correspondence between. \(\bar{x}\) and \(x\) and \(\bar{y}\) and \(y\). Yet for any happening, for example, the momentary visibleness of the tree \(T, S_{0}\), has juss one description \((x, t)\) and \(M_{0}\) just one description \((\bar{x}, \bar{t})\). To the unique description of an event by \(S_{O}\) there corresponds a unique description of that event by \(M_{0}\), and conversely. We qust conclude that the required transformation is linear. It being understood, as previously, that the letters \(A, B, C\), and \(D\) stand for numbers independent of \(x, y\) and \(\bar{x}, \bar{y}\) our present problem becomes:

Given that \(\binom{\bar{x}}{\bar{t}}=\left(\begin{array}{ll}A & B \\ C & -D\end{array}\right) \cdot\binom{x}{t}\), find \(\left(\begin{array}{ll}A & B \\ C & D\end{array}\right)\).
\({ }^{\prime}\) Yes, find \(\left(\begin{array}{ll}A & B \\ C & D\end{array}\right) \cdot{ }^{\circ}\) But subject to what conditions? The only thing we know from experience is the result of the Michelson-Morley experiment, that the velocity of light is invariant. And how are we to make use of this condition? We must inject it into the body of the problem.
- Refer back to Fig.1l. First consider \(S_{O}{ }^{\text {'s }}\) 'Stationary System. What is. the relation between \(x\) and \(t\) ? The flash of light is at \(x=0\) when \(t=0\). Where will it be after time t?. Taking \(c\), as is customary, to. be the velocity of light,
\[
\begin{gathered}
x=c t \\
\therefore x^{*}-\cdots c t=0 .
\end{gathered}
\]

This is supposing, of course, that the flash moves in the positi \({ }^{\circ}\) direction along the rainway track. But this supposition is too restrictive for our purposes; if could well be that \(S_{0}\) flashed his lantern in the opposite direction. to â tree + T' See Fig. 12.

136

If so, having due regard to signs, the velocity of the flash would be

\[
\begin{aligned}
& x=-c t \\
& x+c t=0
\end{aligned}
\]
-i.e.,
Fig. \(12^{i}\)
\[
\%
\]

Needful of coping with either possibility, it is more convenient to handle them conjointly. By multiplying the two equations together, we have
\[
(x-c t)(x+c t)=0
\]
4. a \(1 . e \mathrm{e}:\),
\[
\because x^{2}-c^{2} t^{2}=\infty
\]

And since, if the product of two factors is 0 , then at least one of them must rube 0 , this equation covers both the possibilities.

Next, consider \(M_{0}^{\prime}\) s Moving system. Because the velocity of light is invariant, \(M_{0}{ }^{\prime} s\) movement makes no difference to the velocity with which a flash reaches him. In consequence, similarly, \(\bar{x}\) and \(\bar{t}\) are, such that
\[
\bar{x}^{2}-c^{2} t^{2}=0
\]

From the last two equations we have
\[
\bar{x}^{2}-c^{2} \bar{t}^{2}=x^{2}-c^{2} t^{2}
\]

This, is the condition to which the required transformation is subject. Thus, the completely mathematical.formilation of Einstein's spacetime transformation problem is:

Given that
\[
=\binom{\bar{x}}{\frac{1}{t}}=\left(\begin{array}{ll}
A & B \\
C & D
\end{array}\right)\binom{x}{t}
\]
\[
\$
\]
subject to the condition that
\[
\therefore x^{2}-c^{2} t^{2}=x^{2}-c^{2} t^{2}
\]
'find
\[
-\left(\begin{array}{ll}
A & B \\
C & D
\end{array}\right):
\]

By discovering. this transformation, Einstein opened up a new world and
changed our ideas of space and time.

