ABSTRACT

This paper describes recent patterns of income stratification in American colleges. Data from the Current Population Survey provide estimates of college enrollment stratification by income during the period 1970-1988. The National Longitudinal Study of the High School Class of 1972 and the High School and Beyond survey provide data for two cohorts on the relationships between family income and college graduation. Time trends indicate that for each income quintile, the fraction of youth enrolled in private colleges increased modestly but steadily from the early 1970s through the late 1980s. The fraction of youth in public colleges showed little change during the 1970s, but during the early 1980s the poor lost ground while the rich gained ground. In the late 1980s, public college enrollments strongly increased for all income groups. The distribution of enrollments in 2-year institutions is close to equal across income groups; the inequality is concentrated in four-year institutions. Although enrollments are stratified by income in both public and private four-year colleges, more stratification occurs in the private four-year colleges. Roughly half of all youth who enroll in college do not obtain a bachelor's degree. The reciprocity of a degree is more stratified by income than is college enrollment. Contains five references and an appendix that provides data from the annual October Current Population Survey of the U.S. Census Bureau. (Author/GLR)

ABSTRACT

This paper describes recent patterns of income stratification in American colleges. Data from the Current Population Survey provide a rough estimate of college enrollment stratification by income during the period 1970 - 1988. The National Longitudinal Study of the High School Class of 1972 and the High School and Beyond survey provide data for two cohorts on the relationship between family income and college graduation.

Time trends indicate that for each income quintile, the fraction of youth enrolled in private colleges increased modestly but steadily from the early 1970s through the late 1980s. The fraction of youth in public colleges showed little if any change during the 1970s, but during the early 1980s the poor lost ground and the rich gained ground. In the late 1980s, public college enrollments increased strongly for all income groups.

The data indicate persistent patterns of stratification of college enrollments by income. The distribution of enrollments in two-year institutions is close to equal across income groups; the inequality is concentrated in four-year institutions. Although enrollments are stratified by income in both public and private four-year colleges, more stratification occurs in the private four-year colleges.

Roughly half of all youth who enroll in college do not obtain a bachelor's degree. The reciprocity of a degree is more stratified by income than is college enrollment.

ACKNOWLEDGEMENTS

The author is grateful to Bob Hauser for making available to me his combined extract of the October Current Population Survey and its School Enrollment Supplement. Ted Shen provided able research assistance.

