> Another idea for your launch is, again, I don't know how I feel about this, but is to give them a pool with side length five, and actually have them work on their—or do an independent time of—and explaining the tiling. You've got this patio going around the outside of the five by five square and how many tiles would it take for that patio.

This statement was coded as a *suggestion* because the coach recommended a task and participation structure for the teacher to use during the introduction of a lesson. A similar call for action was also expressed by a coach through the question, "What if you did just one example, not of a one by one, but a five by five or something?" Even though this discursive move is a question, the recommendation of modifying an activity is embedded within the question. Thus, this statement was also coded as a *suggestion*. We coded discursive moves as *suggestions* if the move contained an explicit recommendation for action or a clear, implicit recommendation embedded within a conversational move. This decision allowed the coding process to capture a wider variety of suggestive moves from coaches. However, because this decision required the researchers to analyze conversational moves for the underlying intent, the coding entailed some inference of intent. Besides acknowledging the inferential nature of some of the coding, we have struggled with how to methodologically characterize the nature of our inferences. In summary, accurately identifying suggestions from a coach requires analyzing discourse for both explicit and implicit recommendations directed at the teacher; analyzing for implicit intent, however, causes the coding process to become increasingly inferential.

Characterizing Suggestions

The second challenge in developing the analytic process involved characterizing the actionable nature of the suggestions. Initially, we realized that many of the suggestions were broadly stated, providing considerable latitude in how teachers might interpret and use them. For example, during a planning conversation, a coach said, "You probably want to look for students that have done the different strategies so that you know who you want to share how they did it, how they organized it." In this instance, the coach recommended the teacher monitor student thinking in order to select students to share different strategies during a summary discussion, but did not offer specific guidance as to which strategies to select. In the absence of a specific action, we coded the suggestion as a general suggestion and then coded for whether or not that general action was *present* or *not present* during the teaching of the lesson. However, the general nature of the suggestion made it more difficult to consider the tangible impact of the coach's suggestions. We found other suggestions to be specific; these suggestions provided exact language describing an action a teacher should use during the lesson. For example, a coach said, "You could even ask a question about—there's eight options there. 'If you play it 40 times, how many times would you expect so-and-so to win, and how many times would you expect the other guy to win?'" In this example, the coach recommended the teacher ask questions and provided two specific questions for the teacher to use. Suggestions that were specific were easier to identify in the enacted lesson and code but also represented a more localized impact on practice. Our coding scheme allowed us to distinguish between general and specific suggestions, but we were able to make more definitive decisions for specific suggestions. This poses a dilemma: our coding of uptake may only capture highly tangible evidence of impact while missing potentially more powerful and broader impact from the more general suggestions. Our challenge can be summarized in the following way: general suggestions have the potential to convey broader pedagogical principles than more specific ones, but entail greater inference when coding.

Characterizing Take Up of Suggestions

A third challenge was determining the extent to which a teacher enacted the precise details in a specific coach suggestion. We used a continuum to code the enactments. Coding along a continuum for the presence of specific details in a specific suggestion entailed qualitative characterization of the suggestion. Our continuum had these four characterizations, from low to high presence of a suggestion: a) no part of the suggestion, b) a single part of the suggestion, c) multiple parts of the suggestion, or d) the suggestion in its entirety. As a result, we created the codes *not present*, *partially adhere*, *mostly adhere*, or *fully adhere* to use when coding the teacher's enactment of specific suggestions (i.e. Table 1). As an example of coding a teacher's enactment of a suggestion using this continuum, during a planning conversation a coach said:

> They could even try tossing it three times. You could make it into a situation where a couple kids are playing a game. One kid wins if all three of the tosses match. One kid wins if only two of them match, and is it a fair game idea?

This was coded as a specific suggestion because the coach recommended the teacher use an activity and provided specific context and questions to use in the activity. During the lesson, the teacher facilitated an activity in which students flipped three coins but did not frame the activity as a game that may or may not be fair. Because only a single part of the specific suggestion was enacted by the teacher, the suggestion was coded as *partially present*. This qualitative characterization allowed us to describe accurately the extent to which the teacher enacted the suggestion but posed challenges related to the reliability of our coding.

To limit inference and potentially support more reliable coding, our coding continuum did not evaluate the effectiveness of the enacted suggestion; if a specific suggestion was evident in the lesson, we did not then consider whether or not the enactment was productive. So, while the teacher carried out the suggestion, the way that happened, and the implications of what happened subsequently in the lesson, may not have been aligned with the coach's intent. Avoiding evaluating the productiveness of the enactment of a suggestion has implications for the ways we consider the impact of a coach's suggestion on teacher practice, but using a low-inference coding scheme had its advantages. Although the process was anecdotally deemed reliable by coders during our first round of coding, additional calibration will be needed to reliably code the enactment of specific suggestions using the four leveled codes. In summary, characterizing the ways teachers enact a specific coach suggestion requires the use of a continuum, posing challenges for reliability. This challenge can be partially mitigated by limiting focus to the ways the teacher followed the explicit language of the coach's instruction, not considering intent or effectiveness; yet this limits the extent to which the data can be used to make claims about the impact of the coach on productive practice.

Discussion

Coaching is an increasingly popular professional development practice in mathematics education; however, more needs to be known about how coaches interact with teachers (Gibbons & Cobb, 2016). We presented the methodological challenges and opportunities in characterizing how the *suggestions* of a coach impact the practice of a teacher. Focusing on coaches' suggestions is one start to more fully understanding how coaching influences teaching practice. Researchers should continue to examine how the actions of a coach impact the practice of a teacher. More specifically, because coaches use discourse as a primary tool to engage teachers (Costa & Garmston, 2016; Heineke, 2013), we anticipate similar challenges exist in identifying coaching discursive moves beyond suggestions (e.g. invitational or evaluative). Knowing how discursive moves (i.e. Figure 1, Deussen, Coskie, Robinson, & Autio, 2007; Ippolito, 2010; Sailors & Price, 2015) impact the development of teachers would be beneficial for knowing how to support teachers through coaching. Thus, the specific challenges discussed within this paper relate to more global challenges that will be encountered during any analysis of how the discursive actions of a coach impact the practice of a teacher.

By illuminating the challenges and opportunities learned through our work, we aim to support future researchers by emphasizing the complexity of analyzing the relationship between the discursive moves of a coach and a teacher's practice. For example, when identifying a coach's suggestions within varied discursive moves in a full coaching conversation, we had to consider language that explicitly and implicitly communicated a recommendation to capture the nuanced ways the coach provided suggestions. Coding is this way required us to develop rules that reliably connected the language of a coach to their intent to provide a suggestion. These coding decisions introduced inference. However, not considering intent through implicit language would have constrained our ability to identify instances in which coaches leveraged their expertise to share actionable ideas with teachers for use in a lesson. We anticipate similar challenges will be encountered in identifying other discursive moves of coaches.

The second challenge was characterizing the suggestions in ways that considered the implications on a teacher's enactment of the suggestion. We created two classifications, *general nature* and *specific action*, but found general suggestions can promote broader pedagogical principles than more specific ones, but require greater inference when coding. We posit this challenge will also apply to coding schemes attempting to capture the impact of other coaching discursive moves. For example, a coach using broad or general invitational moves may provide the teacher with more latitude to reflect, but analysis may require higher levels of inference.

Our third challenge was limiting inference when coding for the enactment of specific suggestions; accomplished in part by not considering the effectiveness of the enacted suggestion. Low-inference coding in this context has advantages but disregarding effective enactment prohibits the study from claims about how the actions of a coach connects to changes in the quality of a teacher's practice. In other words, our current process will allow us to make low-inference claims about how teachers used the suggestions of the coach but prevent us from making claims about how the suggestions influenced the quality of the lesson. Discussion of these challenges invites future mathematics education researchers to consider methods to overcome these obstacles.

Much of the research on the development of professional noticing expertise has focused on prospective teachers. We contend that we must investigate practicing teachers as well, and in particular practicing secondary teachers, because they bring with them years of teaching experience and are situated in unique contexts. Hence we studied the longitudinal growth of the professional-noticing expertise of a group of practicing secondary teachers (N=10) as they progressed through a 5-year professional development (PD) about being responsive to students' mathematical thinking. Results indicated that the first half of the PD supported their interpreting and deciding-how-to-respond skills, and the second half of the PD supported their attending skills, which were already strong even before the PD. We compare these results with the activities that occurred in the PD and discuss implications for future research and PD programs.

Keywords: Teacher Education - Inservice / Professional Development, Algebra and Algebraic Thinking

Introduction

Professional noticing of students' mathematical thinking is a specific type of teacher noticing expertise, and it occurs when the teacher notices a student's mathematical strategy during instruction (Jacobs & Spangler, 2017). In that moment, the teacher (a) attends to the details of the student's strategy, (b) interprets the student's mathematical understanding, and (c) decides how to respond to the student on the basis of the student's mathematical understandings (Jacobs, Lamb, & Philipp, 2010). These three component-skills occur simultaneously, are interrelated, and are interdependent. Additionally, this noticing expertise distinguishes itself from other types of noticing expertise that only include the component-skills of attending and interpreting, or that focus on issues other than the student's mathematical thinking (e.g. issues of equity, representations, or funds of knowledge; Dreher & Kuntze, 2015; Hand, 2012; McDuffie et al., 2014). It is important to understand the development of teachers' professional noticing expertise because research has shown that teachers who attend to student thinking support student achievement (e.g. Boaler & Staples, 2008; Jacobs, Franke, Carpenter, Levi, & Battey, 2007) and learn from their practice (Sowder, 2007; Wilson & Berne, 1999).

Teachers can differ in their noticing patterns depending on their experiences, backgrounds, and education (Santagata, Zannoni, & Stigler, 2007; Miller & Zhou, 2007). Professional development (PD) on noticing children's thinking can improve teacher noticing (Sherin & Han, 2004; van Es & Sherin, 2010) and has been shown to extend to the classroom (Sherin & van Es, 2009) and support teacher learning after the PD is complete (Franke, Carpenter, Levi, & Fennema, 2001). With respect to professional noticing of students' mathematical thinking, much of the research has focused on prospective teachers' development (e.g. Fernández, Llinarez, & Valls, 2012; Fisher, Thomas, Schack, Jong, & Tassel, 2018; Monson, Krupa, Lesseig, & Casey, 2018; Simpson & Haltiwanger, 2016; Tyminski, Land, Drake, Zambak, & Simpson, 2014). Few have analyzed the development of

professional noticing expertise among practicing teachers (e.g., Jacobs et al., 2010; LaRochelle, 2018). Practicing teachers differ in important ways from prospective teachers because they bring with them years of teaching experience to PD activities and are situated in contexts that may or may not be conducive to what they learn in the PD (Levin, Hammer, & Coffey, 2009). Hence, it is important for the field to study the growth of this expertise in practicing teachers as well.

Practicing Teachers' Professional Noticing of Students' Mathematical Thinking Expertise

We found two studies that document the growth of professional noticing expertise among practicing teachers. Jacobs and her colleagues (2010) showed us that for practicing primary teachers, teaching experience alone may not adequately support robust professional noticing expertise, and that long-term, sustained PD may be necessary to develop these skills. They found significant positive differences across all three groups of practicing teachers for each component-skill of professional noticing, with attending reaching a ceiling level after 2 years. Hence, for practicing primary teachers, there is a clear need for sustained PD in order to develop this important expertise.

LaRochelle (2018) conducted an analysis similar to Jacobs et al. (2010), comparing the professional noticing expertise of prospective secondary teachers, experienced secondary teachers, and experienced secondary teachers who had completed 4 years of long-term, sustained PD about responding to students' mathematical thinking. Secondary teachers differ in important ways from primary teachers because they experience different school structures (Blatchford, Bassett, & Brown, 2011; Ferguson & Fraser, 1998) and exhibit different conceptions about mathematics, students, and teaching (Weinstein, 1989). However, LaRochelle's findings did indicate that for many practicing secondary teachers, teaching experience may not adequately support this expertise. In particular, the experienced secondary teachers exhibited similar professional noticing skills to the prospective secondary teachers, whereas the experienced secondary teachers with four years of sustained PD exhibited stronger professional noticing skills than the experienced secondary teachers.

However, it is unclear from LaRochelle's (2018) study what trajectories of development might exist for practicing secondary teachers, and what activities might support this development. Hence, we build on his study by documenting the longitudinal growth of a group of practicing secondary teachers as they progressed through a 5-year PD program that focused on being responsive to students' mathematical thinking. Specifically, we measure the growth that we saw in each component-skill of professional noticing at various points in time during the long-term PD. Consequently, we answer the following question: What changes in experienced secondary teachers' professional noticing expertise can be seen across 5 years of sustained PD about being responsive to students' mathematical thinking? Answers to this question allowed us to compare the growth we saw with the activities that occurred during the PD, and we share implications of these results in our discussion section.

Methods

Participants

Initially, we selected a cohort of 32 master teachers (16 mathematics and 16 science) for a five-year fellowship through a highly competitive application process that included analyzing student work, video clips of teaching and an interview (Nickerson et al., 2018). In addition to evidence of student-centered teaching, we sought teachers who had a disposition as a learner. When they began, the 16 mathematics teachers (who are the focus of this paper) had 2 – 30 years of teaching experience, with an average of 13 years. All teachers came from high-needs school districts in the south-western region of the United States. Due to attrition (e.g., moving, changing content areas, and the like), we have longitudinal data for 10 of the teachers.

Mathematics Teacher PD

Here we describe the nature of the PD over the five years of the PD program. We shifted the PD activities over the five years, foregrounding some activities in the first few years and others in the subsequent two years. The focus of the PD in the first few years was on further development of content knowledge and pedagogy. In the latter years, the PD was more explicitly focused on developing teacher leaders. We describe the nature of these activities over time.

In the first year, teachers watched and discussed videotapes of teaching and were introduced to the *professional noticing* skills of attending to, interpreting, and deciding how to respond to students' mathematical thinking. The PD began with a teacher educator interviewing a student to illustrate the challenges and affordances inherent in one-on-one interviews. Teachers discussed how to conduct an interview, including the importance of wait time, questioning, and avoiding directing students to a particular strategy or answer; and what one might learn from an interview, such as how students approach problems, what one can learn from incorrect responses and how those are often steeped with kernels of understanding, students' affect, and so on. The teachers, working in pairs, then interviewed secondary students.

During subsequent PD sessions, the teachers engaged in many other activities that allowed them to discuss students' content-specific ideas and how to build on those ideas. For example, in year 1 teachers solved pattern-generalization problems in multiple ways and made connections among the solutions, and discussions of student thinking naturally occurred during these activities. Teachers also discussed interviews that they conducted with students at their schools and brought artifacts of student work across a variety of content areas to the PD sessions.

In addition to activities that focused on individual students, teachers also learned about complex instruction (Cohen, 1994) and discussed issues related to facilitating group work. During the third year, teachers, accompanied by teacher educators, traveled to school sites to observe each other teach and then debrief and reflect on the experience. Teachers also coached each other in team-teaching a group of middle school students. Discussions of students' ideas were always framed using the Professional Noticing Framework.

Toward the end of year 3 and throughout year 4, we began a more explicit focus supporting teachers in learning how to lead PD. Activities included selecting artifacts and rehearsing situations they may face in their leadership practice. In year 5, they engaged in lesson study, and the lesson debriefs in the lesson study were explicitly structured to attend to and interpret student ideas before discussing how to modify the lesson.

The PD activities described above align with what the literature has shown to be productive activities for supporting teachers' professional noticing expertise (Fisher et al., 2018; Jacobs et al., 2010; Monson et al., 2018). In general, these studies have shown that activities such as doing mathematics together, learning about students' mathematical thinking through frameworks and research articles, *decomposing* (Grossman et al., 2009) the practice of professional noticing, and practicing the component-skills of professional noticing with written artifacts, video artifacts, and in one-on-one interviews with students can support teachers' professional noticing skills.

Data Collection

In May, 2013, we collected (Y0) baseline data; we repeated data collection in year 3 (Y3) and again in Year 5 (Y5). As part of the data collection, participants analyzed and responded to prompts about the Pattern Generalization Video, a video-recording of a class of middle school students engaged in a figural pattern generalization task with beams and rods (National Center for Research in Mathematics and Science Education, 2003).

Pattern Generalization Video. In the Pattern Generalization Video, students are considering a set of rods that are being connected in a way that creates a beam (see Figure 1). The rods are connected to form triangles, and the length of the beam is the number of rods that form the bottom. Students begin by finding a recursive pattern based on beams of lengths 1, 2, 3, and 4. Then, students are challenged to find an explicit rule for finding the number of rods for a beam of any length. Near the end of the video, two groups of students share. The first group sees the number of rods that make up the top of the beam (L-1 rods), the number of rods that make up the middle of the beam (2L rods), and the number of rods that make up the bottom of the beam (L rods). They recognize that the total is the sum of these three sections, and write L + (L-1) + (2L) = total. The second group to present deconstructed the beam in a different way; instead, they see a set of 4 connected rods, a triangle with a rod on top, and they iterate this pattern from left to right until they reach the last set of 4 rods, where they have to erase the last rod on top, and write the equation, total = 4L - 1. Participants have opportunities to notice ideas such as quantitative reasoning, use of algebraic symbols, meanings for operations and symbols, and other generalization concepts (Jurdak & El Mouhayar, 2014; Lannin, Barker, & Townsend, 2006).

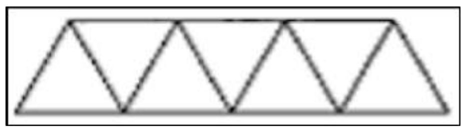

Figure 1. A beam of length 4 has 15 rods.

Prompts. After watching the video, the participants responded to the prompts listed below. The prompts were adapted from Jacobs and her colleagues (2010), and are related to the three professional noticing component-skills:

1. (*Attending*) Describe in detail what the two groups of students who presented at the board did in response to the task.
2. (*Interpreting*) What did you learn about these students' mathematical understandings?
3. (*Deciding how to Respond*) Pretend you are the teacher of these students. What problem(s) might you pose next, and why?

Data Analysis

Analysis procedures followed those of Jacobs et al. (2010). Three researchers independently coded the blinded responses for each of the component skills and then discussed codes to resolve any differences. For attending responses, researchers analyzed the extent to which participants attended to the details of the students' strategies. This coding involved identifying the important details of each student's strategy and counting the number of details each participant shared. For interpreting responses, researchers analyzed the extent to which participants interpreted the students' understandings, which involved looking for evidence that participants interpreted specific and nuanced understandings that were consistent with the students' work and with the research on students' pattern generalization skills (e.g. Jurdak & El Mouhayar, 2014). For the deciding-how-to-respond responses, researchers analyzed the extent to which participants based decisions on the students' mathematical understandings. This analysis involved looking for evidence that participants connected their decisions to the students' mathematical ideas, provided specific problems and/or number choices in the problems they selected, provided a rationale that was consistent with the student work and the research on students' pattern generalization skills, and provided evidence of anticipating or building on the students' thinking. Ultimately, each of these component skills was assigned a score of 0, 1, or 2.

Findings

In Table 1, we provide the mean scores of the ten participants, at three time points, in response to the Pattern Generalization Task, described above. Attending scores started high, remained stable at Y3, and increased to a ceiling level in Y5. Interpreting scores were modest at Y0, grew in Y3, and then remained stable. Means for deciding how to respond started low (most participants provided lack of evidence for deciding how to respond on the basis of students' mathematical ideas), then rose relatively dramatically by Y3, and remained stable.

Table 1: Mean Scores in the three component skills for Y0, Y3, Y5

	Attending			Interpreting			Deciding how to Respond		
Year	Y0	Y3	Y5	Y0	Y3	Y5	Y0	Y3	Y5
Mean	1.4	1.4	1.9	0.7	1.0	0.9	0.3	0.9	0.9

Examples

In this section, we share examples of two participants who exhibited significant improvements in scores on Attending to the details of students' strategies and on Deciding How to Respond from Year 0 to Year 5.

Adam. In Year 0, Adam's responses provide insight into both the relative importance of students' ideas and the detail with which they were shared (see Table 2). For example, in Year 0, Adam recognized that both groups of students connected their formulas to the model, but did not provide details of the strategy. For example, beyond saying that each student used a formula, the actual formula and the students' explanations were not shared. The descriptions were so general that one would be hard-pressed to be able to recreate the strategy, or be able to use what was shared to plan next steps for instruction. In contrast, in Year 5, Adam was able to share the specific formulas that each student used, and provide details about how students connected their formulas to their physical representation of the pattern. This response signifies a change in response from Years 0 to Year 5, not only in the number of details provided but, also implicitly, in the value that Adam placed on the students' strategies. We conjecture that because Adam valued students' ideas and had learned more about students' thinking about pattern generalization, he paid close attention to them and was thus better able to recall those details.

Table 2. Adam's Responses to Attending to the Details, Year 0 to Year 5

Year 0	*Lack of Evidence* *Student 1:* I do not remember. I'm going to assume Tristan is the last girl who presented. The students presented their formula algebraically. Next, they connected the symbols with their model. The students who were part of the group were there for support. Before they presented, they were engaged in the discussion. *Student 2:* She also presented her formula and connected the symbols with the model they had built.
Year 5	*Robust Evidence* *Student 1:* She explained her formula L+(L-1)+2L= total by connecting each part of the formula to the beam diagram. She explained the bottom of the beam was "L", the top of the beam was the length of the bottom minus the one rod and the total middle rods was 2 times the length of the base of the beam. *Student 2:* She also explained her formula which was 4L-1. The teacher asked her to explain how [the formula] was connected to the diagrams. She pointed at the rods beam diagram showing how the rods enclose 4 complete triangles but at the end you are missing one rod to complete the figure. [draws two figures and notates each as follows: 4(1)-1 and 4(2)-1].

Ella. We share the example of Ella to highlight changes from Year 0 to Year 5 in deciding how to respond (see Table 3). First, in Year 0, the problem Ella selected serves a funneling function toward a correct answer (Andrews & Bandemer, 2018) when Ella wanted her students to answer a question about whether the two formulas are, in Ella's words, "the same." Then, in the rationale, Ella appears to use directive language by sharing that she wanted students to *see that* the generalizations are equivalent, rather than, for example, *explore whether* the generalizations are equivalent. Her language "see that" speaks to funneling toward a correct answer rather than an openness to exploring and building on students' ideas or anticipating other student responses. In contrast, in Year 5, Ella suggests four questions, two that are specific to Tristian's and Beverly's formulas, and two that reflect an openness to learning about students' ideas. Two of the questions that Ella posed are specific and specifically related to the students' previous approaches. Further, her question, "What do your results tell you about both generalized formulas?" coupled with her rationale about questioning reflects a stance that values students' ideas and provides students with opportunities to reflect on the connections between the two formulas, rather than funneling students toward a single response. These kinds of changes reflect the sorts of responses we would hope to see and that teachers can eventually enact with their students in the classroom.

Table 3. Ella's Responses in Deciding How to Respond, *Year 0 to Year 5*

Year 0	*Lack of Evidence* Problem or Problems: I may ask students if these 2 formulas are the same. Rationale: The purpose being for students to *see that* even though the problems were deconstructed and generalized differently that the end result, the generalizations are equal. [italics added]
Year 5	*Robust Evidence* Problem or Problems: Can we use Tristan's equation to find the number of rods in a beam of length 10? What about Beverly's? How do the answers compare? What do your results tell you about both generalized formulas? Rationale: This questioning would hopefully lead students to the idea that these 2 generalized expressions are equivalent.

Change in Responses. Looking across both sets of responses provides the reader with the opportunity to see how responses for attending and deciding-how-to-respond changed over time. In both cases, the responses became more detailed and reflected a valuing of and curiosity about students' ideas. This orientation is one that we know is generative. That is, teachers who are attuned to and curious about their students' ideas continue to grow in their mathematics teaching practice long after PD has ended (Franke et al., 2001), and so improved professional noticing is an outcome we seek not only for the specific expertise that teachers develop, but also for their orientation toward students that continues to aid their own learning for years to come.

Discussion: The Development of Practicing Secondary Teachers' Professional Noticing Expertise and Related PD Activities

In our study we found growth from Y0 to Y3 in the Interpreting and Deciding How to Respond component-skills. In the first three years, the teacher educators spent much time engaging teachers in activities and discussions around individual students' ideas, including interviews, analyzing video and written artifacts, and observing each other teach with a protocol that focused on the students' thinking. As other studies have shown (e.g. Jacobs et al., 2010; Monson et al., 2018), these experiences provided many of our teachers with opportunities to learn about and build on student thinking in a rich way and supported them to develop a disposition to build on student thinking, both of which may have helped them to develop their interpreting and deciding-how-to-respond skills. We believe that the opportunities to consider the research on student thinking in pattern generalization and investigate a single student's (or small group of students') ways of reasoning allowed many of our teachers to develop their understanding of students' learning trajectories within the domain of pattern generalizations, which we posit is an important component of developing one's interpreting and deciding-how-to-respond skills (Nickerson, Lamb, & LaRochelle, 2017).

However, our results indicate that many teachers' interpreting and deciding skills had room for improvement. This differs from Jacobs et al.'s (2010) study of primary teachers, wherein most had demonstrated robust professional noticing skills after 4+ years of PD. As Nickerson et al. (2017) point out, there is a difference between the student thinking frameworks for secondary mathematics and for primary mathematics, in that the student thinking frameworks for primary mathematics are much more explicit and well-connected than those available for secondary mathematics. It is likely that well-connected and detailed learning trajectories at the secondary level could help teacher educators further support teachers' professional noticing expertise. For example, we noticed that the video artifact we selected showed students constructing explicit symbolic generalizations that also made connections to the figure, which is a high level of sophistication of generalization skills (Jurdak & El Mouhayar, 2014; Lannin et al., 2006). During the PD activities, teachers talked about some of the earlier stages of students' generalization skills, such as recursive thinking. However, what fruitful directions should teachers pursue after students demonstrate sophisticated generalization skills?

With respect to the attending component-skill, we did not see growth from Y0 to Y3. This also differs from Jacobs et al.'s (2010) study of primary teachers, wherein the primary teachers reached a ceiling level of attending skills after 2 years. However, we noticed that many of the secondary teachers in our study exhibited strong attending skills prior to engaging in the PD. Our teachers were specially selected from a large pool of applications to participate in the 5-year PD program, which may have contributed to our results (Nickerson et al., 2018).

From Y3 to Y5, we saw growth in teachers' attending skills, but not their interpreting and deciding-how-to-respond skills. During these years, teachers focused on issues of coaching and becoming leaders in their respective teaching communities. In year 5, they engaged in a year-long lesson study activity in which they collaboratively planned, taught, re-taught, and debriefed about a lesson. We hoped that lesson study would become a PD structure that they could bring to their respective teaching communities that focused other teachers' attention on student thinking. During discussions about becoming a teacher-leader, we maintained a focus on being responsive to student thinking because instruction that attends to student thinking has many positive benefits for both students and teachers (e.g. Franke et al., 2001; Jacobs et al., 2007). Hence, student thinking was still an important component, but it may have been back-grounded by the other discussions regarding being a teacher-leader. We wondered if the growth in attending may have resulted from the intense focus on attending to evidence of student thinking, in both the lesson study and the discussions of coaching. During lesson study, teachers were required to gather as much evidence of student thinking as possible for the debrief and lesson modification, which may have given them more opportunities to practice attending to student thinking and supported in them a belief that one should attend to student thinking.

These results differ from studies of prospective teachers, which found significant improvements in all three component-skills in much shorter amounts of time (e.g. Fisher et al., 2018; Monson et al., 2018). However, there are many factors that make comparing our results to the results reported in their studies tenuous. First, it is unclear to what extent the surrounding contexts support or constrain teachers' professional noticing skills. Practicing teachers do not often have the luxury of attending a PD on a weekly basis (as do prospective teachers), and the classroom contexts in which they work may or may not be conducive to supporting this expertise (Levin et al., 2009). We imagine that the competing obligations of practicing teachers (and especially our emerging teacher leaders) may have influenced the development of their professional noticing expertise. Second, it is unclear how the selections of artifacts influence the results of these studies. In particular, we wondered if we had overly challenged our teachers by selecting an artifact that exhibited sophisticated generalization skills (Nickerson et al., 2017). Third, we recognize that the field does not have an agreed-upon standard for high quality professional noticing skills. For example, while Monson et al. (2018) used the term "emerging ability" to represent the highest levels of noticing in their study, Fisher et al. (2018) and Jacobs et al. (2010) used the terms "robust evidence" to represent the highest levels of noticing. How do the responses that received the highest scores compare across each study? What we can say for certain is that significant growth was documented in each of these studies. However, comparing the amount of growth with other studies is less obvious.

In this study, we documented the longitudinal changes of a group of practicing secondary teachers as they progressed through a long-term PD about being responsive to student thinking and becoming teacher-leaders. Our results indicated that different PD activities supported each component-skill differentially. Specifically, the activities in the first half of the PD that supported discussions about individual student thinking and how to build on student thinking seem to have supported our teachers' interpreting and deciding-how-to-respond skills. In addition, the activities in the last half of the PD that supported discussions about coaching others and using evidence of student thinking seem to have supported our teachers' already-strong attending skills. These results have implications for both researchers and teacher educators. In particular, our study can inform teacher educators about the nature of the activities that contribute to various components of professional noticing through explicit or implicit practice. Additionally, our study provides researchers with insight about (a) artifacts they might use to measure professional noticing and (b) rubrics for categorizing responses, as well as factors that may support or inhibit practicing secondary teachers' development of professional noticing expertise.

School districts across the United States are turning to mathematics teacher leaders (MTLs) to support the teaching and learning of mathematics. And yet, what does research seem to say about MTLs? In this paper, we report findings from an exploration of PME-NA proceedings between 1984 and 2019 to examine the role of MTLs. In particular, we examine the following: historical MTL submission trends and the extent to which these trends are coupled with the implementation of national MTL events; broad methodological trends; as well as the ways in which MTLS are positioned. Our findings indicate that future research requires explicitly describing MTLs' roles within systems of professional development to better understand their impact on practice and learning.

Keywords: Teacher Education – Inservice/Professional Development, Instructional Leadership

Introduction

Mathematics reformers have long called for improved learning opportunities for all students across preK-12 classrooms in the United States. Although instruction that promotes mathematics as sensemaking and problem solving has been recommended (Cobb et al., 2018), this shift dramatically differs from the way many classroom teachers once learned and taught math (Hiebert, 1999). Thus, local school systems are left to determine how to create conditions that support changes in teachers' instruction (Hopkins et al., 2013). To address this challenge, many schools are hiring mathematics coaches, or as we will refer to in this paper – *mathematics teacher leaders (MTLs)* – as they embody key features of effective professional development (Gibbons & Cobb, 2017). Indeed, MTLs have become a popular professional development fixture in United States schools (Fennell, 2017).

Given the rapidity with which MTL positions have spread, there is an urgency which requires the field of mathematics education to better understand the research surrounding effective MTL implementation. The overarching aim of this paper, then, is to explore and examine the research related to MTLs in the North American Chapter of the International Group for the Psychology of Mathematics Education (PME-NA) proceedings between 1984 and 2019. In doing so, our purpose is to discover patterns, commonalities, and trends across the PME-NA proceedings that will inform future research directions, while simultaneously deepening our own understanding of how MTLs are positioned across varied contexts. We hope to illuminate this important work so that other mathematics education researchers can build upon and advance policy and practice surrounding MTLs as there are many schools without a formalized position. We note that the research presented within this paper is only a small slice of the work our team has initiated in which we are examining MTLs' positionality within educational research studies as a whole.

Guiding Literature

Roles and Responsibilities of MTLs

Using knowledge of best practice regarding professional development, many school districts have created MTL positions to meet the demands of high stakes accountability and to support teachers in their work to provide quality mathematics instruction for each and every student (McGatha & Rogelman, 2017). MTLs are expected to provide professional development within the context of teaching and learning versus the traditional "sit and get" approach to professional development. AMTE provides a broad working definition of a MTL which identifies these individuals as "…teachers, teacher leaders, or coaches who are responsible for supporting effective mathematics instruction and student learning at the classroom, school, district, or state levels" (2013, p.1). To narrow the definition further, we define MTLs as a district- or school-based support person whose knowledge and expertise in mathematics content, pedagogy, and children's learning trajectories assists teachers with their content, pedagogy, and understanding of children's learning trajectories (Campbell & Malkus, 2013).

Even with the definition, the roles and responsibilities of MTLs are complex and ever evolving. Because the term MTL has different and distinct interpretations depending on location, the work of a MTL is diverse and spans across contexts to include administrative tasks, instructional tasks, professional development tasks, and data analysis. To align with our definition, we focus on the type of support MTLs provide. Depending on location and need, there are different models of support that MTLs provide: individual or teacher pair (Barlow et al., 2014), working with teacher groups (Elliott et al., 2009; Lesseig et al., 2016), whole school-level (Campbell et al., 2013; Felux & Snowdy, 2006; McGatha & Rigelman, 2017). Individual and pair support activities could include observations with coaching cycles and modeling lessons. Small group support could include assisting with professional learning communities or team meetings. Whole school support could include trainings and professional development sessions. Additionally, some MTLs are expected to provide support in the form of student intervention; this type of support could model intervention instruction for teachers as a form of professional development. In order to provide this support, MTLs need the necessary expertise in mathematics content and pedagogy and must exhibit key leadership skills in working with adult learners (AMTE, 2013; NCTM, 2012).

Key Historical Events

The use of MTLs to support the teaching and learning of mathematics is not a new call to action. Drawing upon Fennell's (2017) work discussing MTL policy recommendations from a historical perspective, we note key events that have influenced the development and use of MTLs across the United States.

The 1970s saw the emergence of projects that focused on creating positions for MTLs (e.g., *Developing Mathematics Enthusiasts* project, Fennell, 1978). Across these projects, school-level MTLs were identified and employed as mentors to provide content-specific support to other teachers and school stakeholders. In the decade that followed, Fennell notes three key events which underscored the importance of these newly created school-based MTL positions: (1) the National Council of Teachers of Mathematics (NCTM) recommended state certification endorsement for elementary mathematics specialists, (2) John Dossey, the acting president of NCTM during this time frame, published a call for mathematics specialists (Dossey, 1984), and (3) the National Research Council's (NRC) *Everybody Counts* (1989) report expressed the need for elementary mathematics specialists. The combination of these three national events within such a short timeframe highlights the urgency and significance of implementing highly competent and prepared MTLs within schools.

The 1990s were marked by a lull in policy and events related to MTLs. However, this trend came to a halt in the early 2000s with a resurgence of MTL policies and events. Fennell (2017) highlights nine key milestones (p. 6) during this time, including the NCTM's *Principles and Standards for School Mathematics* (2000), the NRCs *Adding it Up* (2001), and the National Mathematics Advisory Panel (2008) documents all making recommendations related to the use of MTLs to support the teaching and learning of mathematics. Additionally, during this time, national legislation centering on No Child Left Behind (2001) and followed by the Every Student Succeeds Act (2015) prompted schools and districts to create MTL positions as a way to address the push for assessment and accountability in mathematics.

Moving into the 2010s, the call for MTLs continued to advance. A major event in 2010 was the release of the *Standards for Elementary Mathematics Specialists: A Reference for Teacher Credentials and Degree Programs* from the Association of Mathematics Teacher Educators (AMTE; revised in 2013). In that same year, a joint position statement calling for all elementary schools to have access to mathematics specialists was released by AMTE, the Association of State Supervisors of Mathematics (ASSM), the National Council of Supervisors of Mathematics (NCSM), and NCTM. Building upon AMTE's standards, NCTM/CAEP released the Elementary Mathematics Specialist Standards (NCTM, 2012), with both sets of standards used by many programs across the country.

Policy recommendations and key events do not stop here. As we progress through the 2010s, we see MTLs referenced in Linda Gojak's NCTM president message (2013), as well as an AMTE research conference focused on elementary mathematics specialists in 2015. When looked at as a whole, this timeline overview shows the call for MTLs has persisted for decades and continues to be at the forefront of research, policy, and organizational recommendations.

Research Questions

The overarching purpose of this paper is to explore PME-NA submissions[1] that center on mathematics teacher leaders (MTLs) during the years 1984-2019. Specifically, we ask the following three research questions:

1. What are the historical trends for PME-NA MTL submissions between the years of 1984 and 2019 and to what extent do these trends align with the implementation of key MTL events and/or policies?
2. What methodological trends are observed across PME-NA submissions between 1984 and 2019?
3. How are MTLs positioned across PME-NA submissions between 1984 and 2019?

Method

Below, we outline the procedure that was systematically used to integrate the research related to MTLs across PME-NA proceedings in years 1984-2019. Additionally, we describe the methodological parameters of our data identification and analysis.

Data Identification

We initiated our exploration by conducting a comprehensive search of PME-NA proceedings between 1984 and 2019. In targeting this date range, we drew upon the key MTL events as identified by Fennell (2017). The lower date range was identified due to the published call for elementary mathematics specialists (Dossey, 1984) mentioned in Fennell's (2017) MTL milestones. The upper date range was identified as 2019 as this was the last year for which PME-NA proceedings were available. We note that the PME-NA proceedings provided us with a data source that was both entirely focused on mathematics and peer-reviewed.

[1] When we use the word submission, we are referring to submissions that appear in published PME-NA proceedings, and may include any of the following: research reports, brief research reports, posters, working groups, and/or plenaries.

To ensure our search maintained high recall and precision (Sadelowski & Barroso, 2007), we used search terms beyond mathematics specialist, mathematics coach and mathematics teacher leader to capture the nuanced ways in which MTLs might be positioned in the proceedings. These terms included: interventionist, response to intervention specialist, resource teacher, instructional coach, Title I Step-Up Mathematics, mathematics lead, and mentor. Initially, we used the search function to apply each of these terms to each published PME-NA proceeding between 1984-2019[2]. In doing so, we noticed that our search brought up many submissions that were not directly related to our central research questions. Thus, we made the decision to only include submissions in which the search terms appeared in the title, abstract, and/or keywords[3]. If the search terms appeared in the body of the submission, but did not appear in the title, abstract, and/or keywords, then that submission was excluded. To examine relevancy across all paper modalities, our collection included papers, research briefs, posters, working groups and plenaries. We also included all methodologies. Last, due to our interest in preK-12 education, we eliminated those entries that emphasized undergraduate mathematics education or faculty studies. Ultimately, our search resulted in 109 unique submissions.

Data Analysis

The submissions in this analysis were coded in several distinct ways. We first completed counts to determine the frequency of submissions for each year, and also looked at spikes and declines in year-to-year submissions (Research Question 1). Next, during our analysis of the methods sections, we applied the following coding scheme for methodology (Research Question 2): qualitative (QUAL), quantitative (QUANT), mixed methods (MIXED), and other (OTHER[4]). Our last coding scheme was also applied while reading the methods section and centered on how the MTL was positioned within the submission (Research Question 3): School-Based Coach, Researcher, Pre-Service Teacher, Pre-Service Teacher Mentor Teacher, Teacher Leader, Mentor Teacher, or Mentor of Students. All codes were mutually exclusive.

Findings

We now present the findings for each of our three research questions in the space that follows.

Research Question 1: Overall Trends

We first explore overall PME-NA MTL submission trends between the years of 1984-2019. As illustrated in Figure 1 below, there are several trends we wish to highlight.

[2] We were unable to include the years 1994, 1993, 1992, 1988, 1986, and 1984 because the search function on those proceedings did not work.

[3] For posters, we only searched for our terms in the titles and/or keywords because those submissions did not have abstracts.

[4] Submissions coded as Other included Plenaries and Working Groups as these submissions did not have a methodology.

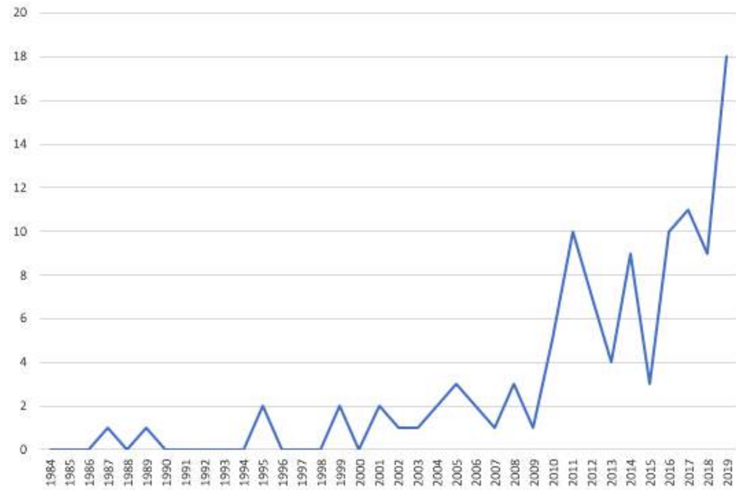

Figure 1: Overall PME-NA MTL Submission Trends from 1984-2019

Overall, there has been an increasing trend in PME-NA MTL submissions between 1984-2019. Starting in 1984, when Dossey published the call for elementary mathematics specialists, there were zero MTL submissions. In 2019, after the implementation of 22 different events for elementary mathematics specialists (Fennell, 2017), there were 18 MTL submissions. This finding indicates the, overall, increased focus on research involving MTLs.

An interesting trend is also noted when comparing year-to-year submission patterns with the key events identified by Fennell (2017). That is, we see the largest spikes in MTL submissions between the years 2010-2011 (increase of 5 MTL submissions), 2013-2014 (increase of 5 MTL submissions), 2015-2016 (increase of 7 MTL submissions), and 2018-2019 (increase of 9 MTL submissions), and these trends are tightly coupled with key MTL events outlined in Table 1. In other words, the largest MTL submission spikes appear to follow the implementation of key MTL national events. Furthermore, we see somewhat pronounced decreasing trends in MTL submissions between the years of 2011-2012 (decrease of 3 submissions), 2012-2013 (decrease of 3 submissions), and 2014-2015 (decrease of 6 submissions). For the most part, these trends are coupled with the absence of key MTL national events. For example, the absence of key MTL events in 2011 and 2014 might help explain the decrease in MTL PME-NA submissions between the years 2011-2012 and 2014-2015.

Table 1: Select MTL Events from Fennell (2017)

Year	Events
2010	AMTE released *Standards for Elementary Mathematics Specialists*
2013	NCTM President's Message from Linda M. Gojak: *It's Elementary! Rethinking the Role of the Elementary Classroom Teacher*
2015	NCTM Research Brief *The Impact of Mathematics Coaching on Teachers and Students* (McGatha, Davis, Stokes) AMTE EMSs Research Conference Every Student Succeeds Act

Research Question 2: Methodological Trends

As previously mentioned, we read the methods section for each of the 109 MTL submissions to better understand broad methodological trends for PME-NA MTL submissions between 1984-2019. Overall, 68% (n = 67) of the MTL submissions were coded as QUAL, 23% (n = 22) were coded as MIXED, and 9% (n = 9) were coded as QUANT. Hence, most submissions involved qualitative investigations, while quantitative investigations surfaced less frequently. Furthermore, preliminary analysis indicates variability in the quality and types of research questions posed, and further analysis is required within each methodological approach.

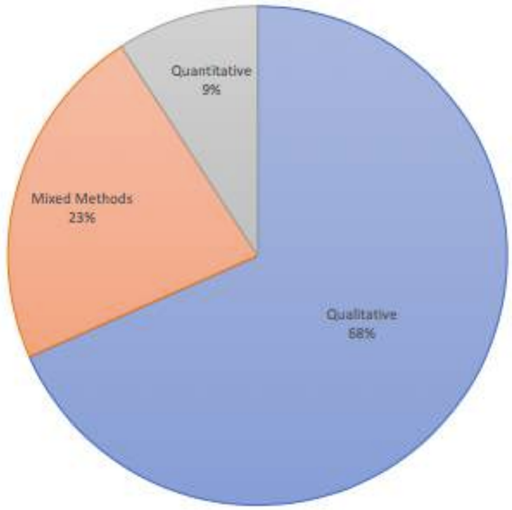

Figure 2: Methodological PME-NA MTL Submission Trends from 1984-2019

Research Question 3: Positioning of MTL

We also analyzed the nuanced ways in which MTLs were positioned in PME-NA submissions from 1984-2019. Across our data set of 109 submissions, MTLs were positioned in seven different ways. In Table 2 below, we provide a description of each of the ways in which MTLs were positioned, as well as a count for each. We note that, overall, MTLs were most frequently positioned as a School-Based Coach (n=44), followed by Researcher (n=22), and then Pre-Service Teacher Mentor Teacher (n=16). Other roles, such as Pre-Service Teacher (n=3) and Mentor of Students (n=2) less frequently emerged.

Table 2: MTL Positioning in PME-NA Submissions from 1984-2019

Positioning	Count	Description
School-Based Coach	44	The MTL is released from their classroom teaching position and is charged with supporting teaching and learning across one or more schools.
Researcher	22	The MTL is a university researcher, faculty member, and/or staff member who serves as a coach/mentor to others in various contexts.
Pre-Service Mentor Teacher	16	The MTL is a classroom teacher that mentors or supervises pre-service teachers at a preK-12 school.
Teacher Leader	12	The MTL is a classroom teacher who receives professional development to become a teacher leader without mention of any supervisory role(s).

Mentor Teacher	5	The MTL is a classroom teacher who mentors their peers/colleagues/in-service teachers, and serves in a supervisory/mentoring role.
Pre-Service Teacher	3	The MTL is a pre-service teacher who provides peer-feedback to other pre-service teachers in the context of a methods course (e.g., rehearsals, reform-based lessons, etc.).
Mentor of Students	2	The MTL is a classroom teacher who mentors preK-12 students.

Discussion and Implications

The overarching purpose of this paper was to initiate the integration of research on MTLs across PME-NA proceedings in years 1984-2019. In the space that follows, we summarize the main findings for each of our three research questions, and also discuss implications.

Overall, we observed an increasing trend in the number of PME-NA MTL submissions during our identified time frame. Furthermore, we observed coupling between year-to-year MTL submission spikes or declines and the presence or absence of national MTL events. That is, large spikes in year-to-year MTL submissions were coupled with the implementation of a national MTL event, while declines in year-to-year MTL submissions were coupled with the lack of national MTL event. This seems to indicate that MTL policies and events at the national level are actively shaping MTL research agendas and publication. That is, in the presence of national MTL policies and events, MTL research is occurring. Conversely, in the absence of national MTL policies and events, there is less attention to MTL research. Whether related to national events or not, there is a general upward trend in MTL research and interest in the mathematics education community in this research.

Regarding methodological trends, our analysis indicated that most of the MTL PME-NA submissions involved qualitative methods, while mixed and quantitative methods were less prevalent. We have several hypotheses to help explain this trend. First, it is possible that researchers seem to be most interested in asking research questions about MTLs that can best be answered using qualitative methods. For example, early stage, qualitative studies are needed to understand MTLs’ work before implementation/impact studies at a large scale can evaluate roles related to variables like student achievement. However, this is – perhaps – too easy of an explanation, and there is likely more going on here. Second, it is possible that the research community lacks quantitative measures and instruments that can validly and reliably be used to document the nuanced work of MTLs. While there is some research that has begun to explore this hypothesis (Harbour, Livers, & Hjalmarson, 2019), more is needed. Third, and relatedly, impact and/or influence is so difficult to measure because there are many confounding variables and multiple levels to MTLs’ work. Ultimately, this makes it rather challenging to tease apart MTLs’ unique impact. Thus, future research should focus on MTLs as part of the system of professional development in the school/district to understand their impact on both teachers' practice and students' learning.

Last, in exploring the ways in which MTLs are positioned across PME-NA proceedings, we identified seven different categories that ranged from MTL as School-Based Coach to MTL as Pre-Service Teacher. This speaks to the wide-spread variation in the ways in which researchers refer to individuals in this position. Although prior research has already suggested that the field lacks a common definition for MTLs (Baker et al., 2017; National Mathematics Advisory Panel [NMAP], 2008), our study adds further evidence in support of this trend. Hence, future research should be developed to explore the characterization of MTL work and practice in order to compare different implementation models, better describe MTL roles within schools/districts and their work with both teachers and students, and further develop MTL knowledge and skills to better support preparation programs and other ongoing professional learning experiences.

To ensure conceptual learning in mathematics, teachers must shift many aspects of their instructional practices. We report on a two-year endeavor using a collaborative and responsive professional development model to help elementary school teachers enact seven shifts in classroom practice. We share evidence of teachers addressing the instructional shifts and discuss the promise of the approach used for those interested in co-constructing collaborations between and among universities and school districts.

Keywords: In-service Teacher Education; Professional Development; Instructional Leadership; Instructional Activities and Practices

Purpose

We report on a two-year professional development (PD) program designed to improve teachers' knowledge of mathematics, strengthen their pedagogical skills, and foster collaboration to reflect on practice and improve teaching. Guided by the Leading for Mathematical Proficiency Framework (Bay-Williams et al., 2014), this PD supported teachers' instructional shifts to better implement the Standards for Mathematical Practice (CCSSO, 2010). As part of the PD team, we (authors) implemented cycles of a "responsive and emergent" curriculum (Confrey & Lachance, 2000, p. 244) to ascertain teachers' thinking and address their needs. We offered multiple, collaborative opportunities for participants to revisit and reflect upon their teaching practices, as they aimed to implement at least some of McGatha and Bay-William's (2013) seven instructional shifts (see Table 1).

Figure 1: Shifts in Classroom Practice (Bay-Williams et al., 2014, p. 24)

Shift 1	From same instruction toward differentiated instruction
Shift 2	From students working individually toward community of learners
Shift3	From mathematical authority coming from the teacher or textbook toward mathematical authority coming from sound student reasoning
Shift 4	From teacher demonstrating 'how to' toward teacher communicating 'expectations' for learning
Shift 5	From content taught in isolation toward content connected to prior knowledge
Shift 6	From focus on correct answer toward focus on explanation and understanding
Shift 7	From mathematics-made-easy for students toward engaging students in productive struggle

These seven shifts support teachers in creating a classroom culture where students are active participants in the learning process, namely: differentiating instruction, having students work as a community of learners, affirming mathematical authority comes from sound student reasoning, communicating clear expectations for learning, connecting content to students' lived experiences and prior knowledge, focusing on explanation and understanding, and engaging students in productive struggle. Our research question was: In what ways has the collaborative and responsive professional development model impacted teachers' shifts in classroom practice?

Theoretical Underpinnings

Change theory (Fullan, 2006) highlights the significance of stakeholders' democratic participation in a continuous and deliberate process to support a shift from existing towards new practices. Underwood (2015) acknowledged the contribution of professional learning communities to encourage teachers to re-think, re-learn, and re-engage with others as they articulate and process the meaning(s) of new practices. The PD team also realized the importance of building trust, acknowledging teachers' opinions and needs, and being willing to rethink our own practices. Therefore, we designed an iterative process, what we call the Collaborative and Responsive Professional Development (CRPD) model, to continuously and deliberately build trust, hear/see teachers' ways of thinking and knowing, and utilize this information to design meaningful experiences for the teacher participants.

Methods

Participants and Setting

The CRPD model emerged from a two-year partnership between a higher education institution and two school corporations. Participants were 60 elementary teachers (Grades K-6) from eight schools. The year-round PD support included: summer workshops, two full-day workshops (one in the Fall and one in the Spring), and four after-school workshops (two in the Fall and two in the Spring).

In this partnership, the PD team included two mathematics educators, one mathematician, one math coach, and two mathematics education graduate students. The full-time math coach was an experienced master elementary and middle school mathematics teacher. This arrangement of the PD model bridged the gaps between the PD team and the teacher participants as the mathematics coach proactively brought the teachers' voices to the planning sessions and helped to translate the projects' goals into meaningful and relevant learning activities for the teachers.

During PD sessions, the teachers were encouraged to work with others from the same grade level across schools and same-school participants from different grade levels so that they can benefit from the experiences of others and continue their interactions during the school year as a community of learners (Wenger, 1998, 2000).

Data Sources and Analysis

Data sources included an initial teacher inventory of classroom practices and teachers' annual self-reports on their instructional practices, self-assessed mathematics proficiency, and their experiences in professional development. The annual self-reports were a deliberate effort to understand the goals teachers had set for making shifts in their practice, capture their thinking about any shifts they had accomplished, and ascertain what shifts they still sought to make. The data comes from teachers' responses to the prompt: 'Have you noticed any changes in your math classroom, your students, or yourself? Could you describe them or share some specific examples?' Analyzing cases for which we had all data for two consecutive years (N = 20).

We used thematic coding analysis (Braun & Clarke, 2006) for coding the teachers' written responses with the seven shifts as the main themes. First, two authors collaborated to code each teacher's response according to whether and how it provided evidence of any of the seven shifts in classroom practice (Figure 1). To ensure a consistent understanding of the coding process, first, both coders worked together to code the first five cases from both years' data. Then, once an established coding system was developed each author separately coded the remaining teachers' responses. Those two authors came back together to discuss their respective codes and reconcile any differences. Those reconciled codes were shared with the other two authors, any differences were discussed, and again, reconciled to get agreement on 100% of the cases.

Results

To capture a holistic picture of how the teachers claimed to have shifted their classroom practices, we examined the distribution of the percentage of teachers whose responses referred to a specific shift (Figure 2).

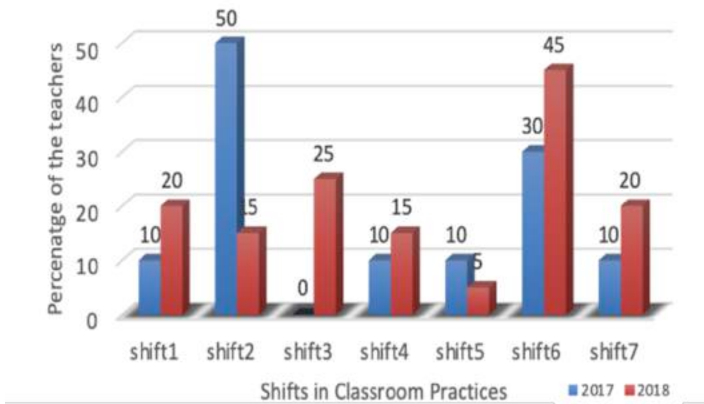

Figure 2: Distribution of Teachers' Self-Reported Shifts in 2017 and 2018

Over the two years, this group of teachers had shifted their instruction in each of the seven ways described by McGatha and Bay-William's (2013). However, two of the shifts (Shifts 2 and 6) stood out in our analysis, as they were mentioned substantially more often by the teachers. Shift 2, towards creating a community of learners, was mentioned by 50% of the teachers in year 1. Shift 6, towards a focus on explanation and understanding, was mentioned by 30% of the teachers in year 1 and 45% in year 2.

Regarding Shift 2, one teacher mentioned, "My students love when it is math time and how they get to share what they did to solve the problem because more than likely it is different than their neighbor's ideas!" (Teacher#6, 2017). Teachers' responses reflected that being engaged in the activities around collaboration influenced their learners' listening, comprehending, accepting, and critiquing multiple ways of mathematical reasoning and thinking. Regarding Shift 6 teachers reported, "Students are stating their claims as 'I agree with…. because' or 'I disagree with …... because' (Teacher#7, 2018), which illustrates students recognizing the significance of using reasons to validate mathematical arguments.

Evidence for Shift 1, toward differentiated instruction, came from many teachers endorsing Math Workshop and Number Talks, as they realized that those instructional practices assisted them in recognizing specific strengths and gaps in their learners' mathematical thinking and guided them in designing appropriate next step instructional activities. While in year1 none of the teachers mentioned Shift 3, toward mathematical authority coming from sound student reasoning, teachers realized that by sharing their mathematical authority with other collaborators in learning, they could positively contribute to their students' learning. For example, one of the teachers stated:

> During math, the kids are the ones that do the teaching. I serve as a guide. Instead of me making sure everybody is doing everything absolutely correct, I am able to sit back and let the kids make mistakes and explore and that's awesome (Teacher#18, 2018).

For Shift 4, toward teachers communicating expectations for learning, teachers started to see that transparency of the instructional objectives and flexibility in accepting various entry or exit points from the learners helped develop a sense of ownership in their students. One teacher mentioned, "mathematics is … more about the process and thinking rather than the right answer" (Teacher#2, 2018). Only a small number of teachers referred to Shift 5, toward content connected to prior knowledge, which might suggest that any change in this shift requires a longer period of instruction and training. Regarding Shift 7, engaging students in productive struggle, teachers realized that changes in their teaching style could help their students' perseverance. One of the teachers shared a success story of her student who did not like math in the early grades, however, made significant gains and contributed often to on-going mathematical class discussions (Teacher#21, 2018).

When examining the distribution of the percentage of the teachers whose responses referred to a specific shift (Figure 2), we found that in general teachers' reports of enacting a specific shift in teaching increased for five of the seven shifts. While there was a decrease in the number of reports of addressing Shift 2, we do not think this necessarily means that teachers were not giving attention to this shift as work on the other shifts implicitly shows they are giving attention to this one. A similar pattern was observed for Shift 5, content connected to prior knowledge. We assume that initially the teachers might have been focusing more on their pedagogical orientation rather than on curricular materials while employing new instructional techniques in their teaching. However, we believe that with the passage of time subtle differences in their content and curricular knowledge will also be visible.

One limitation of this study is that the data sources are self-reports of teachers' perceptions of change in their instructional practices. We tried to minimize the impact of using self-reports by corroborating classroom shifts with the mathematics coach's observations in the teachers' classrooms.

Discussion and Implications

Research has shown that many reform efforts result in existing classroom practices remaining unchanged because it is difficult to shift mathematics understandings, attitudes, and experiences (Ball, 1996; Tzur et al., 2001). Researchers also offer that "professional development that is embedded in daily classroom practices of teachers in which there is a continuous loop of observation, feedback, and discussion in order to sustain learning" (Underwood, 2015, p. 26) helps in developing new capacities to sustain changes in instruction gradually. We are encouraged by the fact that teachers in this PD created achievable learning targets for their students by attending to their needs, interpreting their understandings, and creating opportunities to develop as mathematical doers and thinkers. We think that the shifts reported by the teachers will gradually lead them towards implementing the mathematical practices in their classrooms (Kilpatrick et al., 2001; National Council of Teachers of Mathematics, 2000).

We think this study provides some evidence of the feasibility of facilitating shifts in teachers' practices when professional development is centered on teachers' needs and engages the teachers in ways that we expect them to teach their students. The opportunities afforded by the processes of the Collaborative and Responsive Professional Development (CRPD) model show the potential of promoting teachers' effective shifts in mathematics teaching.

SELF-EFFICACY AND THE KERNEL OF CONTENT KNOWLEDGE

In this study, when mathematics teachers were provided professional development pertaining to physics, their physics content knowledge improved, as did their self-efficacy in teaching mathematics through physics. This analysis reveals how these two improvements interacted and how that interaction changed over time. Also, this study examines what components of self-efficacy were influenced. These results have practical significance for STEM professional development design and implementation, while revealing theoretically significant nuances in the development of teacher knowledge. Intriguingly, self-efficacy gains were correlated with content knowledge gains, but only in the content knowledge that was retained over a longer period of time, suggesting that teachers' content knowledge may have a kernel, or core, that is more correlated with affects and beliefs, such as self-efficacy.

Keywords: Teacher Knowledge, Beliefs

Studies suggest that integrated approaches to teaching STEM (Johnson, 2013; NRC 2002), weaving together science, technology, engineering, and/or mathematics, improves student achievement (Becker & Park, 2011), reflects the nature of STEM professions (Wang et al., 2011), enables deeper understanding (NRC, 2012), and highlights mathematical relevance (GAIMME, 2016). However, integration of insular disciplines brings new needs to teacher education because the diverse knowledge needed to teach integrated STEM is not prevalent in the teacher workforce (Roehrig et al, 2012). Although both the American Academy of the Arts and Sciences (Pallas, Neumann, & Campbell, 2017), and the National Academy of Sciences (2012) recommend creating teaching resources for the integration of STEM disciplines, new resources are insufficient by themselves. Professional development (PD) providers should strive to equip practicing teachers with the content knowledge (CK) and self-efficacy (SE) to effectively teach integrated STEM content.

Teachers' SE (Bandura, 1997) has been shown to correlate with teachers' CK (Swackhamer, 2009), but how might this correlation differ in an area outside a teacher's specialization, such as physics CK with math teachers? In this study, we examine PD that supports physics-based and inquiry-based math teaching, by analyzing teachers' CK and SE. Data from 20 in-service math teachers informs the following questions, for both "short term" (after a 1-week summer workshop) and "long term" (after 4 monthly post-workshop meetings):

1. Based on pre-post data, does inquiry-based PD influence CK about physics-based math, or SE for teaching math through physics, or components thereof?
2. Do pre-post differences in these CK and SE variables correlate with each other?

Theoretical Perspectives

SE pertains to certainty about one's abilities (Bandura, 1997). While some studies have linked teachers' SE to students' achievement and motivation (Caprara, et al., 2006; Skaalvik & Skaalvik, 2007), longitudinal studies have revealed that correlations between teaching SE and instructional quality are not purely causal or consequential (Holzburger, Philipp, & Kunter, 2013). Although some studies have found that continued and objective-focused PD improves SE (Brinkerhoff, 2006), little research has indicated how PD influences teachers' SE in a subject outside their expertise. Examining effectiveness of inquiry-based PD, prior research shows mixed results, sometimes improving and sometimes worsening SE for teaching science (Avery & Meyer, 2012). Few instruments measure SE

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

for teaching math and science in an integrated way. Mobley's (2015) SE for teaching integrated STEM uses a 3-factor model, with a *social* factor, including motivating students, a *personal* factor, including developing new knowledge, and a *material* factor relating to access to tools.

With Common Core came an emphasis on mathematical modeling (CCSS, SMP). However, many practicing teachers had minimal training in mathematical modeling and in the sciences that utilize modeling. While many teacher training programs adapted to include more modeling coursework, PD remained essential for practicing teachers. This landscape accentuates the importance of studies such as this, in which math teachers are supported in the learning of physics or other STEM content. In this study, CK was measured by multiple-choice items similar to math questions found on a physics Advanced Placement test. We consider CK to be similar to Shulman's (1986) *subject matter content knowledge*, and because of the interdisciplinary nature of this study, is related to Ball's (1993) *horizon knowledge*, which implies awareness of how math content spans the curriculum. Considering subdomains of subject matter knowledge (Ball, Thames, & Phelps, 2008), we suspect these subdomains may interact differently with non-cognitive variables, such as affect and belief, and may persist differently over time.

Methods

Professional Development Workshop

The grant-funded workshop, titled *Let's Get Physical! Teaching Mathematics through the Lens of Physics*, included 32.5 hours over 5 consecutive summer days, followed by 4 monthly 1-hour meetings during the following fall semester. The inquiry-based PD highlighted the themes: (a) integration of math and physics and (b) student motivation.

The grant provided each teacher's school with physics lab equipment, including Vernier physics packages, Logger Pro software, spring kits, current probes, circuit boards, refraction blocks, lasers, track systems, and iPads. During days 1-4, the teachers completed 2-3 physics experiments each day and discussed pedagogical topics related to student motivation. On day 5, a mathematics and physics panel of faculty and graduate students made presentations about applied topics and current research. During the 4 follow-up meetings, conducted through video-conferencing, the participating teachers shared lesson ideas and experiences with one another.

The physics labs in the workshop, available online (Author2 & Author1, 2017), were inquiry-based and aligned to standards in middle school math, Algebra I & II, and geometry. In one lab, teachers modeled the behavior of live insects to learn about displacement, velocity, and geometry. In another, teachers dropped coffee filters and modeled their fall to learn about drag, logarithms, and graphical methods. Other labs involved basketballs, toy cars, lasers, and circuits.

Participants and Recruitment

University faculty and administrators from local schools recruited applicants through meetings and emails. Teachers of middle school math, Algebra I & II, and geometry were encouraged to apply. Twenty math teachers, from 5 school systems, were selected. Most held bachelor's degrees in mathematics, 14 held graduate degrees in education, 2 held master's degrees in mathematics, and 2 held master's degrees in physics. Six participants were male, and 14 were female. Because administrators participated in recruitment, more teachers with leadership qualities may have been more likely to apply. Because this workshop was marketed as *Let's Get Physical! Teaching Mathematics through the Lens of Physics*, teachers with more interest and knowledge in physics may have been more likely to apply.

Data Collection and Analysis

Using instruments described in Table 1, data was collected from 20 in-service teachers before and after the week-long summer workshop, and also after 4 monthly post-workshop meetings.

Table 1: Descriptions of Instruments

Construct	Length	Scale	Cronbach Alpha
Self-Efficacy (SE)	8 items	0 = *Certainly I am not capable.* 10 = *Certainly I am capable.*	.96
Content Knowledge (CK)	5 items	0 = incorrect, 1 = correct	.59

We framed the SE inventory using Mobley's (2015) 3 factors - social, personal, and material. Per Bandura's (2006) advice for maintaining content validity, all items were phrased as capability statements, and caution was taken to avoid confusion with self-worth or locus of control. Also, to refine our instrument, we piloted it at a STEM education conference.

Items for the *social* sub-scale of SE say, *I am capable of…*

- leading my students in conducting physics labs in such an effective way that all of my students are motivated to learn math.
- anticipating and preventing likely student errors while conducting physics labs.
- coordinating a superior cross-curricular math lesson with a science teacher at my school.

Items for the *personal* sub-scale of SE say, *I am capable of…*

- making meaningful connections between physics and mathematical concepts.
- revising a physics lesson plan to make it appropriate for my mathematics classroom.
- responding immediately if a student asks me how a math homework problem is related to physics.

Items for the *material* sub-scale of SE say, *I am capable of…*

- finding related physics-based examples, no matter what mathematical concept I am planning to teach.
- teaching students to use technology and equipment to do physics labs, without technical difficulties.

We used paired *t*-tests to detect significantly non-zero pre-to-post differences, and we used regression analysis to determine statistically significant correlations between those differences.

Results

CK in physics-based mathematics improved over the course of the 1-week workshop. Post-test CK scores (M=3.20, SD=1.28) exceeded pre-test scores (M=1.70, SD=1.30). However, some of this acquired CK was impermanent. Four months later, when re-tested, the gains in CK (M=2.37, SD=1.64) were no longer significantly different from pre-test scores. See Table 2.

Table 2: Overview of Results

Research Question	After 1-Week Workshop	After 4 Monthly Meetings
Did the PD influence CK?	$t(19)=4.94$*	$t(18)=1.79$
Did the PD influence SE?	$t(19)=6.10$*	$t(18)=5.57$*
Did CK and SE gains correlate?	$r(18)=.022$	$r(17)=.515$*

*Significant at the .05 level

Regarding SE, however, the benefits did not fade. The teachers showed significant improvement in SE, both in the short-term and in the long-term. Short-term (M=6.69, SD=1.79) and long-term (M=6.91, SD=2.00) post-workshop SE ratings significantly exceeded those pre-workshop (M=4.46, SD=2.06), and also significantly improved in each SE subscale.

Regression analysis was used to test if the gains in SE or its subscales significantly correlated with participants' content knowledge gains. In the short-term, gains in CK and SE were not significantly correlated, and none of the SE subscale gains significantly correlated with CK. However, in the long-term, CK and SE gains did correlate, $r(17)=.515$. For 2 SE sub-scales, the correlation was significant as well. See Table 3.

Table 3: Correlation Tests in Gains after 4 Monthly Post-Workshop Meetings

	correlation with CK gains
self-efficacy (SE) gains	$r(17)=.515$*
SE *social* subscale gains	$r(17)=.514$*
SE *personal* subscale gains	$r(17)=.511$*
SE *material* subscale gains	$r(17)=.374$

*Correlation is significant at the .05 level.

Discussion

The *Improving Teacher Quality* (ITQ) grant program from the U.S. Department of Education, which provided the funding for this PD project, has been de-funded at the federal level. In the face of funding limitations, local and state education agencies are planning various strategies for supporting STEM education. With integrated STEM initiatives, teachers are more frequently expected to collaborate across disciplines and teach content peripheral to their areas of expertise. As math curricula adapt to ever-changing technology, the need for cross-disciplinary PD will increase, and integration of math with computer science, biology, engineering, and data science should be deliberately implemented, with effects on both short-term and long-term CK and SE gains examined. This study suggests that as future PD is provided, implementing an inquiry-based approach will improve the overall effectiveness of these supports. In addition, PD should attend to personal, material, and social concerns about teaching mathematics.

When future studies examine correlations between CK gains and SE gains, the findings of this study should be considered in research design. Our results suggest that short-term studies may not reveal connections that would be apparent in longer-term studies. Future theoretical research about types of CK should also consider changes over time. Because our short-term CK and SE gains were not correlated, but our long-term gains were, we suspect that there was a kernel, or core, of CK that persisted longer, and that this CK kernel was more likely to have influenced teaching practice, since it was correlated to pedagogical SE. Also, one might suspect that teachers who chose to use certain physics-based lessons in their classes in the fall might have retained certain parts of CK, and thus, teaching practice might be influencing both SE and CK. Thus, instead of viewing CK as a substance that can be acquired and then retained, this study substantiates a more complex model of knowledge, one in which teachers participate in a process of using their content knowledge, reminiscent of Sfard's (1998) participation-acquisition framework. Future studies should examine how teaching practice influences CK, and how teachers decide to use inquiry-based lessons in math classes.

CONTRIBUTING FACTORS TO SECONDARY MATHEMATICS TEACHERS' PROFESSIONAL IDENTITY

Our study explores contributing factors informing secondary mathematics teachers' professional identity. Data from five semi-structured interviews were evaluated using the provisional coding method. Results indicate mathematics identity, beliefs about teaching, and beliefs about mathematics all play an integral role in the ways teachers discuss their professional identity with some differences found between teachers' level of experience. This work informs the field by expanding on an existing framework to deepen our understanding of professional identity.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Teacher Beliefs

Research into teachers' professional identity aims to understand the interplay between the social and individual perspectives to identify the thoughts, influences, and impacts they have on a teacher's image of self (Beijaard et.al, 2004). A teachers' professional identity can have a large impact on their persistence in their profession (Hong, 2010). Teachers' view of themselves and their experiences act as motivators for their beliefs, actions, and future goals, which in turn affect their commitment, teaching quality and decision making (Hong et al., 2017). Exploring teacher professional identity has the potential to shed light on the high attrition rate of teachers in the field, factors that may support or inhibit teacher growth, and factors that may link to teacher practices and decisions related to their profession.

This study draws on research identifying specific components as important to teachers' professional identity. For example, Canrinus et al. (2012) asked teachers about their job satisfaction, self-efficacy, occupational commitment, and change in level of motivation as a way of exploring their professional identity. Further, we explored components discussed in prior research alongside teachers' content specific identity (mathematics identity) to better understand how these identities may overlap and inform one another. The research question informing our study is: how do secondary mathematics teachers describe their professional teaching and mathematics identity through the lens of prior research?

Methods

Participants

Table 1: Participant Information

Participant Pseudonym	Degree	Years of Experience	Position
Lilly	Bachelors	1	Primarily teaches grades 6-8 within an elementary school setting
Mary	Bachelors	1	Primarily teaches grades 7-8 within an elementary school setting
Bailey	Masters	5	Primarily teaches grades 9-12, focused on Algebra II, within an high school setting
Eva	Masters	16	Primarily teaches grades 6-8 within an elementary school setting, a Nationally Board Certified Teacher

Anisha	Masters	15	Primarily teaches grades 9-12, focused on Algebra I, within a high school setting

While this study included 36 secondary mathematics and science teachers, for the purpose of this paper, we included 5 secondary mathematics teachers. These teachers were in the first summer of their first year participating in a multi-district professional development grant and had varied levels of experience (see Table 1). These participants were all female and classified themselves as Caucasian, Non-Hispanic.

Data Collection and Analysis

Semi-structured interviews were conducted with each of the participants. In order to capture teachers' professional identity, questions about their self-perceptions (e.g., how would you describe yourself as a math teacher), how others viewed them (e.g., how do you think your administrators view you as a math teacher), motivation for going into the profession (e.g., why did you become a teacher), and future self (e.g., if you exited the field of teaching today, how would people describe the legacy that you left behind) were asked.

The provisional coding method was conducted to code interviews, which entails beginning with a set of a priori codes that draw from prior literature (Saldaña's, 2015). The a priori codes we used were based on five constructs explored in Hong's (2010) article: emotion, commitment, value, micropolitics, and self-efficacy. Hong (2010) included an additional a priori code, knowledge/beliefs, which we did not initially include as it was anticipated that mathematics identity would capture some of these ideas. However, we did end up including some additional codes related to beliefs during the coding process. In addition to these codes, we created a list of a priori codes based on four factors identified in prior research related to mathematics identity (Cribbs et al., 2015): interest, recognition, competence, and performance. After the initial round of coding, the additions to the original list were discussed and a consensus was met on a new list of codes. Further detail about these codes will be provided in the results.

Results

Four overarching themes emerged: professional identity, mathematics identity, beliefs about teaching, and beliefs about mathematics. Aspects of professional identity and other influential factors - taking into account the complexity of construct – will be discussed.

Professional Identity

There were initially five a priori codes (themes) used in exploring professional identity: emotion, commitment, value, micropolitics, and self-efficacy. These themes were further broken into sub-themes, creating a set of 11 themes.

Emotion. Out of the 5 participants, only one participant had evidence of the theme emotion, which connects specifically to stress, burnout, and well-being. Bailey described an incident that was "so rough that I almost decided not to continue teaching." However, it was evident through this interview as well as the other interviews how interconnected many of the themes were. For example, when discussing her struggles with the profession, Bailey indicated that district expectations (micropolitics - structures and support) were a primary reason for the tension she was experiencing in her position. It was only when she moved to a different teaching position that these tensions resolved and her persistence in teaching (commitment) was evident.

Commitment. Statements related to the theme commitment were evident in each of the participant interviews. For example, when responding to a question on how the profession was viewed by those outside of it, Lilly indicated that the perception of math being difficult "motivates" her. In all but one case, Bailey, commitment was discussed with reference to outside perceptions (community or society) of the profession and in terms of countering perceptions or motivating a sense of commitment due to these perceptions.

Value. Within the value theme, utility was evident in two of the interviews where teachers indicated a "calling" related to them pursuing the profession. Interest was evident in four out of the five interviews, with teachers indicating enjoyment in teaching and even connecting the "love" for teaching with caring about kids. Importance was only evident in two interviews with statements relating to making a "difference every day," particularly for their students.

Micropolitics. This theme was evident at a much higher frequency than the previous themes through the three sub-themes (decision making, status, and structures and supports). Decision making was only evident in two of the interviews with Bailey indicating a lack of autonomy as a professional due to requirements by the district ("they took away zoom math and that was something that the district pushed heavily for us to have students use which we didn't always agree with…"). The other sub-themes were evident in all five interviews. With reference to status, both Lilly and Bailey positioned themselves as novice teachers. Other comments indicated differing levels of status within the larger community (others outside of school or society) such as teaching perceived as "not very good" by others or having an elevated status because "you know, just working with that level of students." Finally, teachers had varied levels of support and structures in place as evident in their comments. However, comments seemed to indicate perceived support from administration across all interviews.

Self-efficacy. Self-efficacy was the final theme evident under professional development and included four sub-themes. The first sub-theme was classroom management and was evident in all of the interviews. Comments by Eva and Anisha indicated a high level of efficacy at being a "good classroom manager" compared with the less experienced teachers who expressed comments such as "my classroom management is not the greatest right now." This finding is not surprising given the varying levels of experience. Student engagement was evident in three of the five interviews, with two teachers noting struggles with engaging students with comments such as "I'm guilty of often times kind of being a boring teacher" but also indicating that they viewed engagement as important and necessary for effective teaching. Instructional strategies, much like engagement, focused on challenges and strengths of the teachers. Nearly every teacher mentioned struggling to connect the real world with the math content. Overall, strengths for strategies focused on collaborating and working with students. Finally, the general sub-theme for self-efficacy focused on statements about being effective with teaching, but often without enough specificity to know what that meant to the teacher.

Mathematics Identity

Mathematics identity included the sub-themes interest, performance, competence, and recognition.

Interest. Three of the five teachers indicated interest and/or enjoyment of mathematics as a subject area. All these comments related to why they decided to teach mathematics. For some of the teachers, interest in the content area seemed to connect to their teaching, but this was not the case for other teachers who either discussed these ideas separately or did not discuss interest in the content or interest in teaching.

Recognition. Two of the teachers specifically discussed being recognized in mathematics. One teacher discussed this through teacher recognition when she was a student, and the other teacher discussed her role in helping others, being positioned/recognized as knowing mathematics.

Competence. Three of the five teachers discussed experiences related to their competence with mathematics, with statements such as "it was something that I got." As with interest, most of the comments related to reasons for why the teacher decided to teach mathematics. However, two teachers indicated that students knowing that they [the teacher] understood the content was something they wanted their students to know or felt that they knew about them.

Performance. Three of the five teachers also discussed performance with mathematics. All these comments related directly to their rationale for choosing to teach mathematics.

Beliefs about Teaching

Beliefs about teaching was a theme that emerged in our second round of coding. Four of the five teacher interviews provided evidence of their teaching beliefs. Two of the teachers (Lilly and Bailey) seemed to be trying to reconcile what they thought effective teaching looked like or what they had hoped it would be like with their current practice. Other ideas such as being an enthusiastic teacher, learning through problem solving and different strategies, and students being actively engaged were discussed by the teachers.

Beliefs about Mathematics

Beliefs about mathematics was a theme that also emerged in our second round of coding for two of the four teachers. Lilly's responses seemed to indicate a belief that mathematics is applicable to the real world and that all students have a capacity to learn mathematics. Conversely, Bailey's comments seemed to indicate that students were either a "math person" or not a "math person", such as stating that "he is not a math kid" and "you either love it [math] or you hate it [math]."

Discussion

Findings support the inclusion of the constructs explored in Hong's (2010) study, but also support the inclusion of additional factors that seemed to play a role in teachers' professional identity as evident in the interviews we conducted. Figure 2 provides an overview of themes by participant to help convey some of these patterns with the size of bubbles aligned with the frequency of the code.

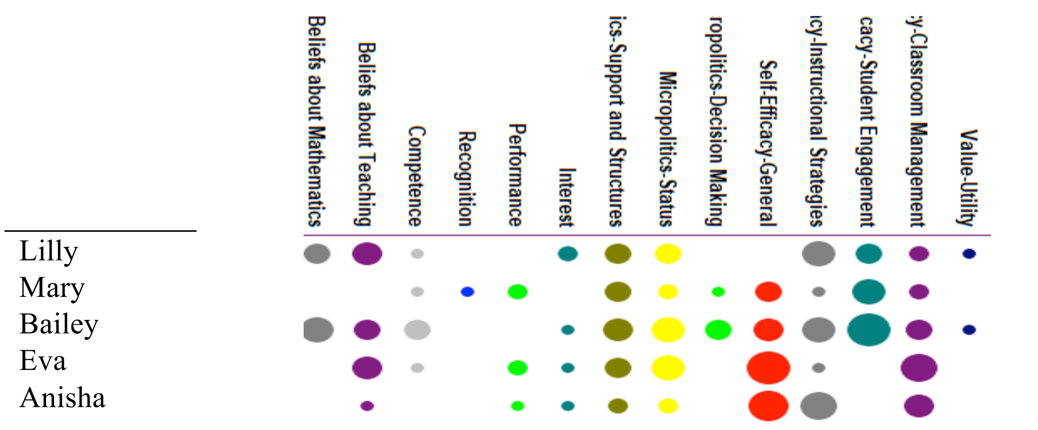

Figure 2: Trends Based on Frequency of Theme and Participant

Although there is value in considering teachers' professional identity individually, exploring the construct in relation to other factors helps to provide a more complete picture of how teachers may see themselves within the larger community of educators.

MATHEMATICS TEACHERS' PERCEPTIONS OF THEIR INSTRUCTION FOR MULTILINGUAL LEARNERS THROUGH PROFESSIONAL DEVELOPMENT EXPERIENCES

Cameron Dexter Torti

sroberts@education.ucsb.edu

Julie A. Bianchini
UC Santa Barbara
jbianchi@ucsb.edu

As the demand to challenge and attend to multilingual learners has increased, teachers have not received adequate professional development to combat biases and perceptions implicitly engrained throughout the education system, especially in mathematics classrooms. This study implemented a studio day professional development cycle with inservice teachers who worked with multilingual students in Math 1 classrooms. This study examined teachers' initial perceptions of multilingual learners and their understanding how to prepare for, challenge, and support multilingual learners. Teachers reported that, while their previous learning experiences around multilingual learners and mathematics were limited, this professional development opportunity allowed them to extend beyond simply attending to vocabulary to consider how to access text in rich ways to engage their students in more meaningful learning.

Keywords: Equity and Diversity; Teacher Education – Inservice/Professional Development; Marginalized Communities; Affect, Emotion, Beliefs, and Attitudes

Multilingual learners are among the fastest growing student populations in U.S. schools (National Clearinghouse for English Language Acquisition, 2009). The increase of multilingual learners is not an isolated phenomenon. Each state has experienced an increase in this population (Cheuk, 2016; Lee & Buxton, 2013), and it is expected that multilingual learners will make up 25% of the students in K-12 settings by 2025 (National Education Association, 2005). Despite the current numbers and projections, problematic trends regarding teacher preparation and practices have persisted in relation to multilingual learners, including deficit-based thinking models among teachers (de Araujo et al., 2016; McLeman & Fernandes, 2012; Pettit, 2011). In an attempt to address such deficit-based thinking, this study used a "studio days" model (Von Esch & Kavanagh, 2017) to introduce teachers to instructional mathematical routines that could engage multilingual learners in rich mathematics content (Kelemanik et al., 2016). This study sought to answer the following research question: How did mathematics teachers' perceptions of multilingual learners and their understanding of how to challenge and support multilingual learners evolve as teachers engaged in professional development experiences?

Theoretical Framework

This study is organized around two complementary theoretical ideas—instructional mathematical routines and key principles of reform-based instruction for multilingual learners. Both are meant to help teachers think about ways to engage multilingual learners with content in meaningful ways.