\subsection*{4.12 Einstein's Solution.}

Recall Theorem A:
Given. that
\[
\binom{\bar{x}}{\bar{y}}=\left(\begin{array}{ll}
A & B \\
C & B
\end{array}\right)\binom{x}{y}
\]
preserves the orientation of the coordinate axes and the distance
\[
\bar{x}^{2}+\bar{y}^{2}=x^{2}+y^{2}
\]
it must. necessarily have the form

There is a similarity, yet only a partial similarity, between
\[
\bar{x}^{2}+\bar{y}^{2}=\dot{x}^{2}
\]
- and
\[
\bar{x}^{2}-(c \bar{t})^{2}=x^{2}-(c t)^{2}
\]
\(\downarrow\) Also, just as we do not allow a transformation \(\bar{x}={ }^{\prime \prime} x, \bar{y}=-y^{\prime}\) which destroy the* orientation of our coordinate system, we cannot allow a transformatiny \(\bar{x}=x\), c \(\bar{t}=-c t\) in spite of the fact that \(x^{2}-c^{2} t^{2}\) would be unchanged under such a substitution: Indeed, the transformation \(\dot{\bar{t}}=\dot{-} t\) would interchange
\[
\begin{aligned}
& \text { 唯: } \\
& \left(\begin{array}{ll}
A & B \\
\text { l } & \text { form } \\
\text { A }
\end{array}\right)=\left(\begin{array}{l}
z \\
-\sqrt{1-z^{2}}
\end{array}\right. \\
& \left.\begin{array}{c}
\sqrt{1-z^{2}} \\
z
\end{array}\right)
\end{aligned}
\]
past and future and make clocks mun backwards. It is aं deep' philosophical quiestion what makes time run in a unique sense and why we cannot change its course by physical devices. We cannot díscùs this problem which has bęen the despair. of wiser men. But, we can use the fact that past and future cannot be interchanged to exclude the special transformation \(\bar{x}=x, \bar{t}=-t\) which plays the same role here as the reflection played in cọordinate transformation.

Thus, had the minus signs been plu's signă, with the substitutions, ct \(=y\), \(\bar{t}=\bar{y}\), Theorem A would have been immediately applicable and our problem solved. What a pity.

Still, wishful thinking has its uses. If we do not makérisis we do not "have a wish to come true. How can we change,
into
\[
\bar{x}^{2}-c^{2} t^{2}=x^{2}-c^{2} t^{2}
\]
\[
\begin{equation*}
\bar{x}^{2}+2^{2} 2=x^{2}+c^{2} t^{2} ? \tag{1}
\end{equation*}
\]

We cannot. ©Yet if we cannat have all our wish, can we have a part of it?. We, write
\[
x^{2}-c^{2} t^{2}=x^{2}+\left(-c^{2} t^{2}\right)
\]

This is a little better; we have introduced a plus. And remembering convens a iently that \(i=\sqrt{-1}\), we have*
\[
--c^{2} t^{2}=-1 \cdot c^{2} t^{2}=1^{2} c^{2} t^{2}
\]
so that
and, similarly,
\[
x^{2}-c^{2} t^{2}=i x^{2}+(i c t)^{2}
\]
\[
\bar{x}^{2}-c^{2} \bar{t}^{2}=\bar{x}^{2}+(i c \bar{t})^{2}
\]

Therefore the condition
\[
\bar{x}^{2}-c^{2} t^{2}=x^{2}-c^{2} t^{2}
\]
may be replaced by the condition
\[
\bar{x}^{2}+(i c \bar{t})^{2}=x^{2}+(i c t)^{2}
\]

Thus it would seem that the best we can do is put
\[
\therefore-y=i c t, \quad \bar{y}=i c \bar{t} .
\]

With these substitutions Theorem \(A\) becomes:
\[
\begin{aligned}
& \text { Given }\binom{\bar{x}}{i c \bar{t}}=\left(\begin{array}{ll}
A & B \\
\vdots & B \\
c & D
\end{array}\right)\binom{x}{i c t} . \\
& \bar{x}^{2}+(i c \bar{t})^{\dot{2}}=x^{2}+(i c t)^{2}
\end{aligned}
\]
if and only if
\[
\left(\begin{array}{cc}
A & B \\
C & D
\end{array}\right)=\left(\begin{array}{cc}
z & \sqrt{1-z^{2}} \\
3 \sqrt{1-z^{2}} & 2
\end{array}\right)
\]