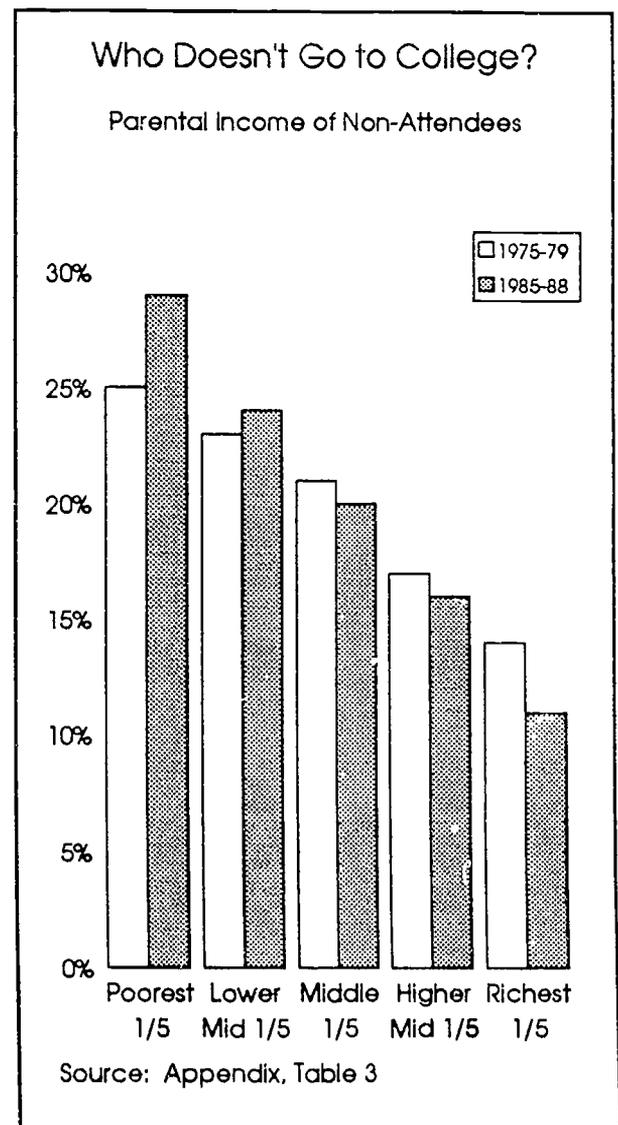

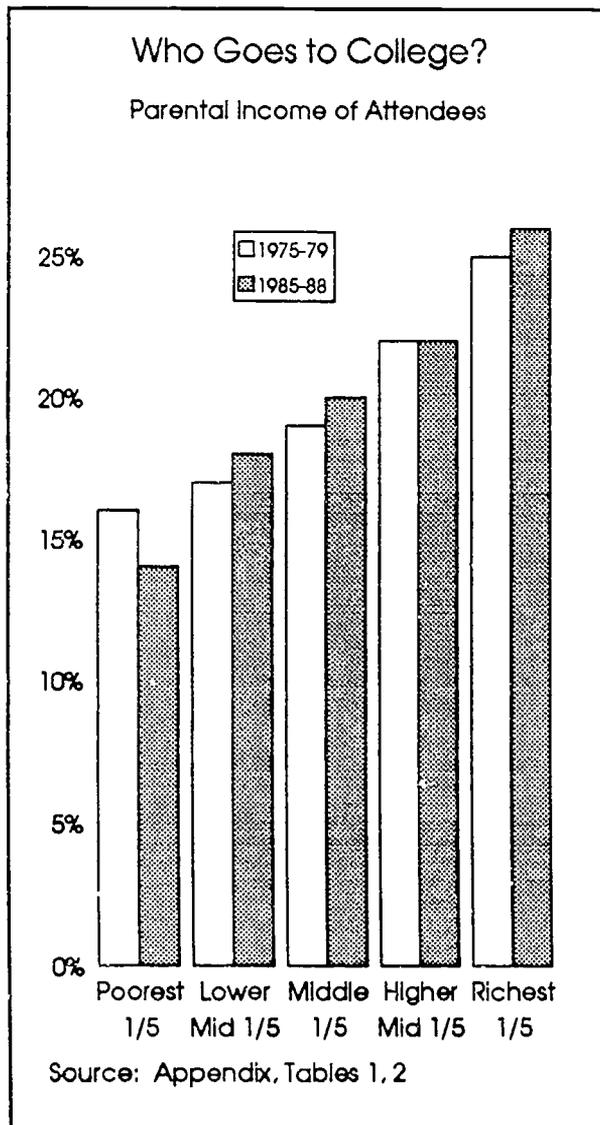

PARENTAL INCOME AND COLLEGE OPPORTUNITY

This paper describes recent patterns of income stratification in American colleges. The broad dimensions of enrollment stratification from 1970 through 1988 can be traced through the Current Population Survey (CPS), whose basic household questionnaire is supplemented each October by a school enrollment survey. The paper presents tabulations of these CPS data and also of data from the National Longitudinal Study of the High School Class of 1972 (NLS72) and the High School and Beyond

(HSB) surveys, and interprets the empirical findings.

The Family Income Distribution of College Enrollments

Respondents to the October Current Population Survey report the current school enrollment status of household members aged 3 through 34. For each enrolled person, respondents report whether the school is public or

private. For each person enrolled in college, respondents report whether the college is a two-year or four-year institution. These enrollment data are available for each of the years 1970 through 1988, with the exception of 1980.¹

