ABSTRACT
        In 1990, a study was conducted at Illinois Central
College (ICC) to identify pre- and post-enrollment variables that
could serve as predictors of student persistence and to compare
persistence between vocational and academic program students. From a
population of 656 Applied Science students and 671 Arts and Science
students who were first-time, full-time, degree-seeking enrollees in
fall 1987, a random sample of 75 students was selected from each
group. Students were classified as persisters if, by fall 1989, they
had graduated, had requested a transcript sent to a four-year
institution, or were still enrolled. Pre-enrollment variables
included age, gender, race, American College Testing Program (ACT)
score, high school rank and class size, and stated educational goal.
Post-enrollment data were obtained from student transcripts.
Additionally, a telephone survey of persisters examined self-reported
success factors. Study findings included the following: (1) no
significant difference was found in persistence rates of vocational
and academic program students; (2) among pre-enrollment vari bles,
only ACT scores, student age, and high school percentile were found
to be significantly related to student persistence; (3) grade point
average and course withdrawal rates were the only significant
post-enrollment variables; (4) students surveyed indicated that
teachers were the institutional factor most important to their
success, while family was the most important personal factor,
followed by work, money and transportation. The survey instrument,
tabulated survey results, and a 30-item bibliography are included.

Introduction

Student retention has been a much studied phenomenon at the
secondary and post-secondary levels. With the recent, growing emphasis
on accountability and student outcomes, renewed interest exists at
post-secondary institutions in improving student retention rates. This
interest in accountability is evidenced by policy makers in
Springfield, as well as by administrators at Illinois Central College.

In September 1989, the Illinois Board of Higher Education (IBHE)
released two studies of student retention in September of 1989. Their
first report, Retention_and_Graduation_Patterns_at_Illinois_Public
Universities_ (IBHE, 1989a), is an analysis of retention and graduation
patterns at public universities which went beyond the previous campus
based studies By incorporating current database techniques, it traced
freshman students enrolled in 1980 through all 4-year degree
institutions for a period of 8 years. The study found that 54% of
freshman enrolled at state universities had graduated within 8 years.
In addressing student retention at the community college, a second
report, Improvement_of_Minority_Student_Baccalaureate_Achievement
Through_Transfer (IBHE, 1989b) described the status of student transfer
from associate to baccalaureate degree-granting institutions in
Illinois, with particular emphasis on the transfer of minority
students. This report found that during fiscal year 1988, 21.6% of the
students in Illinois community colleges were enrolled in transfer
programs and that only 8% of those students received transfer associate
degrees. The media has also placed attention on the transfer rates of
community college students. The Chicago_Sun_Times (November 12, 1989)

6

featured a series in November, 1989 which discussed the transfer rate of community college students and claimed that only 10% of community college students who intend to transfer do so.

The transfer function of the community college is not the only segment which has been under criticism. The National Assessment of Vocational Education (NAVE) used the High School & Beyond (HS&B) 1980 seniors and the National Longitudinal Study of the class of 1972 to follow student program completion (NAVE, 1989). The results of this study found that 17.1% of the HS class of 1980 who had entered the community colleges had received associate degrees in community colleges, while 23% of the high school class of 1972 completed the desired program. In both studies some students had transferred to other institutions while others were still enrolled in the first school entered. The departure rates, i.e. leaving without a degree or certificate, were 42% for the HS class of 1980 and 30% for the class of 1972. The study found no differences between students enrolled in academic and vocational-technical programs. Academic students were defined to be students pursuing two-year transfer degrees and vocational-technical students were those students who are pursuing terminal vocationally oriented degrees.

Problem Statement

This renewed concern about student retention has caused the administrators at Illinois Central College to investigate whether differences exist in the persistence rates of academic and vocational students. While there are several definitions for "persistence" for students attending a community college, in this study a student is

defined to be persistent if he or she transfers to a 4-year institution
and/or completes an associate degree. The college administrators also
need to understand the changing demographics of the student population
enrolling at ICC and how demographic factors, such as age and race, are
associated with predicting success or failure at ICC. Knowing which
factors predict persistences may assist administrators in determining
the programs and services that should be instituted to help students
who are likely to fail. A third topic of interest is which factors
predict persistence once the student enrolls at the institution. A
related concern of the college was knowing exactly what institutional
factors students found helped and hindered them in progressing towards
a degree. This information would be helpful in marketing the strengths
of the college to potential students and strengthening its programs and
support services for students currently enrolled.

