ABSTRACT

In redesigning the data program of the National Center for Education Statistics (NCES), there is a need for standard definitions, constant vigilance against redundancy and excessive data collection, audits and verification on local school data and continued attention to equity results as well as excellence and achievement. Major test scores, such as those obtained from the American College Testing Program and the Scholastic Aptitude Test should not be used to compare and contrast state achievement, since these tests were not designed for that purpose. The limits of the test instruments should appear in publications dealing with results of such tests. The following principles are suggested to guide NCES in data collection activity: (1) the data should be useful to federal, state and local policymakers or decision-makers; (2) the amount of data and number indicators should be limited to that which can be stored and analyzed within three months and reported to policymakers within the year; and (3) data should be drawn from sample rather than total populations. The National Assessment of Educational Progress is federally funded, and one option for including state assessments is to add funds to the contract. Two of the major concerns would be: (1) the cost of the expanded survey; and (2) timeliness of the reports. (JAZ)

TO THE EDUCATIONAL RESOURCES INFORMATION CENTER (ERIC)"

Introduction

The National Center for Education Statistics plays an important role for the federal government -- collecting statistics useful for local, state and federal decision-making about education. I am pleased to join the discussion of how a redesign of NCES' data program will enhance opportunities to collect productive information and, further, promote innovative strategies for distribution, use and analysis. As my comments will illustrate, I support a simplified sampling system of educational attainment. The U.S. needs standard definitions, constant vigilance against redundancy and excessive data collection, audits and verification on local school data, and continued attention to equity results as well as excellence and achievement.

During the 1960's, I was one of several Harvard University professors of educational administration objecting to the position taken by the American Association of School Administrators to oppose national assessment and any suggestion of testing or federal action to find out what children had learned. After some discussion, AASA agreed to a compromise whereby a neutral state-oriented group, the Education Commission of the States, would conduct the national assessment of educational policy. Neither state nor local school districts would be identified in any report.

Less than twenty years later, the governors and legislatures of most states insist on knowing how well the educational system is performing with results available by school district and often by school building.

TM 860 457

As the education officer in one Governor's cabinet and the chief state school officer in another state, I grew very dissatisfied with existing national education data and data collection formats. I remain very critical of the use by top U.S. officials -- including the President and Secretary -- of SAT and ACT results which cannot and should not be used to evaluate state achievement when the tests were intended only to predict college success for individuals. The SAT scores have been made the Dow Jones indicator of educational achievement. This is the wrong scoreboard and inappropriate information to use to compare and contrast states.

Fortunately, the Department of Education has begun to search for other indicators-- the NAEP, as well as longitudinal studies on high school graduates, and other state level data. This is a positive trend.

The Growing Demand for Educational Indicators

For the last twenty-five years, the American public supported increased public expenditures for more comprehensive educational and health services -- especially for those who lacked access to quality schools, clinics and hospitals.

Neither educators nor medical administrators, however, felt obligated to compile or release to the public any systematic data about the accomplishments and failures of their institutions. Now the public wants to know, employers need to know, and government is under an obligation to collect and present these data in understandable and responsible formats.

Recently, the U.S. Department of Health and Human Services National Health Council voted to require every hospital to produce a profile of statistics which would be available to Medicare patients and the general public. Among the more compelling statistics would be the number of persons who die each year in each department of the hospital and from what ailment. Information on costs, admissions practices, length of stay, quality of staff, and a review of facilities are indeed vital statistics for hospital service consumers. Information on deaths per doctor will not be available due in part to very strong objections from the American Medical Association. Taxpayers and people seeking medical services will have considerable information due to this "truth in healing" policy and the help of professional review organizations which will monitor the hospitals.

Concurrently, an industrial location advisory service called FANTUS regularly informs companies looking for a new facility about the quality of state and local educational systems. An employer must know the literacy level of the local workforce from which new workers will be recruited. Also, employees with families transferred to the new site want to know the answer to the queries, "How good are the schools?" and "Where are the best schools?" FANTUS collects and summarizes all the available data on school size, costs, achievement, and other potentially significant indicators of quality, including the numbers of graduates going to college.