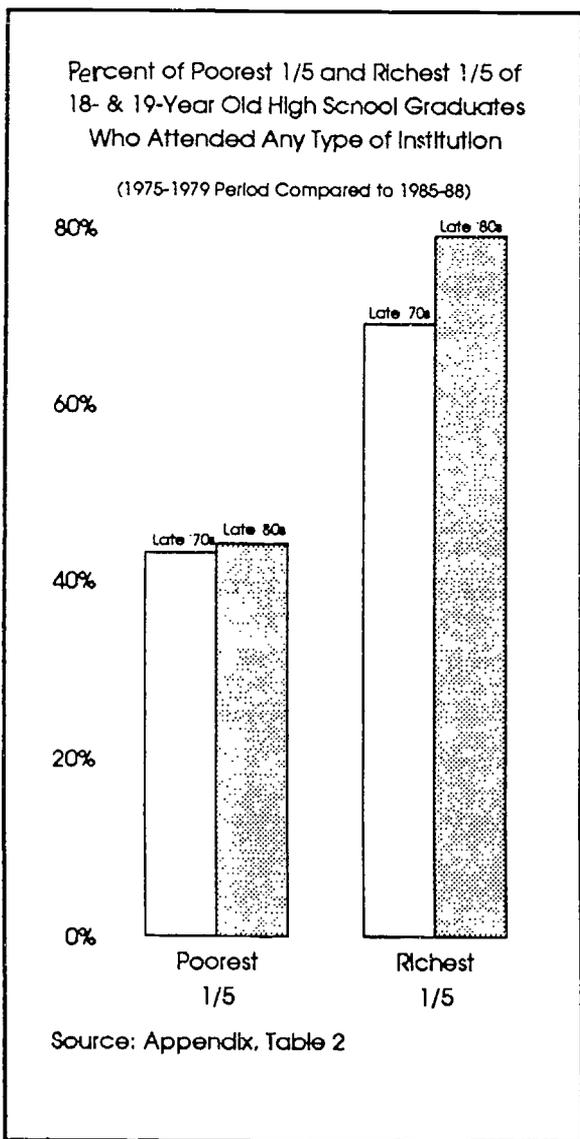

Although a more refined typology of colleges would be useful, the CPS disaggregation of colleges into public and private, two- and four-year programs reveals the basic facts about enrollment stratification.² The CPS is used here to examine the enrollment status of 18- and 19-year old dependent high

school graduates. The economic status of each such person is characterized by the quintile of the income distribution within which his or her family is located.³

The CPS sample sizes are not large enough for reliable interpretation of yearly enrollments but are adequate for interpretation of enrollments during multiple-year periods. The analysis of this paper considers the periods 1970-1974, 1975-1979, 1981-1984, and 1985-1988. The underlying yearly CPS data are presented in Appendix Table A1. The Appendix explains in detail the definitions of variables, the assumptions made in estimating income quintiles, etc.

Table 1 in the Appendix presents the CPS data on enrollment status in the four time periods. We are interested not in the enrollment numbers per se, which partially reflect cohort sizes, but in the enrollment distributions across college type and student economic status. Tables 2 and 3, which are derived from Table 1, view the data from two distributional perspectives. Table 2 shows, for the members of each income quintile, the distribution of enrollments across the four college types; the percentage of persons not enrolling is also given. Table 3 shows, for each college type, the income distribution of enrollments. Tables 4 through 6 show, for purposes of comparison, CPS enrollment figures for dependent high school seniors.

Inspection of the tables reveals the following:

TIME TRENDS IN ENROLLMENTS (Table 2):