In consequence,
\[
\binom{\bar{x}}{i c \bar{t}}=\left(\begin{array}{ll}
z & \sqrt{1-z^{2}} \\
-\sqrt{1-z^{2}} & z
\end{array}\right)\binom{x}{i c t}
\]
so that
\[
\begin{aligned}
& \bar{x}=z x+\sqrt{1-z^{2}} \cdot i c t- \\
& i c \bar{t}=-\sqrt{1-z^{2}} \cdot x+z \cdot i c t .
\end{aligned}
\]

We have succeeded, at least in a formal way, in determining the necessary transformation between \(x, t\) and \(\bar{x}, \bar{t}\). We seem however, to have paid a heavy price for it; there is this wretched number i. of course, a clock can record a time \(t\) or a time ct, yet no clock can record a time dict, Must we'conclaude these equations to be without physical significance?

Consider \(\sqrt{-6} \cdot 1\). This is a sheep in wolf's clothing. Since the notation contains the letter \(i\), it is natural to suppose \(\sqrt{-6} \cdot i\) to be an imaginary number, yet \(\sqrt{-6} \cdot 1=\sqrt{-6}: \sqrt{-1}=\sqrt{(-6)(-1)}=\sqrt{6}\), al real number. Are our transformation equations imposters, also? Jet us unclothe them to find out...

Writing \(\sqrt{-1}\) for \(i\) in the first equation
\[
\begin{align*}
\bar{x} & =z x+\sqrt{1-z^{2}} \cdot \sqrt{-1} \cdot c t \\
& =z x+\sqrt{\left(1-z^{2}\right)(-1)} \cdot c t \\
& =z x+\sqrt{z^{2}-\frac{1}{n}} \cdot c t . \tag{i}
\end{align*}
\]

Making the same substitution in the second equation
\[
\sqrt{-1} \cdot c \bar{t}=-\sqrt[i]{1-z^{2}} ; x+z \sqrt{-1} \cdot c t
\]
dividing both sides by \(\sqrt{-1}\)
\[
\begin{align*}
c \bar{t} & =-\frac{\sqrt{1-z^{2}}}{\sqrt{-1}} \cdot x+z c t \\
& =-\sqrt{\frac{1-z^{2}}{-1}} \cdot x+z c t \\
& =-\sqrt{z^{2}-1} \cdot x+z c t . \tag{a}
\end{align*}
\]

Real coefficients: Provided \(\mathrm{z}^{2} \geq 1\).
Echoing the argument of Section 4.7, it remains to determine the physical significance of \(z\). We return to the railway track. \(M_{0}\) speeds through the night sitting in his engine cab. He says, "I do not budge an inch; I am \(\bar{x}=0^{\prime \prime}\); \(S_{0}\) says, "Oh no, to the contrary, you are moving very fast, you have the same
\% , velocity \(v\) as your train." Putting \(\bar{x}=0\) in (1)

\[
\begin{gathered}
0=z x+\sqrt{z^{2}-1} \cdot c t \\
\\
x=\frac{-\sqrt{z^{2}-1}}{z} \cdot c t .
\end{gathered}
\]

And since, when \({ }^{\circ} t=0, a x=0\), this equation tells us the distance that \(M_{0}\) has traveled from \(S_{0}\) in time \(\ddot{0}^{\prime \prime}\) (by \(S_{0} p_{s}\) watch). \(x\), the distance travelled,

distance .traveled \(=\underset{1}{\text { velocity } \times \text { time spent traveling. }}\)
So? The velocity \(i\) of. \(M_{0}\) and his train relative to. \(S_{0}\) and the track is given by
\[
\cdot v=\frac{-\sqrt{z^{2}-1}}{z_{\infty}} c
\]
where \(v\) is real when the above condition that \(z^{2} \geq 1\) is satisfied. We have found the physical significance of a function of \(z\). This suffices. .

With the remark that it is convenient to begin by writing (1) - and mutatis mutandis ( \(\dot{2}\) ) - in the form

I leave it to the reader to show that
\[
\begin{align*}
& \bar{x}=\frac{x-v t}{\sqrt{1-\frac{v^{2}}{c^{2}}}}  \tag{3}\\
& \bar{t}=\frac{t,-\frac{v x}{c^{2}}}{\sqrt{1-\frac{v^{2}}{c^{2}}}} \tag{4}
\end{align*}
\]
*. 3.

