## 1. Introduction

The purpose of this technical appendix is to share more detailed results and to describe more fully the sample and methods used in the research included in the brief, Learning during COVID-19: An update on student achievement and growth at the start of the 2021-22 school year. ${ }^{\prime}$ We investigated two research questions in this brief:

1. How does student achievement in fall 2021 compare to pre-pandemic levels (namely fall 2019)?
2. How did academic gains between fall 2019 and fall 2021 compare to normative growth expectations?

## 2. Data

## Sample

The data for this study are from the NWEA anonymized longitudinal student achievement database. School districts use NWEA® MAP® Growth ${ }^{\text {TM }}$ assessments to monitor elementary and secondary students' reading and math growth, with assessments typically administered in the fall (usually between August and November), winter (usually December to March), and spring (late March through June). The NWEA data also include demographic information, including student race/ethnicity, gender, and age at assessment. An indicator of student-level socioeconomic status is not available. However, a set of school-level characteristics, including school-level free or reduced priced lunch (FRPL) eligibility was obtained from the 2019-20 school-level Common Core of Data (CCD) files from the National Center for Education Statistics. ${ }^{i i}$

In total, our sample consists of approximately 6.1 million students ${ }^{1}$ in grades $3-8$ in 14,256 public schools who took MAP Growth reading and math assessments in fall 2019 and/or fall 2021. Student test scores for grades 3-8 from the fall of the 2019-20 school year were treated as the reference distribution (representing a "typical" school year), while test scores for grades 3-8 in fall 2021 describe trends at the start of the third school year impacted by COVID-19.

[^0]We limited our sample of schools to a consistent set of U.S. public schools that tested at least ten students in both fall 2019 and fall 2021. This sample restriction guards against the competing explanation that any differences we observe in achievement over time are potentially driven by systematic differences between schools that did and did not consistently test students in both years. Descriptive information for the students in our sample by grade is provided in Table 1 (for reading) and Table 2 (for math). These tables show a comparison of the students in the reference group (fall 2019) and the pandemic impacted group (fall 2021). Overall, the samples of students who tested in 2019 and of same-grade students who tested in fall 2021 were very similar in terms of gender and race/ethnicity, though the number of students tested in each grade was consistently larger in fall 2019. Additionally, Table 3 provides the descriptive statistics for our longitudinal sample (e.g., the students who tested in fall 2019 and tested again two grades later in fall 2021) that was examined using our skip-year norms. ${ }{ }^{\vee}$

Descriptive information for the schools in our cross-sectional and longitudinal samples along with comparison information on the population of U.S. schools is provided in Table 4. The schools in our cross-sectional sample represent roughly $20 \%$ of U.S. public schools in any given grade. Our sample reflects a diversity of schools from across various locales (urban, suburban, rural, and town). However, our sample reflects schools serving slightly higher average percentages of white students, lower average percentages of Hispanic students, and slightly lower percentages of students eligible for FRPL relative to national averages.

## Measure of achievement

Student test scores from the NWEA MAP Growth reading and math assessments, called RIT scores, were used in this study. MAP Growth is a computer adaptive test that precisely measures achievement even for students above or below grade level and is vertically scaled to allow for the estimation of gains across time. The MAP Growth assessments are typically administered three times a year (fall, winter, and spring) and are aligned to state content standards. Test scores are reported on the RIT (Rasch unIT) scale, which is a linear transformation of the logit scale units from the Rasch item response theory model.

In this study, we used achievement percentile ranks calculated using the NWEA 2020 MAP Growth norms. ${ }^{\text {vi }}$ These norms reflect pre-pandemic achievement trends as they are based on a nationally representative sample of students from the 2015-16, 2016-17, and 2017-18 school years. Since MAP Growth can be estimated at any point during the school year, the MAP Growth achievement norms condition on each student's grade, subject, and instructional week of testing (i.e., the week in the school calendar in which a student tested). Instructional weeks were calculated for each student based on their school start date and the individual student's testing dates (for more details on the calculation of instructional weeks, see the norms study). Within each subject, let $\mathrm{Y}_{\mathrm{igt}}$ be a student i's RIT score in grade $g$ at instructional week $t$. The predicted mean $\left(\widehat{Y}_{\mathrm{gt}}\right)$ and standard deviation $\left(\mathrm{SD}\left(\mathrm{Y}_{\mathrm{gt}}\right)\right)$ for a given grade/subject/instructional week combination were pre-calculated based on the NWEA norms model (see Chapter 4 of the norms report). Based on these values, we calculated a standardized estimate of the student's RIT score:

$$
z\left(\mathrm{Y}_{\mathrm{igt}}\right)=\frac{\left(\mathrm{Y}_{\mathrm{igt}}-\widehat{\mathrm{Y}}_{\mathrm{gt}}\right)}{\operatorname{SD}\left(\mathrm{Y}_{\mathrm{gt}}\right)} .
$$