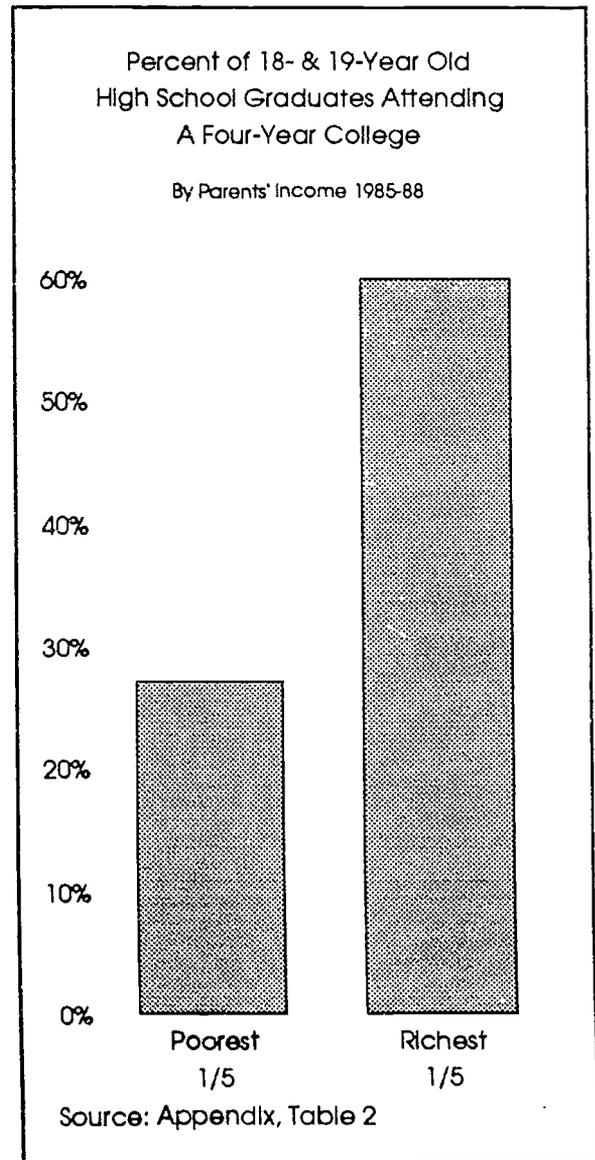

For each income quintile, the fraction of youth enrolled in private colleges increased modestly but steadily from the early 1970s through the late 1980s. In the period 1970-1974, 7 percent of youth in the lowest income quintile, 10 percent in the middle quintile, and 21 percent in the highest quintile were enrolled in private colleges. In the period 1985-1988, the corresponding figures were 9, 14, and 22 percent. For each income quintile, the fraction of youth enrolled in public colleges showed little if any change during the 1970s, but noteworthy changes took place in the 1980s. In the early 1980s, the poor lost and the rich gained. Enrollment by youth in the lowest income quintile dropped sharply (from 35 percent in 1975-1979 to 30 percent in 1981-1984), enrollment by youth in the three middle quintiles remained stable or rose modestly, and enrollment by youth in the highest quintile rose sharply (from 48 percent in 1975-1979 to 54 percent in 1981-1984). In the late 1980s, public college enrollments increased strongly for all income groups. Between 1981-1984 and 1985-1988, enrollments by youth in the lowest quintile rebounded from 30 percent to 36 percent, enrollments in the middle quintile grew from 42 percent to 49 percent, and in the highest quintile grew from 54 percent to 57 percent.

STRATIFICATION OF ENROLLMENTS

(Tables 2 and 3): The data indicate persistent patterns of stratification of college enrollments by income. In the late 1980s, 44 percent of the youth in the lowest income quintile, 62 percent of those in the middle quintile, and 79 percent

in the highest quintile were enrolled in some college (Table 2). Viewed another way, those youth not enrolled in college were drawn 29 percent from the lowest income quintile, 20 percent from the middle quintile, and 11 percent from the highest quintile (Table 3).

Interestingly, the distribution of enrollments in two-year institutions is close to equal across income groups. In the late 1980s, 16 percent of the youth in the lowest income quintile, 20 percent of those in the middle quintile, and