Thirty-six states have required local schools to systematically test school achievement for various reasons including grade to grade promotion and graduation from high school. New York State requires a series of tests of pupil performance evaluations well in advance of the Regents exams for college-bound students.

The Limits on SAT/ACT Data

The President of the United States and NCES ought not to try to make SAT (or ACT) scores the basis for state-by-state comparisons for these reasons:

1. The Scholastic Aptitude Test is not a test of commonly taught or needed skills. The verbal test is a cluster of reading comprehension paragraphs (commonly required skill) and a test of abilities to recognize antonyms and find analogies (which are much less commonly used in classrooms, in writing, or in life). The SAT scores, when compiled with high school grades and rank in class, do appear to predict success in college courses Freshman year. They do not purport to measure achievement in a variety of skills or subjects.
2. The SAT yields only verbal and math scores. It does not, even in the verbal segment, measure writing, speaking or listening skills. The math is somewhat more comprehensive but there are separate College Board achievement tests in algebra, geometry, calculus, and computer sciences beyond what the SAT test tries to measure. In addition, the SAT does not evaluate aptitude in science, foreign language, history, health and other important subjects or skill clusters.

3. A different percentage of high school students take the test in each state. For example, two out of three students in Connecticut (63 percent) take the SAT exams; only one in three Texas students (33 percent) take the test. These variations make comparisons, let alone rankings of the state or conclusions about quality, impossible. The tests were designed to make judgments about each student, not their local schools and certainly not state school systems.

4. State SAT scores, which are now ranked, ignore the demographic composition of each state. For example, New Hampshire, with high student scores on the SAT's, has one of the lowest number of minority students in the nation. The 1.3 percent minority are mainly associated with the air base at Portsmouth where the median education level for minority parents in the service is actually greater than that of the white adult population of New Hampshire. Also, the percentage of handicapped students of New Hampshire is only three-fifths that of Massachusetts or New York. New Hampshire has no large cities, few minorities, and fewer than average handicapped. This may explain why, despite higher than average teacher-pupil ratios and low state support for schools, New Hampshire schools and academies produce comparatively high scores. State SAT scores for New Hampshire include not only local public high schools but large national college prep schools such as St. Paul's School (Concord) and Phillips Exeter Academy, almost all of whose students take and often score very high on the SAT test.

The SAT was never designed to test statewide goals or provide state-by-state data. What is unacceptable is for the President of the United States to set state target scores on either the ACT or SAT aptitude tests since they are not achievement tests at all but specialized problem-solving measures useful for college admissions decisions.

The "Performance Outcome" section of the State Education Statistics (January, 1985) prepared by the Department of Education planning and evaluation service should be discontinued. Let the College Board (and ACT) release trend data as they do each September with the full notes about cautious interpretation. Cancel the publication of a simplistic Department of Education wall chart that does not suggest the limits of the test instrument, and which invites spurious comparison of unlike scores by the states. This chart serves poorly both college admission and national assessment movement.

What Should NCES Collect and Report?

NCES wisely has begun the search for alternative indicators, has asked dozens of researchers and organizations for advice, and issued contracts to at least one university evaluation center. This extensive consultation is prudent and the ideas produced should be useful.

I would like to suggest certain principles to guide data collection activity:

1. The data should be useful to federal, state and local policymakers or decision-makers. Much of educational research and assessment does not immediately suggest or lead to the development of a course of action. However, data on dropouts, bilingual education graduates, college-bound or job-bound students by occupation is very useful.
2. The amount of data and number indicators should be limited to that which can be stored and analyzed within three months and reported to policymakers within the year. Local and state school systems report much data to the federal government each year already that is stored but not summarized or used for other than formal report compliance purposes.
3. Data should be drawn from sample rather than total populations. The information ordinarily will be just as useful and the cost of data collection, especially to local educators, will be dramatically reduced.