This is Einstein's solution.
In brief: Given that \(c\), the velocity of light, is invariant, if \(S_{0}\) de-!. scribes an event as happening at a distance \(x\) from himself at time \(t_{-}\)by his : watch and \(M_{0}\), who is moving with velocity \(v\), describes it as happening at at distance \(\bar{x}\) from himself at time \(\overline{\mathrm{t}}\) by his watch, then the relations between \(\bar{x}, \bar{t}\) and \(x, t\) are given by Equations (3) and (4).

We recall that the completely mathematical formulation of Einstein's prob-lem-- expressed in matrix notation -- is: .

Given that
\[
\binom{\bar{x}}{\bar{t}}=\left(\begin{array}{ll}
A & B \\
\bar{C} & D
\end{array}\right)\binom{x}{t}
\]
is subject 'to the condition that
\[
-\bar{x}^{2}-c^{2} t^{2}=x^{2}-c^{2} t^{2}
\]
\[
\left(\begin{array}{ll}
\mathrm{A} & \mathrm{~B} \\
\mathrm{C} & \mathrm{D}
\end{array}\right)
\]

It is fitting to conclude this section by giving Einstein.'s answer in the same notation." A moment's thought will show that (i) and ( 2 ) ma ty be written as foll lows:

\section*{145}

The matrix

数
\[
\left(\begin{array}{cc}
\frac{1}{\sqrt{1-\frac{v^{2}}{c^{2}}}} & \frac{-v_{4}}{\sqrt{1-\frac{v^{2}}{c^{2}}}} \\
\frac{-\frac{v}{c^{2}}}{\sqrt{1-\frac{v^{2}}{c^{2}}}} & \frac{1}{\sqrt{1-\frac{v^{2}}{c^{2}}}}
\end{array}\right)
\]
first expressed in'this form by the Dutch physicist Lorentz (1853-1928), is known as the Lorentz matrix..' Such matrices are analogous to orthogonal matrices; they constitute a group. The given matrix, when multiplied by a similar matrix, " with only \(v\) replaced, gives another matrix of the same form.

To consolidate this knowledge you are asked to work out, for yourself an \({ }^{\circ}\) elaborętion of Einstein's problem. We introduce" a second motorman \(\dot{M}_{1}\), the origin of the moving system \((\overline{\bar{x}}, \overline{\bar{t}})\), who drives his tain in the fame direction as \(M_{0}\) drives his on a parallel track r See Fig. 13: \(S_{0}\) when \(M_{0}\) does, and all three synchronize their watches). Given that \(M_{1}\)

146
moves with velocity \(\omega\), relative to \(M_{0}\); by using Lorentz matrices in a role analoǵous to that of orthogonal matrices in Section 4.3 , deduce formulae for \(\overline{\bar{x}}\) and \(\overline{\bar{t}}\) in terms of \(x, t\). Confirm your answer by considering the motion of \(M_{1}\), relative to \(S_{0}\).

\subsection*{4.13 Einstein's Achievement.}

I have taken great pains to try to make Einstein's formulation of his space-time transformation problem and hic solution by matrix algebra readily intelligible to the reader who will give his serious attention. Being wise after the event, it is difficult to appreciate the magnitude of his achievement. Now that we have the comforting assurance-of a well sign-posted road that we will reach our destination, we forge that when there was no road there was no road to follow. Yet, making the road yas the eass part. We forget absolutely that without a new destination, there could never have been a new road. Einstein had to see that there was a place to go to before he could figure out how to get - there.