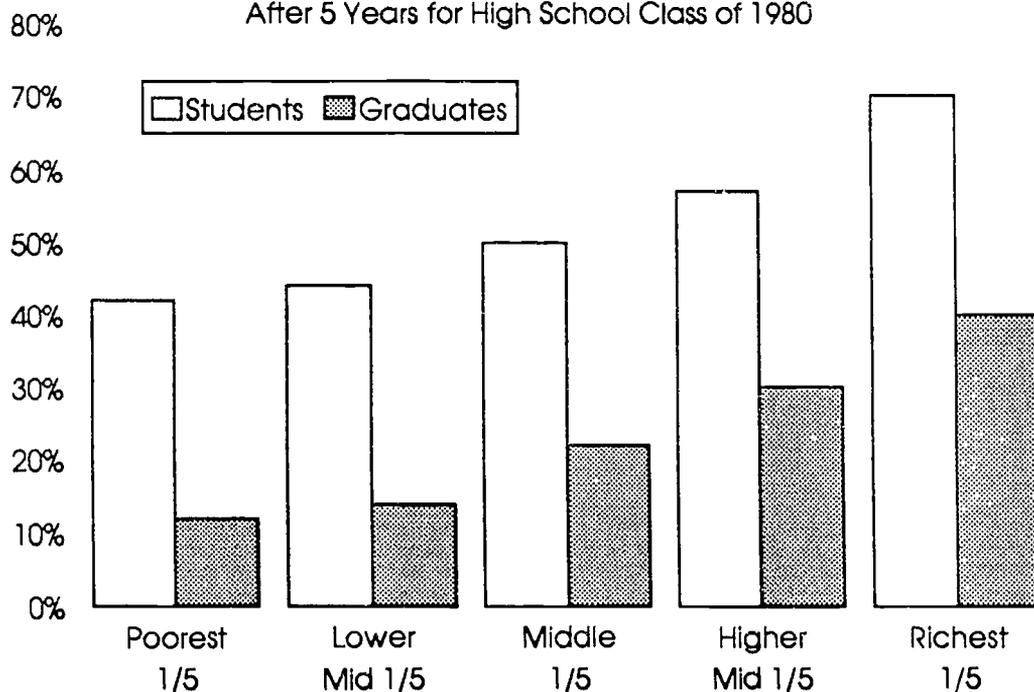

17 percent in the highest quintile were enrolled in two-year public colleges. In every income quintile, the same 2 percent of the youth were enrolled in a two-year private college (Table 2).

The inequality in enrollments occurs only in the four-year institutions. In the late 1980s, 20 percent of the youth in the lowest income quintile, 29 percent of those in the middle quintile, and 40 percent in the highest quintile were enrolled in four-year public colleges. At the same time, 7 percent of the youth in the lowest income quintile, 12 percent of those in the middle quintile, and 20 percent in the highest quintile were enrolled in four-year private colleges (Table 2).

The data indicate that, while enrollments are stratified in both public and private four-year colleges, they are more stratified in the private four-year colleges. In the late 1980s, the chance that a high school graduate from the highest income quintile would enroll in a public four-year college was double that of a youth from the lowest income quintile (40 percent to 20 percent) but the chance that a high school graduate from the highest income quintile would enroll in a private four-year college was triple that of a youth from the lowest income quintile (20 percent to 7 percent) (Table 2). Viewed another way, public

Average Attendance by Income Group 1975-84
vs. Graduation Rate
After 5 Years for High School Class of 1980

Source: Appendix, Tables 2, 9

four-year colleges drew 27 percent of their enrollment from the highest income quintile and 13 percent from the lowest quintile, while private four-year colleges drew 33 percent of their enrollment from the highest quintile and 11 percent from the lowest quintile (Table 3). **COMPARISON WITH ENROLLMENT OF HIGH SCHOOL SENIORS:** Tables 4 through 6 present CPS enrollment data for dependent high school seniors; These tables exclude from consideration non-enrolled youth and do not restrict attention to a specific age group. For the sake of comparability with Tables 1 through 3, Tables 4 through 6 apply the same definition of dependency and the same income quintiles as were used earlier.⁴ The underlying yearly data are presented in Appendix Table A2.

Observe first that, for youth in all but the highest income quintile, the distribution of enrollments between public and private high schools remains essentially unchanged over time (Table 5). For youth in the highest quintile, there are modest fluctuations over time, with some evidence of movement toward private schools. I focus here on the most recent figures, for 1985-1988, and find the following.

Public high schools enroll most high school seniors at all income levels; 95 percent of the youth in the lowest income quintile, 91 percent of those in the middle quintile, and 82 percent in the highest quintile. Income stratification in private high school enrollments is similar to that in private four-year college enrollments. Table 5 shows that, in the late

1980s, 5 percent of the high school seniors in the lowest income quintile, 9 percent of those in the middle quintile, and 18 percent of those in the highest quintile were enrolled in a private high school. So the chance that a high school senior from the highest income quintile was enrolled in a private high school was about three and a half times that of a youth from the lowest income quintile (18 percent to 5 percent); this ratio is close to the three-to-one ratio found in Table 2 for private college enrollments (20 percent to 7 percent). Viewed another way, private high schools drew 31 percent of their enrollment from the highest quintile and 13 percent from the lowest quintile (Table 6); these figures are close to the corresponding 33 percent and 11 percent ones for private four-year colleges (Table 3).