Research Questions

To address the above concerns the following research questions
are addressed in this paper:

Question 1. Does the persistence rate of vocational students (i.e:
those pursuing applied science degrees) differ from that of academic
students (i.e. those pursuing arts and science degrees)?

Question 2. What pre-enrollment factors can be identified
as predictors of persistence?

Question 3. What post-enrollment factors can be identified
as predictors of persistence?

Definition of Terms

For the purpose of this paper the following definitions describe

the classifications for students examined in this study.

Graduate: student who received an applied science (AS) or an arts
and science (AAS) associate degree

Transfer: student who indicated transfer by requesting a
transcript be sent to a 4-year institution but did not graduate

Attendee: student attending Fall 1989

Leaver: student who did not graduate, transfer or was not attending

Persister: graduate, transfer, attendee

Non-persister: leaver

Review of the Literature

This section provides a brief overview of the major studies of
college student retention. It examines their findings (e.g. variables
associated with persistence in college) and research designs.

Predictors_of_Persistence

Astin's 1975 study of student persistence analyzed students from
the 1972 NLS study. In this analysis of students who were seeking
Bachelor's degrees, Astin described persisters as students who had
graduated, were seeking a higher degree than a Bachelor's, or were
still enrolled in college. In this classic study, the term "stop-out"
and "drop-out" were both defined. A stop-out is a student who fails to
attend school for at least one semester and then later returns to the
institution. Astin grouped both voluntary leavers and non-voluntary
leavers together claiming that it is difficult to distinguish between
the groups since some may voluntarily leave due to poor grades and
others may allow grades to drop once the decision to leave is made.

A theoretical model of the factors which affect student

persistence or "departure" was proposed by Bean in 1975. Attempts to verify and refine this classic model have been made by many researchers (Pascarella & Terenzini, 1980; Pascarella & Chapman, 1983; Plascak & Bean, 1988; Webb, 1988; Whitaker, 1987). In Bean's model, institutional fit is a match of the strength of an institution to student needs. Social integration is defined as "finding a social niche in which students share values and support each other through friendship and mutual concern for each other's well being". While Bean's model suggests institutional fit, social integration, and student loyalty as the best predictors of student retention, recent studies involving commuter colleges have found the model quite unsatisfactory (Plascak & Bean, 1988; Webb, 1987; Pascarella, Dubi & Iverson, 1983; Pascarella & Chapman, 1983). These studies have found that factors which are non-predictive for the residential colleges such as gender, race, age, and high school graduation class size, and environmental factors, do predict persistence for commuter students. In particular, external environment, which is defined to be those things over which the college has little control, such as family, health and student jobs, has a direct effect on student retention (Webb, 1988). Intention, the educational goal of the student, is also a predictor of student persistence (Pascarella, Dubi & Iverson, 1983). These community college studies have found that academic integration (e.g. development of proper attitudes towards integrity, delayed gratification and valuing scholarship) is more of a factor in commuter students attrition (Plascak & Bean, 1988; Webb, 1988). GPA is a major contributor to academic integration. Faculty interaction, such as

informal faculty-student contacts can have an effect on this academic
integration which appears to be the strongest predictor (Bean, 1987).
Tinto (1987) in Leaving College states that faculty interaction may be
even more important for marginal students at commuter institutions than
at residential institutions.

A recent model proposed by Pascarella, Dubi and Iverson (1983)
modified Bean's original model by incorporating the findings from
commuter colleges. In this model academic integration provides a direct
effect, with social integration negligible. A copy of this path
analysis model appears in Attachment A.

At the local level, a previous study by Preller (1972) investigated
the differences in persistence at Illinois Central College using the
following variables: gender, ACT, intent, high school percentile rank,
race, and high school size. In this study of the college during the
first four years of its existence, Preller found that the only pre-
enrollment factor which showed significance when using the number of
semesters as a measure of persistence was high school graduation class
size.

Research Designs for Retention Studies

There are three different types of studies of retention: autopsy,
cross-sectional and longitudinal (Bean, 1987). An autopsy model
studies the students after the fact, once the students have left the
institution. While a longitudinal study is certainly the preferred
type, a cross-sectional study can give a description of the students at
a point in time upon which other studies can be built. Although there
exists much research on student retention, typically each institution

has done their own study to fit the particular questions they are

addressing and the available data sources. The results can be used

both as a benchmark to investigate change over time and for other

institutions to use for comparative purposes (Bers, 1988).

Methods and Procedures

Illinois Central College is a large comprehensive community

college located serving a rural-suburban-urban region of central

Illinois. The college has approximately 12,000 students enrolled, with

a full time equivalent enrollment of 5,000 students. As is common in

community colleges, many students attend only on a part-time basis.