From the standardized score, we calculated the percentile rank (e.g., the proportion of the distribution that the student scored as well as, or better than):

$$
p\left(Y_{i g t}\right)=\operatorname{Pr}\left(Y_{i g t} \leq y_{g t}\right)=\int_{-\infty}^{y_{g t}} \phi(z) d z,
$$

where $\phi(z)$ represents the probability density function. The student normative percentile used in this study was scaled to range from 1 to 99 :

$$
\text { Perc }=100 \times p_{s}\left(Y_{i g t}\right)
$$

Additionally, we calculated students' expected fall-to-fall growth across two school years (say fall of grade 3 to fall of grade 5) using NWEA's skip-year growth norms. ${ }{ }^{\text {L }}$ Let $Y_{i g t}$ be a student i's RIT score in grade $g$ at instructional week $t$, while $\mathrm{Y}_{\mathrm{i} g+2, \mathrm{t}}$ is that same student's RIT score two grades later (in grade $g+2$ ) at instructional week $t$ (though students need not test in exactly the same week across years). We denote the observed growth student $i$ from grade $g$ to grade $g+2$ as $\mathrm{G}_{\mathrm{igt}}$, and the expected growth conditional on the student's prior score ( $\mathrm{Y}_{\mathrm{igt}}$ ) as $\widehat{\mathrm{G}}_{\mathrm{gt}}$. Based on these values, we calculated the conditional growth index (CGI) as:

$$
z\left(G_{\mathrm{igt}}\right)=\frac{\left(\mathrm{G}_{\mathrm{igt}}-\widehat{\mathrm{G}}_{\mathrm{gt}}\right)}{\operatorname{SD}\left(\widehat{\mathrm{G}}_{\mathrm{gt}}\right)} .
$$

The conditional growth percentile (CGP) is calculated in the same manner as the status percentile. More details on the CGP calculations can be found in the NWEA 2020 MAP Growth norms report. ${ }^{\text {vi }}$

## 3. Methods

## RQ1: How does student achievement in fall 2021 compare to pre-pandemic levels?

We calculated the median student achievement percentile for each grade level and subject in fall 2019 and fall 2021 based on the NWEA 2020 MAP Growth norms. The results are presented in Tables 5a and 5b. Additionally, we calculated the standardized gap between average test scores in grade $g$ between fall 2019 and fall 2021:

$$
\frac{\overline{\mathrm{RIT}}_{21 g}-\overline{\mathrm{RIT}}_{19 g}}{\sqrt{\frac{\left(\mathrm{~N}_{21 \mathrm{~g}}-1\right) \mathrm{SD}_{21 g}^{2}+\left(\mathrm{N}_{19 g}-1\right) \mathrm{SD}_{19 g}^{2}}{\mathrm{~N}_{21 g}+\mathrm{N}_{19 g}-2}}}
$$

where $\overline{\mathrm{RIT}}_{21 g}$ is the average fall 2021 test score in grade $g, \overline{\mathrm{RIT}}_{19 g}$ is the average fall 2019 test score in grade $g, \mathrm{SD}_{21 g}$ and $\mathrm{SD}_{19 g}$ are the corresponding SD estimates, and $\mathrm{N}_{21 g}$ and $\mathrm{N}_{19 g}$ are the observed sample size in grade $g$ in fall 2021 and 2019 respectively. The mean, SDs, Ns, and standardized effect sizes are also reported in Table 5.

## RQ2: How did academic gains between fall 2019 and fall 2021 compare to normative

 growth expectations?To address the second research question, we calculated the median CGP across fall 2019 and fall 2021 by grade/subject. These results are presented in Tables 6a and 6b. Additionally, we report on differences in median CGP by race/ethnicity, school poverty level, and prior achievement (based on fall 2019 achievement quintile). Achievement quintiles were calculated based on student's fall 2019 percentile (Q1: $<20^{\text {th }}$, Q2 $>=20^{\text {th }} \&<40^{\text {th }}$, Q3 $>=40^{\text {th }} \&<60^{\text {th }}$, Q4: $>=60^{\text {th }} \&<80^{\text {th }}$, Q5: $>=80^{\text {th }}$ ). Figure 1 shows the median CGP by race/ethnicity and Figure 2 shows the median CGP by school poverty.

## 4. Attrition analyses

We examined attrition rates to better understand how representative the students with observed test scores in fall 2021 are of NWEA's typical testing population. Following the "match rate" formula described by Andrew Ho, vii we calculated the percentage of students with observed test scores for a school year who were also observed two years prior (see figure below for a depiction).
fall years

Baseline (fall 2017 to 2019) match rate: $N_{A B}=A \cap B, m_{19}=\frac{N_{A B}}{N_{A}}$, att $t_{19}=1-m_{19}$ COVID-19 (fall 2019 to 2021) match rate: $N_{C D}=C \cap D, m_{21}=\frac{N_{C D}}{N_{C}}$, att $t_{21}=1-m_{21}$