Instructional Mathematical Routines

Instructional mathematical routines are intended to support students to engage productively with content, providing them with tools that they can grow familiar with and return to regularly so as to solve cognitively demanding mathematics tasks (Kelemanik et al., 2016). Routines allow students to focus on their learning, because they provide structured ways for students to make sense of rich, challenging mathematics; build important mathematical thinking habits; and provide more students with access to important mathematics. Zwiers et al. (2017) developed routines specifically for multilingual learners to help teachers amplify, assess, and develop these students' language in

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

mathematics classrooms. As such, multilingual learner student engagement in these mathematical instructional routines can help them develop mathematics thinking and language simultaneously.

Key Principles of Reform-Based Instruction for Multilingual Learners

Five key principles of reform-based instructional practices for multilingual learners in mathematics classrooms also guided this work (Roberts & Bianchini, 2019). These principles grounded our work with teachers, the conversations we had with teacher participants about the teaching and learning of mathematics for multilingual learners, and the analysis of data collected. In this paper, we focus on our fourth principle, *identifying academic language demands and supports for multilingual learners* (Aguirre & Bunch, 2012; Lyon et al., 2016). This principle focuses on the language demands in the tasks teachers provide and asks teachers to implement appropriate supports so that all students can read disciplinary texts, share their ideas and reasons in whole class and small group discussions, and communicate mathematics information in writing.

Methods

Our study was situated in one school district in Central California that included a substantial number of multilingual students. Teachers participating in this ongoing study were engaged in a two-year professional learning program organized around mathematics "studio days" for multilingual learners (Von Esch & Kavanagh, 2017), in which teachers developed and studied a single lesson focused around one instructional routine and one mathematics language principle during each cycle. The findings of this paper come from the first studio day cycle. Using Von Esch and Kavanagh's professional development model of studio days, we created a cycle of three professional development meetings for our participants. The studio day cycle of interest paired the instructional mathematical routine "Three Reads" (Kelemanik et al., 2016), which provides students access to rich text, with the principle *academic language demands and supports.*

Participants

Nine mathematics teachers from three high schools and their district mathematics instructional leader (who helped facilitate the professional development) participated in this study, with four teachers serving as our focal teachers. Of the nine teacher participants, five were female and four were male. Seven were White/Caucasian, one was Latinx, and one was Asian American. One teacher was in her first year, three had 1-4 years of experience, and four had 10-19 years of experience. One teacher was bilingual (Polish), and the rest were monolingual English-speakers. At Ash High School, the percentage of multilingual learners was 4.5%; at Birch High School, 6.0%; and at Cedar High School, 9.4%. Teachers noted that they had both multilingual and reclassified students in their classes.

Data Collection

We conducted two individual semi-structured interviews (Glesne, 2011) with the four focal teacher participants and the district mathematics instructional leader to understand how teachers supported students, especially multilingual students, in accessing mathematical content. More specifically, the pre-interview explored teachers' perceptions of multilingual learners, what they did to support multilingual learners in their classrooms, and their prior experience with preservice or professional development tailored towards challenging and supporting multilingual learners in mathematics. Following the first studio day cycle, in the post-interview, we asked participants about how they supported multilingual students to access text and to attend to academic language demands. We also asked about their experiences with the studio day cycle.

Data Analysis

We qualitatively analyzed both interviews across all five interviewed participants to identify key pieces of talk related to the following: (1) teacher preparation and professional development; and (2) attitudes towards their preparedness for challenging and supporting multilingual learners. We compared participants' responses across the two interviews. We drew on fieldnotes from studio days and classroom observations as ancillary data to triangulate our findings. Throughout the data collection and analytic process, we wrote analytic memos to develop our ideas, test our conjectures, and track our research processes (Yin, 2016).

Findings

Our first set of findings examines teachers' baseline perceptions of multilingual learners and professional learning experiences related to multilingual learners. The second set focuses on teachers' evolving perceptions related to multilingual learners and their preparedness in challenging and supporting multilingual learners in their mathematics classrooms following their participation in the studio day cycle.

Multilingual Learners – Initial Perceptions

All four teachers reported having large Spanish-speaking multilingual learner populations in their Math 1 classes. All four also used strategies in their classes to support their multilingual learners. Specifically, while many students were reclassified throughout the district, the teachers reported that they still implemented academic language support for these students in similar ways to students officially classified as "English learners." For example, Ms. Lacrosse reported that over 50% of students in her typical classroom were classified officially as "English learners." Her approach to supporting multilingual learners in communicating their reasoning was the following: "Even if they don't have a lot of academic knowledge, they do have at least enough to be able to express it at the level they are at and be exposed to others who are richer [in linguistic ability]." One of Mr. Huerta's supports was "rewr[iting] the text to make it simpler." Ms. Parker went further, rewriting two to three of her lessons each week to adapt the text for multilingual learners.

Professional Learning Experiences with Multilingual Learners – Initial Perceptions

Of the four focal teachers participating in this study, three mentioned having extensive experience with multilingual learners through prior teaching assignments, one shared that this was their first school year working with multilingual learners on a full-time basis. Only one of the four focal teachers mentioned receiving any explicit training related to multilingual learners during their teacher education program. The other three focal teachers stated that their preservice teacher education did not include any class or support around multilingual learners in mathematics specifically. All four focal teachers discussed a lack of district-mandated professional learning experiences related to multilingual learners, including during the implementation of a new curriculum three years prior. While Mrs. Hope, the district mathematics instructional leader, did share that she provided supplemental support through her typical interactions and coaching time with the teachers, it appeared this was the only professional development experience regarding multilingual learners and mathematics the district provided.

Perceptions of Multilingual Learners – Post Studio Day 1 Cycle

Through their studio day cycle participation, focal teachers reported shifting their focus for multilingual learners from singular vocabulary words for a given lesson to allowing multilingual learners to access and participate more fully through the implementation of the "Three Reads" mathematics language routine. Ms. Lacrosse discussed that her perception of supports for multilingual learners changed from focusing solely on vocabulary or specific problems to providing access to key mathematical ideas: "It's about reaching out and providing more support so that they can access the material, reading, writing." Focal teachers also discussed that student engagement with the text, including for multilingual learners, increased through the use of the "Three Reads" mathematics language routine. Mr. Huerta brought up the importance the routine had in his class as it was being implemented more frequently, signaling to the students that the process of engaging with the text was important. With multilingual learners engaging with the text at a higher frequency and at a higher cognitive and linguistic level, teacher perceptions of their multilingual learners appeared to be challenged. Still, Mrs. Hope, the district math instructional leader, reiterated the need for a future focus on communicating reasoning while using academic language.

Professional Learning Experiences with Multilingual Learners – Post Studio Day 1 Cycle

Teachers reported the studio day cycle was an effective opportunity to analyze the teaching practices they implemented as they related to academic language, especially with regards to multilingual learners. Ms. Lacrosse discussed both the benefit of having other teachers provide feedback on her teaching and the benefit of watching other teachers implement the same lesson. Mr. Huerta shared that, even though he and another teacher at his school site did not teach the same lesson during the studio day, he was still able to adapt his teaching practice after observing his colleague. All focal teachers explained that a key benefit was being able to interact with and work with other teachers at their school sites and within the district. Mr. Ming reflected on the value of building a community of critical educators on his campus through observing other teachers and reflecting on how those teachers may be working with multilingual learners: He found useful "the whole coming together, drafting of lessons together, then executing the lesson, and then debriefing on it." Mr. Huerta echoed this sentiment, saying, "I would say the other beneficial thing… being able to see the math studio day happen at all three campuses together and having the collaboration of teachers that were in different schools within our district."

Discussion and Conclusions

We found that teachers' perceptions of multilingual learners shifted from holding beliefs that multilingual students could not access text-heavy curriculum at the same level as non-multilingual learners to realizing that they could challenge and support multilingual learners using mathematics language routines. The mathematics language routine of focus, "Three Reads," allowed teachers to engage their multilingual students in more rich content and language learning beyond simply reviewing math vocabulary terms. Teachers were able to provide their students with practice in accessing text and thus in reading, writing, and talking about math in richer ways. Teachers valued this professional learning opportunity and the chance to interact with fellow Math 1 teachers as a way to improve their mathematics teaching practices related to multilingual learners. Our work suggests the need for future professional development and research efforts to focus on other important aspects of academic language in mathematics, including communicating reasoning.

Acknowledgments

This research was supported by a grant from College Preparatory Mathematics.

A FRAMEWORK FOR THE FACILITATION OF ONLINE PROFESSIONAL DEVELOPMENT TO SUPPORT INSTRUCTIONAL CHANGE

UN MARCO PARA LA FACILITACIÓN DEL DESARROLLO PROFESIONAL EN LÍNEA PARA APOYAR EL CAMBIO INSTRUCCIONAL

In this research report we discuss the development of a framework regarding the facilitation of online professional development geared at supporting instructional change at the undergraduate level. The research in undergraduate mathematics education includes various large-scale projects aimed to support individuals or departments in reforming their instruction to align with recommendations from professional organizations and existing mathematics education research standards. One area that needs attention is the use of online synchronous environments to match faculty across the world and form collaborations to support the inclusion of student-centered activities in their mathematics classrooms. This research report discusses the actions that facilitators take in these environments and lays the groundwork for the use of this framework in our and other contexts going forward.

Keywords: Post-Secondary Education; Teacher Education – Inservice / Professional Development; Systemic Change

Instructional shifts towards student-centered pedagogies are taking place throughout North America within mathematics departments. This change is oftentimes centered around individual faculty (e.g., Author, 2019; Speer & Wagner, 2009) but also from the perspective of larger groups of faculty (e.g., Author, under review; Hayward & Laursen, 2016) or even departments at-large (e.g., Apkarian & Reinholz, 2019; Laursen, 2016; Reinholz & Apkarian, 2018). Notably, professional communities also call for this instructional reform (Mathematical Association of America [MAA], 2015). The research in undergraduate mathematics education community has embarked upon numerous large-scale research projects to investigate how to support instructional change (e.g., Author, under review; Kuster et al., 2016), namely to make instruction more student-centered. Additionally, this community has engaged in large scale projects to support departments in improving instruction and student outcomes (e.g., Association of Public & Land-Grant Universities [APLU], 2016).

Our multi-institute collaborative grant, BLINDED, is one such project in which we aimed to not only support mathematicians in reforming their instruction with various support models but to research those support models' impact on the mathematicians and their communities. Our support model consisted of instructional materials (both for the student and faculty), a summer workshop, and online professional development, which we classified as an online working group (OWG). The OWG offered an opportunity for faculty to collaborate on their instruction through a lesson study model (Demir et al. 2013) in online synchronous environments. In this OWG, participants engaged in lesson studies on multiple units of Inquiry-Oriented (IO) materials (Rasmussen & Kwon, 2007) by doing the mathematical tasks from those units, anticipating student thinking that could arise from those units, filming and then subsequently bringing video clips from that instruction to the OWG to share and discuss.

In previous research, we have discussed the development and usage of a framework to categorize and understand the conversation that occurs when OWGs are discussing the sharing of instructional video as a means to support their instructional change (Author, under review). However, the next step that emerged from that work was to analyze the role that the facilitator played in that OWG. Given the importance of the role of a facilitator in professional development settings (van Es et al. 2014), our next research steps were to develop a framework to categorize and understand how facilitation occurs of these OWGs. In this endeavor, we sought to understand the facilitation of OWGs when facilitators initiate discussions about the mathematical content of novel IO curricular materials. We will discuss the development of a framework to understand the facilitation of these OWGs. The research question for this research report is: *What actions do facilitators take within online working groups focused on doing and understanding the mathematical content of novel IO curricular materials?*

Methods

Research Setting and Data Collection

Data from this research report comes from a large NSF funded project, BLINDED. BLINDED recruited mathematicians in 2015-2017 who were interested in changing their instruction to be more student-centered and specifically use one of the IO curricula: differential equations, linear algebra, or abstract algebra. During the first year of the project, the three Principal Investigators led their respective OWG. In subsequent years, the project team was able to double the number of OWGs that could be facilitated by recruiting the previous year's participants to lead their own OWG. Consequently, in 2016 and 2017, 4 facilitators, who were previously participants, each led their own OWG. The development of our framework comes from these 4 individuals' OWGs. Each OWG was screen recorded using QuickTime and all OWGs were transcribed. Each of these OWGs consisted of 3-4 participants. As this analysis focuses on when the facilitators were leading discussion on doing the mathematics from the novel IO curricula, this yielded 14 transcripts for analysis.

Data Analysis

The creation of the framework followed an iterative process of revision and refinement via individual open coding and comparison between the researchers (Creswell & Poth, 2017). Altogether, 14 transcriptions of videos were investigated, coded and compared by at least two researchers in each iteration. During the first iteration, we analyzed two video transcriptions and proposed descriptors for the action that the facilitator took. In crafting our descriptors, we consulted the work from van Es and colleagues (2014) to look for common threads. In their work they focused on developing a framework on *how* facilitators could use in-the-moment moves to support productive discussion while viewing video of instruction (van Es et al., 2014). We then convened and compared our suggestions for each of the corresponding facilitator's actions, by grouping similar descriptions in one category and assigning that category a code. For instance, the expressions *chose participant to start, called on participant* and *called on a participant to share their thoughts* were grouped under *asked participant to share their mathematical work* and assigned the code SHARE; *brought experience from the classroom to the conversation, related it back to what students would do* and *tried to make sense of why students have made mistakes in the past* were coded as PAST to indicate that the facilitator reported on what students have done in the past. This process generated a first draft of the codebook.

Following this step, the remaining twelve video transcriptions were assigned to two researchers each. Every pair individually coded their assigned portions and then came together to compare their results and agree on one code per statement. Then, the three coders convened to discuss the overall results. We saw the need to distinguish between *what* the facilitator is claiming or asking, and *how* they were doing it. In particular, we focused on the type of statement that was being made (imperative, interrogative, exclamatory, and declarative).

This led to the second iteration of coding for the same initial two transcripts, where each statement was assigned a *what* and *how* code. We subsequently reconvened to compare individual results. Additional codes were suggested, initial ones were redacted and eventually we noticed a commonality between some codes which allowed us to create the elements of the framework, the *facilitation (how)* and *conversation (what)* themes. Within the facilitation theme, we generated five categories and two actions that pertain to each category. Additionally, we realized that only imperative and interrogative statements were meaningful in certain actions that the facilitator made under the *gathering* and *verifying* categories.

Results: Facilitation Framework

Figure 1 is the framework for facilitation of online professional development. The framework contains two overarching elements: facilitation and conversation. Facilitation is the element of the framework that would transcend the context of the OWG. The conversation categories emerged from our previous research as well as this analysis and would be different if this framework was applied in different contexts. While we believe the conversation codes could serve as a starting point for other groups, the nature of the content under consideration will largely determine these categories.

Framework Elements	Categories	Action	Description
Facilitation	Progressing Session	Transition	Transitioning to a new or different mathematical task/subtask
		Think	Giving individual think time
	Gathering**	Individual	Asking for a specific individual to share or contribute
		Open	Opening the floor to the group for a response
	Verifying**	Elaborate	Asking for an elaboration or clarification from an individual
		Restate	Inquiring about a participant's contribution by restating that contribution
	Contributing	Provide	Providing input, advice, or insight
		Restate	Restating a participant contribution
	Supporting the Group	Encourage	Encouraging statement
		Acknowledge	Acknowledging or thanking participant(s) for contribution(s)
Conversation	Content	Pedagogy	Teacher instructional moves or ideas about teacher instructional moves
		Goal	Learning goals of task/subtask/lesson
		Time	Timing information about lesson
		Past	Previous students' mathematical reasoning and/or work
		Anticipate	Anticipation of students' mathematical reasoning and/or work
		Mathematics	Mathematical content or mathematical technology

	SubCode	Description
**Subcode for Gathering and Verifying	Imperative	Makes a request or gives a command of some sort
	Interrogative	Asks a question, inquires for more information

Figure 1: Framework for Facilitation on Online Professional Development

Here, we focus on the categories within the facilitation element of the framework. There are five categories of actions that our facilitators did in online working groups. Namely, they Progressed the session, Gathered information, Verified information, Contributed their own thoughts to the session, or Supported the group. Each category yielded two actions, or codes. For example, under the Gathering category, we find two actions: Individual and Open. Individual was a code used to describe when the facilitator was asking a specific individual to share their thoughts whereas Open was used to code for when a facilitator asked for any volunteer to share their thoughts. While both actions concern gathering information, they are clearly two distinct actions a facilitator can take during an OWG. It is worth noting that Restate is an action under the Verifying and Contributing categories as a facilitator would Restate for different purposes. For example, a facilitator would Restate a participant claim with the (implied) intention being to inquire about a participant's contribution. That is, the facilitator would Restate what the participant said for the purposes of having that participant expound on what they had just said. Whereas, a facilitator would also Restate a contribution, potentially in paraphrased ways, as a means to contribute to the conversation with no (implied) intention of getting a response from the original commenter of that statement.

Another important aspect of the framework to note is the inclusion of the subcodes for Gathering and Verifying. All four of the actions under those two categories are about the facilitator doing something that desired a response from someone, whether that be a specific Individual, Opening the floor to a question, asking for an Elaboration, or Restating for the purposes of further explanation. However, in our analyses, it became clear that there were always two different ways to achieve those goals. We used terms from the field of linguistics. Namely, imperative requests are ones in the form of a sort of command; whereas, interrogative requests are ones that ask for more information. For instance, a facilitator would call upon a specific Individual to share or contribute by making a request or giving an Imperative command (e.g., "Participant, tell me what you were thinking about.") This would contrast with the same action, Individual, but could have been asked in the form of an Interrogative question: "Participant, what mathematical theorem led you to that conclusion?" We treated instances such as these as both falling under the action of asking a specific Individual to contribute, but the means the facilitator went about that were different. This was the case for the Gathering and Verifying codes so for all of those codes they received the subcode of either Imperative or Interrogative.

Some coded examples of this are:

Facilitator - Imperative: "So, keep going with that [line of thought] Participant."

Facilitator - Interrogative: "So, I, we are talking about … the Sudoku property and each symmetry appears at most once and each symmetry appears at least once. Is the hint here, so what are students going to approach and how are they gonna approach this question?"

Conclusion

Through our iterative coding process, we developed a framework that captures the actions facilitators take in overseeing online professional developments. These categories including Supporting the group, Progressing the session, Contributing to the discussion, Gathering information, and Verifying information. Part of our framework, within the Gathering and Verifying categories, also notes the different ways in which facilitators can gather or verify information. Namely, we differentiated between imperative requests (e.g., "participant, tell me what you think about that") and interrogative ones (e.g., "participant, do you agree with the other participant's claim?"). Our future work will consist of in-depth case studies of each facilitator to enhance this understanding. Importantly, as noted, the framework we developed shares many similarities to that of van Es and colleagues (2014). The implications from this are important. Characteristics and actions of facilitators are key to understanding how facilitation occurs and how facilitation techniques can be trained and learned, while the content may be salient.

INFLUENCES ON EARLY-CAREER MATHEMATICS' TEACHERS VISION OF TEACHING WITH TECHNOLOGY: A LONGITUDINAL STUDY

Suzanne R. Harper
Miami University
Suzanne.Harper@MiamiOH.edu

Dana C. Cox
Miami University
Dana.Cox@MiamiOH.edu

This paper reports on a longitudinal study of mathematics teachers' development of a vision of teaching with technology where we document professional events and activities that point to continued evolution and devolution of those beliefs. We extend earlier work and ask participants to reflect on the experiences they have had as early career teachers, and how they have influenced their beliefs since graduation. We find that there are significant opportunities for professional learning after graduation, and recommend continued development of graduate-level coursework that is technology-dependent. We also find that the use of Desmos is particularly influential in changing beliefs about the role of technology.

Keywords: Instructional Vision; Technology; Teacher Beliefs; High School Education;

Background

Preservice secondary mathematics teachers (PSMTs) at Miami University take a required mathematics course, where they revisit their own learning of secondary mathematics and investigate concepts by way of problem solving with various technological tools. In previous work, we sought to understand the impact of this course on future teaching practices. We defined *vision of teaching with technology* as an imagined state wherein PSMTs are able to translate their technological beliefs into principles on which they will base future instructional decisions and practice (Cox & Harper, 2016). We found that as a result of participation in this course, PSMTs develop a vision of teaching with technology that is better aligned with that expressed in modern policy documents (e.g., NCTM, 2000, 2014, 2016). We also found that PSMTs draw heavily on their index of personal experiences to illustrate their visions and that descriptions of curricular experiences were central of what PSMTs referred to as "responsible use of technology" (Cox & Harper, 2016).

Drawing on the work of Phillip (2007) and Ertmer (2006), and Pajares (1992), we have delineated technological beliefs as separate from general pedagogical beliefs (Cox & Harper, 2016). We define teachers' technological beliefs as understandings, premises or propositions about the role(s) technology plays in instruction. Thus, when we refer to technological beliefs, we mean those beliefs concerning the role technology plays in mathematics instruction.

We know that inservice teachers seem more likely than PSMTs to perceive the cognitive benefits of technology beyond motivation and fun. Some teachers recognize its power to visualize difficult concepts or meet the needs of diverse learners (e.g., Wachira, Keengwe, & Onchwari, 2008), and inservice teachers seem more likely than PSMTs to believe technology has value beyond a computational device or answer checker (e.g., Wachira & Keengwe, 2011).

Kagan (1992) noted that if a teacher education or professional development program is to be successful at promoting belief change among teachers, "it must require them to make their preexisting personal beliefs explicit; it must challenge the adequacy of those beliefs; and it must give novices extended opportunities to examine, elaborate, and integrate new information into their existing belief systems" (p.77).

After making the PSMTs' preexisting personal beliefs explicit in their vision of teaching with technology, we wanted to examine and document key professional events and activities that point to both continued evolution and devolution of their technology beliefs. This paper reports on a longitudinal study of a mathematics teachers' development of a vision of teaching with technology. Since beliefs and practice are dialectic (Thompson, 1992), it is likely that an individual's vision has been impacted by their teaching and other experiences. Moreover, given the importance of indexing personal experiences when articulating a vision, we wanted to document professional events and activities that point to continued evolution and devolution of mathematics teachers' vision of teaching with technology. We sought to answer the research question, what seminal teaching experiences impact an individual's vision of teaching with technology?

Methodology

Participants in this study are recent graduates (2013-2017) of Miami University who have been teaching secondary (6-12) mathematics for at least two years. Supported by our alumni office and social media connections, we identified a pool of 80 possible alumni. Within that pool, 44 had participated in an earlier phase of this research (Cox & Harper, 2016). Those for whom we had collected earlier writing samples documenting their vision of teaching with technology were sent the *Teaching with Technology–Longitudinal* online survey. The Longitudinal survey was sent to 44 individuals, of which 9 responded (response rate of 20.5%). One of the nine responded that they were not currently teaching mathematics. The remainder of the pool (n=36) were sent the *Teaching with Technology* online survey. Of the 36, thirteen responded (response rate of 36%), all of whom reported that they are currently teaching mathematics.

In the first part of both surveys, we invited participants to narrate their experiences with teaching mathematics with technology. Rather than ask for the titles of specific courses that they recently taught, we asked them to imagine a recent course and then identify the mathematics taught within that course by broad discipline. For instance, a participant might report teaching a course that is 75% algebra, 10% statistics, and 15% trigonometry. Then, they are asked to report the types of technology they used. We chose not to list specific brands of technology, and instead asked for the technology genre. For instance, we asked about Dynamic Geometry Software (DGS), rather than specifying GeoGebra or Desmos.

The *Teaching with Technology–Longitudinal* and the *Teaching with Technology* surveys were conducted digitally using Qualtrix software. Both versions of the survey include two lines of inquiry. First, we asked participants to describe their beliefs about the role technology plays in mathematics teaching. Participants in previous phases of research were familiar with this question having answered something similar at the conclusion of a required mathematics technology course in their undergraduate program. In those cases, we phrased the questions on the survey differently. We provided them with their original *vision of teaching with technology* statements written at the conclusion of the mathematics technology course, and invited them to identify passages that still represent their thinking, as well as passages about which they now think differently. Second, we asked participants to identify experiences such as graduate study, professional development, or classroom episodes; as well as the impact (or lack thereof) the experiences have had on their developing vision of teaching with technology.

Results

We hypothesized that there could be many potential influences on teachers' vision for teaching with technology once they left their teacher preparation program. We chose to focus our questions on three: graduate education, professional development workshops and colleagues. Due to space restrictions, we will expand on only one of these, professional development. Then, we will take a longitudinal look at how these teachers' beliefs have evolved.

Professional Development

Of the 21 participants, fifteen did not report having participated in any professional development (PD) workshops related to the teaching of 6-12 mathematics with technology. Here, we focus on the six who did. Of those six, five were specific about the focus of the PD. Four of the six experienced math-specific professional development. This took two forms. Some of the math-specific technology PD described took the form of individual or department-based PD focused exclusively on Desmos. Other teachers experienced PD at state conferences where they attended sessions about incorporating technology into their classroom planning and teaching. One commented about the benefit of conference-based PD, "I was able to gain insight about other teachers' experiences with new technology and collaborate with other math teachers to learn more about the availability and access of technology for students in other districts."

In addition to math-specific PD, two teachers received other technology-focused PD, but reported that it was oriented toward classroom management or non-mathematical applications such as Kahoot, Google Classroom, or other apps.

Additionally, we asked participants to tell us whether this activity influenced their vision of teaching with technology, or impact how they incorporated technology into their teaching. All felt that they had felt influenced, however the way that they described the influence was different for those experiencing math-specific and non-math-specific professional development. For those who reported non-math specific PD, the influences they expressed were more oriented toward pedagogical shifts in assessment, differentiation, and project-based learning. Those who experienced math-specific PD reported that they now incorporated specific technologies into lesson planning and teaching. These teachers were better at generating content using GeoGebra and Desmos, and felt more confident about how to incorporate it more regularly in their teaching. In all cases, the influences were most often described as improved technical knowledge and in no cases did the descriptions indicate a change in TPCK (Mishra & Koehler, 2006).

A Longitudinal Look

We now narrow our view to just those eight participants who were a part of our earlier study, where they wrote statements about their vision of teaching with technology. For these eight participants, we have additional data wherein they respond to these statements from their current perspective. We chose to categorize these responses as either *renunciations* or *amplifications* of their earlier beliefs. We asked participants to identify up to six passages in their original sample and describe why they either continued or stopped believing something specific and related to teaching mathematics with technology. Not all participants chose to either renounce or amplify a passage, and some teachers chose more than one passage to address.

Renunciation. Three participants identified portions of their previous writing that they wanted to renounce. All three participants no longer believed that students would use technology as a distractor or to "goof off" during class, and came to see it as more valuable than before. "As a teacher I have found that sometimes this free exploration with technology allows for students to make deep connections and allows for them to think freely and oftentimes more critically." One participant went further and renounced their earlier beliefs about technology as indiscriminately good. They wanted to make a more clear distinction between those technologies that simply make teaching easier and those that impact mathematical learning.

Amplification. There were seven times that participants identified portions of their previous writing to amplify. From these passages, we find that early career experiences serve to amplify the need to incorporate digital technologies into education in general. Participants still believe that the educational needs of students change over time and reflects the increased presence of digital technologies in the workforce. As one participant noted, "this passage resonates with me, because I know that I am in a profession where I will have to be continually changing the way I teach. ...our job is to prepare them, and technology allows us teachers to give our students more appropriate learning experiences.

There were two participants who chose to amplify statements that were more specific to mathematics instruction. The first of these focused on the potential of technology to go beyond the application of learned procedure and address the fundamental "why" behind the algorithms. The other participant amplified the role of technology in helping students be more reflective learners of algebra when they use technology to get quick and early feedback.

Discussion

Looking across the three spheres of influence: Additional Coursework, Professional Development and Colleagues, it is clear to us that early career teachers continue to have opportunities to learn about technology for teaching. With more than half pursuing graduate degrees, it would be a good idea to continue to develop graduate-level content courses that incorporate technology for teaching mathematics. Similarly, it is clear that mathematics-specific professional development can influence teachers to utilize new technologies in lesson planning and instruction. Developing stand-alone experiences that can be enacted during department meetings or building-wide PD time might be another way to influence teacher beliefs about the role of technology in mathematics instruction.

Based on specific responses, we recommend incorporating Desmos into professional experiences for early-career teachers. Whether in graduate classes, PD, or in conversations with colleagues, participants are talking about and learning about Desmos. Needing to learn about a technology that students will be using on standardized assessments seemed to be a strong motivator for individual learning, but also district-wide professional development planning. Further, when Desmos is used in graduate-level mathematics curriculum, teachers find that exposure useful and influential.

Conclusion

Our original findings indicated that our mathematics problem solving with technology course had a short-term impact on preservice teacher beliefs about teaching mathematics with technology. This study documents not only the longevity of that belief change, but also the identification of significant experiences in the lives of new teachers that either act to amplify or disrupt those changes over time. This study also positions new teachers as *people from whom we can learn*. We feel that studies that position mathematics teachers as knowledgeable professionals are especially needed at a time where teachers are often deprofessionalized and undervalued.

Mathematics specialists are sometimes known as math coaches, mathematics teacher leaders or other titles. The definition in this paper is a facilitator or leader of teachers focused on professional development in mathematics. The focus of this qualitative synthesis of the literature is to investigate how this role has been studied, defined, and investigated. This preliminary analysis has documented the research methods used in studies, examined the focus of studies, and raises questions about the different types of teacher leadership that may exist.

Keywords: Elementary School Education, Instructional Leadership, Teacher Education - Inservice / Professional Development, Research Methods

The term mathematics specialists were first introduced as a concept in an editorial in *Teaching Children Mathematics* (Dossey, 1984). However, research about mathematics specialists was dormant for a few decades following that call to action until the early 2000s. McGatha and Rigelman (2017) offer a framework that organizes terminology for the different roles that might fall under the umbrella term of mathematics specialist. One set of responsibilities involve the mathematics specialists as professional development facilitator or leader of teachers. A second set of responsibilities involves their work teaching mathematics to students either as a teacher whose primary content to teach is mathematics or as a teacher who might work with small groups of students who need focused instruction in mathematics. We frame these as "responsibilities" because many mathematics specialists have multiple types of responsibilities. For example, the mathematics resource teacher might work with small groups of students in need of extra mathematics support but could also be called on to facilitate lesson study with grade-level teams of teachers. The collection of roles and responsibilities is more like a terrain of options than a set of discrete categories.

Recommendations for professional development for teachers consistently point to needing ongoing, school-based support for mathematics (Darling-Hammond, Hyler, & Gardner, 2017; Woulfin & Rigby, 2017). Models such as lesson study, professional learning communities (PLC), math labs or individual coaching often include a facilitator, coach or specialist at some stage. For instance, a math coach might be assigned at a school to work with all first-grade teachers in a PLC to provide additional knowledge and expertise in mathematics. Their role in that PLC might vary over time and the math coach may work with a different grade-level PLC the following year. However, that role is under-investigated in the research, but studies are emerging about the knowledge and skills required. As such, this paper presents early findings and a preliminary report to raise questions from existing research about mathematics specialists.

Purpose

The purpose of our work is to synthesize existing research and develop understanding of the positioning of mathematics specialists and teacher leaders in the research. Our focus in this analysis is on the mathematics specialists as supporting teacher professional development and not on their work as teachers. We ground our definition in Campbell and Malkus (2013) in recognizing that a mathematics specialist is an on-site support person whose uses knowledge and expertise in mathematics content, pedagogy, and children's learning trajectories to assist teachers with their content, pedagogy, and understanding of children's learning trajectories. While many mathematics specialists are primarily teachers of mathematics, the role should be of interest to mathematics education because of its potential to provide school-based professional development. In this study, we seek to identify patterns and trends in research about mathematics specialists in schools. Our goal is to both create a framework for their roles and responsibilities and to describe how that research has been conducted to gather evidence regarding the complexity of the roles and responsibilities of mathematics specialists. Our purpose is to recommend future directions for research about mathematics specialists and to synthesize what is already known.

Methodology

We have begun working through the stages of qualitative synthesis suggested by Thunder and Berry (2016). The first step was to create criteria for the studies, identify the databases and develop a list of search terms. Each member of the team was responsible for selecting a database for the set of search terms. Then, we aggregated the list across those databases. Our first step was to eliminate pieces that were not articles (e.g., book reviews) and then to eliminate irrelevant articles (e.g., from fields outside education, focused on athletic coaching). For relevance, we included articles focused on mathematics and education. We coded articles that were clearly about mathematics specialists as MC, ADMIN for those regarding school leaders, PD for papers about professional development, and PST for articles about pre-service teachers; some articles were coded with multiple codes. In the portion of the review presented here, we have also pared down the list to identify those articles that mention math specialists (or related terms) in the title or the abstract, and thus coded MC. These articles have the greatest potential to provide insight about mathematics specialists. Later work may investigate how math specialists might appear in other parts of the publications.

Results

Overall, we can see that there has been an increasing trend in research that has been published about mathematics coaches and specialists between our target years of 1991-2018 (see Figure 1). Furthermore, we see the largest spikes in year-to-year publications between 2015-2016 (+7), 2002-2003 (+5), 2009-2010 (+5), and 2016-2017 (+5). Some of these spikes seem to be related to NCTM's release of Research Briefs in 2009 and 2015.

Wanting to better understand broad methodological trends for our 192 publications about mathematics coaches and specialists, we read through the abstracts and methods sections to identify the methods used in each study. As illustrated in Table 1, 72 studies utilized qualitative methods, 48 used mixed methods, and 23 employed quantitative methods. Furthermore, we identified 34 articles that had been published in practitioner journals, and given that they did not have discernable methods, we did not code for methods in this group. Last, we identified 14 items, including book chapters, editorials, and literature reviews that – similar to the practitioner pieces – did not have a discernible method. Thus, we simply coded these as Other. At this point, we are still including them in our database because we are interested in portrayals of the role of the mathematics specialists and different perspectives on the topic. So, while they may not be empirical research, they may still have something to offer in learning more about the work in practice and how it has changed over time.

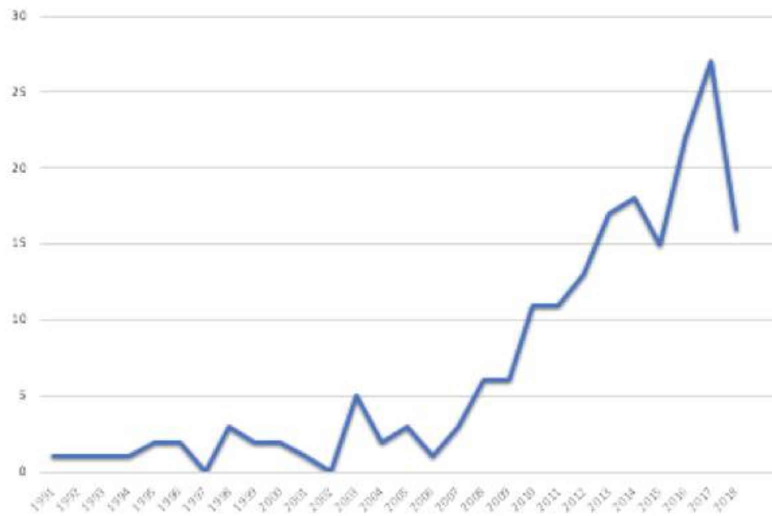

Figure 1. Overall Trends from 1991-2018

Last, and as previously mentioned, we read through the abstracts and assigned at least one of the following codes based on what the article was about: MC (Mathematics Coach), PD (Professional Development), PST (Pre-service Teacher), ADMIN (Administrator). Frequencies for each individual category and overlapping categories can be found above in Table 1.

Table 1. Methodology and Abstract Topic Frequency

Method	**Frequency**
Qualitative	72
Mixed	48
Practitioner	34
Quantitative	23
Other	14
Combination of Codes	**Frequency**
MC (only)	95
MC, PD	57
MC, ADMIN	19
MC, PD, ADMIN	8
MC, PST	8
MC, PD, PST	5
MC, PD, ADMIN, PST	1

Discussion

We are encouraged by the number of studies focused specifically on mathematics specialists and the increasing focus on their work, knowledge, and roles as distinct from other roles in schools. It is not surprising that research about them is likely intertwined with studies of teachers and administrators as their work is designed to include these groups. We are also encouraged to see the variety of methodological approaches that have been used as this will provide a richer and more nuanced understanding of the different types of work mathematics specialists do and its impacts on teaching and learning mathematics.

In narrowing a list of thousands of articles down to a shorter list, we encountered questions about what to eliminate and what articles to keep for our review. Some eliminations were clear (e.g., when the study is in a different field than education), but some questions have been more complicated. Two groups of questions include:(a) determining what makes a study have enough mathematics education to warrant further investigation and (b) considering mentoring pre-service teachers.

The first question we needed to consider was: *What is enough mathematics for a study to be about mathematics teaching and learning?* This may not seem like a complex question, but is complicated when attempting a large synthesis study. The first aspect is when mathematics achievement is used as a student outcome but the abstract does not include discussions of mathematics-focused interventions. Such studies may provide other academic supports for students, but are not focused on mathematics specifically. The second type of ambiguity is when it is not clear the professional development is focused on teaching in mathematics context. We felt only having a mathematics outcome variable was insufficient for inclusion when the intervention was focused on other aspects of teaching and learning. The second question we needed to consider was: *How similar or different the role of mentor teacher is from the role of a math coach?* A collection of studies that emerged focused on mentors of pre-service teachers. We have not yet answered the question posed. A math coach also does one-to-one work with teachers (e.g., co-planning lessons, observations, co-teaching), but mentoring a pre-service teacher may have different features. Both may fall under the broad category of mentoring, but we are not sure yet if mentoring pre-service teachers needs to be analyzed independently from other types of coaching or peer mentoring among teachers.

In addition to the two questions, we also note considerations in regard to abstracts. The first consideration involves the term mathematics specialists being included in the abstract. We have narrowed our list of articles down to 192 that, based on the abstracts, are investigating some aspect of math coaching work. However, there are hundreds more that do not mention that role in the abstract. This supports our claim at this point that mathematics specialists continue to be "hidden players " (Hjalmarson & Baker, 2020) in the research about mathematics specialists. "Hidden" in the present synthesis means that in studies of professional development, the role of the person who might be facilitating the professional development continues to be unmentioned or vague. The second consideration involves the need for more comprehensive, clear, or structured abstracts (Kelly & Yin, 2007) that describe the major aspects of studies (e.g., questions, research design, participants). Some journals already require such abstracts (e.g., *Journal of Engineering Education*). In terms of stakeholders or participants in teacher professional development studies, abstracts could include more about the facilitators of such experiences.

TOWARDS REFLECTION ON THE PRACTICE IN A LEARNING COMMUNITY OF HIGHER-LEVEL MATHEMATICS TEACHERS

HACIA LA REFLEXIÓN SOBRE LA PRÁCTICA EN UNA COMUNIDAD DE APRENDIZAJE DE PROFESORES DE MATEMÁTICAS DE NIVEL MEDIO SUPERIOR

Miguel Ángel Huerta-Vázquez
Cinvestav (México)
mhuerta@cinvestav.mx

Olimpia Figueras
Cinvestav (México)
figuerao@cinvestav.mx

In this report, the authors describe the creation of a learning community for mathematics teachers with the purpose to improve their knowledge about mathematics and its teaching. It also includes a description of how these teachers have structured reflection sessions on class planning, learning activity trials, analysis of teacher performances, and how to improve the design of the teaching sequence. An important result of the first 'Teaching-Reflection Cycle' carried out within the community is that learning about pedagogical content knowledge can be promoted.

Keywords: Teacher's knowledge, reflection on practice, teaching of functions.

Shulman's influential framework (1986, 1987) on the components of effective teachers' knowledge helped stimulate research to improve teaching in many subjects. In particular, for the teaching of mathematics, there are two key investigations. Ball, Thames, & Phelps (2008) extended Shulman's categories for the teaching of mathematics and to build a framework of mathematical knowledge for teaching (MKT). Rowland, Huckstep, & Thwaites (2005) adopted another approach also based on Shulman's work, they built a framework known as The Knowledge Quartet (KQ) focusing on the teacher's mathematics knowledge that emerges within the classroom.

High school teachers frequently do not receive pre-service pedagogical training. In Mexico, teachers of this educational level, start teaching without any type of instruction. They get their pedagogical content knowledge in practice. Courses are often provided. However, the rationale of the lectures is not well planned and sometimes topics are disconnected from the curriculum that teachers follow in their schools (Sánchez & Huchim, 2015; Sosa & Ribeiro, 2014).

Researchers have sustained that mathematical knowledge for teaching could improve the teaching of mathematics (Askew et al., 1997; Rowland et al., 2000).

Considering the aforesaid situation, a group of mathematics teachers –from a Mexican high school– have decided to create a learning community with the aim to ameliorate their teaching by improving their knowledge for teaching mathematics.

For the authors, the 'Learning Community' is a group with a shared identity, characteristics, or purposes. The learning is the objective that brings members together and gives meaning to the community for different purposes (Valdés, Pilz, Rivero, Machado & Walder, 2014, p. 56). A learning community provides: (1) a framework for teachers to learn and develop knowledge together, (2) opportunities to take advantage of teachers' tacit knowledge and make it public to be shared and criticized, and (3) support to be more than technicians who implement others' ideas to become thinkers, researchers and conceptualizers (Elbaz, 1983; Schön, 1983; Wood, 2007).

The purpose of this report is to inform the process of the creation of a learning community; how teachers used reflection to design, apply, and discuss teaching activities and how evidence of teachers gaining knowledge emerges during this process.

Mathematics Teachers' Learning Community

A group of 12 mathematics teachers from a high school level, who works on the same educational center, participated in an academic call to improve their employment status. Aware that they lack the necessary knowledge for teaching, those teachers created a learning community as a means to increase their knowledge and to obtain a promotion. However, during the first period of activities carried out in this community, only 5 teachers continue working together.

To structure the community, teachers used the method employed in the Keli Lesson Study, part of China's professional development program Xingdong Jiaoyu (Huang & Shimizu, 2016, p. 395). The program consists of two stages: practice and reflection. Like the Chinese approach, the community members also focus on professional development through reflective processes that center on how mathematical knowledge manifests itself in practice, and thus teachers gradually transform their practice. An important aspect of the learning community is that there is no institutional intervention, as it is a self-managed initiative of the teachers.

Schön (1983) differentiates two types of reflection that can occur and determine professional knowledge of an individual: reflection in action and reflection on action. Reflection in action is the process of monitoring and adapting behavior in context, while reflection on action is the process of evaluating what has already been done.

Community in Action

The structure of the activities carried out within the community that will be referred to as 'Teaching-Reflection Cycle' is composed of 4 stages:

1. A teacher designs or proposes a Hypothetical Learning Trajectory (HLT) (Simon, 1995) to be revisited by the other members and to plan its trial in the classroom.
2. A member of the community tries out the HLT, and another colleague video-records it.
3. Community members analyze the video and reflect on the teaching activity carried out in the classroom by their colleagues. To think about the teaching process, the teachers use a protocol structured by the researcher (who is a member of the community). Teachers also make suggestions to modify the HLT to apply it later on. All the community sessions are recorded on video and the totality constitutes research data.
4. A process of individual insight reflection is performed.

Activities carried out in a Teaching-Reflection Cycle related to a minimum area problem

1. During the first meeting for the aforementioned cycle, teachers agreed to apply an HLT based on the quadrilateral area problem (see Figure 1) proposed by Lola, a member of the community. She knew the problem from a master's course she took and has implemented it in her classroom several times. The members of the community agreed to deal with it in Mario and Tadeo's groups, but they switch activities. Mario taught the HLT and Tadeo recorded the session in the video.
2. In a second meeting, members of the community watched that video, analyzed and discussed Mario's intervention, and reflected on the teaching and learning processes carried out. They also gave Tadeo's ideas for the next trial.
3. Tadeo taught the HLT in Mario's classroom and Mario video-recorded the trial.
4. In the course of the third meeting, teachers watched the second video, discussed and reflected on both interventions, and reached conclusions concerning how other teachers can use the HLT in their classrooms.
5. Both teachers made an individual insight reflection about what the whole process contributed to their own teaching practices.

Stages 1) and 2) retrieving Schön (1983) are the moments of reflection in action in which teachers analyze and discuss the relevance of the HLT and its implementation. Stages 3) and 4) is the moment of reflection on action, in which teachers evaluate what has been done to make necessary changes considered for future applications.

The Minimum Quadrilateral Area Problem

The HLT of the quadrilateral area problem, included in Figure 1, was designed with the next characteristics:

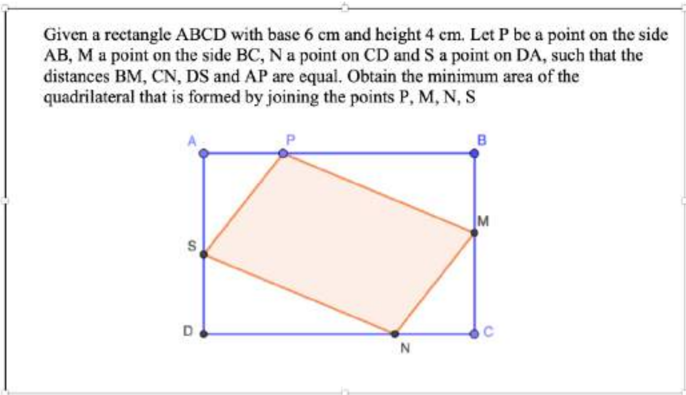

Figure 1: Problem: Compute the minimum area of a quadrilateral

1. Learning goal: Solve the geometry problem by proposing a quadratic function model. In the solving process, students will observe tabular, graphic, and algebraic representations of the quadratic function and learn how to find its minimum.

Learning activities will be applied in a two-hour session as follows: (1) Translate word problem to geometric language, (2) Area computation, (3) Tabulating task, (4) Graphing, (5) Generalization, (6) Identification of the minimum area value.

2. The hypothesis of the learning process: At the end of the activities, students should learn three representations of the quadratic function that models the problem: tabular, graphical, and algebraic, and find the minimum area that solves the problem.

Teachers' Knowledge

Members of the learning community ask themselves what they should know about knowledge for teaching mathematics to be effective teachers. For that purpose, a member of the community introduced the Knowledge Quartet (KQ) proposed by Rowland et al. (2005) as a theoretical framework for the analysis and reflection processes of their teaching activities. From the perspective of KQ, the knowledge and beliefs that are evidenced in the teaching of mathematics can be typified by means of four dimensions: (1) Foundation, (2) Transformation, (3) Connection, and (4) Contingency.

Analysis of Activities within the Learning Community

The KQ framework is also used as a tool for analyzing the 'Teaching-Reflection Cycle' related to the minimum quadrilateral area problem. For the coding of KQ dimensions, the analysis is based on Rowland, Turner & Thwaites (2014, pp. 319–320) where the contributing codes for each dimension are found. Five videos were analyzed using MAXQDA software to transcribe and for coding.

KQ categories that emerge in an episode of the Teaching-Reflection Cycle

The thoughts that appeared in the reflection process about how Mario taught the HLT were incorporated in Tadeo's teaching. This can be seen as a way to build up practical knowledge for teaching quadratic functions. An example of this statement can be appreciated in the next episode.

In Mario's class, a student passed to the blackboard to solve the problem, assuming that the points P, M, N, S were situated in the midpoint of each corresponding side of the rectangle ABCD. This is considered a situation of deviation from the agenda in the teaching process, an aspect that was not expected, so it is a Contingency (a dimension of the KQ framework). Mario dedicated a long period of time to make the students think about the data of the problem in a different way.

A student in Tadeo´s class, while teaching the HLT makes the same interpretation regarding the midpoints, and drew a rhombus inscribed in the rectangle. Tadeo knew in advance that this could happen and manages to lead students to make the most general interpretation considering the problem's conditions.

Tadeo: Well, but ... is everyone clear about what the problem asks you to calculate?
Student 1: The rhombus area.
Tadeo: Well, here I think, that in the wording there is a part that we are not considering because we put the points P, M, N, and S as he said (referring to student 1), you placed it in the midpoint– [pointing P, M, N, and S for each side of the ABCD rectangle] – (See Figure 1).
Student 1: Ah! M and S are not midpoints.
Student 2: Because it had to be the same distance from A to P and from B to M.
Tadeo: Exactly, you already saw that among the conditions of the problem there is a part that says that the distance from B to M, from C to N, from D to S is the same that from A to P. Did you consider that information?

This is an example of the Foundation Dimension of the KQ Framework. The Contingency situation for Mario became a Foundation situation for Tadeo, due to the previous reflection on the first teaching trial within the community.

Discussion

This is the first 'Teaching-Reflection Cycle' of the community, of several more cycles which are being analyzed as part of a broader research work that aims to observe how these cycles can enrich the practical knowledge of the teacher. This methodology of data analysis supported by the KQ framework can be seen as an appropriate frame for analyzing what happens within the community to show how knowledge is produced.

THE EVOLUTION OF TEACHERS' CONCEPTIONS OF TEACHING MATHEMATICAL MODELING THROUGH PARTICIPATION IN LESSON STUDY

Jenifer Hummer
West Chester University
jhummer@wcupa.edu

Mathematical modeling is an important mathematical practice, yet it is a relatively new idea in school mathematics. Limited resources such as lack of teacher preparation have contributed to challenges of teaching modeling. Thus, professional development, such as lesson study, a continuous improvement approach to teaching, might support teachers in implementing modeling. For this study, three secondary teachers with varying levels of experience participated in two cycles of lesson study on mathematical modeling. The teachers were interviewed about their conceptions of teaching mathematical modeling before and after the lesson study. Analysis of the interview transcripts revealed that the teachers' conceptions of teaching modeling evolved in ways that indicated the teachers learned pedagogical strategies, realized further benefits of teaching modeling, and refined their instructional focus for teaching mathematical modeling.

Keywords: Modeling, Teacher Education – Inservice / Professional Development

Policy documents have called for the incorporation of mathematical modeling into the curriculum (e.g., NCTM 2000, 1989; National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). Yet, research has indicated that teachers may have challenges with teaching this important mathematical process that is becoming increasingly more prominent in science, technology, engineering, and mathematics fields (Cirillo, Pelesko, Felton-Koestler, & Rubel, 2016). The challenges of teaching modeling include limited experience, teachers' dispositions and lack of resources (e.g., Meyer, 2015; Newton, Madea, Alexander, & Senk, 2014). These challenges are unfortunate because mathematical modeling can provide students with opportunities to engage in ill-structured problems about authentic real-world situations that are unlike typical textbook tasks. Thus, researchers have recommended that teachers receive professional development (PD), such as lesson study, on implementing mathematical modeling (Turner et al., 2014).

In previous studies lesson study has supported teachers to improve their teaching (e.g., Lewis, 2016; Murata, Bofferding, Pothen, Taylor, & Wischnia, 2012). Lesson study is an iterative process that includes curriculum study, lesson planning, teaching and observing, and reflecting/debriefing. Lesson study could support the teaching of mathematical modeling because lesson study employs a variety of tools and resources that influence improvement of teaching (see e.g., Lewis, C., 2016; Takahashi & McDougal, 2016.) Hence, this study sought to understand: What are teachers' conceptions of teaching mathematical modeling after participating in lesson study on mathematical modeling?

What is Mathematical Modeling?

There are many descriptions of mathematical modeling, but there is no agreed-upon definition. Hence, for the purpose of this study, a working definition of *mathematical modeling* is inspired by Cirillo, Pelesko, Felton-Koestler, and Rubel's (2016) description of the features of mathematical modeling: Mathematical modeling is an iterative process that authentically connects to the real world. It is used to explain phenomena in the real world and/or make predictions about the future behavior of a system in the real world. Mathematical modeling requires creativity and making choices, assumptions, and decisions, and can have multiple approaches and solutions.

Challenges of Teaching Mathematical Modeling

A review of literature revealed multiple challenges for teaching mathematical modeling. For one, preservice and inservice secondary mathematics teachers reported a lack of self-efficacy with respect to pedagogical strategies for teaching mathematical modeling, specifically because of the ill-structured nature of modeling activities (e.g., Kuntze, Siller, & Vogl, 2013; Chan, 2013). Other researchers observed that teachers have struggled with anticipating multiple student responses for mathematical modeling activities. This pedagogical challenge led to other obstacles with respect to classroom management, the handling of multiple student approaches, and the facilitation of whole-class discussions (e.g., Pereira de Oliveria & Barbosa, 2013; Borromeo Ferri & Blum, 2013). These challenges indicate that teachers need further preparation to teach mathematical modeling.

A need for teacher preparation is particularly true when considering the US context. Evidence of insufficient teacher preparation was revealed through a survey of education programs (n = 72). Of the respondents, only 15% of the programs required a mathematical modeling course for preservice secondary teachers (Newton, Madea, Alexander, & Senk, 2014). This finding could indicate that novice secondary teachers may not implement modeling as recommended (see e.g., CCSSM). Gould (2013) found, in a national survey of inservice teachers (n = 274) from 35 states that teachers held misconceptions about mathematical modeling. While Gould's (2013) results indicate that teachers may lack content knowledge for teaching modeling, teachers may also hold beliefs that impact their willingness to teach mathematical modeling. As an example, Anhalt, Cortez, and Bennett (2018) found that after completing a modeling activity, preservice teachers acknowledged that implementing modeling could provide many opportunities for students to engage in rigorous mathematics, rich discussions, and develop multiple solution approaches. At the same time, those teachers were concerned that mathematical modeling activities would be too complex for most secondary students. These types of beliefs may hinder teachers from implementing modeling activities. Moreover, inservice teachers have reported limited resources, such as time and access to quality mathematical modeling curriculum materials prevented them from implementing mathematical modeling regularly, if at all (Gould, 2013; Huson, 2016). To address these challenges researchers have recommended lesson study as a means of professional development to support the teaching of mathematical modeling.

Using Lesson Study to Address Challenges of Teaching Mathematical Modeling

Through the process of lesson study, teachers have opportunities to learn from each other while collaboratively: planning, observing teaching, and debriefing to improve lesson plans (Lewis et al., 2009). Previous studies have found that lesson study provides opportunities for teachers to improve content knowledge, learn pedagogical strategies, and focus on student thinking (e.g., Murata et al., 2012; Lewis et al., 2009). This focus on student thinking can influence teacher learning (e.g., Suh & Seshaiyer, 2014). For instance, teachers observed by Inoue (2011) drew on anticipated student responses to facilitate discussions and support students' engagement with mathematical reasoning. Additionally, Cajkler et al. (2015) observed how teachers' beliefs changed after reflecting on their observations of student thinking for students who typically had minimal classroom participation. These aforementioned aspects of lesson study are likely to support teachers in the implementation of open-ended modeling activities.

Methods

Setting and Participants

Three secondary teachers who were teaching in a diverse vocational high school in the mid-Atlantic region of the United States were recruited based on their interest in improving their teaching of mathematical modeling. Loren, a second-year teacher, earned her bachelor's degree in secondary mathematics education, and as part of her degree program, completed one course on mathematical modeling for secondary teachers. Anne, who had previously been an engineer, had six years of teaching experience. Anne held a bachelor's degree in electrical engineering and a master's degree in curriculum and instruction. Karen had 21 years of experience teaching and had earned a bachelor's degree in computer information systems and a master's degree in education. Karen had participated in professional development on mathematical modeling, and she had some experience teaching modeling.

Lesson Study on Mathematical Modeling. The teachers participated in two lesson study cycles containing the following activities: curriculum study, lesson planning, teaching and observing, and debriefing. During the curriculum study, the researcher introduced mathematical modeling, and the teachers explored curriculum materials related to modeling. For instance, the teachers explored tasks such as those provided in the *Mathematical Modeling Handbook* (Gould, Murray, & Sanfratello, 2012). Next, the researcher facilitated planning meetings and guided teachers in completing an annotated lesson plan, similar to a common format used in Japanese lesson study (e.g., Gorman et al., 2010; Lewis & Hurd, 2011). The lesson plan template contained cells for learning goals, anticipated student responses, planned instructor actions, and rationale for tasks. To complete the lesson study cycles, each teacher enacted the lesson while the lesson study team observed. Then, the team met to debrief the lesson enactments after the first enactment (i.e., Loren's) and the third enactment (i.e., Karen's). During the debrief sessions, the researcher executed a debrief protocol to support revision of the lesson plan based on evidence of student thinking collected by the teachers while observing each other's enactments.

Interview Protocol

Interviews were conducted before and after the lesson study, regarding the teachers' conceptions of teaching mathematical modeling. The questions provided teachers with opportunities to share their conceptions of teaching mathematical modeling. For example, one of the questions was: "Are you currently teaching mathematical modeling, or have you ever taught mathematical modeling? Describe your teaching approach to mathematical modeling (e.g., frequency, resources for tasks, aspects of the modeling cycle addressed)." Then follow-up questions were asked about teaching approaches to modeling, including the benefits and challenges of teaching mathematical modeling. Prior to the lesson study, if the teacher was not currently teaching modeling, then the teacher was asked why modeling was not being taught, and to describe any hypothetical benefits and challenges of teaching modeling.

Data Analysis

Data for the study consisted of audio-recordings and transcripts of two interviews per teacher for a total of six interviews. Once the audio data were transcribed the transcripts were uploaded to Dedoose (2016), web-based qualitative data analysis software. The transcripts were analyzed using a constant comparative approach (e.g., Strauss, 1987; Hatch, 2002). Initial deductive codes were developed using themes that emerged in the literature with respect to the working definition of modeling as well as benefits and challenges of teaching modeling. Then the coding dictionary was revised further as inductive codes emerged from the data. Themes were organized into analytic memos to inform the findings. The analysis of the data revealed three cases about the teachers' conceptions of teaching mathematical modeling: Loren learned pedagogical strategies for teaching mathematical modeling; Anne realized the benefits of teaching mathematical modeling; and Karen focused on shifting her classroom culture.

Findings

Case 1 – Loren: Learned Pedagogical Strategies for Teaching Mathematical Modeling

Before the Lesson Study.

In the pre-lesson study interview, Loren shared that she had not taught authentic mathematical modeling yet, but she expressed several potential benefits and her concerns for challenges of teaching mathematical modeling. For example, she mentioned that teaching mathematical modeling "makes mathematical modeling more interesting to students" and that students could have opportunities to be creative and to see multiple approaches to a modeling activity. Although Loren acknowledged potential benefits of teaching modeling, she also mentioned that modeling activities could be "complicated" and that students could get "easily frustrated" while engaging in modeling. She seemed to think that the complexity of modeling activities could be an obstacle for students. Even though Loren had not been teaching modeling, she indicated that she attempted to provide opportunities to experience similar benefits through her teaching of word problems.

As mentioned earlier, Loren had limited experience with teaching mathematical modeling. She described her approach to teaching modeling as implementing "word problems." When reflecting on her experience teaching modeling she said:

> The only experience that I've really had, and I don't even know if you would classify it as modeling is just like drawing pictures and setting up scenarios with word problems…I'm thinking of when I student taught geometry, and we would do those drawings with the ladder leaning on the house, and I've taught students ways to show mathematical situations, but I don't know if it's truly modeling.

Here, Loren acknowledged that her use of word problems was not quite modeling even though students had opportunities to apply multiple mathematical representations in their solutions. Loren also conveyed enthusiasm for participating in lesson study and improving her teaching of mathematical modeling so that she could genuinely engage her students in the benefits of teaching mathematical modeling.

After the Lesson Study. After participating in lesson study, Loren's observations of students in her classroom and her two colleagues' classrooms influenced her conceptions of the benefits of teaching mathematical modeling. While she mentioned several benefits in her initial interview, Loren added that when the students engaged in modeling during the lesson study, she observed them engage in mathematics that was "valuable in the real world" and "really relevant." She observed that teaching modeling was "a lot more rigorous for them than just teaching them how to do procedures." Loren also recognized how the modeling tasks provided opportunities for students to collaborate with their classmates. Prior to the lesson study, Loren was concerned that mathematical modeling activities would be too complex. However, after focusing on student thinking during lesson study, she saw how students could persevere and collaborate to produce multiple solution pathways for mathematical modeling activities.

Loren's new experience with teaching mathematical modeling also exposed some worthwhile challenges of teaching modeling. Loren found it challenging to support students with "group roles" while they collaborated on the modeling tasks. She also worried about "tutoring [students] too much." Thus, to avoid too much "telling," Loren said she relied on the collaboratively planned lesson which was annotated with possible student responses and questions to ask students. This type of lesson planning seemed to influence Loren's teaching approach to mathematical modeling as she indicated in the transcript below.

> It [lesson planning] really showed me how valuable that is, and I like so enjoyed like going into [the lesson] knowing, what I wanted to say, what I didn't want to say, and what I thought the students

> would say. I planned timing and things like that, but the lesson plan that we did went in depth which was great. So, I think it'll change the way I teach. Not only teaching modeling but just teaching in general because it showed me the importance of lesson planning.

As a new teacher, the lesson planning activities and focus on student thinking during lesson study influenced her approach to teaching mathematical modeling. While Loren expressed some concerns about the challenges of teaching mathematical modeling, she also seemed to indicate that her new knowledge of pedagogical strategies would continue to support her teaching.

Case 2 – Anne: Realized the Benefits of Teaching Mathematical Modeling Before the Lesson Study.

Similarly, to Loren, Anne mentioned that she had not quite taught mathematical modeling before, but she acknowledged potential benefits and challenges of teaching mathematical modeling. Anne, conveyed that mathematical modeling could advance students' mathematical thinking and that teaching modeling was "teaching them more the approach to solving problems rather than just rote memorization of solving problems, different representations and ways to solve things, but mostly just to get them thinking more analytically rather than plugging things into a formula." While Anne recognized that modeling could provide students opportunities to engage in complex mathematics, she also indicated that students could become frustrated with ill-structured modeling tasks. Anne noted that when she had implemented open-ended mathematical tasks her "biggest challenge" was "letting them [students] struggle." She also mentioned that the students were uneasy with tasks that could have multiple student responses and not being "spoon-fed, step-by-step" instructions for solving the tasks. Anne seemed to think that struggling with mathematics would be beneficial for students, but she also mentioned her frustration with the lack of time for including open-ended tasks within her mandated curriculum when she said "It's just sometimes it's hard with so much to get through. There's definitely room for more."

After the Lesson Study. After the lesson study, Anne still maintained her perceived benefits of teaching mathematical modeling. She indicated that she saw students in her classroom, and her two colleagues' classrooms "get better at problem solving." She also thought those skills would translate to other areas outside of the math classroom. A new conception that Anne mentioned was based on her observations of students. She saw that engaging in mathematical modeling gives students opportunities to "collaborate with other students and things like that rather than just being instructed directly." Anne's evolved conceptions about her students were notable. After the lesson study and implementation of mathematical modeling, she discussed how the intentional focus on student thinking allowed her to observe "skills in students that [she] wouldn't have seen in a traditional way of teaching them." More notably, she had the following to say about one of her students in particular:

> One of my students, like I got more out of him from this activity than I have the whole semester. I was able to see his thought process and things like that, that I had never seen before because I guess really, I'm always looking at a paper and what he's writing, and he's not a big sharer in class. So, it was really hard for me to see. But then when I saw what he was doing I was like, wow, he's really, really working on this. Like really his, the way his mind was working, was very much different than what I had thought.

Anne's discussion about her observations of this particular student indicated that her initial beliefs, regarding students' abilities to engage with mathematical modeling, had evolved to see that students could persevere through modeling activities. As a result, Anne mentioned that she was including more modeling tasks and asking more open-ended questions throughout her lessons. Through her participation in the lesson study, Anne's conceptions evolved so that she had a deeper realization of the benefits of teaching mathematical modeling.

Case 3 – Karen: Focused on Shifting Classroom Culture

Before the Lesson Study. As the most experienced teacher, Karen, was well-aware of many benefits and challenges of teaching mathematical modeling prior to the lesson study. When describing the benefits of modeling, she conveyed her implementation of modeling had evolved. For instance, she mentioned how students struggled with the messiness of modeling tasks at first, but then "eventually they started to deeply think about it and contribute to each other's ideas and bounce ideas off of each other and reference each other's input as a class discussion." Because of her previous experience with teaching modeling, unlike her two colleagues, she had a clear vision for implementing modeling. Although Karen recognized many benefits to teaching modeling, she also noted challenges with teaching modeling. Karen's primary concerns about teaching mathematical modeling were with regard to her available resources. She indicated that when it comes to teaching mathematical modeling, "the primary constraint is the lack of great tasks and the lack of time." Karen shared that she implemented a modeling activity within each of her units, but she was looking forward to the opportunity to collaborate with colleagues to further improve her teaching of modeling. Although Karen's conceptions of teaching modeling did not evolve as drastically as her other two colleagues' conceptions, she still found value in the lesson study and her conceptions of teaching modeling emerged to a different teaching focus.

After the Lesson Study. As hypothesized by the researcher, many of Karen's conceptions about the benefits and challenges of teaching mathematical modeling did not change much after teaching the lesson study. Rather than observing noticeable changes in her conceptions, the researcher noted that Karen's focus after the lesson study had moved to cultural aspects of teaching mathematical modeling. For example, Karen noted that she appreciated the level of student engagement she observed during the lesson enactments. She also spoke about her evolved focus on cultivating a classroom culture that would support the teaching of mathematical modeling. Specifically, she said she was challenged with:

> Creating that environment where they want to do this type of math is an ongoing challenge of mine…just getting [students] to be comfortable with being uncomfortable is what I try and get to tell them. I am becoming more and more aware of the importance of establishing appropriate culture, and it doesn't matter what the task is or how wonderful my task is. If I can't get the students to buy what I'm selling, it's not, it's just not going to have the impact that I wanted to have. I need to have these kids believing that they can model.

It seemed as though Karen was less focused on her earlier challenges with limited resources for teaching modeling, and more focused on her teaching approach. She also noted other benefits of participating in the lesson study.

During the post-lesson study interview, Karen expressed that she found the lesson study to be beneficial for multiple reasons. First of all, even though she was the most experienced teacher, she found that the collaborative nature of lesson study supported her to anticipate student thinking for the implemented lessons. Consequently, she communicated that she would like to continue to collaborate with teachers in her school to improve her teaching of mathematical modeling. More specifically, Karen said she appreciated the " ability to plan with someone else and anticipate [student thinking], regardless if it's modeling or not modeling, but I wish I had that with my modeling tasks. I know my modeling tasks would be improved if I could do that." Even though Karen was a veteran teacher, she indicated an aspiration to collaborate with her colleagues in the future to improve her teaching of mathematical modeling.

Reflections Across the Cases

Before the Lesson Study. Prior to the lesson study, all three of the teachers acknowledged that teaching mathematical modeling could have many benefits for students but also challenges for students and teachers (see Table 1). Loren, who had engaged with modeling as a student, and Karen, who had been teaching modeling, both recognized that teaching mathematical modeling could appeal to student interest. Anne also indicated that engaging in modeling would provide more rigorous problem-solving opportunities than typical textbook texts usually provide. Yet, at the same time, Loren and Anne were concerned that the complexity of modeling could discourage some students. Notably, Karen did not focus on challenges for students, but she expressed challenges she faced as a teacher with finding authentic modeling tasks and time to plan and implement mathematical modeling. At the beginning of the study, as expected, the teachers were approaching the teaching of mathematical modeling in various ways, as Loren and Anne had not quite implemented open-ended modeling tasks. When considering, the teachers' early conceptions of teaching modeling, their evolved conceptions after the lesson study suggested that the lesson study had a positive impact on their conceptions of teaching mathematical modeling.

Table 1:Teachers' Conceptions of Teaching Mathematical Modeling

		Benefits	**Challenges**	**Teaching Approach**
Loren	Before	• Student interest • Creativity • Multiple approaches	• Complexity of modeling	• Word-Problems
	After	• Relevant math • Rigorous math • Student collaboration	• Time • Curriculum	• Focus on Student Thinking • Group Roles
Anne	Before	• Problem-solving	• Complexity of modeling	• Word-problems
	After	• Student collaboration • Access for all students • Focus on student thinking	• Culture Shift	• Increased modeling tasks • Open-ended questions
Karen	Before	• Student interest • Student collaboration	• Time • Curriculum	• Modeling in unit plans • Adapting tasks
	After	• Rigor and relevancy • Student collaboration	• Culture Shift	• Collegial Collaboration • Culture Shift

After the Lesson Study. After the lesson study, the teachers' expressions conveyed evidence that indicated their conceptions of teaching mathematical modeling had evolved. As an example, Loren and Anne's concerns about the complexity of modeling tasks being too challenging for students had shifted. Instead, they expressed how teaching modeling provided opportunities to focus on student thinking and observe how all of their students could engage in rigorous mathematics. Similar to Karen, before the lesson study, Loren now conveyed curriculum and time as being her main challenges to implementing modeling. Likewise, Anne's new perceived challenges were aligned with Karen's challenges of creating a classroom culture for teaching modeling. Additionally, Loren and Anne had other conceptions after the lesson study about the benefits of modeling that were similar to Karen's conceptions before the study. For example, before the lesson study, Karen indicated that modeling could appeal to student interest and promote student collaboration; whereas, Loren and Anne did not mention those benefits until after the lesson study. When considering the cross-case findings, it is apparent that the evolution of the teachers' conceptions about teaching mathematical modeling was supported by participating in the activities of lesson study. More importantly, one might hypothesize that Loren's and Anne's conceptions of teaching mathematical modeling progressed more expediently than if Loren and Anne had attempted to implement mathematical modeling on their own or through conventional PD.

Discussion and Conclusions

The teachers' conceptions about teaching mathematical modeling after participating in lesson study indicated that lesson study can, given the right conditions, support the teaching of mathematical modeling. For one, the teachers indicated that participating in lesson study provided opportunities to explore curricular resources and learn new pedagogical strategies. They also had time to collaborate with colleagues to improve mathematical modeling lessons. This finding is important as teachers in previous studies have indicated that they had limited resources for teaching mathematical modeling such as curriculum and time (Gould, 2013; Huson, 2016). The teachers in this study also focused on how their implementation of mathematical modeling provided multiple benefits for students. The teachers spoke about how the lesson study provided opportunities to engage with student thinking in ways that supported students' engagement in the modeling process. This finding is contrary to previous studies where teachers struggled with pedagogical skills needed for teaching modeling such as facilitating multiple student responses (e.g., Kuntz, Siller & Vogl, 2013; Pereira de Oliveria & Barbosa, 2013; Borromeo Ferri & Blum, 2013). Another notable finding from this study was that the teachers observed how all students were capable of engaging in rigorous mathematics. In contrast, teachers in previous studies expressed concerns about students' abilities to engage in complex mathematical modeling tasks (e.g., Anhalt, Cortez, & Bennet, 2018). These cases present compelling evidence for the use of lesson study on mathematical modeling to support teachers' conceptions of teaching mathematical modeling. Further research is needed to understand how lesson study on mathematical modeling can be employed in different contexts to achieve improvements in teachers' content and pedagogical knowledge with respect to modeling.

Acknowledgments

The author would like to thank the teachers and their students for participating in this study.

CHARACTERIZING FEEDBACK GIVEN AMONG MATHEMATICS TEACHERS: CLASSROOM OBSERVATIONS

CARACTERIZANDO LOS COMENTARIOS ENTRE MAESTROS DE MATEMÁTICAS: OBSERVACIONES EN EL SALÓN DE CLASE

Erin E. Krupa

Mika Munakata
Montclair State University
munakatam@montclair.edu

The objective of this study is to analyze the nature of feedback given among 58 middle school mathematics teachers participating in a targeted professional development program. As part of the professional development, teachers participated in instructional rounds in which they worked in groups of five or six to observe and give each other feedback on classroom visits. The feedback was written on forms during the observations and discussed during debrief meetings after the observations. This paper characterizes the feedback written by teachers as they observed their colleagues teaching. The preliminary results show that teachers' written feedback was largely descriptive and focused on instructional, rather than mathematical, elements of the lesson.

Keywords: Teacher Education – Inservice / Professional Development, Systemic Change, Instructional Vision, Middle School Education

The purpose of this research is to characterize the feedback middle school mathematics teachers provide to their peers as part of Instructional Rounds (IR). Instructional Rounds have been proposed as an alternative to the periodic, short-term professional development (PD) workshops that are typically held for a few days during the school year or summer (e.g., Goodwin et al., 2015; Teitel, 2015). They involve a collaborative effort among teachers as they observe each other in the classroom and learn from their collective expertise (City et al., 2009). Instructional Rounds exemplify other features of PD programs that have been shown to have an impact on teachers' practice. For example, they take place in the context of schools (Mewborn & Huberty, 2004; Quick et al., 2009) and encourage teachers to collaborate and problem solve as they reflect upon their experiences of teaching (Hawley & Valli, 2000). Specifically, the research question guiding this research is: *How can the feedback teachers give to one another as part of Instructional Rounds be characterized?*

Theoretical Framework

This study is grounded in the premise that IRs are one way in which teachers can learn and improve their practice as they share their expertise and reflect on their own practice with their peers (Kennedy et al., 2011). However, there is a dearth of research on the types of feedback teachers provide to one another on classroom observations. Scheeler et al. (2004) conducted a meta-analysis of research feedback and found that of the 208 teachers included in the meta-analysis, only 9 teachers were inservice teachers. The nature of feedback university supervisors provide to preservice teachers has shown that immediate feedback following a teaching episode (Cornelius & Nagro, 2014) or using bug-in-ear technology during live teaching (Scheeler et al., 2006) can lead to change in practice.

With respect to inservice teacher education, the recent emergence of video clubs for teachers has provided opportunities to study teachers' observation (e.g., Star & Strickland, 2008) and noticing (e.g., Sherin & van Es, 2005) skills. These studies have described the results of the implementation of video clubs (e.g., Beiseigel, 2018; Wallin & Amador, 2018), or have analyzed teachers' responses to viewing rich clips of classroom episodes (van Es & Sherin, 2008). However, more research is needed to understand how teachers provide feedback to their peers and to categorize and describe the nature of their feedback.

Methods

Context

The participants of this study were 58 middle school mathematics teachers from 7 local school districts. The teachers participated in a three-year PD program consisting of a two-week intensive Summer Institute, followed by four days of follow-up PD during the academic year. In the final year of the program teachers participated in IRs, starting with norms development and team-building during the Summer Institute, and involving peer classroom visits and feedback cycles during the school year. Teachers worked in teams of five or six throughout the IR process.

During the PD teachers participated in targeted activities to help them understand the importance of using one another as instructional resources and to practice giving meaningful feedback. After reading an article on the teachers implementing IRs in schools (Troen & Boles, 2014) and discussing the differences in peer feedback and the standard evaluation measures, teachers practiced giving feedback on a classroom video of a teacher not in the program. Then, teachers gave a short model lesson and received feedback from their peers in the audience. In this way, they practiced giving and receiving feedback in a safe space with their teams.

During the school year, every team traveled together to observe each of their teammates' classrooms. The visits included a pre-observation meeting where the observed teacher described their mathematics and instructional goals for the lesson, a classroom observation, and a post-lesson debrief where the observers provided feedback to the teacher.

Data Collection and Analysis

The data for this study came from the observation forms teachers completed during their classroom visits. To record their thoughts for the debrief sessions, each observer was provided with a form with a section for "Mathematics Goal", "Instructional Focus", and "Other". We collected 244 forms for the observed teachers. The observation forms were parsed into units of analysis that were feedback units distinguished from the next by turns in content. In sum, there were 3,595 feedback units in the teachers' observations forms (μ=14.79).

Based on Schwartz et al. (2018), pre-determined codes for the observation forms were used to code the feedback units. The first level codes determined whether a feedback unit was mathematical (M) or instructional (I) in focus. Feedback related to mathematical thinking, mathematics content, terminology, or notation, was coded as Mathematical (M). Comments related to instructional decisions that were not specific to mathematical content were coded as Instructional (I). The second level determined whether the comment was descriptive (D), suggestive (S), or complimentary (C). Descriptive refers to comments that summarize or describe a situation without any intended suggestion or judgement. Suggestive refers to comments that were meant to have the teacher consider alternatives or to question a move or explanation of content. A comment was coded as complimentary if it connoted a positive attribute of the lesson.

If a feedback unit was coded as descriptive (MD or ID), no additional sub-codes were assigned. Each of the *suggestive* second-level code was coded as either *consideration* (C) or *imperative* (I). A *suggestive, consideration* comment indicates that the mathematical objective or instructional focus was not hindered and that the observer was merely giving the observed teacher a question or alternative to consider. An imperative suggestion includes comments that stood in the way of the mathematical objective of instructional focus being met. A feedback unit with a complimentary code (MC or IC), was either general (G) or specific (S). General compliments consisted of phrasings such as "nice lesson", whereas specific compliments referred to a particular instance during the lesson. Examples of each set of codes are provided in Table 1.

Table 1: Coding Scheme with Examples

Level 1 Code	Level 2 Code	Level 3 Code	Examples
Mathematical (M)	Descriptive (M, D)		"Added all angles to make sure they were 180"
	Suggestive (M,S)	Consideration (M,S,C)	"A 'math talk' anchor chart may help guide discussions"
		Imperative (M,S,I)	"Never really answered the question (problem)"
	Complimentary (M,C)	General (M,C,G)	"Topic well covered"
		Specific (M,C,S)	"Loved the calculator analogy—have to know to use the tool properly"
Instructional (I)	Descriptive (I,D)		"Had the kids organized before the lesson started"
	Suggestive (I,S)	Consideration (I,S,C)	"Students may be more willing to share ideas if they can formulate them first on paper"
		Imperative (I,S,I)	"Wait time—need more"
	Complimentary (I,C)	General (I,C,G)	"Ms. K has a very approachable demeanor"
		Specific (I,C,S)	"These tips are a great foundation to encourage more group talk later on in the year"

Reliability

Each feedback unit was coded by two coders. After initial coding, any discrepancies were discussed until agreement was reached. Thus far, 338 feedback units from one team have been coded for this preliminary analysis. The initial agreement between the coders was 89% for Level I codes (M vs. I), 86% for Level II codes (D/C/S), 82% for Level III codes (C/I or G/S). By October, all ten groups and 3,595 feedback units will be coded and analyzed. Results from the first team, Teachers Being Outstanding (TBO) are presented below.

Results

The raw data for the 338 codes provided by the TBO team are provided in Table 2. The most frequent feedback was instructional descriptive (ID). Though the feedback units coded as mathematical were infrequent, when teachers provided feedback coded as mathematical, it was mostly descriptive in nature. Of the suggestive feedback, none were imperative and there were almost three times as many instructional suggestive consideration (ISC) feedback units than mathematical suggestive considerations (MSC).

Table 2: Counts for Each Code Across TBO Team

Code	MD	MSC	MSI	MCG	MCS	ID	ISC	ISI	ICG	ICS
Count	56	13	0	1	25	144	34	0	13	52

An analysis of Level I codes shows that there were 95 feedback units coded as mathematical and 243 codes as instructional. For the level two codes, there were 200 descriptive, 91 suggestive, and 47 complimentary. At level three there were 47 feedback units coded as consideration and 0 imperative feedback units. There were 14 general level 3 codes and 77 specific, however twice as many feedback units, coded as specific, were instructional in nature.

The percentage of each feedback unit code for the TBO group is provided in Table 3. The percentages represent the frequency of each code relative to the total number of feedback units given by the observer for all teachers observed. For each observer, the code that was most frequent is highlighted in gray. Across all six teachers, the most frequent codes were instructional in nature, with the instructional descriptive codes being the most common among the team of observers.

Table 3: Percentages of Each Code by Observer

	MD	MSC	MSI	MCG	MCS	ID	ISC	ISI	ICG	ICS
Ebony	18.87	1.89	0.00	0.00	0.00	58.49	7.55	0.00	5.66	7.55

Jameka	0.00	19.05	0.00	0.00	0.00	19.05	33.33	0.00	9.52	19.05

Discussion and Conclusions

These preliminary results show that teachers tend to focus on instructional aspects of mathematics lessons and that it is more common for them to provide descriptive comments than suggestive or complimentary, despite the emphasis on constructive and meaningful feedback during the PD sessions preceding the IRs. It is rare for teachers to provide mathematical or instructional suggestions that they believe are imperative in nature. It will be important to conduct this analysis across the other nine IR teams and to disaggregate the results by observer and by team to determine if there are any differences in feedback based on the structure of the teams.

These results have implications for professional development and mathematics teacher leadership programs. Professional development and programs seeking to develop mathematics teacher leaders should consider developing activities to facilitate teachers' observation skills to include a critical eye for providing feedback to their peers. Whole group discussions, interspersed with IR observations, that provide opportunities to review the feedback and consider ways to make it more meaningful would allow for this type of intervention. A study that describes teachers' growth under this model would be illuminating.

Creating a network of teachers that can provide critical, non-evaluative feedback to one another has the potential to make small incremental and sustainable improvements to teachers' practice. The present study shows that teachers provide a range of different feedback types and also suggests that PD should focus on helping teachers provide more suggestive feedback.

EXAMINING IN-SERVICE TEACHERS' DIAGNOSTIC COMPETENCE

Teachers' diagnostic competence is essential for effective mathematics instruction. Prior studies have examined teachers' diagnostic competence using various approaches, such as asking teachers to assess students' erroneous work or anticipate potential learning difficulties. Few studies have examined how teachers interpret the significance of student errors, that is, to what extent the teachers think the flaws in students' work indicate a serious conceptual error or a trivial mistake that can be easily remediated. In this paper, we investigated the diagnostic competence of 2527 elementary in-service teachers by asking them to categorize errors in students' authentic place value errors in the context of decimal operations. Implications are discussed.

Keywords: Diagnostic Competence, Mathematical Error, Misconceptions, Decimal, Place Value

Perspectives

Teaching effectively and efficiently requires teachers to recognize 'what is' and 'how to' respond to the students' errors (Hill et al., 2008). Researchers (e.g., Artelt & Rausch, 2014; Schrader 2009; Südkamp et al., 2012) have defined diagnostic competence as the ability to anticipate or evaluate how well students perform on tasks. Diagnostic competence has been identified as a foundation of teaching expertise for decades (Weinert et al., 1990). Previous studies have worked on the conceptualization and measurement of teachers' diagnostic competence (Klug et al., 2013) as well as exploring how it affects students' learning (Guruzhapov et al., 2019; Helmke & Schrader, 1987). Researchers have assessed teachers' diagnostic competence by examining teachers' ability to analyze and identify errors in the students' work, anticipate common errors, and estimate the difficulty level of given tasks in order (e.g., Ostermann et al., 2018).