Little pre-enrollment data exists for the part time students due to the

application process for part-time students. Therefore, for the purpose

of this study the decision was made to concentrate on full time

students who had at the time of their initial enrollment, the goal of

obtaining a two year associate degree. Full time students who had

fewer than 11 hours were considered as new entering students. College

data tapes of 1986-1989 were reviewed and the Freshman class of Fall,

1987 was selected as the cohort group since two years would have passed

since initial enrollment. This allowed the investigator the

opportunity to determine student graduation rates and to reach students

for follow-up questions.

Sample

From a population of 656 Applied Science students and 671 Arts and

Science students, who enrolled for the first time in Fall 1987 as full

time students, a random sample of 75 students was selected from each

group. This provided an 1% sample from each population. The selection

was done by the investigator using a table of random numbers. A cross-sectional study which would study the students at this moment in time, rather like a snapshot, was selected as the sampling design, with the intention that this study would become the basis for a larger longitudinal study.

Variables

Pre-enrollment data which were available from the data tapes and which had been found to be predictors of student persistence in other studies included: birthdate (i.e. age), gender, race, ACT score, high school rank, high school graduation class size, and intent (e.g. goal). The self-reported variables were race and intent. "Intent", an item scale, included as responses: prepare for new career, improve skills, explore courses, transfer to a 4 year school, remedy basic skills, personal interest, prepare for HS diploma, and other. The post enrollment data was obtained from a review of transcripts. Transcripts of the 150 students in the sample were obtained and the following information was compiled: the number of semester hours enrolled each of 5 semesters and the number of semester hours completed for the first 4 semesters. Enrollment during summer sessions was not included in this study. Also, since there was some thought that withdrawal rates might be a predictor of success, the number of semester hours withdrawn each semester was recorded. Withdrawal rate was defined to be the number of hours from which the student formally withdrew divided by the total number of hours attempted. A grade point code from 0-8 was coded for each semester, with 8 being equivalent to a 4.0. The official ICC definition of full time is being enrolled in 12 or more hours. The

number of semesters that the student attended full time was determined,
with 9 hours or more being selected as full time after the first
semester.   The college requirements for participation on speech and
athletic teams have this 9 hour requirement.   In order to provide for
reliability in the transcript analysis, each transcript was analyzed by
both the investigator and another individual trained in transcript
analysis.   Discrepancies in the data were corrected following
independent reviews of each transcript.

Since 66% of students who transfer from community colleges to 4
year schools in Illinois have not completed an associate's degree
(ICCB, 1984) student transfer was defined in the following manner.
Students who had earned more than 15 credit hours, who had a transcript
sent to a 4-year institution and who were no longer attending ICC were
coded as having transferred.

The intent code variable was redefined using three indicators
appropriate for this study.   The responses of "transfer to a 4-year
school" and "prepare for a new career degree" were determined to be
directly relevant to the study. The limited number of responses in the
other 5 categories were grouped together as "other".   A graduation code
was established as indicated in Table 1.   A persistence code was also
established using a modification of Astin's (1975) definition of
persistence.   Student's were considered to have persisted if they had
graduated, assumed to have transferre', or were still in attendance.

TABLE 1

Study Variables

Pre-enrollment: Post enrollment:

Degree type   Number of hours per semester
    1 Associates Arts and Science   5 semesters
    2 Associates Applied Science   Number of hours withdrawal
Sex (Gender)   per semester
    1 Male   Grade point per semester
    2 Female   0   0.00 - .49
Race   1   0.50 - .99
    1 White   2   1.00 - 1.49
    2 Non-white   3   1.50 - 1.99
Age   4   2.00 - 2.49
    Age in years in 1987   5   2.50 - 2.99
ACT   6   3.00 - 3.49
    Composite ACT score   7   3.50 - 3.99
HSPercentile   8   4.00
    High school graduation   Withdrawal rate
        class percentile   Total hours withdrawn/Total
                    hours
HSSize   Graduation code
    High school graduation class   0 Did not graduate or
      size   transfer
      0   1-99   1 Transferred
      1 100-199   2 Graduated
      2 200-299   Persistence code
      3 300-399   0 Leaver
      4 400-499   1 Graduated, transferred,
      5 500-599   enrolled

    Intent
       0 other
       1 prepare for a new career
       2 transfer to a 4 year school

Statistical Analysis

    The data were analyzed using SPSS X using frequency diagrams,

T-tests, analysis of variance (ANOVA), analysis of covariance (ANCOVA),

scatterplots to determine correlation, regression on pre-enrollment and

post-enrollment variables, and discriminant analysis. A two tailed T-

test was used to answer the first research question- whether there was

a difference in number of semesters attended between AS and AAS

students. An equality of proportions test was used to determine whether

there were differences in persistence rates between AS and AAS

students. Equality of proportion tests were also used to determine

whether there were differences in persistence rates on the variables of

gender, race and intent. ANOVA was used to determine whether mean ACT

scores differed between persisters and non-persisters.