Analogy will help us to see his achievement in perspective.
Given a hammer, a bag of nails, and the instruction, "Get busy," what does a boy do? Drive a few nails in the wooden floor? Fun for a youngster yet unimaginative. Or, drive a nail in the door to improvise a hat peg? That's a more intelligent thing to do. Or, drive \(\overline{\text { dozens }}\) of. pegs? The boy who does this runs pur of ideas.before he runs ut of nails. But what ábout the highly imaginative boy? He drives his hat peg nails into the. door up to their heads so that their points stick out on the other side. Why, don't you see? Take the door off its hinges -- and there's a fakir's bed of nails: Not every Tom, Dick, or Harry would think of that. It takes imagination. What's that you say? A crazy idea. Come to think of it that's just what a lot. of physicists at first said about Einstein's 1905 space-time transformation paper.

Einstein"saw what contemporary mathematical physicists failed to see; he
saw how to "get busy". He'did what his contemporaries failed to do; he used matrices with bold Ḯmagination."
4.14

Important Consequences
Equations (1) and (2), (page \(\left.{ }^{144}\right)^{2}\) are the basis of Einstein's Special Theory of Relativity. We may or may not be disposed " \({ }^{+} \dot{\circ}\) accept them. But whether or y not we like it; the fact remains \({ }^{\prime}\), that these are necessarily consequences of the invariance of the velocity of light.

In this, the final section, we shall consider three major consequences of these equations, consequences that shatter our complacency. To accept the basis of the Special Theory of Relativity without accepting its consequences is flog-, ital. If we are willing to accept the evidence of the Michelson-Morley expertmont; we should \(1 \mathbf{k e w i s e}\) treat its logical consequences. .
(a) Faster astronauts age more slowly.
,We return to the railway track again. Suppose that \(S_{0}\) sees the tree, by the track momentarily made visible by the flash of light from his lantern at 12:01 by his watch, ie., when \(t=12: 01\). Does \(M_{0}\) see it before or after . . \(S_{0}\) ? Remember that they synchronized their watches when \(M_{0}\) was at \(S_{0}\) : In other words, is \(\overline{=}\) less than or greater than \(t\) ?

Since \(S_{0}\) remains at the "origin of his system \(x=0\), so that (2) becomes
\[
\begin{equation*}
\bar{t}=\frac{t}{\sqrt{1-\frac{v^{2}}{c^{2}}}} \tag{1}
\end{equation*}
\]

And since the velocity of the train \(v\) is, of course, \(>0\),

Therefore \(M_{0}\) describes the event that the tree was momentarily visible as occurring later:- Suppose, to be definite y \({ }^{M} 0\) says that the event occurred at

12:02. 'What does \(S_{0}\) conclude? He says, on the basis of the event, timedtby his watch as happening at 12:01 and timed by the moving watch as not. taking place until lej: 02 , that the moving watch runs fast and that events as described. by the moving man lag behind the same events as described by himself.

Although equations (1) and.(2) are simple, their physical application is - 䋉
most difficult; it makes no concession to mudde-headedness. We must be clear that \(\bar{t}\) is the time recorded by a watch that moves relative to a watch that records time t. (1) may be expressed
\[
\text { moving clock time }=\frac{\text { stationary clock time }}{\sqrt{1-\frac{v^{2}}{c^{2}}}}
\]
and ('2)
moving clock time \(>\) stationary clock time.
Suppose the station master has a stop watch whose hand makes a full turn in' one second. The motorman would think that the stop watch is slow because in his, opinion the time \(\overline{\mathrm{t}}\) for such a turn is more than a second. But suppose he is given an identical stop watch. Then he will now say that his own stop watheh is correct and that its hand makes one turn per second. However, the station master looking in will conclude that the engineer's stop watch is slow, since he moves relative to the train and now his time scale is increased. Thus, the total consequence of ( \(2^{1}\) ) is as follows. A process of physics which would take at rest an amount of time \(t\) appears to an observer moving relative to it à longer. If you ask, therefore, who of two obseryers is more justified in ascribing time to a given physical phenomenon, we should say that that observer will have the better judgment who rests relative to the apparatus or phenomenon which is to be jụdged.

Equations (1') and (2') have most important fonsequences for space travel at velocities near that of light.