Other analysts/contributors of advice to NIE will explain how the state of testing can now produce unlimited analyses of pupil performance on a thousand measures. But these important questions should be asked: Who needs it? Who will use it? For what purposes? These are deliberately hard questions, and they should be raised repeatedly about the entire program of data collection.

The state profiles and "National Report Card" should reflect a consensus among state level educators as well as educational philosophers, psychologists and psychometricians about what is worth knowing about the schools. State agency

data collectors already have a strong sense of what information now is not used, or used very little or erroneously. Heed their advice. They, each and all, collect many reams of reports and tapes from local schools; they know the costs and can suggest which, if any, are beneficial.

What would be useful for policymakers to know is student achievement in grades 4, 8, and 11 or 12 in these subject skills:

- Reading
- Writing - not proofreading but a composition test
- Computation
- Computer Skills - from keyboard to programming
- Listening
- Foreign Language
- Physical Education and Fitness
- Music
- Art appreciation
- Personal health and safety
- History and government
- Citizenship

Also, it is important to know these indicators on a state by state basis:

- College (or postsecondary) intentions, and actual enrollment
- Job placement, including Military
- Dropout rates - by age and grade (with a common definition)
- Handicapped student enrollment
- Bilingual student enrollment, and length of time in a program.

The Secretary's report on excellence, A Nation At Risk, emphasized the "new basics" which were really the traditional academic subjects of reading, writing, mathematics, science, and only one "new" secondary school subject -- computer studies.

The Secretary's recommendations on the curriculum were too limited. For several decades, the Council on Basic Education has included art, music and foreign languages (all very traditional subjects associated with the cultivated, civilized, well-educated person) in their definition of basic history. NAEP included these subjects in the early assessments. The College Board and the New York Board of Regents provides achievement tests in those areas. So should any rigorous, systematic, national evaluation of education in the United States.

One caveat about computers. Technology may be a more appropriate topic. Ernest Boyer, in his volume High School, points out the limits to teaching skills or computer languages that may be obsolete in five years. More so, he suggests that the study of machines, of systems, of the history and limits of technology is of more enduring importance. If so, work might properly begin on the outline of an evaluation strategy for the 1990's in a world of fibre optics, laser technology, artificial intelligence, and genetic engineering in which computers play a major role but not the only one worthy of systematic study.

Finally, NAEP in the early years measured the educational attainment of young adults (early 1920's). Since some youth complete high school at night or during their military service, these data are part of the full picture and should be once again collected and analyzed.

Relevance, Quality and Utility of Data Collection Activities

Usually, the federal government collects data by preparing survey instruments which are screened by one or more committees and then sent out to local schools, often by a state education agency whose staff helps to administer and monitor federal education programs. This is typically the way information is collected on vocational education, handicapped education programs, Chapter One basic skill programs, food and nutrition programs, and other services where the state and local responsibilities are shared.

On several occasions, the task of data collection and analysis has been assigned to a contractor or center -- as illustrated by the use, first, of the Education Commission of the States, and now, Educational Testing Service for the National

Assessment of Educational Progress. Also, the analysis of graduating seniors and their subsequent decisions was contracted to the National Opinion Research Center. These are, for the most part, appropriate alternatives to surveying state and local school systems directly for data on educational achievement and family decisions.

The direct burden on local school systems to produce reports is much heavier than either researchers or federal program administrators realize. The U.S. has thousands of school districts with a few schools and a very small central office consisting of a superintendent and secretary, possibly a business manager. Weeks of work go into the preparation of periodic reports.