Stepwise regression was used on the pre-enrollment variables of

age, sex, race, intent, ACT, and high school rank to determine which

factors predicted persistence.

Stepwise regression was used on the post-enrollment variables

of GPA and withdrawal rates. Pascarella and Chapman (1983) reported

that student's academic integration is determined primarily by the

student's academic performance. GPA as a measure of academic

integration has been reported earlier to be the major predictor of

success. Withdrawal rate had not been used in any of the literature

and, thus it was a speculative concept as a predictor.

Discriminant analysis was used to determine which variables

distingushed between the three groups: those who had graduated, those

who had transferred and those who had done neither. The dependent

variable was graduation code.

Survey

The quantitative methods above describe the sample but do not

address the question of what qualitative factors might affect student

persistence. To find what factors students thought affected their success in persisting, a telephone survey was developed with the assistance of the Vice-president for Planning and Information Services (Attachment B).

The autopsy approach of asking students who had departed or dropped out to identify the factors that influenced their decision has often resulted in biased responses (Astin, 1975). This technique was cons...ered but not adopted since previously the technique had proven unsuccessful. In a recent report completed for the college by the Director of Advisement and Assessment students were sought who had left the college with GPA's of 0.0. Many students could not be found and no students reported academic failure as a reason (Teal, 1989). The need for students to report a reason which is socially acceptable has been described by both Bean (1987) and Astin (1975).

The decision was made to ask students who were successful what factors helped them to persist. The students from the sample of 150 who either transferred, graduated or were still attending were telephoned to attempt to identify the following: if and where they were in school, if they were employed, whether they were employed in the degree area, and what their current goals were. Also, the survey sought to identify: what institutional variables affected their success, what personal factors aided them, what institutional factors were difficult to overcome, and what personal factors were difficult to overcome. An open-ended question as to what the college could do to assist students was also asked.

The survey was pilot tested with six students who were in the

original population, but not part of the sample. The telephone survey was done by persons other than the investigator to avoid biasing the results as recommended by Graves and Kahn (1979). The telephone interviewers selected had experience at the college as students and were familiar with the college environment. Formal interviewing instructions were given to the interviewers and an opportunity was provided for them to ask questions about the survey. Each interviewer practiced the survey under supervision of the investigator. The interviewers worked together and were monitored by the investigator. The time period selected was the Christmas vacation in order to improve response rates by reaching students who were away at college.

Limitations of the Data

The pre-enrollment data were limited by the following missing data: not all students had high school transcripts sent to the college, not all students had ACT scores, and the self reported information of race and intent was not completed by each student at the time of admission.

Students were assumed to have transferred if a transcript had been sent to a university or college and the student was no longer attending ICC.

Another limitation in the data (and thus was not addressed in the study) was the frequency with which students changed programs and curriculums. Students who began in applied science degree programs did not necessarily remain in these programs. The original intent may have been incorrectly marked by the student or the student may not have understood the difference in degree programs at the time of enrollment.

Results

The results of the study will be organized in the following manner.

First, a description of the sample will be given in terms of persisters

and non-persisters. Second, the sample distribution of leavers,

transfers, graduates and attendees will be described. Next, the

research questions will be answered. Finally, the results of the

telephone survey will be presented.

A Description of Persisters and Non-persisters

The results of the study show that in the sample, the percentage

of persisters as defined above was 55% persisters and 45% non-

persisters with the differences between AAS and AS students as

indicated in Figure 1. The persistence rate is very similar for the

two groups.