We now suppose \(M_{0}\) to 'be an astronaut heading straight for a distant star \(\therefore\) from the earth at " \(\mathrm{S}_{0}\). When he is hurting through outer space with velocith v ,
his clock, which measures time \(\bar{t}\), is at rest relative to him; and the 'tarestia clock, which measures time \(t\), is moving relativeato him. This is the crucial point: In \(M_{0}^{\prime}\) s experience, \(\bar{t}\) is his local or stationary clock time, \(t\) is terrestrial or moving clock time. And since he moves at velocity \(v\) relafive to the earth, the earth moves at -v . relative to him. But \((-\mathrm{v})^{2}=\mathrm{v}^{2}\), so that by ( \(1^{\prime}\) ), for "M
\[
\begin{equation*}
t^{\prime}=\frac{. \bar{t}}{\sqrt{1-\frac{v^{2}}{c^{2}}}} \tag{*}
\end{equation*}
\]
ie.,
\[
\begin{aligned}
& \text { terrestrial clock time }=\frac{M_{0}^{\prime} \mathrm{s} \text { time }}{\sqrt{\leftarrow}} \\
& \quad . \quad .
\end{aligned}
\]
ration with easy arithmetic, that \(M_{0}\) travels with \(\sqrt{\frac{99}{100}}\), the velocity of light. With \(v=\sqrt{\frac{99}{100}} \mathrm{c}, \frac{\mathrm{v}^{2}}{\mathrm{c}^{2}}=\frac{99}{100}\) so that
\[
\sqrt{1-\frac{\stackrel{v}{v}^{2}}{c^{2}}}=\sqrt{1-\frac{99}{100}}=\sqrt{\frac{1}{100}}=\frac{1}{10}
\]
and
\[
t=\frac{\bar{t}}{\frac{1}{10}}
\]
ie.,
\[
, \stackrel{\bar{t}}{ }=\frac{1}{10} t .
\]

Thus the duration of \(M_{0}\) 's experience in traveling from the earth to a distant . star at a velocity of \(\bar{j} \sqrt{\frac{99}{100}} \cdot \mathrm{c}\) is only one tenth that of the terrestrial observert's experience.

Suppose that according to \(S_{0}\) 's watch \(M_{0}\) takes 200 years to reach the distant star. Had \(M_{0}\). set out at the age of 25 , his body would be \(225 \cdots\) years old when herreachef his destination. Surely he would have arrived a corpse:No, \(t=200\) years is the duration of the flight in the experience of \(s_{0}\) and his descendants, the people who stay at home. \(M_{0}\), the man who goes, lives his
experience in his own time \(\bar{t}\), that of the watch he takes with him: Whes \(t=200, \bar{t}=\frac{1}{10} \cdot 200=20 . M_{0}\) will bé \(45^{2}\) years old, not 225 , when he, reaches his destination.

That the faster an astronaut travels the more slowly he eges gives us hope of men living long enough to visit the stars, all way out beyond the solar system. Yet you may, be disposed to retort: Súch subt,le arguments are good, clean fun, but would any hard-headed astronaut be prepared to set. out on a 200 year journey because it had been argued by a few longí-haired professors that he would be only 20 years older when he got there? Not very likely. If I tear a page off my desk calendar and call today the first of September instead of the first of August, it doesn't make me any older physically. Next you will. be telling me, that if \(I\) forget to wind my watch, then- \(I^{\prime} l l\). stop aging when it stops -- and live forever!
* No, the pgint is that each physical phenomenon runs its natural course.in the system in which it rests, and lifo is a physical phenomenon. The moving astronaut lives his regular life inhis'space capsule: He does not have any benefit from the fact that an observer on a different system (which moves with very high speed relative to him) thinks that he lives very much longer. At this moment there are many galaxies which move relative to the earth with fantastic speed, nearly the velocity of light. If there were'in such a galaxy a star with intelligent observers, they would think that we humans are practically immortal. This does not do us much good. However, for such purposes this différience in aging is a great use. While according to our'system of accounting, an astronaut might 'need 200 years to. reach a distant object; in his time scale he would need only 20 years and thus be able to survive his trip.