The present study is designed on the premise of defining teachers' diagnostic competence as how they infer the significance in the student errors. Such competence is important as it bridges teachers' diagnostic thinking of interpreting student work and making corresponding instructional decisions (Loibl et al., 2020). For example, while working on a multiplication problem such as 15 times 0.6, if a teacher considers a student response of 90 to be a *minor error* (e.g., a procedural error that misses the decimal point), he or she may respond by reminding students to add the decimal point after obtaining the solution of the mathematical operation. On the other hand, a teacher who regards this response as a *major error* (e.g., a conceptual error indicates a limited understanding of place value), might lead to a substantial intervention focused on the significance of the decimal point and place value. That is, perceiving an error as a *major error* more likely leads to conceptual instead of procedural remediation. This said we defined major and minor errors using the following text in the survey: "*Major errors* indicate a misunderstanding of key ideas that may persist even after sustained follow-up instruction; whereas *Minor errors* indicate a lack of awareness or inattention that can be addressed with brief follow-up instruction."

Markovits and Even (1999) reported a range of teachers' diverse interpretations and responses to instructional situations involving a decimal point. The data helped us in gaining an initial understanding of teachers' diagnostic competence on their knowledge related to decimal topics. To explore teachers' diagnoses of the significance of student errors more broadly, we focused on teachers' views concerning typical errors related to arithmetic operation with decimal notation. This research study was narrowly focused to better understand one case of teachers' diagnostic

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

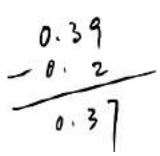
competency by answering the following research question: *How do in-service elementary teachers differ in their diagnosis of the significance of student errors with decimal place value?*

Method

The data for this study is drawn from a large-scale assessment focusing on evaluating teachers' knowledge for teaching rational numbers. For this paper, we included data from two items about teachers' diagnostic competence on decimal topics (see Figure 1). Both items are related to fourth-grade common core standards. Item 1 involves decimal subtraction (0.39 – 0.2 = 0.37) and Item 2 involves multiplication of a decimal and a whole number (15 × 0.6 = 90). The errors in both the items relate to the placement of decimal points. This error can be understood from two perspectives. If the error is understood to be procedural, it reflects students' missteps in completing an algorithm. In this case, the teacher may address the error by reminding the student about the correct steps of the algorithm. On the other hand, if the error is conceptual, it is reflective of students' inadequate understanding of place value. A teacher who considers the error as evidence of a misunderstanding, she or he may respond with more extensive instruction that is aimed at developing student understanding.

In this study, we tried to gain a better picture of how teachers interpret students' erroneous work. We provided definitions for the examinees of the two categories described above as major and minor errors, respectively. We then asked teachers to select the best option to complete the statement about each sample of student work, "In this student work sample, error or imprecision is (a) major and related to this topic, (b) minor and related to this topic, (c) related to a different topic, or (d) not evident." (Figure 1). Teachers who selected option (c) were asked to provide text to explain their reasoning.

Item 1



Considering the topic of place value, select the best option to complete the statement.

Item 2

Considering the topic of multiplying whole numbers and decimals, select the best option to complete the statement.

Figure 1. Two Item Samples

To answer the research question, we report the distribution of responses for all the options across 2527 elementary in-service teachers. To further understand teachers' reasoning on these questions, we analyzed all teachers' textual responses to option (c) (For Item 1, 3 were blank, thus n = 42; for Item 2, 3 were blank, thus n=36; see Table 2 and 3) using open coding (Cresswell & Poth, 2017). The teachers' exhibiting similar mathematical or pedagogical reasoning were grouped within one theme. For example, a teacher selected (c) related to a different topic and typed "Need to follow the same number value (tenth and hundredth)" for Item 1 which was categorized into the theme *place value* in Table 2. These themes and associated findings were discussed and reconciled during weekly group meetings.

Results

Teachers' Perspectives on the Significance of Student Errors

We found that teachers hold different perspectives on the importance of the same student errors. For the error in Item 1, 59% of the teachers interpreted it as a major error while 36% of them perceived it as a minor error. For the error in Item 2, 35% of participants indicated this error as a major error and 60% consider this is a minor and related error. A small percentage of teachers did not recognize the error in Item 1 (4%) or Item 2 (3%). For each item, around 2% of teachers thought the error was related to a different topic and reported their judgments on which topic was involved textually.

Table 1: The Distribution of Teachers' Perceptions of the Two Tasks

Option	Item 1		Item 2	
	N	%	N	%
Major and related to this topic	1482	59%	878	35%
Minor and related to this topic	904	36%	1521	60%
Related to a different topic	45	2%	39	2%
Not evident	96	4%	68	3%
Missing data	0	0%	21	1%

These data indicate that elementary teachers were more likely to classify the decimal notation error in the decimal subtraction problem as a conceptual error than they were the error in the decimal multiplication problem. From analyzing teachers' open-ended responses, we found more evidence to support this argument. We noticed that 42 teachers offered textual responses and 25 (60%) of them said the error was about place value (Table 2). We interpreted these responses as evidence that these teachers viewed the error as conceptual. Although these 25 teachers were able to identify this is a related error, they did not decide whether this was a major or a minor error, which may indicate the challenges of evaluating the importance of the error for these teachers. For example, one teacher responded "this is related to the topic, but the student could use interventions in decimal place value. This intervention could be beneficial to show him that .2 = .20 helping him to better line up his decimal number." The teacher has shown an understanding of the student's error and even offered intervention to remediate it, but she or he did not make a judgment about the importance of the error.

Table 2: Themes from Open-ended Responses on Item 1 (Option (c))

Theme of Responses (n = 42)	Number of Teachers (%)
Place value	25 (60%)
Computation/difference/algorithm/subtraction/operations	9 (21%)
Decimal addition vs subtraction	5 (12%)
Others	3 (7%)

Nine participants thought the error in Item 1 is related to broader topics such as computation, difference/subtraction, algorithm, and operations, which suggests these teachers noticed the error but did not necessarily interpret it to be related to place value error (Table 2). Five teachers thought the students should use addition instead of subtraction to solve the original word problem. In the "Others" category, one teacher thought students should use 0.02, one teacher suggested the student did not understand which number to subtract.

The teachers who offer textual responses to Item 2 (n = 36) held a more diverse interpretation of the student's decimal multiplication error. Contrary to Item 1, the teachers' responses were less dominated with the *place value* for Item 2 (n = 10, 28%). Four participants attributed the error to a lack of number sense. A teacher wrote that "[the student] doesn't understand the concept of a decimal - if you start with 15 groups of a number less than 1, your answer can't be larger than 15". Another teacher argued that the error related to "understanding the reasonableness of the answer due to values. For example, about 1/2 of 15 couldn't possibly be 60." These teachers seemed to identify a conceptual reason for the error but did not identify and describe the student's specific error, which may inhibit students' understanding of decimal (Markovits & Even, 1999). Nine teachers (25%) identified the error as procedural, relating to "carrying the decimal" or "placing the decimal point." Ten teachers (28%) thought the error was related to broad topics, such as "multiplying with decimals", "decimal", or "multiplication." Three teachers responded with something else such as "multiplying decimals is not a fourth-grade level math operation", "6", and "money".

Table 3: Themes from Open-ended Responses on Item 2 (Option C)

Theme open responses (n = 36)	*Number* (%)
Place value	10 (28%)
Number sense	4 (11%)
Decimal point placement	9 (25%)
Decimal multiplication or computation	10 (28%)
Others (e.g., not a 4th grade topic)	3 (8%)

In brief, from the teachers' written responses, we gained confidence in the larger finding that more teachers tended to identify the error in Item 1 as a conceptual error while more teachers interpreted the error in Item 2 error as a procedural error.

Discussion

Through this study, we found that two errors involving decimal notation were viewed by teachers in substantially different ways, with far more teachers classifying an error in decimal subtraction as major than a related error in decimal multiplication. These findings suggest the need to explore teachers' diagnostic competence concerning students' errors, and in particular to see how teachers perceive the importance of the error in students' mathematical learning. Such exploration goes beyond simply noticing students' errors because it requires teachers to identify students' errors, locate the error within certain mathematical topics, and justify its significance while providing conceptual remediation. This aspect of teacher knowledge may be more predictive of teachers' instruction because it requires teachers to apply their knowledge of student thinking to instructional decisions.

One limitation of this study is the possibility that some teachers held different interpretations of the terms major or minor error as these terms are not commonly used, which may affect the percentages of each option but may hardly affect teachers' general perception of each item. Although we provided the definitions before each item, some teachers may not have understood them as we expected. Thus, this study calls for future qualitative exploration of how teachers understand the major and minor error, the rationale of their option selections, and how they normally deal with such student errors through interviewing teachers and observing their teaching. How teachers interpret errors involving the decimal point in different mathematical contexts may deepen our understanding of teachers' knowledge for teaching decimals, an area in which little is presently known (Takker & Subramaniam, 2019).

It is important to design professional development (PD) around teachers' professional thinking and needs. Researchers have explored how teachers center on and build upon students' thinking in mathematics teaching, but few studies have investigated how to identify and be responsive to teachers' ongoing needs while planning and enacting effective PD. As such, this study presents a Collaborative Responsive Professional Development (CRPD) model that arose from efforts to elicit and validate teachers' voices to design PD experiences that were relevant and meaningful to them. We share the rationale of the model design, its implementation during a two-year PD project, and its impact on teachers' instructional practice.

Keywords: Teacher Education – Inservice / Professional Development; Teacher Educators

Purpose

Avalos (2011) defined PD as "teachers learning, learning to learn, and transforming their knowledge into practice for the benefit of their students' growth" (p. 10). Putnam and Borko (1997) argued that teacher educators should engage mathematics teachers in PD in a way that is parallel to how we expect them to engage their students. Similarly, Spangler (2019) advocated that just as we are asking teachers to attend to their students' mathematical thinking, "we as teacher educators need to demonstrate the curiosity and intellectual humility that allows us to understand how and why something a teacher did or said came from a place that made sense to them" (p. 2). Additionally, researchers have noted the importance of supporting the affective side of teachers' professional growth throughout the PD process (Cross Francis, 2019, Cross Francis et al., 2019). The literature on effective PD indicates a necessary shift towards attending to teachers' needs holistically.

However, identifying and holistically responding to teachers' needs is a challenging task (Lee, 2005). Such efforts require a systematically designed PD process that situates teachers' thinking and voices as core components to all decision-making moves (Jez & Luneta, 2018; Lee, 2005). In this study, we share what we call a Collaborative Responsive Professional Development (CRPD) model (see Figure 1), aimed at systematically centering teachers' voices and needs in an iterative process of designing, implementing, and assessing the effectiveness of our PD curriculum. Our research question was: *To what extent was the implementation of the CRPD model effective for teachers' professional development?*

The Design of the CRPD Model

One core aim of the CRPD model is to ensure that teachers' voices, especially regarding their professional thinking and needs, were collected in various ways, analyzed through multiple perspectives, and utilized to inform instructional decisions. We share three big ideas that undergird the CRPD Model: the research on effective PD with mathematics teachers; creating a structure for collaboration on the design of PD activities; and creating structures for systematically collecting and being responsive to teachers' voices.

The Research on Effective PD with Mathematics Teachers

We used three core features of effective PD as pillars upon which we built our CRPD model. The first feature is focusing on developing teachers' content and pedagogical knowledge for teaching mathematics (Darling-Hammond et al., 2017; Garet et al., 2001). This focus is responsive to strengthening elementary teachers' mathematical content knowledge and quality of mathematics instruction (Ma, 1999). The second feature is engaging teachers in active learning (Darling-Hammond et al., 2017; Garet et al., 2001; Loucks-Harsley, 1996) to strengthen their pedagogical skills. Guided by the Leading for Mathematical Proficiency Framework (Bay-Williams & McGatha, 2014), we aimed to support teachers' shifts in classroom practice. The third feature is enabling and promoting collaboration among teachers, so they feel they belong to a supportive community (Darling-Hammond et al., 2017; Galindo et al., 2014; Garet et al., 2001; Loucks-Harsley et al., 1996). Teachers built their professional learning communities in which they collaboratively reflected on and felt empowered and supported to make incremental, but powerful, shifts in their practice.

Creating a Structure for Collaboration on the Design of PD Activities.

University-school partnerships are a collaborative format for facilitating teachers' professional growth widely used in the field of mathematics education (Avalos, 2011; Bartholomew & Sandholtz, 2009). Our PD was designed as a two-year partnership between a higher education institution and elementary mathematics teachers from eight schools (Grades K-6) in two school corporations. There are challenges in building an efficient, effective partnership (Bartholomew & Sandholtz, 2009; Grossman, 1994; Winitzky et al., 1992). One way to strengthen the researcher-teacher (university-school) partnership is to work collaboratively with a range of stakeholders to develop a shared vision and identifiable goals (Association of Mathematics Teacher Educators, 2017) and enable stakeholders, especially teachers, to democratically engage in decision-making via a continuous and deliberate process.

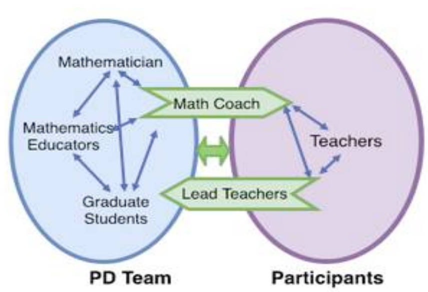

Figure 1: Forming a Structure for Centering on Teachers' Needs

The CRPD collaborative structure included two major groups: The University Team (PD Team) and In-service Mathematics Teachers Team (Participants). The Participants included classroom teachers and a Lead Teacher from each school. The PD Team included two mathematics teacher educators (MTEs), one mathematician, one mathematics coach (an experienced upper elementary and middle school teacher), and two international mathematics education graduate students (Figure 1). We should note the PD Team involved people with, at times, divergent perspectives on what they considered to be the most effective content and pedagogy curriculum or learning activities for the PD workshops.

One unique feature of this model is that the mathematics coach and lead teachers served as crucial conduits between the Participants and the PD Team. The lead teachers recognized the professional learning needs of the teachers at their schools from both practical and theoretical perspectives. Having lead teachers in the CRPD model helped create a sense of community among the participants as they felt safe sharing their concerns with someone they knew and trusted. One major role played by the coach was to visit teachers' classrooms daily to get an insight into the content and pedagogical needs of the teachers (Darling-Hammond et al., 2017; Gibbons & Cobb, 2016). The coach and lead teachers were instrumental in building trusting relations between the two groups, the PD Team, and the Participants, so we could interact effectively and symbiotically.

Creating Structures for Systematically Collecting Teachers' Voices

Teachers, as adult learners, do not enter any PD session as blank slates. Instead, they bring experiences, knowledge, skills, and dispositions which impact their PD engagement, contribution, and outcomes (Ball, 1996). For the PD sessions to be meaningful and relevant, we realized the need to create structures that would provide us with continuous feedback from teachers (Darling-Hammond et al., 2017; Yoon et al., 2007). Thus, we employed survey tools to identify teachers' PD goals, as well as their long-term and short-term needs.

First, to identify specific PD goals, we conducted an *Initial Survey* that went out to all teachers during the PD planning stage. Second, to ascertain long-term needs, each teacher completed an *Annual Reflection and Personal Growth Plan form*, at the beginning of 2016, 2017, and 2018, where they described what they wanted to improve in their teaching practice and shared important takeaways from the PD project. Third, to ascertain short-term needs, we designed a Workshop Feedback form to collect teachers' feedback, using both Likert-scale ratings and open-ended comments, on the quality and relevance of each learning activity in each PD session, as well as their needs and requests for future PD learning activities. In these three ways, the CRPD model design positioned teachers as active professional developers, having both a say about what professional growth they wanted and the means to attain their goals.

The Implementation of the CRPD Model

The project served 60 teachers from eight schools in two school corporations. Teachers' participation in the project included 80 hours per year, distributed among summer workshops (40 hours), two full-day workshops during the school year (one in the Fall and one in the Spring), and four after school sessions throughout the school year.

Adjusting Objectives for PD Workshops According to Teachers' Voice

Based on the *Initial Survey* results, we specified the main goals for this PD. After each PD session, the PD Team analyzed the *Workshop Feedback Form* via four stages. First, immediately after the workshop, the PD team quickly read through and sorted the surveys to identify those with fairly high Likert-scale ratings and those with lower ratings. Second, shortly after the workshop, we scanned the sorted survey responses and emailed that file to the PD team, who read through and analyzed the teachers' open-ended comments for themes. Third, email conversations took place about what themes we observed, and we brainstormed topics related to those themes that we might cover for the next PD. Finally, meetings were scheduled (in person and via Zoom) at which the PD Team worked together with the mathematics coach and the lead teachers to discuss our brainstorm ideas and to plan the agenda for the next PD based on the teachers' feedback, the coach's classroom observations, and the lead teachers' suggestions. At the end of each PD year, we used a similar process to systematically examine teachers' responses to the *Annual Reflection and Personal Growth Plan form*. This process systematically centered the teachers' feedback so that we were able to be responsive to it.

The Impact of the CRPD Model on Teachers' Professional Growth

Two foci of the PD were supporting teachers' understanding and implementation of the Standards for Mathematical Practice (CCSSO, 2010) and developing teachers' pedagogical content knowledge (Galindo et al., 2018). We examined the effectiveness of the CRPD model by analyzing teachers' statements about their major takeaways from the project and about shifts they had implemented in their instructional practice. Data sources included teachers' responses to the Reflection and Personal Growth Plan from 2017 and 2018.

From teachers' reflections about their main takeaways from the project, we found that the teachers' responses were largely centered on two process standards: 'Making sense of problems and persevere in solving them' (MPS1) and 'Constructing viable argument and critique the reasoning of others' (MPS3). Regarding MPS1, teachers acknowledged the significance of allowing students more time to explore problems to elicit multiple strategies and develop strong sense-making for the concepts. Teachers' responses signified the importance of using challenging mathematics tasks that elicit students' thinking and then assisting students in making sense of and persevering to solve the problem. For MPS3, the teachers initially expressed their inclination towards engaging students in discursive practices by promoting collaboration and communication. However, early on they were not reflecting on their role in establishing (or not) such a dialogic learning environment. Gradually, they realized that mathematical communication in their classrooms was too often teacher-dominated. One teacher wrote, "Teachers talk way too much and we all know it, we just can't stop…. I now let them share so much more and I just listen, whether it's right or wrong, I just listen. Then I ask a question, and I listen again. It is amazing the things our students can think of when we give them time to think and share." This teacher realized her role is to intentionally utilize questioning and listening to create ample opportunities and space for students to share their ideas and critique others' reasoning. These takeaways indicate the effectiveness of the PD project in promoting teachers' understanding and implementation of the mathematical practices.

In their reflections, teachers also wrote about their prior experiences as learners of mathematics and stated how experiences from this PD project changed their perceptions of mathematics and self as a mathematician. One teacher wrote, "I was not a confident math student during my school years and had a math phobia… I have learned so much from this experience. I even find myself using the strategies in my daily life. I am more confident in teaching math and helping my students. I actually love math now." Another teacher stated, "[As a learner] I memorized the algorithms we learned in school and didn't really ever question the why behind it. I feel that this training has helped deepen my understanding of math and math concepts." These statements point to the effectiveness of the PD project in positively impacting their relationship with mathematics as a subject.

Discussion and Implication

We sought to create a safe environment for the teachers to express their needs and provide honest feedback on PD learning activities, with an understanding that their voices would be heard, and the PD team would develop a responsive PD curriculum. We confirmed that cycles of emergent and responsive curriculum (Confrey & Lachance, 2000) development are a powerful tool for centering and addressing the needs of teachers. The CRPD model democratizes PD by sharing decision-making power among the Participants and the PD Team. Teachers are given an active voice in their learning, and the math coach and lead teachers serve as strong advocates for teacher participants. Being collaborative and responsive in curriculum design requires systematic and iterative cycles of planning, implementing, and reflecting during which teachers' voices are centered, valued, and utilized.

POSITION AND SENSEMAKING IN REHEARSAL DEBRIEF DISCUSSIONS

Jen Munson, Northwestern University, jmunson@northwestern.edu
Erin E. Baldinger, University of Minnesota, eebaldinger@umn.edu
Sarah Larison, Northwestern University, slarison@u.northwestern.edu

Following rehearsals of instructional practices, teacher educators often facilitate debrief discussions for participants to reflect on and make sense of their experience. This study explores the ways in which rehearsing and non-rehearsing teachers, who act as teachers and students respectively, make sense of that experience collectively and how their positions as teachers and students are reflected in their talk. Data from eight rehearsal debriefs conducted with in-service secondary mathematics teachers during practice-based professional development are examined.

Keywords: Teacher Education – Inservice / Professional Development, Learning Theory

Recent literature in mathematics teacher preparation focuses on how coached rehearsals can be used to support the learning of complex instructional practices (Ghousseini, 2017; Lampert et al., 2013). In these approximations of practice, one person typically takes on the role of teacher, while the rest of the group takes on the role of student. The rehearsal is facilitated by a teacher educator (TE) who takes on the role of coach (Kazemi et al., 2016). As these approximations of practice have gained prominence in both pre-service and in-service professional development, research has focused on the learning of participants who take on the role of teacher (Ghousseini, 2017; Lampert et al., 2013) and the structures used during the rehearsal to support the enactment of teaching practices (Kazemi et al., 2016). However, we know less about the ways in which debrief discussions following the rehearsal, in which both the rehearsing teachers (RTs) and non-rehearsing teachers (NRTs) participate, support the sensemaking and learning of both. In this paper, we contrast the experiences of rehearsing and non-rehearsing secondary mathematics teachers following rehearsals during a summer professional development institute. In particular, we describe how both RTs and NRTs make sense of their experiences during the reflective debrief discussions that follow each rehearsal, and ask how their position as student or teacher in the rehearsal is reflected in their talk.

Prior Literature

Often, after a rehearsal, all participants (RTs, NRTs, and TEs) engage in a debrief discussion. This kind of reflective post-rehearsal discussion, facilitated by the TE, represents an opportunity for public sensemaking, or "collaborat[ing] on sensemaking as a shared group goal" (Ruef, 2016). Through public sensemaking, RTs, NRTs, and TEs all have a chance to learn from one another and reflect on the rehearsal experience. Public sensemaking is also valuable from an analytic perspective, because it gives insight into some (but not all) of participants' sensemaking about a given experience. In this kind of reflective debrief structure, we wonder about what sensemaking RTs and NRTs share publicly and how they might collaborate to make sense.

What teachers can and do say during debrief discussions is influenced by the role they played during the rehearsal. While all participants are intended to learn as teachers, only RTs participate in the rehearsal as teachers; NRTs spend rehearsals acting as students. In other words, NRTs are asked to change their position, moving from student in the rehearsal to teacher during the debrief. How a person positions themselves or is positioned in an interaction can influence the obligations they feel (Aaron & Herbst, 2012; Herbst & Chazan, 2012). In particular, being positioned as a teacher or as a student can change how people react to the same contexts (Baldinger & Lai, 2019). Position is thus an important consideration that might help explain how public sensemaking is constructed in rehearsal debriefs.

We explore public sensemaking analytically through the lens of professional noticing. When engaging in the work of noticing, teachers *attend* to *interpret* specific details, imbuing them with meaning (Mason, 2002; Sherin et al., 2008). In the context of a debrief discussion, teachers might attend to and interpret an event that occurred during the rehearsal, elevating that event for public consideration. Because teachers' goals in participating in coached rehearsals are ultimately to inform and shape their teaching practice, teachers might also describe implications or connections that extend their thinking beyond the specific context of the rehearsal itself (Baldinger & Munson, 2020). This framework of noticing and implicating provides a lens through which we can describe the public contributions made during debrief discussions. Given this, we ask the following research questions: (1) How do RTs and NRTs use debrief discussions to publicly make sense of their experiences during rehearsals? (2) How is position reflected in RTs and NRTs sensemaking of the rehearsal during the debrief discussion?

Methods

Setting and Participants

This study took place in the context of professional development program for early-career (2nd-7th year) secondary mathematics teachers serving lower-income schools. This two-year fellowship included two-week summer institutes and ongoing online coaching during both school years. Our research considers the second summer institute, which focused on facilitating collaborative group work. Participants included 22 high school mathematics teachers from comprehensive public, magnet, and charter schools across the US.

Design

The summer institute culminated in a full day during which all participants had the opportunity to rehearse leading collaborative group work. Rehearsing teachers focused on the practice of conferring (Munson, 2018) to support productive engagement in cognitively demand task and equitable participation within collaborative groups. Teachers were randomly assigned to one of two rehearsal rooms. Four rehearsals were conducted in each room (eight total rehearsals), so that each teacher had the opportunity to rehearse the focal practice once and participated as an NRT three times. Additional math teachers were recruited to participate as NRTs to increase the class size in each room. After each rehearsal, the TE prompted the group to discuss the experience, beginning by asking RTs to share "some of the things in your head right now" and then pose any questions they had for the NRTs. Debriefs then pivoted to NRTs addressing any RT reflection questions and segued into general reflection. All debriefs ended with "final thoughts" from the RTs.

Data Sources and Analysis

This study draws on audio and video recordings of the debrief discussions following each of the eight rehearsals. Debrief discussions ranged in length from 14 to 23 minutes. Each was professionally transcribed for qualitative analysis. Each talk turn (n = 961) was coded by participant (RT, NRT, TE). All RT and NRT talk turns were then segmented and coded based on the type of sensemaking represented in the speech, (i.e., attending, interpreting, implicating), where *attending* and *interpreting* were defined by prior research (Sherin et al., 2011) and *implicating* was defined as making connections beyond the rehearsal (e.g., to the speaker's own classroom) or considering alternative pathways for the rehearsal. Any speech that did not fit these codes was not coded. Each talk turn segment was then coded for the position the speaker took (i.e., teacher, student). If an utterance took more than one position, it was further segmented such that each utterance could be given a single position and sensemaking code pair (n = 983). Code matrices were developed within and across the eight rehearsals to explore patterns of participation.

Findings

While the TEs structured the debrief by inviting RTs and NRTs to reflect during different parts of the discussion, the ways they participated in sensemaking were strikingly similar. Of the coded talk turn segments, 29% of RT talk and 34% of NRT talk attended to observable details about the rehearsal, while 47% of RT talk and 46% of NRT talk interpreted the details of the rehearsal, indicating the meaning the speaker made of events (see Figure 1). Together, these acts of public noticing made up approximately the same proportion of speech, 75% of RT and 80% of NRT coded talk turn segments. The vast majority of all contributions in the rehearsal debrief focused on noticing the rehearsal, making specific details of events public and offering ways of understanding the meaning of those events.

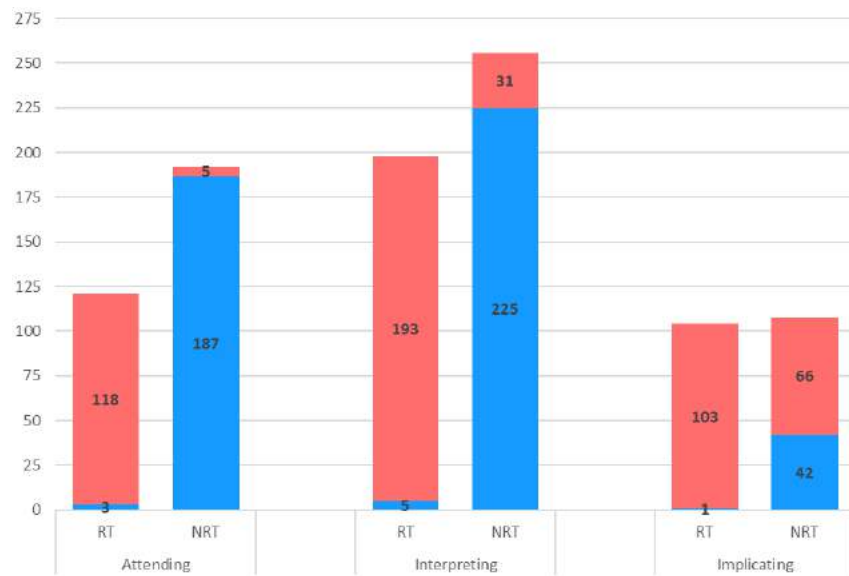

Figure 1: Attending, interpreting, and implicating talk turn segments for RTs and NRTs, by teacher (red) and student (blue) position of the speaker.

For the balance of coded talk turn segments, RTs (25%) and NRTs (20%) made implications, moving beyond the rehearsal as it occurred to consider the meaning the events might have for teaching or alternative scenarios for the rehearsal. All the data generated through noticing the rehearsal fueled reasoning about teaching and learning when implicating. These overall patterns of talk were not substantively different across the two rooms or any of the eight rehearsals.

While RTs and NRTs noticed and implicated in similar proportions, there were pronounced differences in the positions each assumed when speaking (see Figure 1). RTs overwhelmingly (98%) maintained their position as teacher when speaking, regardless of whether they were attending to or interpreting the rehearsal, or drawing implications beyond it. There was a coherence in their role throughout that is reflected in these data; as teacher-learners they were asked to act as teachers and learn from those acts as teachers. NRTs were asked to perform a more complex position move; as teacher-learners they were asked to act as students and learn from their experience as teachers. In contrast to RTs, NRTs overwhelmingly noticed the rehearsal from the position of student (92%). But when implicating beyond the rehearsal, NRTs took on a more complex stance, at times maintaining their rehearsal position of student (39%), but more often flipping to their learner position of teacher (61%).

Notably, while RTs were largely fixed in their position as teachers, they actively sought the perspectives the NRTs gained from being students, data to which they would otherwise not have access. These rhetorical moves from the RTs were striking in how they shaped the ongoing discussion in the debrief and contributed to the "expected" patterns described above. RTs asked pointed questions of their NRT colleagues to unearth how the teaching moves they used were experienced by the students in the rehearsal. They prompted NRTs with statements such as "I kinda want to know how it [the rehearsal] was from your [NRT] lens," "I'm curious to get feedback on… the groupworthiness of the task," and "Was there ever a moment when you [NRTs] wished we [RTs] had jumped in and we didn't?" to elicit the student position experience.

Conversely, when NRTs offered their own noticings, there is evidence in the data that these could fuel implications from RTs. For instance, after a string of 12 talk turns in when three NRTs attended to and interpreted a challenge they faced setting up graphical representations during the task, one RT made the following implication:

> What I'm hearing is, there's the potential for this to hang up a group? … So maybe if I had caught onto the idea that you were really hung up here, if I had observed that…I might have like, nudged you forward.

In this excerpt, the RT took up the NRTs' noticings to consider what they could have done differently, particularly if the RT had noticed, in the moment, what the NRTs did, that their struggle was impeding their mathematical progress. When NRTs offered their noticings as students, they were simultaneously supporting their own sensemaking of the experience and providing insight to RTs who wanted to understand how students experienced their teaching. These results foreground the interactive nature of sensemaking among RTs and NRTs.

Significance

The similarities of the proportions of talk across participates' roles, across both rehearsal rooms, and all eight rehearsals points toward the possibility that public sensemaking grounded in a shared experience like a rehearsal may more generally focus on noticing with a smaller portion of implicating beyond the experience. In previous work (Baldinger & Munson, 2020), we have suggested that debrief discussions may be venues for NRTs to develop adaptive expertise (Hatano & Inagaki, 1986) in the wake of rehearsal by promoting data-driven forward reasoning. This new analysis suggests that rehearsal debrief discussions may serve a similar function for RTs; future work could investigate whether the nature of what is noticed by RTs and NRTs and the types of implications they draw supports such a claim.

Position played a critical role in the ways that RTs and NRTs publicly made sense of their experience together. Prior research is premised on the safe environment that rehearsing among colleagues can provide to teacher-learners (Lampert et al., 2013), but the current research indicates that the roles NRTs play can provide an additional advantage. The rehearsal experience and the debrief discussion that followed offered participants a window into the experiences of students, supporting NRTs in learning from a rehearsal in which they did not teach and RTs in learning about the ways in which their pedagogical choices impacted students. NRTs were then not just safe colleagues with whom to approximate practice, but safe students from whom to elicit feedback on instruction. Future research could investigate how the structure of the debrief discussion can support RTs in gaining access to the student experience data in ways that can inform their learning from the rehearsal experience.

AISSPOMMOOTSIIO'PA – A COLLABORATION TO IMPROVE TEACHING AND LEARNING MATHEMATICS AT THE KAINAI NATION

Armando Paulino Preciado Babb
University of Calgary
apprecia@ucalagry.ca

Jodi Harker
Kainai Board of Education
jodi@harker5.com

The Kainai Board of Education, situated at the Kainai First Nations Reserve in Southern Alberta, Canada, initiated the Aisspommootsiio'pa project in 2017. The project intended to develop teacher leadership capacity aimed at improving mathematics teaching and learning at elementary and secondary levels. In this paper, we indicate the theoretical foundations for the project. We also report on its implementation during the first two years, which involved seventeen teachers, and offer suggestions for the extension of the project at a larger scale within the Kanai Nation.

Keywords: Elementary School Education, Mathematical Knowledge for Teaching, Teacher Education - Inservice / Professional Development, First Nations and Indigenous cultures

The Aisspommootsiio'pa Project

In 2017, the Kainai Board of Education (KBE) contacted the Werklund School of Education, University of Calgary, to initiate what was later called the *Aisspommootsiio'pa* project: Translated into English, *Aisspommootsiio'pa* means "supporting each other." Since then, a group of teachers engaged in a professional learning series that included reflection on classroom observations. One specific purpose of the project was to identify and develop mentorship capacity within KBE for future, sustained support for other teachers within the school district, which comprises two elementary schools, one secondary school, and one high school.

During the first year of implementation, a group of observers supported the project creating records of observed lessons for teachers to reflect on. Every observation included at least two observers who recorded images, notes, and events in a timeline, and who rated each lesson using an observation protocol based on a teaching model developed by the Math Minds Initiative (Preciado et al., 2019a). In the second year of the project, teachers also participated as observers and created the reports.

The first two years of the project are considered a pilot in preparation for a future intervention at a larger scale at KBE.

The RaPID Model

The work with teachers in the Aisspommootsiio'pa project followed, and ultimately informed, the Mind Minds Initiative. Research results from this initiative include a sustained improvement in student performance, as measured by the Canadian Test for Basic Skills (Nelson, 1997). This initiative has developed the Raveling, Prompting, Interpreting, and Deciding (RaPID) model for teaching based on research findings on classroom observation and student performance and engagement in mathematics for more than seven years (Preciado Babb et al. 2019a; 2019b). This empirically developed model is consistent with well-established theories of learning from the cognitive sciences, such as: embodied cognition (Varela et al., 1991); socio-cultural theory (Vygotsky, 1986); spatial reasoning (Davis, et al., 2015); conceptual metaphor theory (Lakoff & Johnson, 1999); and conceptual blending theory (Fauconnier & Turner, 2003). The model also draws from theories of influencing learning, such as: affordance theory (Gibson, 1979); variation theory (Marton, 2014); mastery learning (Bloom, 1968); meaningful learning (Novak, 2002); and expert–novice research (Ericsson, et al., 2006).

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Protocol for Classroom Observation

The Math Minds Initiative developed a classroom observation protocol, which was used in the Aisspommootsiio'pa project. Table 1 summarizes Levels 1 and 4 of the protocol used for the project in 2018 and 2019. A refined version with details of the RaPID model was later elaborated on by Preciado Babb and colleagues (2019a).

Table 1: Summary classroom observation protocol for Levels 4 and 1

	Level 4	Level 1
Connecting (a) (Raveling)	Contrasting ideas build on prior contrasts and toward a generalized learning target.	Contrasts do not build on prior contrasts. It is challenging to identify a learning target.
Connecting (b) (Raveling)	The known and unknown are systematically bridged; each new idea is anchored to prior understanding that has been effectively summarized to carry forward.	There is little attempt to bridge known and unknown; new ideas are not anchored to prior understanding
Prompting (a)	The teacher separates and effectively draws attention to the key idea; contrasts are clearly juxtaposed, highlighted, and appropriately sequenced.	Key critical features are overlooked.
Prompting (b)	Clear prompt [to each critical discernment] requires learners to make key distinctions.	Multiple ideas are presented before students are offered an opportunity to engage; those who attempt to engage on their own may fall behind.
Monitoring (a) (Interpreting)	Quick/perceptible means of response that provides meaningful information re: student understanding.	Students do not show evidence of understanding or are asked to indicate whether or not they understand: "What part don't you understand?" "Thumbs up if that makes sense."
Monitoring (b) (Interpreting)	All students checked.	Few checked; e.g., individual students called on to respond (out loud or on the board).
Adapting (a) (Deciding)	Group response attends to diverse needs.	Response limited to few learners; many waiting for help or extension; e.g., lengthy conversations with a single child.
Adapting (b) (Deciding)	The teacher clarifies contrasts and adjusts sequencing in ways that address all learners; e.g., clarifying a pattern of variation also allows extended consideration of the related variable(s).	The teacher repeats strategies that didn't work or are unnecessary; the repeated explanation is insufficient for those who didn't get it the first time and redundant for those who did
Engagement	All students engage together in continuously extending understanding	Many students do not participate.

The Aisspommootsiio'pa project included the adoption of resources developed by JUMP Math (https://jumpmath.org/) for teachers at the elementary level. JUMP Math is a member of Math Minds and the teaching resources have informed the development of the RaPID model.

Methods

In order to document the implementation of the Aisspommootsiio'pa project, a qualitative case study was conducted (Yin, 2018) to address the following questions: How do mathematics teaching practices and use of resources change when adopting the selected resource and participating in the learning series? What factors enabled or hampered the implementation of the RaPID model in the classroom?

A thematic analysis was conducted on surveys administrated at the end of each professional learning session (four session each year). These data were contrasted to the classroom observation reports (five rounds of classroom observation each year), which included images, notes, and timelines generated using the LessonNote app. Figure 1 shows the timelines generated for two lessons. The image on the left corresponds to what is called a *block lesson* in the Math Minds initiative, while the image on the right corresponds to a *ribbon lesson*. The latter assumes cycles of prompting, interpreting, and deciding, consistent with the RaPID model, whereas the former reflects minimal instruction and support to student during class.

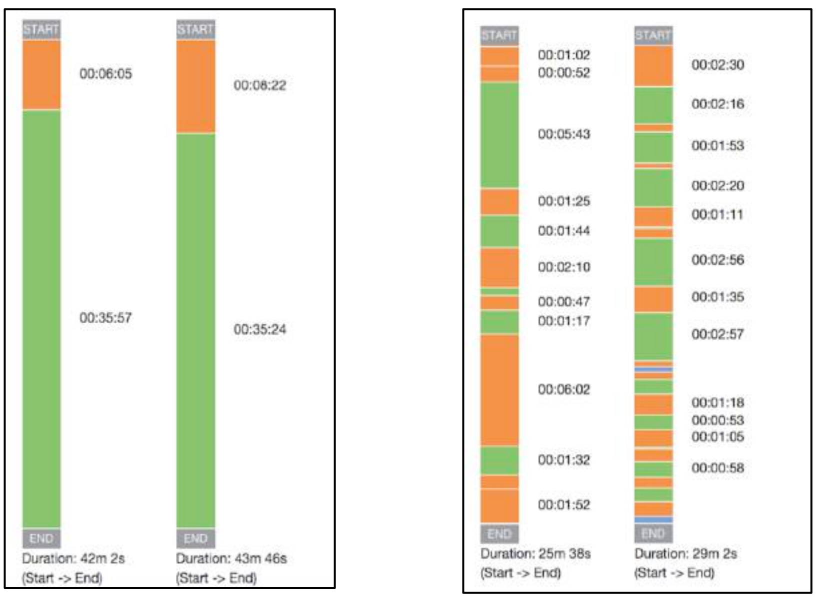

Figure 1: Timelines of classroom observation for two lessons: block lesson in the left and ribbon lesson in the right

Findings

Results of this study are presented as follows in three emergent categories.

Classroom Practices and Teachers' Learning

Teachers reported an appreciation of the RaPID model in the surveys administrated at the end of the professional learning sessions. Some teachers explicitly mentioned teaching practices related to the cycles of interpreting and deciding; this resulted in a more ribbon-like lesson, as shown in Figure 1. The survey entries also included learning about specific aspects of mathematics for teaching, such as different ways of understanding division (partitive vs. quotative). With respect to JUMP Math resource, some teachers indicated that the resource helped them to teach in "small chunks" that focused on critical mathematical features (Marton, 2014) required for students to understand the targeted concepts. Some teachers also indicated that the RaPID model started to inform their teaching of other subjects, not only mathematics.

Implementation Challenges

Despite evidence from surveys of teachers' learning and the impact of the implementation on their teaching practices, there was also indication of challenges for the implementation of the model. These challenges were confirmed by classroom observations and field notes.

One of the challenges in the project related to the adoption of the JUMP Math student teaching and practice booklets. The resources arrived late in the first year of the project and not all the teachers were following the program consistently. In fact, one teacher confessed that she only used the resource for the class that was observed as part of the project. Other teachers in the second year identified the need to try the resource for some years in order to become familiar with it and to be more confident using it.

Lack of time for debriefing and reflecting on observed lessons was also a challenge identified by some teachers. This challenge prompts to the need to allocate specific time for this purpose.

Some teachers also acknowledged the need for more targeted professional learning regarding the mathematics concepts; this was required to better "unravel" the concepts for students, prompt to critical features, interpret students' understanding, and make appropriate decisions.

Mentorship and Capacity Building

One of the observers in the project, also one of the authors of this report, provided feedback to teachers after classroom observation. These teachers emphasized in the surveys and with explicit comments in the professional learning sessions, the support they received from this other teacher, who holds a master's degree in mathematics education. This information was new to the KBE and prompted the need to identify mentorship capacity at KBE.

During the second year of the project, teachers reported being more comfortable having peers observing their class. They also indicated learning through classroom observation. This experience also helped to conceptualize mentorship as peer support in a horizontal fashion, as opposed to a vertical approach in which the mentor is regarded as an expert.

It was also noticed that observers required time to learn to use both the LessonNote application as a tool and the observation protocol used to guide classroom observations.

Discussion

This case study shows evidence of the viability of extending the Aisspommootsiio'pa project to other teachers in the school district and of developing mentorship capacity. The findings in the study can be translated into specific suggestions for this purpose, namely: considering time for teachers to become familiar with the teaching resources; allocating time for classroom debriefing and teacher reflection; training teachers to implement classroom observations; building a trustful relationship between classroom observers and teachers; and embedding teacher professional learning for all teachers involved in the project. These suggestions could be followed with other means of data that could be used to assess the impact of the project on mathematics student learning at the Kainai Nation.

Language is a vital component in mathematics classrooms and researchers have thoroughly examined how language functions in instruction. However, less is known about how teachers think about language enacted in their own classrooms. In this report, we describe how a teacher, Olivia, explicitly attended to language, particularly with emergent bilinguals. We describe affordances and tensions as she thought through language in the context of a professional development and in video-stimulated recall interviews.

Keywords: Classroom Discourse, Elementary School Education, Teacher Education - Inservice / Professional Development

There is a large amount of research on the role of language in mathematics classrooms. Scholars characterized language as a high need area for research given the growing diversity in the United States, diversity of language in the classroom and its impact on mathematics education (e.g., Barwell et al., 2017). Language supports constructing mathematical concepts, positioning of individuals and groups, developing mathematical argumentation, and shaping mathematical communities (Herbel-Eisenmann et al., 2017). Even with such a rich connection between language and mathematics, there is little research on teachers' thinking about language in their own instruction (Hajer & Norén, 2017). This dearth reflects how researchers' voices and interpretations, not teachers, are elevated in the research on language in mathematics classrooms. In this report, we add to this work by conducting a case study on Olivia, a third-grade teacher, and how she made sense of language in her instruction. We ask: *What are affordances and tensions Olivia perceived as she attended to mathematical language development?* We describe how Olivia's attention to both heritage (i.e., Spanish) and mathematical language was tied to mathematical development and participation and access, particularly for Latinx students.

Theoretical Framework & Professional Development Model

In order to explore how Olivia made sense of the language in her classroom through tensions and affordances, we frame our understanding of language and teacher knowledge. We view language similarly to how Gee (2005) described small-d and big-D discourse (which we will write as discourse and Discourse, respectively). First, he described discourse as "language-in-use" or the material of communication such as words and gestures in order to "design or build things." In this report, we use "language" at times to describe mathematical language but also as heritage languages (e.g., Spanish, English). Second, Gee described Discourse as other "language stuff" that enact specific identities and activities such as ways of acting and believing. We see Discourse bearing on how Olivia thinks about her language use as a marker of not only doing mathematics but also enacting a particular identity.

We view the nature of teacher knowledge as embedded in practice as opposed to an outside body of knowledge (e.g., contained within academia) that needs to be "learned" by teachers. Cochran-Smith

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

and Lytle (1999) described teaching as “an uncertain and spontaneous craft situated and constructed in response to the particularities of everyday life in schools and classrooms” (p. 262) and thus, teacher knowledge draws from “their own reasoning and decisions, and their own inventions of new knowledge to fit unique and shifting classroom situations” (p. 267). This knowledge is highly sensitive to time and space. Based on this view of teacher knowledge, we co-designed and facilitated a professional development environment for elementary teachers called Learning Labs (LLs) (see Kazemi et al., 2018 for an elaboration of the model) focused on developing practices of mathematical argumentation. Additionally, this model aligns with Cochran-Smith and Lytle’s (1999) description of teacher knowledge as generated by teachers and based on their own actions.

Context, Data, and Analysis

Lockwood Elementary is situated in an urban area in the United States Midwest. In 2018-2019, the school served 443 students including 40% Latinx students. We began our LLs in January of 2019, having completed 8 LLs to date. Olivia, a 14-year bilingual Latina teacher participating in the LLs, taught at Lockwood Elementary for eight years by the time of the LLs. She taught in a third-grade Dual Language Immersion program (DLI) where native Spanish and native English speakers were placed in the same class with instruction in both Spanish and English. We conducted a case study (Merriam, 1998) in order to “develop an intensive, holistic description and analysis of a single, bounded unit” (p. 232-233). Olivia’s central belief is supporting language and empowering students, making her participation an important case to study. We reviewed materials from 2 interviews, written artifacts and verbal contributions in the 8 LLs, and 2 video-stimulated recall interviews (VSRs) from filmed classroom lessons with Olivia. Because Olivia frequently made statements about mathematical language development across data sources, through analysis we used the sensitizing question, “When Olivia talks about mathematical language development, what does this allow her to know about her students and do as a teacher?” and, “When Olivia talks about language development, does she perceive an opposing concept?” to identify affordances and tensions, respectively.

Results

In this section, we describe the affordances and tensions Olivia experienced as she considered supporting her students’ language development. We provide examples from written work during the LLs and one VSR lesson, where Olivia facilitated a choral count by fourths.

Affordances

Mathematical connections. Olivia’s focus on precise language (i.e. discourse) afforded her to challenge students’ thinking and help foster connections. For instance, during the VSR, she wanted to know how students would describe the count after three-fourths. She wanted students to “verbalize specific fractions where we’ve specifically been talking about how to simplify and making connections to the wholes.” As she expected, students had varied responses after three-fourths including “four-fourths” and “one.” Olivia facilitated a conversation asking students to prove the connection between them with a drawing. Additionally, Olivia said the task “opened up another conversation and then they were making connections to money and then we ended it where we made a connection to the clock and looking at a quarter and how we say the time.”

Engagement. Olivia predominantly focused on engaging with mathematics and participating in a classroom community (i.e. supporting Discourse) through language support. In LL4, Olivia recalled how conversation can have power and meaning, claiming it is about

> listening and trying to understand what someone else is saying. What someone is trying to restate… this goes back to the power piece, where we’d finished turn and talk and there was still [chatting] and [a student] said ‘no no no wait, I want to share something.’ He was trying to make a point.

In interviews, Olivia explained that through a language focus, she wanted more participation for emergent bilingual students (EBs). By trying a new instructional activity called choral counting, she noticed how it could engage EBs, such as her student, Esteban, and how he participated in the conversation about selecting "one" or "four-fourths." She recounted asking Esteban "who was very, very emergent with his English" what the class should say, "and he raised his hand and very clearly he said four-fourths. So it was such a small moment, but I feel like it was so important for him because he was able to participate."

Tensions

Content vs. language. In many instances, Olivia viewed developing language as separate from developing mathematical ideas. As Olivia worked to encourage students to have meaningful discussions, she struggled to find a balance between language socialization and mathematical content because she described these two in opposition. In LL6, Olivia reflected on students' shared mathematical ideas,

> It's been challenging rephrasing or paraphrasing [students'] ideas not because of the math but because of their language development. At the beginning I noticed many students were eager and talking around. But with their vocab and grammar it was really hard to understand the ideas they were trying to get across.

In the VSR, Olivia talked about the same tension while watching a lesson she taught in Spanish. The VSR was also conducted in Spanish. She apologetically reflected,

Yo admito que en la elección me alejé un poco del contenido de matemáticas porque quería enfocar más en aprovechando que los niños estaban tratando de explicar todo lo que podían… Es un proceso. Quizás alejé demasiado a las matemáticas, pero me hizo sentir y pensar que era obvio o es obvio de qué tanto, qué tanto tengo que regresar o repasar acerca de cómo compartir y cómo usar las palabras en matemáticas cuando estamos compartiendo.	I admit my decision to move away from the math content because I wanted to focus more on taking advantage of the fact that the children were trying to explain everything they could… It is a process. Maybe I took math away too much, but it made me feel and think if it was obvious or how obvious how much I have to go back or review how to share and how to use words in math when we are sharing.

Olivia recognized students need time to express their ideas but focusing on Spanish language development can take away from mathematical ideas. Although she saw the importance of language and mathematical content, she struggled with balancing the two.

Speaking Spanish vs. Spanish speakers. Prominent in the interviews, Olivia described a disconnect between the language of instruction, Spanish, and students who spoke Spanish. Olivia felt speaking Spanish as something students do but also something empowering. She saw language as part of one's identity. In the initial interview, Olivia reflected on the lives of Latinx students and if this has any bearing on their identity and how they participate in school,

> I feel is there more privilege, more access to resources outside of school that [White students] are able to partake in that my Latino students aren't able to… do my Latino students—do they feel empowered being native Spanish speakers and being in this program where there's this part where the Spanish, that's their language, that's them, their identity? And I do wonder how they feel as Latino students in [the DLI] program… the students don't want to use their Spanish and I see a lot of my Latino students that they start to because they

> are hesitant in Spanish. And that, for me, part of that identity, it's like, ‘But this is you. This is your family.’

After the first set of LLs, Olivia noted an improvement in the quality of student contributions in discussions. However, her Latinx students would still hesitate, “I see so many of my Latino students, even during Spanish when we're having conversations… this is their first language, and they're hiding in the conversations or they're not raising their hands.” Olivia wants “them to be proud of being able to participate in the conversation or even dominate the conversation the way native English speakers may be able to dominate more in English.” In the VSR, Olivia described,

Había un grupo de niños acá, algunas niñas que siempre están compartiendo en español y son muy buenos modelos para el español y el lenguaje, que tenían mucha pena y tienen tanta confianza cuando están hablando en español, pero tienen menos confianza cuando se trata de matemáticas.	There was a group of children here, some girls who are always sharing in Spanish and are very good models for Spanish and language, who get embarrassed but are confident when they are speaking in Spanish, but have less confidence when it comes to math.

Such moments demonstrate a tension Olivia experienced between improving discourse (students speaking) and hesitant Discourse (confident participation). It functioned as an overarching goal of empowering students, particularly Latinx students, their language, and their culture.

Discussion and Implications

We highlighted tensions and affordances an elementary school teacher, Olivia, perceived as she attended to developing language in her mathematics class. Underlying all the affordances and tensions we described, a central belief guided Olivia’s sentiment, “This is you. This is your family.” For Olivia, the lines between discourse and Discourse are blurred. Developing ways of speaking and heritage languages is not just about engaging in mathematical discussions or using appropriate words. Her attention to language is rooted in empowering Latinx students.

Olivia demonstrated attending to language is complex. Researchers have prescribed how teachers should think through and about language diversity in classrooms and confronting English dominance (e.g. Palmer, 2009). Working in a DLI setting affords Olivia to work on this confrontation but still handle tensions of balancing student empowerment, language development, and mathematical content. Due to space constraints, we could not further attend to how affordances and tensions of language impacted Olivia’s instructional considerations around attending to mathematical vocabulary, supporting students to engage in each other’s ideas, and building a math talk community. More work is needed to understand how teachers think through these ideas and how they learn to address this balance. Additionally, research on language should not just pay attention to language as it relates to status, power, or language resources (Barwell et al., 2017), but also how teachers make sense of these ideas inside instruction.

This communication is about the case of a secondary school teacher and forms part of an investigation carried out with teachers. The aim is to identify the mathematical knowledge of the teacher, who has a vast educational experience when designing and teaching multiplicative problems with fractions, as well as to associate her reflections on her practice when she teaches those mathematical contents in the classroom. The methodological instruments applied in the tracing of this case were a questionnaire and three individual interviews of a didactic nature with feedback. This paper integrates only the tasks designed by the teacher in third interview that allow to show relevant data of the teaching that the teacher proposed and her corresponding purposes.

Keywords: Fractions, teacher's knowledge, multiplicative problems

Introduction

The relevance of the study of fractions and their operations is that it provides a basis for subsequent algebraic relationships. The understanding of rational numbers is fundamental for the development and management of mathematical ideas. In this sense, the teacher can propitiate suitable situations for the learning of Mathematics and guides the student towards the critical aspects of rational or fractional number knowledge (Kieren, 1988).

The knowledge that teacher owns for the teaching has been the subject of study for several decades. Researchers like Shulman (1986) suggest the importance of observing the transformation of the teacher's knowledge content in the knowledge content of instruction on a given topic. In this sense, Ball (1990) is focused on how teachers think about their pedagogical and mathematical knowledge and reasoning. In this case, we consider that teachers with experience in the class of Mathematics, show wealth in the various strategies and forms of long-term representation through the teaching of multiplicative problems associated with fractions. Derived from the above, we consider the data provided in this report to be relevant because they reveal the commonly inaccessible aspect of a teacher's thinking in usual practice, which allow us to interpret here the underlying thoughts that motivate their decisions; the reflections that arise from solving that tasks and if the awareness of this knowledge contributes to the educative improvement.

The main objective of this research is to identify the mathematic knowledge of in-service teachers, with a vast experience in decision-making situations and tasks design for the teaching of contents related to multiplicative problems about fractions. The questions that guide this study are a) what is the teacher's knowledge for the design and teaching of multiplicative problems linked to fractions? b) What knowledge rise during the thoughtful self-analysis of their teaching practice?

Theoretical framework

Some researchers (Ball, 2000, Ball & Bass, 2000, Ball, Thames & Phelps, 2008, & Smith, Bill, & Raith, 2018) link the relevance of the firm knowledge of the teacher about the subject matter she (he) teaches to the learning opportunities that he (she) can provide to students starting from the understanding what the official curriculum mentions and to adapt the actions scheduled for teaching taking into account the needs of their students.

Hart (1981); Jensen & Hohense (2016); Sharp & Welder (2014) and Tirosh (2000), among other researchers, have contributed to the teaching of fractional numbers and their operations. Their results indicate possible deficiencies in the teaching and students' difficulties to solve this type of problems because operations such as multiplication and division with fractional numbers are based on the use of rules and algorithms, putting aside the ideas or multiplicative relationships to provide their explanations and also the students' tendency to attribute the properties to the operations with natural numbers to the operations with fractional numbers. This is particularly important because we identified the last aspect in association with the designs and conceptions on the own teaching realized by the teacher of present research.

The background of the teaching on fractional numbers leads to the first concepts that Kieren (1983) provided. Such researcher mentions that fractions are made up of subconstructs with four meanings: measure, quotient, reason, and multiplicative operator. These subconstructs are the basis for the knowledge of the rational numbers.

Researchers like Behr, Lesh, Post, & Silver (1983) suggest the importance of representing geometrical regions, sets of discrete objects y numerical line as the most widely used models to represent fractions in the elemental education.

Freudenthal (1983) identifies fraction as fracturer, comparator, and multiplicative operator. We can find fractions in an operator in three discernible modes: fracturing operator, ratio operator, and fraction operator. The fracturing operator is associated with situations where specific objects are acted upon, separating them in equivalent parts. Through the ratio operator, we place two a magnitudes in a ratio, a magnitude correlated to another one. The fraction operator is recognized only in the number domain where it satisfies the need for the inverse of multipliers.

Vergnaud (1983) established conceptual fields and refers to them as problems and situations for the treatment of concepts, procedures, and representations of different types. Two of those conceptual fields that he established play an important role in the present research: additive and multiplication structures, in which the problems involve arithmetic operations. We will focus on the multiplicative structure that incorporates different semantic categories of verbal problems: isomorphism of measures and product of measures.

Methodological Design

This case study was carried out in a public secondary school under regulation of the Ministry of Education (Secretaría de Educación Pública, SEP) in Mexico City. The teacher who participated in our research has a Bachelor's Degree in Mathematics Education. We selected this participant because of the data she provided, her vast didactic and mathematical procedures and concepts, and the great communication she produces through her didactic design.

For data collection, we designed a questionnaire and an individual interview of didactic cut, with feedback supported by Valdemoros (2004) and Valdemoros, Ramírez, & Lamadrid (2015). The purpose of the questionnaire was to identify the knowledge and strategies of three Mathematics teachers when solving multiplicative problems linked to the use of fractional numbers. This instrument allowed us to choose the participant and some tasks of the interview.

The didactic interview with feedback included tasks already solved in the questionnaire to make explicit the thoughts that arise during teaching. The interview was oriented to think about the decisions and cognitive processes linked to the teacher's practice when she favors a strategy one another one; the representations she uses and how she link them to procedures to solve the related tasks with multiplication problems that involve fractional numbers. From this instrument, we took the data to prepare the present communication (whose research process has taken more than a year); we collected it through the application of several didactic interviews with feedback. The validation of interviews results is given through the triangulations of the instruments since different data collection methods will be used to study the posed problem in this research (in a next phase we will incorporate the observation in class, sessions carried out in a brief empirical course with others in-service teachers and new didactic interview with feedback).

Analysis of Results

Next is the relevant data of a previous teaching practice in which the teacher expressed the teaching processes she had utilized in her experience over 20 years. That is, we attempted to identify her teaching knowledge and what emerged from the reflection of her educational practice. We chose a multiplication problem and a division task with fractional numbers. Some fragments of the individual interview are exposed here, which include two tasks previously solved in the questionnaire to feedback on what the teacher does at the time she solves them. For the analysis of data, we considered the contributions Behr et al. (1983); Freudenthal (1983), Kieren (1983, 1988), Valdemoros et al. (2015) and Vergnaud (1983), among other researchers.

The multiplication problem

A rectangular building is on the corner of two streets. One of its fronts occupies a third of a street and the other occupies two-fifths of the other street. How much of the block does the building occupy? This task was taken from Jiménez (2015).

To solve the multiplication problem, the teacher used a pictorial representation (a rectangle); she partitioned it to represent the problem data and shaded it by saying "*Let's divide this front into thirds, we take the third part and from the other side of the fix we are going to divide it into fifth parts and we will take two of them.*" We asked her why she used this type of representation and she emphasized that the region with double shading allowed her to represent the graphic solution to the problem and show the multiplication fractions to students.

Subsequently, the teacher operated with the multiplication algorithm and associated the parts of the figure with the algorithmic answer, expressing: "*the students are going to realize that the result from multiplying the numerators corresponds to the part with double shading and the denominator corresponds the total of parts*. Perhaps the teacher used the pictorial representation to give sense to the operation; however, in this task she did not link the answer to the unit of reference. She focused on the main use of the algorithm, as reported researchers like Hart (1981); Kieren (1988), and Vergnaud (1983), among other researchers.

The inverse of the multiplication problem

A painter will paint a mural on a wall that has an area of $3\frac{1}{4}$ m^2; he knows the length is $2\frac{3}{5}$ m. What is the length of the area of the fence?

During third the interview, the teacher reaffirmed that the pictorial representation allowed her to make explicit to students the association of data of the figure with the formula: "*We know how to obtain the area: by multiplying the base by height over two; students know that from elementary school*". Immediately after, she wrote the formula of the area and substituted the data of the problem represented in the rectangle. She emphasized this strategy to make easier the teaching of this type of situation and said: "*we can find that value by substituting the formula of the area through an inverse operation; in this case is a division of fractions* $3\frac{1}{4} \div 2\frac{3}{5}$*, which will allow us to know the missing value*". The teacher referred to the inverse operation although she expressed it ambiguously (the observer seemed to refer to the notational displacements occurred in an equation), and so she justified the division of fraction.

The knowledge that emerged during the interview refers to the predominant use of rules and algorithms over the meaning of operations according (Hart, 1981), geometric representations as teaching models as stated by Behr et al. (1983), and to link the data to the problem. We also identified the use of fractions in the sense of measure, quotient, and multiplicative operator *indicated by* Kieren (1983).

The teacher suggested simplifying an equation to solve the problem of division; and so she vindicated the use of the rule to divide fractions, leaving aside the meaning of the inverse operation in multiplication as reported in the study by Valdemoros et al. (2015).

Discussion of results

From the data analysis, it is possible to infer that teacher's thoughts and decisions were defined by her teaching experiences, which also permeated her strategies based on her students' learning difficulties about the fractional numbers that she identified through her vast teaching experience. The teacher tried to solve this type of obstacle by embedding the teaching into a practice supported by the use of algorithms and rules that she considered students have strengthened since their passage through elementary school.

The teacher favored the use of a pictorial representation highlighting the area model (associated with calculating the area of the rectangle), which allowed her to justify operations with fractional numbers and link the algorithm to what she represented graphically. However, these representations did not provide enough elements to illustrate the case of division because she only used the geometrical representation to associate the data of the problem with the formula and replace them. She did not justify the meaning of the inverse operation of multiplication. She was based on an equation, as has been previously reported by Valdemoros et al. (2015). She also favored the use of the algorithm over the comprehension of intuitive relationships in which the operating situation was immersed.

Esta comunicación sobre el caso de una maestra de secundaria se presenta en el marco de una investigación llevada a cabo con profesores. El propósito es identificar el conocimiento matemático de la maestra con amplia experiencia educativa, cuando realiza el diseño y la enseñanza de problemas multiplicativos ligados a las fracciones, así como vincular las reflexiones que realiza sobre su práctica cuando enseña esos contenidos matemáticos en el aula. Los instrumentos metodológicos aplicados en el seguimiento de este caso fueron un cuestionario y tres entrevistas didácticas individuales con retroalimentación. En el presente reporte se integran sólo tareas diseñadas por la maestra en la tercera entrevista que permiten mostrar datos relevantes de la enseñanza propuesta por la profesora y sus correspondientes propósitos.

Palabras clave: Fracciones, conocimientos del profesor, problemas multiplicativos.

Introducción

La importancia del estudio de las fracciones y sus operaciones reside en que hay un fundamento para las relaciones algebraicas posteriores. La comprensión de los números racionales es básica para el desarrollo y control de las ideas matemáticas, en este sentido, el maestro puede crear situaciones favorecedoras para el aprendizaje de la matemática y orientar al estudiante hacia los aspectos críticos del conocimiento de número racional o fraccionario (Kieren, 1988).

El conocimiento que posee un profesor para la enseñanza ha sido objeto de estudio desde hace varias décadas; investigadores como Shulman (1986) sugieren la importancia de observar la transformación del conocimiento del profesor en el conocimiento de la instrucción sobre un tema determinado, en este sentido Ball (1990) se enfoca en cómo piensan los maestros sobre su conocimiento y el razonamiento matemático y pedagógico. En este caso, consideramos que los docentes con experiencia en la clase de Matemáticas, muestran riqueza en las diversas estrategias y formas de representación prolongadas a través de la enseñanza de problemas multiplicativos ligados a las fracciones. Derivado de lo anterior, consideramos relevantes los datos aportados en este reporte, porque muestran los aspectos comúnmente inaccessibles del pensamiento de un profesor en la práctica habitual, lo cual nos permite presentar aquí los pensamientos subyacentes que motivan sus decisiones, las reflexiones que surgen ante la resolución de dichas tareas y si la toma de conciencia de esos saberes coadyuva a la mejora educativa.

El objetivo general de la investigación es identificar los conocimientos matemáticos de profesores en ejercicio con amplia experiencia ante situaciones de toma de decisiones y diseño de tareas para la enseñanza de contenidos relacionados a problemas multiplicativos acerca de las fracciones. Las preguntas que guían el presente estudio son: a*) ¿Cuáles son los conocimientos que posee el profesor para el diseño y la enseñanza de problemas multiplicativos ligados a las fracciones?, b) ¿Qué conocimientos emergen durante el autoanálisis reflexivo de su propia práctica docente?*

Marco Teórico

Algunos investigadores (Ball, 2000, Ball y Bass, 2000, Ball, Thames y Phelps, 2008 y Smith, Bill y Raith, 2018), vinculan la importancia de los conocimientos sólidos del profesor acerca de la materia que enseña y las oportunidades de aprendizaje que puede brindar a los estudiantes a partir de entender lo que menciona el curriculum oficial y hacer una adaptación de las acciones programadas para la enseñanza tomando como referente las necesidades de sus alumnos.

Investigadores como Hart (1981); Jensen y Hohense (2016); Sharp y Welder (2014), y Tirosh (2000), entre otros, han realizado aportaciones a la enseñanza de números fraccionarios y sus operaciones. Sus resultados apuntan a posibles carencias de la enseñanza y dificultades por parte de los estudiantes para resolver este tipo de problemas, debido a que operaciones como la multiplicación y división con números fraccionarios se sustentan con el uso de reglas y algoritmos, dejando de lado las ideas o relaciones multiplicativas para proporcionar sus explicaciones, tanto como la posible tendencia de los estudiantes a atribuir propiedades de operaciones de números naturales a las operaciones con números fraccionarios. Esto es particularmente importante porque los últimos aspectos los identificamos en asociación con los diseños y las concepciones sobre la propia enseñanza realizada por la profesora participante en esta investigación.

La enseñanza de números fraccionarios tiene antecedentes en los primeros conceptos aportados por Kieren (1983). Dicho investigador menciona que las fracciones están constituidas por subconstructos con cuatro significados: medida, cociente, razón y operador multiplicativo, estos subconstructos forman las bases del conocimiento de número racional.

Investigadores como Behr, Lesh, Post y Silver (1983) sugieren la importancia de la representación de regiones geométricas, conjuntos de objetos discretos y la recta numérica como los modelos más utilizados para representar fracciones en la educación elemental.

Freudenthal (1983) identifica la fracción como fracturador, comparador y operador. La fracción en un operador que se encuentra en tres modalidades discernibles: operador fracturante, operador razón y operador fracción. El operador fracturante se asocia con situaciones en las que se actúa sobre objetos concretos, rompiéndolos en partes equivalentes; mediante el operador razón colocamos las magnitudes en una razón: una con respecto a otra; el operador fracción actúa sobre el puro dominio del número, donde satisface la necesidad de inverso de los multiplicadores.

Por otra parte, Vergnaud (1983) establece campos conceptuales y se refiere a ellos como los problemas y situaciones para el tratamiento de conceptos, procedimientos y representaciones de diferentes tipos. Establece dos campos conceptuales como principales para esta investigación, estructuras aditivas y multiplicativas, en donde los problemas involucran operaciones aritméticas.

Para el trabajo interesan las estructuras multiplicativas, las que integran distintas categorías semánticas de problemas verbales: isomorfismo de medidas y producto de medidas.

Diseño Metodológico

Este estudio de caso se realizó en una escuela secundaria que pertenece a la Secretaría de Educación Pública en la Ciudad de México, participó una profesora con una Licenciatura en Educación Matemática. Elegimos a esta participante debido a la relevancia de los datos que ella aporta, la amplia experiencia didáctica y matemática que posee y lo mucho que comunica en sus diseños didácticos.

Para la recopilación de datos, diseñamos un cuestionario y una entrevista individual de corte didáctico con retroalimentación sustendada por Valdemoros (2004) y Valdemoros, Ramírez y Lamadrid (2015). El propósito del cuestionario fue identificar los conocimientos y estrategias de tres profesores de Matemáticas al resolver problemas multiplicativos vinvulados al uso del número fraccionario, este instrumento nos permitió elegir a la profesora y de él derivamos algunas tareas a la entrevista.

La entrevista didáctica con retroalimentación incluyó tareas ya resueltas en el cuestionario con la finalidad de hacer explícitos los pensamientos que surgen durante la enseñanza. La entrevista estuvo orientada a reflexionar sobre las decisiones y procesos cognitivos vinculados a la práctica de la maestra cuando privilegia una estrategia sobre otra; las representaciones que utiliza y cómo las vincula con los procedimientos para resolver tareas relacionadas con problemas multiplicativos donde involucra números fraccionarios. De este intrumento tomamos los datos para elaborar la presente comunicación (proceso de investigación que ha llevado más de un año); los recopilamos mediante la aplicación de varias entrevistas didácticas con retroalimentación. La validación de los resultados se da a través de la triangulación de los instrumentos ya que se van a utilizar diferentes métodos de recogida de datos para estudiar el problema planteado en esta investigación (en una etapa próxima agregaremos la observación de clase, sesiones en un breve curso empírico con profesores en servicio y una entrevista adicional con retroalimentación).

Análisis de Resultados

A continuación mostramos datos relevantes de la práctica docente precedente, donde la profesora manifiesta procesos de enseñanza ejercidos en su experiencia durante más de 20 años. Tratamos de identificar los conocimientos para la enseñanza que ella posee y lo que surge a partir de la reflexión de su práctica educativa. Hemos seleccionado para este reporte un problema de multiplicación y otro de división de números fraccionarios. Se presentan fragmentos de la entrevista individual, en donde se incluyen dos tareas ya resueltas con anterioridad en el cuestionario, con la finalidad de ir retroalimentando lo que la profesora hacía mientras las resolvía. Para el análisis de datos consideramos las aportaciones de Behr et al. (1983); Freudenthal (1983); Kieren (1983, 1988); Valdemoros et al. (2015) y Vergnaud (1983), entre otros investigadores.

El problema de la multiplicación

Un edificio de planta rectangular hace esquina con dos calles. Uno de sus frentes ocupa un tercio de una calle, y el otro frente ocupa dos quintos de la otra calle. ¿Qué parte de la manzana está ocupada por el edificio? Tarea tomada de Jiménez (2015).

Para resolver el problema de multiplicación la profesora utilizó una representación pictórica (el rectángulo), realizó particiones para representar los datos del problema y los sombreó diciendo:“ *vamos a dividir este frente en tercios, tomando una tercera parte y el otro lado del arreglo rectangular lo vamos a dividir en quintas partes de las cuales vamos a tomar dos*”; cuestionamos la razón de ese tipo de representación, ella hizo énfasis en que la región con doble sombreado le permitía representar la solución gráfica del problema y mostrar a los estudiantes la multiplicación de fracciones.

Posteriormente, la profesora realizó la operación con el algoritmo de multiplicación y relacionó las partes de la figura con la respuesta algorítmica expresando: *"los estudiantes van a darse cuenta de que el resultado de multiplicar los numeradores es la parte con doble sombreado y el denominador corresponde al total de las partes"*. Posiblemente, la profesora utilizó la representación pictórica para dar sentido a la operación, sin embargo, no relacionó la respuesta con la unidad de referencia, se enfocó en el uso preponderante del algoritmo, situación reportada por Hart (1981); Kieren (1988) y Vergnaud (1983), entre otros investigadores.

Problemas del inverso de la multiplicación

Un pintor va a realizar un mural en una pared que tiene un área de $3\frac{1}{4}$ m^2, sabe que de largo mide $2\frac{3}{5}$ m. ¿Cuánto mide la longitud que corresponde al ancho de la barda?

Durante la tercera entrevista, la profesora reiteró que la representación pictórica le permite explicitar a sus estudiantes la asociación de los datos de la figura con la fórmula: *"sabemos que el área se obtiene multiplicando la base por la altura, eso lo saben desde la primaria"*. Inmediatamente ella escribió la fórmula del área, sustituyendo los datos del problema representados en la figura geométrica (rectángulo), hizo énfasis en esta estrategia para facilitar la enseñanza de este tipo de situaciones y agregó: *"podemos conocer ese valor en la sustitución de la fórmula del área a través de una operación inversa que en este caso es una división de fracciones* $3\frac{1}{4} \div 2\frac{3}{5}$*, nos va a permitir conocer el valor que hace falta*", la maestra hizo referencia a tal operación inversa, aunque lo expresó de un modo ambiguo, ya que a los ojos de la observadora parecía referirse a los desplazamientos notacionales generados en una ecuación, con esta acción justificó la división de fracciones.

Los conocimientos presentes en la entrevista se refieren al uso preponderante de reglas y algoritmos sobre el sentido de las operaciones según Hart (1981), el uso de representaciones geométricas como modelos de enseñanza conforme a lo planteado por Behr et al. (1983), y para relacionar los datos del problema. Identificamos el uso de la fracción con el significado de medida, cociente y operador de acuerdo a Kieren (1983).

Un pasaje importante de la entrevista es el momento en que la profesora sugiere el despeje de una ecuación para resolver el problema de división, con lo anterior la maestra justifica el uso de la regla para dividir fracciones, dejando de lado el significado de la operación inversa de la multiplicación como se ha reportado con anterioridad (Valdemoros et al., 2015)

Discusión de resultados

Con el análisis de datos, es posible suponer que los pensamientos y decisiones de la profesora estaban definidas por su experiencia de enseñanza que también impregnaron sus estrategias basadas en las dificultades de aprendizaje de sus estudiantes sobre los números fraccionarios identificados a través de su vasta experiencia de enseñanza. La maestra trató de resolver este tipo de obstáculo integrando la enseñanza en una práctica respaldada por el uso de los algoritmos y reglas que a su consideración los estudiantes tenían afianzados desde su paso por la escuela primaria.

La profesora privilegió el uso de la representación pictórica destacando el modelo del área (asociado al cálculo del área del rectángulo), el cual le permitió justificar las operaciones con números fraccionarios y relacionar el algoritmo con lo que realizó gráficamente. Sin embargo, estas representaciones no aportaron los elementos suficientes para ilustrar el caso de la división, porque sólo utilizó la representación geométrica para asociar los datos del problema con la fórmula y sustituirlos, no justificó el significado de la operación inversa de la multiplicación, se apoyó en despejar una ecuación, como se ha reportado con anterioridad Valdemoros et al. (2015). Asimismo, favoreció el uso del algoritmo sobre la comprensión de las relaciones intuitivas en la que estaba inmersa la situación operatoria.

CHALLENGES INFLUENCING SECONDARY MATHEMATICS TEACHER'S TRANSITION TOWARDS TEACHING WITH VIRTUAL MANIPULATIVES

Lindsay Reiten
University of Northern Colorado
lindsay.reiten@unco.edu

To increase teachers' use of virtual manipulatives and tasks within secondary mathematics classrooms and support changes to teachers' instructional practice, this study investigated situational challenges influencing teachers' implementation efforts during the course of a professional development (PD) opportunity. Identified situational challenges included: using Chromebooks, teachers' curriculum resource package, student needs, instructional time/planning, and teachers' collaborators. To promote the success of future PD opportunities, recommendations for acknowledging and embracing the situational challenges are provided.

Keywords: Technology, Instructional Vision, Teacher Education – Inservice / Professional Development

Despite expectations for teachers to use technology to support students' sense making and mathematical reasoning (AMTE, 2017), teachers claim that they are not prepared to use technology effectively in their instruction (Albion, Tondeur, Forkosh-Baruch, & Peeraer, 2015). Effectively teaching *with* technology describes teachers using technology to promote students' development of understanding through communicating and reflecting on mathematics, as well as through using and connecting mathematical representations (Reiten, 2018b). Using an interactive whiteboard and a virtual manipulative (VM) to explore how changing the slope and *y*-intercept of a graph changes its equation is an example of teaching *with* technology. Students reflect and build on possible relationships shared by themselves and peers. Through the use of the VM, they dynamically see the resulting graphs when the equations are changed. A VM is "an interactive, technology-enabled visual representation of a dynamic mathematical object…that presents opportunities for constructing mathematical knowledge" (Moyer-Packenham & Bolyard, 2016, p. 13). Teaching *near* technology describes using technology in a manner that does not promote opportunities for students to communicate, reflect, or connect mathematical representations. Using technology merely as an attention grabber (an example of teaching *near* technology) is a misuse of technology (Suh, 2016).

Though teachers have been encouraged to implement VMs for decades (e.g., NCTM, 2000), their use of VMs decrease as students get older (Moyer-Packenham & Westenskow, 2013). To increase teachers' use of VMs and tasks within middle and high school mathematics classrooms and support changes to teachers' instructional practice, this study investigated a targeted professional development (PD) opportunity aimed at supporting teacher learning (Driskell et al., 2016). To promote the success of future PD opportunities, this study investigated situational challenges teachers experienced (Yamagata-Lynch & Haudenschild, 2009) during the course of the PD opportunity that influenced their use of VMs and tasks. Which leads to the question at the core of this study, *what challenges faced the teachers, participating in a targeted PD opportunity, as they transitioned from teaching* near *towards teaching* with *VMs?*

Methods

Fourteen teachers participated in a year-long professional development (PD) opportunity aimed at supporting their use of VMs and tasks aligned with their curricular units (Reiten, 2018a, 2020). Grounded in activity theory (Engeström, 1987), this study investigated the teachers' participation during a PD and their reported practices related to implementing VMs and tasks. Rather than

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

studying teachers' practices in isolation, teachers' reported practices were considered mediated by several factors (e.g., tools and mediating artifacts, community members, rules). Specifically, this study investigated the situational challenges the middle and high school (i.e., secondary) mathematics teachers faced as they transitioned from teaching *near* technology towards teaching *with* technology.

Figure 1 is an example of an activity system in this study. Teachers' conversations and reflections throughout the PD were used to investigate the situational challenges teachers experienced (Yamagata-Lynch & Haudenschild, 2008) as they began shifting their practices towards teaching *with* technology. Situational challenges or tensions (i.e., internal contradictions between and within components of an activity system) are opportunities for growth and learning (Engeström & Sannino, 2010). Interviews with four volunteer teachers (two 6th grade, one 6th/7th intervention teacher/former 8th grade teacher, and one high school teacher) provided insight into teachers' reactions to tools and VM tasks introduced during the PD, teachers' practices (during the PD and their classroom practices related to implementing VM tasks), and teachers' thoughts regarding what supported their implementation efforts.

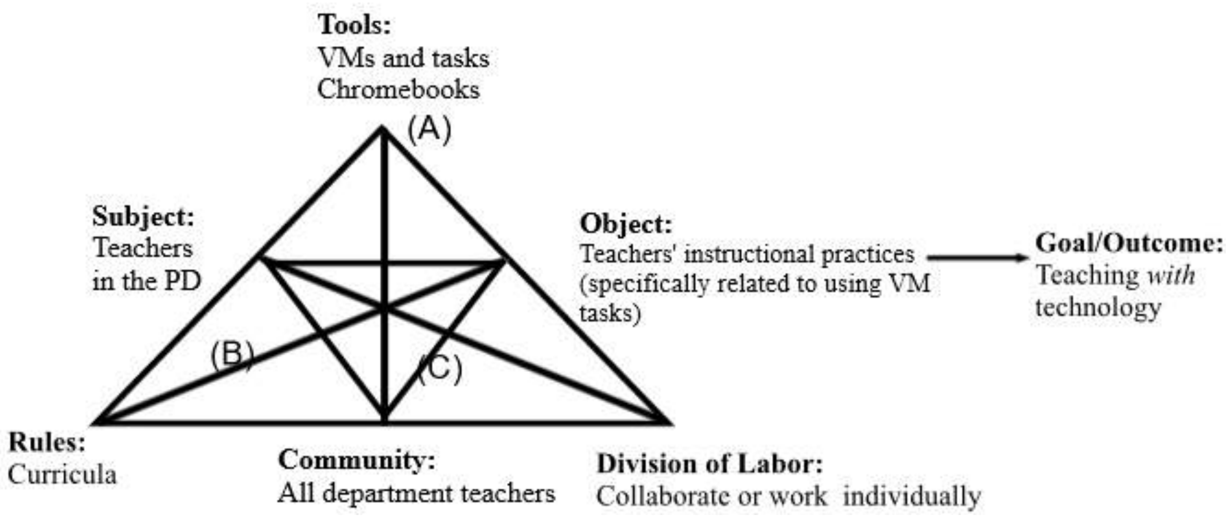

Figure 1: Example of an Activity System and Identified Challenges

The constant comparative method (Glaser & Strauss, 1967) was used as it drew our attention to the situational challenges (tensions) teachers experienced through simultaneous coding and analysis. Transcripts were coded to identify challenges based on what teachers reported (e.g., time, limitations of tools) and contradictions the researcher identified in the data (e.g., use of time during PD). Challenges within the same category were compared and category definitions were refined based on the commonalities and themes between coded data excerpts within the tension category. Data excerpts contained at least a complete sentence, and often consisted of multiple sentences (or small paragraphs) focused on the same topic. The number of data excerpts is provided to give readers a descriptive understanding of the relevance of various tensions.