Student Retention
Persisters   Non-persisters

Percent of sample

	Persisters	Non-pers
AAS	55%	45%
AS	56%	44%

AAS   AS
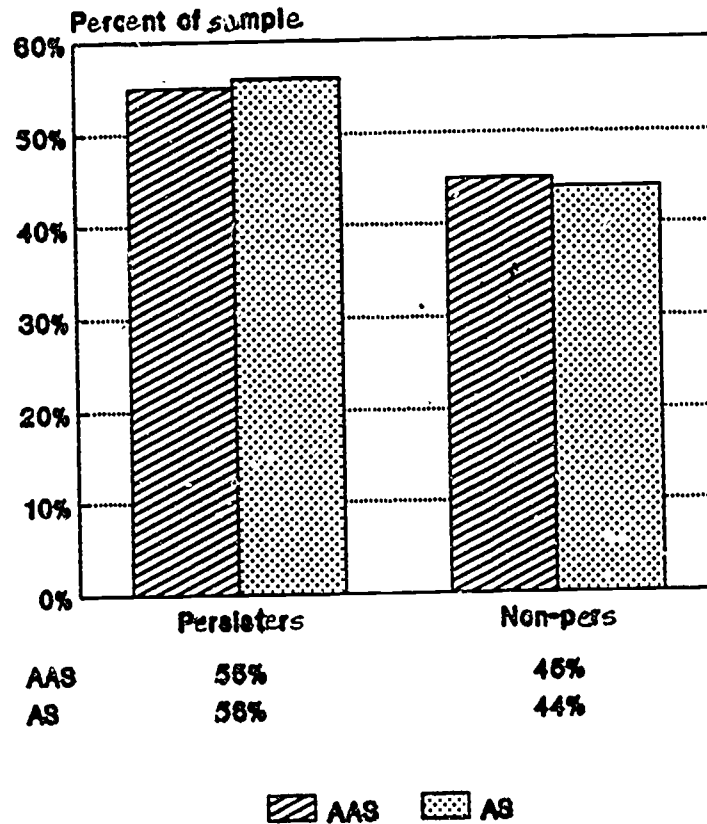

<u>Figure 1</u>. Perre ' of persisters and non-persisters in AS and AAS degree programs.

The distribution of persisters, classified as transfers, graduates and students still attending, is given in Figure 2. From the sample of 150 students, 67 students left the college, 34 in arts and science, and 33 in applied science. Twenty-four students had graduated during the two year period, 11 in arts and science and 13 in applied science. The number of non-graduate transfers was 14 students, with 11 in arts and

science and 4 in applied science. Forty-five students were still in

attendance during the Fall of 1989, with 19 in arts and science and 26

in applied science.

Retention Profile
Random Sample 150 students:198?
Figure 2. Distribution of persisters classified as transfers graduates

~~d students till attending.

The students who left, which are those who neither stopped-out
and returned, transferred nor graduated, did not vary greatly from
semester to semester. The number of students who left each semester
was highly consistent across all four semesters: 17, 15, 17, and 17.
This is in conflict with the literature which claims that most students
who leave do so before the first grading period (Webb, 1988; Whitaker,
1987). Figure 3 shows the distribution of students who left after each
of the four semesters which were analyzed during the study.

Non-returning students
Includes graduates, trans, stop-outs
Figure 3. Distribution of leavers by semester.

Research question 1

Does the persistence rate of AS students differ from that of AAS students?

Due to the more personalized advisement by students in career programs and the close-knit environment of these programs it was thought that applied science students might be more likely to persist than students in transfer programs. A t-test using the number of semesters from 1 to 5 as a measure of persistence showed non significance in comparing the two groups. (see Table 2)

Table 2

Two-tailed T-test

Group	Mean	Std_D	df	T	p
AAS	2.5867	1.415			
			148	-1.05	.296
AS	2.8267	1.389			

Note: Dependent Variable = number of semesters   (N=150)

To test whether the proportion of students who persisted was equal in the two groups of students (AAS and AS) an equality of proportions test was performed. Using the definition of persistence where a student is considered to persist if he/she has graduated, transferred or is still attending, instead of the number of semesters, once again there was no significant difference in the two groups, as indicated in Table 3.

Table 3
_____

Equality of Proportions

Group	n	x	Per cent	Z	p
AAS	75	41	.5467		
				.172	.871
AS	75	42	.5600		
_____

Note: Dependent Variable = persistence   (N=150)

Since students in career programs tend to come from lower
academic high school groups (NAVE, 1989), this factor might mask the
difference in persistence between academic and vocational students. A
crosstabs was done on high school rank with the two groups. Six more
students in the academic group were in the upper 50 percentile than in
the vocational group. An ("OVA was done with academic and career
groups using high school class rank as the covariate. This also showed
no significance in persistence between the two groups. It should be
noted that only 111 pieces of data could be used, since class rank data
were missing for 79 students.