Students were counted as "observed" in a school year if they had an observed test score in the fall term (typically between instructional week 1 and 12) in a given subject within a school where testing was offered. We have chosen to present these findings as attrition rates (e.g., 1 minus the observed match rate), which are presented in Table 7 by grade level and subject. Overall, the attrition rates during the COVID-19 impacted year ranged from 24 to $42 \%$ (average of 35\%) of students, when looking at all students testing. As a reference, the attrition rates ranged from 18 to $38 \%$ (average of $25 \%$ ) during a typical period. Subgroup attrition rates are presented in Table 8 separately by math and reading. We find higher attrition among Asian American, Black, Hispanic, and American Indian or Alaska Native (AIAN) students relative to White students in some grades/subjects, though the pattern is not consistently present for all grades and subjects. Likewise, when considering students' prior MAP Growth score quintile, we see the largest attrition rates amongst students in the lowest and second lowest quintiles of the distribution in the earlier grades in math, but this pattern does not replicate in reading. It is possible for a student to not show up in the sample two years later for many reasons, including (a) switching schools or districts (to a non-tested school), (b) testing opt-out, and (c) selective testing in later
year (e.g., the school may have decided to only test a subset of students in the subsequent fall). These attrition rates do not imply all of the missing students have unenrolled from the schools.

## 5. Limitations

There are several important limitations worth noting. Most importantly, we only included schools that tested in both fall 2019 and fall 2021. Schools that consistently tested across this two-year span are likely different than schools that tested in just one or the other year. Given the composition of the schools that met our inclusion criteria and the stability inherent in testing consistently across a two-year span, we expect percentile declines in the schools excluded from our sample would be more severe than what is reported here. In addition, the higher attrition rate observed between 2019-2021 as compared to the 2017-2019 period is another factor in the observed percentile rank declines. Given the higher attrition rate among students of color and students at the lowest quintiles of the MAP Growth score distributions from the prior year, we expect that the magnitude of our results is perhaps less pronounced than in the larger U.S. student population. Finally, we had access to limited demographic information on students and are unable to disaggregate our data by student-level poverty, English Language status, or special education status.

## 6. Conclusion

Our study found that academic achievement in fall 2021 was lower than a typical year for all students, with larger relative declines in math than in reading. Black, Hispanic, and AIAN students, as well as students in high poverty schools were disproportionately impacted, particularly in the elementary grades we studied. We also find that math gains between fall 2019 and fall 2021, more so than reading gains, were well below typical normative growth trends. We are currently working with school districts across the country to better understand the most effective recovery efforts for students most impacted by the pandemic. viii Through our ongoing work, we seek to provide data to inform evidence-based policies to support our students, teachers, and families on the path to recovery and deploy resources where they are most needed, now and into the future.

| U.S. public schools | 7 | 32,265 | 484 | 56\% | 50\% | 16\% | 24\% | 3\% | 27\% | 34\% | 27\% | 12\% |
| U.S. public schools | 8 | 32,507 | 486 | 56\% | 50\% | 16\% | 24\% | 3\% | 27\% | 34\% | 27\% | 12\% |

Note: F21=Fall 2021; FRPL=free or reduced priced lunch. The cross-sectional sample is the sample of schools that tested at least ten students in a grade in both fall 2019 and fall 2021, while the longitudinal sample represents the schools that had at least ten students with longitudinal data observed across both years. This table is presented for the schools included in the reading samples, but results are highly similar for math. The sources of the variables are the Common Core of Data (CCD) collected by the National Center for Educational Statistics. The U.S. public school population comparison for each grade was determined by limiting to the schools that were operational in 2020-21 and enrolled students in that grade level.

Note. AIAN= American Indian or Alaska Native. These results were calculated using our cross-sectional sample (described in Table 2). We classified schools into three poverty levels: (a) "Low Poverty" - less than 25\% FRPL eligibility,
(b) "Mid Poverty" - 25-75\% FRPL eligibility, and (c) "High Poverty" - greater than 75\% FRPL eligibility.

[^0]:    ${ }^{1}$ Our previous COVID research has excluded students tested in grades K-2 given concerns about whether remote and in-person assessments were sufficiently comparable in those grades. In this study we continue to restrict our data to students in grades 3-8, given some inconsistencies we observe in achievement trends for younger students. For example, in preliminary analyses of fall 2021 data, we observe trends for first and second grade students that are roughly comparable with trends for students in grades 3-8 (i.e., lower achievement in fall 2021 relative to prepandemic historic averages). However, data for kindergarteners are less consistent with these trends, with some data showing that kindergarten student achievement may be higher than in prior years. Sample-related factors make it challenging to confidently interpret these inconsistencies and understand if these are real and meaningful differences in achievement patterns. For example, drops in public school enrollment during the pandemic have been especially sharp for the youngest learners. iii,iv As a result, there is less comparability between current and previous groups of K-2 students (in terms of factors such as age, socioeconomic status, exposure to preschool, etc.) which makes comparisons of achievement trends over time challenging. However, with the near universal return to in-person learning in the 2021-22 school year, we intend to fill this critical information gap with future studies on achievement patterns for the youngest students currently in school, especially in the context of district and state recovery efforts.