You may be quite bewildered and upset by our argument. But remember that your expérience in life has been in systems of very slow motion, and there \({ }^{\circ}\) is nothing which could prepare your imagination to experiences of high speed travel in outer space. Wherever, experfence.fails us, insight and intultion will fall ince. air bnly guide is our reason strengthened by mathematical argument, \(15 l^{\prime}\),
ERIC,

We might be prong in our extrapolations, but until now the predictions of science have been more frequently verified than falsified.
) Do you know what a radioactive substance is? It consists of a large numbbert, of atoms, of which, during a given period, a certain percentage disintegrates or dies. Uranium atoms, then placed in a cyclotron, are made to travel at nearly the velocity of light-- just as we suppose \(M_{0}\) to do. It is found that uranium subjected to such cyclotron experience decays much more' slowly than uranium subjected to ordinary terrestrial experience. Here is Evidence in favor of Eint stein's time contraction formula. And isn't our aging, a physiological process whose rate is that at which tissue and that, sort of thing decay?
(2) No traveling faster than light.

Using (1) and (2), we divide \(\bar{x}\) by \(\bar{t}\). This is annie thing to do for it eliminates the square root.
\[
\frac{\cdot \bar{x}}{\bar{t}}=\frac{x-v t}{t-\frac{v x}{c^{2}}}=\frac{\frac{x}{t}-v}{c^{1-\frac{v}{c}} \cdot \frac{x}{t}} \cdot
\]

The algebra is very easy; the physical interpretation -- without which the algerbra is pointless -- not quite so obvious.

Once again we return to our railway tracy. A passenger, \(p\), traveling without a ticket, is, for reasons best'known ta himself, running along the train (att. uniform velocity) from \(M_{0}\), where he was when \(M_{0}\) passed \(S_{0}\). See Fig. 14.

Since \(P\) has' coordinates \((\bar{x}, \bar{t})\) on the train, he has moved distance \(\bar{x}\) relarive, to \(M_{0}\) in time \(\bar{t}\). Accordingly, \(M_{0}\) says that: \(P^{\prime} s\) velocity is \(\frac{\bar{x}}{\bar{t}}\). And since \(P\) has coordinates ( \(x, t\) ) relative to \(S_{0} S_{0}\) says that \(p\) has moved distance \(x\) in time \(t\) and that therefore 152 velocity is \(\frac{x}{t}\). For

This function is a kind of generalized sum, of, \(u\) and \(v\). It satisfiès the commutative and associative laws of ađdition:

If \(u\), and \(v\) are eaph less than \(f\), the same will be true for this sum velocity. An experimental verification for this law of addition of velocities can be found in an experiment by Fizeau which was., in fact, performed before, the theory of relativity was even formulated. As you probably know, the yelocity of light in water \(u\) is slightly lower than the velocity of light in empty space \(c\). Suppose now that we send a ray of light through a body of water whioh moves Zfself in the direction of the ray with the velocity \(v\). According to classical physics, the total elocity of the light ray should be \(u+v\) since the ray \({ }_{2}\) runs through the water with speed \(u\), and the whole arrangement is carried forward with the velocity v. Fizeau carried out a very precise measuremerit of the velocity of such a ray in a moving medium. - But to his surprise he discovered the following fact. The velocity of the light in the moving fluid was
\[
\begin{equation*}
\bar{u}=u+v\left(1-\frac{\dot{u}^{2}}{c^{2}}\right) \tag{6}
\end{equation*}
\]

Again, \(u\) is the velocity of light in the water and \(v\) is the stream velocity. - of the water.

Consider now the addition law (4). Observe that the flow'velocity \(\vec{v}^{\prime}\) is very small compared to the velocity of light c. Hence \(\frac{\text { uv }}{2}\) is a very smáll manber. We may use the geometric series formula to write
\[
\frac{1}{1+\frac{u v}{c^{2}}}=1-\frac{\frac{u v}{c^{2}}}{c^{2}}+\left(\frac{u v}{c^{2}}\right)^{2}-\left(\frac{u v}{c^{2}}\right)^{3} \mp \ldots .
\]

We commit a" very smali error if we put
\[
\frac{I}{1+\frac{u v}{c^{2}}} \approx i-\frac{\frac{\mu v}{c^{2}} .}{}
\]

Observe that with the approximation the addition law (4) becomes the formula (6) established by Fizeau. The error due to our approximation is so small that the
experimenter could not possibly observe it.' Thus, Fizeau's formula is a brilliant justification for the addition law (4) of velocities.