_____

Note: Dependent Variable = persistence   (n=111)

An equality of proportions test investigating race as a factor in persistence found race to be barely significant at p<.048. A small sample of only six minority students and the fact that there were 6% non responders to race suggests that this is not a statistically significant factor. The nine non-responders to race was evenly divided with 5 being non-persisters, and 4 persisters. The persistence rate of non-whites does appear much lower than that of whites as reported in the IBHE study (IBHE, 1989b). Using 1 as a measure of persistence over a two year period, the mean for the 135 white students was .5778 while that of the non-white students was .1667. Gender, which was found to be a contributing factor in community college persistence by Pascarella, Dubi & Iverson (1983) showed no significance with p=.151 although females did better than males. Intent did not seem to be significant with a p=.206.

Transfer to a 4-year school	42	17	.415		

Note: Dependent variable= persistence   (N=150)   *p<.05

Previous studies have indicated that ACT is a factor in persistence (Pascarella, Dubi & Iverson, 1983). In analyzing the data for this sample, ACT did seem to be a factor. An ANOVA of ACT by Persistence found ACT scores to differ between persisters, with $p<.001$. (see Table 6)

Table 6

Note: ACT by Pers (n=111)

In recent efforts to encourage high school consolidation in Illinois, the Illinois State Board of Education (ISBE) has suggested that high school size is a factor in student performance at the post-secondary level (ISBE, 1985). In this study, the ISBE claims that students from small high schools, those less than 500 students, do not perform as well as those from larger high schools. In his study of

Illinois Central College, Preller found the opposite to be true, with students from smaller schools performing better. In analyzing high school graduation class size as a variable in this study, with the number of semesters as a measure of persistence as was done by Preller, no significance was found. (see Table 7) Clustering the graduation class sizes into two groups, with students in graduation classes with 100 or fewer students being one group and those in classes greater than 100, the other group showed no significance. (see Table 8)

Pre-enrollment Factors Predicting Persistence

Selected pre-enrollment factors have predicted persistence in other studies (National Longitudinal Study of High School Seniors (NLS), 1977). The NLS, 1977 study found that the background characteristics of non-persisters differed significantly from persisters. To verify this finding in this study, stepwise linear regression using all pre-enrollment factors was used focusing on the following factors: age, race, gender, HS percentile, ACT, and intent. The only factors which entered into the equation were HS percentile and age. HS percentile contributed .19, age added only an additional .05 to R-square. The average age of students at college entrance was 20.7 and 80% of all students were under age 21. The results of the stepwise linear regression are found in Table 9.

Table 9

Multiple Regression on Pre-enrollment variables

				Int	.072	.5301

Note: Dependent Variable = Persistence   (N=150, n=64)

With an R-square of .248 only 25% of student college persistence
can be predicted by the stated pre-enrollment factors. This low level
of prediction is supported by previous studies which included SES as
well as the above variables. These studies found results varying from
.17 to .228 (Whitaker, 1987; Pascarella & Chapman, 1983; Pascarella,
Smart & Etherton, 1986) A major limitation of the regression analysis
is that only 64 of the 150 records provided all pieces of data.

Post-enrollment Factors Predicting Persistence

GPA is the key factor in predicting success. This measure of
academic integration has been a major factor reported in recent studies
involving commuter students (Pascarella, Dubi & Iverson 1983;

Pascarella, Smart & Ethington,1986; Plascak & Bean, 1988).

While the investigator was analyzing the transcripts it seemed
that withdrawal patterns might also be a potential predictor of
persistence. Withdrawal in this study means formal withdrawal from one
or more registered courses. Construction of a scattergram depicting
the total hours withdrawn and persistence indicated that withdrawal
might be a negative predictor of persistence. Stepwise regression
using GPA and withdrawal as independent variables with persistence as
the dependent variable entered GPA on step one with an R-square of
.378, with withdrawal being entered on step 2 and contributing an
additional .06. The two variables, GPA and withdrawal, contribute 43%
to the prediction of student persistence. Table 10 summarizes the
results.

Note: Dependent Variable = Persistence (N=150, n=150)

Defining student academic success as having a GPA greater than or equal to **2.0** shows a marked difference between persisters and leavers. Figure 4 presents a bar chart indicating the percentage of academically successful students, with success being defined as having a grade point greater than or equal ⊃ **2.0**. The figure shows a considerable difference in the academic success rates of persisters and non-persisters.

From these data it appe s that academic non-success is certainly a characteristic of leavers.