THE FAMILY INCOME DISTRIBUTION OF COLLEGE GRADUATES: Roughly half of all youth who enroll in college do not persist to a bachelor's degree. It is therefore important to ask whether the income stratification patterns found among 18 and 19 year old enrollees are indicative of stratification among college graduates. The CPS cannot be used to answer this question but the National Longitudinal Study of the High School Class of 1972 and the High School and Beyond surveys can, at least for the high school classes of 1972 and 1980.

Respondents to NLS72 were first interviewed in the spring of 1972, when they were high school seniors, and were followed through October 1979.⁵ Thus, the NLS72 data can be

used to learn the family income distribution of recipients of bachelor's degrees seven years after high school graduation. Respondents to HSB were first interviewed in the spring of 1980, when they were high school seniors, and were followed through early 1986. Thus, the HSB data can be used to learn the family income distribution of recipients of bachelor's degrees five-and-a-half years after high school graduation.⁶ For details on the NLS72 and HSB survey designs, see Riccobono et al. (1981) and Sebring et al. (1987) respectively. Tables 7 through 9 show the NLS72 and HSB enrollment and graduation distributions. Tables 7 and 8, which report spring high school enrollments and fall college enrollments in 1972 and 1980, are included for comparison with the CPS data in Tables 5 and 2 respectively. Although the NLS72, HSB, and CPS sampling frames and variable definitions differ in significant respects, the data sources show enrollment patterns that are broadly similar and match well in most details.⁷

Table 9 reveals that bachelor's degree recipiency is more income-stratified than is college enrollment. Because the NLS72 and HSB patterns are so similar, only the more recent HSB data will be discussed here. By early 1986, only 12 percent of the 1980 high school seniors with family income in the lowest quintile had received a bachelor's degree; of these 9 percent were from public four-year colleges and 3 percent were from private colleges. In the middle quintile, 24 percent had degrees, with 16 percent from public colleges and 8 percent from private ones. In the highest

quintile, 39 percent had degrees, with 22 percent from public colleges and 17 percent from private ones. Thus, compared with a youth in the lowest income quintile, a youth in the highest quintile had two and a half times the chance of receiving a bachelor's degree from a public college (22 percent to 9 percent) and almost six times the chance of receiving a degree from a private college (17 percent to 3 percent).

CONCLUSIONS

The main empirical finding is that American colleges remain substantially stratified by income. The consequences of income stratification are known only in part. Ample empirical evidence relates college graduation to later labor market outcomes. In fact, recent studies indicate that the income return to college-going increased during the 1980s (see, for example, Murphy and Welch, 1989). This evidence, combined with that presented here, indicates a continuing problem of intergenerational immobility: youth from low-income families tend not to graduate from college, and then have low incomes themselves.

There is little empirical evidence relating the type of college one attends to labor market outcomes. In particular, we do not know whether, controlling for ability, students who graduate from private colleges earn higher incomes than ones who graduate from public colleges. In the absence of this information, we cannot say whether the more pronounced income stratification of private college enrollments should be a matter of public concern.

Notes

¹Prior to 1970, respondents were not asked to distinguish two-year from four-year colleges. In 1980, the Bureau of the Census did not release data on whether schools were publicly or privately controlled. See the Appendix for further information.

²The various college types differ substantially in their costs of enrollment. It is reported in Congressional Budget Office (1991, Table B-4) that, in fall 1986, the "adjusted net cost" of attendance per student was \$7124 in private four-year institutions, \$3498 in public four-year institutions, and \$2049 in public two-year institutions. Adjusted net cost was defined as cost (tuitions, fees, room and board, books and supplies, and transportation costs) minus grants minus 40 percent of loans.