Findings

Drawing from the ways teachers described using technology in their classroom, findings indicate that at least 11 out of 14 teachers in the PD transitioned towards teaching *with* technology. Initially, teachers reported using technology due to district, parent, and student expectations or because they thought the students may enjoy a particular technology-based task or game. By the end of the PD, teachers were selecting VMs and tasks based on their potential for supporting student understanding (Reiten, 2020). However, as teachers made changes to their practice, they experienced challenges within and between components of an activity system for the PD (e.g., see *A*, *B*, and *C* in Figure 1). Numbers in parentheses indicate the number of data excerpts for the identified challenge. The most common challenges related to: using Chromebooks (35), their curriculum package (26), student needs (24), use of worktime during the PD (25), and collaborators (22). It is posited that these challenges are relevant to other PD opportunities aimed at supporting teachers to teach with technology as the identified challenges extended beyond the particular technology tool to consider aspects of the teachers' community (e.g., teachers with whom they taught as well as the students in their classroom) and structure of the PD opportunity.

Figure 1 highlights three challenges confronting the eighth grade teachers (i.e., Erin, Mari, Pam, and Stan) in the PD that influenced their implementation of VMs and tasks. Occurring within and across components of an activity system for the PD, challenges teachers faced as they strove to teach *with* VMs and tasks included *(A)* limitations of the tools, *(B)* their curriculum resource package, and *(C)* their collaborators.

During the November PD session, as the eighth grade teachers were critiquing a VM task, Stan, Mari, and Erin became frustrated. They wanted to either enter specific side lengths for right triangles or have the side lengths always be integers. Neither option was capable with this VM (see *A* in Figure 1*)*. Specifically, Stan said, "I wish that this would be whole numbers. I wish it would stick to whole numbers. 'Cause the decimals, that doesn't even register with ME, [Erin: Right] if those are equal." Due to rounding errors, Stan and Erin thought that some of their students might struggle to identify the pattern in the table, thus feeling uncertain whether this VM would be worthwhile. Due to this challenge (located within the *tools* component), the teachers chose not to implement this particular VM with their students.

The eighth grade team of teachers also found it challenging to integrate VMs and tasks within their instruction due to their curriculum investigations building on each other *(*see *B* in Figure 1*)*. Mari wanted to use a VM to replace an investigation or as a pre-teaching tool with her "lowest students." She was not able to do so because all 8^{th} grade math teachers needed to implement the same thing. Replacing an investigation in one part of the unit with a VM could lead to investigations in the following lessons needing to be modified due to students not having the background information from previous investigations. Specifically, Stan stated, "[w]ith our curriculum, if you were going to use this (the VM), it would have to be in addition to or a summary. Or a reflection. Because otherwise, why do you do investigation one and two? … There's no reason to use Section 3.1, if you're not going to continue on." This situational challenge existed between the *rules* and *object* components of the activity system depicted in Figure 1. Additionally, drawing from his experience with a previous K-12 math leader, Stan was adamant that VM tasks could not replace investigations. Rather they needed to "trust and stick to the curriculum" even when students struggled to understand the investigation (see *C* in Figure 1). This situational challenge existed between the *community* and *object* components of the activity system depicted in Figure 1. Meaning Mari's instructional practices related to implementing a VM task were influenced by teachers in her community (e.g., Stan) beyond her control. Stan's belief in the role of his curriculum resource package as well the curriculum itself influenced if and how he chose to implement a particular VM task.

Discussion and Conclusion

Despite the expectation for secondary mathematics teachers to use technology tools in an effective and innovative way, many teachers report that they are not prepared to do so (Albion et al., 2015). How teachers are supported to teach *with* technology as opposed to *near* technology is an important issue facing the field. Teachers do not work in isolation, rather a variety of components influence their practices related to teaching *with* technology. Ultimately, the situational challenges described earlier influenced teachers' transition towards teaching *with* VMs and tasks. When acknowledged and embraced, these challenges provide opportunities for teachers to grow in their understanding of how to teach *with* technology tools. When designing opportunities to support teachers to teach *with* technology, the challenges highlighted in this study are important to consider and address.

The following recommendations highlight embracing challenges as opportunities to support teachers' growth rather than as something to be ignored. Because teachers often do not teach in isolation, it is important to address the ways teachers' peers support their integration efforts. When designing PD, intentionally integrating opportunities for collaborators to discuss and recognize personal beliefs related to the role of technology, curriculum, and so forth is important.

To address challenges related to teachers' curricula packages, consider supporting teachers in aligning specific VMs or tasks to their curricular units. Providing examples of VMs or tasks aligned to instructional units may initially support teachers in understanding the different ways tasks may be used in relation to their current curriculum (e.g., supplementing, replacing, or introducing their curricular investigations). Another way to start this process might be to have teachers observe other teachers teaching with technology while implementing the same curriculum. Debriefs after the observations provide additional opportunities to address challenges related to the role of the curriculum in deciding when, how, and why to add in specific technology based tasks. In the case of this PD, teachers were initially provided specific VM tasks aligned to their unit. As the PD progressed, teachers took on the responsibility for selecting VMs and tasks to explore that aligned to their learning goals.

Rather than focusing only on positive aspects or benefits when using a specific technology tool, acknowledging the limitations of a particular tool and potential ways to address the limitations may support teachers' comfortability with the tool. It is especially important to acknowledge how tool limitations may influence students' engagement in the mathematics and strategies for addressing the limitations. In the case of the 8^{th} grade teachers, they chose to not use a VM task due to concerns over whether students would recognize the intended pattern due to rounding errors. Potential strategies for addressing this concern include giving students dimensions of triangles to explore, reviewing with students the influence of rounding errors when squaring decimals, and looking for a new VM. Due to the cumbersome nature for creating triangles with given side lengths, the teachers chose not to use the initial VM and instead explored a different one that allowed students to enter measures of specific leg lengths.

The aforementioned suggestions are in response to the challenges revealed in the examples with the eighth grade teachers. It is important to keep in mind, that teachers may experience the various situational challenges differently compared to their peers. Therefore, we recommend providing opportunities for teachers to see successful integration efforts and reflect on their practice. Furthermore, though the recommendations stem from working with teachers during a PD, we posit these recommendations are important to consider when preparing and supporting pre-service teachers to teach *with* technology.

The call to improve mathematics outcomes for children ages zero to eight requires the development of effective professional development approaches for early childhood mathematics educators. In this study, we looked at how six facilitators created workshops on spatial reasoning, mathematical play, number sense, and theories of learning for early childhood educators. Drawing on Desimone's components of effective professional development, we interviewed these facilitators to understand how they defined a successful professional development and how these definitions aligned with the workshops they created. Interviews showed that all the facilitators in this study designed their workshops to be engaging and interactive for their participants while drawing on the components of coherence, collective participation, and duration.

Keywords: Teacher Education - Inservice / Professional Development, Early Childhood Mathematics, Spatial Thinking, Teacher Knowledge

Introduction and Purpose

Scholars and educators have called for initiatives to improve mathematics outcomes for children ages zero to eight. This calls for effective professional development (PD) to be implemented on ways of thinking about early learning as multimodal, playful, and responsive to the varied sociocultural and linguistic contexts in diverse communities. As PD is crucial in supporting teachers' knowledge and skills that lead to changes in classroom practice (Garet et al., 2001), it is necessary to understand how PD facilitators approach such a vital call. In this study, a nonprofit math and science education center aimed to engender ways of thinking about early math learning through an extensive initiative that partnered with roughly 100 early childhood educational leaders across a Western U.S. state. Central to this initiative were PD workshops led by mathematics coaches who focused on the areas of spatial reasoning, number sense, mathematical play, and theories of learning for children ages 0-8. As the National Council of Teacher of Mathematics (NCTM, 2014) acknowledges the critical role of mathematics coaches in enhancing teacher capacity and positively influencing teacher beliefs, this study aims to understand the goals of the PD workshops established by the mathematics coaches themselves. We asked the following research question:

1. How do experienced facilitators use current research on successful PD to inform their own workshops?

Conceptual Framework

We drew on Desimone's (2009) five dimensions for effective PD as a lens to understand how the PD facilitators structured their workshops. See Table 1 for descriptions of these dimensions.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Table 1: Components of Effective Professional Development

Framework Component	Definition
Coherence	Incorporating participants' individual goals with that of the larger group (Gordon, 2004).
Duration	Follow-up activities and ongoing support in the form of coaching and interacting with colleagues (Ball, 1996).
Content Focus	Textbooks, kits, curriculum units, and other forms of content that focus not only on what the content is, but how it is learned by students (Garet et al., 2001).
Collective Participation	PD that is developed and administered for groups of teachers that come from the same school or department that allows teachers to work together to discuss content, skills, and problems that they experience in their teaching (Garet et al., 2001).
Active Learning	Providing first-hand experiences with the content where teachers can actively participate instead of passively learn through lecture-based sessions (Penuel et al., 2007).

Methods

Study Context and Participants

This study is part of an ongoing project focused on providing and evaluating an early childhood mathematics professional development offered to approximately 100 participants representing 30 educational agencies across a Western U.S. state. For this study, we focused on the workshops designed and facilitated by the PD mathematics coaches during the week-long PD held in July 2019. Participants attended 90-minute sessions about learning theories, culturally relevant pedagogy, spatial reasoning, number-sense tasks, and mathematical play, all centered around enhancing early childhood mathematics education.

Data Collection and Analysis

We conducted one-on-one interviews with each PD workshop facilitator (n=6) after their sessions. Facilitators were asked questions about the professional development workshops they designed for this session, including how they defined a successful PD, how they imagined their participants would implement the content and theory they presented, and what research they based their work on. Using emergent coding (Strauss & Corbin, 1994), we looked to see what themes arose when facilitators defined effective PD and described how they designed their workshops. In particular, we examined ways in which the facilitators' descriptions of their workshops compared or comported with what they described as the components required for a successful PD. This analysis provided insight about the many different evidence-based approaches the facilitators took to create and implement their workshops.

Results

Below we address our findings for the workshops on Mathematical Play, Spatial Reasoning, Theories of Learning, and Number Sense.

Mathematical Play

Peter's session engaged participants in a discussion about the various ways that they play in their own daily lives and asked participants to consider whether "learning" might also be a way to describe these activities. Peter challenged his participants to not think of play and learning as separate ideas, but as potentially one and the same: "Children develop meaning by interacting with objects and posing problems through play." After some time for group discussion about this idea, Peter presented information on the history of early childhood play. Next, participants were given time to play with non-traditional pattern blocks and reflect on what problems they posed during their play, what mathematics they drew on in their play, and how this playful experience impacted their identity as a mathematics learner.

When asked about what defines a successful PD in his post-interview, Peter specifically mentioned all five components of Desimone's (2009) framework. Peter explained the importance of creating PD that engages participants in the kinds of experiences they would do with their own learners. Drawing on Desimone's framework for content-focused active learning, Peter anchored the workshop by drawing on participants' experiences with play, which resonates with creating a coherent PD experience. Peter described a practice-focused approach to support participants in implementing strategies in their own contexts and highlighted the importance of treating participants as professionals, drawing on play as a way to enact a more equitable approach to PD. Lastly, Peter described learning math through play as a way to promote attitudes and dispositions toward mathematics that are playful and fun rather than intimidating or unapproachable.

Spatial Reasoning

At the beginning of their session on spatial reasoning, Shane and Ana encouraged participants to think about how they got from the parking lot to the room where the session was held. Then, participants created written instructions or a visual sketch for traveling the distance. Shane and Ana defined spatial reasoning as the concepts, tools, and processes involving the location and movement of objects and persons, either mentally or physically, in space; they also introduced Piaget's three mountain task and the importance of spatial reasoning for mathematics learning. Next, participants engaged in nine different spatial reasoning activities, including Piaget's three mountain task and water level task, mental rotation visualization tests, and mental folding. Participants engaged in a group discussion about the challenges they encountered when engaging in these activities and whether their view of the importance of spatial reasoning had changed.

In their post-PD interview, Shane and Ana explained that they wanted participants to leave with an expanded understanding of spatial reasoning. Furthermore, Shane and Ana wanted to connect what they presented in the spatial reasoning session to other sessions that were offered at the week-long institute. In this way, Shane and Ana's session aligned with Desimone's components of content focus and active learning. Finally, Shane and Ana hoped that participants would provide similar learning experiences for the teachers they worked with. In order to encourage this post-PD implementation, Shane and Ana discussed the need to support their participants in applying what they learned in their own contexts, whether they worked with infants/toddlers or preschool-aged children.

Theories of Learning

Sam and Evelyn began their session by engaging participants in a discussion about what it feels like to be a learner, "to have the participants experience describing an object as a child would. We wanted the participants to put on the hat of a learner." In order to mirror what it is like to develop a concept as a child, they introduced an unfamiliar word: "Tutusa". Tutusa was a made-up concept the PD facilitators developed that represented objects that weighed the same but looked different. Sam and Evelyn gave a few visual examples and non-examples of Tutusa, then provided cubes of different sizes, color, and weight, as well as measurement scales so that participants could work in small groups to determine the meaning of Tutusa. At the end of the session, each group was asked to *nonverbally* share what they believed Tutusa meant. Nonverbal communication was an added challenge to engage participants in communicating meaning without words, through gesture or movement.

In their post-PD interview, Sam and Evelyn stressed the importance of creating an engaging and interactive activity by drawing on the backgrounds, knowledge, and needs of their participants. In this way, they placed an importance on coherence throughout their session. Sam and Evelyn also highlighted how a successful PD needs to include regular follow-up and ongoing support for all participants. As Evelyn explained, the follow-up is "just as significant as the institute itself, if not more." These responses align directly with Desimone's components that attend to duration, collective participation, and active learning.

Number Sense

Becky's session on number sense engaged participants in recognizing developmental progressions for various number concepts, such as number word sequence, one-to-one correspondence, and strategic reasoning. Becky showed six different videos of preschool-aged children reciting number word sequences to twenty, for example, and asked participants to look for cues that could provide insight in the child's counting processes. She then provided participants with concrete "what to do" strategies to support children in various stages of development. For example, for a child in an early stage, she highlighted how teachers could support children in developing one-to-one correspondence. Becky's goals for the session included wanting to engage participants in thinking about how young children come to think about numbers and number concepts. Becky acknowledged that "counting is a complex learning experience," so she wanted to support participants in thinking about how young children "make connections to place value" or other such concepts.

In her post-PD interview, Becky positioned herself as a learner, taking a reflexive stance towards her own facilitation practices. She stated that she not only hoped participants learned from the session–ideally, she intended to learn from participants as well. She wanted to draw on the expertise in her audience to help everyone in the room "understand more deeply and connect to other learnings they have had." In preparing her session, Becky explained, she developed an agenda but would likely end up changing her plan depending on the identities and experiences of her audience. In reference to Desimone's framework, Becky's responses align with both coherence and active learning; she activated participants' prior experiences and leveraged these for learning in her session.

Discussion and Conclusion

Overall, participants stressed that a successful PD includes follow-up coaching and ongoing support, both of which are consistent with the importance of duration in effective PD. In addition, the PD facilitators created workshops that were engaging for their participants, drawing on the active learning component. We argue that the four sessions presented here are exemplary cases of rigorous and ambitious PD aligned with current research and grounded in the needs of the practitioners in the room. This report reveals important insights about how experienced PD facilitators approach their practice to provide a professional learning event that seeks to go beyond the week-long institute itself.

This study reports on efforts over several years to design and implement a yearlong intervention intended to support secondary mathematics teachers in their early years of teaching. The intervention is designed to support these teachers' development of meaningful professional relationships with a school-based mentor and to create an online community of practice for support with other professionals. The intervention itself consists of early career teachers and their mentors participating in monthly professional development sessions such as online meetings, Zoom panels with experts, and collaboratively reading and discussing timely, purposeful, and relevant content. The intervention is designed to not over burden the participants and to be feasible for national implementation with little funding. The goal of the intervention is to try to retain secondary mathematics teachers in the profession by providing them with meaningful and targeted support.

Keywords: Teacher Education - Inservice / Professional Development, Teaching Tools and Resources

Purpose of Study

Half of all teachers leave the profession within the first five years, and this rate is highest for mathematics positions in high poverty schools (Fantilli & McDougall, 2009; Goldring et al., 2014). Furthermore, half of all current teachers in the U.S. retiring in the next five years (Foster, 2010), enrollment in teacher preparation programs declining, and teacher turnover is costing America $7.3 billion annually (National Math + Science Initiative, 2013), which represents a crisis for public education in the U.S. These conditions lead to classrooms staffed with underprepared/unqualified teachers, which profoundly affects the mathematical preparation of students in high school, college, and beyond. Experts agree that addressing the mathematics-teaching crisis meaningfully will require building a more cohesive system of teacher preparation, support, and development (Mehta, Theisen-Homer, Braslow, & Lopatin 2015). The purpose of this study is to report on the design and implementation of a cost effective, easily replicable intervention for early career secondary mathematics teachers with the goal of positively impacting teacher retention. We also present lessons learned over two years of implementing the intervention and provide suggestions for future research.

Background

Transforming the preparation of secondary mathematics teachers across the U.S. is at the core of the Mathematics Teacher Education Partnership (MTE-P). Since its inception, this initiative has continued to improve mathematics teacher education across the nation (for more information about the partnership see (Martin et al., 2020). MTE-P has established guiding principles and five Research Action Clusters (RACs) to carry out these principles. The authors of this paper are members of the RAC guided by a focus on teacher retention and induction in line with standard P.5-Recruitment and Retention of Teacher candidates, which is included in the Standards for Preparing Teachers of Mathematics (AMTE, 2017).

Novice teachers often feel isolated and those feelings of isolation are often associated with teachers leaving the field (Carroll & Fulton, 2004; Schlichte, Yssel, & Merbler, 2005). This RAC is grounded in the perspective that teacher retention would improve with the development of communities of practice to provide a support network to draw upon, including online communities (Wenger, 2011). Communities of practice are "groups of people who share a concern or a passion for something they do and learn how to do it better as they interact regularly" (Wenger, 2011, p.1). Wenger further shared three features that characterize communities of practice: a domain of interest, a community (members who participate in joint activities and discussions), and shared practice. For our work, our domain of interest is teaching high school mathematics during the early years of a teacher's career. The community consists of early career teachers, mid-career mentoring teachers, curriculum specialists, and university program coordinators and mathematics teacher education faculty. The practice of focus is teaching mathematics. We recognize that the work of retaining teachers requires, in part, a focus on developing relationships within the educational community and promoting connectedness within the larger community (Minarik, Thornton, & Perreault, 2003).

Past Work: Driving the Design

To respond to the teacher retention crisis, the RAC created a survey as an initial step to study the current support systems of early career secondary mathematics teachers. One research question guiding this work was: *What is the perceived scope, nature, and impact of professional support for early career mathematics teachers?* This survey was created through an iterative design and vetting process that extended from the fall of 2014 to early 2016. The main goal of the survey was to better understand the degree to which early career mathematics teachers perceived various learning opportunities as influential to their interest in teaching mathematics. By better understanding current support systems, the RAC could develop interventions that would strengthen and replicate systems that were working and attempt to improve broken ones. The survey consisted of 25 questions asking respondents to report on their current support systems, job satisfaction, projected longevity in the field, and other related topics. The survey was given in November of 2016 and gleaned 141 responses from teachers across the nation. Results from this study are presented in Amick et al. (2020).

The vast majority of novice teachers had received mentoring or coaching from someone at their school site, and almost (89%) found that experience to be moderately or very influential to their enthusiasm for teaching mathematics. This finding is consistent with other research on induction programs (Ingersoll & Strong, 2011; Youngs et al., 2019). In their review, Ingersoll and Strong (2011) found that induction programs and *especially teacher mentoring programs* positively influenced novice teachers' satisfaction, commitment, and/or retention. Further, Ingersoll (2012) found that retention was significantly impacted when a mentor and novice teacher taught in the same subject area and had a common planning time, as well. He also found that having multiple induction supports had a strong positive effect on retention. Thus, the work of this RAC, to develop systems that can effectively support early career teachers with the overarching goal to increase their job satisfaction and longevity in the field, was built upon past research, as well as the survey results.

Methods

Our overall methodology for this work has been a design experiment approach (Cobb et al., 2003), focusing on a problem in practice and pragmatically designing an intervention to impact that problem with multiple iterations of implementation and (re)design. We used constant comparative analysis to modify the intervention and methods as the investigation evolves based on new findings from analyzing the data collected.

Design

Due to both current research in the field and the RAC's survey results pointing towards mentoring as an extremely impactful induction experience, our group focused on the mentoring relationship as the basis for the first year of implementation of our intervention. The first year intervention was implemented throughout the 2018-2019 academic year. The intervention was designed to provide targeted support to first-year teachers by: (1) strengthening the mentor/mentee relationship through monthly communications; (2) suggesting targeted discussion topics between the mentor/mentee teachers; (3) and providing synchronous online meetings to build a professional community. In keeping with a design experiment approach, the intervention was modified over the course of the year, based on continuous analyses, in an effort to improve the intervention. After the first year of implementation the team went through a (re)design process during the summer of 2019 to prepare for the second year of implementation.

In order to avoid overburdening early career teachers, the intervention was designed to include only one hour of active participation each month. Furthermore, the intervention was designed to engage the early career teachers with their mentors to allow them to take part in an online community such that each pair had opportunities to engage in learning about research-based teaching practices together. Including mentor teachers in the study, was meant to provide a supported space for mentor teachers and first-year teachers to build positive relationships.

The monthly engagement activities were selected/designed by the research team to be timely, and several of the selected topics are also aligned to the Common Core Standards of Mathematical Practice and NCTM's Effective Mathematics Teaching Practices. For example, in September an email was sent with several self-care resources and asked the participants to peruse and discuss with their mentor teachers. In October, a Zoom panel was put together where participants have a sounding board to vent frustrations, ask questions, and seek advice. The panelists included teachers who are past their first few years of teaching, but who are still in their early years of their careers as to be relatable to the participants. We ended each year with an anonymous feedback form for the early career teachers to complete. One addition we made during the second intervention year was the creation of a Facebook group for participants to engage. We posted resources frequently (at least once a week) on the group feed to attempt to create an online space for dialogue and further support online community development.

Participants

To recruit early career teachers, the researchers on this project extended email invitations to recent graduates of their teacher preparation programs. For our first year of implementation, we only invited teachers in their first year of teaching. Participants were asked to commit one hour a month to the study, and to recruit a mentor teacher if they did not have one assigned to them. We strongly suggested that mentor teachers also teach math. The participants for both years of implementation included a diverse group that taught a variety of courses and grade levels (6-12), and have settings that range from large urban districts to small rural schools. During year 1, we had seven teachers volunteer to participate and during year 2 we improved our recruitment of early career teachers and had 15 teachers register.

Data Sources

The main data sources of this study consist of feedback from the participants over the course of the year via email, and a mid-year and end-of-year survey for each intervention year. The end-of-year survey is used to collect information on how useful the new teachers found each of the monthly interventions to be in supporting them and what supports they still wish they had. There are also questions for the new teachers asking specifically if the support received had an impact on whether or not they intend to continue in the profession in the future.

Results

We recently completed our second year of implementation and thus far, the results have been mixed as to the usefulness of the intervention. For those participants who remain engaged with the group we have received overwhelmingly good feedback as to the usefulness of the Zoom teacher panels. The participants report it being helpful to connect and talk to others that are and have been in similar situations. They also greatly appreciated the very practical advice. Unfortunately, the attendance for the Zoom teacher panels has been low with only 2-5 early career teachers participating. In addition, though we have encouraged the engagement of mentor teachers we have so far not had any join our conversations. Many of our participating teachers also reported that they had very little interaction with their mentor teachers. The teachers we have received feedback from often report feeling overwhelmed, primarily with issues of student engagement and planning. We have had little success with engaging early career teachers with Facebook in spite of many attempts to try to draw them into the conversation. Overall, we have struggled to keep teachers involved and engaged in the intervention beyond the first few months, which has led us to begin to rethink our approach.

Discussion/Summary

Similar to the results that we have seen, Youngs et al. (2019) in their synthesis of research on teacher induction programs that lead to retention of STEM teachers found that interventions with first year teachers seem to have little effect, which they attribute to teachers likely being overwhelmed. We are now considering focusing on teachers in their second and third years of teaching and would recommend that focus for future research. Another consideration is to focus on mentors or teacher leaders for the intervention and how to help them support groups of mentees. This would be a significant shift in focus for our interventions and recruitment of participants but might help to develop strong mentorship teams focused on a mentor. We have also considered taking a school team approach and involving an administrator as past research has shown the value of perceived administrator support (Youngs et al., 2019). We propose one approach could be to have school-based teams including all early career teachers, 1-2 mentor teachers, and an administrator and focusing on how to develop relationships and build community in the teams. We continue to look for impactful ways of supporting and retaining early career teachers and we believe the lessons we have learned will be useful to others in mathematics teacher education.

COLLABORATIVE LEARNING WITHIN AN INFORMAL COMMUNITY: HOW ONLINE SPACES CAN CATALYZE CHANGE

Heather West	Robin Keturah Anderson	Amanda Kates
NC State University	NC State University	NC State University
hmwest@ncsu.edu	randers6@ncsu.edu	ajgosek@ncsu.edu

Online learning communities are an increasingly prevalent informal learning site for teachers. These sites offer an emotionally and philosophically supportive space for teachers who advocate for change. In this study, our analysis of the interactions transpiring within one mathematics education Facebook group illuminates a critical conversation taking place, instruction based on students' perceived abilities. Teachers discuss systems level tracking and classroom level ability grouping to catalyze change and subvert the structures that produce tracking in schools. This collaborative environment both informed and empowered teachers to make educative decisions about inclusive strategies that built heterogeneous groups of learners.

Keywords: affect, emotion, beliefs, and attitudes; equity and diversity; informal education; technology

The negative effects of tracking are clearly articulated within the National Council of Teachers of Mathematics' publications *Principles to Action* (2014) and *Catalyst for Change* (2018), yet this practice continues to dominate K-12 classrooms. Choices made based on ill-informed assumptions about students' academic ability (Ladson-Billings, 1997) have led school systems to track students into mathematics classrooms that often do not prepare students for futures in STEM fields (Oakes, 1990). Course sequencing and perceived ability grouping continue to have negative effects on students such as: the continuation of social reproduction (Reichelt, Collischon, & Eberl, 2019), lack of student motivation (Lessard, Larose, & Duchesne, 2018), and lower beliefs about one's mathematical ability (Mijs, 2016).

Teachers are becoming more aware of the effects of tracking and some are attempting to change the oppressive system from within their schools and classrooms. The purpose of this study is to highlight the voice of teachers engaged in a social media network seeking support on how to make a change in their schools. In what follows, we begin by situating our work within social learning perspectives and previous research on the negative effects of tracking. We then outline our findings and discuss how a social media space can emotionally and philosophically support teachers as they advocate for change.

Framing

Teacher Learning

Grounding our work within the context of social learning, "communities of practice" offer a lens to examine the dynamic interactions that occur within an informal learning environment. Wenger (2006) defines communities of practice as "groups of people who share a concern or passion for something they do and learn how to do it better as they interact regularly" (p. 1). Communities of practice foster a sense of belonging where members share a common goal. Teachers' participation and interaction within these spaces allow them to develop shared knowledge, learn together, and support one another in their practice (Wenger, 1998).

Teachers' beliefs about teaching and learning play a significant role in shaping their instructional practice (Schoen & LaVenia, 2019). Kyndt and colleagues (2016) utilized the results of their meta-analysis on informal teacher learning to identity three key learning outcomes that resulted from participation in these learning communities: (1) improved content knowledge, (2) stronger pedagogical knowledge and skills, and (3) a change in attitudes and identities. Macia and Garcia (2016) further explored the nuances of informal learning spaces and found that teachers often entered into these spaces to support the context-specific needs of their classroom. For example, one contextual demand teachers frequently sought advice on was how to best group students for mathematics instruction. These findings suggest that an informal learning community can serve as a source of instructional support for mathematics teachers.

Ability Grouping

In mathematics instruction, ability grouping is a teaching practice implemented by many teachers (Anthony & Hunter, 2017). Ability grouping refers to students that have been grouped based on their perceived academic ability, which is often determined by their performance on an assessment. While teachers identify the use of ability grouping as a way to cater to their students' diverse learning needs and raise student performance (Hunter, Hunter, & Anthony, 2019), these practices continue to fuel the inequities in our education system. In the era of No Child Left Behind, categorizing students based on their performance with particular labels has contributed to the specific language that teachers use when talking about students (Datnow et al., 2018). For instance, using words such as "high" or "low" communicates the belief that students have fixed mathematical abilities. In order to help teachers shift their beliefs about students' abilities and vision of equitable mathematics instruction, opportunities for professional learning and growth within a supportive environment are needed.

These opportunities expand beyond traditional face-to-face learning environments as the demands placed on teachers continue to grow. For this reason, informal learning communities have become particularly appealing. These communities offer a flexible space for teachers to collaborate, advocate, learn from one another, share ideas or resources, seek information or support, and reflect on one's own knowledge or practice with other teachers from around the world (Macia & Garcia, 2016). In this study, we examine one Facebook group where teachers network together to build a learning community focused on mathematics education.

Methodology

In this qualitative study, a grounded theory approach (Charmaz, 1983) was employed to conceptualize the nature of the interactions taking place in a mathematics education Facebook group. The group was created by a university-based mathematics education research group and had 14,943 members at the time of data collection. In this space, members can pose questions, celebrate successes, share struggles, elicit support, and share resources. On average, the group generates seven original posts per day, and 95 comments on existing posts. In this study, data gathered from this Facebook group includes 2,600 original posts with comments.

The constant comparative elements of grounded theory (Charmaz, 1983) warrant the use of an inductive content analysis (Roller & Lavrakas, 2015) to identify themes and patterns within the data. The coding process took place across three phases. In phase one, the research team open-coded a subset of the data to form emergent themes (Creswell & Poth, 2018) and generated an initial codebook. The research team met to discuss the 49 initial codes and collapsed them into 15 overarching themes. In phase two, the research team drew on these 15 themes to analyze a different subset of data. Additional codes emerged and two themes were added, yielding a total of 17 overarching themes. To establish intercoder agreement (Creswell & Poth, 2018), the research team analyzed a final subset of data and achieved an 84% agreement score. In phase three, the entire data set was hand-coded using the 17 themes.

For the purposes of identifying conversations around tracking, only posts coded for the following three themes were included: (1) beliefs about teaching and learning mathematics, (2) challenges experienced by teachers and students when teaching and learning mathematics, and (3) any mention of students' experiences learning mathematics. A total of 147 posts were included and analyzed.

Results

In what follows, we report on one prevailing topic, tracking, that emerged as teachers discussed their experiences in this informal learning community. Our analysis suggests that members often come to this community to share their frustration and solicit help to become change agents - teachers actively trying to address inequitable practices within their schools. Teachers appear to recognize the negative impact tracking can have on students at a classroom and systems level; however, there is a disconnect between what they believe and the pressure they receive from colleagues, administration, parents, and district leaders to enact ineffective grouping practices. We draw upon two illustrative posts that represent our findings around how this online learning community discusses systems level tracking and classroom level ability grouping to catalyze change and undo, or subvert, the structures that produce tracking within today's schools.

System Level

In one interaction, a teacher described the negative impact tracking has had on her high school students. She wrote, "I have been teaching the 'lower' track now for 4 years and most of my students tell me they feel stupid for being in my track. Kids make fun of them and feel like they are better than them because of what track they got placed in." At a staff meeting, this teacher advocated against the use of tracking in mathematics but was met with opposition. "I guess, I was surprised of [sic] the resistance."

In her post, she continued by asking, "Was wondering if anyone has had any success in convincing change at their schools?" The post generated 54 replies, which led to a critical conversation around this type of practice. Many of these replies created a feeling of connectedness among the group members that engaged in the conversation. That is, they seemed to share similar beliefs about tracking. Some replies built a bond through words of encouragement, such as, "You have planted the seed! You are right - all kids DO deserve better." Other members of the group shared similar experiences where they too were met with resistance and unsuccessful in their own attempts to lead change. In another reply, a teacher wrote, "I have had absolutely no luck at all. My school is very set...and I can't see anything changing not even in the medium-term future."

This post demonstrates a desire to make a change at a systemic level. These teachers seem to think beyond their own instruction and consider the changes needed to transform education on a larger scale. While teachers may recognize the need for a systemic change in education, they also seem aware of the impeding barriers and obstacles. To mitigate the impact of system level choices, many group members that replied to the post suggested that the original poster take on the issues within her own classroom and mitigate the negative effects through practices she could control immediately.

Classroom Level

One reply encouraged the original poster to address systemic issues of tracking within her own classroom, "You should just go all 'Stand and Deliver' on them and teach the 'lower' track so well that they surpass the other track!" Similarly, another teacher wrote, "Keep your mouth shut and prove them wrong! Do solid teaching with your 'low' kids and let them prove that your methods work on the lowest kids. I love proving people wrong with data." Both of these replies called for the teacher to subvert the systemic level practice of tracking by using good teaching practices, which are less likely used in lower tracks (Mijs, 2016), to create noticeable change through student performance.

Members of the Facebook group discussed their experiences and struggles with ability grouping within their individual classrooms and the impact this has had on their students. One teacher shared how his colleague is "stuck on grouping." As this teacher described his colleague's students, he used language such as, "fast kids" and "slower kids," though he indicated he did not care for those terms. This teacher described the tension between promoting heterogeneous grouping practices and the pressure of time constraints and curriculum expectations. To help his colleague shift away from these harmful teaching practices, he posed the following question to the group, "How can I help her [colleague] with this transition without homogenous grouping and/or what recommendations do you have to help get her students to being able to work together and help each other?" Interestingly, this post did not evoke the same level of engagement. While the previous post generated rich dialogue among members, replies to this post were limited. These replies guided the original poster, and the readers of the interaction, towards inclusive strategies that built heterogeneous groups of learners.

Discussion

Educators have leveraged the use of social media, such as Facebook, as a platform for informal learning. Given its flexibility and appeal, teachers gravitate towards these spaces to improve their knowledge and practice (Anderson, 2019). In our analysis of one Facebook group, we found teachers engaged in critical conversations to catalyze change and undo the structures that produce tracking within today's schools. Research has consistently found that ability grouping fails to benefit the student and further exacerbates the inequities in our school systems; however, conversations within this online community suggest that these practices continue to prevail. Our findings suggest that membership in this type of learning community provides individuals affective resources (Brodie, 2020) through emotional support, which is often overlooked in these spaces. This group also provides emotional support through confirming other members' feelings of frustration, while encouraging them to continue to fight for change at their schools.

While some teachers in this Facebook group recognize the impact of ability grouping and hope to dismantle these practices on a systems level, others navigate these waters within their own classroom. As members from the group share their subversive practices and call for others to "prove them wrong", they are advocating for Creative Insubordination practices such as, "using the master's tools" and "flying under the radar" (Gutiérrez, 2016, p. 54). These practices encourage teachers to work within the system and use required tools, such as student assessment and imposed ability groups, to produce outcomes contrary to those often expected. Using Creative Insubordination practices allow teachers to be instigators of change while still working within the confines of a deeply flawed system that continues to impose tracking.

Online learning communities, such as this Facebook group, provide technologically-enhanced ways for teachers to build their understanding of how mathematics is taught and learned. Further research within social media facilitated learning communities should investigate how these spaces are changing the field's perception of collaborative learning within a community of practice. These online spaces are critically important to some educators and will continue to serve as a professional learning site for teachers.

SELF-DIRECTED LEARNING FOR RURAL MATHEMATICS TEACHERS

Robin Keturah Anderson
NC State University
randers6@ncsu.edu

Kelly L. Boles
Stanford University
kboles@stanford.edu

Twenty-seven percent of American public-school teachers are located in rural areas of the country (National Center for Education Statistics, 2012), yet their professional learning needs and experiences are under-studied. Limited research has highlighted some of the particular challenges of being a rural teacher of mathematics: geographic isolation, professional isolation, and insufficient opportunities for high-quality professional learning (Royster as cited in Cady & Rearden, 2009). One strategy used to address these issues has been to form inter-district networks of faculty for purposes of professional learning, but this has been met with uneven success (Howley & Howley, 2005).

This study considers a model of teacher professional learning within a rural inter-district learning cooperative situated within economically disadvantaged Appalachia. The model utilized invites teachers to direct their own learning, by first identifying their learning needs and then requesting financial grants of up to $1,000 from the cooperative in order to realize them. Similar to Slavit and McDuffie (2013), we draw on adult learning theory to explore the individualized and self-directed nature of the participating rural teachers' professional learning experiences and examine the following research question: *How do rural mathematics teachers describe their motivation, needs, and learning within self-directed professional learning experiences?*

The authors analyzed videos of the final summative presentation from eight teachers receiving the cooperative grant. For these analyses, three broad codes from Knowles (1975) were utilized: (1) identify areas of growth (why participate), (2) finding people and resources to learn from (what is needed), and 3) evaluate the learning that they have experienced (lessons learned). Analytic memos were created for each of the three broad themes.

The reasons for participation teachers identified often reflected the situation of their practice in a rural, socio-economically disadvantaged region and/or the needs of their students as a whole. Two teachers considered the economic outlook of the region, choosing to supplement their current practice with skills that might support their students in creating or capitalizing upon emerging economic opportunities. These teachers worked to incorporate computer programming and making skills into their mathematics classrooms. The resources teachers utilized to realize their goals were largely unsurprising. Grant monies were used to purchase tools for makerspaces, laboratory materials for cross-curricular STEM units, computer science applications, and pieces of technological equipment. All teachers reported successful learning experiences. While some teachers shared unexpected learnings, such as re-imaging the use and application of educational technology, others reported constraints on learning often associated with technology adoption.

Findings from this study suggest that when rural teachers are supported in designing and self-directing their own learning, their motivation for doing so is often grounded in the needs of their students and the needs of the local community. Most of the resources purchased with the mini-grants were typical educational supplies, but some also reflected the cultural heritage of the region. While material resources were procured with relative ease, expertise was not. This was evidenced both within the constraints of technology implementation and teachers' first-time attempts to design cross-curricular content. Future research should consider the ways in which rural teachers can access and draw upon others' expertise to inform their self-directed professional learning experiences.

EXPLORING VIDEO COACHING PRACTICES OF ONLINE MATHEMATICS COACHES

Cynthia Carson
University of Rochester
ccarson@warner.rochester.edu

Jeffrey Choppin
University of Rochester
jchoppin@warner.rochester.edu

Keywords: Teacher Education – Inservice / Professional Development, Technology

Coaching has become a common practice to support teachers (Coburn & Russell, 2008; Foltos, 2014; Knight, 2007). While much of the coaching research has focused on the roles and responsibilities of coaches (Gibbons & Cobb, 2017; Mudzimiri et al., 2014) there is a lack of empirical research on what occurs in the interactions between a coach and teacher and the mechanisms by which these interactions support teacher learning. This study aims to understand both *how* and *why* coaches engaged in specific coaching practices.

We analyzed interviews with four mathematics coaches in which they reflected on the purposes, goals, and practices they perceived as critical for supporting teachers in a fully online coaching model. For three years, these coaches had used an online content-focused coaching model with rural middle school mathematics teachers. The online coaching model was an adaptation of West and Staub's (2003) content-focused coaching, which prioritizes focusing on mathematical content knowledge and student thinking. In this study, the coach and teacher co-planned a lesson via Zoom, the teacher enacted the lesson and recorded with a Swivl robot and iPad, and the coach and teacher debriefed the lesson via Zoom. The lesson video was uploaded automatically to a shared library, through which the coach and teacher viewed and annotated the lesson video prior to the post-lesson conference.

Analysis and Findings

We used Barlow et al.'s (2014) dimensions of coaching purposes: interacting with teachers about mathematics content, promoting teacher reflection, and negotiating professional relationships between coach and teacher. This framework helped us to identify specific coaching practices and connect the coaches' rationale to how these practices supported teacher learning. For example, coaches described doing the mathematics of the lesson with the teacher in the planning meeting because it afforded richer discussions of how students learn the mathematical content and how instructional decisions would influence whether they met the goals of the lesson. Coaches also reported that doing the mathematics together provided opportunities for the coach to deepen the teacher's mathematical content knowledge.

Additionally, several coaching practices were indicated as being critical to prompting teacher reflection and negotiating professional relationships: annotating the lesson video, making suggestions, and discussing evidence from the video related to the learning goals of the lesson and instructional practices goals of the teacher. The coaches indicated these practices led to collaborative and more reflective relationship with a teacher.

The results of these analyses provide examples of how and why specific coaching practices can support the development of teachers' instructional practices. We believe this study will support the coaching research community.

Keywords: Teacher Beliefs, STEM / STEAM, Elementary School Education

Teachers in the elementary grades often teach all subjects and are expected to have appropriate content knowledge of a wide range of disciplines. Current recommendations suggest teachers should integrate multiple disciplines into the same lesson, for instance, when teaching integrated STEM lessons. Although there are many similarities between STEM fields, there are also epistemological differences to be understood by students and teachers (see, e.g., Conner & Kittleson, 2009). How to teach STEM lessons without ignoring the unique characteristics, depth, and rigor of each discipline is an open question (Kertil & Gurel, 2016). This study investigated teachers' beliefs about teaching mathematics and science using argumentation and the epistemological and contextual factors that may have influenced these beliefs.

This qualitative study was conducted in a professional development course designed for elementary teachers. Participants in this study included 14 teachers from a rural school district in the southeastern United States. Data sources include video recordings and transcripts from one in-class meeting of the course and two semi-structured interviews with each participant.

The majority of elementary teachers in this study believed argumentation was an important part of teaching all subjects. Their beliefs about argumentation in science suggest that they see argumentation as inherent in the learning of science: "Scientific inquiry is very similar to argumentation" (Gloria, Int. 2). Teachers' statements about argumentation in mathematics, on the other hand, suggest that students need to know the mathematical content prior to engaging in argumentation. For instance, "I didn't [engage them in argumentation] because of understanding …they were not intellectually ready for that concept" (Bill, Int. 2).

Teachers' beliefs about different epistemological underpinnings of mathematics and science, along with contextual constraints, led to different beliefs and intentions for practice with respect to argumentation in these disciplines. The contextual constraint of testing and the amount of curriculum the teachers perceived as essential focused more attention on the teaching of mathematics, which could be seen as benefiting student learning of mathematics. On the other hand, the perception of science as involving wonder, curiosity, and inherently positive and interesting ideas may lead to the creation of a more positive learning environment for the teaching of science. These questions remain open and need to be studied further: What are the consequences of perceiving argumentation in mathematics as limited to concepts already well-understood? Can integrating the teaching of mathematics and science lead to more exploratory and inquiry-based teaching of mathematical ideas alongside scientific ones?

THE SEMIOSPHERE: A LENS TO LOOK AT LESSON STUDY PRACTICES IN THEIR CULTURAL CONTEXT

Carola Manolino
University of Turin
carola.manolino@unito.it

Keywords: Teacher Education - Inservice / Professional Development; Cross-cultural Studies.

Gallimore (1996) claims that changes in teaching and learning practices are challenging. He ascribes this resistance to change to the fact that "we are dealing with cultural matters", and not just psychological and pedagogical issues (*ibid*., p. 230). Cultural aspects have therefore become one of the focus of research attention in Mathematics Education in the last twenty years (Bartolini Bussi & Martignone, 2013). How cultural and social aspects affect teacher critical reflection during professional development experiences of in-service and prospective mathematics teachers? I address the issue of how to deepen culturally sensitive understandings of such processes. I am inspired by Lotman's concept of Semiosphere (Lotman, 1990) that I identify and use to read the processes of teachers' professional development experiences. Strengthened by the tradition of the Italian school in Research in Mathematics Education and rooted in it, which grants considerable importance to semiotic studies (Arzarello, 2006; Bartolini Bussi, 1996), I propose the Semiosphere as a theoretical lens that attempts to react to Skott and Møller's call (2020) to look at the issues of policies and culture in the teachers' local professional development setting, and to react to the need underlined by Yves Chevallard (1981) to take into account the codetermination of the various knowledge signs into the Noosphere.

In Italy, as a foreign cultural element, Lesson Study (LS) has been implemented in order to allow mathematics teachers and researchers to reflect on and thus to question their own didactic practices and intentionality (Bartolini Bussi & Ramploud, 2018; Mellone, Ramploud, Martignone & Di Paola, 2019). Designing, implementing and observing, and afterwards reviewing a one-hour lesson have been uncommon spaces for collaborative reflection of Italian mathematics teachers, because of their cultural tradition. Even critical reflection therefore becomes a cultural activity and, as such, pervasive and not easy to study. We need a culturally sensitive lens that can help us to identify and study reflection practices. Through the qualitative analysis of a LS experience, looking at the dialogues between teachers and their practices of shared critical reflection, I can state that the Semiosphere highlights the asymmetries between the systems of signs that exist in a culture, in a practice, in a methodology, in a professional development path, or in a lesson planning. It is in this space that the process of cultural transposition takes place. In fact, as pointed out by Vygotsky (1999) signs do not appear as *mediators* of activity, as is the case in other sociocultural approaches, but as an *integral part* of human thinking and human activity. The Semiosphere allows to keep identifying the constituent elements of a reality even from the identification of elements external to it. In fact, precisely because of its asymmetric and non-homogeneous character, based on dialogue, the Semiosphere creates not only its own internal organization, but also its own type of external disorganization. It defines what is not itself. The LS teachers' meetings can be pictured as a multidimensional dialogue in the Semiosphere during which each choice of teaching/learning, in contact with another, can become "more aware" (Jullien, 2005). Here the critical dialogue and reflection of the teachers, if read from the point of view of the Semiosphere, do not lose contact with the reality in which they are born. So, the problem of possible integration between Lotman and Chevallard lenses according to the Networking of Theories approach (Radford, 2008) arises spontaneously. The analysis of the institutional aspects and the levels of co-determination seems enriched by a dynamic interchange perspective, and vice versa this can be integrated with the aspects

of power and the institutional constraints typical of a school system governed by laws. Future studies could tell us about the connection of the two theories as lenses for professional development practices.

FROM TERRIFIED TO COMFORTABLE: A FOURTH-GRADE TEACHER'S JOURNEY IN TEACHING CODING

Jenna Menke
University of Georgia
jennamenke@uga.edu

Claire Miller
University of Georgia
claire17@uga.edu

Keywords: Teacher Beliefs; STEM / STEAM; Teacher Education - Inservice / Professional Development; Elementary School Education

Collective Argumentation Learning and Coding (CALC) is a project focused on providing teachers with strategies to engage students in collective argumentation in mathematics, science, and coding. Collective argumentation can be characterized by any instance where multiple people (teachers and students) work together to establish a claim and provide evidence to support it (Conner et al., 2014b). Collective argumentation is an effective approach for promoting critical and higher order thinking and supporting students' ability to articulate and justify claims (Nussbaum, 2008). The goal of the CALC project is to help elementary school teachers extend the use of collective argumentation from teaching mathematics and science to teaching coding. Doing so increases the probability that teachers will integrate coding in regular classroom instruction, making it accessible to all students.

A total of 32 elementary school teachers participated in the CALC project, which included a semester long course focused on coding content and strategies to implement collective argumentation in the classroom. Teachers were interviewed before and after the course. Ten teachers were selected to participate in the enactment phase, in which classroom observations and stimulated recall interviews were conducted. All class meetings, observations, and interviews were audio- and video-recorded. Data were analyzed using previously established analysis methods for beliefs and argumentation (Conner et al., 2014a; Conner et al., 2011; Kim et al., 2013). We highlight Gloria (pseudonym), a fourth-grade teacher from Cohort 1 because of the extent to which she went from fear of coding to fluent implementation.

Initially Gloria was comfortable engaging her students in argumentation, explaining they already used it in mathematics with Cognitively Guided Instruction (CGI). However, she was "terrified" (Int 2) about learning to code because she didn't view herself as proficient with technology. She was willing to overcome her fear of coding because she saw the value in providing her students with coding experiences that would help them develop necessary skills for our increasingly technological society. Gloria saw coding fitting naturally into mathematics, but she asked for ideas on how to integrate coding into other subjects: "Yeah, I can do shapes. What else can I do that's beyond that? What's something I can push the limit on?" (Int 2).

In our first observation, Gloria requested not to wear a microphone and asked members of the CALC project to co-teach with her. In this lesson, her students engaged in argumentation while coding prebuilt robots to travel around a rectangle with a specified perimeter. In our final observation, Gloria successfully implemented a lesson that included students programming more complex robots to travel a map of the Oregon Trail. Reflecting on this lesson, Gloria was "proud" that her support moves had become less leading, allowing for more student discovery and argumentation (Post-obs Int 2). In the course of three months, Gloria's instruction progressed from using simple coding activities to more sophisticated coding platforms. This progression in her coding instruction paralleled the change in her personal feelings about coding as she moved from "terrified" to "comfortable with it" (Post-obs Int 2).

GETTING A FOOT IN THE DOOR: EXAMINING MATHEMATICS COACHES' STRATEGIES FOR GAINING ACCESS TO CLASSROOMS

Jen Munson
Northwestern University
jmunson@northwestern.edu

Evthokia Stephanie Saclarides
University of Cincinnati
saclares@ucmail.uc.edu

Keywords: Teacher Education – Inservice / Professional Development

Mathematics coaches are called upon to provide productive, job-embedded professional development for teachers (Gibbons & Cobb, 2017), but their capacity to do so hinges on gaining access to classrooms. Even in schools or districts where coaching is pervasive, teachers are under no obligation to participating in coaching and often have autonomy about whether, when, and for what they invite coaches into their classrooms to do joint work (Saclarides & Lubienski, 2020). Much of what we know about access comes from skilled practitioners (Killion, 2008, Knight, 2017) and a modest body of empirical research (Hartmann, 2013; Mangin, 2005), both of which point to the challenges and importance of gaining access. This study asks: What strategies to elementary mathematics coaches draw upon and enact when negotiating access to teachers' classrooms? What relationships exist between these strategies?

Eleven full-time, school-based elementary mathematics coaches in a public school district located in a southeastern, metropolitan area of the United States were interviewed using a semi-structured protocol. All interviews were audio recorded and transcribed. All statements that described strategies, or action the coach took to gain access to classrooms, were identified and inductively coded to describe the nature of the strategy. Strategies were counted for each coach as either present or absent and then clustered into larger categories based on related functions through an iterative process. Last, statements in which multiple strategies were discussed in tandem were used to create a model for how coaches coordinated strategies to gain access.

Mathematics coaches reported 33 distinct strategies for gaining access to classrooms, with each coach reporting 10 – 20 strategies (median=13). These strategies spanned two related tiers. In the first tier, all coaches engaged in *relational* and *structural strategies* to position themselves and their coaching work as embedded in school routines, creating conditions to move into classrooms. In the second tier, coaches drew from four strategy types (*pitching in, cloaked coaching strategies, indirect strategies, direct offers*) to gain physical access to classrooms. The strategies in this second tier varied in their directness. While direct offers were open invitations to coaching, other types offered non-coaching assistance in the classroom, engaged teachers in coaching while avoiding directly describing the coach's intent, or created opportunities for teachers to approach coaches. These less direct strategies enabled access when coaches perceived that direct offers would be rejected. Coaches deliberately selected the types of strategies they used with different teachers, based on their perceptions of teachers' dispositions and experience.

Gaining access was found to be complex work for all coaches interviewed, requiring a suite of well-coordinated strategies. Future research might investigate whether and how gaining access for mathematics coaching, particularly in the elementary grades studied here, might require different types of strategies from coaching in other disciplines.

Acknowledgments

This research was supported by a grant from the University of Alabama, awarded to Dr. Saclarides.

COTEACHING AS PROFESSIONAL DEVELOPMENT: A STUDY OF SECONDARY MATHEMATICS TEACHERS PARTNERING TO TRANSITION PRACTICE

Jessica Tybursky Nuzzi
Montclair State University
JTyNuzzi@gmail.com

Keywords: Teacher Education – Inservice / Professional Development; Standards (broadly defined); Mathematical Knowledge for Teaching

There have been many efforts to move mathematics teaching towards student-centered instruction based in problem solving and reasoning. Despite these efforts, Cohen and Mehta (2017) found that U.S. mathematics classrooms remain mostly teacher-centered and instruction remains procedural. Kennedy (2005) explains the ideals are "barely visible in the complex landscape of competing intentions and the multiple areas of concerns that are important to teachers" (p. 61). Currently the field recognizes that professional change occurs through intensive, prolonged, and focused models. One promising model is *coteaching*, where two teachers work collaboratively, which provides "immediacy of the relationship between thought and action" (Roth, 2002, p. 59) and allows for risk-taking and moving away from 'conservative pedagogies' (Gallo-Fox, 2010). Coteaching, without a hyphen, is defined as "a commitment to coplanning, copractice, and coreflection" (Murphy & Martin, 2015, p. 277). These three stages can provide mutual understanding and subsequent learning through zones of proximal development (ZPD). ZPD can then be used as a lens to capture professional growth where interpersonal interactions are transformed to the intrapersonal plane and integrated into each teacher's practice. Murphy, Scantlebury, and Milne (2015) connected six elements in their ZPD framework for coteaching, which will be discussed in the findings below to address the research question: *How can secondary mathematics teachers in a coteaching partnership serve as resources for each other's professional growth towards reform-oriented standards?*

This study analyzes a single, holistic case study (Yin, 2018) of two secondary mathematics teachers striving to accomplish progressive standards in their coteaching of four Algebra 1 sections. The design of the study emerged as part of the researcher's teaching practice, resulting in a naturalistic inquiry of an authentic situation. Sources of data include audio recordings of researcher-participant coplanning and coreflection meetings, some of which developed into responsive interviews, coenactment of lessons, and teaching material artifacts. Qualitative thematic analysis was done in relation to the six elements of coteaching. As an example, in one of the first lessons that altered the coteacher's typical lesson structure, she was challenged to consider how non-direct instruction opens up unpredictable situations. She states: "I just have to think these things out in my head like you know what if it's not working out the way I want it to work out? This is, this is different." This 'bud of development' (Vygotsky, 1978) represents the coteacher's hesitant but promising transition towards enacting student-centered lessons.

Through partnering with another, issues in the classroom can be explicitly recognized and alternatives can be reflected upon and enacted. Furthermore, joint reflection of enacted lessons "provides the opportunity for the deconstruction of those experiences and the reconstruction of a shared meaning in a way that transforms understandings and changes practice" (Crow & Smith, 2005, p. 491). Implicit beliefs about teaching and learning can be critically analyzed, conflicts may be resolved, and sensitivity can increase. The complex landscape of teacher beliefs, dispositions, experiences, and knowledge can be influenced through the coteaching model.

Engaging students in collective mathematical argumentation is a practice leading to authentic learning in mathematics classrooms (see, e.g., Krummheuer, 1995). Researchers have reported multiple cases of expert teachers supporting collective argumentation and described student learning in these cases (e.g., Krummheuer, 2007). However, little is known about how novice teachers learn to support their students in making mathematical arguments. Our goals of professional development (PD) with beginning teachers included stimulating learning through reflection and documenting the learning as evidenced by both practice and conversations about practice. The following research question guided our study: *How did the ways in which a beginning mathematics teacher used repeating to support collective argumentation change and mature over time while participating in professional development activities?* For this study, we focus on the PD activities in which a secondary mathematics teacher, Jill (a pseudonym), participated during her first 3 years of teaching. During the PD activities, we engaged Jill in identifying and diagramming arguments from her teaching using Toulmin's (2003) diagram, and in analyzing and reflecting upon her own practices with respect to supporting argumentation using Conner et al.'s (2014) Teacher Support for Collective Argumentation framework. To encourage and facilitate Jill's learning to support argumentation, a mathematics teacher educator-researcher (MTE-R) asked questions and provided feedback and assistance to her during 14 one-on-one PD meetings, structured similarly to stimulated recall interviews. We video-recorded all the meetings. To answer our research question, we focused on instances in which Jill identified, analyzed, and critiqued her repeating actions, such as restating and displaying. We wrote memos describing changes in Jill's use of repeating over time. The analysis is in the initial stage and is ongoing. In year 1 PD, we see Jill enacting one of two repeating actions rather naturally in her practice as she restated student contributions to the collective. Through focused reflections on her practice with the guidance of the MTE-R, Jill learned more about how she could use both restating and displaying actions to support collective argumentation. As we followed Jill's learning into year 3 PD, we found that Jill used both repeating actions in purposeful ways. She also used these actions in strategic ways to support her students in taking a more active role in the classroom discourse and argumentation. Jill serves as a case to demonstrate how a novice teacher learned to support argumentation through stimulated recall interviews of practice.

Mathematical argumentation is an important feature in the development of conceptual understanding for students (Osborne et al., 2019; Staples & Newton, 2016). Research has generally focused on how argumentation plays out in the classroom, with little focus on how teachers learn this complex work. This study explores teacher's understanding in facilitating argumentation and its implementation over time in the context of a professional development initiative. We address the following questions: How do teachers understand argumentation as a practice? How do teachers implement argumentation in their classrooms as they participate in the professional development? Our work is framed around an understanding that teacher learning is contexual, with a focus on interactions in the content (Greeno & Engeström 2014) and built off of teachers' practices (Kazemi and Hubbard, 2008). We consider argumentation as reasoning about a claim to build agreement across a community, as established by Knudsen et al. (2018).

Eight elementary teachers participated in Learning Labs (Gibbons et al., 2017), a series of monthly professional development sessions with interim support by coaches on implementing the practices. Each Learning Lab consisted of a cycle of new learning, planning a lesson using mathematical argumentation, enacting the lesson, and a debrief of the experience. Data included field notes from each Learning Lab, teachers' written reflections, and pre- and post-interviews for each teacher. We conducted cross-data analysis, with the sensitizing question of *how do teachers understand argumentation and how do they make plans to facilitate argumentation in their classrooms?* We analyzed perceptions and actions involving argumentation over the series of Learning Labs to understand moments of teacher insight and change regarding argumentation.

Findings show a change over time in teachers' understanding and facilitation of argumentation in practice. Early understandings focused on argumentation as explaining one's thinking. Teachers grappled with the distinction between explaining and justifying and with how to implement argumentation in the classroom (see Ghousseini et al., 2019). Over time, teachers developed more nuanced ideas of what counts as argumentation (making claims, providing evidence). Their new understandings helped them generate supports for students to participation in argumentation, ranging from claim comparisons to creating rough drafts of ideas. For example, one teacher worked to provide a set of claims for students to promote discussion that focused on justifying support or disagreement with each. Another teacher worked on language supports for argumentation and forms of modeling justification to move beyond students simply explaining a strategy. While the growth shown in teachers shows a more complex and practice-oriented understanding of argumentation, the differences across individual teachers represent the unique ways they connected to the professional development experiences. These findings show the effectiveness and significance of explicit and practice-oriented professional development for teachers' understanding of mathematical argumentation.

REMOTE ENGAGEMENT IN EARLY MATHEMATICS PROFESSIONAL DEVELOPMENT: USING TANGIBLE ARTIFACTS TO MEDIATE PARTICIPATION

Paul N. Reimer

Although the field has recognized the importance of early mathematics education for young children, many early childhood educators do not have access to high-quality, engaging professional development in math or science (McClure et al., 2017). In particular, educators in rural communities lack opportunities to grow professionally due to geographical isolation or under-resourced programs. In addition, many professional development opportunities offer prescribed programs that do not encourage active participation and are not connected to teachers' existing practices or approaches (Kennedy, 2016).

Building on frameworks for effective professional development (Fishman, Davis, & Chan, 2014) and embodied design (Abrahamson & Lindgren, 2014), we used video conferencing technology paired with tangible materials to engage a cohort of remote online early childhood educators in four sessions of professional development in early mathematics education. Each session was one hour in length and included opportunities for online teacher learners to engage with tangible materials (e.g., Froebel gifts, triangle construction materials) to explore mathematical concepts central to early childhood development. Our approach was designed to 1) engage teachers as learners with carefully designed materials to develop their own understanding, and 2) open pathways for mediated participation through the sharing of physical constructions via video conferencing. In this poster, we focus on the following research question: How do participants' material constructions and interactions act as mediating resources in their participation in remote online professional learning?

We video recorded two of the professional learning sessions, surveyed participants, and interviewed a sample of participants about their experiences in the professional learning. Our findings suggest that tangible materials allowed for common sense-making and active participation throughout the sessions. Furthermore, tangible materials served as resources for mathematical engagement and dialogue in spite of educators' remote participation. This poster will highlight the professional development approach and suggest several implications for the use of tangible materials to enhance online professional development engagement.

Keywords: Teacher Education – Inservice / Professional Development; Instructional Leadership

Mathematics coaching is deeply complex work that requires coaches to develop and draw upon multiple forms of expertise related to mathematics, mathematics teaching, and mathematics coaching (Polly, Mraz, & Algozzine, 2013). Yet, few studies have explored how professional learning experiences for mathematics coaches might support their development of these forms of expertise (Jackson et al., 2015). Through an analysis of a representative instance in which elementary mathematics coaches participated in a professional development activity called *doing the math* (Loucks-Horsley et al., 2010), we aim to contribute to the growing body of research focused on how coaches' own professional learning opportunities might be structured.

Our study took place in Hamilton School District, which is a public school district located in a metropolitan area in the southeastern United States. We partnered with one district administrator and 12 elementary mathematics coaches. Eight of the coaches were entering their fifth year as coaches, while three were in their first or second year. Data sources included video data of these professional development sessions (n=6) as well as interview data (n=15) in which participants described their own learning. All data were professionally transcribed.

To understand what opportunities for professional learning were opened up or closed down, we first coded for representations of practice and epistemic claims in the *doing the math* transcript segments. Next, we addressed whether a representation of practice or an epistemic claim was centered on students, mathematics, mathematics teaching, and/or mathematics coaching. To understand our participants' perspectives on the benefits and drawbacks of participating in *doing the math*, we engaged in an open coding process using interview transcripts (Creswell, 2013).

Our analysis showed that as the coaches engaged in *doing the math* together, opportunities were opened up for them to discuss students' and their own mathematical thinking, the mathematical concepts and disciplinary practices included in the task, how those concepts and practices were related to grade level expectations, how tasks could be put to practical use by teachers, and the ways in which teachers can enhance mathematical access for all students. Yet, our analysis also showed that through *doing the math*, explicit conversations about mathematics coaching were not typically available for discussion. Our participants discussed four benefits of engaging in *doing the math*: being placed in the seat of a learner, deepening their own understanding of the mathematics standards, deepening their understanding of how to support students' access to mathematical tasks, and sharing the task as a resource with teachers. They also cited two drawbacks to consider when implementing *doing the math* as a professional development activity, including a lack of time and teacher resistance.

Our study adds much needed research describing how coaches' professional learning might be structured. Future research might consider exploring how to interweave explicit conversations about coaching into coaches' professional learning opportunities.

This study is an effort to address the challenge of supporting the enhancement of teaching practice. Our model situates professional development (PD) in mathematics instruction occurring in a summer program for fifth grade students. This PD model has two parts. First, participants engage in "legitimate peripheral participation" (Lave & Wenger, 1991) in teaching in this fifth grade classroom through structured conversations about the lesson plans, close observation of teaching, and analysis of student tasks. Second, participants engage in focused learning on leading mathematics discussions through simulations and rehearsals. Two groups of teachers participated, one onsite with a facilitator, and the second at a remote site with an in-person facilitator who delivered the leading mathematics discussion professional development. We study the impact of our PD model. Specifically, we ask: Does teachers' participation impact their own teaching practice, and if so, in what ways?

Twenty-one teachers participated across the two groups. We collected and analyzed a set of pre- and post-videos of classroom discussions. Participants were asked to record three mathematics discussions two months before the PD occurred and three such lessons two months after participation. A tool that captured techniques named in our decomposition of discussion (Selling et al., 2015), including advanced techniques utilized by experienced teachers, was applied to all videos by two research team members.

Prior to the intervention, the means of technique usage of the remote participants were higher than those of the onsite group on almost every dimension ($p < .05$). Thus, we share the findings for the two groups separately. The onsite group (lower pre-intervention mean) did not appear to be leading discussions before the intervention. They showed slight increases in both orienting students to the thinking of others and concluding discussions. Since the intervention was focused on orienting students, likely an unfamiliar area of work, we hypothesize that this was the focus of their practice post-intervention. Conversely, the remote group (higher pre-intervention mean), who appeared to be leading discussions before the intervention, decreased on several categories and showed near significant growth on connecting and extending student thinking. One possible explanation for these decreases is the timing of the post-data collection at the beginning of the year when they may have been explicitly teaching their students how to engage in discussion, leading to fewer instances of particular discussion-leading moves. The increase in connecting and extending may have been due to readiness to take on this difficult work.

A MATHEMATICS TEACHER'S CURRICULAR DECISIONS

Elizabeth Suazo-Flores
Purdue University
esuazo@purdue.edu

Although research uncovered some factors that inform mathematics teachers' curricular decisions, it is less clear how they make such decisions. I used the practical knowledge framework to explore the construct of image with a veteran eighth-grade mathematics teacher. Images are teachers' perceptions of teaching that involve emotionality, morality, and are intimately connected to personal and professional narratives. Data consisted of transcripts of conversations, weekly journals, and student-written work. The analysis uncovered two images: 1) Bringing the outside in, and 2) Reading students and moments. Both images express how the teacher made curricular decisions: Using lessons that brought the outside in and following her students. This study expands research on curriculum by illuminating how teachers make curricular decisions and therefore revealing teachers' practical knowledge in practice.

Keywords: curriculum development, narrative inquiry, mathematics teachers

Research has identified diversity in teacher curricular decisions (Heaton, 2000; Lampert, 1985; Remillard & Bryans, 2004; Remillard et al., 2009; Sztajn, 2003). *Curricular decisions* are those involving selection of tasks as well as pedagogical approaches taken to teach such tasks. Although Remillard et al. (2009) identified factors interacting in teachers' curricular decisions, they called for exploring the nature and decision-making process.

Practical Knowledge Framework and the Image Construct

Teachers' practical knowledge ([PK], Elbaz, 1983) framed this study. Teachers face various situations and "draw on a variety of sources of knowledge to help them to deal with these" (Elbaz, 1983, p. 47). Rather than describing knowledge in the form of cognitive structures, Elbaz (1981, 1983) described teachers' knowledge as situated in experience. *Image* is a construct derived from PK and refers to teachers' perceptions of their teaching that involve emotionality, morality, and connections to personal and professional narratives (Clandinin, 1985; Elbaz, 1983). I explored: How does an eighth-grade mathematics teacher make curricular decisions?

Methodology and Methods

Building from a collaborative relationship (Suazo-Flores, 2016), Elizabeth, the author, narratively inquired (Clandinin & Connelly, 2000) into Lisa's curricular decisions while both planned and taught a lesson over three months. Lisa was an eighth-grade mathematics teacher. Elizabeth conducted narrative analysis (Polkinghorne, 1995) to transcripts of conversations (Clandinin & Connelly, 1994), students' written work, and Elizabeth's personal weekly journal.

Findings and Conclusion

Two images convey how the teacher made curricular decisions: *Bringing the outside in* and *Reading students and moments*. Lisa enjoyed teaching lessons that would take students on field trips and embedded in real-world contexts. Lisa also paid attention to what students were doing and saying to decide her next teaching step. This study contributes to existing studies in curriculum-development by illuminating how teachers make curricular decisions and therefore revealing teachers' PK.

FROM HIGHLY RECEPTIVE TO HIGHLY SKEPTICAL: ENGAGING ALL TEACHERS THROUGH RESPONSIVE PD FACILITATION

Christine Taylor
Indiana State University
Christine.Taylor@indstate.edu

Jean S. Lee
University of Indianapolis
jslee@uindy.edu

We suggest five PD participant portraits to initiate a discussion on how best to support and facilitate PD with a wide range of participants. Our preliminary findings include five teacher portraits. We discuss how facilitators were responsive to all teachers' needs.

Keywords: Teacher Education – Inservice / Professional Development

Professional developments (PD) play a central role in efforts to improve teachers' mathematical content knowledge, pedagogical content knowledge, and beliefs about what it means to 'do mathematics' (Ball, 1990; Hill, 2007). Creating Algebra Teaching Communities for Hoosiers was the result of a Math-Science Partnership grant from Indiana's Department of Education in 2015. The study involved 15 middle and high school urban teachers, with a focus on enriching teachers' knowledge and skills for teaching algebra. This study examines: How do teacher portraits help facilitate the activities in the PD experience?

This study focuses on exploring how PD facilitators used facilitation techniques to support participants based on character portraits (Sztajn, Borko, & Smith (2017), and contributes to an area of research needed on skillful facilitation techniques (e.g., Bobis, 2011; van es, 2014) to prepare and support PD facilitators. Findings culminated in five teacher portraits.

Highly Skeptical Teacher (HST) is an experienced teacher but is uncomfortable being observed by colleagues. HST doubts students can be successful with the PD tasks. Others followed the skepticism because of HST's experience in the classroom. Facilitators probed questions to interrupt preconceived perceptions of students. **Cautiously Receptive Teacher (CRT)** is eager to apply the theories into practice but struggles to bring ideas into reality in the classroom. CRT is hesitant to try new things, but gradually over time buys into the vision of the PD. Trying out activities with students was the best technique to convince CRT of novel teaching practices. **Highly Receptive Teacher (HRT)** is highly reflective and collaborative. HRT sees the potential of all students to be mathematical learners and makes connections between teaching, the PD, and everyday life experiences. PD facilitators would ask HRT to point out students' mathematical thinking. **Box-Checker Teacher (BCT)** is extremely organized, thrives on explicit directions and timeline, and most comfortable with direct instruction. BCT's intense focus on clear tasks and schedules, and high anxiety made the group dynamics tense. PD facilitators solicited input from BCT on the clarity of expectations. **Lopsided Engager Teacher** (LET) has great relationships with all students, even the most disruptive, and is deeply troubled when other teachers do not believe that all students can learn mathematics. LET displays turns of both low engagement and intense engagement. PD facilitators stoked this passion to engage in rich discussions, and showed empathy to situations where relationships take priority over learning.

This study begins a conversation about mathematics teaching facilitation and how best to support and facilitate with a wide range of participants.

A CASE OF SHARED AUTHORITY DURING A STUDENT DEMONSTRATION IN A MATHEMATICS CLASSROOM

Sunghwan Byun
Michigan State University
byunsun3@msu.edu

Lee Melvin Peralta
Michigan State University
peralt11@msu.edu

Beth Herbel-Eisenmann
National Science Foundation
bherbele@nsf.gov

By applying a conversation analytic approach to analyze the fine-grained manifestation of authority in classroom interaction, we examine the interaction between a teacher and a student while the student presented a solution at the whiteboard. This case highlights the complexity of shared authority and the ways that authority is construed by discourse practices and negotiations over the ownership of knowledge. We offer a nuanced interpretation of how the teacher and student shared epistemic authority through their joint activity. Further, we argue for the importance of distinguishing teachers' epistemic authority and deontic authority to further our understanding of how a teacher can share authority with students during instruction.

Keywords: Classroom Discourse, Authority, Student Demonstration, Conversation Analysis

The flow and concentration of authority in mathematics classrooms can impact students' identities as knowers and doers of mathematics (Boaler & Greeno, 2000; Esmonde & Langer-Osuna, 2013, Langer-Osuna, 2017). In our view, authority is not static but rather is relational (e.g., a teacher is presumed to have more authority than a student) and interactional (e.g., a student sharing a solution may imbue the student with authority). Moreover, our analysis focuses on the relative nature of authority, meaning participants may have greater or less authority, but this may shift over the course of interaction. In this paper, we explore a case of one mathematics teacher's attempts to share authority when a student (i.e., a *demonstrator*) shared a solution at the front of the room. This case study of a teacher negotiating authority with students during a common classroom activity (i.e., presenting a solution at the board) offers an opportunity to examine the complexity of shared authority in mathematics classrooms. Our analysis highlights the ways that authority is construed by discourse practices and negotiations over the ownership of knowledge.

This paper uses data from a partnership with mathematics teachers designed to support teachers to do action research on their discourse practices. Here, we build on that research using a conversation analytic (CA) approach to foreground the role of language and knowledge in the sharing of authority in mathematics classrooms. We approach our analysis under the assumption that knowledge is public and interactionally managed and occurs within and is constituted as a situated discursive practice (Barwell, 2013; Edwards, 1993). By attending to how teachers and students *perform* knowledge rather than what knowledge they *have* (Byun, 2019), our analysis centers the knowledge displays and negotiation that are an integral part of the process of sharing authority in classroom interactions. In this paper, we argue that the physical arrangement and position of a student alone—such as the physical location of a student at the front of the room—may not be enough to account for how authority is shared in the classroom. Instead, authority can be shared through discursive moves that orient classroom members to the knowledge domains in which one or more students are the primary authorities.

Authority in Mathematics Classrooms

Teachers exercise tremendous authority in their classrooms (Amit & Fried, 2005; Oyler, 1996; Wagner & Herbel-Eisenmann, 2014b). In mathematics classrooms, teacher authority is also influenced by the institution of schools and common discourses of mathematics. As a student in an

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

interview stated, “[mathematics] is not like literature where someone can say this way, and someone can say this way" (Amit & Fried, 2005, p. 158). This commonly held belief reflects the common practice of mathematics teachers determining what is correct or incorrect as arbiters of truth. As mathematics educators try to move from teacher-centered to student-centered ways of teaching, sharing authority has been a central theme in the discussion (e.g., Ball, 1993; Cobb, Wood, Yackel, & McNeal, 1992; Cohen, 1990; Hamm & Perry, 2002; Lampert, 1990).

Scholars have examined authority and authority relations in mathematics classrooms from multiple perspectives. Amit and Fried (2005) found that students portray parents, teachers, and peers as authority figures while placing teachers at the center of authority. Wagner and Herbel-Eisenmann (2014b) found that teachers attributed authority to not only people but also institutions (e.g., school board) and tools and artifacts (e.g., textbooks, manipulatives). Authority in mathematics classrooms thus has complex origins and relations that manifest in overt and covert ways (Wagner & Herbel-Eisenmann, 2014a).

Authority can also have different discursive functions in unfolding classroom interactions. Oyler (1996) distinguished two dimensions of teacher authority: teacher being *an* authority and being *in* authority. These two kinds of authority, respectively, represent a content dimension of mathematical knowledge and a process dimension of organizing and orchestrating learning activities. Similarly, Langer-Osuna (2016) examined both intellectual authority and directive authority in student-to-student interactions. Although these two kinds of authority are interdependent (Langer-Osuna, 2016), it is important not to conflate these two. As we argue in this paper, process authority can be a resource for teachers to share content authority in the unfolding classroom interactions. To further examine teacher authority in the context of classroom interaction, we draw on two major discussions on authority in social interaction: epistemic authority and deontic authority.

Epistemic and Deontic Authority: A Conversation Analytic View

CA scholars found that participants orient to relative authority in two broad ways during interactions. First, epistemic authority concerns the relative difference in participants' depth of knowledge at hand. To be clear, the concern is not with the depth of knowledge in participants' minds, but rather how the participants treat themselves and others as more or less knowledgeable in the interaction. As we discussed earlier, institutional roles such as being a teacher or a student, in part, shape the epistemic authority. CA approaches can uncover how such authority manifests in a local, interactional context. For instance, Heritage and Raymond (2005) illustrated how, when a person assesses and describes something before others share, they are often ascribed with more epistemic authority than doing so after someone else. They observed when a participant with less authority makes a claim first, the participant mitigates the associated epistemic authority by downgrading their assertion (e.g., pre-facing with "I think," adding a tag question, seeking confirmation). Thus, epistemic authority can originate from not only being *a teacher* but also from a local, interactional role such as being a *teller of news* or *teller of trouble*. In our case, a student being someone who shares a solution at the board afforded her with epistemic authority, though limited.

Second, deontic authority concerns someone’s "right to determine others’ future actions" (Stevanovic & Peräkylä, 2012, p. 298). Although epistemic authority is about "description," deontic authority is about "prescription" (p. 298). In a classroom setting, process-authority aligns with deontic authority, with which a teacher directs the future actions of the class, such as selecting who will speak next and choosing a topic for the class to discuss (Mehan, 1979). Directives and proposals are often associated with deontic authority, but the recipients of these actions may resist the speaker’s deontic authority by refusing to comply or framing their compliance as their autonomous action (Kent, 2012). As Steveanoci and Peräkylä (2012) stated, "[d]eontic authority is an interactional achievement, claimed, displayed, and negotiated at the level of the turn-by-turn sequential unfolding of the interaction" (p. 315).

A CA approach fits our investigation on teacher authority in classroom interactions for at least two reasons. First, teacher authority is "created and maintained through interactions" (Oyler, 1996, p. 23). A CA approach brings our attention to teacher authority situated in interactions, thereby allowing us to see how authority is instantiated and shifts as the interaction unfolds. Second, a CA approach offers a systematic way to formulate empirically grounded interpretations of authority in social interaction. Based on its root in ethnomethodology, a CA approach attends to how participants orient to authority based on the subtle details of moment-to-moment interactions. Based on this theoretical grounding, we investigated the following research question: *How do epistemic and deontic authority instantiate and interact with each other when a student is a demonstrator?*

Data and Methods

This study was part of a larger partnership focused on supporting secondary mathematics teachers to use action research to examine their classroom discourse by focusing on, for example, issues of status, and positioning in mathematics classrooms. Data came from classroom videos of participating teachers that they collected to examine changes in their discourse patterns. Among multiple cases of student demonstrations, this case of Ms. Reed was selected for this report because on the surface, her case illustrated evidence of overt teacher authority. She regularly used directives (e.g., “stop,” “continue,” “ask”), and the length of the student demonstration was approximately 13 minutes, which was longer than many of the other observed student demonstrations. This was intriguing for us because we anticipated that the greater the authority that a teacher exercises, the less knowledge can be shared from demonstrating students, thus resulting in a shorter demonstration length. This led to a more fine-grained analysis of this selected case to understand how teacher authority manifested during this relatively longer student demonstration.

Following the tradition of conversation analysis, we adopted the Jefferson Transcription System (Jefferson, 2004) to capture a range of speech features (e.g., delays in response, elongated pronunciation, intonation changes) that may be significant to examine authority in interaction. Here, we only report the following features: silence in 1/10 sec, (.x); silence shorter than 0.3 sec, (.); overlapping talk, [ ]; vowel elongation, : ; emphasis, _ ; unrecoverable speech, ( ), as we referred to them in our findings section. By examining both what the teacher does and how students respond, we examined how the teacher and students are orienting to both epistemic and deontic authority. Based on the participants' orientation, we made an empirically grounded interpretation of authority.

Findings

In this section, we analyze transcript extracts from a demonstration by Anika, an 8th grade student. Before the demonstration, students were engaged in two warm-up problems, each of which asked them to create an equation of a line passing through two given points. After the students solved the problems individually, Ms. Reed called on students to share their answers. Anika volunteered to share her solution. Ms. Reed asked Anika to share her method at the front of the room on a digital interactive whiteboard. Our analysis highlights the nuanced ways that authority was shared through the joint discursive activity of members in the class. This analysis also points to the importance of distinguishing teachers’ deontic and epistemic authority.