Student Retention Profile
Percent of students:Success
Success:GPA >'' 2.0
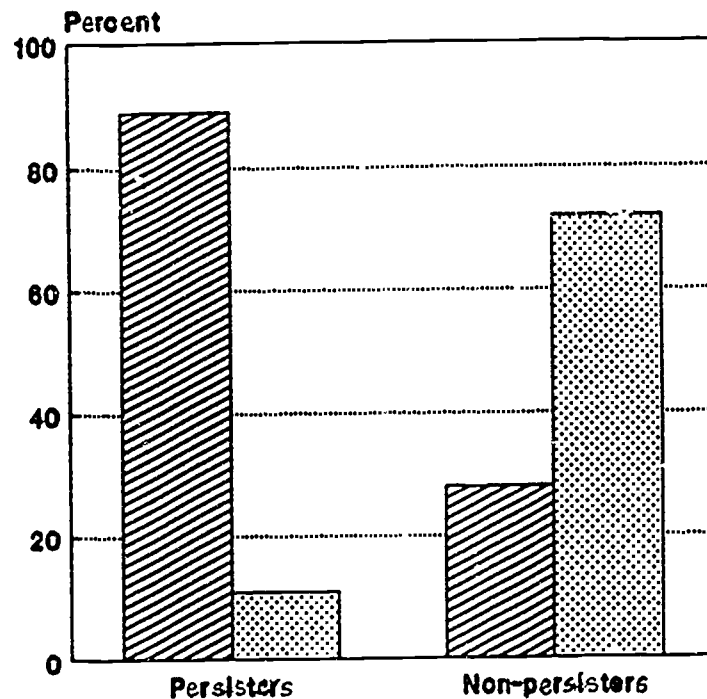

Persisters: Grad, Trans, Attend   ▨ Success   ▢ Non-Success

Figure 4. Distribution of persisters and non-persisters with GPA >= 2.0

Discriminant analysis was used to determine linear combinations of the predictor variables that show large differences in group means. The graduation code, which was coded 2 for graduates, 1 for transfers and 0 otherwise was used as the dependent variable. The first discriminant function was found to be significant at alpha=.0001, while the second d.scriminant function was not significant. GPA was the most heavily weighted variable for the first discrminant function. Withdrawal rate is the most heavily weighted variable for the second discriminant function. (Table 11) A graph of the group centroids indicates that the first discriminant function separates graduates and transfers from those who are not persistent, while the second discriminant function, though not significant, seems to separate graduates from transfers. (Figure 5)

Survey Results
The response rate from the follow-up telephone survey was 74% of

the 83 students. This 74% response rate was considered quite

successful. In discussing response rate from telephone surveys, Graves

and Kahn (1979) state that a 70% response rate compares favorably with

a questionnaire response rate of 74%. Each student was called at least three times at various times of the day to maximize the response rate. As be expected, several phones were disconnected and a few students left no phone numbers in the ICC records.

The results of the survey of the 38 students who had graduated or transferred were compiled separately from the 45 students who were still attending and can be found in Attachment C. From the 38 graduates and transfers there were 28 responders with 20 being in school full time and with one attending part time. Thirteen different colleges were represented by these 21 students. Some respondents cited multiple reasons for the institutional and personal factors which influenced their success favorably and unfavorably.

Among the 28 students surveyed, the institutional factor which students stated had the greatest influence on their success was their teachers, with 15 students so responding. Location-convenience was next in importance, with 7 responses. Program offerings, schedule of classes, and advisers were all cited by 3 to 5 students. Social life and special services were not mentioned.

Among the positive personal factors stated by students, family was most important (14) followed by work, money, and transportation all of which were cited by four students. Three students cited other items such as motivation and a coach. The personal factors which were most difficult to overcome were: money (7), transportation (6), with work and "other" each receiving three responses. The open ended question, what other assistance could the college have provided, resulted in 15 students responding with "none", three students giving no response and

10 citing the suggestions in Attachment C.

The results of the survey for students still in attending ICC are found in Attachment D. The **35** students still attending who responded stated that teachers and convenience-location were the major institutional factors contributing to success. Family was also the major positive personal contributing factor for this group. Twenty-one students responded that there were no personal factors which were problematic, while money and work were cited by a few. The open ended question also found 26 students indicating that there was nothing additional which the college could do to improve their success. Four students cited counseling as a difficulty. This level of satisfaction with the community college's programs and services by successful students exceeds that found in a study of Wyoming community colleges (Wyoming Community College Commission, 1988) which found 64% of students responding that there was nothing more that the college could do to help them succeed.

The telephone survey data were also analyzed to determine what factors distinguish students who graduate within two years from those who are still in attendance. The one factor in the survey which seemed quite different between the two groups was the number of hours worked by students, and the number of students who worked. Eleven of the twenty-eight students who had graduated or transferred had worked more than twenty hours per week, while 25 of the 35 students who were still in attendance worked more than twenty hours per week. This result supports previous research that environmental factors influence community college students (Webb, 1988).