But now we should, add a remark which shows particularly well the great power of mathematical theory. Suppose a good mathematician had heard of Fizeau's experiment and of hisfformula (6) but had never heard of relativity theory and of the law (4) of addition of velocities. He might logk at (6) and muse about
~ its meaning. It is something like an addition law for \(u\) and \(v\), but it does not satisfy the commutative and associative laws (5). The mathematician might sispect that (6) is only approximately true and is a good approximation to an addition law, \(f(u, v)\) in the case of small \(v,{ }^{\text {He might then ask the question: }}\) What is the function \(f(u, v)\) which satisfies (5) and becomes very nearly (6) for small values of \(v ?\) It can be shown that the only possible choice for \(f(u, v)\) is the function (4). Thus, the mathematician could have deduced the correćt law of addition of velocities from an approximate experimental formula. Think this over! You will understand why scientists call mathematics our sixth sense with which to experience neality.
(3) Energy has mass.
\(\ell\)
Funđámentál to the stady ó "even the most etementary dynamics is Newton's, famous law that the force acting on a body is proportional to the mass times the acceleration of the body:s
\[
F=m \cdot a
\]

In consequence, if a given body is acted upon by a constant force, it has á constant acceleration. But, if its acceleration is cosstant, then its' velocity continually increases, so that finally it will gosaster than light, on the other hand, if we accept the well verified Michelson-Morley result that the velocity of light is invariant, we are forced to accept its logical consequencé that nothing can go faster than light: Something must happen to reduce the body's acceleration at high velocities.
A.

To concentrate on the acceleration \(a\), we isolate it by writing Newton's.
law in the form
\[
\frac{\mathrm{F}}{\mathrm{~m}}=\mathrm{a} .
\]

Since a. must decrease for high velocities, so must the ratio \(\frac{F}{m}\). But, by hypothesis, \(F\) is a fixed force, so what do, you conciude? Yes, that for high velocities at least \(m\) must increase as the velocity of the body increases. However, it would be most odd if the increase were not continuous. In consequence, the only explanation Einstein could find is that mas's must increase with velocity. Mass must become progressively harder to push with increasing velocity.

In his famous paper of 1905 Einstein argued that ta the mass of a body at rest \(m_{0}\) must be added the energy, \(E\) of the body times \(\frac{1}{2}\) to give it mass \(m_{v}\), its mass at velocity. \(v\) :
\[
m_{v}=m_{0} * \frac{E}{c^{2}}
\]

But the difference between masses \(m_{0}\) and \(m_{y}\) is surely a mass, so that energy itself must be transformable into mass:
\[
\rho \dot{E}=-m \dot{c}^{2}
\]

At that time this was:a fantastic idea. Nobody had ever before thought - that mass and energy "could be eggs out of the same basket. Energy is mass in motion mass itself is something that can be weighed, static, on a pair of scales. Surely energy is not the sort of stuff which can be weighed? Even in . 1905 when Einstein was startled by, his own idea he suggested that.a study of . - radioactive substances -- where tremendous renergies are hidden -r would very possibly show that energy can be transformed into mass and mass into energy. Forty, years later, in 1945, this was all too dramatically verified; his thesis that, \(E=m c^{2}\) was the basis of calcutation for the atomic bomb as well as for atomic power.

\subsection*{4.15 In•Retrospect.}

Given the Michelson-Morley experimental result; "what follows? We now know the more important consequences and the simple mathematics used to deduce them. In particular, 'we have seen what can be done with matrices when used with bold imagination. Of course, what was done elegantly with matrices could have been done inelegantly without them; but, who wants to drive nails with stones? Yet never forget that it is the man who handles the hammer that counts. Such simple mathematics enabled Einstein to change our entire conception of the physical world and to make prediction, forty years in advance, that heralded new master of our world. This is an example of the power and the glory of mathematiss -- and the genius of Einstein.