Exclusive Deontic Authority

Extract 1: Use of Directives

085            so: this would be x two: and then this would x one
086            so then it would be negative two: (1.0)
087  Ms.R:     okay sto:p (.) question.
088  JOHN:     u[:m  ] why is the uh seven uh y two and the fi- and
089  Ms.R:      [John]
090  JOHN:     the uh negative two x two.
```

Throughout the demonstration, Ms. Reed acts with deontic authority in at least two ways. First, she stops the speaker to direct the class to another activity (line 87). Ms. Reed's falling intonation when she says "question." indicates that this is a directive rather than seeking a question. Second, Ms. Reed selects the next speaker (line 89). Note that John starts his speech with "um" (line 88) occupying the conversational floor with his speech and vying for his right to speak. As soon as Ms. Reed names John as the next speaker, John starts his question. In both accounts, students orient to Ms. Reed's deontic authority with immediate compliance. That is, Anika stops her demonstration and John initiates and begins his question with full compliance with Ms. Reed's directives.

Sharing Epistemic Authority

Contrary to Ms. Reed's deontic authority, we found that Ms. Reed orients to Anika's epistemic authority, thereby sharing epistemic authority with Anika. Ms. Reed does so with particular kinds of actions (e.g., highlighting Anika's epistemic access, seeking confirmation). Some of these actions occur even before Anika walks to the front of the room. We illustrate this pre-work with Extract 2 below.

Extract 2: Constructing Anika as an Expert

```
023  ANIKA:    so I found the slope and then I (substituted it)
024            into it. (                        )
025  Ms.R:     okay so (1.0) we are gonna look at (.) your method.
026            (0.5)
027            Tanner? as you listen to Anika is that- does that
028            sound similar to (.) what approach you took?
029            (.)
030            she said y two minus y one::, (1.0) she did some
031            subtracting over x two minus x one,
032            (1.0)
033  TANNER:   (             )
034  Ms.R:     so can I- can I ask you:?
035            (0.5)
036            what is tha:t formula= where did you get that.
037            (1.0)
038  ANIKA:    u:m I learned it (        )=
039  Ms.R:     =okay
040  ANIKA:    during the summer.
```

After Anika described her approach to the problem, Ms. Reed says "we are gonna look at your method" (line 25). With her lexical choice of the possessive pronoun, "your", Ms. Reed orients to Anika's ownership of the method. This lexical pattern continues. As Ms. Reed asks Tanner to compare his ideas with Anika's (lines 27-28), she indicates that the method originated from Anika by pre-facing her clauses with "she said" and "she did" (line 30).

Another salient point in this extract is the way Ms. Reed makes Anika's exclusive epistemic access public by asking Anika about the source of her method (line 36). Although what Anika names as the source of knowledge is unrecoverable for the analysis (line 38), we can see, in contrast to deontic authority, Anika takes up her epistemic authority. Anika expands her turn by adding "during the summer" (line 40) despite Ms. Reed's earlier acknowledgment token, "okay" (line 39). Anika's expansion of her turn shows Anika's orientation to her exclusive epistemic access to the method since "the summer" refers to a time beyond the school year, which lies outside of the class's shared experience.

In these interactions Anika is constructed as a person with knowledge that the rest of class may not have. In the following extracts, we discuss instantiations of Ms. Reed's orientation to Anika's epistemic authority. Notably, some of the orientation is displayed with Ms. Reed's deontic authority.

Extract 3: Treating Anika with Epistemic Authority

```
JOHN:     u[:m  ] why is the uh seven uh y two and the fi- and
Ms.R:      [John]
JOHN:     the uh negative two x two.
          (1.5)
ANIKA:    u:m I guess it's just the way it's placed? so if this
          was the: first two coordinates and this was second
          two coordinates that-
JOHN:     (            ) closer to the x two uh (0.5) closer to
          y intercept is:  (1.0) for (0.5)
Ms.R:     I think she mea:ns that's the first point?
          (0.5)
JOHN:     a[::h      ]
Ms.R:      [and that]'s the second point=
JOHN:     =okay
Ms.R:     that's the x from the first one, and the y from the
          first one so that's how she said x one y one and
          that's the x: and y from the second one.
          (.)
          is that what you mean?
ANIKA:    yeah
```

When Ms. Reed has students ask questions, John poses a question (line 88). Anika, thus not Ms. Reed, answers John's question. The source of knowledge is Anika in this question and answer sequence. This contrasts with the deontic authority that Ms. Reed exercises by selecting John as the next speaker, as discussed earlier. Ms. Reed exercises her deontic authority to coordinate the activity of others and get the work of teaching done (Oyler, 1996). However, Ms. Reed tacitly acknowledges that Anika is the person from whom the flow of knowledge originates. For instance, Ms. Reed downgrades her epistemic stance as she explains Anika's method. In line 97, she pre-faces her statement with "I think" and finishes her turn with a rising intonation (noted as "?") despite her statement's declarative syntax.

Most notably, after revoicing Anika's method (lines 100-104), Ms. Reed seeks Anika's confirmation (line 106), to which Anika responds with a positive confirmation, "yeah" (line 107). This interaction marks a significant shift in how Ms. Reed overtly shares authority with Anika. By seeking confirmation, Ms. Reed once again downgrades her epistemic stance and signals to the class that she is not the expert over the information being clarified. With both Ms. Reed's confirmation-seeking and Anika's response, both of them treat Anika with epistemic authority.

Extract 4: Centering on What Anika Does