As a chief state school officer, I began to realize that local school officials tended to blame the state since the survey forms and envelopes indicated the forms, with few exceptions, must be returned to the state education agency. This makes sense because each state needs the information, and states, not the federal government, have the constitutional requirement to keep track of local school resources and activities. But, as I argued in an article entitled "The Federal Takeover of Education," the federal government puts up 5-10 percent of the funds and accounts for 50 percent of the data requests of local schools. Data on handicapped children and programs on vocational education are among the most complex, voluminous and time-consuming surveys to complete.

Since leaving the state education office, I have learned that local educators on occasion will meet a deadline by estimating the number of students served by a program. Rarely would anyone deliberately falsify statistics, even if the flow of dollars depended on a certain number. But the time and level of detail is difficult for small and medium-sized school districts and cumbersome for the large districts.

Other issues of technical quality relate to definitions. Student dropout rates are defined differently by the several states. It cannot be assumed that the reported numbers carry the same meaning from state to state. A technical task force of federal and state educators should compile all of the definitions, point out the contradictions and anomalies, and propose a consensus position for the state boards, chief state school officers and NCES to adopt.

Also, the federal government must convene a group which would standardize the definition of handicapped terms. At present, the same words carry different meanings in these agencies: Office of Civil Rights, Vocational Education, NCES, Handicapped Education, Health and Human Services, and Bilingual Education (which has a legitimate need to know how many students are both bilingual and handicapped). A few states, such as Massachusetts, have legislated the abolition of handicapped labels which tend to stigmatize, denigrate and to reduce teacher expectations.

However, certain federal bureaus and offices use outmoded or differing classification terms which make tabulation, comparison, and analysis quite difficult.

The issues summarized above can be addressed by these approaches:

1. Use of large and reputable data collection and analysis services for complex, longitudinal and analytical work on achievement and effects of educators;
2. Periodic verification of local and state data as reported on survey forms;
3. Annual reviews of data reduction options and possible redundancies;
4. A task force to review definitions of educational conditions, e.g., dropouts and handicapped;
5. An effort to obtain a uniform federal definition of handicapped services and programs.

Data Series Important to Administrators

In my tenure as a state superintendent, I needed to be informed about pupil enrollment trends, school closings, consolidations, and emerging shortages of teachers and, eventually, of facilities.

The data series on enrollments, school completions, percent in non-public school, length of school term, transportation trends, average attendance - these are bread and butter statistics needed to confirm or confront the conventional wisdom about school needs and trends.

For example, legislators suggest that if school enrollment is declining no new funds are needed. Yet, all over America, class sizes are dropping and costs of education rising. These are important trends for education advocates and legislative analysts to consider.

Data on race and linguistic background are important to administrators of bilingual programs and of intergroup or intercultural education.

At the college level, the information on earned degrees, placements and salaries are important to institutional planners and statewide coordinators of higher education programs.

Information on tuition, fees, and scholarship awards are much too skimpy given the importance of federal and state grant and loan programs. The Congress in 1980 found great gaps in knowledge about these higher education aid programs (which consume \$7 billion dollars or almost half of the federal education budget and some funds from other agencies and departments). Subsequently, Congress created a National Commission on Student Financial Assistance to conduct studies and collect data which NIE/NCES might have reported. Data on grant recipients, their income levels, their race and sex, their completion rates, default rates - all of these are important to Congress and to the states. NCES can begin by reviewing the questions assigned to the National Commission and the reports filed by Commission staff and consultants, many of which should be collected at least on a biennial basis.

On the whole, this commentator believes that the NCES data series on finance and administration fills important information gaps about the resources made available to education and educators.

Other Measures of Educational Productivity

What data should be collected other than achievement data, test scores, the percentage passing courses or graduating from high school or college?

Considerations for the 1990's include:

1. The number of youth who participated in community service programs, required or voluntary, should be tabulated. The Carnegie Foundation for the Advancement of Teaching has advanced this proposal which some high schools have

adopted. This 120 hour requirement becomes a new "Carnegie Unit" and since NCES maintains the scorecard, it is important to add this tally of community service/ citizenship education requirements.