Both groups of students reported that teachers had a positive

impact on their success. This response of faculty having impact on

student success is supported by many other studies and will be

addressed in the recommendations (Webb, 1988; Endo & Harpel, 1982;

Cohen, 1988; Pascarella & Terenzini, 1980).

Conclusions

This study examined student persistence and a set of related

predictive factors at a major Illinois community college.

Transcript and telephone survey data were used to identify a series of

factors related to completion of associate degree programs by full-time

students. From a total enrollment of 12,859 students of which 3,732

were full time during the Fall of 1987, 1,327 full time degree seeking

freshman were selected as the population to be studied.

When compared to other community colleges the drop out rate at

Illinois Central College is not as high as that reported by others.

The drop-out, leaver, and departure rate of 41 of the 150 students or

27% after freshman year is far less than that reported by ACT (1989) of

47% for all community college students. In fact, it is similar to that

which is reported by ACT for BA/BS institutions. Tinto (1987) reported

a 46% freshman attrition rate for 2-year institutions with open

admissions policies. Compared with Flaherty's (1989) transfer study of

Chicago area community colleges which reported a transfer rate of 10%,

22 students out of the original 75 students (29%) who were originally

enrolled in the two year transfer program did transfer. Even if one

doubled Flaherty's rate to account for the two years of the program,

ICC students do better. Although the demographics of the Chicago area

are quite different from central Illinois, the mission of the community college is similar. The ICC 45% attrition rate appears similar to that reported by NAVE (1989). However, students at Illinois Central do not leave mainly after the first semester. Student attrition appears to be a continuous process spread evenly throughout the 2 years. There is no difference in persistence rates of different groups of students. The only factor which seems to be predictive in pre-enrollment variables is HS percentile rank, however that only contributes 20% of the variance in student persistence. With regards to post-enrollment variables, academic integration (i.e. GPA) seems to be the only major predictor with withdrawal being a secondary indicator of importance.

The importance of academic success as a predictor of student success (i.e. student completion) has been recognized by the college for several years. A program exists to identify and assist students who are academically at risk. This program aids students whose grades fall below a 1.9 by providing special advisement and mentoring by department chairpersons. The students are encouraged to take advantage of skill building programs. Many of the recommendations listed by Cohen (1988) to improve student retention at community colleges are already in place at the college.

The results this study suggest that using withdrawal as an early warning signal might identify some of the at-risk students earlier. Further, the results strongly confirm the need to make faculty continuously aware of their important role in student retention. Encouraging faculty members to use the existing college referral programs for weak students might help identify marginal students before

they becc·. part of that group of non-successful students with low grade-point averages.

The results of this study strongly support what Bean, Pascarella, Webb and others have discovered: different factors influence commuter student persistence when compared to persistence of residential students. Concerns about social integration and institutional fit do not seem important at commuter colleges. The fact that not a single student from the survey found the social life to be a positive factor in his/her success illustrates this fact.

Recommendations

The results of this study can be used as baseline information for future studies. To better understand exactly what happens to community college students over time, a longitudinal study of current freshman students should be initiated. This longitudinal study might track a sample of from 100-200 students from the time they originally enter the college for a period of five years. Qualitative, in-depth data could be obtained to discover their failures and successes. Exactly how faculty influence them in pursuing a degree could be explored.

_nce academic integration is a strong predictor of student retention, more individualized efforts with academically at risk students, as suggested by IBHE reports, are clearly needed. As stated by Bean (1987) "Retention programs must serve individual students."

Efforts to retain students should not just occur at the beginning of the student's college career. Students do not drop out only after the first semester. Retention efforts should take place throughout the

student's college experience.

The focus on academic performance should be a comprehensive initiative, involving faculty members, administrators, counselors and others. The provision of such assistance would not be viewed solely as the responsibility of student services. All parts of the institution, especially individual faculty members, should take an active role in retention efforts.

Faculty need to identify at-risk students prior to mid-semester and direct these students to labs and student services programs where they can get the appropriate assistance.

Each faculty member should take an active role in encouraging students to stay in school. A student who has been absent more than two times should be called by the faculty member.

Faculty advisors need to receive inservice training in order to better advise transfer students. Faculty should be made accountable in the evaluation process for their role in student retention efforts.

Another approach might be to have selected faculty members (with reduced teaching loads) in each department appointed as "mentors or advisors" with the responsibility of monitoring, counseling, and tutoring all students who are in trouble academically.