```
ANIKA:    so then (.) y is equal to negative two fifths
          ((Anika writes on the board))
          times (1.8) three (1.0) plus (       )
Ms.R:     k (.) stop (.) questions so far?
          (.)
          what is she doing?
          (2.0)
          we talked about how she found her slo:pe and that was
          similar to just the change in y over change in x that
          we done (0.7) Azad (.) what is she doing?
AZAD:     exploiting the x y coordinates: to (.) find b.
          (1.7)
Ms.R:     Molly?
MOLLY:    what's the three in parentheses?
Ms.R:     ask (0.7) Anika
MOLLY:    what's [the  th-]
ANIKA:           [it's  x.]
```

Ms. Reed continues to exercise deontic authority throughout the student demonstration. Once again, Ms. Reed uses a directive, “ask” (line 165). Prior to this, Molly poses a question (line 164). From the extract, it is not clear who the recipient of the question is. Nonetheless, Ms. Reed treats Molly's question as not directed to Anika, and she uses a directive to direct her question toward Anika (line 165). Molly, in turn, starts to repeat the same question (line 166), but Anika answers Molly's question even before Molly finishes her repetition (line 167). In other words, Anika projects Molly’s question to be identical to the question Molly asked earlier, and she acts as if the recipient of the original question was herself. This is another illustration of how Ms. Reed’s deontic authority manifests overtly. Ms. Reeds suspends the ongoing questioning and answering activity and makes the recipient of the question relevant to the degree that the identical question has to be repeated.

Although Ms. Reed’s use of deontic authority may seem pedantic, it plays an important role in the lens of epistemic authority. By having Molly direct her question to Anika, Ms. Reed orients to Anika with epistemic authority over the information being presented (i.e., Anika’s method). In a similar vein, Ms. Reed stops Anika’s demonstration and prompts the class to ask questions (line 154). Because no student responds (line 155), Ms. Reed asks, “what is she doing?” (line 156). Note Ms. Reed’s use of the pronoun “she”, which indicates Anika as the agent of the activity. This utterance implicitly orients to Anika’s epistemic authority since Anika has the primary right to describe what she is doing.

Ms. Reed then selects Azad as the next speaker. The interesting feature of this question and answer sequence is the absence of evaluation or feedback after Azad’s response. This contrasts with the common Initiate-Response-Evaluate (IRE) pattern (Mehan, 1969) and reinforces how Ms. Reed is sharing epistemic authority with Anika because Ms. Reed is tacitly deferring her epistemic authority that otherwise would have been used to confirm the correctness of Azad’s response.

We initially hypothesized Ms. Reed’s exclusive deontic authority and her deferring epistemic authority throughout Anika’s demonstration. Our fine-grained examination, however, revealed deviant cases of such a claim (i.e., moments of Ms. Reed’s asserting epistemic authority). In ethnomethodological studies, considering deviant cases is crucial to develop a more nuanced interpretation of the phenomena (Heritage, 1984). In the following, we present one of these deviant cases and further explore how Ms. Reed does, and does not, share epistemic authority.

Deviant Case: Not Sharing Epistemic Authority

Extract 5: Choral Chant

Ms.R: two divided by five (.) is what
(1.2)
S?: (point) (.) four
Ms.R: point four. (0.5) negative point four. (0.5)
<u>neg</u>ative two divided by five is,
(0.9)
STs: (negative point four). ((Choral Chant))
Ms.R: negative two point four because (.) negative divided
by a positive (.) is negative (0.8) two divided by a
negative five is,
STs: negative - [WOO]
Ms.R: negative [point four] because a positive
divided by a negative is
(1.1)
STs: a negative
Ms.R: so: (.) as long as you have one negative (0.8) you
can place it (.) <u>wherever</u> you like in your fraction
(.) because it has the very same value. (.) okay?

Ms. Reed facilitates choral chants through which she rhetorically constructs common knowledge within the classroom (Edwards & Mercer, 1987). The choral chant occurs after a student asks a question relating to the equivalence of the fractions (-2)/5, -(2/5), and 2/(-5). In contrast to Extract 4, in which Ms. Reed did not evaluate Azad's response, Ms. Reed confirms each response during the choral chant with her repetition (lines 239, 243, and 247 through 249). This indicates that Ms. Reed, not Anika, had epistemic authority during this interaction despite the fact that Anika is still at the front of the room. Further, in these IRE sequences, Ms. Reed justifies each response as indicated by her use of "because" (lines 239, 243, and 249). Her consistent justifications can be explained as her efforts to orient to the authority of mathematics as a discipline; yet, Ms. Reed remains to be the person who confirms the correctness.

Although we do not include the corresponding transcripts here, we also note other moments when Ms. Reed asserted her epistemic authority during Anika's demonstration. For instance, when one student asked if Anika's method is similar to what they have learned before, Ms. Reed offered confirmation, "exactly what it is," again with her account of how Anika's method relates to their prior learning. These deviant cases lead to a more nuanced understanding of how epistemic authority was shared during Anika's demonstration. Within the knowledge domain of Anika's method, Ms. Reed orients to Anika's epistemic authority. However, when the topic of discussion deviates from Anika's method (e.g., how her method connects to the class's prior learning, equivalence of fractions), Ms. Reed retains her epistemic authority to confirm the necessary knowledge for students to meaningfully engage with Anika's method.

Discussions and Implications

The push to develop student-centered classrooms should not imply the abdication of teacher authority (Oyler, 1996). This case demonstrates that teachers' deontic authority can aid in designating students' epistemic authority. Discussions about student-centered classrooms that misconstrue the role of teacher authority can paralyze teachers' efforts to facilitate productive mathematical discussions. Rather, there is a need to further examine how teachers can utilize deontic authority to share epistemic authority with students so that students can share and co-construct knowledge productively against a backdrop of institutional constraints such as curricular requirements and time limits. In professional development settings, this distinction can be helpful in designing a range of teacher moves that can be used to share epistemic authority (Herbel-Eisenmann et al., 2017).

This case also highlights the importance of how mathematics knowledge is introduced and framed by the teacher. Anika's method is quite conventional and is based on procedures that are often introduced in textbooks. However, Ms. Reed and the class treated her method as novel and, more interestingly, as a knowledge domain over which Anika had primary authority. This shows the situated nature of mathematical knowledge within a community in terms of authority. Although Ms. Reed might have known the conventional nature of Anika's method, Ms. Reed performed knowledge in ways that imbued Anika with primary epistemic authority. This had the effect of reconfiguring Anika's knowledge, converting it from a conventional method learned during the summer into an owned resource lying within Anika's epistemic domain. This was made possible through Ms. Reed's deontic authority, the exercise of which enabled her to demarcate lines along a terrain of mathematical knowledge. By setting boundaries around who owns what knowledge, Ms. Reed was able to portray Anika as someone who was not merely repeating a textbook method.

We also see potential for this study to contribute to discussions of equity in mathematics education research. As Byun (2019) discussed, teachers need authority to control the topic of classroom discussion so that students are steered toward different knowledge domains that can position minoritized students in more powerful positions. Without this deliberate reshaping of the epistemic terrain, participation patterns would likely continue to marginalize groups of students with particular social markers (e.g., race or gender). Although we did not attend to the racialized and gendered aspects of authority in classroom interactions in this study, we suggest further investigating the question of who teachers share epistemic authority with and its consequences for equity in mathematics classrooms. For instance, this case could be seen as an example of a female student of color who re-authors a conventional mathematical method through joint activity with her teacher, thereby challenging dominant conceptions about the authorship of mathematical ideas. Further work along these lines may offer valuable insights into equity issues in mathematics classrooms.

Acknowledgments

We thank the teachers, students, and parents for the partnership. We also thank NSF (Award #0918117) and the MSU Graduate School for their financial support. Any opinions, findings, and conclusions or recommendations expressed in this paper are those of the authors and do not necessarily reflect the views of the granting agencies.

The purpose of this research study is to characterize secondary teachers' orientations toward mathematics engagement. Results indicated that these 16 high school mathematics teachers tended to emphasize a cognitive dimension for engagement in their orientations, usually intertwined with an additional dimension (affective, social, or behavioral). Understanding teachers' thinking about engagement is a critical step toward helping teachers improve their practice to support their students' engagement in mathematics learning.

Keywords: High School Education; Teacher Beliefs; Instructional Vision; Affect, Emotion, Beliefs, and Attitudes.

In this study, we describe how high school mathematics teachers think about mathematics engagement. Teachers' efforts to engage students during their instruction are likely to be informed by their thinking about mathematics engagement. Understanding mathematics teachers' orientations toward engagement at the secondary level is particularly important because students' motivation and engagement has been found to decline over time as students move through levels of education. For instance, Chouinard and Roy (2008) found that students' self-efficacy, enjoyment, and sense of the utility of mathematics decreased as they move through middle school and into high school, and students became more disengaged over time in high school.

Students' motivation and engagement is malleable, socially situated, and influenced by teachers' instructional practices in the moment and by the classroom climate (Anderson, Hamilton, & Hattie, 2004). Teachers' instructional practices can impact students' motivation and engagement, and engagement is an important step on students' path toward learning mathematics. We conjecture that understanding high school teachers' orientations toward engagement is essential for supporting teachers to create secondary mathematics classrooms that disrupt declines in students' motivation and engagement.

Mathematics Engagement

Engagement in school manifests as students' expression of affect, beliefs about themselves, sense of belonging, and observable behaviors in the school setting (Jimerson, Campos, & Greif, 2003). Engagement is thus a complex meta-construct that simultaneously accounts for cognitive, affective, and behavioral dimensions (Fredricks, Blumenfeld, & Paris, 2004). Middleton, Jansen, & Goldin (2017) extended these dimensions to add a fourth with respect to mathematics learning: social engagement. Mathematics engagement is an interactive relationship between students and the subject matter, and it is manifested in the moment through expressions of behavior and experiences of emotion and cognitive activity; engagement is constructed through opportunities to do mathematics, as situated in both current and past experiences (c.f., Middleton, Jansen, & Goldin, 2017).

For students to learn mathematics, they must be engaged with experiences that support learning. In a study of almost 4,000 middle school and high school students in Western Pennsylvania, researchers

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

found that higher levels of cognitive, behavioral, emotional, and social engagement predicted students' course grades in mathematics (Wang, Fredricks, Yea, Hofkens, & Linn, 2016). According to Greene (2015), it is well-established in prior research that motivation constructs such as students' self-efficacy support students' engagement in ways that lead to learning. However, it is possible that some teachers might speak about engagement in ways that are not always connected to learning, instead more connected to students' behaviors.

Teachers' thinking about students' mathematics engagement

Very few prior research studies have been conducted on secondary teachers' thinking about mathematics engagement, but some relatively recent research from Australia provides insights. Skilling, Bobis, Martin, Anderson, and Way (2016) conducted interviews with 31 secondary mathematics teachers from ten schools. Their results indicated that teachers in their study tended to describe students' engagement in terms of students' behavioral, affective, or emotional engagement; they spoke less often and less extensively about students' cognitive engagement. About one-third of these teachers reported an instrumental orientation, such that they strove to provide students with examples of how mathematics was a part of their lives outside of school. Some of these teachers also emphasized a relatedness dimension of engagement as they reported making efforts to build relationships with students to promote engagement. Their stance, which we also adopt, was that multi-dimensional orientations toward engagement would be more productive for teachers to hold.

Bobis, Way, Anderson, and Martin (2016) investigated changes in teachers' thinking about engagement, particularly among teachers who initially thought about engagement in terms of students' behavior primarily. After professional development, these teachers began to view engagement as more multi-faceted, beyond behavior management, and more than whether students were on-task. For the purposes of this study, we view behavioral engagement as the least productive dimension of engagement, because students could be on-task but not intellectually connecting with mathematics. We view cognitive engagement a potentially productive dimension, as it focuses is on students' mathematical thinking and learning.

Teachers' orientations

The term "orientation" is usually not defined explicitly in research literature on teaching and teacher education. Researchers' use of the term seems to imply that an orientation is a constellation of beliefs (e.g., Ambrose, 2004) or a set of perspectives and dispositions (Remillard & Bryans, 2004). It is particularly compelling to consider the root idea of "orienting," as these ways of thinking about teaching and learning can provide a direction for teachers' decision making. In this study, we define teachers' orientations toward mathematics engagement to be the set of teachers' beliefs about what it means for students to interact with mathematical tasks and each other productively during mathematics class, and together this set of beliefs provides direction for how teachers would enact instruction to engage their students.

By "beliefs," we mean what a teacher holds to be true. Beliefs are different from knowledge in that they are personal truths (Rokeach, 1968), and they have stronger, more affective components than knowledge (Nespor, 1987). Beliefs must be inferred by what a person says or does; they cannot be directly observed (Pajares, 1992). According to Rokeach (1968), ''All beliefs are predispositions to action'' (p. 113). Similarly, Aguirre and Speer (1999) explain that beliefs are "conceptions, personal ideologies, world views and values that shape practice and orient knowledge" (p. 328). Following Leatham (2006), we assume that teachers' beliefs are sensible to them, so we do not attempt to investigate whether teachers' actions appear consistent with their beliefs from a researchers' perspective.

Our stance toward teachers' orientations reflects that beliefs can cluster together within a system of beliefs. Green (1971) writes of beliefs having varying levels of psychological strength, some beliefs in a cluster are more central and others are more peripheral. Our investigation of teachers' orientations toward engagement targets the cluster of beliefs about the meaning of mathematics engagement, identifying which are more central in their belief clusters.

This study was guided by the following research question: *What are secondary teachers' orientations toward mathematics engagement?* We investigated dimensions of engagement that teachers reported when talking about engagement in interviews about their teaching practice.

Methods

This exploratory study was conducted during the second year of a three-year NSF-funded project designed to investigate engagement in high school mathematics classrooms. In Fall 2018 and Spring 2019, project team members interviewed 16 teachers in two states (one in the Southwestern region of the United States and one in the Mid-Atlantic region). Schools in these areas of the country use different curricular approaches: integrated mathematics in the Mid-Atlantic and topics-based courses in the Southwest. The three Mid-Atlantic schools implemented a block schedule with approximately 90-minute class periods. In the Southwest, the class periods were approximately 50 minutes long.

We gathered data from six schools (three from each state). In the Mid-Atlantic, the schools' demographics ranged from 9-30% low income, 24-57% white, 27-46% Black, 7-24% Latinx, and 5% or less Asian-American, Native American, or mixed-race students. In the Southwest, the schools' demographics ranged from 85-94% low income, 2-5% white, 1-15% Black, 74-96% Latinx, and 5% or less Asian-American, Native American, or mixed-race students.

Teachers were recruited for this study by soliciting nominations from district curriculum supervisors and mathematics coaches. The 16 participating teachers averaged 10.8 years of teaching experience, ranging from 1 to 27 years. Twelve teachers had earned a Master's degree. They self-identified their races as follows: 14 white, one Asian-American, one Hispanic/Latinx. They self-identified their genders as eleven female and five male.

Data Collection

Each teacher completed a baseline survey online at the start of each course. Survey items were open-ended, such as: *In your own words, what does "engaging students with mathematics" mean?* Interviews took place at the end of the semester in the Mid-Atlantic region, where schools had block scheduling, and it was at the end of the academic year in the Southwestern region. Interviews lasted from 35 minutes to about an hour and 15 minutes. Prior to the interviews, we video recorded classroom observations between two and four times per class period; observations targeted a lesson activity that the teacher conjectured would be likely to engage students. Interview questions included: *What are some of your favorite strategies you use to engage students? Why do you use these?* and *Can you tell me about a time when you have successfully engaged students with mathematics?* During the interview, we also asked teachers to elaborate on their definition for engagement on their baseline survey. Additionally, the interviews incorporated a video viewing session protocol; we showed teachers a video clip of their lesson, and we asked them to reflect on their students' engagement and their approaches to engaging them.

Data Analysis

The goal of our analysis was to describe the orientations each teacher used to conceptualize students' mathematics engagement. We compared descriptions of orientations to map a framework of ways in which mathematics teachers think about engagement along six dimensions identified in the engagement literature. Any of these dimensions could be either central or peripheral in a teacher's orientation, or in the constellation of beliefs the teacher held about mathematics engagement.

Each interview transcript had three sections, and we applied four levels of analysis to the transcripts. The interview's three sections were: (a) teachers' definitions for mathematics engagement, (b) teachers' strategies for engaging students, and (c) teachers' reflections on students' engagement during a classroom video episode. Interviews were transcribed prior to analysis. Each interview was coded independently by two researchers. All disagreements were resolved.

We operationally defined a teacher's orientation to be composed of dimensions of engagement that they reported in the three sections of the interview. Each transcript was analyzed at four levels: (1) we applied descriptive coding techniques (Saldaña, 2013) to identify the dimension(s) of mathematics engagement to which each teacher was oriented [see Table 1].

Table 1: Indicators for Dimensions of Mathematics Engagement

Dimension of Engagement	Indicators of Engagement that Teachers Described
Affective	Students' emotional responses, interest, attitudes, and expressions of values.
Cognitive	The process of students coming to understand, learn, and make sense of mathematics.
Social	Students interact with one another for the purpose of learning mathematics.
Behavioral	Observable actions of students, including whether or not they were on task.
Relatedness	Enactments of interpersonal care or personal connections between the teacher and students and among students.
Instrumentality	Students see mathematics as useful and relevant to their lives.

(2) We analytically identified the centrality of the dimensions in each interview section based on the teacher's use of repetition, level of detail, and emphasis terms. Central dimensions had two of these three features (repetition, detail, or emphasis). Peripheral dimensions did not. (3) We analytically determined the degree to which a dimension was central to a teacher's orientation by identifying whether the dimension was central to the teacher across more than one section of the interview. (4) Finally, we applied axial coding across each teacher's interview (Saldaña, 2013) and compared teachers' central dimensions to identify categories of orientations.

Results

In Table 2, we summarize the central and peripheral dimensions of mathematics engagement reported by these teachers at the case-level, or across the interview for each teacher. Central dimensions are labeled with a shaded 1 and peripheral with an unshaded 2. Zero indicates no evidence of this dimension in teachers' responses.

Table 2: Teachers' Orientations toward Mathematics Engagement

Teacher	Cognitive	Affect	Social	Behavioral	Instrumentality	Relatedness
Elise	1	1	1	1	0	0
Ken	1	1	1	2	2	1
Chloe	1	1	2	1	2	0
Addie	1	1	2	2	2	0
Jessica	1	1	2	2	0	0

Nancy	1	1	0	2	1	1
Jimena	1	2	1	2	2	2
Julie	1	2	1	2	0	2
Nicole	1	2	2	1	2	2
Peter	1	2	2	1	0	0
Colton	1	2	2	2	1	2
Tori	1	2	2	2	1	0
James	1	2	2	2	0	2
Rachel	1	2	2	2	0	0
Anne	2	1	2	2	1	2
Craig	2	2	0	1	2	0

All of these secondary mathematics teachers expressed a multi-faceted orientation toward mathematics engagement--they all spoke about engagement with at least four dimensions, either at the central or peripheral level. Table 3 (below) shows four prevalent orientations that teachers reported.

Table 3: Four Prevalent Orientations Toward Mathematics Engagement among Secondary Teachers

Orientations toward mathematics engagement	Summary of each orientation
Cognitive-Affective	Support students' learning of mathematics while cultivating enjoyment, interest, and a desire to learn mathematics.
Cognitive-Social	Learning mathematics is a process of coming to know mathematics through discourse.
Cognitive-Behavioral	For students to be actively involved in mathematics learning, teachers must manage students' behavior.
Cognitive-Instrumental	Opportunities to learn are enhanced by connections between school mathematics and students' lives.

All but two of these teachers (87.5%) reported a central cognitive dimension in their orientation such that engagement involves students thinking mathematically or making sense of mathematics. This is important because previous research indicates that mathematics teachers tend to think about engagement in terms of its behavioral dimension primarily, unless they had had support from professional development (e.g., Bobis, Way, Anderson, & Martin, 2016; Skilling, Bobis, Martin, Anderson, & Way, 2016). Our findings illustrate counter evidence, indicating that secondary teachers can strongly consider learning processes when they talk about mathematics engagement.

Teachers consistently paired statements about cognitive engagement with statements about one or more other dimension. Affective, social, and behavioral engagement, and instrumentality were viewed as critical contributors to students' efforts to grapple with and understand important mathematical concepts and procedures. Rather than speaking about goals for cognitive engagement and then speaking about other facets separately, teachers' responses concurrently emphasized the role of affect, social or behavioral dimensions in supporting cognitive engagement. In particular, when speaking about strategies and practices that contribute to students' math engagement, these facets were reasoned as important for helping students engage in learning the mathematics productively.

Relatedness and instrumentality were the dimensions reported least by these teachers, but these dimensions were still a part of most of these teachers' orientations. At least half of the studied teachers mentioned relatedness and instrumentality in at least one of the sections of the interview at some level (either central or peripheral). It is interesting to note that these dimensions displayed the most variability in teachers' responses. Half of the teachers in the sample did not mention relatedness as somewhat central to their conceptions of engagement, and six did not mention instrumentality.

Cognitive-Affective Orientation toward Mathematics Engagement

Six secondary teachers reported a cognitive-affective orientation toward mathematics engagement (Jessica, Addie, Chloe, Elise, Ken, Nancy). They said that students are engaged when they invest their thinking in order to learn (cognitive) and their investment will increase if they enjoy the experience and feel a desire to learn (affective). Addie wrote that engagement is "Where students are excited to learn the beautiful world of mathematics." (baseline survey) "I think it's taking where students are at, because that's where they're comfortable, and then expanding their knowledge in different ways that aren't necessarily lecture based in order to get students really interested in mathematics." (22-25, interview). When Addie spoke about engagement in terms of learning (cognitive), she also wrote about affective experiences of excitement, beauty, comfort, and interest. Nancy said, "I feel like engagement is having them be actually, like, cognitively thinking about the mathematics that are happening and not just copying down the notes… it's about having them actually think about it… having, like, some sort of level of fascination or even just curiosity, or seeing a goal with it. Just, kind of, finding a purpose in it." (39-46, interview). Nancy valued fostering curiosity (affective) so that students engage in deep mathematical thinking (cognitive). The teachers spoke about productive opportunities for students to understand mathematics in ways that also provided powerful opportunities for students to develop strong relationships with the discipline of mathematics.

Cognitive-Social Orientation toward Student Engagement

Four teachers (Julie, Jimena, Elise, and Ken) reported a cognitive-social orientation toward engagement. They described engagement as investing thinking in order to learn (cognitive) through a process of coming to understand mathematics through discourse (social). (We note that some teachers, such as Elise and Ken, were examples of more than one of these four orientations, because their orientations contained more than two dimensions.)

Julie's baseline assessment provided a concise example of a cognitive-social orientation. She wrote, "Engaging students with mathematics means finding ways for students to think about and discuss mathematics in a way that deepens their understanding." Thinking (cognitive) and discussing (social) were integral to Julie's view of engagement.

These teachers tended to characterize cognitive engagement as a process of grappling with mathematics. For instance, Elise said, "I want them to say, 'What am I doing that's not making sense?' Or, 'What pieces could I be missing that are not connecting?' I want them to ... if they find an answer, interpret that answer. Is it a useful answer? Does it answer the problem you're trying to figure out? Does the answer make sense?" Similarly, Julie said, "So I like to ... from time to time, after we've done a concept, to kind of pose a question that forces them to really, first of all, think on their own. Can they generate their own thought? But then to have those discussions with their peers to see, 'Well, what do you think about that? I didn't think about it. How can we maybe expand on each other's ideas to see different ways of viewing the same kind of problem?' " (27 – 39, interview) These teachers talked about learning and understanding in ways that involve making sense, interpreting their work, and wrestling with concepts as they talk them through with peers.

Cognitive-Behavioral Orientation to Students' Engagement

A cognitive-behavioral orientation toward mathematics manifested in four teachers' talk (Nicole, Peter, Chloe, and Elise). They reported that they wanted students to be actively involved in the learning process (cognitive), but they also reported having to manage behavior so this would happen (behavioral). On his baseline survey, Peter wrote, "Engaging students means that all students are working on what are supposed to. All students are actively participating in their own learning, with no exceptions. Engaged means 'doing.'" Elise spoke about engagement challenges as being about the range of ways students engage behaviorally and cognitively.

> You have different levels of engagement. You have the kid that hasn't even attempted to pick up a pencil… the kid that looks like he's listening or she's listening, but hasn't even read the question or hasn't tried to understand the directions and the task. And then you have the kids like, 'Oh, I got an answer. I'm done.' … It's such a big spectrum of engagement and lack of engagement that you try to address every day. (50-59, interview)

Engaging their students cognitively and behaviorally was reported by these teachers as something they constantly worked to accomplish. For instance, Nicole talked about cold calling (behavior management) as a way to engage students to think about mathematics (cognitive engagement), as she said,

> I kind of force them to be a little bit more engaged for the Popsicle sticks. And then also, if they didn't know the answer, they had to listen to somebody else, and then they had to repeat it back. Like, [student] didn't know what to do, so somebody else gave the answer. And then, I made [student] repeat it so that he was listening, at least. I don't know if that's considered engagement, because to me, he's just listening, and he's just repeating. But, at least it's trying to get them to think. If I could see the rest of the class, I believe most of them ... No, probably 50% of them were actually engaged, because I'm hearing talking in the background. I don't know where that came from. (370-380, interview)

The teachers who intertwined behavioral engagement with cognitive engagement spoke about using classroom management practices to bring about productive behavior in hopes that it would lead to stronger intellectual investment among students.

These teachers spoke about the cognitive dimension of learning in ways that appeared to be more closely aligned with procedural fluency than conceptual understanding. When teachers articulated a cognitive-behavioral orientation, there was a focus on getting answers over sense making, modeling procedures through lecture, and guided practice of steps to solve a task. This perspective on cognitive engagement contrasted with teachers who reported a cognitive-affective, cognitive-social, or cognitive-instrumental orientation, which illustrated a focus on interpreting and understanding mathematics.

Cognitive-Instrumental

A cognitive-instrumental orientation toward engagement was illustrated by three teachers (Tori, Colton, and Nancy) who talked about opportunities to understand (cognitive) being enhanced by connections between school mathematics and students' lives (instrumental). Tori reported the following on her baseline assessment: "For me, engaging students with mathematics means using the real-world information to understand the concepts in mathematics, and hopefully apply what the students have learned to their personal lives and become lifelong learners of mathematics." Colton described engagement on his baseline survey as "Giving them something more to connect with." Nancy reported the power of connecting mathematics and students' lives. When discussing functional relationships, such as whether the relationship between time and location is a function, she said, "I think that part of the reason why it was so engaging is because some of those things allow them to challenge math. … I think it's cool when they can make that, like, real-world connection."

These teachers could leverage opportunities to connect with mathematics (instrumental) in ways that enhanced students' opportunities to understand mathematics (cognitive).

Discussion

We conjecture that quality mathematics instruction can be best supported when teachers go beyond a focus on behavioral engagement in their orientations. The secondary teachers in our study emphasized cognitive engagement primarily, with other dimensions serving as supports and influential catalysts for helping students engage cognitively. If teachers tend to prioritize cognitive engagement in their orientations, and if they hold multiple dimensions of engagement in their orientations, they are likely to have productive resources and strategies they can call upon to support their students.

Future research could investigate whether teachers' instructional practice varies depending on their orientations toward mathematics engagement. It is possible that a teacher who holds multiple dimensions toward mathematics engagement in their orientations is more flexible in their approach to engaging students. Alternatively, it may also be possible that teachers who hold only two dimensions – such as cognitive-affective, cognitive-social, or cognitive-instrumental – could effectively engage their students in mathematics learning. The necessary and sufficient conditions for improving student cognitive engagement through integration of two or more dimensions is an open question.

To support teachers in developing their orientations, we propose two goals for teachers' learning about mathematics engagement: (1) Teachers can strive to more fully enact their orientations toward mathematics engagement in their teaching practice; and (2) Teachers can work to enhance additional dimensions toward mathematics engagement in their orientations. Teachers' orientations reveal some insight about their instructional vision for engaging students with mathematics (Munter, 2014). With appropriate coaching support or collaborative inquiry with teachers who hold similar orientations, teachers may be able to approach enacting teaching in ways that more closely align with their orientations. Alternatively, teachers could learn to take up instructional strategies aligned with additional dimensions of engagement to further develop their practice.

We describe an instructional intervention designed to help teachers engage English learner (EL) students in mathematical problem solving and learn the mathematics register. The "Discursive Assessment Protocol" (DAP) integrates Pólya's classic problem solving framework with research-based instructional strategies that benefit EL students. The research-based instructional strategies are grounded in theories of academic language development. A sample problem-solving episode is provided that demonstrates how an EL student wrote a "multiplication story" involving fractions and what we learned from using the DAP to support him and other EL students develop the mathematics register in English. Among the implications of this study is the value of selecting tasks that are not only worthwhile mathematically, but worthwhile in that they have potential to develop students' mathematics register.

Keywords: Equity and Diversity, Marginalized communities, Problem Solving.

Schools are struggling to meet the needs of English Learners (ELs) in the United States (Borjian, 2008; Valenzuela, 2005). ELs largely enter U.S. schools performing below English Proficient (EP) students in core academic subjects (Abedi & Gándara, 2006) and dropout rates for ELs are considerably higher than EP students (Borjian, 2008; Kanno & Cromley, 2013). Schools experiencing an influx of EL students must adjust to meet these students' educational needs (Barrio, 2017; Irizarry, 2011). In this paper, we describe an instructional intervention designed to help teachers support the mathematical learning of their EL students and how it informed instruction during a problem-solving episode. The "Discursive Assessment Protocol" (DAP) integrates Pólya's (1945/1986) classic problem solving framework with research-based instructional strategies that benefit ELs. The research-based instructional strategies are grounded in theories of academic language development that afford EL students repeated and consistent opportunities to express their mathematical ideas and negotiate meaning with others (Moschkovich, 2013; 2015). The integrated design of the DAP is intended to guide teachers to provide their students with needed supports to learn and use the mathematics register during problem solving episodes.

Since the fall of 2019, we have been working with "Ms. Ware," a 5th grade teacher in an urban school district. A goal of this work has been to examine the DAP as an instructional intervention in Ms. Ware's mathematics classes to understand how effectively it guides her to elicit students' mathematical reasoning and develop their use of the mathematics register in English during problem-solving episodes. In all of her classes, Ms. Ware teaches a high percentage of ELs. She is fluent in Spanish and is devoted to providing her EL students with a high quality education in mathematics. The research question we explore here is: How does the DAP used during problem-solving episodes inform how to support EL students to develop the mathematics register in English?

Background on the Discursive Assessment Protocol

Early iterations of the DAP built upon and were an extension of a clinical interview protocol (see Kitchen & Wilson, 2004; Kulm, Wilson, & Kitchen, 2005). The DAP was designed for use with individual ELs or groups of EL students during mathematics problem-solving episodes, but can also be used with the general student population. During piloting of the DAP with middle school students over the course of two years (2007-09), the DAP guided teachers to provide students with opportunities to ask questions, to be creative, to test and revise their solution strategies, and to explore mathematical ideas deeply (see Kitchen, Burr, & Castellón, 2010; Castellón, Burr, & Kitchen, 2011). Such instruction is a clear departure from instruction historically found in schools that serve high percentages of low-income EL students in which the memorization of math facts, algorithms, vocabulary, and procedures are the focal point of instruction (Kitchen, DePree, Celedón-Pattichis, & Brinkerhoff, 2007; Moschkovich, 2013). Moreover, the DAP is intended to help teachers provide students with opportunities to make sense of the language demands of mathematical problems as well as to provide scaffolded supports for EL students to engage in mathematical discourse to explain their ideas and to listen to and make sense of the ideas of others. As students engage in mathematical discourse, they build on their prior experiences and knowledge to achieve more advanced understandings of mathematical concepts (Ryve, 2011).

Incorporating Pólya's (1945/1986) four-stage problem solving framework, the DAP is designed to be administered during problem-solving episodes involving worthwhile mathematics tasks, ensuring that students have something to talk about (Silver & Smith, 1996). In the example that we provide here, we used a performance assessment task (referred to simply as "task" throughout) that is publicly accessible for free through the Illustrative Mathematics (IM) project. Rich tasks such as performance assessment tasks "engage students in thinking and reasoning about important mathematical ideas" (Franke, Kazemi, & Battey, 2007, p. 234). Though the use of such tasks does not guarantee high-level student responses, cognitively demanding tasks provide the means for teachers to engage students in mathematical discourse in which students are actively sharing their thinking, comparing their solution strategies, making conjectures, and generalizing (Silver & Smith, 1996).

An important goal of instruction for EL students should be amplifying rather than complexifying English language speech or text (Zwiers et al., 2017). This entails providing students with multiple opportunities to understand mathematical ideas and terms by providing support for learning with concrete materials such as manipulatives and mathematical models, engaging students in think-alouds, and using culturally relevant and authentic contexts. ELs need repeated opportunities to understand the problem at hand, not only because English is a second language, but because the learning of mathematics is embedded within the linguistic patterns of academic language development. Academic language has been defined as the linguistic expectations of students to learn, speak, read and write about academic subjects such as mathematics (Schleppegrell, 2004). Discipline-specific registers can further refine academic language. Described as words, expressions, and meanings specific to mathematics (Secada, 1992), the mathematics register is the disciplinary-specific reading, writing, listening and speaking norms of content teaching and learning that is more complex than everyday English. It is helpful to think of the academic register as a series of resources that promote meaning making, or a set of linguistic features, such as words, symbols, and forms (Schleppegrell, 2004). A unique feature of the DAP is that instructional strategies designed to support the development of EL students' mathematics register, also referred to as English as a Second Language (ESL) instructional strategies, are incorporated throughout its four stages, such as acknowledging and using gestures, integrating cognates, revoicing, and incorporating graphic organizers (see Figure 1 below).

1. Understand the problem	
Check for understanding	- Students underline important information in problem - Teachers ask: "What is the problem asking you to do? What do you know that can help you figure this out?" - Students define new words and begin using them in sentences.
Teacher deliberately incorporates ESL strategies	- Students use a picture, diagram, or some type of mathematical representation to concretely model problem.
Teacher maintains high expectations and recognizes students' intellectual assets	- Teachers look for opportunities to highlight students' mathematical ideas with other students.
2. Create a plan to solve the problem	
Students create plan to solve problem	- Teachers ask: "What strategy, representation or tool will work best to solve the problem?" - Teachers assess student understanding of their plan.
Teacher deliberately incorporates ESL strategies	- Teachers integrate graphic organizers and mathematical models during small group instruction and discourse.
3. Carry out the plan to solve the problem	
Teacher engages students in mathematical discourse and meaning making	- Teachers engage whole class in mathematical discourse and asks questions while highlighting student work. - Teachers integrate the mathematics register in discourse and instruction.
Teacher continues to use deliberate ESL strategies	- Teachers use gestures, cognates, revoicing, graphic organizers and mathematical models.
Students refine and revise their solutions	- Teachers do not need to be overly concerned in this stage about students' production of "correct" English.
4. Looking back	
Students reflect on their solutions	- Teachers ask: "Does your solution make sense? How do you know? What questions do you still have at this point?"
Teacher works to help students use the formalized mathematics register	- Students write up their final solution to the problem using the mathematics register.

Figure 1: The Discursive Assessment Protocol (DAP)

The first stage of the DAP involves understanding the task/problem (Pólya, 1945/1986). In this stage, Pólya advocates that students consider a picture, diagram, or some type of mathematical model that could be helpful for solving the problem. Modeling helps EL students learn the mathematics register by touching the objects that represent mathematical ideas and repeatedly hearing and then repeating the words represented by these objects (Garrison & Mora, 2005). After developing a mathematical model to make sense of the problem, students share their ideas with peers to solicit feedback and modify their models. To ensure ELs have repeated opportunities to understand the problem at hand, teachers ask questions during this stage such as "What is the problem asking you to do?" and "How are you going to figure this out?" In this stage, teachers need to define words used in the problem under consideration. In the second stage, students devise a plan to solve the problem (Pólya, 1945/1986). Working in small groups, students share their ideas with peers and their teacher to get feedback on their solution strategies. This process ensures that students have opportunities to reflect upon their problem-solving strategy to determine whether the strategy makes sense. Students need support in this stage to develop self-regulation strategies such as devoting significant time to analyze and plan how to attack the problem similar to accomplished problem solvers (Schoenfeld, 1985).

In the third stage, students carry out their plan to solve the problem (Pólya, 1945/1986). Students have opportunities to share their mathematical thinking with peers and their teacher through mathematical discourse. When possible, the teacher seeks to integrate the mathematics register in discourse and instruction, though does not need to be overly concerned with students using "correct" English. A key in this stage is that the teacher asks meaningful questions and actively works to highlight and build on students' ideas to support students reflecting on their mathematical thinking and errors (Schoenfeld 1985). Instruction should leverage ELs' knowledge in their first language as a means to help them comprehend a second language (Cummins, 2000). To support ELs in particular, the teacher "re-voices" students' explanations, references students' mathematical ideas, and asks clarifying questions. In this manner, the DAP functions as a formative assessment tool, supporting teachers to examine, understand, and leverage students' mathematical ideas and thinking as a means to inform their instruction (Kitchen, 2014). In the fourth stage, students look back at their solutions and check their results (Pólya, 1945/1986). In this stage, the teacher asks: "Does your solution make sense? How do you know? What questions do you still have at this point?" In addition to reviewing and checking their answers, ELs need opportunities to explain their ideas using the mathematics register. In this stage, students explain their problem solutions in writing with the expectation that they will include the mathematics register in their write ups. Having had time to think about, solve and revise their solutions also means students' anxiety level, the affective filter (Krashen, 2009), has been lowered and ELs may have more confidence explaining their ideas in writing.

Research Methodology

Starting in the fall of 2019, our research team (Richard, Libni and Karla) has been collaborating with Ms. Ware to implement the DAP during problem-solving episodes with her two 5th grade mathematics classes. Both of these classes have a high percentage of ELs (20% or more). To date, we have co-taught with Ms. Ware during problem-solving episodes on four occasions. We employed a team teaching approach to co-teach in which instruction was divided up among the four of us (Cook & Friend, 1995; Sileo & van Garderen, 2010). Each problem-solving episode typically lasted between 40 and 60 minutes and involved students solving a performance assessment task. During each episode, we worked to follow the four stages of the DAP as students solved a given task. Primarily in the second and third stages of DAP implementation, all three members of the research team circulated throughout the classroom with Ms. Ware, asking individual and groups of students questions engaging in discourse. Prior to each problem-solving episode, we planned how we hoped to co-teach during the episode, identified questions to ask, and discussed English words and phrases that we hoped to develop during instruction to support EL students' emerging mathematics register. During the problem-solving episodes, we videotaped Ms. Ware and students who had provided consent. At the conclusion of these episodes, we collected all the work students had created.

To illuminate how the DAP informs instruction, a sample student solution to a performance assessment task is provided. Specifically, we highlight how one EL student, "Fernando," solved a given task and how his solution informed us vis-à-vis how to support Fernando and other EL students to more fluently construct English sentences in the "multiplication stories" that they devised. The data used in the example provided came from copies of collected student work samples and from videotapes made during the problem-solving episode. Student work samples and videotapes were interpreted using interpretative methods (Creswell, 2014). The student work samples were initially read or viewed as a whole, followed by a period of open coding to reflect upon and clarify how students were solving a given task and how they used the mathematics register to express their solutions. An iterative process of coding, reflecting upon, and then clarifying what we learned from reviewing student work samples then took place (Miles, Huberman & Saldana, 2013). This process went through multiple revisions as the data were repeatedly read and reviewed to check the consistency of findings. This process continued until either no new categories were developed or consistency was achieved. After we established how to characterize students' solutions to tasks posed, we searched for commonalities and differences across these solutions to further examine how the DAP could be used to inform instruction intended to support the development of EL students' mathematics register. We went through a similar process when reviewing videotapes of problem-solving episodes.

Research Findings

We now offer an example of how through the use of the DAP, we gained insight into how to support the development of an EL student's mathematics register in English during a problem-solving episode. Immediately prior to the problem-solving episode, Karla and Libni led a brief lesson on fractions to Ms. Ware's students. They had students identify unit fractions in both columns and rows of a rectangular whole similar to the rectangular whole displayed in Figure 2. In several exercises, students identified equivalent fractions in diagrams given to them such as 1/5 and 2/10. Karla and Libni also had students identify the fraction created when two of these fractions overlapped, something Ms. Ware had been doing with her students for at least a week prior to this lesson. In addition, students began identifying an equation that could be derived through fraction multiplication. The purpose was to emphasize the meaning of fractions as operator (e.g., 1/4 of 1/3). Following this brief lesson, the four stages of the DAP were administered during implementation of the following IM task shown in Figure 2.

The diagram below represents one whole. 	Problem: Write a multiplication story that could be solved using this diagram with its two types of shading. Explain how your story context relates to the diagram provided (http://tasks.illustrativemathematics.org/content-standards/5/NF/B/4/tasks/2075).

Figure 2: Task Implemented with the DAP

Ms. Ware introduced the task by asking three different students to read the problem out loud to the whole class and give brief explanations about what the problem was asking as a means to check for understanding (first stage of the DAP: Understand the problem). In addition, as planned prior to the lesson, Ms. Ware began asking questions we had collaboratively identified such as *What is the problem asking you to do? What is the whole? What is a multiplication story?* She also checked for understanding of the terms "two types of shading" and "relates." Once Ms. Ware was satisfied that her students, for the most part, understood the task because a number of them could express what the task was asking of them, she moved on to the second stage of the DAP.

Initially working alone, students started devising a plan to solve the task (second stage of the DAP: Create a plan to solve the problem). It was in this stage that Fernando devised a multiplication story involving videogames. In his written solution, he started by making sense of the diagram given in Figure 2; he identified the whole, circling the entire diagram and writing "The Whole." He also identified both of the fractions represented in the diagram (3/4 and 1/5). Lastly, Fernando wrote the following expression that he believed was represented in the diagram: 3/4 x 1/5.

In his write-up (stage 3 of DAP, Carry out plan), Fernando created a story that was mathematically sophisticated involving videogames:

"Sam got to play videogames 1/5 of an hour. After he did his homework he got to play 3/4 of the 1/5 that he played. How much does he play after homework?"

During the third stage of the DAP, teachers engage the whole class in mathematical discourse and ask questions while highlighting student work. Fernando shared his story in his small group. At one point, he also responded to another student's story during a whole class discussion that took place. The language that he used in the context of his story is specific to the operator concept of fraction (e.g., *"he got to play 3/4 of the 1/5")*. The operator subconstruct has two different interpretations, as stretcher/shrinker and as a duplicator/partition-reducer. The difference between the two is that with stretcher/shrinker, the transformation of the fraction results in the same number of units of different size (e.g. 3/4 should be interpreted as 3 x [1/4 of a unit]), and with the duplicator/partition-reducer the fraction result elicits a different number of units of the same size (e.g. 1/4 x [3 units]) (Charalambous & PittaPantazi, 2007). The operator subconstruct can also be considered a function, a set of operations that need to be done to get a result (Lamon, 2007). In this case, Fernando used the duplicator/partition-reducer interpretation.

While Fernando's story is mathematically sophisticated, the clarity of the story could be improved in at least two ways. First, he could modify the second sentence to read, "*After he did his homework, he got to play 3/4 of the 1/5* of an hour *that he had already played*." The inclusion of the phrase "of an hour" in Fernando's sentence clarifies the amount of time that he originally played videogames. Another option is to modify the sentence to read, "*After he did his homework, he got to play 3/4 of the* amount of time he had already played." Secondly, in *"How much does he play after homework?,"* it is unclear whether Fernando is asking for a unit of time (e.g., hours, minutes) or possibly some number of videogames. To clarify, the question posed could be modified to reference a unit of time. For example, the question could be *"How much* time *does he play after homework*?" or *"How* many hours *does he play after homework*?" These potential modifications are examples of sentence frames (Wisconsin Center for Education Research (WCER) (2014). Fernando's story informed us about how sentence frames such as "How __ of __ of an hour" or "How many hours" could have helped him and other students to tell their stories using fluent sentences that included details (Coleman & Goldenberg, 2009). As we progressed through the four stages of the DAP, we came to recognize the complex language needed to develop a multiplication story. Rather than simply devising questions and addressing keywords in this problem-solving episode, Fernando and other EL students would have benefitted from being given sentence frames that they could have applied directly in their stories.

Discussion and Implications

In this paper, we described what we learned from using the DAP during a problem-solving episode to support Fernando and other EL students to develop their use of the mathematics register in English. Fernando created a multiplication story in response to a task that demonstrates his mathematical understanding of the part-whole notion of fractions as well as the concept of fraction as operator (Charalambous & Pitta-Pantazi, 2007; Lamon, 2007). While Fernando's story is mathematically sophisticated, it was also the case that the story could be improved with the addition of a few key phrases. We observed this during the third stage of the DAP when students were presenting their stories to peers and the entire class.

This example demonstrates how the DAP can be a helpful tool to inform instruction about how to support EL students with the linguistic expectations associated with writing mathematics related stories. Specifically, in this case, how the introduction of words and expressions through the use of sentence frames could support the development of students' English language fluency in the domain of mathematics. Undoubtedly, the demands of writing a multiplication story are linguistically complex (Martiniello, 2008). To address this complexity, an implication for instruction is how through the explicit use of sentence frames (WCER, 2014), we could have helped EL students such as Fernando address this complexity by providing them at the initiation of the problem-solving episode with expressions such as "how much time" and "how many hours" that they could have used in their stories.

After observing Fernando's response and other students' responses to the task, we noted the importance of not only identifying potential questions and key phrases and words needed to support EL students during task implementation, but the value as well of identifying potential language supports for students such as sentence frames that students could have used in their stories. The use of the DAP helped us gain this insight. In addition to providing guidance on how to integrate ESL strategies as students worked through Pólya's (1945/1986) four stages of problem solving, the use of the DAP informed us about how to support students' burgeoning mathematics register to construct fluent and detailed sentences involving time.

DISENTANGLING THE ROLE OF CONTEXT AND COMMUNITY IN TEACHER PROFESSIONAL DEVELOPMENT UPTAKE

Karen Koellner	Nicora Placa	Nanette Seago	Grace Yormak
Hunter College	Hunter College	WestEd	The Dalton School
karen.koellner@asu.edu	p798@hunter.cuny.edu	nseago@wested.org	graceyormak@gmail.com

The study presented here utilized a cross case comparison of three different professional development programs to examine the contextual factors associated with uptake related to what teachers learned related to content, pedagogy and the resources used in their professional development (PD) workshops. From a theoretical perspective this study draws on a situative perspective to guide our analyses on how uptake across different PD projects impacted teacher learning. Findings indicate that teachers' perceptions of learning may be associated with explicit goals and intentions of the PD program, their perceptions of community and the relevance of the content, pedagogy and resources provided to their everyday work in mathematics classrooms. Differences were found to be related to where they fell on the adaptive-specified continuum.

Keywords: Research Methods, Professional Development, Teacher Knowledge, Teaching Tools And Resources

One central challenge for the field of teacher professional development (PD) is how to design interventions that target teacher knowledge, while also maintaining a focus on instructional practice and student learning (Jacobs, Koellner, Seago, Garnier & Wang, 2020). A number of researchers have worked to address this challenge and there is now a strong research base delineating critical design features of effective PD (e.g., Borko, Jacobs & Koellner, 2010). The consensus in the current PD discourse about features of effective PD include a focus on mathematics content, student learning of content, active learning opportunities for teachers, coherence, duration, and collective participation (Sztajn, Borko, & Smith, 2017). Although some PD programs that adhere to design recommendations by the literature have produced encouraging results (e.g. Franke, Carpenter, Levi & Fennema, 2001), others have proven much less successful (e.g. Jacob, Hill & Corey, 2017). We believe that context, as well as the nature of the PD on the adaptive-specified continuum, might be key to helping us understand and uncover impact aspects related to how teachers perceive their learning of content and pedagogy as well as their use of resources.

At present, very little is known about the degree to which context impacts teachers' learning from PD. The one area that researchers have focused on and have found some evidence of how context plays a role in teacher learning is social and political contexts of schools and their impact on the implementation and effectiveness of mathematics of PD.

The study reported here goes beyond social and political aspects that impact PD and includes multiple contextual factors related to what teachers take up and implement after participating in a particular PD. The study uses comparative case study analysis to examine three different and distinct professional development programs that are geographically situated across the US, focused on different mathematical content, and different PD structures. We aim to disentangle the role that context plays in uptake of PD content, pedagogy and resources of these three ambitious PD projects by analyzing teachers' perceived uptake in these areas.

Theoretical Frameworks

Situative theorists define learning as changes in participation in socially organized activity (Greeno, Collins, & Resnick, 1996). They consider the acquisition and use of knowledge as aspects of an individual's participation in social practices. With respect to professional learning, situative theorists

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

focus on the importance of creating opportunities for teachers to work together on improving their practice and locating these learning opportunities in the everyday practice of teaching (Ball & Cohen, 1999). All three PDs were designed around this premise. A situative perspective suggests that groups of teachers who take part in different PD workshops using different materials, with different facilitators, and are situated within different educational contexts (e.g., different geographical locations within the United States) might have very different learning opportunities and experiences impacted by the role of context.

PD Model Continuum: Adaptive Through Specified

PD models fall on a continuum from adaptive to specified (Borko, Koellner, Jacobs & Seago, 2011). On one end of the continuum are *adaptive* models, in which the learning goals and resources are derived from the local context and shared artefacts are generally from the classrooms of the participating teachers. In these models, the artefact is selected and sequenced by the facilitator and/or the participating teachers, and the related activities are based on general guidelines that take into account the perceived needs and interests of the group. On the other end of the continuum, specified models of PD typically incorporate published materials that specify in advance teacher learning goals. In video-based specified PD, the video clips are typically pre-selected and come from other teachers' classrooms.

The nature of what teachers take up and use across the continuum has the potential to shed light on factors that are associated with the teacher learning related to content and pedagogy. This study examines three professional developments that fall on different parts of the continuum. The goal is not to determine which types of PD are "best" because each has its affordances and challenges, but rather to better understand the variance of teacher uptake and use within and across these PD experiences. Understanding and deeply analyzing and unpacking variance among and between types of PD offers the potential to identify the factors that impact uptake and use from PD. This paper examines how teachers' self-reported uptake differs across PDs located at different points on the adaptive-specified continuum. Specifically, one is highly adaptive, one is highly specified, and one lands in the middle. We believe conducting a cross case comparison will aid in helping us understand the factors associated with uptake related to content, pedagogy and resources.

Oerview of TaDD Project

This three-year impact study, Taking a Deep Dive (TaDD) is collecting qualitative data from three large U.S. National Science Foundation PD projects in order to use case studies and cross case analysis to further inform what teachers take up and use in different PDs in different contexts and why some teachers appear to take up and use more than others and why some PDs have better results than others. This paper uses a comparative case analysis and focuses on the portion of the TaDD study that investigates self-reported learning related to pedagogy, content and resources taken up and used from the following three NSF PD projects one to two years after the project and funding ended. In the next section, we briefly describe the three different PD projects.

Learning and Teaching Geometry (LTG)

The first NSF project, LTG, an efficacy study of the learning and teaching geometry professional development materials: Examining impact and context-based adaptations, sought to improve teacher's own knowledge and instructional strategies in transformations-based geometry. This PD consists of 54 hours of highly specified video-based PD that is grounded in modules of dynamic transformations-based geometry which is aligned with the Common Core State Standards in mathematics (CCSSM). Through video analysis, teachers work together to solve problems and further their knowledge in mathematics teaching in the domain of geometry. The PD allows teachers to better support students in their attempt to gain a deeper understanding of transformations-based geometry through activities like rate of change on a graph, scaling activities, and similarity tools. The material strongly connects to other critical domains including similarity, proportional reasoning, slope, and linear functions. LTG is a specified PD as the content and pedagogical goals of the PD are clearly articulated for each workshop in the packaged materials.

Lesson Study (LS)

The second NSF project, Collaborative research: TRUmath and Lesson Study: Supporting fundamental and sustainable improvement in high school mathematics teaching (LS), aimed to engage in design research to develop and implement a replicable model for a coherent, department-wide approach to professional learning focused on creating classroom environments that produce students that can be powerful mathematical thinkers. In the PD, teachers work to create lesson plans that are focused and coherent and allow for a deeper and richer understanding of mathematics and the ability to make connections and implement curriculum more effectively. In this project, teachers were taught the *TruMath* framework. This is an observation instrument that can be used to analyze classroom interaction across different dimensions. Teacher teams engaged in LS as a way to work on specific shifts in teaching practice that aligned with the TRU dimensions. LS is an adaptive form of PD that utilized the TRU framework but allowed for teachers' ideas to guide the workshops.

Visual Access to Mathematics (VAM)

The third NSF project, Visual access to mathematics: Professional development for teachers of English learners (VAM), aimed to build skills in mathematical problem solving and communication through the use of visual representations. This PD consisted of face-to-face PD as well as online workshops where teachers implemented problems from the PD and shared their student work to discuss access for English Learner's (EL's) and all students. The project investigated the instructional strategies and supports that teachers of EL's need to provide access to mathematical learning while advancing academic language development. The approach was grounded in the use of visual representations, such as diagrams and geometric drawings, for mathematical problem-solving with integrated language support strategies. The intended goals of VAM were to help teachers to properly select appropriate visual representations for the use of different rational number task types and communication tools to show and explain mathematical thinking. VAM fell in the middle of the adaptive-specified framework as the face-to-face workshops had specified and intentional goals and the online professional learning meetings were guided by the teachers and used artefacts of practice, mainly lesson plans, to guide their discussions.

Methodology

Sixty-six participants from the three NSF projects took a 32-question survey LTG had 28 participants, VAM had 25 and Lesson Study had 13). This survey included questions that asked participants to reflect back on their PD experience and characterize their past and/or current use of the PD content, pedagogy and materials. The survey included seven Likert scale questions, where participants responded to statements on a scale of 1-10, as well as eighteen follow up questions that allowed the participants to explain and provide more details about their numeric response. To analyze the data, we used descriptive statistics and ANOVAs to understand the differences and similarities between uptake by project (LTG, VAM, Lesson Study) with ANOVAs followed by pairwise comparisons. Given the small sample sizes in this study, we report significance levels at the $p<.10$ level as well as the typical $p<.05$ level.

Qualitative responses were coded to move deeper into the data and unpack the quantitative results. Three project researchers coded the qualitative responses to better understand teachers' perceptions of uptake after participating in professional development. The seven Likert scale questions were used as the baseline and the coded eighteen qualitative questions were used to analyze participants perception and vision of uptake from their learning experiences in PD. Finally, we compared the differences among and between programs and present case studies of each project.

Results

We examined one-way differences by project by finding averages of the seven Likert scale questions on the survey. Likert survey questions ranged from 1 (not at all) to 10 (a lot). In comparing the three projects, VAM participants had consistently higher average ratings than LTG and Lesson Study. We found 6 areas that were significant at $p<.05$ and one at $p<.10$. While all three projects reported a high degree of established community within their respective PD experiences, VAM participants reported a stronger ($p<.10$) sense of community than Lesson Study participants. Furthermore, VAM participants reported greater ($p<.10$) use of materials and resources than Lesson Study. Other significant differences include VAM participants reporting higher levels of district support than both Lesson Study and LTG ($p<.05$). Reports of content and pedagogy use, as well as how well the facilitator met the goals of the participants, were significantly higher ($p<.05$) for VAM than LTG.

Table 1: Average teacher survey descriptions of PD uptake and use, by group: means and standard deviations (N=66)

Likert Scale Survey Question: Codes for Likert Scale Survey Questions ranged from 1 (not at all) to 10 (a lot)	LTG (n=28)	VAM (n=25)	LS (n=13)	*p*-value
To what degree, was the community established in your PD?[1]	8.46 (2.12)	9.24 (1.01)	8.00 (1.41)	p<.10
How much did your district support your attendance and implementation of the PD in your classroom?[2,3]	5.21 (3.34)	7.44 (2.62)	4.77 (3.32)	p<.05
How much of the content from your project do you use in your classroom?[3]	5.29 (3.10)	7.24 (2.28)	5.54 (2.67)	p<.05
How much of the pedagogy from your project do you use in your classroom?[3]	5.54 (3.12)	7.56 (1.92)	6.62 (2.90)	p<.05
How much of the resources/materials from your project do you use in your classroom?[1]	4.57 (3.34)	6.16 (2.76)	3.69 (2.72)	p<.05
To what degree was the facilitator focused on the intended goals of the PD from your own perspective?[3]	7.57 (2.67)	9.16 (1.38)	7.69 (2.53)	p<.05
To what degree was the facilitator meeting the needs of the participating teachers?[4]	6.54 (2.72)	8.84 (1.34)	6.46 (2.33)	p<.001

Of the three studies, teachers in the VAM project had higher self-report data on several dimensions related to the uptake of content, pedagogy and resources. In order to better understand specific

1 VAM > Lesson Study, p<.10.
2VAM > Lesson Study, p<.05.
3VAM > LTG, p<.05.
4VAM > Lesson Study and LTG, p<.01.

uptake, we analyzed the qualitative data using a coding manual consisting of 33 codes that span content, pedagogy and resources in general, as well as specific areas such as representations, technology, principal and coach support, facilitator impact and theoretical alignment. Three project staff initially coded three surveys from each project and compared their results, discussed discrepancies and resolved differences by refining and agreeing upon codes.

VAM

Almost all of the VAM participants were able to identify representations from the PD that they used to teach relevant content including ratio, proportion, percent, dilation, and scaling. Additionally, approximately 50% of participants mentioned specific pedagogical strategies such as the Three Read Strategy that they learned in the PD. Participants were also able to describe how they used resources such as specific tasks, applets, and computer-based activities from the PD in their classroom practice. Only two participants didn't respond or identify any specific uptake from the PD. The majority (92%) of the participants responded with an abundance of uptake. One participant explained, "I use the number line as often as I can. I try to help students see that it can be used with multiple patterns as an underlying skill for the double number line." Some participants took up general strategies that could be used across mathematics lessons and others in other content areas. For instance, one person explained,

> "Generally, I've found that using visuals to access mathematics and the conceptual understanding in math has greatly benefited my students. The teaching strategies around using visuals to support understanding is something I use regularly."

In regard to principal and district support, the majority of VAM participants reported high levels of support. Others reported support related to release time. In general, no one reported anything negative related to support. Participants also reported that principals were generally supportive. In terms of community, VAM participants reflected on the collaborative nature of both the on-line and in-person sessions. One participant noted,

> "I felt part of the community at the PD, my voice was heard and mattered. The small zoom sessions were also helpful and supportive. Getting to know and ask questions to a smaller cohort was less intimidating and educational. The moderators were so supportive and helpful and always followed through with any issues that needed follow-up or extra clarification."

Participants also felt they benefited from working on problems together as learners, "As we explored activities and experienced them as learners ourselves, we really opened up to one another and got to know one another."

LTG

Participants reported lower levels of uptake for LTG than VAM. About 50% of participants responded "none" or "nothing" in terms of content they currently use in their classroom. Several noted that this was because they were not currently teaching geometry. The participants who did report content uptake mentioned specific transformation-based content from the PD. For example, one participant noted, "Rotations, translations and dilations are helpful for students to see and visualize different possibilities for real world problems they are interested in solving." In terms of pedagogy, LTG teachers talked about using dynamic strategies that were closely related to the transformation-based geometry content, including the use of manipulatives and representations. Other teachers mentioned more general pedagogical strategies that were modelled by the facilitator of the PD, such as strategies for facilitating discussions, incorporating vocabulary and helping students develop explanations. As one participant noted, "I learned how to let students have a discussion to sort out their own ideas and practice defending their answers. In terms of resources, 75% of participants described how they currently used specific resources, such as patty paper or tasks and activities from the binder they were given at the PD. However, 25% of participants reported that they did not use any resources from the PD. As described by this participant, this may be due to the content or grade level the teacher is currently teaching: "I do not use any of the paper materials that we were given in the binder because it does not apply to 6th grade or is very introductory for 7th grade." In terms of district and principal support, teachers generally responded neutrally, and many stated that the district was not involved and sometimes not aware of the PD. Principal support varied greatly between school sites. Several reported that the principal was very supportive whereas other teachers reported lack of support. In terms of community, most teachers noted that they felt part of the community and enjoyed working on problems and discussing strategies together. For example, one participant noted that there were, "lots of discussion and opportunities to share. All opinions and strategies and thoughts were valued." Another added, "We worked during PD hours together and discussed our shared teaching experiences at other times. The PD leaders made sure everyone felt engaged and included."

LS

The LS project also had much lower responses than VAM when looking at the quantitative findings for each category. LS participants did not perceive that they took up any content. Not one of the respondents referred to specific mathematics content in their responses. Most responded that they didn't have anything to report or that it was not applicable. On the other hand, when responding to pedagogical uptake, many responded positively and focused on different aspects of pedagogy that they took up and new instructional strategies that they were continuing to try to use. Three participants mentioned the TRU framework that was used to analyze lessons related to effective instruction throughout their PD. Other than two respondents that said the pedagogy was not applicable, the positive respondents shared different strategies they took away from the PD. One participant commented,

> "I engage in much more formative assessment with students and I constantly try to elicit more student thinking to determine how students are thinking through problems and then tailoring my instruction to meet students' needs for understanding in real-time. I also think that I am much more focused on the central mathematics and big ideas of a unit or a lesson. This has allowed me to tweak my lessons, so I can make better decisions about which content is ancillary, extension or extraneous."

The other three responses were focused on assessment and questioning. Other LS teachers focused on questioning. For instance, one teacher reported that she has changed, "questioning strategies during a lesson to cultivate student's critical thinking." It is not clear why four out of 13 teachers in the LS program had very targeted pedagogical uptake related to assessment, questioning, and meeting students' needs whereas the rest of the participants found little to respond to related to content, pedagogy and resources. One participant did note, "Developing a focus for the work that applied to all teachers concerns proved to be difficult." In terms of resources, none of the LS teachers reported acquiring or using any resources from the PD. Three reported using some strategies with other teachers in planning lessons. In regard to principal and district support teachers reported a range of feelings from negative to positive but as a whole appeared to fall somewhat in the middle. One teacher might sum this up the best when explaining, "Somewhat? The district didn't play an active role in either supporting us or hindering us." In terms of community, most reported they felt part of the community and several highlighted the importance of the community builders that were done at the beginning and end of each session. However, one reported mixed feelings about their colleagues and community, "There were moments of brilliance during these sessions. Unfortunately, the department, in general, always leaves a bad taste in my mouth because we have a lot of dead weight in our department. It makes everything more difficult"

Discussion and Implications

Teachers perceptions of uptake differed across the three sites. It appeared that where a PD falls on the continuum may have impacted self-report data. VAM, which falls in the middle of the continuum, had the highest self-report data among teachers. The more specified the goals, the clearer teachers were able to indicate whether the PD was useful to the types of mathematics classes they were currently teaching. On the other hand, if the PD was more adaptive and the nature of the goals and intentions were evolving, teachers appeared to indicate quite different aspects of the PD that were relevant to their planning and teaching. If a PD was both adaptive and specified at times, more teachers had positive and similar experiences associated with uptake.

For instance, the VAM PD was specified enough to allow participants to recall and identify specific resources or pedagogical tools (such as double number lines or the Three Reads Strategy) that they could use in their classrooms. It was also adaptive enough that participants had time to think about how to modify the tools and resources that they learned about during the PD. On the other hand, the adaptive nature of LS might have made it difficult for participants to report how they were using the skills they learned because some of the goals and intentions of the program were not articulated during the PD. The goals were evolving simultaneously during the PD as teachers were engaging in developing one lesson plan per cycle for one specific classroom. In addition, teachers may have had a harder time generalizing the relevance from a particular lesson study cycle to their specific classrooms and contexts. The adaptive nature of the LS PD has many more complexities than the other two. For example, the goals and intentions are continually evolving and therefore teachers may take up very different aspects of the PD that are relevant to their teaching. This is unique to adaptive PD because it has the potential to meet teachers where they are at. On the other hand, the specified nature of LTG might have impacted self-report in that if teachers were not teaching transformations-based geometry, they may not have been able to explicitly identify content, pedagogy or resources when they were teaching other content, even if there were underlying connections that could have been made. Many of the LTG teachers were able to identify tasks and tools when asked but at the same time may or may not have found the narrowly focused and specified content relevant to their current teaching. However, the teachers who were currently teaching geometry reported positive levels of uptake because they highly motivated to use and then teach the LTG content with their students.

The nature of the PDs and the ways in which participants felt as if they were members of the community may also influence uptake. The LS PD was the only one of the three where teachers visited each other's classrooms. The impact of visiting classrooms on community needs to be explored as we hypothesize that this may make teachers more vulnerable and may influence their perceptions of their learning. On the other hand, VAM was the only PD that had both an online and in-person community as part of the professional development. This role of this on teacher learning also needs to be explored further. We argue that this self-report data does not indicate whether classroom practice or student learning was impacted. More research is needed on the impact of context on classroom uptake. Case study classroom videotape data and interviews will provide us more information on the classroom uptake of participants in these three studies and will help us investigate the ways in which the three different types of PD have different affordances and constraints on teacher uptake.

SUPPORTING INCLUSION OF STUDENTS THAT TYPICALLY STRUGGLE WITH MATHEMATICS IN COGNITIVELY DEMANDING SMALL-GROUP DISCOURSE

Dr. Kristy Litster
Valdosta State University
klitster@valdosta.edu

This study examined how two small-group discourse types (Reflective and Exploratory) supported the inclusion and enacted levels of cognitive demand of students who typically struggle with mathematics in real-world, task-based assessment activities. The study focused on 11 fifth-grade students within a larger study involving 97 fifth-grade students engaging with 24 mathematics task-based assessment activities. Results showed that students that typically struggle with mathematics were more likely to participate in group discourse during reflective discourse. Additionally, discourse contributions by these students were more likely to be high cognitive demand during reflective discourse. Reflective discourse provided students with time to think through and write down their own strategies which may have increased student confidence and willingness to engage in explaining and justifying their thinking.

Keywords: Cognition; Classroom Discourse; Elementary School Education; Equity and Diversity

Task-based assessments provide educators with an understanding of students' ability to apply their mathematics understanding to real-world situations. Mathematics discourse can also provide a formative assessment of students' cognitive understandings and misconceptions. Research on mathematics discourse is divided on timing - after (Reflective) or during (Exploratory) student engagement with mathematical tasks –to best support the inclusion of all students' ideas. Thus, the purpose of this study was to examine how these two discourse types supported the inclusion and enacted levels of cognitive demand (CD) for students in four Grade 5 classrooms who typically struggle with mathematics, when engaging with 24 task-based assessment activities.

Theoretical Perspective

Cognitive demand is the number and strength of the connections within and between mental networks, or schema, to solve a specific task (Webb, 1997). High student-enacted levels of cognitive demand (HCD) are defined as students' mental actions that require two or more schema connections to make inferences or connections between mathematical ideas or contexts. HCD can promote deeper student understanding of mathematics properties and procedures, increase students' ability to solve related mathematics problems, and reinforce mathematics connections (Stein, Grover, & Henningsen, 1996). This is especially important for students that typically struggle with mathematics.

Multiple factors can influence student-enacted CD when engaging with mathematics tasks. The Discourse and Interpretation Influences on Cognitive Demand Framework in Figure 1 illustrates a few of these factors. The intended CD, the number of connections anticipated for a student to complete a task (e.g., the designed tasks at specific DOK levels in this study), as well as the implemented CD, teacher actions that encourage different student physical and mental actions (e.g., using recall or reasoning), can influence what and how a task is presented to the students (Webb, 1999; Boston & Smith, 2009). However, research shows that students' interpretation of a task primarily influences their enacted CD (e.g., Otten, 2012). Students may enact multiple elements of HCD or low cognitive demand (LCD) in response to a single task (e.g., using recall of facts to support counter-argument).

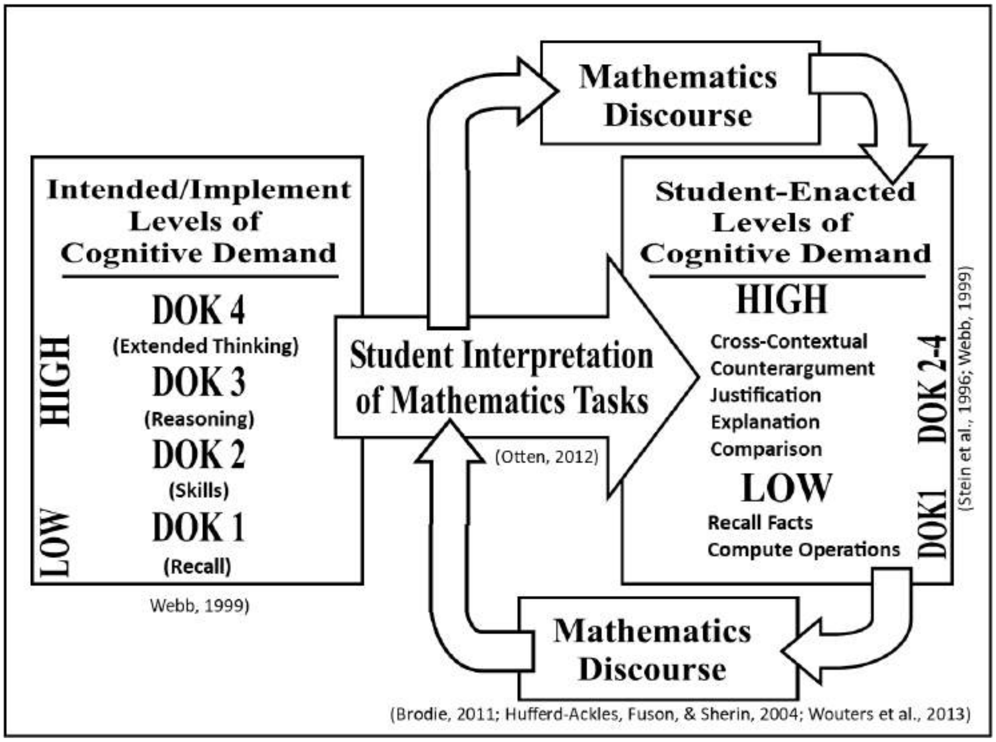

Figure 1. Discourse and Interpretation Influences on Cognitive Demand

As seen in Figure 1, mathematics discourse can influence students' interpretation of mathematics tasks. Mathematics discourse has the potential to increase student-enacted CD by eliciting student participation in HCD actions such as evaluating and reasoning about mathematical properties or procedures (Charalambous & Litke, 2018; NCTM, 2014).

Placement of discourse may also influence verbal and written student-enacted CD. Reflective Discourse takes place after students have engaged with the tasks independently, while Exploratory Discourse takes place while students are engaging with the task. Students' internal discourse and written CD after engaging with Reflective Discourse can influence their verbal contributions towards the social mathematics discourse. Group reflection on differences between verbal contributions, may prompt a change in students' interpretation of the task to develop a more advanced conception of the mathematics task (e.g., Silverman & Thompson, 2008) and may even prompt a change in student-enacted CD. Students' interpretations of mathematics tasks will also influence their verbal contributions towards exploratory discourse as students' personal understandings are negotiated to form a group understanding of the problem (Bruner, 1986; Clements & Battista, 2009; Forman, 2003) and the written CD for the task.

Researchers are conflicted on which placement of discourse is the best. Walter (2018) explains that delaying discourse until students have sufficient time to process the mathematics or write down their own ideas can promote the inclusion of students who might otherwise be ignored, such as typically struggling students. Rojas-Drummond and Mercer (2003) contest that waiting to engage in discourse until after the task is complete results in LCD cumulative talk where students, such as those that struggle with mathematics, simply agree with one dominant idea. Instead, they recommend Exploratory Discourse, which allows students to inclusively discuss relevant information in a timely manner.

Methods

This study utilized a mixed methods research design (Tashakkori & Teddlie, 2010) to answer the research question: How do two types of small group discourse (exploratory and reflective) support the inclusion and enacted levels of cognitive demand (CD) of students that typically struggle with mathematics during real-world tasks?

Participants

This paper focused on 11 of 97 fifth-grade students from a larger study (Litster, 2019). Focus students were identified as typically struggling with mathematics based on self-identification (N=7) during group discourse (e.g., I'm usually wrong/I just don't really get how to do math) or identified with a mathematics IEP (N=4). Six students were identified as English Learners (ELs).

Procedures

Students in four fifth-grade classrooms completed two real-world, task-based assessment activities (12 tasks per set), in groups of two or three. Typically struggling students were in different groups during the study. Students worked collaboratively with a small group on one set, engaging in Exploratory Discourse of solutions and strategies; and individually on a second set, followed by Reflective Discourse of solutions and strategies. Using a crossover design (Shadish, Cook, & Campell, 2002), two classes completed Set-1 with Exploratory Discourse and Set-2 with Reflective Discourse, while the other two classes completed Set-1 with Reflective Discourse and Set-2 with Exploratory Discourse.

Data Sources and Analysis

There were two main data sources in this study: students' written work relating to the mathematics tasks and video/audio recordings of students' interactions and discourse while engaging with the tasks.

The researcher used qualitative magnitude coding to identify and "quantitize" (Saldaña, 2015, p. 86) the enacted levels of CD in students' verbal responses to the mathematics tasks as high cognitive demand (HCD) or low cognitive demand (LCD). Twelve percent of the data were double coded with a relatively high inter-coder reliability (α=0.9212) (Hayes & Krippendorff, 2007). The researcher created frequency tables to compare quantitative results relating to enacted CD. Timestamps from the video data were used to identify time engaged in active mathematics discourse.

The researcher qualitatively coded students' verbal responses using pattern and structural coding to identify patterns in students' actions that seemed to increase or decrease typically struggling students' participation in the small group mathematics discourse

Results

Results found that overall, Reflective Discourse was more likely to support higher levels of cognitive demand in discourse contributions by typically struggling students than Exploratory Discourse. Table 1 shows a comparison of the cognitive demand in student's discourse contributions, based on ability and discourse type.

Table 1: CD of Mathematics Discourse Contributions by Ability and Discourse Type

Mathematics Ability	Reflective Discourse		Exploratory Discourse	
	LCD	HCD	LCD	HCD
Typically Struggling	37.71%	62.29%	50.72%	49.28%
Everyone Else	32.46%	67.54%	29.92%	70.08%

As seen in Table 1, students that typically struggled with mathematics were engaged in HCD discourse for a larger percentage of time during reflective discourse than exploratory discourse. Additionally, there was a smaller difference between ability groups in the percentage of time students engaged in HCD discourse during reflective discourse (5.25%) than exploratory discourse (20.8%).

Reflective Discourse was also more likely to support the inclusion of typically struggling students than Exploratory Discourse. Most groups of students engaged in active mathematics discourse for about 12 minutes per task-set, with an average difference of less than one across the discourse types. However, not every student participated in the discussion for all 12 tasks in each task-set. Table 2 shows the count and average number of tasks where a student remained silent and did not participate in the discussion for an entire task, based on ability and discourse type.

Table 2: Count of Tasks Where a Student Remained Silent

Discourse	Struggling Students (n=11)	Everyone Else (n=86)
Reflective	11 (1.00 per student)	45 (0.52 per student)
Exploratory	57 (5.18 per student)	21 (0.24 per student)

As seen in Table 2, students that typically struggle with mathematics were more likely to remain silent during the discussion of tasks during Exploratory Discourse than during Reflective Discourse. Additionally, there was a larger discrepancy between ability groups in the average number of tasks where a student remained silent for exploratory discourse (5 tasks) than for reflective discourse (<1 task).

Qualitative analyses supported the quantitative results. During Exploratory Discourse, the typically struggling students often said little to nothing during the entire set and were often ignored by their group. For example, the only phrase one student with an IEP, Penny, said while completing a set using Exploratory Discourse was, "You are going too fast." After this comment, her group told her the answers and what to write on her paper after they solved each task. Other struggling students often went without speaking for three or four tasks in a row. Most students who were silent during exploratory discourse appeared to be engaged in active listening (e.g., looking at other students in group and writing on paper in response to other students' comments). However, students who struggled with the mathematics were more likely to disengaged with the tasks completely (e.g., playing with paperclips in their desk).

In contrast, during Reflective Discourse, the typically struggling students were more likely to ask for help. For example, Penny, who talked once during Exploratory Discourse, contributed 19 different times during Reflective Discourse. Most of Penny's contributions confirmed shared answers (e.g., "Yeah, I got that too"); however, occasionally she would ask her group for help or contribute new ideas. An example of this is found in the excerpt below where the group is engaging in reflective discourse after trying tasks 1-3 from Task-Set 1 on their own. In these tasks, students are calculating revenue from movie sales [T1], book sales [T2], and comparisons between the two [T3] for Harry Potter and the Half-Blood Prince.

Wendy: What did you get down here [pointing to T2] cause I didn't finish.
Penny: I am pretty slow writer and thinker so I did not make it down there. But show me what you did.
Wendy: I did .5 million times 12.99. [points to work for 500,000 times 12.99 that is half finished]
Penny: It says round. $12.99 is like $13 so can you just do 13 times 5?
Xander: So I did that and I got 65.

Wendy: So on this one [points to T3], I am pretty sure this is the movie [points to T1] and this is the books [points to T2]

Penny: Paperbacks means books

Wendy: So yea, so up here [T1] is 247.24 million and the highest one here [T2] was just 65 million so I think down here people saw the movie more.

Penny: Yea, I think they saw the movie more. That's [pointing to 247.24 on her page] way bigger than that [pointing to 65 on Xander's paper].

Xander: The price [on the books] was bigger than $7 [price of movie ticket] and the price was bigger but it is a smaller number [total book revenue].

Penny: Yea and I think people don't really like reading any more.

[Video 210H1, 0:31-2:35]

In this excerpt, we can see that, not only is Penny asking for help, her group is willing to explain their answers rather than just asking her to copy them. Additionally, Penny was able to add ideas and strategies to the discussion, such as rounding 12.99 to 13 for an easier computation problem, a comparison to justify an agreement, and a possible context for the lower book revenue. Although no one in the group caught the mathematical error for multiplying 13 x 5 instead of 13 x .5, there was evidence of high verbal CD by all three students: Penny's counterexample for rounding $12.99 to $13, Wendy's justification of why people saw the movie more, and Xander's comparison of the inverse relationship between T1 and T2.

One factor that may help explain the increased discourse and HCD contributions by typically struggling students is that groups engaged in reflective discourse often had one student (not typically struggling) who started the discussion by asking about a task they struggled with. For example, in this excerpt Wendy moved the discussion directly to Task 2 because she struggled to complete her very large (and unnecessary, though mathematically accurate) calculation. Seeing other students struggle may have helped students who typically struggle feel more comfortable asking for help or offering ideas. It also may have helped the other students in the group feel more patient with their explanations because they could point to their work during their explanation or compare their work to the struggling student's work to find where their calculations diverged.

Qualitative analyses also noted a pattern in validation of student ideas. During exploratory discourse, struggling students' ideas were often devalued by other members of their group. However, this was not the case during Reflective Discourse. The following excerpts from the group working with Miguel, a Latino EL student with a Math IEP, provide examples of this behavioral pattern. In this first excerpt, Miguel, Tara, and Ryan are engaging in exploratory discourse to solve task 5 in Task-Set 1. In this task, students are comparing different sources of online movie ratings for Harry Potter and the Half-Blood Prince.

Ryan: So Amazon is 3 3/4, minus iTunes, which is 4.

[Ryan and Tara start to subtract the fractions]

Miguel: It's 1/4

Tara: You have to show your work

Miguel: I just know it

Tara: Then how did you do it in your head? Cause you can't minus that. That would equal 1 ¾ so how did you do that in your head?

Miguel: It's just like . . . [pointing to line plot] .

Tara: [interrupting] If you can't say it then you need to do it.

Miguel: Maybe if you do 4 minus 3 and you get 1 . . . and then minus ¾

Tara: You can't do that or you would get negative. You have to change this to improper fraction and that makes 4/1 and this [points to 3 ¾] makes 9/4 and you have to make a common denominator so this is 16/4 and then you subtract so it's 7/4 and then you have to change it to a mixed number so the answer is 1 ¾.

Miguel: Yours is probably correct.

[Video 460H2, 11:30-13:20]

In this excerpt, we can see that even though Miguel had the correct answer and what appeared to be a valid strategy to get to the answer, Tara's interruption did not give him the time to fully work out his reasoning to support his answer. In the end, Miguel conceded that Tara was probably correct, even though her calculations were incorrect. This pattern of concession was similar among other typically struggling students whose divergent answers or strategies were not valued or explored (e.g., "Okay, you're the smart one, so what's the answer;" or "You are probably right cause you are usually right.").

In this second excerpt, Miguel, Tara, and Ryan each completed Tasks 6-10 in Task-Set 2 on their own and came together during Reflective Discourse to discuss their answers and strategies. In these tasks, students are calculating and comparing production and retail costs for the Diary of a Wimpy Kid book series. In the excerpt from Task 7 below, they are discussing their calculations for possible fractional discounts [e.g. ½] off the rounded retail price [$60].

Tara: So on this one I multiplied and ½ times 60 is 30.

Miguel: I divided.

Tara: No, so you have to multiply. You change this to an improper fraction so 60 is on top of 1 and then 60 times 1 is 60 and . . .

Miguel: [interrupts] But it's the same answer [points to paper].

Ryan: Me too. So 1/3 of 60 is like 20.

Tara: Yep and 1/4 times 60 is 40.

Miguel: It's 15. Cause 40 + 40 + 40 + 40 is more than 60.

Ryan: So 1/5 of 60 is 12.

Miguel: And 60 divided by 10 is 6.

Tara: So 1/7 times 60 is . . . 49?

Miguel: [Shows Tara his division] so it rounds to 8.

Tara: Ok [revises her answer]

[Video 460D2, 2:51-3:54]

In this excerpt, Miguel had a chance to try out his strategies before comparing answers with Ryan and Tara, which may explain why he appears more confident in his answers and in his strategies than he was in the exploratory excerpt. During Reflective Discourse, Miguel was able to show Tara that his strategy produced the same answer as hers on the first few calculations. This may have helped Tara to accept his strategies and answers on the later calculations that did not match her answers. One reason Reflective Discourse was more likely to support the inclusion of typically struggling students may be that it provided students time to think through their own strategies. Miguel was able to conceptualize a unit-fraction discount as a whole number division problem, a strategy that was only used by one other person in the entire study.

One exception to these patterns was Summer, a Native American EL student with an IEP. Summer's group was very patient with her and never took over her work. For example, if Summer said, "I need help," her group would ask, "Which part," or "Would you like to try . . . [specific strategy from class]." Additionally, Summer's group would use questioning techniques such as "Do you remember how [teacher's name] taught us last week?" or "Okay, so what do you need next to be able to do that?" at least three times before offering a specific suggestion for the next step. During both exploratory discourse and reflective discourse, Summer's group waited to continue until Summer was confident in her work. Group support and validation may have provided Summer with the support to ask questions, request more time to complete a task, and offer the occasional strategy to complete a task, regardless of discourse type.

Conclusions

In conclusion, both discourse types elicited HCD discussions such as evaluating and reasoning about mathematical properties or procedures, similar to other research results (e.g., Charalambous & Litke, 2018; NCTM, 2014). However, Reflective Discourse practices were more likely to support the inclusion and HCD discourse contributions of students that typically struggle with mathematics, during the real-world tasks in this study. These results are similar to other research on reflective discourse practices such as Kalamar (2018) who found that by the end of her three-week intervention, 100% of minority and typically struggling students in an intervention class were participating during Reflective Discourse.

Similar to Walter's (2018) findings, wait time may play an important role in increased participation of typically struggling students. Reflective discourse practices allow students time to think through and try out their strategies prior to the discussion. Having a clear train of thought, as well as a tangible artifact to refer to, may have increased student confidence and willingness to participate in the discussion. In this study, students who do not typically struggle with mathematics were more likely to admit when they were struggling with a problem or answer during reflective discourse than during exploratory discourse. This may have also contributed to an environment where the typically struggling students were more willing to ask questions or propose their own ideas.

Finally, the results relating to Summer and her group bring forward the need for future studies relating to group norms, such as those used by Summer's small group, that may support the inclusion of students who are traditionally excluded from small group discourse, regardless of discourse type.

As the field draws to greater consensus around components of productive mathematics classrooms, the need increases to answer questions about how we operationalize and measure these components and how we can actualize such practice in classrooms. This research report shares an analysis from a larger project aimed at describing and quantifying student and teacher components of productive classrooms at a fine-grain level. We share results from this analysis of 39 mathematics lessons with a focus on teacher moves and catalytic teaching habits that characterize these lessons. A cluster analysis identified four profiles of lessons differentiated by the existence of these catalytic teaching habits and subsequent work with student ideas. Further, these clusters appeared to account for differences in student contributions in lessons.

Keywords: Instructional activities and practices

There is general consensus that productive mathematics classrooms are ones where student thinking is integral and student discussion permeates (Jacobs & Spangler, 2017). A mathematics classroom can be conceptualized in terms of the interrelations between student(s), teachers, and content, often deemed the instructional triangle (e.g., Hawkins, 2002). The relationships between these areas can serve to position students towards engagement in meaningful mathematics. In this work, we share an analysis of residue from the instructional triangle measured via the Math Habits Tool (MHT; Melhuish, et al., 2020). The MHT was developed to capture *mathematically productive components* of classrooms in terms of both what teachers and students do in-the-moment. We conjectured that we could categorize different types of mathematics classrooms based on the existence of, and patterns within, habits of mind/interaction (student engagement in mathematics and with each other), catalytic teaching habits (teaching moves to engender student engagement with the content), and teaching routines (teaching structures that position and encourage students as contributors to mathematics).

In order to begin this discussion, we share results from an analysis of 39 lessons spanning grades 4-8. These results illustrate a partition of lessons into four clusters differentiated based on how student ideas were prompted/treated: student ideas are not prevalent and teacher-prompts are limited as well as unvaried (cluster 1); student ideas are in discourse, prompts are more prominent yet unvaried (cluster 2); student ideas are in discourse with varied prompts for student ideas with a focus on expanding ideas (cluster 3); student ideas are in discourse with varied prompts for student ideas with a focus on students engaging with each others' ideas (cluster 4).

Literature Background

Researchers and policy documents alike have identified attention to student mathematical thinking as a key component of mathematically productive classrooms (Jacobs & Spangler, 2017; National Council of Teachers of Mathematics, 2014). In Jacobs and Spangler's (2017) overview of the literature on teaching, they have unpacked this attention into two core teaching practices: noticing students thinking and orchestrating classroom discussion. Classrooms that incorporate these practices

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

provide settings where student ideas serve as the grounds for moving the mathematics forward. Teachers research student ideas, provide space for student ideas to become part of the classroom discourse, and develop a shared community in which students take ownership of mathematics.

These core teaching practices have one commonality: teaching centered on students' mathematical ideas. We have identified four essential purposes for teacher moves related to students' mathematical ideas: engaging students in idea generation, researching student ideas, engaging students in expanding their ideas, and orienting students to each other's ideas. Productive idea generation can be supported through mechanisms such as allowing for private reasoning time (e.g., Kelemanik, et al., 2016) and providing and maintaining high cognitive demand tasks (e.g., Stein, et al., 1996). Researching student thinking occurs when teachers press for sharing reasoning and meaning behind student ideas to allow teachers to attend to, interpret, and decide how to respond to student thinking (e.g., Jacobs, et al., 2010). Expanding ideas then includes prompts for students to justify their responses (e.g., Boaler & Staples, 2008) or reflect on their thinking (e.g., Schneider & Artelt, 2010). The last essential component to a student idea-driven classroom is orienting students' to each other's ideas. This involves bringing student ideas into the public discourse to establish common ground (e.g., Staples, 2007), and asking students to interpret and compare each other's ideas (e.g., Stein, et al., 2008).

Theoretical Orientation and Analytic Framework

The theory underlying our work is that of the instructional triangle (Hawkins, 2002). Hawkins posited that instruction can be viewed through the relationships between teachers, students, and content. Lampert (2001) expanded on this work in analyzing her own practice, noting how instruction occurs through the arrows and introduced that the teacher plays a mediating role on the arrow reflecting the relationship between student and content. Further, Cohen et al. (2003) brought attention to not just "student" but the additional layers of interactions between students within a classroom.

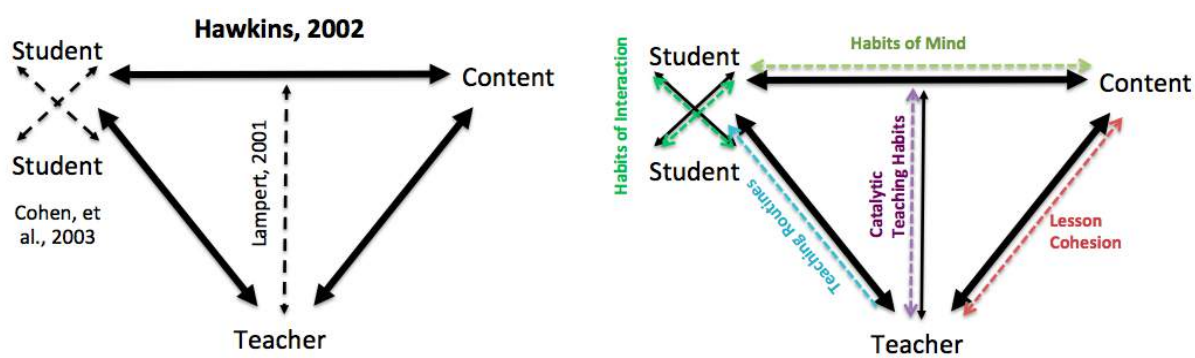

Figure 1: Instructional Triangle and the MHT Framework

In our operationalization of this triangle, we focus on key relationships within those triangles: productive ways students engage in mathematics (habits of mind), with each other around mathematics (habits of interaction), productive teaching structures (teaching routines), and individual teaching moves that can serve to catalyze student productive engagement with mathematics (catalytic teaching habits.) In this report, we focus on the category of catalytic teaching habits (CTHs) as they are both highly observable and play a key role in mediating the relationship between students and content. Recall, CTHs are prompts by the teacher to bring about students' engagement within the lesson and are represented in the instructional triangle by the line, added by Lampert, originating from the Teacher to the line connecting Students to Content. The CTHs can be found in Figure 2 in the Results section. We will also briefly analyze students' habits of interation (HoIs) which relate to communicating mathematical ideas primarly mapped to the Student-to-Student interactions within the instructional triangle. Examples of HoIs include explaining mathematical ideas, critiquing and debating, comparing ideas, exploring multiple pathways, and asking genuine questions.

Methods

For the scope of this project, we are analyzing lessons from two school districts: elementary schools (grades 4-5) from a large urban district and middle schools (grades 6-8) from a mid-size urban district, both in the United States. We are analyzing a lesson at the end of the year from all of the teachers from the middle school group, and a stratified random sample, according to Mathematical Quality of Instruction (Hill, 2014) scores, from the larger set of elementary teachers. Currently, we have coded 39 lessons (19 from 4-5 and 20 from 6-8).

Two trained coders independently watched each video-recorded lesson and qualitatively coded the classroom interaction by interpreting teacher moves and student contributions using the MHT codebook as a guide. The unit of analysis was at the contribution level so a student (or group of students) explaining one idea would be a single unit. Each substantive mathematical contribution from a student(s) would have a single HoI code. Similarly, a teacher press would be a unit. During this process, coders took detailed notes to keep a record of their rationale for assigning particular codes. Then, the two coders met to discuss and reconcile their individual interpretations until agreement was reached. In addition to student and teacher interaction, coders also noted portions of class time spent on whole class discussion (or teacher lecture), small group work, and individual work as well as rated each lesson holistically across a number of categories including *overall teacher* and *overall student*. Each lesson was rated a 1, 2, 3 or 4 within each holistic coding category where 1 represents the lowest rating and 4 represents the highest rating. The *overall teaching* captures the degree to which teacher moves reflect catalytic teaching habits, teaching structures including productive routines (such as selecting and sequencing), and ultimately if teachers prompted students towards justifying or generalizing (a requirement for a score of 4). Similarly, the *overall student* code captured whether students were engaged in math habits of mind and interaction with a scores ranging from no engagement (1), some engagement (2), engagement in many habits (3) and engagement with many habits including justifying or generalizing (4). We calculated Krippendorff (2004)'s alpha for *overall student* at 0.679 and *overall teacher* 0.764, both meeting the acceptable cutoff for reliability.

At the current stage, we focus our detailed analysis on the CTHs. To simplify this analysis, we considered a binary variable for each CTH on each lesson (occurred or did not occur.) We then conducted a two-step cluster analysis using a log-likelihood distance in order to cluster together lessons that were similar in terms of CTH profiles. Four clusters provided a fair classification with each cluster containing at least eight lessons. We further situate these clusters in relation to the summary variables: *overall student* and *overall teacher* scores.

Results

An Overview of CTHs in Lessons

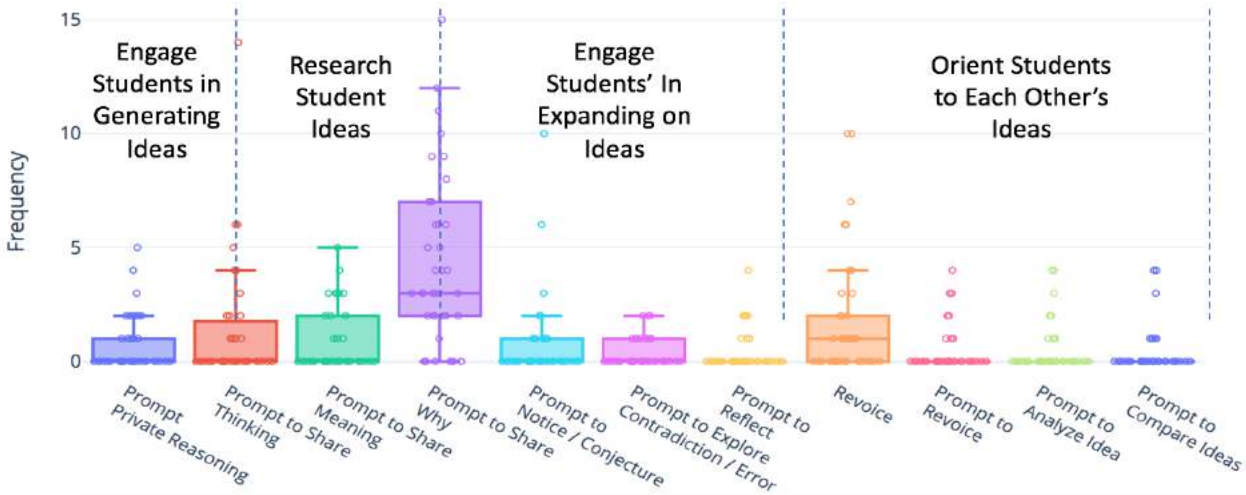

Figure 2: Boxplots Reflecting Frequency of CTHs Per Lesson

An overview of the frequency of various CTHs can be found in Figure 2. This figure contains box plots along with data points (each dot is one lesson) representing the range in frequency for each class. Notice that prompts to *share why* are most common, with well over half of the lessons including multiple occurrences. In contrast, the majority of lessons had zero prompts for students to analyze ideas (see the density of dots at 0 frequency).

Profiling Lessons Based on Types of CTHs Present

Catalytic Teaching Habit	Cluster 1 (14 lessons)	Cluster 2 (8 lessons)	Cluster 3 (8 lessons)	Cluster 4 (9 lessons)
Prompt for Private Reasoning	0%	0%	100%	77.8%
Prompt to Share Thinking	14.3%	25%	87.5%	44.4%
Prompt to Share Meaning	35.7%	0%	75%	44.4%
Prompt to Share Why	57.1%	100%	100%	100%
Prompt to Notice/Conjecture	28.6%	12.5%	25%	44.4%
Prompt to Explore Contradiction/Error	7.1%	62.5%	12.5%	44.4%
Prompt to Reflect	0%	12.5%	37.5%	55.6%
Revoices Student Idea	14.3%	87.5%	87.5%	55.6%
Prompt to Revoice Student Idea	0%	12.5%	0%	88.9%
Prompt to Analyze a Student Idea	0%	12.5%	25%	66.7%
Prompt to Compare Student Ideas	0%	0%	0%	88.9%

Table 1: Percentage of Lessons in Each Cluster with Relevant CTH Occurrence

Table 1 contains the cluster analysis results where the percentages in each cell indicate what percentage of lessons in that cluster contain the given CTH (e.g. 14.3% of lessons in cluster 1 contain a prompt to share thinking). The coloring reflects the density of lessons in that cluster containing that CTH (red: less than or equal to 25% of lessons, yellow: between 25% and 75%, green: 75% or more of lessons). Lessons in cluster 1 tended to have few CTHs with no or few variations in prompts related to students contributing ideas. Lessons in cluster 2 all included at least a basic prompt for a student to share their idea, and most included a teacher revoicing a student idea, pushing student ideas into the classroom public space. Cluster 3 reflected a greater variation in CTHs with the majority containing not just *explain why* prompts, but also general prompts to share thinking and share understanding of a mathematical idea. However, like cluster 2, student ideas were revoiced by the teacher. Cluster 4 reflected less variation in initial idea sharing mechanisms, but substantial prompts for students to engage in each other's ideas. Notice the extremely high proportion of lessons in cluster 4 that contained *prompt to revoice student idea*, *prompt to analyze a student idea*, and *prompt to compare student ideas*. These moves shift the intellectual responsibility back to the students to make sense and engage with one another's ideas.

Examples of CTHs and Corresponding Student Contributions By Cluster

In order to further situate these clusters, we share a representative exchange from a classroom in each cluster.

Cluster 1, Minimal Use of Student Ideas. The following exchange comes from a 7th grade classroom where students were guided by the teacher during a lesson about demonstrating the Pythagorean theorem using pictorial models. While displaying a visual of a right triangle, and pointing to the right angle, the teacher asked:

Teacher: What are we claiming that we have here? [pointing to right angle]
Students: Right Angle

The teacher endorsed the response, by repeating it, and continued with their explanation which included prompts for students to give short answers to teacher questions. This exchange was of a unidirectional nature (Brendefur & Frykholm, 2000) in which the teacher directed the instruction, and students were asked closed questions. Such exchanges typified lessons in cluster 1 in which few, if any, CTHs occurred. Note, an exchange such as this, with short "fill in the blank" style answers, were not categorized as any of the *Share* codes (2nd, 3rd, 4th in Table 1). The MHT codes require a request for more substantive student contributions before such thresholds are reached.

Cluster 2, Some Use of Student Ideas. In cluster 2, the lessons were characterized by *share why* CTHs and teacher revoicing of student ideas. For example, consider the following exchange from an 8th grade classroom that focused on converting between scientific and standard notation:

Teacher: It's in the tens place, but why I'm [sic] adding a zero? (CTH: Share why)
Student: In the tens, the power says two numbers. (HoI: Explain)
Teacher: Oh, very good, it says that there are two numbers. (CTH: Teacher revoice)

In this exchange, the teacher prompted the students to explain why a zero was added into the tens place based on the power. The student provided a short explanation, and then the teacher revoiced the explanation. This interaction was typical within the entirety of the lesson in which the teacher guided the exploration, but requested contributions beyond short answers from students that were then acknowledged/evaluated and revoiced.

Cluster 3, Use and Press for Expansion of Student Ideas. This next exchange comes from a 4th grade classroom during a lesson centered on understanding the definition of a pyramid. A student volunteered the definition as a solid with a polygon base. The teacher began working with this idea:

Teacher: Hmmm, what is a polygon. A square is a polygon. Triangle is a polygon. What makes those polygons? (CTH: Prompt to Share Meaning)
Student: They are closed shapes that have a straight line. (HoI: Explain)

At this point, the teacher prompted the student to repeat the idea, then the teacher revoiced the idea, “straight lines, closed shapes.” The teacher then continued to prompt students to add onto this definition. In contrast to the prior example, the teacher prompt was more than just a prompt to share reasoning, but to connect a student idea to mathematical meaning.

Cluster 4, Presses for Engagement with (and Uses) Student Ideas. The subsequent exchange comes from a lesson about volumes of rectangular prisms in a 5th grade classroom. A student was presenting their solution to a problem that asked them to find volume, and the teacher asked this student to compare their contribution to a previously discussed student strategy:

Teacher: [Student A], how could you tell [Student B] that he actually did something similar, what did he actually use? (CTH: Prompt to Compare Student Ideas)

Student A: Well, he used addition... and it’s basically the same thing because with this like the 3 is kind of like right here and then it would be like 7 times the width like that. (HoI: Compare)

The teacher followed up by restating Student A’s multiplication strategy to explicitly connect to the addition strategy offered by Student B. Having students explain and compare each other’s ideas distinguished cluster 4 from the other clusters.

Situating the CTH Profiles in Terms of Student Contributions

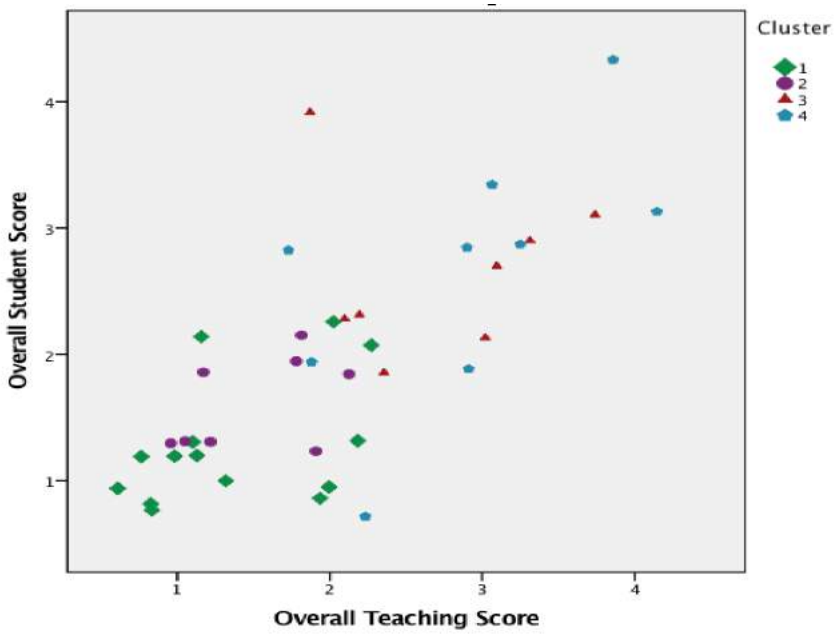

Figure 3: Scatterplot Representing Lessons on Overall Student and Overall Teaching Scores by Cluster. Note: the dots are jittered to be visible.

In order to further situate these results within the whole lesson overall, we explored how these clusters related to *overall student* and *overall teacher* scores (see Figure 3). First, we note that there *is* a substantial positive relationship between *overall teaching* and *overall student* scores as measured via the MHT. An increase in *overall teaching* score was associated with an increase in the odds of higher *overall student* score, with an odds ratio of 2.494 (95% CI, 1.410 to 3.579), Wald $\chi^2(1) = 20.314$, $p < .001$. If we then look at our lesson clusters we can discern that cluster 1 tends to have low ratings for both teacher and student. Cluster 2 includes both low and middling scores on both, and lessons in clusters 3 and 4 tend to have higher *overall teaching* and *overall student* scores.

Figure 4: Boxplots of Frequencies of Student Contributions by Cluster (as reflected by Habit of Interaction occurrences)

Further analysis examines whether these CTH prompts for more student-to-student engagement (as evidenced in cluster 4) actually relates to increased amounts of such interactions by students. A glance at student contributions paints a similar picture (see Figure 4). When comparing the number of occurrences of habits of interaction (HoI; a proxy for student math idea contribution), a one-way ANOVA identified significant differences between clusters ($F(3)=11.1215$, $p<.001$). The average number of student HoI in a cluster 1 lesson was 3.00 (sd=2.386), cluster 2—8.25 (sd=8.892), cluster 3 – 19.875 (sd=10.789), and cluster 4 – 28.889 (sd=19.915). A Tukey HSD post hoc test identified significant differences between cluster 1 and 3, 1 and 4, and 2 and 4. This reflects that variation in catalytic teaching habits seems to correspond to the number of math contributions from students.

Discussion and Future Research Plans

This analysis serves as an initial view into profiles of different mathematics classrooms. In nearly all of our analyzed lessons, teachers pressed for students to contribute to the lesson. However, the nature of these presses and how teachers worked with student ideas varied. We identified two types of lessons that were not characterized by rich use of student ideas: lessons with minimal prompting for mathematical reasoning and lessons in which student ideas were asked for and revoiced by the teacher. We also identified two distinct, productive types of lessons: those focused on generating and expanding mathematical ideas and those focused on engaging students with each other's mathematical ideas. We conjecture that both types of lessons are essential for students to engage richly with mathematics.

The aim of the MHT is to complement existing analyses of classrooms including: qualitatively robust analyses of classrooms (e.g., Stein, et al., 2008; Staples, 2007), and quantitative analysis based on a set of overall scores (e.g., Lynch, Chin, & Blazar, 2017). This existing research base has established the productivity of particular teaching moves in case studies, and that measures of overall quality of instruction can be linked to student achievement. Our work acts as a bridge between the detail of qualitatively analyzing lessons and the power of quantitative analysis of many lessons. By identifying (literature-based productive) teacher moves and student contributions in-the-moment across many lessons, we are able to profile various types of lessons. In this phase, we are creating profiles via the types of CTHs occurring. This is paired with an initial analysis of student contributions that reflect a high degree of relationships between CTH lesson profile and student contributions.

Through the course of this project, we plan to enrich and expand these initial profiles by including more than twice the number of lessons presented here and incorporating further information about student discourse. For example, this initial analysis reveals that the presence of CTHs can statistically cluster lesson types; that these lesson types are related to correlations between higher *overall teacher* scores and higher *overall student* scores. For example, lessons in cluster 4 are associated with high *overall student* scores as well as included more CTHs prompting student-to-student interaction, and nearly 10 times as many student HoI codes when compared to cluster 1 lessons. Furthermore, the student codes for habits of mind (HoMs), of particular interest to many educators, could be further linked to specific CTHs as well as to larger teaching routines. Focusing primarily on HoIs, we have not discussed HoMs in detail in this report. Where HoIs focus on the existence of student contributions and interaction, HoMs focus on the mathematical practices embedded within those interactions. For example, a student can share their thinking (an HoI) and within that exchange can make reference to a graphical *representation* as well as generate a *conjecture* (HoMs). The skeleton of such a relationship is building—CTHs are denser and more varied within clusters 3 and 4 and lessons in those clusters are largely associated with high *student overall* codes. Furthermore, clusters 3 and 4 also reveal far greater frequencies of student HoI codes.

In our next phase of analysis, we plan to expand out the components in the cluster analysis, move towards a distance metric that is non-binary to account for frequency, and begin cluster analysis leveraging the timing of the teacher and student contributions. We look forward to further exploration of the mechanisms that may promote more student interactions and deeper student engagement with mathematics.

PRACTICES OF FACILITATORS WHEN PLANNING MATHEMATICAL MODELING ACTIVITIES IN AN INFORMAL SETTING

Adewale, A.S
Montana State University
adewaleadeolu@msu.motana.edu

This qualitative study used Yinger's (1980) process model to investigate mathematical modeling facilitators' planning practices. Four university-based facilitators planned and implemented mathematical modeling tasks during a summer camp for middle and high school youth. Analysis of interviews and planning documents revealed that in the problem-finding phase, facilitators engaged in joint work (brainstorming) and used necessary resources (social, material, and conceptual) and prepared lesson plans. In the second phase, facilitators elaborate on the instructional ideas they had generated at the problem-finding stage. Finally, in the third phase, they categorize their solutions as successful or not and could either add to their repertoire of knowledge (routinization) or go through the process all over to come up with a refined solution. Strategies employed by participants in this study extend our knowledge regarding the facilitators' practices at the planning phase of modeling activities

Introduction and Background

Mathematical modeling, an emerging branch of K-12 mathematics learning, is a process by which mathematicians develop and use mathematical tools to represent, understand, and solve real-world problems (Lesh and Doerr 2003; Ang, 2004). Students do not always see connections between life and mathematics and miss opportunities to apply what they learn in mathematics to the situations around them (Tran & Dougherty, 2014; Verschaffel, De Corte, & Vierstraete, 1999). Mathematics teachers play a significant role in making students see the relationship between mathematics and the real-world through effective teaching.

Effective teaching is a product of a well-planned instructional process. Efficient planning is essential in teaching mathematical modeling because of its demanding nature for teachers during its implementation. This demanding nature occurs because teaching is more open and less predictable in modeling situations (Carlson, in press; Cai, et al., 2014). During planning, teachers anticipate and prepare to respond to students' mathematical ideas, questions, and challenges. They consider strategies students are likely to use, develop responses to them, as well as strategies that might be productive to highlight during the lesson (Smith & Stein, 2012).

Purpose of the Study

This study describes the planning practices of four facilitators (faculty members) of modeling activities during a summer camp for middle and high school youth. This study will provide insights for researchers who are working to understand how facilitators plan and implement mathematical modeling activities, especially in an informal setting. In this study, an informal setting refers to the modeling environment where activities are independent of the class curriculum, age, or grade. Research questions investigated are: What problem-finding strategies do facilitators exhibit when planning modeling activities? How do facilitators elaborate, investigate, and adapt these strategies in their planning of modeling activities? How do facilitators evaluate these strategies?

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Conceptual Framework

Yinger (1980) identified three stages of planning: the problem-finding, problem formulation/solution design, and implementation, evaluation, & routinization. He theorized that the problem-finding step is the discovery of a potential instructional idea that requires further elaboration at the problem formulation stage. At the formulation stage, the dilemmas from the problem-finding stage are continually expounded and verified mentally until a desirable solution is obtained through elaboration, investigation, and adaptation. The planner relies on their repertoire of methods for solving problems during elaboration and investigation phases. Yinger viewed the implementation, evaluation, and routinization phase as part of teacher planning, and this is where the formulated solutions are tried out and assessed. Whatever the outcome is at this stage, successful or not, it forms a basis for knowledge and experience for future planning.

Methodology

Setting and Participants

This study is a part of a larger project focused on rural youth learning to use mathematical modeling to investigate issues in their home communities. Twenty-nine youth and nine adult mentors from six rural communities participated in a summer camp where they worked on modeling activities. The facilitators were the participants for this study, and they are all university mathematics teacher educators and researchers on the larger project.

Data Collection

Data sources included planning documents of modeling activities during camp and semi-structured interviews with the four participants. See modeling activities in Table 1.

Table 1: Description of modeling activities at the summer camp

Task	Description	Purpose