2. The amount of extra or co-curricular activities offered by U.S. high schools and the rate of student participation. For fifty years the textbooks on school leadership have agreed that students learn from student council service, from debate club, band or chorus, basketball and soccer, future teachers or farmers, and other school activities
3. The numbers of handicapped students who have been served in programs (such as those funded by 94-142) and who have:
 - a. been mainstreamed, sent to less restrictive alternatives,
 - b. graduated into either vocational or college preparatory programs,
 - c. become gainfully employed or enrolled in college.

Now, one way to accomplish this is to engage in annual surveys. The other technique, potentially even more useful, is the periodic study of "high school and beyond," the systematic sampling of school graduates and their subsequent decisions about careers and continuing education.

The same approach pertains to bilingual education where federal and state policy-makers need to know the answers to these questions:

- a. How many bilingual students remain in school and graduate?
- b. How many graduate from transitional bilingual education classes or programs?
- c. What is the level of linguistic competence, both in English and in another language, of those who participate in bilingual programs for one school year or more?

Data Collection Strategies

A strong argument has been advanced for broadening the role of the National Assessment of Educational Progress to include state assessments as well. NAEP for several years has offered such a service to state education agencies. Several states, including Minnesota and Connecticut, have made extensive use of the data collection format and many other states have obtained test items or subsections of the NAEP instruments.

NAEP is federally funded, and one option is to add funds to the contract to enable all states to be included. Two of the major concerns will be:

1. The cost of this expanded survey, especially if NAEP requires the hiring of local test administrators as is the current practice, and
2. Timeliness of the reports, especially in more complicated assessments such as on writing skills.

The issues of cost and timeliness will be important ones to address. If assessment is too labor-intensive and costly, then inevitably some components important to civilization such as art and music or citizenship education will be eliminated.

Also, a report is useful to decision-makers if results are available within six to ten weeks -- such as the College Board and ETS can provide to college admissions officials. According to some long-term participants in NCES and state education decision-making, the NAEP state survey data can take a year or more to analyze and report. A more timely analysis would presumably cost more money.

Does NAEP need to cost more money to obtain state results? Three tasks must be undertaken:

1. Legislators and chief state school officers should comment on the usefulness of the information produced by NAEP. Which findings or results are merely

interesting, and which provide data and analyses on which local and state decision-makers can act?

2. State education agency staff should be asked whether NAEP should hire and assign test administrators for each local assessment site. In carrying out an assessment (an inventory of their educational progress), Illinois found that the expensive practice of assigning an assessment administrator was unnecessary. Illinois assessment results without the local assessment administrators were not significantly different.
3. The speed of analysis and reporting must be timed to a decision-making cycle, to the planning/budgeting cycles of states (which vary) or to either a federal reauthorization or budget. Data must be current -- which is one reason why the annual SAT score reports attract so much attention.

If not NAEP, there remains the alternative of asking the larger state agencies to agree on common achievement data collection or at least a common core of testing and evaluation activity. The Council of Chief State School Officers has begun this work and NCES/Department of Education should strongly support this effort. It is quite possible that assessment activity by a coalition of state educational agencies can be more cost-effective, more useful and more comprehensive than NAEP at present.

This argues against an early decision (1986) on a single ten-year format for state-by-state assessments. The Department has already made serious errors in publishing state SAT and ACT scores. The Department should consult with state-based groups, especially the legislators and chiefs and state boards of education. States do respond to incentives, to capacity-building grants, and to cost-sharing programs. The state appetite for assessment data has grown enormously in the 1980's, well ahead of any scientific consensus on how to evaluate education sensitively and thoroughly. This is an example of how federalism can work, a sharing of state and national resources.

What seems highly desirable is an agreement to use the energy and commitment of the Council of Chief State School Officers to agree on common indicators of educational progress. Such a consultation should include the tests of comprehensiveness, cost-effectiveness, and usefulness to state as well as federal policymakers.