³Because the CPS reporting unit is the household, the available income data do not necessarily describe the economic status of the family in which a person grew up. On the other hand, the CPS data do permit one to determine with little ambiguity those persons who are dependent members of their family's households; the Appendix describes how this may be done. I restrict attention to 18- and 19-year-olds because the great majority of these persons are still dependents.

⁴Thus the income quintiles of Tables 4 through 6 refer not to the distribution of family income among dependent high school seniors but to the distribu-

tion of family income among dependent high school graduates. Table 4 shows that the quintiles of the latter distribution are higher than are those of the former one. The entries for 1985-1988, for example, show 24 percent of the youth in the lowest income quintile and 16 percent in the highest quintile rather than 20 percent in each quintile.

⁵A sub-sample of respondents were later interviewed in 1986. These data are not used here.

⁶The HSB survey also interviewed youth who were high school sophomores in spring 1980 and followed them into 1986. But this time span is not sufficiently long for these persons to complete a four-year college program; hence data from the sophomore cohort are not reported here.

⁷In each of the NLS72 and HSB surveys, a sample of high schools was drawn and a sample of students were interviewed in each high school. The enrollment, degree, and family income data are student self-reports. For the sake of comparability with the CPS data, the income quintiles applied in Tables 7 through 9 are the CPS quintiles given in the Appendix. The NLS72 and HSB data do show some different enrollment patterns than do the CPS ones. In particular, the former data sets indicate a sizeable shift of high income high school seniors from public to private schools between 1972 and 1980 (Table 7).

Appendix

DATA SOURCE: The source for Tables A1 and A2 (and for the summary Tables 1 through 6) is the annual October Current Population Survey (CPS) of the U.S. Census Bureau. The School Enrollment Supplement to the October CPS provides enrollment status data for those household members aged 3-34. The schooling data and household background data for these persons have been combined into a single, unified file by Hauser et al. (1991). The present tables are based on the Hauser CPS extract.

The entries in Table A1 are obtained by applying CPS-provided weights to the raw data for dependent high school graduates aged 18 and 19. The entries in Table A2 are obtained in the same way for dependent high school seniors. The CPS does not directly report a person's dependency status. In the tables, a person is defined to be dependent if he or she is neither the head of a household nor the spouse of the head and if the head of the person's household is at least 39 years old. The tables restrict attention to dependent persons because the household data reported in the CPS refer to the household in which a respondent is located at the time of interview, although college students living in dormitories are not considered to constitute separate households.

A person is considered to be enrolled in college (or as a high school senior) if he or she was enrolled full-time or part-time in a two- or four-year college (or in the twelfth grade). Youth enrolled in noncollegiate postsecondary schools are not included in Table A1; these persons are reported as not enrolled.

RELATIONSHIP TO SERIES P-20 FIGURES: The U.S. Census Bureau, in its Series P-20 Current Population Reports, presents October CPS figures for the number of 18- and 19-year-old persons who are high school graduates and who are enrolled in college. The figures reported in Table A1 range from 80 to 90 percent as large as those given in Series P-20. One reason for the reduction in size is my restriction of attention to dependent youth. A second reason is that the table uses data only on those persons for whom actual income and other survey responses are available. The Census Bureau practice of "allocating" respondents with missing responses to response categories is not followed here.

INCOME QUINTILES: In these tables, income quintiles refer to the income distribution of the families of 18- and 19-year-old dependent high school graduates. Each year's income distribution was estimated from the October CPS income responses, as follows.

Respondents to the October CPS are asked to report yearly household income in current-dollar income intervals; the number of intervals and their end points have varied from year to year. To derive a complete income distribution from interval-coded data requires an assumption about how income is distributed within each interval. I assumed that income is distributed uniformly within each interval. (This assumption cannot be maintained in the highest reporting interval, which is open ended. In all cases, however, less than 20 percent of households had income in the highest interval; so no assumption about the distribution of income within the highest interval was required.) The estimated income quintiles for each year were, in current dollar terms:

| Year | INCOME QUINTILE | | | | |
|------|-----------------|----------|----------|----------|----------|
| | 1 | 2 | 3 | 4 | 5 |
| 1970 | \$0 | \$6,808 | \$9,684 | \$12,774 | \$18,036 |
| 1971 | \$0 | \$6,875 | \$9,955 | \$13,311 | \$19,644 |
| 1972 | \$0 | \$7,260 | \$10,907 | \$14,092 | \$21,033 |
| 1973 | \$0 | \$8,342 | \$12,183 | \$15,750 | \$22,576 |
| 1974 | \$0 | \$8,821 | \$12,937 | \$16,868 | \$23,208 |
| 1975 | \$0 | \$9,683 | \$13,743 | \$18,136 | \$23,910 |
| 1976 | \$0 | \$9,800 | \$14,636 | \$19,648 | \$27,162 |
| 1977 | \$0 | \$10,835 | \$15,883 | \$21,094 | \$32,456 |
| 1978 | \$0 | \$11,491 | \$17,368 | \$22,972 | \$36,439 |
| 1979 | \$0 | \$12,458 | \$19,479 | \$25,229 | \$40,519 |
| 1980 | \$0 | \$13,307 | \$20,306 | \$28,300 | \$42,345 |
| 1981 | \$0 | \$13,916 | \$21,875 | \$31,889 | \$45,013 |
| 1982 | \$0 | \$14,183 | \$23,474 | \$32,000 | \$44,199 |
| 1983 | \$0 | \$14,210 | \$23,834 | \$33,080 | \$46,283 |
| 1984 | \$0 | \$15,813 | \$25,714 | \$35,060 | \$48,939 |
| 1985 | \$0 | \$16,861 | \$26,789 | \$36,734 | \$50,364 |
| 1986 | \$0 | \$17,151 | \$28,563 | \$39,606 | \$56,603 |
| 1987 | \$0 | \$17,500 | \$30,242 | \$41,294 | \$60,911 |
| 1988 | \$0 | \$20,561 | \$32,400 | \$44,383 | \$63,387 |

Once the income quintiles were estimated, it was necessary to assign each sampled person to the appropriate quintile. This is straightforward in those cases in which a CPS income-reporting interval lies completely within a single quintile span. Some intervals, however, cross quintile boundaries. Given the assumption that income is distributed uniformly within each reporting interval, the correct way to deal with this is to allocate persons fractionally to adjacent quintiles.

For example, one of the CPS reporting intervals in 1988 was [\$30,000, \$34,999]. This interval lies partly

In the second quintile [\$20,561,\$32,400] and partly in the third quintile [\$32,400,\$44,393]. Under the assumption that income is distributed uniformly within reporting intervals, the probability that a person with family income in the interval [\$30,000,\$34,999] has income less than \$32,400 is .48. Hence, each person with income in the interval [\$30,000,\$34,999] was allocated with fractional weight .48 to the second income quintile and with weight .52 to the third quintile.

ABSENCE OF DATA FOR 1980: In 1980, the Bureau of the Census did not release data on the public or private control of the schools where students were enrolled. Apparently, the Bureau decided that problems in the wording of the 1980 survey question concerning school control made unambiguous interpretation of the responses infeasible.

SAMPLING ERROR IN TABLES 2 and 5: Each October, 3000 or more 18- and 19-year-old dependent high school graduates appear in the CPS. Each income quintile contains roughly 20 percent of the observations. (Each need not contain ex-

actly 20 percent of the raw observations, as our quintiles are based on the weighted rather than raw samples.) Hence, the yearly samples on which Table 2 is based contain roughly 600 observations. The table aggregates over four- or five-year periods, yielding 2400 or more observations in each income quintile category. These sample sizes imply that the standard errors for the entries in Table 2 are 1.0 percent or less. The CPS samples of dependent high seniors are somewhat more than half the size of those of the dependent 18 and 19 year-old high school graduates. As a consequence, the standard errors for the entries in Table 5 are 1.5 percent or less.

SAMPLING ERROR IN TABLES 3 AND 6: The sample size for each school type is proportional to the enrollment in the type; hence the standard errors for the entries in Tables 3 and 6 vary as well, roughly as follows: public two-year colleges (2.3 percent or less); public four-year colleges (1.8 percent or less); private two-year colleges (7.0 percent or less); private four-year colleges (2.9 percent or less); public high schools (1.5 percent or less); private high schools (4.5 percent or less).