Cookie Task	This activity allows youths to decide what chocolate chip cookie is "best." The problem springs from a real-world situation, and its solution allows approaches from many perspectives.	• To use qualitative attributes in a mathematical model - How do we deal with a primarily qualitative question like "best" in mathematical modeling.
Agent-Based Modeling	This activity models some complex systems in the world. For instance, modeling a population involving healthy and sick people and how the system evolves with time.	• To learn how a technology-based approach could be used to model a real-life scenario—for instance, using NetLogo to model sick and healthy people.
Mapping Activity	Activity that enables modelers to create representations of their lived experiences in map format.	• To know the importance of maps and realize how values effect info stored on maps.

The planning documents for these activities were studied and used to develop an interview protocol that served as the primary data source. I conducted an average of 60 minutes of semi-structured interviews with each participant roughly 18weeks after the camp. I coded the transcripts, organized the codes into themes, and then organized the themes around phases of the process model.

Data Analysis

I commenced the analysis by looking at lesson plans facilitators prepared for camp activities. Essential keywords that captured the initial analysis of facilitators' intentions formed the basis for the interview protocol developed for the interview. These keywords include activity goals - modeling goals, mathematics goals, & statistical goals; resources for facilitation; modeling practices; anticipated challenges and strategies to respond; and modelers' exploration. I organized raw data from participants' interviews to make sense of the contents and then conducted open and axial coding (Corbin and Strauss, 2007). Then I looked for connections that linked categories of codes to the three phases of process model: problem-finding, problem formulation; Implementation, evaluation, and routinization.

Results

I organized the findings of this study by the three stages of the process model to provide a holistic understanding of the data collected.

Problem-finding

When planning modeling tasks, facilitators engaged in joint work (brainstorming). They used social, material, and conceptual resources, prepared lesson plans and relied on teaching experiences. They also embraced multiple perspectives, constructed questions to launch the activity, guessed modelers' ability, and considered the interest of modelers. Sally, in her words, said: "Theresa and I met and kind of just worked through it. Furthermore, during the prep week, actually doing it and getting feedback from there helped us figure out more details of how we are going to facilitate it." Facilitators also conducted ethnographic research about modelers' environment and their interest in understanding youth characteristics. About the Agent-Based Model, Edward said:

> One of the groups talked a lot, during our ethnographic research in their community, about physically closing off some lanes of traffic and one of the ways that you can understand or make predictions about that is through an agent-based model.

Knowledge and past experiences of facilitators interrelate with teaching goals and materials (resources) when finding instructional ideas for a new modeling task. Edward described how his previous experience with Agent-based Modeling directed him to locate the right human resource who helped out in his planning.

> I have some familiarity with the Agent-Based Modeling from doing it in some of my classes as a graduate student. Nevertheless, it was not really on my radar. Here is what happened, Kelvin, who was sort of founding participant in this project, is vast into technology. One of the technologies that he was thinking about was agent-based modeling, which made sense to me because I had experience with it.

When giving an account on how her background knowledge with modeling interrelates with the teaching goals when preparing for the cookie task, Isabella, said the following:

> Thus, the cookie task – we thought of a few reasons for choosing it. One is that we thought it was something that would be fun and low stakes for the first night of camp. We thought that it would be something that all students know something about it. Moreover, we also thought that it was an activity that would facilitate work through a lot of the modeling cycle.

These scenarios show how facilitators discover potential instructional ideas for efficient planning. These ideas are then elaborated at the problem-formulation stage of their plan.

Problem formulation

At the problem formulation stage, knowledge and experiences of facilitators played essential roles. Their past experiences enabled them to anticipate what modelers might do on the tasks. To do this efficiently, they needed to elaborate on the instructional ideas they had generated at the problem-finding stage. At this stage, elaboration means creating a suitable response to the ideas discovered in the problem-finding phase. Isabella described doing this via deep thought: "As a team, we thought deeply about kind of different knowledge bases they might bring to bear on problems, especially their local problem-solving practices."

When elaborating, facilitators perceived their roles like that of a "coach" who gives support Theresa recounted that her role is to set modelers up to interpret the real-world to their mathematical world with little or no help from the facilitator. To achieve this, facilitators needed to anticipate modelers' behavior during Implementation. They narrated that modelers bring different initiatives to modeling space, a situation that facilitators must speculate when planning.

Implementation, evaluation, and routinization

Implementation, evaluation, and routinization is the last phase in the instructional planning process. In this phase, facilitators try out solutions developed at the problem-solving stage. Facilitators in this study did this through the preparation week preceding the camp week for evaluation. Sally gave the following response to a prompt: “And during the prep week, actually doing it and getting feedback from there helped us to figure out more details of how we are gonna facilitate it.” At this stage, facilitators considered solutions to be successful or not. If successful, they would add the solutions to their repertoire of knowledge (routinization). Otherwise, they would iterate the process for a refined solution.

Discussion and Conclusion

This study sought to document facilitators' planning practices of modeling activities. From the results and analysis, I found some practices to be general to facilitators in this study. These results suggest that facilitators build on their previous facilitating knowledge to anticipate what modelers would do. The facilitators paid attention to modelers' interests and what they care about when engaging in problem-solving. Facilitators also considered how modelers would engage with the task and think about multiple perspectives modelers would bring into the modeling space. Facilitators anticipate what modelers will do and will not do on a task and identify where and when modelers might deviate from a better approach to solving a task.

For this reason, facilitators thought about modelers' possible approaches to solving modeling tasks. Facilitators considered necessary resources to accomplish tasks and considered multiple perspectives in their approaches by brainstorming with colleagues to anticipate what modelers would do in various dimensions. Finally, they thought about questions modelers could ask and then prepare some canned responses. This study agrees with Munthe & Conway (2017) on how planning involves shared knowledge construction and professional learning. This study also finds that planning is a process of preparing a framework guiding teachers' actions. As Young (1998) found what teachers do at planning to include identifying content, developing a timeline, identifying goals, skills, and objectives, deciding on instructional materials and so on, this study finds that facilitators of modeling identified settings, resources, and teaching goals as necessary when planning modeling tasks. As this study took place in an informal setting, findings herein may not necessarily be generalizable to a curriculum-based classroom but can be helpful. For future work, researchers may consider investigating facilitators' planning practices in a formal setting. The findings from this study are productive strategies that could be reproduced by researchers, especially in an informal setting.

EXPLORING TEACHERS' CONSTRUCTIONS OF EQUITY IN MATHEMATICS EDUCATION: AN ECOLOGICAL APPROACH

Megan Brunner
Oregon State University
brunnerm@oregonstate.edu

Research in mathematics education over the recent decades has resulted in a large number of definitions, conceptual framings, and operationalizations of what it means to do equitable teaching. An exploration of the activity system of equitable mathematics teaching is necessary to synthesize current literature and to work from teachers' current understandings of equity in education. A systems-approach to exploring equitable mathematics teaching is necessary to capture how individuals navigate structures of culture, power, and privilege to engage in equity work. We must re-center the voices of teachers to understand how they construct notions of equity in mathematics education. The object-constructions held by teachers inform their goals for instruction, which then influence the types of instruction enacted in classrooms.

Keywords: Equity and Diversity; Instructional Activities and Practices; Instructional Vision; Systemic Change

Equity research in mathematics education has only grown in the last few decades, resulting in a variety of perspectives on and definitions of equitable mathematics teaching and learning. The PME-NA Equity Statement captures a broad swath of framings: "include ideas ranging from access to educational resources, to positioning students as capable and humans as valid sources of knowledge, to questioning the curriculum and high stakes assessment practices, to promoting critical social justice perspectives of mathematics as sociopolitical." These variations in definitions and resultant frameworks guiding practice exist for researchers as well as practitioners. It is critical to clarify how teachers define equity, for this "directly relates to how we seek to both measure and achieve it in our schools" (Gutiérrez, 2002, p. 152). Teachers work within classrooms, school departments and districts, and broadly as part of the professional community, to achieve equitable mathematics teaching. Explicating how teachers construct their understandings of equity and social justice provides context for unpacking the goals they hold for instruction.

Researchers have explored teacher identities in the classroom and how that impacts attention towards equity and social justice in schools, broadly, or pedagogy, locally (Wager, & Foote, 2012). Others attend to what teachers are disposed to notice in classroom interactions (Edwards, 2011; Hand, 2012) or the orientations that drive decision-making in instructional moments (Schoenfeld, 2010). One's personal experiences, values, and beliefs influence the ways teachers engage in the profession, especially around equity work (Gutierrez, 2002; Wager & Foote, 2012). Commentaries on the roles power structures, in the form of culture (Louie, 2017, 2018), race (Martin, 2009), class, and whiteness, among other social identifiers the perpetuate hierarchies of inequity, explore how the teaching and learning of mathematics is inherently situated within systems that privilege certain perspectives of the discipline (Rubel, 2017). Although there is a rich body of research on equity in mathematics education that focuses on teacher conceptions and identity, and a separate but equally fertile body of literature on equity in mathematics education that addresses issues of power and oppression, literature that attends to both is still emerging. Reed & Oppong (2005) worked with teachers on their definitions of equity, noting how race and class influence how equity is carried out in practice. Bartell (2013) explored how teachers' goals for instruction may align with goals for social justice. While these arguments are critical, we must consider how systems interrelate with activity on an empirical scale to understand how these relationships play out within instructional

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

settings, departments and districts, as well as interactions among members of the profession. A common implication for future scholarship across these studies explicates this need: a call for systems-focused research on *equitable mathematics teaching* that investigates how structures of power and culture interact with teachers' goals for instruction and their resultant practice (Louie, 2018).

Systems-focused research would target the integration of micro-, meso-, and macro-environments that influence how teachers make sense of and work towards more equitable forms mathematics teaching and learning. Bronfenbrenner states, "studies of learning should take into account the social ecology that forms the context for human activity. An ecological approach considers the development of an individual in relation to the "immediate environment, and the way in which this relation is mediated by forces emanating from more remote regions in the larger physical and social milieu" (1979, p. 13). Teachers' commitments to equity may draw upon their personal experiences in and outside of the classroom environment, as well policies or practices held as normative within their school organization, understandings of the field of mathematics educators interested in social justice work, and broader understandings of the ways societal hierarchies of power and privilege shape teaching and learning for individuals. An ecological approach frames ones' experiences within the cultural and historical milieu that make meaning through personal and professional commitments to equity and how one acts in service of those commitments.

Theoretical Framework

I leverage Engeström's (1987) Cultural-Historical Activity Theory (CHAT) as a way to capture how teachers navigate interlocking systems to engage in the activity of equitable math teaching. Activity "involves people operating jointly in a persistent system of relations with other people and institutions," asking us to conceptualize equitable mathematics teaching as something which is constantly developing through the joint work of teachers with others in the community (Foot, 2014, p.9). Communities are not defined by proximity, but span place and space in pursuit of some shared values or goal (Wenger, 1998). Members of an activity system identify a specific need, or an object, that drives collective action. In this instance, we consider the collective of teachers across the profession actively oriented towards the object of equity in mathematics education.

Objects and Object Construction

The motivating need, or object, of an activity system is a complex idea that cannot be explicitly identified or captured, but rather, shifts and expands as actors within the system work to achieve it. An object is worked-towards on an individual level, by subjects setting and achieving goals through actions. Individuals within the activity systems may hold varying constructions of the object under focus that shape the goals they set (Engeström, 1987). For example, some teachers may consider equity in mathematics education as the equitable distribution of opportunities to learn, while others may prioritize curriculum that are relevant to students' lives (Bartell, et al., 2008). Engeström (1990) notes that the historical development of object-constructions - in this case, what equity in mathematics education has looked like and meant throughout time - affords and constrains how teachers perceive of and engage in it, including the resources and conceptual tools they take up to guide their work. It is also important to note the teacher's personal experience can include their learning journey, professional experience, their positions within power structures, and environmental characteristics of their classroom, school, and surrounding contexts (Foot, 2014).

A teacher's object-construction of equity in mathematics education informs their goals for instruction. Goals may directly or indirectly relate to the object-conception held by the subject; for example, a teacher whose object-conception of equitable mathematics teaching is that of Teaching Mathematics for Social Justice (TMfSJ) (Gutstein, 2006), which includes the use of socio-political mathematical tasks in the classroom as a key component, their goal might be the implementation of a particular curriculum across the year. Another goal for that teacher may be incorporating reflective questions and discourse into their mathematics tasks so that students can engage actively in reading the world using mathematics. Both of these goals are tangible, actionable steps the teacher can work to achieve that serve the object-conception of engaging in TMSJ. The object as each individual has constructed it will lead to different actions within the activity system. Unpacking the ways teachers construct equity and social justice in relation to mathematics teaching and learning provides opportunities to clarify how they move towards instructional goals that align or contradict those intentions (Bartell, 2013).

The research question explored in this presentation is part of a larger study that attempts to explicate the activity system of equitable mathematics teaching. Foot (2014) comments that "understanding an activity system requires understanding its object" (p. 10); thus, to understand the object of equity in mathematics teaching, we must first explore how teachers involved in the activity system construct their object-conception and related goals for teaching. Thus, this session explores how teachers committed to equity and social justice construct the object of equity in mathematics education. Further, how do teachers draw upon micro-, meso-, and macro-levels of educational systems in their constructions and resultant goals for instruction?

Methodology

This study collaborates with secondary math teachers committed to equitable mathematics teaching to understand how they construct the object of equity in math education. Participants are mathematics educators at a non-profit educational organization for rising middle school students in the Bay Area. This program's mission is explicitly oriented towards creating equitable educational spaces for students, and this mission is a key factor in hiring. Educators in this organization have made an explicit commitment to equitable teaching through their employment status and program-offered professional development opportunities to reflect on their teaching and inequities in education. All participants are licensed educators, yet their experiences teaching in a non-traditional learning environment offer considerations for disrupting existing educational systems and transforming spaces for learning towards more equitable ends (Freire, 2000; hooks, 1994; Martin, 2009).

The participants engaged with questionnaires and follow up interviews to explore their commitments to equity in teaching mathematics. The questionnaires provided a baseline operationalization for how each teacher constructs equity in mathematics education and how they see it play out in an ideal classroom setting. A series of three interviews following the questionnaire allowed opportunities to probe for more detail and to have participants explain their experiences and perspectives that inform their object-construction. Each interview, and subsequent analysis, attended to a different layer of micro-, meso-, and macro-level ecological systems. Analysis of the data included iterations of structural coding and inductive thematic coding (Auerbach & Silverstein, 2003). First, data from both sources was linked for participants and segmented by topic, which provided context for codable instances and captured detail on the ways teachers saw equity issues in their practice. Next, I applied structural codes, noting when teachers drew upon micro- (such as classroom tools or norms), meso- (like site or program policies for mathematics teaching), and macro-systems (for example, the resources available in the broader professional community for TMfSJ or ideological systems like racism or whiteness) as they construct and work towards goals for equitable mathematics teaching and learning. I coded all teacher responses, allowing their language to drive the creation of themes for how teachers in the activity system of equitable mathematics teaching construct the object of equity. Across these codes, trends emerged that outline the landscape for how teachers make sense of equity in their practice. Throughout this process, I continuously engaged in member-checking with participants to accurately amplify their voices and regularly constructed memos to process my positionality and understandings of participant experiences (Auerbach & Silverstein, 2003).

Findings and Discussion

The study is ongoing, and thus, there are no clear themes to report as of yet. However, the expectation is that teachers generally conceptualize equity in ways that have been previously discussed in the field, though not consistently explicitly linking to the frameworks with which their constructions of equity are aligned. Teachers describe aspects of equity in mathematics to contextualize how these constructions are worked upon in practice, connecting to their goals for mathematics teaching and learning. These goals will provide nuance to aid in explicating how equitable mathematics teaching is understood and taken up by committed practitioners, including understanding the tangible goals for instruction each is oriented towards. Finally, these responses illuminate how teachers recognize, draw upon, and negotiate concentric systems of education. For example, how might one teacher's construction of equity in mathematics education as a status concern between students, drawing on the work of Complex Instruction (Cohen & Lotan, 1995) (macro-) align or contradict with departmental expectations for tracking students into courses (meso-) or their instructional strategies for inviting classroom discourse (micro-level).

This session contributes to the field of research on equity in mathematics education by centering teachers' constructions of equity and attending to how these constructions shape and are shaped by their goals for instruction. The lens of Engeström's (1987) CHAT provides opportunity to highlight ecological systems teachers work within as they negotiate their practice. I draw explicitly on notions of objects and object-constructions to understand how teachers committed to equity in mathematics education makes sense of this driving object and how their constructions are both similar and different. Further, I consider the link between one's construction of equity in math education and the goals they hold for instruction to understand how teachers are acting towards their object-conceptions. These results provide a more nuanced understanding of how teachers take up the work of equitable mathematics teaching within their educational contexts.

This research is part of a larger study that aims to articulate the activity system of equitable mathematics teaching. As objects are one of the centering tenets of an activity system, it is paramount we begin describing the activity system with the collective themes for how teachers construct equity in mathematics education. Future goals of this research include understanding how teachers committed to equity work towards their goals for instruction, employing equitable mathematics teaching practices and navigating systems in their disruptive action. This study will support grounding research on equitable mathematics teaching in the lives and work of teachers committed to equity. I also claim that the systems-level approach will bring light to the contradictions and tensions across everyday professional practice, which in turn opens space for professional development, restructuring of school policies, and future research on equitable mathematics teaching to explicate and reduce these challenges so that the field can more successfully move towards our object of equity in mathematics education.

PRESERVICE TEACHERS' PERCEPTIONS OF DEPICTIONS OF MATHEMATICS TEACHING PRACTICE WHEN ENDURING INDIVIDUAL CHARACTERISTICS ARE INTRODUCED

Lawrence M. Clark
University of Maryland
lmclark@umd.edu

Blake O'Neal Turner
University of Maryland
bclark37@umd.edu

Kristyn Lue
University of Maryland
kriselue@umd.edu

This study investigates the extent to which the introduction of enduring individual characteristics of students and teachers in depictions of teaching practice produces systematically different responses from preservice teachers. Enduring individual characteristics include characters' skin tones, names, and descriptions of the school and school community. Fifty-six preservice teachers were randomly assigned to one of two survey depiction formats: one including enduring individual characteristics of students and teachers. Teacher practices and student problem solving were held constant across both formats. Results indicate that, for several survey items, participants responded differently depending on the survey depiction format they were assigned. Interpretations of results suggest that enduring individual differences may be of critical importance to include in rich media resources utilized in mathematics teacher education.

Keywords: Teacher Beliefs, Teaching Tools and Resources, Teacher Education - Preservice

Purpose of the Study & Guiding Framework

Online, rich media platforms are transforming the ways individuals across a range of professions are prepared and practice. One such platform, *LessonSketch*[1], allows mathematics teacher educators and preservice teachers to develop and engage with materials where users can create, share, and discuss scenarios that represent classroom interaction (Herbst & Chieu, 2011). Initial uses of LessonSketch deliberately provided depictions of teaching practices absent of individual characteristics. As Herbst et al. (2017) describe in prior work, *LessonSketch* characters were nondescript characters whose role was to depict practice rather than individuals. However, later updates to the platform began to incorporate contextual markers in teaching classrooms, such as skin tone, hairstyles, and body size. Furthermore, Herbst et al. (2017) describe the differences between the original, generalized depictions in earlier versions of LessonSketch as *enacted individual differences* (e.g. facial expressions, body orientation), and the updated contextual markers as *enduring individual differences* (e.g. body size, race, gender, or class).

The introduction of the option of incorporating enduring individual differences in depictions of instructional practice allows for the opportunity to explore the complex nature of the role of enduring individual differences in preservice teachers' perceptions of classroom interactions. While teachers may outwardly and consciously hold beliefs that all children can learn mathematics, a life immersed in the social discourse of gender, racial, and wealth hierarchies may lead them to rely on enduring individual differences in their interactions with students in ways that teachers may not be aware (Clark, Whitney, & Chazan, 2009). This study aims to explore the instability of the relationship between teacher resources, instructional practice, and student learning due to a host of normative, instrumental, and situational factors that influence a teacher's affective and cognitive resources in

varied and specific racial contexts and at particular moments in time (Chazan, Herbst, & Clark, 2016). Our research question for this exploratory study is: *Do preservice teachers systematically respond differently to rich media depictions of mathematics classrooms when enduring individual differences are introduced?*

Methods

Our research question has important sub-questions. As we seek to investigate whether the introduction of enduring individual differences produces systematically different responses to depictions of teaching practice we also want to know, if so, where? And, which teacher practices produce different results? Further, we contend that enduring individual differences such as skin tone may contribute to systematic differences due to implicit bias (Greenwald & Krieger, 2006). It should be noted that this study is an exploratory one; the broader research questions we provide cannot be answered substantially through this study alone. Further work and refinement are necessary.

Participants were presented with scenarios of mathematics classroom interactions. The design of scenarios and survey questions was guided by several frameworks utilized in teacher education, mathematics teacher education, and mathematics education research (Hiebert, 1986; Martin, 2000; McKown & Weinstein, 2008; National Governors Association, 2010; TeachingWorks, 2020). Participants then answered 120 questions related to the scenarios. Participants were randomly assigned to view and respond to a format of the scenarios with one of two different degrees of individuality: *enacted only individual (henceforth enacted) difference and enacted and enduring (henceforth enduring) individual difference.* Enacted individual difference depictions (Figure 1) do not contain any visual or descriptive markers such as skin tone of students and teachers; enduring individual difference depictions (Figure 2) contain such markers. The depicted students' mathematical thinking and students' mathematical practices are held constant across both formats. The depicted teacher's instructional practices are also held constant across both formats. Twenty-eight preservice teachers responded to the enacted individual difference survey format and 28 preservice teachers responded to the enduring individual difference survey format.

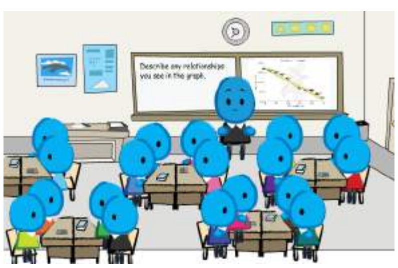

Figure 1. Enacted Individual Difference

Figure 2. Enduring Individual Difference

The survey consisted of three sections: a division scenario, a multiplication scenario, and questions related to school and classroom context. The majority of survey questions were measured on a 6-point Likert scale (from strongly disagree to strongly agree).

Results

Results are indicated in the tables below. The items contained in the tables refer to items where preservice teachers assigned to the enacted difference form responded significantly differently to the preservice teachers assigned to the enduring difference. In Tables 1 and 2, items are grouped by the extent to which they focus on teacher practice or student thinking.

Table 1. Division Scenario

Scenario 1: Students are placed in pairs and assigned division problems. Student A uses a non-traditional algorithm and Student B is confused. The teacher interacts with the pair of students and encourages them to practice the traditional algorithm. Student B raises questions suggesting that he has some conceptual understanding of the nontraditional division algorithm.

Survey Format		Enacted difference (Blue skin tones)		Enduring difference (Brown skin tones)		Mann-Whitney U
Perceptions of Teacher Practice		Mdn.	Mean	Mdn.	Mean	Sig.
Q20	The teacher is effectively setting up and managing small group work.	3	2.75	2	2.18	0.038
Q30	The teacher is effectively checking for student A's procedural understanding of division.	3	3.04	2	2.25	0.015
Q31	The teacher is effectively checking for student B's conceptual understanding of division.	2	2.46	2	1.71	0.007
Q32	The teacher is effectively checking for student B's procedural understanding of division.	2	2.39	1	1.57	0.001
Perceptions of Student Thinking/Cognition		Mdn.	Mean	Mdn.	Mean	Sig.
Q26	Student B is likely to do well on the division problems on the chapter test.	2	2	3	2.82	0.003
Q41	For each student, indicate if they are most likely above level, on level, or below level-- Student B*	0	0.18	0.5	0.54	0.011

* Q41 was measured on a 3-point scale, from below-level (0) to above-level (2)

Table 2. Multiplication Scenario

Scenario 2: Students are placed in pairs and assigned multiplication problems. Student D uses the traditional algorithm. Student C computes answers through use of the partial product method. The teacher acknowledges that partial product method but encourages both students to use the traditional algorithm for efficiency and accuracy on the test.

Survey Format		Enacted difference (Blue skin tones)		Enduring difference (Brown skin tones)		Mann-Whitney U
Perceptions of Teacher Practice		Mdn.	Mean	Mdn.	Mean	Sig.
Q53	The teacher is effectively managing small group work	3	3.29	2	2.68	0.030
Q70	The teacher should review the traditional algorithm to multiplication with all students.	5	4.71	4	4.21	0.036
Perceptions of Student Thinking/Cognition		Mdn.	Mean	Mdn.	Mean	Sig.
Q76	Student C was likely assigned as the helper in the group.	2	2.21	2.5	3	0.036

Table 3. School and Classroom Context

School and classroom context: Participants are asked to respond to questions related to how they perceive aspects of the school and classroom.

Survey Format		Enacted Difference (Blue skin tones)		Enduring Difference (Brown skin tones)		Mann-Whitney U
		Mdn.	Mean	Mdn.	Mean	Sig.
Q86	Do you think this is most likely a 3rd, 4th, 5th, or 6th grade class?*	4	3.75	4	4.11	0.014
Q88	I would feel comfortable teaching this class.	5	4.71	4	4	0.003
Q89	I would feel comfortable teaching at this school.	5	4.54	4	3.64	0.001
Q90	I would want access to instructional support if I were teaching this class.	5	4.64	4	3.86	0.006
Q91	I would want access to instructional support if I were teaching at this school	5	4.75	4	3.79	0.000

*Q86 was measured on a 4-point scale, from 3rd grade (3) to 6th grade (6).

Discussion

The results of this study suggest that, for several survey items, preservice teachers' perceptions of depictions differ when the depiction formats vary by the inclusion or exclusion of enduring individual differences of depiction characters. In particular, preservice teachers perceived that teachers' practices associated with the management of small group work and checking for student understanding was less effective when brown skin color tones of characters were introduced to the depiction. Furthermore, preservice teachers were more likely to assign a higher grade level to characters with brown skin tones. Lastly, preservice teachers reported that they would be less comfortable teaching the class or in the school when brown skin tones were introduced. Overall, findings suggest that further exploration is needed to better understand if preservice teachers' perceptions are influenced by the introduction of enduring individual characteristics, and, further, if influenced by the introduction of specific racialized enduring individual characteristics such as brown skin tones.

INSTRUCTIONAL TENSIONS FACED WHILE ENGAGING HIGH SCHOOL GEOMETRY STUDENTS IN SMP3 TASKS

Kimberly Conner
University of Northern Iowa
kimberly.conner@uni.edu

Brooke Krejci
Winona State University
brooke.krejci@winona.edu

This study engaged HS geometry students in the reasoning-and-proving process through the use of novel tasks aligned with Standard for Mathematical Practice (SMP3) (construct viable arguments and critique the reasoning of others). The tasks facilitated opportunities for students to engage in SMP3 by (a) proposing a conjecture; (b) drafting an argument for their conjecture; (c) critiquing each other's arguments; and (d) revising their arguments based on peer feedback. In this study, we describe the instructional tensions that surfaced during the implementation of the tasks and the way the teacher addressed those tensions in her class (Berry, 2007). The two most common tensions were between action and intent when launching the tasks and between telling and growth during the draft and critique phases. Findings raised important questions of how to support students in learning what counts as a mathematical conjecture or critique.

Keywords: Instructional activities and practices, Reasoning and Proof, Instructional Vision

Introduction and Purpose

The Standards for Mathematical Practice (SMP) articulate eight domains of mathematical thinking students should gain expertise in across K-12 grades (National Governors Association [NGA] Center for Best Practices & Council of Chief State School Officers [CCSSO], 2010). Specifically, SMP 3 states that students should "construct viable arguments and critique the reasoning of others." Historically, constructing formal deductive arguments (proofs) has been restricted to high school geometry courses (Herbst, 2002). Proof tasks in commonly used U.S. Geometry textbooks provide opportunities for students to engage in some aspects of SMP3, such as posing a conjecture, constructing a proof, investigating a statement, and developing a rationale (justification) for mathematical claims with varying degrees of frequency across categories (Otten, Gilbertson, Males, & Clark, 2014). In contrast, the textbooks analyzed provided relatively few opportunities for students to find a counterexample and did not explicitly ask students to respond to the reasoning of others or construct arguments with the goal of communicating to their peers. Although Otten and colleagues (2014) did not report the percentage of textbook exercises where students were asked to engage in multiple forms of reasoning-and-proving activity within the same task, the differences between categories suggests that students are not consistently engaging in the multifaceted process described in SMP 3.

The purpose of this study was to implement a series of novel tasks designed to engage high school geometry students in the reasoning-and-proving process (Stylianides, 2007) in alignment with the multifaceted approach described in SMP 3. Specifically, the tasks were novel in that students were asked to (a) propose and investigate their own conjecture instead of one provided for them; (b) critique each other's arguments; and (c) revise their argument based on peer feedback instead of teacher feedback. In this preliminary study, we analyze the instructional tensions (Berry, 2007) that arose when implementing the tasks. In doing so, we contribute greater insights into challenges that classroom teachers might face when navigating across classroom cultures, towards one that is centered around students' mathematical ideas instead of one based on ideas presented by the teacher or textbook.

Theoretical Framework

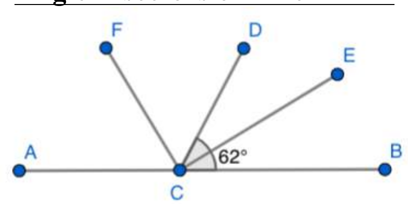
Teacher's instructional decisions are shaped by their personal knowledge and beliefs as well as their obligations to a variety of stakeholders, including the mathematics discipline, individual students, interpersonal dynamics in the classroom, and their broader institutional context (Herbst & Balacheff, 2009; Herbst & Chazan, 2003). Tensional dilemmas, or tensions, surface when there is a contradiction between their beliefs, knowledge, and obligations such that there is no clear decision that adequately addresses all of their concerns (Lampert, 1985). Some teachers choose to prioritize one obligation over another, while other teachers, such as Lampert (1985), instead try to manage the tensions through instructional decisions that reduce the dilemma without completely resolving it. For example, Berry (2007) described six instructional tensions she experienced in her role as a teacher-educator: telling and growth; confidence and uncertainty; action and intent; safety and challenge; valuing and reconstructing experience; and planning and being responsive. Although instructional tensions have been described across multiple contexts (e.g., Berry, 2007; Herbst, 2003; Rouleau & Liljedahl, 2017, Webel & Platt, 2015), more research is needed with respect to teachers' experiences when enacting the Standards for Mathematical Practice (SMPs).

Methods

Instructional Sequence

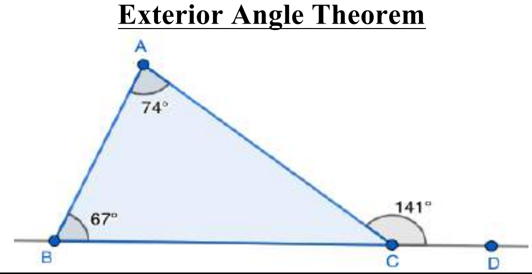
The tasks used in this study were developed with the goal of engaging students in multiple facets of SMP3. Two of the tasks had been previously implemented with secondary students (Conner, 2018); the remaining three tasks were constructed using similar design principles. Each task allowed students to develop a conjecture about a geometric relationship involving an infinite class of objects. The diagonals of a parallelogram and classes of similar polygon tasks also allowed for students to pose and investigate multiple correct conjectures (see Figure 1).

Angle Bisectors of Linear Pair



Given: $\underline{CE}$ bisects $\measuredangle BCD$; $\underline{CF}$ bisects $\measuredangle ACD$

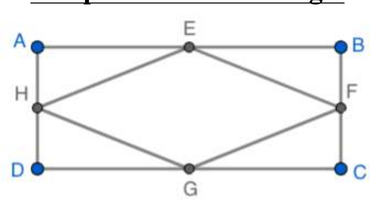
Exterior Angle Theorem



Diagonals of Parallelograms

Draw a few parallelograms on your paper. Draw in the diagonals. Make a conjecture about the diagonals of all parallelograms.

Midpoints of a Rectangle



What quadrilateral is formed when you connect the midpoints of a rectangle?

Classes of Similar Polygons

After describing what it meant for all quadrilaterals to be similar, students were asked to conjecture which classes of polygons (e.g., squares) were all similar to one another.

Figure 1: SMP3 Tasks

The teacher launched each task by posing a scenario for students to consider through the use of a verbal description or a computer-generated representation. Students then formed an initial conjecture about the generalization of the relationship. Next, the teacher either discussed the individual/group conjectures with the class and had all students prove the same conjecture or students proved their own conjecture without a whole-class discussion. For example, students wrote a proof for their own conjectures about the diagonals of a parallelogram. Their conjectures included: diagonals are congruent, diagonals are perpendicular, diagonals create two pairs of congruent triangles across from one another, and diagonal intersect at each other's midpoint. Students worked individually or in small groups to develop a draft argument proving or disproving their conjecture. Once draft arguments were completed, students exchanged papers and provided feedback to one another. Students then drew on their initial arguments and peer feedback to complete a final draft of their argument. The task concluded with a whole-class discussion around how to prove one of the conjectures, which drew on ideas from students' written work. In instances where there were multiple student-conjectures, the remaining ones were discussed in class but not proven.

Context

The study took place in three geometry classes, all taught by the second author, located in a rural high school in the Midwest region of the United States. Proof-writing was a regular part of instruction, with proofs written weekly in class and, less frequently, assigned as homework. Each task was completed in 1 – 1.5 class periods (roughly 60 - 90 minutes).

Data and Analysis

Data for this study consists of a HS geometry teacher's oral reflections after each of the five tasks (see Figure 1). During the reflection process, the first author asked open-ended questions, such as "How do you think the task went?" and "What issues arose during the lesson?" Since the classes were not video recorded, the teacher consulted students' written work and was read portions of the researcher's field notes to help recall what happened.

Using Berry's (2007) framework, the researcher coded the teacher's reflections after each task for the instructional tensions that surfaced and then looked for themes across tasks. Next, the researcher qualitatively coded the reflections for instances where the teacher described how she navigated the identified tension during the lesson. In order to establish trustworthiness and reliability, the researcher and teacher conducted a member check on the themes and how she addressed the identified tensions in her teaching (Lincoln & Guba, 1985).

Findings

Action versus Intent

The teacher's goals (intent) was to provide students with opportunities to engage in different facets of SMP3 and improve their proof writing skills. Her goal for students to pose and investigate their own conjectures resulted in tensions regarding how to introduce the tasks in a way that did not undermine this goal. For instance, after noticing that students had relied on examples during a previous task, she described questioning how to introduce the diagonals of the parallelogram task in a way that would encourage students to generalize past specific examples.

> I was so hesitant. I didn't want to label the angles. And I didn't do one [diagram] as a class collectively. Trying to get them *again* to generalize past the examples, cause now that I had that experience with, 'oh, they just draw in examples'… how to word my language to try to get them to move that way initially, and not waiting until the revisement [discussion] period.

In this task, the teacher's actions at the beginning of the task did not undermine her goal to have students form conjectures. Instead, having students construct multiple examples and discuss their conjectures in small groups resulted in them realizing on their own when a conjecture was false.

During the exterior angle theorem, the teacher ultimately launched the task in a way that guided students towards the specific angle relationship, despite her goal of having students pose their own conjecture. The teacher initially told students to "make a conjecture about the exterior angle of a triangle and its interior angles". This resulted in the student conjecture that $m\measuredangle ACB$ and $m\measuredangle ACD$ added to 180°. Recognizing that their conjecture would not result in meaningful reasoning-and-proving activity, the teacher and researcher decided to guide students towards the anticipated angle relationship using a series of questions about what the students noticed in the diagram. "We had a purpose, so at that moment it was less about individual student and more about whole class so we could move forward" (Teacher).This tension between focusing on the intended mathematical content and allowing students to engage in the SMP3 process using their own conjectures was present throughout the lessons.

Telling versus Growth

Throughout the draft and critique phases of the lessons, the teacher experienced tensions between giving students direct feedback or guidance and allowing them to discover and improve their arguments on their own. For example, when a group's draft argument did not match their conjecture, the teacher struggled to make sure she was not saying "too much to them," hoping other groups would notice and provide that feedback. When a student asked if they could create a drawing to prove their conjecture, the teacher struggled to respond while also being "very conscientious of not saying that they were right or wrong." During the critique phase, the teacher felt like she had to encourage students to write down their questions and comments and "give them permission to be critical" when providing feedback to their peers.

The teacher used the whole class summary as a way of resolving prior tensions to directly address issues in students' work related to their justifications, precision in language, and generality of their arguments. She drew on students' ideas throughout the proof construction process to show she valued the thinking they did in the previous lesson phases.

> I remember trying to think of how to tie in what they were doing to what I was saying. So you guys used examples and this is how we go further. […] I remember trying to draw on what they did, so that it didn't seem like a waste of time.

Across the lessons, the teacher prioritized students' growth and voice during the beginning parts of the lesson. During the summary, she built on students' comments while also making sure the argument encompassed all cases and used mathematically precise language.

Implications

Teachers, often implicitly, navigate tensions throughout their lessons as a result of competing obligations that surface (e.g., Cohen, 1990; Herbst, 2003). In this study, the specific tensions surfaced in part due to a desire for students to have ownership in all stages of the tasks. When preparing teachers to incorporate SMP3 into their practice, it can be helpful to acknowledge these potential tensions and support teachers in reflecting on how they might navigate them in their class. Although the tensions experienced were not specific to the novel task used (see e.g., Rouleau & Liljedahl, 2017), the focus on SMP3 surfaced additional questions around how to support students in developing understanding of what counts as a mathematical conjecture or useful critique. Specifically, to what extent should teachers intervene when students pose conjectures that will limit their reasoning-and-proving opportunities (e.g., a conjecture that is a direct application of a definition)? What are ways teachers can support students in providing meaningful critiques? How can teachers balance the tension between developing students' understanding of proof and providing opportunities to engage in the different facets of SMP3?

MATHEMATICS INSTRUCTORS' ATTENTION TO INSTRUCTIONAL INTERACTIONS IN DISCUSSIONS OF TEACHING REHEARSALS

Lindsay Czap

In our project, we develop curricular materials to support prospective secondary teachers' development of MKT and provide professional development (PD) opportunities for instructors who will teach with these materials. In this paper, we examine the ways in which mathematics faculty engage in the teaching rehearsal debriefs included in the PD to answer the question: To what instructional interactions do instructors of mathematics content courses attend during rehearsal debriefs enacted in PD? Findings show that mathematics instructors attend to all types of interactions but attention is influenced by instructors' mathematical knowledge.

Keywords: Mathematical Knowledge for Teaching, Teacher Education – Preservice

Purpose of the Study

The preparation of secondary mathematics teachers spans content and pedagogy, and includes development of mathematical knowledge for teaching (MKT; Ball et al., 2008; CBMS, 2012; AMTE, 2017). However, teachers perceive a disconnect between tertiary mathematics experiences and secondary teaching practice (Goulding et al., 2003; Ticknor, 2012; Wasserman et al., 2018; Zazkis & Leikin, 2010). To address this disconnect, the MODULE(S^2) Project (Lischka et al., 2020) has designed educative curricular materials (Davis & Krajcik, 2005) to be implemented in undergraduate mathematics content courses, including those often taught by mathematicians (Murray & Star, 2013), that situate mathematical content in pedagogical settings and utilize high-leverage teaching practices (e.g., Ball et al., 2009). To provide support for instructors implementing the materials, the project organizes professional development (PD) opportunities in which instructors receive support in enacting elements of the materials with which they may be unfamiliar. One tool used in the MODULE(S^2) Project PD is teaching rehearsals with group debriefs (Ghousseini, 2017).

Although there is much literature regarding PD with K-12 mathematics teachers (e.g., Farmer et al., 2003; Loucks-Horsley et al., 2010), there is less known about how tertiary instructors interact with and take up PD. The purpose of this paper is to draw on the experiences of the MODULE(S^2) Project PD in an exploratory case study (Yin, 2014) to develop more understanding of PD with tertiary instructors. We address the following research question: To what instructional interactions do instructors of mathematics content courses attend during rehearsal debriefs enacted in PD?

Theoretical Perspective and Framework

We define *instruction* to be the "interactions among teachers and students around content, in environments" over time (Cohen, et al., 2003, p.122). Calling upon Lampert (2001) and Cohen and colleagues (2003), these interactions can be modeled by an instructional triangle (see Figure 1), which demonstrates the interactions between teachers, students, and content.

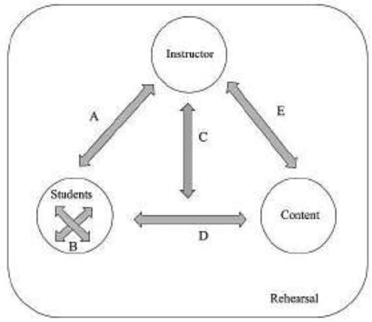

Figure 1: The instructional triangle

Approximations of practice (Grossman, et al., 2009) are useful in supporting teachers to gain experience with and knowledge of the various interactions demonstrated in the instructional triangle. One such approximation is a teaching *rehearsal* in which novice instructors are engaged in the "deliberate practice of well-specified instructional activities" with support from knowledgeable others (Ghousseini, 2017, p. 191). Teaching rehearsals provide instructors the opportunity to engage in approximations of future instruction supplemented by knowledgeable feedback. Ghousseni concluded that the structure of these rehearsals provided prospective secondary teachers the opportunity to "improve their performance in response to feedback that drew on mathematics and student learning of mathematics" (p. 198), bringing together the development of teaching practice and understanding of content knowledge. We build on Ghousseini's work with rehearsals and guided debriefs in the context of PD with tertiary instructors and assert that teaching rehearsals and debriefs may similarly provide opportunities for mathematics instructors to develop teaching practice and content knowledge needed for the preparation of prospective secondary teachers.

Methods and Modes of Inquiry

Contexts, Participants, and Data Sources

The participants in this study were three mathematics faculty from different undergraduate institutions who were engaged in PD for the implementation of MODULE(S^2) Project materials for an algebra content course. Henceforth these mathematics faculty will be referred to as *participants*. Data collected for this study includes video recording of the three teaching rehearsals, video recording of the respective three debriefs, artifacts from the rehearsal lessons, and reflections from the participants.

During a teaching rehearsal, one participant takes on the role of *acting instructor* and the remaining participants take on the role of *acting students* (i.e. the prospective teachers in the undergraduate courses in which materials will be implemented). During a teaching rehearsal, the acting instructor prepares a lesson from the MODULE(S^2) materials and teaches for approximately 10 minutes. These ten minutes of rehearsal are video recorded, then immediately played back to all participants. Following the viewing of the recorded rehearsal, a facilitator from the MODULE(S^2) project conducts a debrief in which participants discuss what occurred in the recorded lesson. For this report, we focus on the videos of these debriefs.

Three teaching rehearsals occurred during the PD, giving each participant the opportunity to serve as an acting instructor once and as an acting student in the other two rehearsals. The lessons chosen for the three rehearsals were respectively on the concepts of inverse functions, the covariational view of functions, and relations. The general goal of the rehearsals and debriefs was to develop instructors' skills in enacting the high-leverage practices embedded within the curriculum materials. Thus, our goal was for instructors to focus on interaction C in Figure 1.

Analysis

Two researchers separately coded each debrief video using a priori codes based on the instructional triangle framework and then came together to reconcile their coding. We categorized every statement made by participants during the debrief as referencing interaction A, B, C, D, or E as labeled in Figure 1. To clarify the coding, consider the following vignette from the debrief of the rehearsal on the topic of covariational and correspondence view of a function:

> During a discussion regarding the clarity of a hypothetical secondary student's quote in the lesson materials, the acting instructor comments that they did not realize that the quote could be misleading until one of the acting students pointed out its obscurity. In reaction to this comment, an acting student stated a way in which they had misinterpreted the quote during the rehearsal lesson. A second acting student followed this with an insight into this misleading quote that they discussed with a fellow acting student during the rehearsal.

Using the categories of interactions indicated in Figure 1, the acting instructor's statement would be coded as referencing a category C interaction, the first acting student's statement as referencing a category D interaction, and the second acting student's statement as referencing a category B interaction. We describe the trends that emerged in codes across the three debriefs to reveal evidence of participants' attention to aspects of instruction during the debrief discussions.

Results

During Debrief 1, participants discussed a rehearsal in which the acting instructor taught a lesson on the topic of relations and their inverses. The debrief began with an acting student commenting on how the acting teacher's use of precise mathematical language when discussing the definitions of range and codomain could, "promote students' mathematical precision." A second acting student shifted the conversation toward how the acting instructor used both table and ordered pair representations of relations during their lesson. The acting instructor replied, "our goal [in the rehearsals] is to have multiple representations." The same acting student continued by asking if the discussion of defining the domain and codomain sets "had emerged as a consequence of [their] discussion" during the rehearsal. "Yes...this comes up all the time when I talk about functions and relations...I think that it is really important" replied the acting instructor. Participants continued the discussion of leveraging student reasoning by pointing out that the acting instructor had written a suggested incorrect answer on the board. "Was the teacher giving enough space?" the acting instructor asked the group, wondering if students had enough individual thinking time during the rehearsal, as the debrief concluded.

In Debrief 2, participants discussed a rehearsal in which the acting instructor taught a lesson on how a secondary student may think about the topic of correspondence and covariational views of functions. "I really liked how the instructor asked 'why, as a teacher, would it be important to figure out their reasoning?'" an acting student commented to begin the debrief. "The teacher kept a complete poker face and let us go with that," a second acting student pointed out when the acting students incorrectly categorized the hypothetical student's view of a function. Some confusion as to whether this categorization was actually incorrect arose from this statement. For the remainder of the debrief, the participants discussed the acting instructor's and acting students' conceptualizations of the difference between a correspondence and covariational view of a function. "I guess the 'co' in covariation and correspondence means that you have to look at both variables," the acting instructor responds to an acting student claiming that correspondence only requires reasoning with one variable.

In the final debrief (3), participants discussed a rehearsal in which the acting instructor taught a lesson on the topic of graphs of relations. "I liked...having the chance to have individual thought...before getting into groups," an acting student began the debrief. They then pointed out a moment in which the acting instructor admitted to the acting students that they were unsure themselves of the answer to these questions. The acting instructor responded that they wanted to explore the questions with a "level of authenticity." During the rehearsal, the acting instructor posed a question that encouraged the acting students to think about the differences between the definitions of a graphs of a relation and of an equation, which acting students said "seemed open ended." "You said 'let's look at an example'," an acting student pointed out an instructional decision to move the lesson forward. The acting instructor then stated that they aimed to collect "helpful student comments or quotes that [the instructor] can then revisit." From this, the participants discussed how they know when it is appropriate to use different teaching strategies. Table 1 displays how our coding reflected the discussions in these three debriefs.

Table 1: Instructional Triangle Coding Counts for the Debriefs

	A	B	C	D	E	Content
Debrief 1	4	0	11	3	6	0
Debrief 2	1	2	21	7	2	13
Debrief 3	4	0	12	0	5	1
Total	9	2	43	10	13	14

Discussion

This study aimed to build knowledge concerning the aspects of instruction to which tertiary instructors attend during debriefs of teaching rehearsals enacted in PD. Our data shows that instructors participating in debrief discussions attended to each component of the instructional triangle, with the majority of the discussions attending to interaction C (how the instructor interacts with students and content together), which was the goal of the PD. However, in one debrief (Debrief 2), the instructors lack of comfort with the mathematical content superseded the ability to focus on student thinking. Instead, attention focused on the content itself. These results show that if the participating instructors are developing necessary content knowledge, this may influence the focus of attention during the debrief.

This work demonstrates that teaching rehearsals are a useful tool to engage tertiary instructors in discussions of student thinking. Further, these results point to the need to structure PD in a way that first supports participants content knowledge development prior to requesting participants to focus on student thinking. Similar research in other content areas is needed to identify concepts for which a focus on student thinking will be best supported by first supporting instructors' content knowledge.

ORCHESTRATING BOTH STUDENT AUTHORITY AND ACCOUNTABILITY TO THE DISCIPLINE WHEN GUIDING STUDENTS PRESENTING A PROOF

Mette Andresen

Mette.Andresen@uib.no

Bettina Dahl
University of Bergen
Bettina.Dahl.Soendergaard@uib.no

Teachers often find it hard to balance between justice to the students' input and leading the class towards the decided goal. We focus on how the teacher orchestrates the balance between whole class student authority and accountability to the discipline. In the case a student presents the result from group work but at some point needs help. The teacher de-personalises the discussion and directs the class' attention to the subject and not to individual students. Thereby, the class is treated as a community with a shared authority. By the end, collective learning has taken place.

Keywords: Classroom discourse, Communication, High school education, Reasoning and proof

Introduction

The teacher's responsibility is to lead classroom discussions that build on student thinking and guides the class to "strike an appropriate balance between giving students authority over their mathematical work and ensuring that the work is held accountable to the discipline" (Stein et al., 2008, p. 332). Teacher-class discussions were analysed as acquisition of mathematical knowledge (Prediger et al., 2015). Less attention has been paid to how teachers manage situations where students' presentations fail to present the group's end result or provide understandable explanations. How can the teacher respond without simply taking over the explanation? This paper focuses on a case where the teacher intervenes during a student's presentation and manages to give clear responses without "outshining" the students.

Theoretical framework

Participation

The *participationist perspective* denotes all approaches where learning is conceptualized as participation in classroom discourses and collectively implemented activities (Sfard, 2008). Learning mathematics is a process of enculturation into mathematical practices including discursive practices and how they are interactively established in classroom micro-cultures. Mathematical practices capture collective mathematical development and describe interactively established ways of joint action in mathematics classrooms. The participation perspective intertwines *discursive participation*, taking part in discourse practices according to discursive norms and *epistemic participation*, taking part in the joint epistemic processes of knowledge constitution (Erath et al., 2018).

Discursive approach and collective learning

Cobb et al. (2011) write about the collective learning of the classroom community as the evolution of classroom mathematical practices. In line with this, Lerman (2002) outlines the principles of a cultural, discursive psychology, where learning is an initiation into the practices of school mathematics including learning to speak mathematically. The teacher has a vital role in showing what is approved within the discourse, i.e. the accountability to the discipline. Furthermore: "interactions should not be seen as windows on the mind but as discursive contributions that may pull others forward into their increasing participation in mathematical speaking/thinking" (Lerman, 2002, p. 89), which is in line with Sfard's (2008) view of learning as a combination of acquisition and participation.

Gravemeijer (2004, p. 126) points to "the proactive role of the teacher in establishing an appropriate classroom culture, in choosing and introducing instructional tasks, organising group work, framing topics for discussion, and orchestrating discussion". In line with this, Stein et al. (2008, p. 320) emphasise the importance of "whole-class discussions in which the teacher actively shapes the ideas that students produce to lead them to more powerful, efficient, and accurate mathematical thinking." In the Discursive Approach by Sierpinska (2005), the teachers' role in classroom conversations is similarly characterised by an obligation to lead the discussion in the direction of relevant mathematical ideas and themes. In line with this, we introduced the term *captivating dialogue* (Andresen & Dahl, 2018) to situations where students are progressively initiated into the practices of school mathematics through a whole class discussion.

Research question

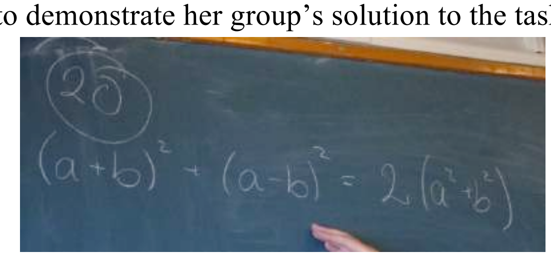
How can a teacher's orchestrate a balance between student authority and accountability to the discipline while guiding the presentation of students' group work?

Methodology

The data consisted of video recordings (30 hours) of teaching during the autumn of 2013 in eight Norwegian upper secondary classrooms as part of the EU research project *KeyCoMath* about students' strategies for creative problem-solving (Andresen, 2015, 2018). The aim of the project was to develop and study teaching that encourages students' inquiry, and intellectual autonomy. The teachers were experienced teacher who volunteered to develop exploratory mathematics tasks to their own classes with the purpose of stimulating student inquiry. This paper focuses on one sequence (6 minutes, 28 seconds, translated to English) and discusses the interactions between the student at the blackboard, the rest of the students, and the teacher. The utterances are not analysed as isolated events but as they occur in a context of sequential utterances and the analysis does not evaluate each utterances in terms of whether or not they are evidence of learning, as we perceive learning as a result of a combination of a series of events.

Data and analysis

Tina teaches a mathematics class of 24 students from a larger town. The excerpt is from the final lesson of a 'Mathematics Day' where the students worked in groups with tasks from 'Proofs without words' (Nelsen, 1993). Each task asks for an explanation of the connection between its figure and its formula. This type of tasks was novel to the students. The excerpt shows a student (Ingvild) who volunteered to demonstrate her group's solution to the task in Figure 1.



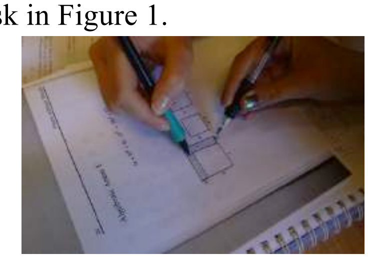


Figure 1: Task as shown on the blackboard (left), student work from book (right)

Ingvild appears calm and relaxed. The task and a drawing of the square is seen on both the blackboard and the book (see Figure 1, left & right & Figure 2, left side of the left equation).

Ingvild: We are supposed to deduct something, right?
Ingvild: But okay. I was thinking ... it was ... [looks at Tina]
Tina: They [the class] are the ones you are supposed to explain it to

Ingvild: Okay [smiling]. It is $(a + b)2$ because ehh we have a times a here [points to the smaller square inside the bigger square and writes a^2 on this square] and ehh no [looks at Tina and appears doubtful]

Tina: Help [aimed at the class]

Tina: There is a lot of help [several hands have been raised]

After 41 seconds Ingvild hesitates and looks appealing at Tina who stands next to the blackboard. Two points of interest: i) Tina gives the *authority to Ingvild* to explain something to the whole class and not only to Tina. Here, Tina emphasizes the *class' understanding* rather than checking the correctness of the result or *Ingvild's understanding*. ii) Ingvild gets stuck almost immediately, but Tina does not take over the explanation but directs Ingvild's attention to the class and requires Ingvild to get help from the class ("There is a lot of help"). By that, Tina assigns the *authority to the class* and encourages interaction between Ingvild and the class.

Next, different students in the class contribute to the task's solution, and one student says: "On the one side it is $a + b$ and the same down. Therefore, in a way it becomes $a + b$ times $a + b$ and we can write this as $(a + b)^2$ …". To which Ingvild responds: "But where does a^2 come from [points at a^2 in the square]". Several students then start to explain at the same time. After 1 minute and 18 seconds Tina interrupts and says: "Someone needs to come up [to the blackboard] and explain it". No one volunteers but several students provide explanations from their seat. Ingvild frequently replies "Hmm", nods and points at the mentioned places on the figure. In our interpretation, the class accepts the authority given by Tina and willingly participates in explaining. Ingvild can follow the suggestions and although she failed to explain the task on her own, she does not appear timid by the situation and her peers do not appear to ridicule her.

After 2 minutes and 20 seconds, Ingvild takes over again and draws the second square with side length $a - b$ (see Figure 2, left) and explains:

Ingvild: And it becomes $a - b$ and $a - b$ [points to each side and then looks at Tina]

Tina: Hm-hm [accepting sound]

This time, Tina does not ask the class for help, but indicates that Ingvild is on track, which we interpret as Tina showing accountability to the discipline by focusing on mathematical content. Until 4 minutes and 48 seconds into the recording, Ingvild draws the rest of the figures seen in Figure 2 while she and some students are discussing what to do. Next, Ingvild hands out the chalk with a happy smile, as if she thinks she has finished. But Tina intervenes:

Tina: I do not quite understand it all. [Tina points to a^2 and b^2]. But these ones? [pointing at the two strips on the left side of the right equality while turning towards the class]

Until 6 minutes and 17 seconds into the recording, Tina exchanges with different students, including Ingvild. The intriguing part of the reasoning, illustrated in Figure 2 (right side), appears to be that the dark rectangles (a times b) 'overlap' in the second square on the left side, and, therefore, must be added (as b times b) to the last square on the right side. Tina asks questions like: "How big is this piece?" to make sure that all the areas in the squares on the left side of the equality sign are represented at the right side of the equality sign. Then Tina asks: "Is it correct?" and concludes by saying: "So based on this where we have drawn – thank you [to Ingvild] – two squares". At this point the class apparently impulsively applauses while Ingvild returns to her seat. Visible signs of agreement are students' nodding and confirming answers, and nobody asks more questions although the atmosphere is forthcoming.

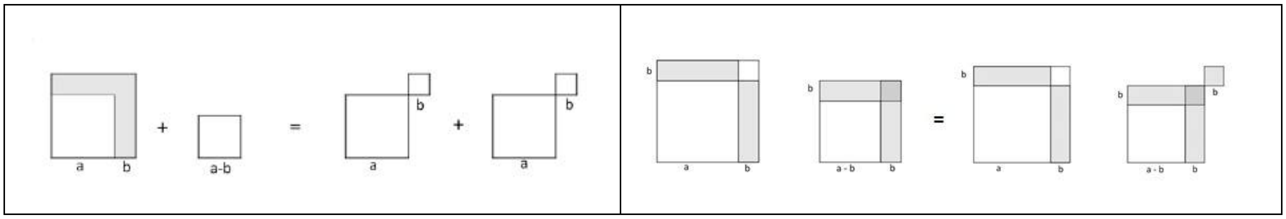

Figure 2: Figures from the task (left), figures from the blackboard (right)

Discussion

Accountability and authority

In our interpretation, Tina shows accountability to the discipline by spending almost one fourth of the sequence's time (towards the end) to make sure that all figures to the right have been covered by the figures to the left. The accountability is balanced with student authority as Tina directs focus of attention to the interaction between the whole class and the subject on the blackboard rather than focusing on the interaction between Ingvild and herself. Further, Tina gives the authority to the community of students when she requests help. We also see that teacher authority is not the same as teacher monologue, Tina orchestrates is in complete control even though she is at the background most of the time.

Classroom culture, participation and collective learning

Ingvild had volunteered and does not exhibit discomfort when she gets stuck. Tina thanks Ingvild during the conclusion of the sequence, and the class applauds even though it was not a brilliant presentation. This shows a classroom culture with ample space for student authority and for discussion. We also see that Tina does not only focus on student authority. Stein et al. (2008) describes that sometimes a focus on student thinking is perceived to imply that the teacher "must avoid providing any substantive guidance at all" (p. 316). In Tina's case, providing substantive guidance is not in itself a contradiction to a student-centred classroom culture. Tina manages the balance and establishes a classroom culture in which the students through discursive participation create the basis for collective learning. By the end of the sequence, collective learning (Cobb et al., 2011) has taken place and *the class* knows the solution. Tina ensures that the class is on the path which is in line with Sierpinska's (2005) views of the role of the teacher as someone who has the responsibility of leading a class in a relevant direction.

Conclusions

In this paper we address how a teacher orchestrates the balance between accountability to the discipline and authority to the students. We focus on students in the classroom as a group and analyse a sequence from a lesson where a student presents the result of group work. The teacher avoids the face-to-face communication with the presenting student, which could otherwise have been the teacher's choice of action when a student gets stuck in the explanation. Thereby the teacher manages to insist on the inclusion of the whole class into the discussion. Furthermore, the teacher avoids taking over from the student and giving the explanations using her authority. Rather, the teacher encourages and supports the rest of the class to develop the appropriate explanations. In our interpretation, the students' authority therefore remains acknowledged together with relevant mathematics that is held accountable to the discipline.

REVIEWING THE LITERATURE ON FLIPPED MATHEMATICS INSTRUCTION: A QUALITATIVE META-ANALYSIS

Ruby L. Ellis
University of Missouri (USA)
ruby.ellis@missouri.edu

Jaepil Han
University of Missouri (USA)
jaepilhan@mail.missouri.edu

Zandra de Araujo
University of Missouri (USA)
dearaujoz@missouri.edu

Samuel Otten
University of Missouri (USA)
ottensa@missouri.edu

Flipped instruction is often viewed in relation to what is done outside of class (e.g., watching instructional videos) but it is also important to attend to what happens in class. Flipped instruction also has similarities to inverted or blended learning, but "flipping" terminology has garnered enough traction in practice and research as a contemporary phenomenon that it is worthwhile examining it on its own terms. In this research brief, we presented an overview of some initial findings from an ongoing meta-analysis of literature on flipped mathematics instruction. Understanding the research methods previously used to study flipped instruction and the contexts in which those methods were used, will provide future researchers and practitioners with a greater understanding of the impact of flipped instruction on the teaching and learning of mathematics at all levels.

Keywords: Technology; Instructional Activities and Practices; Curriculum Enactment; Research Methods.

Introduction

With the rise of YouTube and other video platforms, flipped instruction—also called "flipped learning" or "flipped classrooms," defined by videos or other multimedia assigned as homework rather than skill practice or problem set homework—has become more prevalent over the past decade (Smith, 2014; Talbert,2018). It has been implemented most often in mathematics and science, especially at the post-secondary levels (Uzunboylu & Karagozlu, 2015). But even in K12 schools, more than 10% of teachers report flipping mathematics lessons at least once a week (Banilower et al., 2018).

As an innovation, flipped mathematics instruction has been predominantly teacher driven, with individual teachers deciding to try it as a way to, for example, accommodate students who miss class or have difficulty following a live lecture and to free up more time in class for active student work (de Araujo, Otten, & Birichi, 2017). Practical implementations, therefore, were outpacing research until recently when a surge of empirical studies on flipped instruction began (Talbert, 2018). The emerging literature, however, encompasses studies with different foci in terms of the outcomes of interest, from student attendance (Asarta & Schmidt, 2015) to their attitude and engagement (Clark, 2015) to measures of content learning (Ichinose & Clinkenbeard, 2017). Even studies that focus on similar outcomes have produced potentially conflicting results. For example, Clark (2015) had positive findings in favor of flipped mathematics instruction but De Santis and colleagues (2015) had neutral-to-negative findings.

Because of the wide range of contexts and foci for research on flipped instruction, and because of the contradictions in preliminary findings, it is important to systematically review the literature. The specific question guiding this review was, In what ways and to what extent has prior research examined flipped mathematics instruction? This literature review study complements existing reviews such as that of DeLozier and Rhodes (2017) that examined instructional activities that are included in studies of flipped instruction and Zainuddin and colleagues (2019) who, like us, examined methodological approaches and overarching results but which looked across multiple subject areas over a short period of time (2017-2018). Our study will focus on flipped mathematics instruction, specifically, and will include a broader timespan.

Framing Flipped Instruction

Flipped instruction is often viewed in relation to what is done outside of class (e.g., watching instructional videos) but it is also important to attend to what happens in class. Bergman and Sams (2012), for example, wrote about flipped instruction but focused largely on ways of using newly-available in-class time. de Araujo et al., (2017) have also pointed out the importance of planning for in-class activities, which is what separates flipped instruction from fully-online instruction. Flipped instruction, because of the possibility of content delivery occurring at home, also has similarities to inverted (e.g., Strayer, 2012) or blended (e.g., Graham, Woodfield, & Harrison, 2013) learning, but "flipping" terminology has garnered enough traction in practice and research as a contemporary phenomenon that it is worthwhile examining it on its own terms.

Method

For this qualitative meta-analysis of the literature on flipped instruction in mathematics classroom, the authors identified the publications through searches on multiple databases and individual journals, excluded the relevant publications using criteria (e.g., empirical, mathematics focused), and screened and recorded each article's details (e.g., definition of flipped instruction, methodology, findings). The details of each phase will be unpacked in the following sections.

Article Identification

To identify the publications relevant to this qualitative meta-analysis, we conducted our initial search in the ERIC database. Using the search terms "flip*" and "flipp*," our search focused on titles, abstracts, and keywords. Our search was restricted to peer-reviewed empirical articles (means have some forms of research questions, methods, and findings in them) published and available as of August 2018. During our initial search, we realized that some scholarly journals in mathematics education (e.g., ESM, SSM) or computer journals (e.g., EJMSTE) were not listed in the index on the ERIC database, we expanded our searches to the individual journals listed in top 7 mathematics education journals, as defined by William and Leatham (2017), or appeared within top 10 mathematics education either Scopus or Google Scholar Metrics. We did the same to the computer journals ranked within top 10 on either Google Scholar Metrics, Scopus, or Web of Science. For these individual journals, we searched peer-reviewed empirical articles using the search terms focusing on titles, abstracts, and keywords on their website or through ProQuest. If the individual journals did not allow us to search using either of titles, abstracts, and keywords, then we expanded our searches to full text if the option was available. If the individual journals did not have a searchable engine on their website, then we used Google Scholar and searched the full text using the same search terms.

Article Inclusion and Exclusion

Overall, as of August 2018, after further removing duplicates, we retrieved 1148 entries (822 from the ERIC database and 326 from the individual journals). For the 1148 publications, we read through their abstracts to check whether each article focuses on flipped instruction for teaching and learning mathematics (e.g., geometry, college algebra, statistics). Thus, we used the following criteria of inclusion: peer-reviewed empirical article, flipped instruction, and content area. Two raters individually read through the abstract and individually examined each criterion as "Yes," "Maybe," or "No." If the examination of each article was not matched, the raters discussed until they agreed with one or another. Also, if the abstract is not available, the raters skimmed through the full article and examined the criteria. After the first round of coding, there were 105 Yes's, 851 No's, and 192 Maybe's. For the Maybe's, both raters skimmed through the full article and examined the criteria, and it turned out that there were 12 Yes's and 180 No's. Consequently, we identified 117 Yes's and 1031 No's after the initial round of coding.

Coding the Literature

Both the screening and coding of the studies were conducted by the authors. To ensure the quality of these as key steps in our qualitative meta-analysis, we utilized a spreadsheet to organize and record the details of each study. The authors developed an initial coding scheme and recorded each article's definition of flipped instruction, research questions, overall methodology, details of methodology and data sources, participant information, mathematics content of focus, measured outcomes, and findings. Using the initial coding scheme, the authors coded two articles together in order to get familiar with the coding scheme and to test how the coding scheme works. Then, the research team deviated the articles and coded independently, and then met to discuss any issues or concerns that emerged while coding the articles. After discussing the issues that arose during the coding process, the team decided to add two more dimensions—length of study and details of the flipped classroom and comparison classroom (if applicable)—to the coding scheme.

Findings

We conducted a synthesis of literature within each category using an inductive and iterative process. As of February 2020, 97 of the 117 articles selected for inclusion in this qualitative meta-analysis were coded. The findings presented in this paper represent a brief overview of the methodology, geographic location, mathematics course, participant grade band, and findings in favor, against, or mixed of flipped instruction from the 97 coded articles. Coding of remaining articles is ongoing. Findings resulting from ongoing synthesis of literature involving the theoretical frameworks and definitions of flipped instruction guiding each study, instruments and measures, specific mathematics content, and activities used within each study, if provided, will be presented in future manuscripts.

Methodology and Context of Included Studies

The methodology used by the researchers and contexts of the included studies provided a picture of how and where flipped instruction was being studied. Of the 97 coded articles, we found that nearly 49% of the studies used quantitative research methods, 12% used qualitative research methods, and 39% used both qualitative and quantitative methods. Study participants included elementary, secondary, and post-secondary students in the United States, Canada, Europe, Asia, Africa, and Australia. Our synthesis of the literature revealed that an overwhelming majority of the studies were conducted within post-secondary institutions in the United States (n = 71); and very few studies were conducted in elementary classrooms (n = 3) (see Table 1).

Table 1: Geographic Location and Grade Band of Participants

Grade Band	Total	*Geographic Location				
		United States	Canada	Europe	Asia	Australia
Elementary K - 5	3	3	0	0	0	0
Secondary 6 - 12	22	15	1	1	2	0
Post Secondary	71	52	2	2	3	2
TOTAL	97	70	4	3	5	2

*if specified

The mathematics content studied ranged from fourth-grade mathematics content through graduate level mathematics courses. Post-secondary mathematics course content represented nearly 70% of mathematics content in classrooms using flipped instruction, with statistics (21.5%) and calculus (15.2%) courses being the majority (see Figure 1). Few studies included elementary mathematics content. Of the 7 studies that included elementary mathematics content, participants in 4 of those studies were undergraduate students majoring in elementary education.

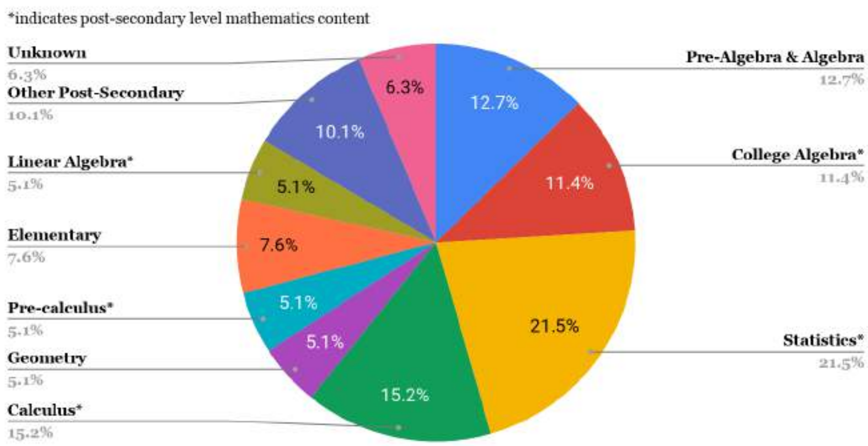

Figure 1: Mathematics Content

Findings in Favor, Against, or Neutral of Flipped Instruction

Findings from included studies revealed numerous positive findings in favor of flipped instruction in mathematics classrooms. Of the 57 included studies (from the 97 coded studies) that measured mathematics achievement of students in classrooms with flipped and non-flipped instruction, 53 of those studies reported at least one statistically significant result in favor of flipped instruction. Fifteen studies reported at least one result that did not show a statistically significant difference in student achievement; and, 3 studies reported at least one statistically significant result in favor of non-flipped instruction. Additional reported findings included both positive and negative reports of participants' perceived impact of flipped instruction on mathematics achievement, level of anxiety, class attendance, motivation, and study habits.

Conclusion

In this research brief, we presented an overview of some initial findings from an ongoing meta-analysis of literature on flipped mathematics instruction. Understanding the research methods previously used to study flipped instruction and the contexts in which those methods were used, will provide future researchers and practitioners with a greater understanding of the impact of flipped instruction on the teaching and learning of mathematics at all levels. As coding and synthesis of the studies included in our meta-analysis continues, the findings presented in this research brief are expected to change.

CONNECTING IDEAS AND GESTURING DURING WHOLE-CLASS DISCUSSIONS

Jonathan K. Foster
University of Georgia
fosterjk@uga.edu

This study extends our understanding of teachers' use of gestures during mathematics instruction. In particular, I examined the relation between teachers' gesture and the kind of mathematical connection verbally identified during whole-class discussions. Analysis of video-recordings of two teachers implementing a common unit of instruction revealed, in general, the teachers were more likely to use pointing and writing gestures rather than depictive gestures to make mathematical connections or support connection-making. However, the teachers used gestures differently during discussions based on the kind of mathematical connections discussed. These differences included the use of more than one type of gesture for an entity in a connection and whether both entities of a connection co-occurred in speech and gesture.

Keywords: Communication; embodiment and gesture; instructional activities and practices

In their review of research on learning and teaching with understanding, Hiebert and Carpenter (1992) found that explicit attention to mathematical connections during instruction was generative for students' learning, promoted recall, and supported students to develop a positive disposition toward mathematics. Unfortunately, The Third International Mathematics and Science Study (TIMSS) 1999 Video Study revealed there were few opportunities for and practically no discussions of mathematical connections in US mathematics classrooms (Hiebert et al., 2003). Interestingly, teachers in higher, achieving countries, such as Japan, were more likely to not only discuss connections but also to use gesture while doing so (Richland, 2015). While there is a growing body of evidence that gestures are beneficial for student comprehension (c.f., Hostetter, 2011) and support students' contributions during a discussion (Alibali et al., 2019), it is unclear if there is any relationship between teachers' gestures and the specific kind of mathematical connections made during instruction beyond connecting representations. This paper describes how two teachers' gestures varied in relation to the kind of mathematical connection being discussed during whole-class instruction.

Theoretical Foundation and Constructs

Embodiment and Situative Perspectives on Gestures

Broadly defined, *gestures* are movements of the body, usually of the hands and arms, for the purpose of communicating, and they sometimes accompany speech (McNeill, 1992). To understand how and why teachers gesture during instruction, I draw on the theoretical perspectives from embodied and situated cognition. From an embodied perspective, gestures emerge from simulated actions or perceptual states (Hostetter & Alibali, 2019). For example, asking an individual to think about a cup is also likely to activate the mental actions needed to hold a cup and so the individual may produce a "cupping gesture" with one hand. However, individuals may produce gestures that do not have roots in simulated actions or perceptual states. For example, a teacher may point at a mathematical object so that students may follow the referent of her speech (e.g., Is this [points at an expression] the same as this [points to a second expression]?). From a situated perspective, gestures are a semiotic resource that support interaction by developing, refining, or clarifying ideas (Goodwin, 2000). For example, Keene, Rasmussen, and Stephan (2012) argued that a sequence of gestures between an instructor and students over a series of lesson supported students' understanding of equilibrium solutions.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

In this study, I followed Alibali et al. (2014) in distinguishing between depictive, pointing, and writing gestures. *Depictive gestures* are "gestures that portray aspects of semantic content directly, via hand shape or motion trajectory, either literally or metaphorically" (Alibali et al., 2014, p. 76). Depictive gestures align with an embodied perspective of gestures. *Pointing gestures* are "gestures that indicate objects, locations, or inscriptions, usually with an extended finger or hand" (Alibali et al., 2014, p. 76). *Writing gestures* are "writing or drawing actions that were integrated with speech in the way that hand gestures are typically integrated with speech but that were produced while holding a writing instrument (usually chalk or marker) and that involved writing to indicate or illustrate the content of the accompanying speech" (Alibali et al., 2014, p. 76). Pointing and writing gestures align with a situative perspective of gestures.

Mathematical Connections

M*athematical connections* are the discursive ways in which an individual or community makes or describes a relationship between two or more mathematical entities. Entity is meant to encompass ideas, concepts, objects, representations, procedures, or methods. An individual or community may make a mathematical connection in variety of ways such as *connecting through comparison* (e.g., $\sqrt{a^2 + b^2}$ is the same as $\sqrt{b^2 + a^2}$), *connecting through logical implication* (e.g., If two distinct lines have the same slope, then the lines are parallel), *connecting methods* (e.g., Using the Pythagorean theorem or the distance formula can be used to find the distance between two points), or *connecting specifics to generalities* (e.g. A 6-8-10 triangle is an example of a Pythagorean triple; Singletary, 2012).

Methods

Participants and Data Collection

Melissa and Robin (pseudonyms) were selected to be part of this study from a larger research project that followed a cohort of secondary mathematics teachers in their teacher preparation program. Melissa and Robin were white females in their early twenties. They co-planned and co-taught an advanced 9th grade coordinate algebra course together during their student-teaching. Course goals included leveraging algebra to deepen and extend students' understanding of geometry. The data included lesson materials from one unit of instruction and video-recordings of the enactment of those lessons in two different class periods. This included 8 instructional days with Melissa as the focus teacher and 6 instructional days with Robin as the focus teacher. Each lesson recording was approximately 70 minutes in duration.

Data Analysis

First, I transcribed all video recordings of the lessons and included screen captures of the teachers' gestures with a short description. Then, I reduced the data to episodes of whole-class discussions about content-related activity (e.g., discussing the solution to a mathematical task) and not the day-to-day operation of school (e.g., checking attendance). From the reduced data, I then coded for connecting-periods (i.e., moments in whole-class discussions when a student or teacher made a mathematical connection). I will call connecting-periods just periods for simplicity. I excluded any periods if the mathematical connection in the period had already been discussed previously. This exclusion was done because Alibali et al. (2014) found that teachers were more likely to use gestures when the connection was novel to students. Next, using the Mathematical Connections Framework (Singletary, 2012), I coded the kind of mathematical connection expressed in the period. Finally, I coded and described the modalities (speech and/or gesture) used by the teacher for each entity in the connection.

Results

Across the lessons, there was a total of 60 periods. The teachers generally used at least one gesture (e.g., depicting, pointing, or writing) during a period (45 of 60). In about one-third of the periods, the teachers used two or more gestures to accompany speech about a mathematical connection (21 of 60). There were 13 periods when the teachers did not use any gestures and 2 periods where I was unable to determine if a teacher used a gesture due to the position of the camera (e.g., a teacher walked off camera).

The teachers' gestures differed depending on the kind of connection. For instance, they were more likely to use two or more types of gestures with speech to support discussions when connecting through comparison (13 of 23) or connecting methods (8 of 11). In contrast, there were few instances of a teacher gesturing with two or more types when connecting specifics to generalities (3 of 14). There were no instances of a teacher supporting discussions of connecting through logical implications using two or more types of gestures (0 of 11). In fact, it was somewhat common for connections through logical implication and connections of specifics to generalities to be unaccompanied by teachers' gestures (7 of 12 and 5 of 14, respectively).

Table 1. Modalities across kinds of connections

	Kind of mathematical connection			
	Comparison	Logical implication	Methods	Specifics to generalities
Two or more gestures with speech	13	0	8	3
At least one gesture with speech	21	4	11	9
Unable to determine	1	1	0	0
No gesture	1	7	0	5
Total	23	12	11	14

Furthermore, the teachers generally expressed both entities of a mathematical connection with gestures when connecting through comparison (14 of 23) and connecting methods (9 of 11) during instruction. In contrast, the teachers seldom expressed both entities when connecting through logical implication (2 of 12) and connecting specifics to generalities (3 of 14).

Table 2: Gesture use for entities within each kind of connection

	Kind of mathematical connection			
	Comparison	Logical implication	Methods	Specifics to generalities
One entity	7	2	2	6
Both entities	14	2	9	3
Neither entity	1	7	0	5
Unable to determine	1	1	0	0
Total	23	12	11	14

Lastly, for all kinds of connections, teachers often used pointing and writing gestures with speech over depictive gestures in relation to a single entity of a mathematical connection. This finding is in agreement with what Alibali et al. (2014) found. Therefore, there was no relation between the kind of mathematical connection and the type of gesture. Table 3 outlines the type of gesture for at least one entity of a mathematical connection in relation to the kind of mathematical connection. Note that the sum for each kind of mathematical connection is different in Table 3 than the other tables because one entity of a mathematical connection could have been expressed multimodally (e.g., with a pointing and writing gesture).

Table 3. Type of gesture and kind of mathematical connection

Type of gesture (for at least one entity)	Kind of mathematical connection			
	Comparison	Logical implication	Methods	Specifics to generalities
Depictive	4	1	5	1
Pointing	16	1	8	4
Writing	14	3	7	8

Discussion

Novice teachers do gesture when discussing mathematical connections or supporting students' connection-making during instruction. This outcome is a distinctive shift from the TIMSS 1999 Video Study results and most likely reflects the recent emphasis on facilitating student-centered mathematical discussions in mathematics teacher education in the US. Novice teachers' use of gestures during discussions is also important because teachers' use of gestures has been found to lead to greater student comprehension (c.f., Hostetter, 2011) and promote students' contributions during a discussion (Alibali et al., 2019). Further, these novice teachers seldom used gestures when connecting through logical implication and connecting specifics to generalities. This is noteworthy because gestures are a semiotic resource for students' meaning making and a teacher's gestures may be a resource for moving students to a more productive meanings of logical implications (Hoyles & Küchemann, 2002) or to more sophisticated generalizations (Ellis, 2007). However, I do not argue that all the connections were productive for students or that gestures alone always lead students to develop productive meanings of connections. For example, Lobato et al. (2003) described how a teacher's use of ambiguous language of "goes up by" when describing the slope of a line along with her use of a sweeping gestures along one column in a table of values may have contributed to students' overgeneralization of slope as a difference rather than a ratio. One productive direction for future research is to determine if teachers are able to notice whether and how their own gestures are (not) productive for students' mathematical connection-making.

The use of questioning is an effective strategy for orchestrating collective argumentation. However, teachers with minimal experience facilitating argumentation may conceive of effective support as providing little to no verbal input in the argumentation. In this study, we analyzed one teacher's analysis and critique of her support for collective argumentation during her first three years of teaching. We argue that learning to analyze her support for collective argumentation enriched the teacher's understanding of questioning. More specifically, by explicitly identifying how her questions elicited components of arguments from students, the teacher re-evaluated her questions, focusing on purpose rather than form. Implications from this study draw connections between learning to facilitate argumentation and the dilemma of telling that teachers encounter when trying to teach mathematics in ways that honor students' thinking and sense-making.

Keywords: Classroom discourse, High school education, Instructional activities and practices

Teachers have a pivotal role in orchestrating argumentation. Teacher moves such as revoicing and establishing social and sociomathematical norms are supportive of mathematical argumentation (Forman et al., 1998; Yackel, 2002). Further, researchers (e.g., Hunter, 2007; Martino & Maher, 1999) have recognized that teacher questioning is a key factor in supporting mathematical argumentation. For instance, Martino and Maher suggested that a sequence of questions that offer an opportunity for generalization help students to build mathematical arguments. However, teachers have difficulties incorporating questioning strategies in their classroom teaching, even when supported by curricular materials (e.g., Sahin & Kulm, 2008). Furthermore, some researchers argued that teachers may not have a clear understanding of what effective questioning strategies are or how to implement them in order to support argumentative discourse (e.g., Kosko et al., 2014; Zhuang & Conner, 2018). In particular, Kosko et al. (2014) found that some teachers envision mathematical argumentation being left to the responsibility of students with relatively limited input from the teacher. The purpose of this paper is to demonstrate how a teacher learned to analyze her support for argumentation while also co-developing an understanding of her role in supporting argumentation with a special focus on questioning as a strategy for supporting argumentation.

Theoretical Perspective and Conceptual Framework

Drawing from a situative perspective, we conceptualize learning as socially constructed; it takes place through interaction with other human beings, within a specific context, and through active engagement and participation in meaningful practices (Lave & Wenger, 1991). In this study, the situative perspective led us to attend to a teacher's participation and use of analytic tools when discussing selected video representations of her teaching. As the teacher examined, commented on, and critiqued her support of argumentation with another more experienced other (i.e., the mathematics teacher educator-researcher, MTE-R), they built and negotiated the meaning of the practice of supporting argumentation in school mathematics.

Following Toulmin's (1958/2003) model of argumentation, an argument consists of at minimum a *claim* (statement whose validity is being established), *data* (support provided for the claim), and *warrant* (statement that connect data with claims). In this paper, we focus on collective argumentation (i.e., individuals working together to determine the validity of a claim). According to the Teacher Support for Collective Argumentation (TSCA) framework (Conner et al., 2014), teachers can support collective argumentation in three ways: directly contributing to the argument (e.g., providing a claim), asking a question (e.g., requesting an action or information from students), or using other supportive actions (e.g., repeating a student's claim to the class). For the purpose of this paper, we focus on the teacher's questions and her critique of those questions.

Methods

Participant and Data

Jill (a pseudonym) was a participant in a 6-year longitudinal study focused on understanding how beginning teachers learn to facilitate collective argumentation. Jill agreed to participate in the final phase of the study, which was to follow her into her first three years of high school teaching. For this paper, we analyzed data from the first and third years of Jill's teaching because we noticed a significant shift in Jill's participation in analyzing her support for collective argumentation between those two time points and that this contrast provided insights into her understanding of questioning to support argumentation. Data includes 6 classroom observations in her first year and 9 classroom observations during her third year. The research team video-recorded each lesson observation, collected lesson artifacts (e.g., worksheets), and made field notes. After each lesson observation, the team identified episodes of argumentation in the video-recordings and referred to lesson artifacts and field notes as needed to make sense of what happened in the video-recordings. In post-lesson interviews (Interview 6 through Interview 19), the third author interviewed Jill to discuss her supportive actions with respect to collective argumentation by having her analyze selected argumentation episodes from the lesson's video-recordings. The focus of these interviews was to assist Jill in analyzing her support for argumentation, understand Jill's goals for the lesson, and gain insights into Jill's perspective of the school context in which she worked. All post-lesson interviews and video clips were transcribed as data sources.

Data Analysis

At the first stage of analysis, the research team diagrammed episodes of argumentation identified in Jill's lessons using a revised Toulmin's (1958/2003) model (as described in Conner, 2008). The team classified all of Jill's supportive actions for argumentation using the TSCA framework, including Jill's direct contributions to arguments, questions, and other supportive actions. In the second stage, the team developed a codebook to identify moments when Jill analyzed her support for argumentation. The subset of the codes included *identifies argument* (i.e., teacher identifies an argument or episode of argumentation), *identifies component* (i.e., teacher identifies data, claim, or warrant of an argument), *identifies support* (i.e., teacher identifies a question or other supportive action), *teacher critique of support* (i.e., teacher's evaluation of her own support or observation about the presence of support or lack thereof), and *teacher analysis of support* (i.e., teacher categories or otherwise gives ideas about what kinds of support she provided). After coding all the post-lesson interviews from Jill's first and third year, the team generated reports of all the instances of these codes in the data. The team used these reports to compare Jill's analysis of her questioning over time. This analysis is ongoing; initial results are presented in this paper.

Results

Year one: "Very leading on my part, I think"

During her first year of teaching, Jill did not perceive a teacher's questioning as essential support for students to make arguments. For example, Jill asked the MTE-R at the end of the first post-lesson interview, "How [do I] get them (students) to actually form arguments themselves without me having to do it for them? Like without me having to say 'Well, why do you think that?' You know, dictating every little step of it." (Interview 6). Typically, when the MTE-R asked Jill to describe what she noticed after watching video clips of her first year of teaching, Jill described her questioning as leading. For example, "I said, 'Well, what are the slopes of the two lines?' and then she [the student] said, 'Well, they're opposite reciprocals'...So it was very, very leading on my part, I think." (Interview 8). We interpreted Jill's description of leading similarly to how she described her questioning in the first interview as "dictating every little step." In other words, a question was leading to Jill if it resulted in the claim or warrant that she was expecting students to make in the argument.

In an attempt for Jill to see her questioning as supportive of argumentation, the MTE-R asked Jill in the last interview during her first year of teaching to provide examples of leading questions that she used during an episode of argumentation. As Jill went through the transcript, she began to re-evaluate some of her questioning. For example, Jill stated, "I think, where I say, 'Wait, what else do we know?' that was not a leading question. That was very open" (Interview 8). This question had the potential to elicit an unexpected claim from students, and she evaluated it as not leading, which supports our interpretation of her meaning for "leading." The MTE-R next assisted Jill in identifying how her questioning supported students in contributing claims or warrants (Interview 8):

> MTE-R: You say, "How do we know these are right angles?" So, you're emphasizing, okay, the claim here that we're looking at. It is these are right angles, right?
>
> Jill: These are right angles (nodding).
>
> MTE-R: And so, then a student says, "Because of the slope." So, you are then saying, 'Okay, let's go with that. Because of the slope, what do we need to know about the slope essentially?' Right?

Jill often described her questioning in her first year of teaching as leading, but she seldom considered how her questions supported students to make contributions to the argument, such as providing a claim or warrant. We argue that having Jill examine her questioning in relation to supporting students to contribute claims or reasoning for the claims assisted her to reconsider the purpose of her questioning and how it was a useful strategy to support collective argumentation. The MTE-R provided these opportunities to Jill over the course of her second and third years of teaching. Jill identified argument components (e.g., claims or warrants) and her supportive actions, such as questioning, in relation to students' contribution of those components.

Year three: "But that's different than leading"

At the end of her third year of teaching, Jill was provided with an episode of argumentation from her class and asked to identify what she did to support students to contribute components of the argument. Jill pointed out several questions she used to support students' contribution of claims or warrants. For example, Jill stated, "Okay so… 'Why does 6 not work?' would be [what] got her to say that [warrant] but it goes to [give reason for] that [claim]. So that [question] was my support for that part of this little [warrant]" (Interview 17). Jill even identified claims or warrants that were unprompted by her: "And then...so her friend said that [claim]. I don't think I said anything really" (Interview 17). After identifying all of her supportive actions (questioning and other supportive actions), Jill reflected on her questioning without any prompting.

> Jill: So, really, I think I didn't, I didn't say too many leading things here.

MTE-R: Huh-uh (affirmative).
Jill: Which is probably what made this argument good. Because I didn't say anything.
MTE-R: No, you said things.
Jill: Well I just, I gave her…
MTE-R: You said appropriate things.
Jill: Slight direction. Nothing leading.
MTE-R: True, true.
Jill: But slight direction I think sometimes is necessary because they're still new with things.
MTE-R: Oh yeah. Mm-hmm (affirmative).
Jill: But that's different than leading them. (Interview 17)

This was a shift in Jill's analysis of her questioning in relation to her observations from her first-year interview. Recall, Jill initially asked the MTE-R how to get students to make arguments without her having to "dictate every little step." By her third year of analyzing her questioning, Jill described her questioning as supportive of getting students to contribute to the argument and reflected that asking those questions "sometimes is necessary."

Discussion

Kosko et al. (2014) hypothesized two reasons for why teachers envisioned providing minimal scaffolds, such as questions, during argumentation: lack of teaching experience with argumentative discourse or falling victim to the conception of "not telling" (Lobato et al., 2005). This study provides support for the latter hypothesis. Early in Jill's analysis of her support, she critiqued her questions as "too leading" based on their *form* (i.e., a question that does not allow for multiple contributions from students) rather than their *function* (i.e., getting students to make claims or provide explicit warrants). Reformulation of telling in terms of function rather than form was an important consideration to make explicit for Jill when first learning to analyze her support of mathematical arguments. Jill's analysis of her questioning with assistance from the MTE-R and the TSCA framework (Conner et al., 2014) supported her to reformulate the purpose of her questioning. Lobato et al. (2005) also argued for the reformulation of telling in terms of conceptual rather than procedural content of the new information and the relationship of the "telling" action to other teacher actions. While Jill initially focused on the form, rather than the function, of her questions to support argumentation, it is reasonable that these other reformulations may need to be explicitly addressed with teachers as they learn to facilitate argumentation. Nonetheless, this study provides evidence for the interaction between a teacher's learning to facilitate argumentation and the dilemma of telling regarding the form and function of her questions when trying to honor students' mathematical thinking.

STEM INSTRUCTORS' NOTICING AND RESPONDING TO STUDENT THINKING

Jessica R. Gehrtz
University of Georgia
Jessica.Gehrtz@uga.edu

Effective instruction is enabled by an instructor's attention to student thinking and their ability to respond. Further, instruction that is student-thinking-centered can lead to increased conceptual understandings and improved learning experiences for students. Despite this evidence, there is limited research about college instructors' noticing of student thinking. The purpose of this study is to better understand what college STEM faculty notice, and how this enables or constrains their ability to respond to student thinking. STEM faculty, who taught introductory courses, were filmed and interviewed using a semi-structured stimulated recall protocol. Transcripts were analyzed using open coding and thematic analysis. Initial results highlight differences in how faculty elicit student thinking, what is noticed about student understanding, and how this impacts the degree to which faculty can be responsive to student thinking.

Keywords: Instructional activities and practices, Post-secondary education, STEM

There have been calls for increased attention to the teaching of introductory undergraduate science, technology, engineering, and mathematics (STEM) courses and professional development (PD) for those who teach these courses, in an effort to improve enrollment and retention rates in STEM disciplines (Bok, 2013; Holdren & Lander, 2012). Effective instruction is enabled by an instructor's attention to student thinking (e.g., Erickson, 2011). Further, instruction that leverages student thinking can lead to increased conceptual understanding and more positive learning experiences for students (Carpenter et al., 1989; Thornton, 2006). The purpose of this study is to investigate what college STEM instructors notice about student thinking, and the ways in which instructors respond as they make instructional decisions.

Research on Professional Noticing

The noticing required for effective teaching is specialized and goes beyond simply being observant (Ball, 2011). Most scholars agree that it consists of attending to and making sense of particular events during instruction (Sherin, Jacobs, & Philipp, 2011). Jacobs, Lamb, and Philipp (2010) narrow this scope and describe professional noticing as three interrelated skills: attending, interpreting, and deciding how to respond to students' mathematical strategies.

Despite the growing amount of research investigating teacher noticing at the K-12 level, there is little known about what this construct looks like at the college level. Amador's (2014) work investigating future mathematics teacher educators' noticing, one of the few studies at the post-secondary level, found no significant changes in participants' noticing over the short term of the study, but suggested that teachers continued engagement with noticing and reflecting could promote professional growth in this area. This is also supported by evidence that instructors can develop their ability to notice through PD (e.g., van Es & Sherin, 2002).

In order to support college STEM instructors' ability to notice and respond to student thinking, it is first essential to gain a better understanding of what instructors notice, and how they respond through instructional decisions that leverage student thinking. In this paper, I investigate the following research questions: (1) What do college STEM instructors notice about their students' understanding? (2) In what ways are college STEM instructors responsive to their students' understanding (i.e. use student thinking to inform instructional decisions)?

I focus this study broadly on college STEM instructors since little is known about what instructors notice at the post-secondary level, and how this interacts with how they respond to student thinking. It is worth noting that when investigating teacher noticing at the K-12 level, it is common for both science and mathematics education researchers to draw on literature from both disciplines, which points to the similarity and translatability of this work across disciplines. For example, there is evidence at the K-12 level that both science and mathematics instructors attend to students process skills or errors as novices and can develop skills for noticing the disciplinary substance of student thinking (e.g., Stockero, 2014; Barnhart & van Es, 2014). Focusing on STEM more broadly will also afford the opportunity to consider disciplinary differences that may arise and would be beneficial to consider in designing and implementing PD to support instructor noticing and responding at the college level.

Methodology

Faculty from various STEM departments, including Math, Biology, Physics, and Chemistry, who were recognized by their colleagues as individuals who made thoughtful decisions about their teaching were invited and agreed to participate (N=8). Participants were experienced instructors who regularly taught introductory STEM courses. For this proposal, I focus on two participants, Dr. Bio (full professor in Biology) and Dr. Chem (career-line instructor in Chemistry) who taught large enrollment (70 and 270, respectively) introductory STEM courses.

Participants were interviewed before and after a class period which they selected to have filmed (the target class). The pre-observation interview was a semi-structured interview designed to elicit the instructors' goals for class, knowledge of student understanding regarding the topic to be covered, and how this knowledge impacted their planning for class. Clips from the target class (2-5 clips) were selected using selection criteria, and included moments where student thinking was illuminated. These clips were used in the semi-structure post-observation interview to prompt discussion about student thinking and instructional decisions. Interviews were transcribed and analyzed using open coding and thematic analysis to identify emergent themes related to the ways in which instructors notice and respond to student thinking.

STEM Instructors Eliciting, Noticing, and Responding to Student Thinking

The thematic analysis illustrated similarities and differences between how participants gained insight into student understanding by eliciting student thinking, what was noticed about students' understanding, and then how this enabled or constrained their ability to respond.

Eliciting Student Thinking

Dr. Bio and Dr. Chem both created opportunities in class for students to share their thinking, though they differed in what their eliciting allowed them to learn about their students' thinking. Dr. Chem strategically designed free response clicker questions to draw out connections and common student errors. She anticipated where students would struggle and leveraged that as an opportunity to engage students. Dr. Chem stated, "I know where they're going to get hung up. So, I purposely designed questions to get them hung up, because I think that if you do it wrong it helps you remember how to do it right." Additionally, before class, Dr. Chem worked through the clicker questions, anticipating common student mistakes, so that she could address these errors in class. She said,

> I calculated the wrong answer beforehand … [because] when the results come in for the question, I look at how many people answered it wrong, and there's more than one wrong way to do it, and I look at the most common ways and address it.

When using clicker questions, Dr. Bio created multiple-choice questions that would set students up to answer incorrectly. He said, "I'm able to set up what I think is a logical straw man for them. They almost always go for [it]." This type of question does not create an opportunity to elicit student thinking and to gauge how students are thinking about the content.

Noticing Student Thinking

Dr. Bio and Dr. Chem noticed different things about student thinking. Dr. Bio noticed that students did not always take away the main points that he was trying to communicate, saying:

> Because obviously, I'm focused on them getting this one point. And then somebody is telling me, 'Oh, what about this?' And I was like, that's sort of in there, but that's not where I was going. And sometimes I realize … that where I'm going is not where the class is going.

Dr. Bio did not regularly gauge where students were at with their understanding. Thus, he was limited in what he could notice about student thinking, and did not have an opportunity to understand what constrained students' ability to make the connections he desired. Dr. Bio relied on end of semester surveys for feedback on areas that students felt were challenging; he said,

> [I think about the] student comments from the end of the semester, about their perception of the course being disorganized. So, I have, over the years, taken that to heart as constructive criticism and try to make the connections more apparent and meaningful to them.

This comment highlights that he responds to student confusion by working to improve his course from semester to semester, but he is not equipped with the knowledge or tools to assess how impactful these changes are on student learning.

Dr. Chem notices when students are stuck by their facial expressions, understands what students are likely struggling with, and anticipates how she might respond. She said,

> I put the question up, and then I anticipate they're going to read the question, they're going to start working, and then they're going to look at me really perplexed. I wait until I get the look, and then I ask them if they're stuck and they are. So, I will say, 'do you remember this … from earlier this semester?' And then they go, 'Oh', and then they start working again.

Additionally, Dr. Chem used a variety of approaches (including clicker questions, whole class discussions, eavesdropping, facial expressions, interactions in office hours) to gauge where students were at with their understanding, and thus could adjust her plans for class accordingly.

Responding to Student Thinking

Dr. Bio and Dr. Chem responded differently based on what they noticed about student thinking. Dr. Bio made changes each semester, but rarely made changes during class or between classes, saying, "I don't always incorporate [it] right on the fly. And sometimes it's a year delay between when I got that question [and] when I can actually address it in class". Since Dr. Bio did not create opportunities to elicit and notice the substance of student thinking, he was constrained in his ability to make changes that were rooted in students' understanding. He discussed putting himself "in the mindset of the student" when bridging parts of class that were disjoint, saying,

> [I am] going through those notes sections [of the slides] and making sure that they are written in such a way that a student looking at that slide, if she's confused by it, should be able to read those notes and come away saying, 'Oh, now I see what this slide is about.'

Although Dr. Bio provided opportunities for students to ask and answer questions during class, if the students' contribution was not what he had thought about prior to the lesson he tended to redirect back to his prescribed plan for the class. For example, Dr. Bio said,

> I figured that kind of response was kind of off base. I mean ... it just kind of threw me. And so that's probably why I immediately, before I lost the thought of - what do I really want to accomplish with this - I just went ahead and told them.

Dr. Bio's vision of what he wanted to accomplish in this class period, and his struggle to connect the students' thinking with his goal, constrained his ability to notice how this student was understanding the content and the connections that the student was trying to make. Dr. Bio cared about student learning and wanted to improve semester to semester as an instructor, but he did not have the knowledge or the tools to effectively engage with and respond to student thinking.

Dr. Chem regularly made changes from one class to the next, and made changes each semester. Specifically, Dr. Chem planned for instruction based on students' current understanding of the material, stating, "I won't move forward if they're not getting it. There's no reason to. I actually wanted to get farther on Tuesday then I did, but the class wasn't ready to go farther." Dr. Chem also discussed adding clicker questions for the next class to provide students more opportunities to engage with key concepts. Dr. Chem made the following comment after discussing a topic her students were currently struggling with: "I have a new question that will address it. … I've posted the annotated slides so they can see how to do it, but … we're going to do another question that's similar to that [in class]." This comment highlights that Dr. Chem provided her students with the resources to revisit what they were struggling with in addition to creating an additional opportunity to revisit the material. Dr. Chem also discussed making changes from semester to semester, saying,

> I'll take notes of like - 'I'll need to spend more time on this', or '[students] really struggled with this'. Then when I get ready for class the next semester, I go back to that and that's what prompts me to make new slides.

Discussion

Both Dr. Bio and Dr. Chem were experienced instructors, but they noticed different things about their students' thinking, which then enabled or constrained their ability to leverage and respond to student understanding. Specifically, Dr. Bio noticed that students were struggling to make connections, and did not understand what was underlying these difficulties. Consequently, he was limited in what he could respond to. Dr. Chem noticed specific student struggles and built on her existing knowledge of student thinking. Her awareness of students' understanding enabled her to respond both during in-the-moment instruction and in her planning.

Dr. Bio's goal for instruction was to help students appreciate the connections between the seemingly disconnected content through the sharing of his knowledge. Dr. Chem, on the other hand, viewed her course as an opportunity to challenge common student errors and to support students in developing a more complete and correct way of thinking about the content. Consequently, it seems as if Dr. Bio and Dr. Chem had differing dispositions towards student thinking, which impacted their approach to instruction and the opportunities that they created to notice and leverage student thinking. This highlights that it could be important to foster a responsive disposition that values student thinking when developing PD to support faculty in their ability to elicit, notice, and respond to student thinking.

An exploratory study of the impact on transforming mathematics teaching and learning practices into the classroom is presented by means of introducing a hybrid learning environment, in this case, designed to address the topic of functions in the first year of finance at college. This topic is normally covered in two weeks in the classroom. In this exploration, the students worked independently on the topic using materials or resources available in a digital teaching platform throughout the first week. In addition, the topic was addressed in the classroom under the teacher's guidance during the second week. The results show collaboration between students to refine or validate their conceptions, which also could support connectivist hypothesis of distributed knowledge.

Key words: Teaching tools and resources, distance education, post-secondary education, communication

Introduction

According to Heffernan et al. (2012, p.101), if school practices must change in order to keep pace with the development of new technologies and to meet students' expectations regarding their use, then the efforts on teacher’s education and in-service teacher development must be altered, there must be a greater number of interactive educational technologies developed in the cloud and implemented in the classroom.

In the exploratory study we are presenting here, we worked on the design and set up of a hybrid scenario of learning. Participant students worked autonomously during one week of the first semester of finance at college. In the following week, teaching and learning were continued now into the classroom under the teacher's guidance. The usage of this hybrid scenario of teaching and learning, in this case on functions, allowed us to investigate possible productive collaborations between students as a consequence of their autonomous work within the activities in the digital platform. Here we report what was done by the students, it suggests a significative transformation of usual teaching and learning of mathematics in the classroom, and also allow us to advance connectivist learning hypotheses.

Theoretical Frame and Methodology

It is noteworthy that the work of Sutherland and Balacheff (1999) early on announced the possibility, now already materialized, of online courses or digital devices for teaching freed from tutoring by the teacher, accessible outside of school and operated via digital media, such as the Internet. By means of online materials or devices, in this case, like videos or forums as digital tools, students are left with the responsibility of unchain their own forms of appropriation of knowledge, and it is mainly through the exchange of opinions between peers that are attained possible advances in one subject's learning. (Downes, 2009).

One of important theories underlying the design and implementation of online and hybrid learning environments is connectivism, mainly developed by Siemens (2006) and Downes (2009). Connectivism is a theory of learning that emerged linked mainly to the use of the Internet, as well as virtual education. Many researchers still question what this theory explains, provides or suggests, for

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

example, regarding the incorporation of technology in the classroom (see, for example, Kop & Hill, 2008). Whether it could do this regardless of previous theories or as an extension of some of them, or of theoretical models that have so far been applied to study the integration of technology in school (to see some of these models, see Zbieck & Hollebrands, 2008; Olive et al., 2010; Ruthven, 2014). However, according to Downes (2009), what connectivism has to exhibit is to what extent is an emerging theory, and empirically proving in what sense is a new paradigm that would specifically explain the case of network learning and collective distributed knowledge.

Finally, it is also important to highlight that student productions become registered data when working within a digital teaching platform, and availability of all these records in order to classify and analyze them is one of the advantages of using and designing digital teaching platforms (Dedé & Richards, 2012), since in this way teachers in charge of conducting courses in the classroom can then have in advance these type of records and use them as a diagnosis of difficulties or opportunities for points to be addressed in their classroom.

Thus, for the concentration and interrelation of the students' productions, in this exploratory study an Excel sheet was used and the SOLO taxonomy of Biggs and Collis (1982) was applied. SOLO taxonomy is an analysis tool for a structured classification into four levels of development or evolution of student knowledge around a concept. In general, according to these authors, the four possible levels of classification, starting from the simplest to the most complex, are the following: pre-structural, uni-structural, multi-structural and relational. This taxonomy allowed to identify the refinement and validation of the students' conceptions, formulated through their communication exchanges in the forums on the subject.

Having at hand all these data allowed us the identification of student communication exchanges for productive collaboration. It should be noticed that here the term productive collaboration between students refers precisely to the refinement or validation of conceptions between the students carrying out productive collaboration or critical communication exchange.

Next, in Figure 1, a small part of the concentrate and classification of the students' productions is presented.

Analysis and Results

As previously mentioned, this exploratory study sought to identify cases of collaboration or productive interrelation between students. Below it is shown an image of the classification we accomplished of the different levels of development of the students' conceptions on the subject, extracted from our analysis or classification of their participation in the forums. Likewise, a paradigmatic example of student productive collaboration is also presented.

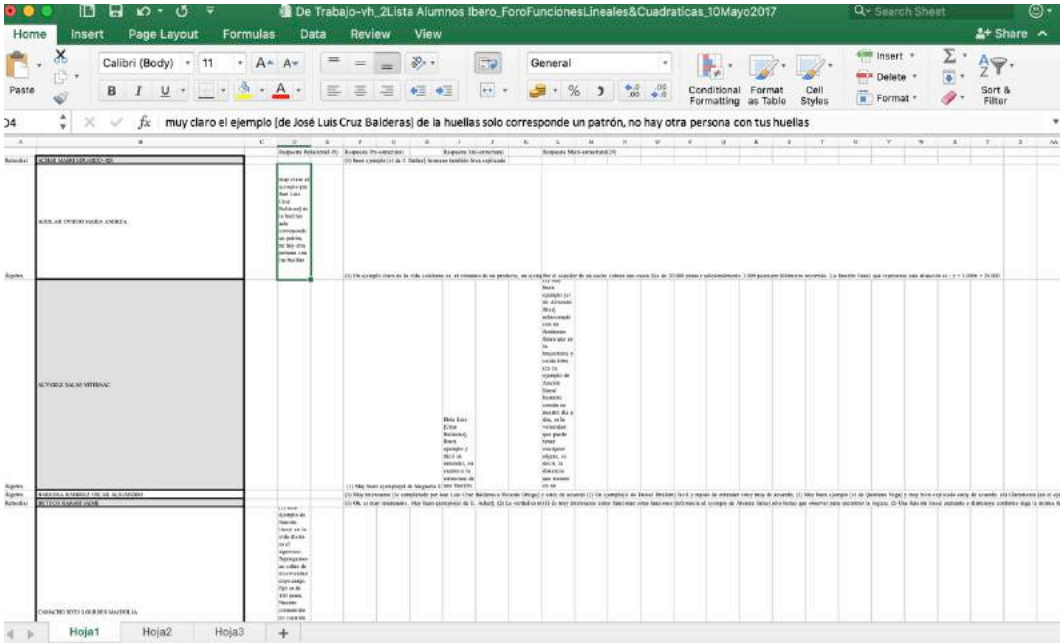

Figure 1. Synthesis of the students' productions, according to the SOLO taxonomy, in search of identifying critical communication exchanges or productive collaboration.

Examples of student production at different levels of development according to the SOLO Taxonomy

Pre-structural level

Student MAA: "A clear example of everyday life is the consumption of a product, an example is the purchase of phones, there are different phones: price levels, with x = the phone and y = the price depending on which phone you would like, the price increases, but all phones have the same function: communicating. [Another] excellent example [in the one given by CS], it was very clear to me how we apply linear functions in daily life. [It is also] an excellent example [the one of AS] because it helps you understand what a linear function is, very simple, with an example from daily life."

Uni-structural level

Student ALA: "When throwing a ball, it first goes up and forward, then falls while continuing to advance, thus forming a path shaped like an inverted parabola."

Multi-structural level

Student YAS: "Very good example [the one given by BA] related to a physical phenomenon that is the trajectory and free fall. [Another] example of a fairly common linear function in our day to day is the speed that any object can have, that is, the distance it travels in a given time. Speaking a little more specifically, assuming that a car on a flat road tends to travel 20 km in 5 minutes, with a linear function, the distance it will travel in 25 minutes could be determined. The algebraic expression, in this example, could be f (x) = 4x. Where x represents the minutes' time you want to calculate to see the distance traveled."

Relational level

Student MAA: "The example [by student JL] of the footprints is very clear, only one pattern corresponds, [because] there is no other person with your footprints"

Student LMC: “Another example of a linear function in daily life is as follows. Let us suppose an electricity charge whose fixed amount is for 100 pesos. Our consumer in question has had a consumption of x watts amount and each watt price is 2 pesos. The function would be expressed in the following way: f (x) = 2x + 100. Thus 2 is our value in a, and 100 is the constant that we add. [Also] a very good example [the one of AS] about something that has an application in daily life, although it should be mentioned that this is only valid for uniform movements (where speed is constant). [In addition, I also] understand the example [the one given by CF] and it seems valid to me, but I consider that because having two antecedents for the same image (this does not meet the definition of function) we would need just one person wanting two things at the same time and not that two people are the same since x1 could be equal to x2 without this affecting the function as long as f (x1) is equal to f(x2). [Finally, also] I agree with another example [the one from MAA], two phones can have the same price, therefore, the same image can have two antecedents, but a singular phone would not have two prices (obviously if we only talk from a provider) so an antecedent could not have two images.”

From the examples and classification presented here, it is clear, according to Heffernan et al. (2012, p. 92), that the materials and activities developed on a digital teaching platform can be used in a multiplicity of ways, among others, so that students receive feedback from their classmates on their actions, which can later be capitalized on reviewing the topic in class or solving questions associated with feedback on the exam. Furthermore, according to data issued from our exploration, these devices also could serve to unchain refinement or validation of students' conceptions of the subject to be learned, as it will be shown by the following paradigmatic example of this type of interrelation or student productive collaboration.

Productive collaboration between students: A paradigmatic example

An example of feedback, or productive collaboration between students, which from our point of view shows the refinement or validation of the concepts at stake on the subject, is shown below.

JL: "Hello ..... my example is fingerprints. There is only one pattern for each person. ”

...

RO: "An example of a function in soccer could be a free kick to the goal because it starts from a zero point, rises and falls again."

JL: "Hello RO, I agree with your example, as long as it is specified that the function is the position of the ball in a certain time when making the free kick."

It is clear, in the case of the communication exchange between JL and RO (given by means of a forum), that the feedback that JL provides to RO is crucial to validate his function’s example, which was formulated in a so schematic way. Practically, it is JL contribution that rescues the visualization of the phenomenon provided by RO’s example, in fact, completes and reformulates it. It is to say that JL filters, refines, and produces a formulation of a function that underlies in the visualization of the phenomenon initially provided by RO.

In summary, the knowledge or formulation of the function at stake did not reside in a single location but rather through a reformulation of a confluence of information originated, in this case, by the exchange of critical information or productive collaboration between two individuals who sought to investigate mathematical functions, a common subject of interest, that finally produced feedback to each other, what is consistent with connectivist learning or distributed knowledge as pointed out by Downes (2009).

EMBRACING PROVING INTO EVERYDAY LESSON BY PROBLEM POSING

Hangil Kim
The University of Texas at Austin
hangil_kim@utexas.edu

Proof plays significant roles in the context of school mathematics and is a tool for enhancing student's understanding of mathematics. Lack of opportunities for proving in textbook has been documented. This study was conducted to consider an instructional way to make proving as everyday lesson by formulating more opportunities than did textbooks. The guiding assumption of this study is that conjectures which students come up with can be initiatives for learning how to prove. This preliminary study will show that problem posing is a strategic tool with potential to bridge everyday instruction and the practice of proving so as to teach how to prove more meaningfully and authentically.

Keywords: Reasoning and Proof, Instructional Activities and Practices, Classroom Discourse

Proof and proving have been considered as central in the context of school mathematics with its roles (Knuth, 2002a) which are "inseparable in doing, communicating, and recording mathematics" (Schoenfeld, 1994). In *Principles and Standards for School Mathematics* (NCTM, 2000), authors argue that "Mathematical reasoning and proof offer powerful ways of developing and expressing insights about a wide range of phenomena." (p. 59). However, it yields difficulty for students to understand it and for teachers to teach it (Stylianides, Stylianides, & Weber, 2010). The disagreement of its centrality for *all* in secondary school mathematics exists among in-service teachers (Knuth, 2002a). Even worse, there are not many opportunities available for students to engage in reasoning and proving in textbooks (Bieda et al., 2014; Thompson, Senk, & Johnson, 2005). Thus, to cultivate a context where students are introduced to proving, engage in the practice, and, ultimately, recognize proving as fundamental in learning of mathematics, need to authentically formulate opportunities beyond those available in textbook should be met. That way, with opportunities to engage in proving in a mathematically meaningful way rather than to take part in a mere ritual as spectators—such as reading and understanding proofs given in textbook without formulating or exploring conjectures, both students and teachers can be more fluent in proving. In this report, a-year-long study of problem-posing activity with particular interest in proving and teacher's instructional interventions which foster student's reasoning and developing proof will be analyzed.

Literature Review

Proof and Reasoning in School Mathematics

Proof and reasoning are neither mere content to be learned with chosen topics nor reserved for certain grade levels. NCTM (2000) states "Reasoning and proof should be a *consistent* part of students' mathematical experience in prekindergarten through grade 12. Reasoning mathematically is a habit of mind, and like all habits, it must be developed through consistent use in *many contexts*." (p. 56, italics added). In the context of secondary school mathematics, the only place in which proof is substantially treated is geometry (Knuth, 2002b). The proofs in the subject and do not show the variety of ways of proving (e.g., proof by contrapositive, reductio ad absurdum). As Thompson, Senk, & Johnson (2005) argued "Because many research studies have shown that writing proofs is difficult for students at all levels, it seems to us that students need more opportunities to engage in varied aspects of proof-related reasoning in order to become more fluent in reasoning and proving."(p. 286) Furthermore, there are not many opportunities for students to engage in reasoning and proving tasks across textbooks which are considered to be primary sources of teaching and

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

learning mathematics (Bieda et al., 2014; Thompson, Senk, & Johnson, 2012). Mathematics teachers need to take on an active role in teaching reasoning and proving beyond what is available in textbook and have strategic knowledge of instructional practice and its relation to student's learning of proof (Stylianides & Ball, 2008) and how it can be more impactful.

In *Proofs and Refutations*, Lakatos (1976) exemplified use of examples when exploring, formulating, qualifying a conjecture, developing a proof and making revisions when encountered with counter examples—either *global* or *local*. Although there exists heterogeneity in appearance among them, mathematically similar objects enable observers to notice regularity between them and the regularity becomes a mathematical conjecture—possibly to be proven true thus to be a theorem. For teacher's specific interest and intent to teach certain theorems, some may argue that designed examples can be given to students as resources to experience transition from empirical arguments to formal proofs. However, the main focus of this study is not on teacher's designing or displaying examples as intended for teaching specific content but on teaching how to strategically generate examples with same constraints in order for students to look for examples (or counter examples) not restricted to those within their reach.

What is problem posing? Silver (1994) defines the term as "both the generation of new problems and the re-formulation, of given problems." (p. 19). According to the author, problem posing can also offer insight into solution of a problem: when developing a proof, posing problems can be a pathway to gain insight into proof. As a way of posing problems, Brown & Walter (1983) suggested "What-If-not?" strategy which new problems can be generated by varying some of the given conditions of a problem. For example, after solving a problem that a sum of two even numbers is even or odd, one can pose a new problem with a question "what would it be if I add two odd numbers?". Lockwood et al. (2013) studied how a mathematician uses examples when proving and disproving. By referring back and forth to examples of relevance to a conjecture, the mathematician gained insight of proof by leveraging idea of one insightful example. In the same line with what Balacheff (1988) called a *generic example*, a representative example of the domain of a conjecture suffices to be developed to a proof by *syntactic proof production* (Weber & Alcock, 2004) or *transformation of images* (Harel & Sowder, 1998). However, unlike teachers and mathematicians, this may be improbable for students to do as such.

Methods

Participants

Geographically located at the vertical center of the Korean peninsula, the school where was the locus of this study is a high school with male students only and located in an urban area. Nearly all students intended to enroll the school to prepare for their admission to college.

As a high school mathematics teacher and the researcher in this project, I had taught junior high students for 3 years and started to teach high school students for the first time by the time this study began. The guiding assumption was that every student is *a theory builder* (Carey, 1985) who can come up with a conjecture or a plausible argument which makes the most sense to them based on their observations and that most of students are able to develop and write proofs by themselves or with a little help offered by *a teacher* or *a more capable peer* (Vygotsky, 1978).

Data Collection

The data collected for the study include student's written assignments, teacher's verbal and written communication with individual students, and two video-taped lessons of which duration is roughly 50 minutes. Based on "What-If-Not?" (Walter & Brown, 1983), for consistency in structure and organization of the assignment, it was structured in a worksheet. Before administering the work sheet weekly, the instructor demonstrated how to use it and explained what is expected as the end result in each step. Until everyone reached understanding of the activity, there had been discussions and negotiations of what it means to be *true*, *valid*, and *appropriate* (Stylianides, 2007; Stylianides et al., 2016) when evaluating validity of a proof.

Data Analysis

Since it may be premature to present a framework which will be used in the later analysis, I shall present the working framework in the process of conducting an initial analysis through the general inductive approach (Thomas, 2006) to highlight themes of relevance to the purpose of this study.

Preliminary Results and Discussions

"What-If-Not" strategy has a potential to offer a strategic way for students to better identify and understand what assumptions are given and conclusions they should prove. For example, one of students in the class was attempting to solve a problem: find the maximum area of a rectangle inscribed in a given isosceles triangle. The student reached at a solution which was not the solution of the problem since he solved a problem without taking the condition "isosceles" into account. Then, after some conversation with him, it came into his attention that he left the condition out. As described in this instance, the student was able to take all the conditions into account after discourse with the teacher. Then, the teacher posed a question as an extension of the problem: "what if the triangle is a right triangle? Or what if the triangle is an acute triangle?" Even though it took a few days for the student to figure out how to solve it, the student reported the teacher that this extended discourse with him led the student to use the strategy in evaluating his understanding of problems by manipulating the given.

Problem posing can offer a strategic way for students to generate examples beyond the individual potential example space (Watson & Mason, 2005) and gain insight into how proof looks like. As it enhances student's understanding of what constraints are given and should be verified by making negation or eliminating and reinstating some of the given and the to-be-verified, it can scaffold student's generation of examples under the conditions met by examples or counter examples. There was a student had issues with qualifying examples and non-examples based on the given constraints. He often said that it is difficult to come up with a counterexample when attempting to disprove a conjecture. The teacher asked the student to think of examples meeting the *least* (i.e. the maximum number of the given conditions as many as he can consider simultaneously into account) subset of the given. Then the teacher demonstrated how to add the rest of the given one by one and accordingly prompted the student to list a number of examples each time. The teacher demonstrated how to qualify examples by adding an additional constraint and left the student doing the rest to reach at being able to generate examples or counterexamples thereafter. The student soon became capable with manipulating the constraints by leaving out and reinstating some of them. This student seemed to show the potential of "what-if-not" strategy as a way of generating examples (or counterexamples) beyond his reach in that he did not try to recall the examples from his experience but qualify examples by adding the given condition into his consideration and narrowing them down to the domain of the argument of his interest. This is not meant to argue that the strategy itself suffices to extend the example space but that it has potential to do as such only with teacher's careful consideration and helpful prompts rather than simply offering the caveat. The kinds of prompts which are crucial in teaching and learning of proof will be identified and discussed in what follows next.

Teacher's role is crucial and critical in the success of teaching and learning of proof. As documented in Stylianou & Blanton (2011), teacher's role becomes of more importance in the teaching proof. In this study, it was the teacher who extended the discourse with individual student to offer an opportunity to engage in exploring and revising conjectures, developing a proof, and prompting student to revise the proof for the greater proximity to the degree of formal proofs. This study will identify three types of prompts by what the teacher intended to elicit from students at a given time: those for *justification, elaboration,* and *generalization*. The instructional intent of prompts was to extend and structure discussions and to attend to what can improve student's proof in terms of precision (in use of mathematical terms, expressions, or representations), clarity (in use of language), and generality (of the proof). The working definitions of the prompts are as follows:

1. *prompts for justification* are meant to point out unexplained parts and request to fill logical gaps or challenge truth of conjectures assumed to be true or referred to in student's argument;
2. *prompts for elaboration* are meant to call attention to what requires clarification or discrepancy between what is intended by student and understood by others; and
3. *prompts for generalization* are meant to pose questions which possibly lead to generalization of part of student's reasoning or examples.

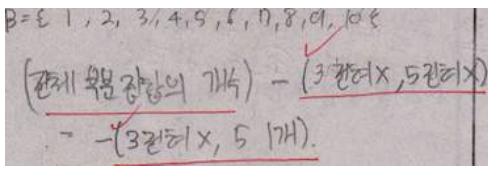

Figure 1. Examples of *Elaboration*

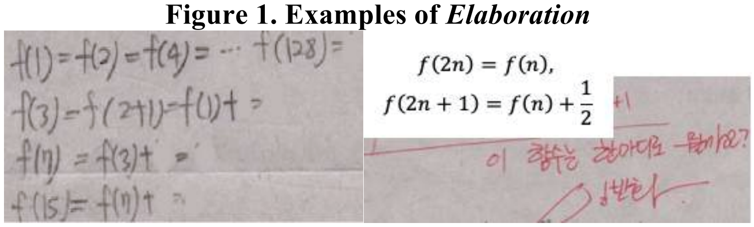

Figure 2. Examples of *Generalization*

There are a few limitations in this study that should be examined through research involving different individual participants, classroom culture, and society. As Cobb & Yackel (1996) pointed out, the results of a well-designed (or well-controlled) research can hardly argue that the study is conducted independently of any aspect of the context of the socio-cultural or individual (or psychological) peculiarity of the participants, the classroom, and the society involved. I acknowledge that this study is not the case that the results are drawn independently of the individuals, the classroom culture, and the society. Future research in the similar perspective toward problem posing and instruction of proof taken in this study will let light be on the unpaved paths I have not taken in this study and nourish the literature.

Centering class discussions around student mathematical thinking has been identified as one of the critical components of teaching that engages students in justifying and generalizing. This report shares analysis from a larger project aimed at describing and quantifying student and teacher components of productive classrooms at a fine-grain level. We share results from this analysis of 39 mathematics lessons with a focus working with public records of students' mathematical thinking.

Keywords: Instructional activities and practices, Teacher Education-Inservice/Professional Development

The goal of *Working with Public Records of Students' Mathematical Thinking* is to make student thinking available to all students (Ghousseini, 2009), and to maintain common ground (Staples, 2007). This may look like recording student ideas (Cengiz et al., 2011; Staples, 2007) and engaging the class to work with it. Publicizing student work has the potential to position students as contributors to mathematics (Cohen, 1994). We illustrate an analysis of how public records of students' thinking were used in 39 lessons of grades 4-8 classrooms to productively generate meaningful student discourse. Students can learn mathematics when engaging with each other around mathematics (Schwartz, Black, & Strange, 1991). Teacher prompts that elicit reflection, communication, and meaningful explanations regarding a student's work and their thinking have been identified as essential and beneficial for mathematical learning and understanding (Hiebert, et al., 1997; Henningsen & Stein, 1997; Hiebert & Wearne, 1993; Kazemi & Stipek, 2001).We hypothesized that lessons in which teachers engaged students in examining public records of students' mathematical thinking would generate more and higher-levels of student discourse. Our research questions were: (1) How prevalent are public records of students' mathematical thinking within the lessons? (2) Do lessons that contain public records include more student-level engagement, specifically higher-level cognitive engagement? Do those lessons that also contain selected and sequenced public records include even more than those with either a) no selected and sequence public records and b) more than those with no public records at all?

Theoretical Orientation and Analytic Framework

There is a general consensus in the mathematics education community that high-quality mathematics classrooms are those in which student voices are heard, and student thinking is leveraged as the means to move instruction forward (e.g., Ball, 1993; Jacobs & Spangler, 2017; Nasir, & Cobb, 2006; Schoenfeld, 2011; Turner, Dominguez, Maldonado, & Empson, 2013). Enacting practices that foreground student thinking is complex, requires intentional and strategic moves, and persistence in enacting these moves over time (Staples, 2007; Boaler & Staples 2008; Franke, Kazemi & Battey, 2007). Mathematically productive teaching routines are a set of teaching routines designed for accessing and working with student mathematical thinking. Research

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

has emphasized attending to students' mathematical thinking as one of the most essential aspects of impactful teaching (Jacobs & Spangler, 2018; Lampert et al., 2013).

One such teaching routine is *Working With Public Records of Students' Mathematical Thinking* (described above). This routine can be situated within the teaching routine *Working With Selected and Sequenced Student Math Ideas*. The goal of this routine is to advance student understanding by fostering connections related to the core mathematical ideas on which the lesson/task focuses. Once teachers have learned about how their students are thinking, they need to choose how to build ideas with the whole class by selecting and sequencing how student ideas are shared (Stein, Engle, Smith, & Hughes, 2008, Stein & Smith, 2011).

Methods

The 39 coded lessons for this project stem from two urban school districts in the United States: grades 4-5 were from a large urban district, whilst grades 6-8 came from a mid-sized urban district. The 20 lessons from the middle school were taken from each teacher at the end of the school year, and the 19 lessons from the elementary school teachers were a stratified random sample, according to Mathematical Quality of Instruction (Hill, 2014) scores. Because this paper focuses on two teaching routines (*Working With Public Records of Students' Mathematical Thinking* and *Working With Selected and Sequenced Student Math Ideas*), all lessons were coded for those two teaching routines. Each lesson was also coded for Students' Habits of Mind (HoM) and Habits of Interaction (HoI). HoI focus on students' verbal interaction with the teacher as well as with one another. HoI include *Explaining* their thinking, asking *Genuine Questions*, *Revoicing* other students' contributions, *Private Reasoning Time*, *Compare* logic and ideas for similarities or differences, exploring multiple *Pathways* to solving a problem, and *Critique* one another's ideas. HoM can happen within an HoI and focus on the cognitive activity embedded within their verbal interaction. HoM are noted here as *Representations (Reps), Connections* within and across two mathematical concepts, strategies, or structures, *Regularity and Structure* using patterns, properties, or mathematical structures, *Metacognition (Meta)* or reflection on their own thinking, recognizing, examining, or using their own or each other's *Mistakes,* engage in *Meaning of tasks and terms, Justify* their thinking, and *Generalize* ideas. To summarize, HoI are the ways a student can interact with others whereas HoM are the mathematical activities embedded within such an interaction. These codes were developed for a larger study involving the Math Habits Tool, which was developed to capture *mathematically productive components* of classrooms in terms of both student and teacher in-the-moment actions.

All coding was completed by graduate students who took part in a three-day coding training camp that focused on the various student and teacher-level codes used in this project. Each lesson was then assigned to two graduate students to code independently. After each coder had completed their initial coding of the lesson, the pairs of coders meet to compare their independent coding and reconcile any differences and disagreements. Disagreements that could not be reconciled between the two coders were sent to a third person for final decision.

In considering our research questions, we grouped the 39 lessons into three themes: (1) lessons containing public records where at least two public records were selected and sequenced; (2) lessons containing at least one public record, but none that were selected and sequenced; and (3) lessons containing no public records. We then compared those groups in terms of quantity and type of HoI, and HoM within the lesson.

Results

Of the 39 lessons, 26 lessons (67%) did not contain public records of students' mathematical thinking (Group 3), thus, student work was not displayed and worked with at all. Of the 13 lessons (33%) that did include public records of students' mathematical thinking, six were further situated in a *selecting and sequencing* routine (Group 1), while seven were not (Group 2). Thus, only 33% of the lessons contained student work that was actively displayed and worked with, and about half of those were situated in a selected and sequenced routine.

Across all three groups, the Habits of Interaction *Explain* and *Questions* were frequently used. Similarly, the Habit of Interaction *Private Reasoning* occurred sporadically throughout some of the lessons. Thus, explaining mathematics, asking genuine questions, and prompting students to use private reasoning about mathematics are habits of interaction that are seemingly not dependent on reasoning with students' work within a public record, so we removed those three HoI from our next level of data analysis. *Generalize* was not present in any of the lessons, so it too was removed from the next level of data analysis.

We found that while there was generally infrequent use of higher-level Habits of Mind and Interaction across all 39 lessons, lessons that did use public records engaged students in higher-level HoM and HoI more frequently than lessons that did not. Furthermore, lessons that selected and sequenced the public records were found to include student engagement in these codes more often than lessons that did not select and sequence their public records. (See table 1.)

Table 1: Percentage of Lessons in Each Category with Relevant Student Habit Occurrence

	Compare	Pathways	Revoice	Critique	Reps	Connect	Structure	Mistakes	Meta	Meaning	Justify
Group 1	83%	67%	83%	50%	83%	67%	33%	50%	50%	17%	50%
Group 2	14%	0%	29%	14%	86%	29%	43%	14%	29%	0%	0%
Group 3	8%	4%	0%	0%	23%	12%	8%	4%	0%	12%	8%

Moreover, we found this to not only be true of the lessons, but within the public records themselves. Next, we consider how the student engagement within a lesson compares to the engagement specifically during a public record portion of class. Table 2 highlights the average percentage frequency of a student habit for a whole lesson in the group's top row, and the average percentage frequency of a student habit for the public records portion of a lesson in the group's bottom row. For example, of all the higher-level student habits used in Group 1 lessons, 15% were *Compare* and 8% of those habits took place within a public record. Because Group 3 lessons contained no public record, there are no student habits within a public record to display (i.e. the second row is empty). Notice that 50% or more of the student habits in Group 1 lessons happen within a public record, and with the exception of *Compare*, *Critique*, and *Mistakes*.

Table 2: Frequency Percentage of Habits Per Lessons & Public Record in Each Group

	Average Time	Compare	Pathways	Revoice	Critique	Reps	Connect	Structure	Mistakes	Meta	Meaning	Justify
Group 1	56:50	15%	7%	14%	4%	28%	12%	2%	3%	8%	2%	5%
	17:46	8%	4%	10%	2%	22%	8%	1%	2%	7%	2%	5%
Group 2	58:30	2%	0%	14%	5%	43%	17%	10%	2%	7%	0%	0%
	09:02	0%	0%	12%	2%	26%	14%	7%	0%	5%	0%	0%
Group 3	45:00	11%	9%	0%	0%	32%	7%	20%	2%	0%	7%	11%

Discussion and Future Research Plans

Only 13 lessons (33%) engaged students using a public record of students' mathematical thinking. Only 6 (15%) lessons selected and sequenced the public records. Lessons with public records showed a higher percentage usage of higher-level cognitive engagement. Lessons which selected and sequenced the public records engage student in higher-level mathematical habits consistently more than lessons that did not. In fact, on average, lessons that selected and sequenced the public records of students' mathematical thinking showed a 46% increase in higher-level cognitive engagement compared to lessons that did not.

One explanation for this drastic difference is that in selecting and sequencing public records, students are exploring multiple pathways, comparing strategies, and inevitably critiquing and debating any contradictory or different ideas. Thus, by selecting and sequencing students' ideas, teachers make these habits of interaction more accessible for the students and can more advantageously create a dialog around multiple ideas.

Close to 50% or more of the student codes in Groups 1 and 2 lessons occurred within public records. Thus, public records are creating a time for students to engage in mathematical discourse more frequently and at a higher-level than time outside of the public record.

Although important to make student thinking available to all students and work with it, it is not enough. Providing access to students' ways of thinking offers ways of engaging; however, without selecting and sequencing the engagement is shallow and less frequent. Thus, by selecting and sequencing the public records of students' mathematical thinking, an exploration and dialog using the habits of interaction can be sparked to ignite the higher-level conversation that leads to deeper, more frequent usage of habits of mind such as making meaning and justification. Therefore, as evident from literature (Stein, Engle, Smith, & Hughes, 2008, Stein & Smith, 2011), having students' present their ideas to the class is not as effective in creating productive student discourse as carefully monitoring, selecting, and sequencing student ideas. Moreover, the results we have stated here illustrate the effects on students' engagement when a teacher effectively selects and sequences students' mathematical ideas. Further work will involve continued analysis of 61 more lessons to see if this pattern still holds. Additionally, this work focused on only student engagement in the lesson, but future work will also include analysis on teacher prompts for student engagement.

AN INSTRUCTOR'S ACTIONS FOR MAINTAINING THE COGNITIVE DEMANDS OF TASKS IN TEACHING MATHEMATICAL INDUCTION

Vladislav Kokushkin
Virginia Tech
vladkok@vt.edu

Marcie Tiraphatna
Virginia Tech
marciet@vt.edu

Mathematical tasks are central to students' learning since they can influence and structure the ways in which students think about mathematics. Carefully selected tasks have potential to broaden students' views of a subject matter and facilitate their mathematical growth. However, research identifies that cognitive demands of tasks may change as the tasks are enacted during instruction. For this reason, it is important to understand what instructors can do to maintain the intended cognitive demands. In this paper, we investigate a teacher's actions for maintaining high-level cognitive demands of tasks in teaching proof by mathematical induction. Our findings suggest that the method of quasi-induction (Harel, 2002) may be considered as an example of a productive scaffolding strategy for assisting students in mastering proof by induction.

Keywords: Classroom Discourse, Reasoning and Proof, University Mathematics

Proof by mathematical induction is a technique for proving statements about natural numbers. To prove that proposition $P(n)$ holds for any natural number n, one needs to check that (1) $P(1)$ is true (the base case) and (2) if $P(k)$ is true for some fixed but arbitrary natural number k, then $P(k+1)$ is also true (inductive implication). The principle of mathematical induction poses conceptual difficulties to college students (Dubinsky, 1991; Harel, 2002; Movshovitz-Hadar, 1993; Stylianides, Stylianides, & Philippou, 2007).

Carefully selected tasks can help students overcome cognitive obstacles associated with proof by mathematical induction. Mathematical tasks play a crucial role in students' learning. They can shape students' conceptions about the subject. Furthermore, they offer an opportunity for teachers to lower their authority in the classroom, in turn allowing students to create mathematics for themselves. However, one must be able to strike a balance when determining the appropriate difficulty of task for a student. When tasks do not significantly challenge the student, they may become routine or discourage creativity. In contrast, if a task is too difficult, students may make insufficient progress toward the intended mathematical goal.

The cognitive demand of a task represents its level of difficulty (Stein, Grover, & Henningsen, 1996). The cognitive demands of tasks for K-12 students have been well documented (Spears and Chávez, 2014; Bieda, 2010; Henningsen and Stein, 1997). However, to our knowledge, cognitive demands of have not been extensively explored at the undergraduate level. This study aims to contribute to the research on cognitive demands of tasks by considering problems an instructor used in teaching proof by mathematical induction. Specifically, the purpose of this case study is to investigate a teacher's actions during the enactment of high-level tasks. Results address the following research question: *what are the teachers' actions for maintaining high-level cognitive demands of tasks in teaching proof by mathematical induction?*

Theoretical Framework

The present study is guided by the Mathematical Tasks Framework (Stein et al., 1996). This model describes the evolution of a task through three phases of classroom: as written in instructional materials, as set up by a teacher in the classroom, and as implemented by the students. Ultimately, a mathematical task should lead to student learning.

For the purposes of this study, we distinguish between *planned* and *enacted* mathematical instruction. Planned instruction refers to how teachers plan a mathematical task and how they pose it in the classroom. Enacted instruction is the actual teaching that occurs, including the active roles of both teachers and students (Remillard, 2005). The Mathematical Tasks Framework represents planned instruction by the first two phases and enacted by the third one.

The framework further specifies two dimensions of tasks, task features and cognitive demands, that may affect the transition between phases. This study is centered around cognitive demand. Cognitive demand refers to the variation in the kind of thinking processes required of students while engaging with the tasks. According to Stein et al., (2009), there are four levels of cognitive demands: a) memorization, b) procedures without connections, c) procedures with connections and d) doing mathematics. The first two levels are traditionally considered low-level demands, while the latter refer to high-level demands.

The enactment of mathematical tasks of high cognitive demands allows students to develop sense-making and reasoning skills, critique their peers' solutions, formulate examples and counterexamples, create viable justifications, and properly communicate their reasoning. Therefore, implementation of high-level tasks may be beneficial for students' mathematical growth. Planning the implementation of a task is crucial to students' learning that occurs around this task. However, research identifies that teachers have difficulty enacting high-level tasks even if they were planned as such (Boston & Smith, 2009). Teachers may either maintain the high cognitive level or they may lower it to make tasks more accessible for students. Stein and Smith (1998) suggest a list of factors associated with the maintenance of high-level cognitive demands. These factors include teachers giving sufficient time, making conceptual connections, pressing for justifications, and scaffolding student thinking and reasoning.

The term scaffolding has been used in various contexts. Anderson (1989) highlighted the importance of the Vygotskian notion of scaffolding in supporting students' high-level thinking processes. Henderson and Stein (1997) define scaffolding as a teacher's assistance in response to a student's struggle with a task. This assistance enables the student to complete the task alone, but does not reduce the cognitive demands of the task. William and Baxter (1996) separate the constructs of analytic and social scaffolding. Social scaffolding refers to the scaffolding of social norms; analytic scaffolding is the "scaffolding of mathematical ideas for students" (p. 24). Speer and Wagner (2009) consider analytic scaffolding as guiding students "further toward the desired mathematical goal(s) by using selected student contributions" (p. 536). For the purposes of our data analysis, we put these ideas together and define the construct of scaffolding as a *teacher's pedagogical strategies or actions toward the desired mathematical goals in response to or in anticipation of students' struggles.* Furthermore, we introduce the term *productive scaffolding* to refer to *scaffolding that maintains the cognitive demands of the task*.

Data and Methods

This study used one white male instructor's materials and three episodes of teaching proof by mathematical induction at a large public research university in the southeastern United States. The course is a junior-level course designed to teach mathematics majors typical mathematical proof techniques. The data used are part of a larger project studying cognitive components of proof by mathematical induction. For this project, research-based instruction was developed and implemented. Teaching episodes were video and audio recorded and transcribed by the authors.

We analyzed the instructor's lecture notes as written prior to instruction. All mathematical tasks were categorized using the Tasks Analysis Guide (TAG) (Stein et al., 2000) with respect to Stein et al.'s (1996) levels of cognitive demands. Once a consensus was reached between us, we went through two phases of video analysis and coding. During the first round of video analysis, we classified each mathematical task's level of cognitive demand as it was presented in the classroom. We then coded the teacher's actions for instances of Stein et al.'s (2009) factors for maintaining cognitive demands, using Vygotsky's notion of scaffolding. After identifying the factors, we returned to our data to closely study the instances of scaffolding using our definition.

Results and Discussion

During the observed teaching episodes, the instructor used PowerPoint slides with three tasks displayed on three big screens around the room (Figure 1).

1. For each of the following parts, decide whether the given information is enough to conclude that the following claim is true.

   Claim: $P(n)$ is true for all $n \in Z^{+}$.

   If the given information is not enough, offer a brief explanation on why (perhaps listing a value of n for which $P(n)$, is not known to be true).
   a) $P(1)$ is true and there is an integer $k \geq 1$, such that $P(k) \rightarrow P(k+1)$.
   b) $P(1)$ is true and for all integers $k \geq 1$, $P(k) \rightarrow P(k+1)$.
   c) For all integers $k \geq 1$, $P(k) \rightarrow P(k+1)$.
   d) $P(1)$ is true and for all integers $k \geq 2$, $P(k) \rightarrow P(k+1)$.
2. a) Prove that for all natural numbers n, 3 divides $8^n - 5^n$.
   b) Prove that if 3 divides $8^6 - 5^6$, then 3 divides $8^7 - 5^7$.
3. Prove that for all natural numbers n, $2 + 2^2 + 2^3 + \cdots + 2^n = 2^{n+1} - 2$.

Figure 1: Tasks

When presenting the tasks to the class, the instructor provided students with little preliminary explanation. He typically displayed the tasks on the screens and encouraged students to work in small groups. For this reason, we can claim that these tasks were set up by the teacher in the same way that they were presented in the instructional materials. In the following discussion, we will refer to the tasks of first or second phase (Stein et al., 1996) as planned.

We further used TAG as an instrument to analyze the cognitive demands of tasks. All the tasks exhibited key attributes of "Doing Mathematics" tasks (see Stein et al., 2000). The problems required complex and non-algorithmic thinking and considerable cognitive effort. They also encouraged students to explore and understand the nature of mathematical concepts and to access relevant knowledge and experience.

The first round of analysis revealed the presence of most of the factors associated with maintaining high-level cognitive demands of tasks (Henningsen & Stein, 1997, Boston & Smith, 2009). First, the instructor seemed to allot an appropriate amount of time for the students to engage with the tasks through small-group discussion. Second, students received formal instruction on logical implication before they were introduced to the principle of mathematical induction. Given that logical implication is an important part of each task, we can argue that the tasks build on students' prior knowledge. Third, the instructor constantly questioned students by asking them to rephrase and justify their reasoning. He also frequently made conceptual connections between the tasks and students' solutions and modeled high-level performance through presenting counterexamples to students' erroneous claims.

Scaffolding

Avital and Libeskind (1978) introduced the method of "naïve induction" to assist students in overcoming their bewilderment of the transition from the base case to the inductive step. Naïve induction has been elaborated by Harel (2002) and labeled as "quasi-induction." Prior research has identified quasi-induction as a fruitful instructional approach (Harel, 2002; Cusi & Malara, 2008). This method engages students in repeated application of the inductive implication $P(k) \rightarrow P(k+1)$

for beginning values of k, reinforcing the logical reasoning that is essential in proof by mathematical induction. More specifically, students first establish that $P(1)$ is true. Then, they create a chain of logical implications $P(1) \rightarrow P(2), P(2) \rightarrow P(3), P(3) \rightarrow P(4),$ and so on. After considering these first few implications, students can then infer that the process must continue until eventually $P(n)$ is shown to be true.

The idea of quasi-induction was built into the overall observed instruction. In anticipation of students' struggle with formal proof, Tasks 1 and 2 were designed to engage students in quasi-inductive reasoning. Quasi-induction was first explicitly introduced by one of the students in the discussion of Task 1c who said, "1 works, so $P(1+1)$ works, so 2 works. And you can plug 2 back in for k and the logic repeats itself." In response to the student's reasoning, the instructor discussed mathematical rigor of quasi-induction, but accepted the suggested solution. Furthermore, during the group work on Task 3, students in one of the groups were not engaged with the task. The instructor suggested they use quasi-induction: "Sometimes it helps to do – just try a bunch of cases, just to get a feel of what's going on." This prompt allowed the task to still have the key attributes of Doing Mathematics while making it more accessible for the students.

Task 2a was introduced at the very beginning of the first class. One of the students suggested using the binomial expansion to prove the statement. The teacher acknowledged this idea but encouraged the students "to practice something inductive." The instructor anticipated students' struggle with formal solution using proof by mathematical induction. For this reason, after the students went through Tasks 1a-1d, he presented an "easier" Task 2b. The use of Task 2b did not reduce the cognitive demand of Task 2a. However, the students were given means to generalize the proof of $P(k) \rightarrow P(k+1)$ from a particular case of logical implication $P(5) \rightarrow P(6)$. Therefore, we consider the idea of generalization from a particular case as another example of what we call productive scaffolding.

Conclusion

This study provides an example of instructor's strategies for maintaining high-level cognitive demands of tasks in teaching proof by mathematical induction. The actions discussed above may inform instructors in preparation for and implementation of teaching mathematical induction. Our findings are consistent with the factors suggested by the extant literature (Henningsen & Stein, 1997, Boston & Smith, 2009 Stein & Smith, 1998). Namely, the teacher actively built upon students' prior knowledge, constantly asked students to explain their reasoning, and purposefully facilitated conceptual connections. We also report that scaffolding plays a central role in teaching proofs. In the context of proof by mathematical induction, the method of quasi-induction is suggested to be an example of what we call a productive scaffolding.

Although formal mathematical induction may be considered as a generalization of quasi-induction, there is still a cognitive gap between the two, which the students are not always able to bridge. Harel (2002) described this gap as a difference in perception of the inference $P(n) \rightarrow P(n+1)$. Future research must elucidate scaffolds as students attempt to bridge the gap.

RELATIONSHIPS WITH MATHEMATICS: THE IMPORTANCE OF AGENCY AND AUTHORITY

Tanya LaMar
Stanford University
tlamar@stanford.edu

Mathematics classrooms are spaces where teachers provide students with opportunities that will inevitably shape their conceptions of the subject and their own abilities to learn it. Therefore, it is important to understand how a classroom community defines mathematical knowledge, mathematical practice, and what it takes to be a person who is successful in mathematics. The study uses interviews with teachers and students in two classrooms plus a district wide survey to understand the relationships with mathematics they construct. The paper ends with a discussion of specific areas of pedagogy that could support the development of productive relationships with mathematics by more authentically centering student thinking in the classroom.

Keywords: Teacher Knowledge, Equity and Diversity

Introduction

For many, math is seen as requiring rote memorization and the regurgitation of procedures with little to no room for free thinking. Research shows that such approaches to math learning are related to low achievement (Boaler & Zoido, 2016, PISA, 2012, Gray & Tall, 1994). Mathematics classrooms are spaces where teachers provide students with opportunities that will inevitably shape their conceptions of the subject and their own abilities to learn it. Therefore, it is important to understand how a classroom community defines mathematical knowledge, mathematical practice, and what it takes to be a person who is successful in mathematics. This paper builds upon Boaler's 2002 framework for a relationship with mathematics in terms of knowledge, practice, and identity. The study uses interviews with teachers and students in two classrooms plus a district wide survey to understand the relationships with mathematics they construct. The paper ends with a discussion of specific areas of pedagogy that could support the development of productive relationships with mathematics by more authentically centering student thinking in the classroom. These include a shift towards open and project-based curriculum and an increase in value placed on student mistakes and struggle.

Literature Review

Aguirre, Mayfield-Ingram, and Martin (2013) define mathematics identity as "the dispositions and deeply held beliefs that students develop about their ability to participate and perform effectively in mathematical contexts and to use mathematics in powerful ways across the contexts of their lives" (p. 14). A student's mathematics identity will be formed in part by the ways they have been positioned in their particular learning context (Holland et. al, 1998). However, these conceptions of math identity are missing a key component to students' experience in the mathematics classroom-- the behaviors and practices they are expected to engage with while doing mathematics.

Teacher expectations of student mathematical behavior can be thought of through the lens of agency and authority. Agency refers to the extent to which students are able to express and use their own ideas in mathematical problem solving and authoring (Boaler, 2002). Student agency depends deeply upon the beliefs held by both teachers and students about what is expected of students in their role as problem solvers. This ranges from one end of a spectrum where the students are able to approach problem solving creatively, using their own ideas and methods to the opposite end where students are expected to use one specific procedure that's been told to them by another authority (i.e. the teacher or textbook). Part of this type of agency involves the extent to which students see this aspect of problem solving as being within their control. Gutstein (2007) found that when students experienced a strong sense of agency in their problem solving, they were empowered to interrogate knowledge sources and critically analyze material rather than simply receive it as truth. This sense of agency resulted in students deconstructing representations using mathematics to deepen their understandings of new material rather than searching for a pre-determined solution strategy.

Similar to the concept of student agency in the classroom is the concept of student authority. According to Cobb, Gresalfi, and Hodge (2009), authority in the mathematics classroom pertains to who decides what constitutes mathematical legitimacy. In some classrooms, this authority could lie solely with the teacher or textbook whereas in other classrooms it may be shared between the students, teacher, and textbook. Amit and Fried (2005) found that when the teacher is the main authority figure, students oftentimes use mathematical concepts introduced by the teacher unreflectively. In other words, students blindly reproduce what the teacher has shown without further thinking. These authors also found that this particular authority dynamic can hinder the productivity of collaborative learning efforts. For example, when students are working in groups, but the teacher is seen as the authority, little impetus exists for authentic collaborative problem solving.

Relationships with Mathematics

Boaler (2002) introduced the concept of a disciplinary relationship (see Figure 1). As knowledge, practice, and identity develop for a mathematics student, they each contribute to an overall relationship with mathematics. First, we consider the identity aspect of the relationship which is broken down into two parts: beliefs about one's role, and one's mindset. Within a mathematics learning setting, students will develop their own beliefs about what it means to learn math. A student may expect to be a passive receiver of knowledge, an active participant exercising agency and mathematical authority, or somewhere in between (Belenky, Clinchy, Goldberger, & Tarule, 1986). Additionally, they may believe that their mathematical abilities are static and fixed, or that they can be cultivated and grown (Dweck, 2005). Second, we consider the knowledge and practice aspects of the relationship with mathematics which together constitute the student's beliefs about the nature of mathematics and doing mathematics. The student may believe that knowledge in mathematics is made up of facts and procedures to be memorized, or they may see math as a web of ideas connected by logic and reasoning (Boaler & Zoido, 2016, PISA, 2012, Gray & Tall, 1994). Finally, the student may see the practice of doing mathematics as effortlessly and quickly understanding material or requiring struggle, learning from mistakes, and creative thinking (Boaler, 2015).

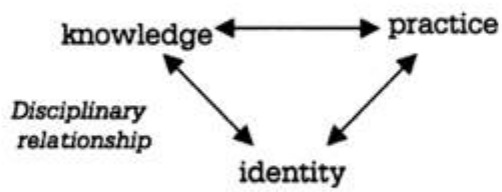

Figure 1. Framework for Disciplinary Relationships adapted from Boaler, 2002

Oftentimes, when a student has developed an unproductive relationship with mathematics, they respond to creative approaches in problem solving by stating something like, "am I allowed to do that?" As part of Boaler's 2002 study, she observed many classrooms referred to as "traditional" and "reform"- oriented. One of the most observable differences between these two types of classes were the role that agency played in each of them. Within the traditionally oriented classrooms, students were expected to follow standard procedures of the discipline. In these cases, the students' relationships with mathematics revolved around the agency and authority of the discipline. The students expected to follow the procedures and practices defined by the discipline.

In the reform-oriented classrooms students were "required to propose 'theories', critique each other's ideas, suggest the direction of mathematical problem solving, ask questions, and 'author' some of the mathematical methods and directions in the classroom" (Boaler, 2002, p.45). While it appeared that these classes offered more agency to students, Boaler clarifies that these students engaged with what Pickering (1995) calls the "dance of agency" between the established methods of the discipline and their own knowledge and practices (Boaler, 2002). (Note: Pickering (1995) found that professional mathematicians also engage with the "dance of agency" when developing and discovering new mathematics.) Through this "dance of agency" students would employ standard procedures coupled with their own ideas to adapt and extend methods in new and unknown contexts. The students developed mathematics relationships that gave them a sense of agency and allowed them some authority over their mathematical knowledge construction.

It is important to note that these students' opportunities to engage with the "dance of agency" were dependent on a number of things including the presence of an engaging project based curriculum but also the practices that teachers expected students to exhibit (Boaler, 2002). When it comes to mathematical practices (or ways of engaging with mathematics), the field provides what seems like a never-ending list of possible practices that teachers might focus their classroom towards (CCSS Mathematical Practices, 2010; NCTM Process Standards; Stipek et al., 1998). These practices include: communication, reasoning, proof, representations, justification, argument, sense making, and many more. While each of these practices are undoubtedly important, teachers cannot be expected to prioritize each one to the same extent so they must make choices based on their pedagogical beliefs or the needs of their students.

The decision of what to prioritize is complex in today's mathematics classrooms where students enter with an increasingly diverse range of strengths and needs. That is not to say that heterogenous classrooms are an issue. In fact, many research studies have shown that all students benefit from learning in de-tracked and heterogenous classrooms (Boaler, 2006 & 2011; Burris, Heubert, & Levin, 2006; Horn, 2008; Porter et al, 1994). However, knowing that the expectations for practice in the mathematics classroom will form the normative identity and ultimately influence the students' relationships with mathematics, it is imperative to know what teachers emphasize and how these priorities are taken up by students. This leads to the research question guiding this study: How are teachers and students constructing relationships with mathematics together?

Research Methods

Study Context and Participants

Although no two students will have the same relationship with mathematics, theoretically, the widest range of differences in these relationships would be apparent in a heterogeneous classroom where students represent a great range of prior experience and achievement levels. For this reason, this study focuses on heterogenous Algebra 1 classrooms.

The data for this study comes from a research project on a large urban school district in the Bay Area that had recently implemented a district-wide change of their mathematics course taking sequence by de-tracking mathematics through sophomore year and enrolling all 9th grade students in Algebra 1. Previous to this policy, students took algebra in eighth grade and 40% of students were failing and re-taking Algebra 1 (Hull Barnes & Torres, 2018). Since the implementation of the de-tracking policy, this failure rate has dropped to just 8% (Hull Barnes & Torres, 2018).

The student body of the district is culturally diverse with about 35% of students identifying as Asian, 27% Latinx, 15% White, 7% African American, 5% Filipino ,1% pacific islander, and <1%

American Indian (Facts, 2018). Furthermore, approximately 55% of students are considered Socioeconomically Disadvantaged, 29% of students are designated as Language Learners, and 11% are students diagnosed with Special Educational Needs (Facts, 2018). The students at Park High School represent an even more diverse community than that of the district with a higher percentage of socioeconomically disadvantaged students and greater percentage of students of color.

The participants in this study include two Algebra 1 teachers at Park High School and 6 of their students, for a total of 12 students. See Table 1 for more details about the participants.

Table 1: Participant Details

Teachers	Teacher Details	Student Pairs and designation[1]
Ms. Anderson	Early career teacher	Jackie and Kim (high achieving)
		Silvia and Arthur (turn around)
		Leta and Jose (low achieving)
Mr. Lang	Veteran teacher	Teresa and Mario (high achieving)
		Chantel and Steven (turn around)
		Marina and Lucy (low achieving)

Data

The data includes interviews with teachers and students in the two focal classrooms and results from a survey on mathematical mindset administered to 555 9th grade algebra students across the district. The interview questions for both teachers and students were developed using Rubin & Rubin (2008) as a guide. Teachers were interviewed during their prep periods and students were interviewed in pairs during class time.

The Mathematical Mindset Survey was developed by the youcubed research team and validated through previous research studies. The survey contains 27 questions with Likert scale answer options: Strongly Disagree, Disagree, Somewhat Disagree, Somewhat Agree, Agree, and Strongly Agree. The survey was conducted using the Qualtrics online software and offered in English, Spanish and Chinese. There are approximately 4,750 ninth grade students in the district, and the email requested teachers to give the survey to at least one of their 9th grade Algebra 1 classes. The distribution of the survey resulted in a total of 555 student responses to the survey representing a sample from 8 different high schools and 23 different teachers within the district.

Methods

Interview Data

To analyze this data, the researcher followed the analysis guidelines for inductive coding found in Miles, Huberman, & Saldana (2013). First, she open-coded each teacher interview to generate an initial set codes that were subsequently collapsed the codes into a broader set of codes and shared these with an expert in mathematics education for feedback. This resulted in a final teacher codebook that was applied to both teacher interviews.

From here, the researcher conducted a theme analysis which included exporting all excerpts coded with the same code into an excel spreadsheet and re-reading the excerpts, making note of the general theme(s) coming up in that code. From this process the teacher themes were generated and written up as one summary paragraph per theme.

[1] Teachers nominated a pair of students for each designation, "turn around" refers to students who started the school year low achieving but had improved throughout the school year.

Following the analysis of the teacher interviews, the researcher completed the same process with the student interview data which resulted in summary paragraphs for the student themes.

Since the research question asks about how the teachers and students construct relationships with mathematics together, the next step in the analysis required making connections across the two data sets. This process started with a comparison of the theme paragraphs from both sets of data and then a grouping strategy to create general themes. In some cases, this process was straight forward because both teacher and student themes already matched. For example, both the student and the teacher analyses resulted in a theme around mathematical authority, so those were grouped together as a general theme across both data sets. However, for themes that were less straight forward, the researcher would group similar ones together and then generate a heading for that theme. As she made her way through the list of teacher and student themes, she would first try to place the theme into one of the already existing headings, adjusting the title of the heading to better suit the themes included. In the cases where she was unable to reasonably connect the theme to a heading, she would generate a new heading. This was an iterative process that resulted in four general themes that cover all of the teacher and student themes where the most noteworthy findings centered upon agency and authority in the classroom.

Survey Data

The survey response data was first downloaded from the Qualtrics site and uploaded into the STATA quantitative data analysis software by another member of the research team. Then, the researcher created a table for each survey question that displays the spread of student responses by both frequency and percentage. To draw connections between the interview data and survey data, the researcher combined all agree answers into one metric and all disagree answers into another.

Findings

Both the teacher and student interviews surfaced a theme around agency and authority. The teachers want their students to work with one another to make mathematical decisions, choose methods, share ideas, and come to their own understandings around the content and take control of their learning. In an effort to encourage these practices, both teachers report trying to take a step back so that students can have genuine experiences of doing math with one another – and making mathematical decisions - without the teacher as the main authority.

> Ms. Anderson: I think that if I was constantly stepping in, it doesn't... I think that that just puts me back at this position of: 'I hold all the knowledge and I'm in charge of all of this.' And there are already enough times when I am that, and I am playing that role. And I've had some experiences this year where I blatantly did something wrong, and the kids didn't say anything to me. And I was like, 'Guys, what? You let me go through that whole thing.' And they were like, 'We figured you must have been right.' And I was like, 'Well, I'm flattered that you think I'm great.' Like, 'No, if you... You guys need to trust, trust yourself.' So I think that there are so many times where I already have all that power and control that if I'm gonna let a student go to the board, I don't wanna make that be a pseudo experience. I would rather have them actually be in control of it.

Mr. Lang shares his thinking around the value of students exercising mathematical authority and sharing their work with the class, especially when the class is struggling with a particular topic.

> Mr Lang: I think the more that when we work on something and there's some sort of place where we get stuck, to have a student or a student group go and present their solutions or how they're thinking about it. We're not ready for the more— I think I read this is largely a common thread in Chinese mathematics classes where they actually look for people to do good mistakes, if you will, to present it on the board and have that be learning— I don't think we're there yet, we're probably more showing the thinking and the steps towards what's gonna be a productive solution, but to have more students talk both so that they can get their ideas heard and be seen as students that can

> bring good mathematical knowledge to the class, as well as their articulation of what they understand about math, I believe, really helps them sort of solidify whatever understanding they develop.

Although Mr. Lang would like for his students to have agency and authority in approaching math through their own different ways of thinking, he sees his class as ready to discuss correct or “productive” thinking only. Herein lies a tension, there is both a sense of freedom and confinement of student thinking embedded in his statements: he wants them to feel the freedom to express their ideas but confines which ideas he values. This focus on correct thinking and answers is reflected in the student responses in terms of their beliefs in their own mathematical agency and authority in the classroom.

The students’ feelings of agency in mathematical problem solving are limited to choosing and utilizing different resources (such as calculators or peers) rather than choosing or creating their own mathematical ideas. For example, Kim, a high achieving student, explains that she is aware that she can utilize a variety of resources to succeed in math.

> Kim: I think what we need to do to be successful in our class is to ask more questions and ask for help, and really use the kind of resources we have around us, like our teachers and our peers, to help us.

This response is similarly reflected in the survey results where 89.1% of students agreed with the statement: “I am in charge of my own learning journey in math.” However, only 66% agreed that “In math class I feel creativity is valued”. While many students feel that they are in charge of their “learning journey”, fewer see creativity valued in the classroom. If we consider creativity as original thinking, then we can understand this result to communicate that students do feel agency over their math learning more generally, but not necessarily mathematical agency, meaning, students are not expressing and utilizing their own mathematical ideas. Students feel free to utilize resources (including the teacher and peers) but when it comes to sharing their unique ideas about math (creativity) they feel less freedom.

This apparent lack of expressions of mathematical thinking is closely intertwined with the students’ perception of mathematical authority. For these students, the act of deciding mathematical legitimacy was whittled down to merely deciding which answers are right and which ones are wrong rather than an interrogation of another’s mathematical reasoning or justification. For example, Silvia, a “turn around” student, was asked how she when the mathematical work she is doing is right and gave the following explanation:

> Silvia: We don't know. [chuckle] I mean, I don’t know when I’m doing my work, I don't know if it’s right or wrong. I would probably just ask a teammate or Ms. Anderson but yeah.

Of the twelve students interviewed, eleven students believed that their peers can help them decide what is right and wrong but that their teacher is the ultimate authority on the material. Perhaps the greatest detailed expression of the teacher’s mathematical authority came from Lucy’s explanation of what she does to decide if her work is right.

> Lucy: Oh, I just ask the teacher time and time again like, "Is this right?" And then when the teacher sees the problem on the work we try to show, then the teacher just sits down with us and then explains it deeply and deeply like, "What you need, what's this thing called and what's that thing called?" And then you answer it and then you... And then once the teacher is like, "That's correct," then you write it down with it. You write down step-by-step, how do you do that and how you do that, which is really helpful.

The belief that the teacher is the main source of mathematical authority appears to also be shared by a portion of the students surveyed. The results showed that 42% of students agree with the statement: “The teacher is the only one that knows if I understand or not”.

The focus on correct or incorrect answers rather than mathematical thinking seemed to manifest in a fear of mistakes and struggle. The students interviewed talked about struggle as something that is negative and should be avoided. For students, struggling is a sign that you don’t understand rather than a key part of the learning process.

> Kim: Whenever I get stuck, it makes me feel frustrated, and it's really uncomfortable because I feel like I could do it, but it just stalls, and my brain is like blank.

For Kim, and other students, getting stuck brings forth feelings of frustration and an inability to keep moving forward. Silvia expressed how continued instances of struggle begin to discourage her from mathematics learning.

> Silvia: I wouldn’t say I hate math, but it is frustrating. I was raised to be always a good kid, so I always like to be really good at what I’m doing. But when it comes to math, when I don’t get something, it just feels so frustrating. I'm just like, ‘you know what? Nevermind. Forget it. I’m not doing this,’ and I kinda just get stuck with that mindset…Yeah, it is really frustrating ‘cause you’re trying to actually be present in the group and trying to help other people. But then you’re just like, ‘Welp, I’m stuck.’ And it’s kind of (pause) ugly to have to be asking other people constantly about what's going on.

This communicates a low level of student agency as the students become debilitated by their own signs of struggle. These sentiments are reflected in the survey responses, where just over half (52%) of the students surveyed responded that they agree with the statement: “It is important not to make mistakes in math”, and 77% agreed with the statement: “I feel discouraged when I get a low grade in math”. The majority of students see mistakes and struggle as negative indications of one’s math learning and math ability. Furthermore, feelings of agency are thwarted as students feel discouraged by their struggles.

Overall, both the teachers and students varied in their reports about agency and authority in the classroom. The teachers want students to have agency and authority in their classrooms and they attempt to cultivate these dispositions by asking students to present their work to the class or share their thinking with peers. However, Mr. Lang notes that he feels his class is not ready to share incorrect thinking with one another. The students explain that they do share their work with one another, but with a focus on obtaining the right answers rather than sharing their thinking. Both teachers emphasize a desire for students to see themselves and one another as mathematical authorities rather than relying on the teacher without question. However, for eleven of the twelve students, the ultimate authority lies with the teacher.

Discussion and Conclusion

Together, the teachers and students in this study have constructed particular relationships with mathematics that can be thought of in terms of identity, knowledge and practice. In terms of identity, students seem to expect to take on a role that is not entirely passive but not quite active either. They report interacting with their peers but mostly for the purposes of verifying they are getting right answers instead of for the purpose of sharing their mathematical thinking. Mathematical knowledge has taken the form of the ability to decide what answers are right or wrong. In terms of practice, teachers and students value producing right answers above exploring the value of mistakes and struggle. Teachers report focusing student attention on what’s deemed “productive”. For the students, even though they see effort as important for success, there is a tension here where students actually wish to avoid struggling and spending too much time on any one topic as this feeling of struggle becomes debilitating for them, as noted by Kim who finds that when she gets stuck, “my brain is like blank”. The lack of value placed on struggle and mistakes works against the feelings of agency for students.

The teachers feel that students are not ready to discuss mistakes and instead focus on student solutions that are “productive”. This begs the question of who are the students that are producing what Mr. Lang describes as “productive” solutions and “good mathematical knowledge”. The avoidance of engaging with struggle and mistakes keeps the focus on being right and therefore devalues asking too many questions or asking for too much support. Furthermore, it increases the risk of sharing your thinking if you are not sure it is correct. Although the teachers express a desire for students to experience agency and authority in the classroom, it appears that the development of these dispositions are thwarted by a fear of mistakes and struggle on behalf of both the teachers and the students. Students are focused on asking questions to obtain the right answers or making sure they are doing the right steps rather than engaging in collaborative mathematical sensemaking.

An expansion of what is mathematically valuable would allow a wider range of students to see themselves (and be seen) as productive and important contributors to the mathematics community and expand beliefs about who is good at math.

We draw on our experiences researching teachers' use of student thinking to theoretically unpack the work of attending to student contributions in order to articulate the student mathematics (SM) of those contribution. We propose four articulation-related categories of student contributions that occur in mathematics classrooms and require different teacher actions:(a) Stand Alone, which requires no inference to determine the SM; (b) Inference-Needed, which requires inferring from the context to determine the SM; (c) Clarification-Needed, which requires student clarification to determine the SM; and (d) Non-Mathematical, which has no SM. Experience articulating the SM of student contributions has the potential to increase teachers' abilities to notice and productively use student mathematical thinking during instruction.

Keywords: Classroom Discourse, Communication, Instructional Activities and Practices

Productive use of student mathematical thinking during instruction is a critical aspect of effective teaching (National Council of Teachers of Mathematics, 2014). Along with other researchers (e.g., Sherin et al., 2011), we see noticing, in particular *attending* to student mathematical thinking, *interpreting* it, and *deciding* what to do with it (Jacobs et al., 2010), as critical skills that support this productive use. Although teachers who are adept at productively using student mathematical thinking might have developed intuition and skills that allow them to notice important aspects of student contributions, such practice needs to be unpacked to support more novice teachers' learning (Boerst et al., 2011). Toward that end, in this paper we draw on our experiences researching teachers' use of student thinking to theoretically unpack the work of attending to student contributions to articulate the student mathematics in those contributions. Our goal is to contribute to the knowledge base for developing teachers' abilities to notice student mathematical thinking during instruction, abilities that lay the groundwork for productive use of that thinking.

We conceptualized a set of high-leverage instances of student mathematical thinking—what we called **M**athematically significant pedagogical **O**pportunities to build on **S**tudent **T**hinking, or MOSTs (Leatham et al., 2015). We proposed that *building* on MOSTs—turning the MOST over to the class for them to collectively make sense of it—was a productive way to use student mathematical thinking (see Van Zoest et al., 2016 for an elaboration of *building*). The first (of six) criteria for determining a MOST is "Student Mathematics" and requires evaluating a given student contribution to determine whether students' words and actions provide "sufficient evidence to make reasonable inferences" (p. 92) about what the student is saying mathematically. This way of conceptualizing *student mathematics* (SM) is how we view what it means to attend to the mathematics in student contributions. Attending to students' mathematics in this way requires attending to what students are and are not saying and being careful about the inferences we make in that regard. Such attention positions a teacher to "confidently articulate" the SM of the student contribution so that they can interpret that thinking and decide what to do with it based on the mathematics the contribution makes available for the class to engage with.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

There is evidence that experience articulating SM can positively impact teachers' noticing. Teuscher et al. (2017) studied two pairs of student teachers, of which one pair had had experience articulating the SM for student contributions in a data set of secondary mathematics lessons. The differences between the two pairs' written reflections on student mathematical thinking during lesson observations were striking. All four consistently attended to student mathematics, but not to the same level of detail. The two who had previous experience articulating SM demonstrated skill in doing so in their reflections. The other two were only moderately able to provide a detailed articulation. This study suggests that developing teachers' skills in articulating SM positions them to attend to the mathematics of student contributions.

The Work of Articulating: Four Categories of Student Contributions

According to our view, articulating SM requires that one provide a reasoned argument for any inferences. Based on our experience justifying such inferences, we propose four distinct articulation-related categories of student contributions that require different teacher actions:

1. Stand Alone Contributions require no inference to determine the SM.
2. Inference-Needed Contributions require inferring from the context to determine the SM.
3. Clarification-Needed Contributions require student clarification to determine the SM.
4. Non-Mathematical Contributions have no SM because they are not mathematical.

Stand-Alone Contributions

Stand-alone student contributions are the easiest instances to identify the SM for, because the student contribution itself is the SM—no inference is required. This category of student contribution is straightforward and makes clear what mathematics the contribution makes available for the class to engage with. For example, consider a student contribution during an introductory lesson on adding fractions, where a student asks: "Is $\frac{2}{5}+\frac{1}{5}=\frac{3}{10}$?" The SM of this contribution is simply: *Is* $\frac{2}{5}+\frac{1}{5}=\frac{3}{10}$*?* The statement is clear (though not mathematically correct) and complete. This SM demonstrates that SM need not be true, and also that SM can come in a variety of forms, including questions.

Inference-Needed Contributions

Conversational norms dictate that we do not always use complete sentences or make explicit references. Instead, we use pronouns and take other communication shortcuts. Students do the same. Because it is impossible to know exactly what students are thinking, teachers make inferences about their students' contributions. These inferences are based on observations of what students say, gesture, and write. Thus, these shortcuts often need to be filled in to make sense of what mathematics the student contribution makes available. In these situations, although the work of inferring the SM can be done, it requires making inferences from the context. Teachers must take care, however, to not infer beyond the evidence provided by the student contribution. In particular, there is a tendency to fill in the gaps with what one wants to hear. When a student makes a contribution, it is their mathematics that needs to be attended to.

Suppose, for example, a class is asked a general question such as, "Do you understand?" and a student responds, "No." We know that the student does not understand something, but their contribution does not provide evidence of what they do not understand. In contrast, if the class was asked, "Is Ax + By = C a linear equation?," it could be reasonably inferred that if a student says "No," they actually mean *No, Ax + By = C is not a linear equation*. Here, it is reasonable to infer that the student is answering the teacher's question and the italicized statement articulates the mathematics that the contribution makes available and thus is the SM of the contribution.

In drawing such inferences, one must stay as close to the context as possible. For example, if a student says, "Can it ever have two y-intercepts?" in the context of an introductory discussion about the slope-intercept form of linear equations, a reasonably inferred SM is: *Can a graph of a linear* *equation ever have two y-intercepts?* Although it is possible that this student is wondering about the multiplicity of y-intercepts for graphs of all types of equations, the contextual evidence suggests it is more likely that they are thinking only about linear equations.

This section illustrates how articulating the SM makes explicit things that were implicit because of communication norms and the context, but does so without altering the mathematical content of the student contribution. The resulting SM is a clear articulation of a reasoned inference of what the student is expressing mathematically in the contribution.

Clarification-Needed Contributions

Clarification-needed contributions require additional information from the student to determine the SM. These contributions do not contain enough information to reasonably infer the SM; thus, we cannot reasonably articulate their SM. Sometimes clarification-needed contributions are students' attempts to articulate ideas that are particularly insightful and relevant. This is why it is critical for teachers to learn to recognize when clarification is needed and how to productively seek that clarification.

There are several ways in which a student contribution that appears mathematical may not contain enough information to reasonably infer the contribution's mathematics. For example, students often express general confusion by saying things such as, "I don't get it." Without further information we cannot reasonably infer the mathematics underlying their confusion. Sometimes students' contributions are too convoluted to make sense of what they are saying without clarification. For example, during a discussion about why ¼ times 3 is ¾, a student may state, "The 3 is like 3 and then you have a ¼." The student recognizes that there is a 3 and a ¼ involved, but how they see the relationship between these numbers is unclear. Thus, there seems to be mathematical thinking going on, but we cannot infer what it is.

Another subset of clarification-needed contributions are clarifiably ambiguous (Peterson et al., 2019). These contributions have two or more viable interpretations, and we cannot make a reasoned argument for which one best articulates the SM of the contribution. Consider the interchange when a teacher says, "Could we use unit rate to solve the proportion $\frac{6}{4} = \frac{x}{10}$?" and a student responds, "Yes, by dividing." We can infer that the student is saying, "Yes, we can use unit rate to solve the proportion $\frac{6}{4} = \frac{x}{10}$ by dividing." The latter part of the sentence, however, is ambiguous; there is no indication of which quantity would be divided by which other quantity. There are several legitimate possibilities for these quantities, resulting in multiple interpretations for this student's statement. The student might be saying "divide 6 by 4" to get 1.5 or they might be saying "divide the numerator by 2 and the denominator by 2" to simplify 6/4 to 3/2. Both of these are viable interpretations for what the student might mean by dividing. Of course, there are other possible interpretations that might reveal misconceptions about the "unit rate" strategy or about proportions in general. Thus we cannot with any level of confidence infer the SM. In order to articulate the SM of this contribution, we would need to ask the student to clarify what is being divided by what. Regardless of the reason that clarification is needed, moving forward without clarifying such contributions could lead to misunderstandings. Students could think that different ideas are being considered, leading to cross-talk and general confusion. Also, without knowing the SM of a contribution, teachers would not be able to determine whether that thinking is worth pursuing.

Non-Mathematical Contributions

Sometimes students say things like, "I need a pencil" that clearly have no mathematical content. Other times we have evidence THAT students are thinking, but there is not enough evidence to infer whether WHAT they are thinking is mathematical. For example, instances of general agreement (e.g., "Okay" or "Yeah") in response to a vague teacher question (e.g., "Does this make sense?" or

"Was this problem the same as the ones last week?"). Even when a student is engaged in mathematics, they can make contributions that have no mathematical content. For example, a student describing their graph might say, "I made my line pink because pink is my favorite color." Non-mathematical contributions have no SM to infer.

Summary and Conclusion

We identified four categories of student contributions based on the inferability of their SM. The Stand Alone category requires no inference by a teacher because the student contribution and its SM are the same. The Inference-Needed category requires drawing on the context to infer the SM of the contribution. For both of these categories, we are able to articulate the SM of the contribution. For the Clarification-Needed and Non-Mathematical categories, we are not able to articulate an SM for the contribution; the Non-Mathematical because there is no mathematics involved and the Clarification-Needed because it needs clarification to articulate the SM. To make a Clarification-Needed contribution the focus of a whole-class discussion in its current state would likely be unproductive—at best wasting valuable instructional time and at worst introducing misconceptions. In our own work articulating the SM of student contributions from a variety of classrooms where students are given the opportunity to share their thinking, we have found many Inference-Needed and Clarification-Needed contributions in every classroom—the types of contributions that require drawing (or deciding not to draw) inferences. Thus, reflection on or observation of almost any mathematics lessons provides ample opportunities to practice this critical work of attending "within" (Stockero et al., 2017) student contributions. Attending to student contributions with the necessary precision to articulate the SM is one important aspect of the "close listening" (Confrey, 1993, p. 311) teachers need to facilitate meaningful classroom mathematics discourse. Such listening is "not mastered instantaneously" but is truly a "habit of listening" (p. 312). Experience articulating the SM of student contributions has the potential develop this habit and increase teachers' abilities to notice student thinking during instruction.

A classroom where a wide range of student contributions are available creates a complicated environment in which to carry out the work of teaching. Teachers must continually decide which students' ideas to make the object of a class discussion and which to respond to in other ways. In this paper we unpacked the process of figuring out what students are expressing mathematically, a foundational skill for the productive use of student thinking. Being deliberate about making reasoned inferences of the SM of a student contribution sets teachers up to make informed decisions about whether and how they use the student thinking that is available to them.

MAKING ADDITION VISUAL: SUBITIZING AND SCAFFOLDING

Tina Rapke	Matthew Cheung	Heather Bourrie
York University	York University	York University
trapke@edu.yorku.ca	matthew_cheung@edu.yorku.ca	bourrie@edu.yorku.ca

In this qualitative empirical study, we discuss new perspectives on how the teaching of addition can be made visual for young learners. Our research is framed by scaffolding (specifically the development of conceptual discourse through representational tools) and subitizing. Subitizing is generally described as seeing how many suddenly without counting each individual item and representation tools are resources that support students and teachers to discuss and reflect on mathematical ideas. We describe one of many short Grade 2 classroom episodes that occurred weekly during an entire school year in Canada. Episodes were centered around the use of small round manipulatives that were arranged based on subitizing literature. We make initial claims about making the teaching of addition visual through student subitizing abilities, correctly solving an arithmetic problem and student explanations and responses to what they saw and did.

Keywords: Number Concepts and Operations, Elementary School Education.

Objective

By examining a short classroom episode on addition through the lenses of scaffolding and subitizing, this study aligns with the PME-NA goal of deepening and understanding the psychological aspects of the teaching and learning of mathematics. Using subitizing, a construct that is firmly rooted in psychology (Kaufman et al., 1949; Revkin, et al., 2008), leads to new perspectives and pathways to discuss the issues of teaching number concepts and operations. This qualitative study pairs mathematics education literature (e.g., scaffolding) with psychological concepts (e.g., subitizing) with the aim of examining the question: How can the teaching of addition be grounded in visualization through capitalizing on subitizing?

The difficulties and issues young students face when learning about how to solve basic arithmetic problems are well documented in mathematics education research (e.g., Boaler, 2015; Baroody et al., 2009; Jordan & Montani, 1997) and is even apparent in media pieces with public calls for 'back to the basics' (Rushowy, 2019). Boaler (2015) states, "[w]hen students focus on memorizing…they often memorize facts without number sense, which means they are very limited in what they can do and are prone to making errors" (p. 2). Similarily, Kamii and Domenick (1998) suggest that when young students are pushed to memorizing algorithms too soon (such as the traditional addition algorithm where students stack the numbers and "carry"), the algorithms "unteach" place value which in turn hinders the acquisition of number sense.

'How to' manuals and daily teaching activities have appeared and have great potential to address issues of basic arithmetic. The two we identify as having the most potential and influence are 'number talks' and 'making thinking visible'. These activities and manuals could benefit from conceptual framing and infusing/weaving of psychological research with explicit connections to teaching. Number talks are brief daily talks where students talk about their strategies to mentally solve computational questions (Humphreys & Parker, 2015). Number talks (Parrish, 2010) align with research findings that suggest that students learn basic arithmetic gradually over time (Bruce & Chang, 2013). 'Making thinking visible' for the purpose of enhancing teaching can be found in the form of books for teachers (e.g., Hull, Balka, D. S., & Miles, 2011). Ritchart, Church and Morrison (2011) explain how active use of knowledge (including retention and understanding) is achieved through learning experiences that require learners to think about and with what they are learning.

Understanding and explicating student thinking is a difficult task (Leatham et al., 2015) because thinking is largely invisible and often conceived as an internal process (Ritchhart, Church, Morrison, 2011).

Here, ideas from 'number talks' and 'visible thinking' inspired us to develop short classroom episodes on addition and subtraction where small round manipulative were spatially arranged based on recommendations in subitizing research. In essence, these lessons aimed to make individual student's addition and subtraction solution strategies visible so that they could be discussed.

Conceptual framing

Subitizing is generally described as "instantly seeing how many" (Clements, 1999, p. 400). Clements (1999) categorized subitizing into two types: perceptual and conceptual. Perceptual subitizing is "[r]ecognizing a number without consciously using other mental or mathematical processes and then naming it" (Clements, 1999, p. 401). Whereas, conceptual subitizing applies the perceptual process repeatedly and quickly uniting those numbers. For example, a child can perceptual subitize "4" by simply recognizing it and naming it and conceptually subitize 4 by recognizing 4 consists of 2 groups of 2. It is important to note that the way objects are spatially arranged can impact the ease at which a student subitizes (Clements, 1999). Indeed, studies (e.g., Mandler & Shebo, 1982) about subitizing have concluded that students make less mistakes (i.e., find it easier) when dots appear as they do on dominoes—e.g. 10 as two sets of five as you would see a five on a dice face.

Subitizing is deeply linked to visualization and images, and it has clearly been suggested that subitizing should be capitalized on for the learning and teaching of addition (Clements, et al., 2019). Clements (1999), while making these recommendations, draws on the work of Markovits and Hershkowitz (1997) to go as far as saying that "[c]onceptual subitizing is a component of visualization in all its forms…and [c]hildren refer to mental images when they discuss their strategies" (p. 403). Noteworthy is that a literature search on subitizing and number operations reveals many pieces from psychology and points to a scarcity of classroom-based research in how subitizing can be/has been used in the service of teaching addition.

The wide use of scaffolding in math education is apparent in Bakker, Smit, and Wegerif's (2015) literature review. In 2006, Anghileri related scaffolding specifically to math contexts based on previous research on scaffolding outside of math (e.g., Wood et al., 1976). She put forward three levels of scaffolding with the aim to provide language that can be used to describe actual acts of teaching in mathematics classrooms. Scholars (e.g., Bakker, Smit, and Wegerif, 2015), have used Anghileri's three leveled framework to analyze data from math classrooms.

Level 3: *developing conceptual thinking* comprises of two subcategories: making connections and developing representational tools. This level is "less commonly found but identified as the most effective interactions" (p. 47). Level 3 scaffolds are most relevant to this study because of representational tools. Representational tools support students and teachers in building conceptual discourse, as they "constitute as a resource that students can use to express, communicate, and reflect on their mathematical activity" (p. 48). Anghileri (2006) explains that representational tools can provide "powerful visual imagery" (p. 47) and are important because "[m]uch of mathematical learning relates to the interpretation and use of systems of images, words, and symbols that are integral to mathematical reasoning" (p.47). The most common form of representational tools take the form of symbolic records of students' ideas that occur through teachers noting students' interpretations and solution strategies. Representational tools can take other forms such as graphs, and in Dove and Hollenbrands' (2015) study which examined scaffolds provided by high school geometry teachers, Geometer's Sketchpad was considered a representational tool.

In terms of most effective teaching and Level 3 scaffolds, Anghleri (2006) gives a sense that mathematics classrooms should go beyond the individual and there should be evidence of "shared", “togetherness”, “communal” and “cooperation”. This is apparent when she describes “real mathematics learning in the classroom” in terms of “struggle for shared meaning… a process of cooperatively figuring things out determines what can be said and understood by both teacher and students” (p. 46). She explains that with Level 3 scaffolding “understanding comes to be shared as the individuals engage in the communal act of making mathematical meanings” (p.49). Meaning that effective teaching (or *developing conceptual thinking)* can be evidenced through the development and the use of representational tools that are communal.

Methods

This study took place in a Grade 2 class, in which, researchers and the classroom teacher co-planned short (typically 7-8 minute) weekly lessons/episodes, throughout the 2018-2019 school year. There were approximately 20 students involved in each episode which took place in a predominantly English-speaking public school in a highly populated Canadian city. One of the researchers (not the assigned teacher) acted as the lead teacher during the classroom episodes.

During the lessons, the study participants were seated on a carpet together in front of the screen. Students were given an arithmetic problem (18+12) and asked to think about how they would solve it. Small circular objects (flat circular candies that are ¾ cm in diameter) were laid out and projected on a screen to represent numbers in questions. Numbers were often colour coded (i.e., for 18+12; 18 was represented by blue objects and 12 by green objects, Figure 1).

Eight of the 42 collected episodes were analyzed for this report. One episode was chosen because our conceptual framework points to the development of representational tools being communal acts that involves ‘shared’ and ‘together’. Hence, we looked for what we call ‘chorus’ in the data. These are incidents in the videos where students joined in ‘chorus’ speaking with the teacher or in response to teacher questions about what they saw. It is difficult to identify, from the audio of the video recorded data, how many students form chorus but it is clear that it is much more than 10 students. Data was analyzed using Powell et al.’s (2003) model for studying the development of learners’ mathematical ideas and reasoning using videotape data.

Results (Episode of 18+12)

The episode begins with the teacher directing students' attention to a pile of 18 blue candies and a pile of 12 green candies (with no structured arrangement) and asking students how many blue candies there are. A student comes to the projector and begins to move the candies one by one to create two strings of 3 candies each. The teacher interrupts the student and says: “Can I offer you an idea? I would really like 5s” and the teacher arranges five of the blue candies as you would see on the face of a dice. Before the student begins to re-arrange the objects, the teacher addresses the entire class with: “Does everyone agree this is five?” as she circles the five candies she re-arranged with her finger. A chorus of students calls out “yes”. Subitizing is confirmed with immediate student chorus confirmation to the question “can you see it right away?”.

The student rearranges the rest of the blue candies and declares 18. The teacher verbally repeats the number 18 and asks the student “How do you know that?”. The student explains he (re)composed the larger number 18 by saying “five, ten, fifteen, eighteen” while simultaneously pointing at the manipulatives. The teacher says: “OK. Five, ten, fifteen, 16, 17, 18”. There is a chorus of students that join for “five, ten, fifteen” only the teacher says “16”, more students join for 17, and then there is a chorus for 18. Another student moves up to the projector and rearranged the green candies in a similar way. The student states: “five, ten, eleven, twelve” providing evidence of conceptual subitizing. The students are then told the goal of the teaching episode is to figure out how many candies are on the projector (i.e., to solve 18 + 12) and figure out as many strategies as they can.

The teacher invites another student to the projector to use counting on as a strategy to solve 18 +12. The student starts by recognizing the 18 blue candies. Then the teacher and student count one-by-one together using their hands and fingers "19, 20, 21, …" until 30 (note that the manipulatives are not used). The teacher then prompts for connection making by pointing to the candies individually as she says "19, 20, 21, …" until 30. There is no audible chorus with her as she spoke and she asks how many students used the strategy of counting on. Two other students lift their hands to indicate they used a solution strategy of counting on by 1s.

The teacher asked, "who used a different strategy?" A student offers a strategy that counts by 5s and 10s. The student starts by pointing at two blue groups of 5s that are already formed and saying "five, ten, fifteen, twenty, twenty-five [pause] then I moved these two and put them together" as she moved the two green candies to be with the three blue candies to form a five as you would see on the face of a dice (Figure 1).

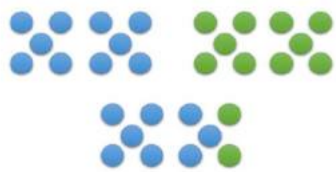

Figure 1: 18 + 12

Discussion and/or Conclusions

We conclude that addition was made visual, as teaching was grounded in visualization. Given the issues that students experience with addition, this study should be of great interest, as we offer a different way to teach addition that follows underlying principles of teacher resources ('Number Talks' and 'making thinking visible') but extends practical suggestions by infusing math education research and psychology research. In essence, we have shown how the teaching of addition can be made visual through using small objects that are spatial arranged in specific ways that are inline with research on subitizing.

Our results evidence teaching grounded in visualization through conceptual subitizing ("a component of visualization in all its forms") and the development and use of a representational tool that is communal. Students used conceptual subitizing to identify 12 and 18 items. There are indications of a representational tool that is communal when students respond in chorus and when solving 18+12. Spatially arranging small round manipulatives in a very specific way provoked one student to describe how she solved 18+12 by composing the last group of 5 (conceptually subitizing 5) by composing 3 blue and 2 green candies.

Although it has been recommended that subitizing can and should be used to support students in arithmetic, there is a scarcity of studies that respond to these recommendations and calls by enacting and researching them in actual mathematics classrooms. Significantly, through conducting classroom based research and analyzing our data through scaffolding and subitizing, we highlight how number talks that focus on making thinking visible by capitalizing on subitizing can be used to make the teaching of addition grounded in visualization.

LINKING A MATHEMATICIAN'S BELIEFS AND INSTRUCTION: A CASE STUDY

Rachel Rupnow
Northern Illinois University
rrupnow@niu.edu

Teachers' beliefs impact their instructional choices, but characterizations of that relationship are limited in college settings. Based on interviews and classroom video from three units of instruction, this paper examines a full-time instructor's stated beliefs about teaching and ways these beliefs manifested in their teaching. The instructor made curricular choices clearly aligned with their stated beliefs about math, learning, and teaching. Day-to-day instructional choices reflected these beliefs as well, but tensions between beliefs also manifested. Characterizations of the interactivity of classes are provided through descriptive and quantitative measures. These characterizations of instruction highlight changes in instruction throughout the semester.

Keywords: Classroom Discourse; Teacher Beliefs; University Mathematics

Beliefs impact the ways people perceive, interpret, and respond to situations (Pajares, 1992). Thus, numerous studies have examined teachers' beliefs, including three handbook chapters on teachers' beliefs in math education (Thompson, 1992; Richardson, 1996; Philipp, 2007). However, less is known about mathematicians' beliefs and their impact on instruction. Similarly, limited research has been conducted on semester-long college instructional practice. In response to these gaps, this study addresses the following research questions: (1) How did an instructor describe their beliefs about math, learning, and teaching? (2) How can their instructional practice be characterized? (3) What relationship exists between their beliefs and instructional practice?

Literature Review and Conceptual Framework

Extensive research describes the coordination of beliefs into a belief system. Philipp (2007) synthesized previous belief system characterizations as: "A metaphor for describing the manner in which one's beliefs are organized in a cluster, generally around a particular idea or object" (p. 259). Prior work on beliefs highlighted how they are influenced by a teacher's view of the nature of math (Ernest, 1991), prior school experiences, and immediate classroom situations (Raymond, 1997) as well as their effect on instructional practice (Wilkins, 2008). One of the distinctions between studies is how researchers address perceived inconsistencies in teachers' statements and actions. Early studies examined differences between what a teacher claimed and what they did (e.g. Cohen, 1990). Later studies examined both teachers' beliefs and practices before drawing conclusions (e.g. Schoenfeld, 2003; Speer, 2005; Speer 2008) and emphasized the importance of observing teachers for a long period to see how beliefs impact instruction (Skott, 2001).

While extensive research has been conducted on K-12 teachers' beliefs (e.g., Beswick, 2012), fewer studies have examined teachers' beliefs or instruction at the university level. Weber (2004) examined a real analysis professor's lecture-based teaching but observed the teaching style varied based on the material. Johnson, Caughman, Fredericks, and Gibson (2013) examined teachers' priorities for instruction while using Inquiry-Oriented (IO) materials, especially noting content coverage concerns, goals for student learning, and student opportunities to discover mathematics. Surveys of abstract algebra instructors have examined influences on lecturers' teaching (Johnson, Keller, & Fukawa-Connelly, 2018; Johnson, Keller, Peterson, & Fukawa-Connelly, 2019). Those most influential (in order of frequency) were their experience as a teacher, experience as a student, and talking to colleagues. These instructors self-reported their time spent on types of instruction, leaving questions about how to characterize college teaching.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

The theoretical framework in this study is Leatham's (2006) construct of sensible systems. This framework posits that belief systems can be organized such that beliefs that seem contradictory to an outsider are not examined together by the teacher holding the belief, allowing "inconsistent" beliefs to coexist. Alternatively, certain beliefs could be held as ideal while others are given priority in specific situations. Generally, he suggested that if a researcher concluded a teacher's beliefs were inconsistent, the researcher did not have all of the information.

Methods

In this case study, the instructor participant, Dr. Bailey (a pseudonym), was a full-time instructor teaching an introductory abstract algebra course. Bailey's class met three times per week in 50-minute periods that were a mixture of lecture and "lab" days. They engaged in two semi-structured interviews (Fylan, 2005) lasting one hour each. Interviews were audio and video recorded and coded using thematic analysis (Braun & Clarke, 2006). Classroom data were collected in the middle of a unit on groups and through the whole units on group isomorphism and quotient groups. Classroom data were analyzed with the Toolkit for Assessing Mathematics Instruction–Observation Protocol (TAMI-OP) (Hayward, Laursen, & Westin, 2017) and the Inquiry-Oriented Instructional Measure (IOIM) (Kuster, Johnson, Rupnow, & Wilhelm, 2019).

The TAMI-OP is an observation protocol that aids recording what the instructor and students do in a classroom, broken into 2-minute segments of instruction. The IOIM was a rubric that provided a way to characterize how IO a class was. The IOIM uses a five-point scale and scores seven practices (below) that reflect the principles of IO instruction.

1. Teachers facilitate student engagement in meaningful tasks and mathematical activity related to an important mathematical point.
2. Teachers elicit student reasoning and contributions.
3. Teachers actively inquire into student thinking.
4. Teachers are responsive to student contributions, using student contributions to inform the lesson.
5. Teachers engage students in one another's reasoning.
6. Teachers guide and manage the mathematical agenda.
7. Teachers support formalizing of student ideas and contributions and introduce formal language and notation when appropriate. (Kuster et al., 2019)

Results

Instructor Beliefs

Bailey highlighted mathematicians' search for theorems as a purpose of math: "So I think mathematics is the search for theorems which…I would take to mean things that both can be proven…and then also the actual pursuit of proof…" Bailey emphasized actively doing math to learn it: "I'm a firm believer in learning by doing is best, so…every class I try to give the students something to do even if it's…here I'm gonna put this…example on the board for two minutes, let you guys work on it…." They based these ideas on how they learned: "I have to be …coming up with my own examples or coming up with my own proofs and just really synthesizing for it to stick." They were aware that how they learned could differ from how others learn, just as people have different ways of thinking in other contexts: "Different people have different frames for interpreting politics…so I think the same applies to learning."

Bailey discussed the role of different types of instruction within a class period when addressing the nature of teaching math. On lecture days, they would focus more on exploring the definitions and proofs in the class with a few smaller examples worked in. On lab days, they would expand the interaction that students were engaged in, especially for addressing examples.

They valued lecture as a way to make sure they taught all of the intended material and were satisfied with the interaction/coverage balance struck with two lectures and one lab per week.

Bailey identified two main ways that their beliefs about the nature of math, learning math, or teaching math were reflected in their instruction: the use of different types of instruction to reach different types of learners and an emphasis on students doing mathematics.

> It reflects my belief that people learn in different ways, and so, try not to use the same style throughout and also do different things….All my undergraduate mathematics classes were what I've been referring to as lecture.…I wasn't great at following what was going on in the lectures at that point in time. The group work is the kind of thing that would have helped me, so…putting in that different element for maybe people who do learn in a different way.

Their beliefs about creating a variety of learning opportunities for their students sprang from their experiences as a learner. In this case, the lack of alignment between their experiences and what would have helped them appeared to be formative. This relates to Johnson et al. (2018), in which the second most reported influence on instruction was experiences as a student.

Characterizing Instruction

Instruction is characterized based on data and analysis from the IOIM and TAMI-OP. IOIM practice scores are listed by practice (e.g. column P1 shows Practice 1 scores) with lecture scores on the left and lab scores on the right. TAMI-OP data rates are presented to the nearest whole percent. Counts of time blocks refer to numbers of 2-minute blocks (e.g. 9/31 segments lecturing means 9 of the 31 2-minute segments had some time spent on lecturing).

Table 1: IOIM Practice Scores in Lectures/Labs

Unit	P1	P2	P3	P4	P5	P6	P7
Groups	2/4	2/4	½	2/3	2/3	3/2	1/2
Isomorphism	2/3	2/2	2/2	2/3	1/2	3/2	2/2
Quotient Groups	2/2	2/2	2/2	1/2	1/1	3/3	1/1

In the Group unit, the lectures received low (1) to medium (3) IOIM scores, and the lab received medium-low (2) to medium-high (4) scores, as shown in line one of Table 1. These scores indicate the lecture days were not well aligned with IO instruction whereas the lab days were somewhat aligned with IO instruction. Similar scores were given in the Isomorphism unit. In the Quotient Group unit, the lab days received scores similar to lecture days; the only difference was on Practice 4, where the lab score was higher. Students engaged in less discussion with each other on lab days at all but one table, which depressed the IOIM scores. Across the three units, lecture scores held steady or decreased, except for Practice 7 in the Isomorphism unit. There, the lab started the unit, allowing some informal notation and ideas to come from the students before isomorphism was fully explained. The lab scores decreased or held steady except for Practice 6, where students were given more closure in a whole class setting in the last unit.

The results from the IOIM are also reflected in the TAMI-OP. In Table 2, we see lecture days in the Group and Isomorphism units were dominated by the instructor lecturing and included less time for students to work individually or in groups, whereas the allocation of time was flipped on the lab days. In the Quotient Group unit, more time was spent lecturing and students spent less time working than in previous units. Furthermore, unlike the previous units, where labs received a full day each time, this unit's labs received only partial days or spread over two days.

Table 2: Time Averages Across All Three Units

Day	Segments Lecturing	Segments Students Working	Segments Student Presenting	Segments Whole Class Discussion
Group Lecture	49/51	9/51	0/51	0/51
Group Lab	3/25	23/25	0/25	0/25
Group Ave.	68%	42%	0%	0%
Isomorphism Lecture	47/51	5/51	0/51	0/51
Isomorphism Lab	6/26	26/26	0/26	0/26
Isomorphism Ave.	69%	40%	0%	0%
Quotient Gp. Lecture	168/177	12/177	0/177	0/177
Quotient Gp. Lab	4/36	36/36	0/36	0/36
Quotient Group Ave.	81%	18%	0%	0%

Combining the information from the IOIM and the TAMI-OPs paints a picture of a class strongly guided by the instructor's mathematical knowledge but with some opportunities for student exploration. The mathematical authority rested with Bailey, who was in charge of moving the class forward. As the semester progressed, students were given less time to work and the amount of time the instructor spent lecturing increased, especially in the final unit.

Discussion and Conclusion

Dr. Bailey's stated beliefs about the nature of math focused on the structure of mathematics and the search for theorems. Their instruction reflected a belief in math as the search for theorems through their emphasis on proof in lecture, which they addressed by lecturing twice as much as they provided labs. Most of the time on lecture days was devoted to presenting proofs of theorems and thinking through implications of the work the instructor did at the board. However, the existence of two types of instructional days, opportunities to work on problems for extended periods, and opportunities to interact aligned with Bailey's stated desire to use many types of instruction to reach many types of learners. Although most groups experienced largely lecture and individual work time in class instead of varied amounts of discussion, this was still more instructional variety than might be expected in a "typical" lecture class. Bailey noted that their previous semester's section had been more interactive, so it is possible this was more due to the students' preferences than Bailey's intention. Here we have a tension between Bailey's belief that students should be interactive and that students should be free to make choices about how they want to learn. In keeping with Leatham (2006), it seems Bailey acted more on the latter belief, indicating they considered aligning to students' learning preferences more important than the incorporation of discussion while learning math.

Bailey seemed to intend to enact the interactive classroom described in the interviews. However, as the semester wore on, other factors seem to have gotten in the way. When behind their schedule, they pressed to finish by reducing the student work time to half days for labs. The instructor did not state a desire to reduce student work time, so it is possible they did not notice they were shifting how much time they spent on different activities. Nevertheless, this raises questions for further research on the influence of instructional pressures across a semester.

Untangling the relationships between teaching, learning, and content is complex. This study focuses on one aspect of these relationships, i.e., the at times challenging role that language can play in mathematical tasks, discussions, and student access. The authors analyze two video banks to identify and operationalize combinations of teacher and student actions that support student access to mathematical tasks and language.

Keywords: Classroom Discourse, Instructional Activities and Practices, Equity and Diversity

Mathematics education reforms and standards movements highlight the vital role that language and discussion plays in teaching and learning (National Council of Teachers of Mathematics (NCTM), 2010, 2014; National Governor's Association Center for Best Practices & Council of Chief School Officers (NGACBP & CCSO), 2010). Yet, the complex nature of mathematical tasks and discussions can become an obstacle for students' participation in mathematics classrooms (Aguirre & Bunch, 2012; Chval & Chavez, 2012). In order to support student access, teachers must develop practices that facilitate student access to mathematical tasks and language (Boaler & Staples, 2008; Chval, Pinnow, & Thomas, 2014; Staples, 2007).

This study comes from a decades long collaboration between K-12 schools, a nonprofit education organization focused on professional development and coaching for teachers of mathematics, and mathematics education faculty. In recent years, the partners collaborated to develop an app-based observation tool (Melhuish & Thanheiser, 2017) designed to provide teachers with formative assessment data about their implementation of observable mathematical teaching and learning practices. As part of this work, the authors are refining the tool to add or amplify student and teacher practices that support access to mathematical tasks and language. In alignment with this goal, this study was guided by the following research questions: (1) what observable teaching practices support students in making meaning of mathematical tasks and language, and (2) how might students engage in these making meaning practices?

Theoretical Orientation

Hawkins (2002) represents effective instruction by the relationships that exist between and among the vertices of the instructional triangle (see Figure 1a). In this triangle, the teacher builds a relationship with the student for purposes of understanding the student's relationship to the content, and then the teacher responds in ways that engage the student in thinking about and interacting with others and ideas that are intended to lead to a deeper understanding of the content. Lampert's (2003) expands on Hawkin's triangle by explaining, through examples from her own practice, how the problem space of teaching occurs along each of the arrows connecting the vertices of the triangle. Lampert adds a fourth arrow to the diagram to represent the relationship between the teacher and the arrow between students and content (see Figure 1b). Both Lampert (2003) and Cohen, Raudenbush, and Ball (2003) write explicitly about the need to consider how these triangular relationships function in the context of a teacher's work with individual students as well as in a classroom full of students. Cohen et al. (2003) make this explicit by adding a representation of multiple students interacting at the "student" vertex.

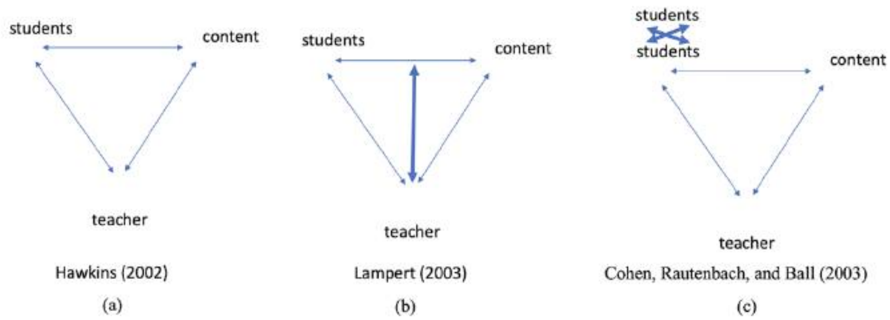

Figure 1. Three different representations of the student, teacher, content triangle.

The study team is working to delineate the complexities of these relationships in ways that make the actions both observable and learnable. By overlaying the triangle on the tool, one can see that the relationships are embedded (see Figure 2). Teachers initiate and enact catalytic teaching habits (CTH) and teaching routines (TR) to elicit student ideas and/or in response to what they understand students to be saying, doing, or understanding. These teacher actions are designed to prompt students to engage in habits of mind and interaction as a means of deepening their understanding of mathematical content. This study focuses on the project team's efforts to operationalize specific components of the tool (see highlighted text in Figure 2). What results is a smaller set of actions by and among teachers, students, and content that we hypothesize will support students in making meaning of tasks, contexts, and language.

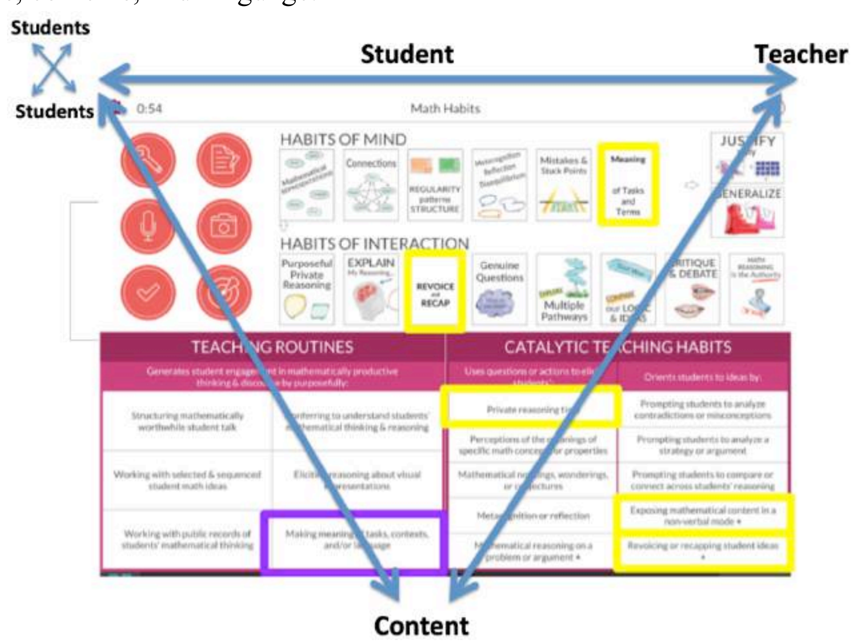

Figure 2. Teacher and student moves that support access to learning opportunities.

Methods

We drew upon two video banks of mathematics lessons spanning K-8 classrooms to identify teacher and student actions that supported students in making meaning of tasks and language. We initially developed a codebook that operationalized research-based practices (e.g., Ball, 1993; Jacobs &

Spangler, 2017; Nasir, & Cobb, 2006; Schoenfeld, 2011; Staples, 2007). Initial data analysis began with the development of a codebook with decision rules for the coding process and descriptions for each code. For example, we created distinct rules for coding TR stanzas and CTH stanzas with each stanza representing a discrete coded section of transcript data (Saldaña, 2013). TRs were defined as a collection of teacher-initiated moves that engaged students in prolonged mathematical discourse and/or productive thinking, while CTHs were defined as single teacher moves to elicit or focus student thinking. Additionally, student contributions were classified as a habit of mind (ways in which students engage with the mathematics) or habit of interaction (ways in which students engage with each other around the mathematics). These codes were then further refined through testing in classrooms and with video. Two researchers independently coded video transcripts, and then met to compare coding and resolve inconsistencies to reach interpretive convergence (Saldaña, 2013).

Findings

We present two excerpts that explicate the ways in which teachers might support students in making meaning of tasks and language. In the first transcript, the teacher implements a teaching routine to support students in making sense of a mathematical task before they start working on the task. The task states, “In a school gymnasium, 375 students have gathered for an assembly. The students are seated in 15 equal rows. How many students are seated in each row?”

Transcript	**Code(s)**
Teacher (reading the task aloud): In a school gymnasium, 375 students have gathered for an assembly. Okay, any questions there? Everybody knows what an assembly is? Although we haven't had many this year. We are going have one tomorrow. *Student*: We are? *Student*: Two *Teacher*: Two tomorrow. So we're going to be in an assembly tomorrow. Everybody gathers in the gym and we'll watch a show or something like that, presentation. …	**TR** (turns on): Making meaning of tasks, contexts, and/or language
Teacher: Okay, the students are seated in 15 equal rows. Any questions on rows? Rows are side to side. Columns are up and down. Anybody has been to a sporting event? *Student*: I have. *Teacher*: Usually your ticket says row so and so. So rows are like all the seats going across. Although we don't have rows in our assembly, some places do. How many students are seated in a row, in each row? Alright	**CTH**: Perceptions of the meanings of specific math concepts or properties **TR** (turns off): Making meaning of tasks, contexts, and/or language

Figure 3. Teacher practice analyzed with the meaning-making codes.

Here, the teacher uses the students’ shared experiences of going to assemblies in their school and possibly attending sporting events to make meaning of the context of the task. Within this longer TR, the teacher then uses a CTH to define the specific mathematical concepts of rows and columns. Noticeably, the students were not observed actively contributing to making meaning of the task or language.

Conversely, in this second transcript the teacher and students both engage in making meaning of the task and language. This excerpt occurs after the students had been working through several story problems. The teacher implements the TR of making meaning of tasks and language after he notices that the wording of a particular task was confusing to some students. This task states, “How many periods of time, each ⅓ of an hour long, does a 8-hour period of time represent?”

Transcript	Code(s)
Teacher: So the question says how many period of times right? How many periods of time. Does it ask you how much time? Okay, it's asking how many periods of time. So what is that? It's kind of confusing right there. Periods of time. What is that mean periods of time?	**TR** (turns on): Making meaning of tasks, contexts, and/or language
Student: Periods of time means how many sections of time there is in certain amount of time. So, there is two periods of time in an hour that's half an hour long.	**HOM:** Meaning of Tasks & Terms
Teacher: So, who heard Gabby said about period of time?	**CTH:** Revoice and recap student ideas
Student: Basically, she said that each…okay…in this equation periods of time would be 8.	**HOM:** Meaning of Tasks & Terms **HOI:** Revoice & recap
Teacher: Eight, eight 1/3. That's you said. You haven't started middle school yet so you don't have period right? So period of time in that would be like you got a math class the first period. Second period you go to English, third period, fourth period okay. So that's periods of time. So we don't want to know that math is 60 minutes. We just call that first period or second period, third period. So periods of time. They are not looking for a time here. They are looking for how many periods of time. Does that make sense? So we are not going to have time here. We are going to have a number period. Like, how many periods do you have in middle school? I have 6 periods. How long are those periods? 50 minutes each or 60 minutes each, okay? That's different.	
Student: That's what I thought. It says how many, not how long.	**HOI:** Compare our logic and ideas
Teacher: Great! So, how long would be the time, right? ...Is it helpful for you guys in this conversation to know what [student] just said. He is helping clarify what we are talking about. It says how long are they so we want time. How many is how many periods are there. Different thinking on that.	**CTH:** Revoice and recap student ideas **TR** (turns off): Making meaning of tasks, contexts, and/or language

Figure 4. Student teacher interaction analyzed with the meaning-making codes.

During this TR, the teacher first elicits students' understandings of the concept of periods of time rather than merely defining a period of time. This leads to a student engaging in the meaning making HOM. The teacher then extends this with a CTH by asking other students to revoice the original student's ideas. The teacher adds to this definition by introducing the real world context of class periods in middle school. Finally, the clarification is made that a period of time refers to how many not how long, which leads to a student spontaneously engaging in a HOI to compare their thinking with the thinking being discussed. Taken together, these excerpts show how a teacher might implement a TR to support students in making meaning of task and language, and how the engagement of students during this TR may vary based on teacher responses.

Discussion

This work comes from a focus on how to support student access to mathematical content and discussions. We build upon Cohen and colleagues' (2003), Hawkin's (2002), and Lampert's (2003) conceptualization of the instructional triangle in order to support this goal. Through multiple rounds of theoretical and empirical exploration, we have identified teacher and student actions that appear to support students in making meaning of tasks and language. By explicitly naming these teacher and student actions, we hope to bridge the theory to practice divide by supporting teachers in learning about and implementing these practices in their own classrooms.

MATHEMATICS TEACHERS' EPISTEMIC DISPOSITIONS AND THEIR RELATIONSHIP WITH TEACHER INSTRUCTION AND STUDENT LEARNING: A SYSTEMATIC RESEARCH SYNTHESIS

Ian Thacker
University of Texas, San Antonio
ian.thacker@utsa.edu

Richard Rasiej
University of Southern California
rr_447@usc.edu

Some research suggests that teachers' beliefs and thoughts about the nature of mathematical knowledge and knowing (broadly termed epistemic dispositions) comprise an important factor that influences their practice. However, to date, there is no systematic review of the empirical literature on mathematics teachers' epistemic dispositions. The purpose of this systematic research synthesis was to assess the existing empirical literature in order to (a) describe mathematics teachers' epistemic dispositions, (b) to identify whether such dispositions correlate with teacher's use of constructivist teaching practices, and (c) correlate with student learning outcomes. A systematic assessment of 30 relevant studies suggest that teachers, on average, hold constructivist epistemic dispositions regarding mathematics. Few studies reported correlations between epistemic cognition indices and teacher practice or student outcomes.

Keywords: epistemic cognition, epistemic beliefs, epistemological beliefs, teacher beliefs

Cognitive processes involved in constructing and evaluating arguments—called *epistemic cognition*—has been well studied in the educational psychology literature. Epistemic cognition concerns itself with the thinking that people do about what they know and how they know it (Chinn, Rinehart, & Buckland, 2014; Sandoval, Greene, Bråten, 2016). For example, a learner engages in epistemic cognition when they explain "how they know" that a mathematical assertion is true or justified. A common object of investigation in epistemic cognition research is people's beliefs about the nature of mathematics, mathematical knowledge, and processes of knowing—sometimes termed *epistemic beliefs* (e.g., Cooney, 1985; Ernest, 1989; Muis, 2004; Thompson, 1984). Existing research syntheses suggest that students' epistemic beliefs support their motivation, selection of productive problem-solving strategies, and achievement outcomes in mathematics (e.g., Muis, 2004) and are involved in teachers' lesson planning, evaluation of student work, and instructional techniques (e.g., Maggioni & Parkinson, 2008). Yet, despite several decades of research consistently confirming that epistemic cognition plays a crucial role in facilitating teaching and learning in many disciplines, little to no research focuses on synthesizing findings regarding teachers' epistemic cognition in the domain of mathematics.

The purpose of this systematic review was therefore to synthesize the existing work on epistemic cognition in mathematics teaching in order to specify teachers' epistemic dispositions and identify whether epistemic dispositions are associated with instructional practice and student achievement. Specifically, we sought to answer three central questions: (a) *What are teachers' epistemic dispositions towards mathematics?* (b) *To what extent are epistemic dispositions associated with teacher instruction? (c) To what extent are epistemic dispositions associated with student learning?*

Theoretical Framework

Epistemic cognition can be defined as the thinking that people do about knowledge and knowing (Greene et al., 2016). A common focus in epistemic cognition research is on the beliefs that people hold about knowledge and knowing—or epistemic beliefs—which are studied both as both a domain-general and domain-specific construct. Three decades of research from various disciplines have yielded multiple domain-general models of epistemic cognition that broadly fall into three categories:

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

developmental, multidimensional, and philosophically informed models (e.g., Sandoval et al., 2016). *Developmental models* of epistemic cognition investigate how people's views of knowledge progress through a series of levels over time (e.g., Kuhn, 1991; Moshman, 2015; Perry, 1970). *Multidimensional models* explore epistemic cognition as a set of multiple, relatively independent dimensions of beliefs (e.g., Hofer & Pintrich, 1997; Schommer, 1990). *Philosophically informed models* more broadly conceive of epistemic cognition as encompassing not only beliefs, but cognitive processes that take into account motivation, emotion, and practices that dynamically interact with beliefs in context (e.g., Chinn et al., 2014).

Theoretical Models of Epistemic Cognition Specific to Mathematics

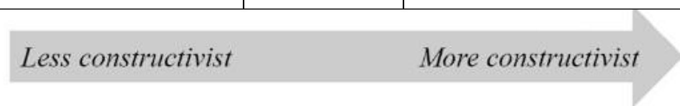
Much of the literature on mathematical epistemic cognition focuses on individuals' beliefs about mathematics and the nature and acquisition of mathematical knowledge (e.g., epistemic beliefs; Ernest, 1989; Thompson, 1984). The most commonly cited model of teachers' beliefs about mathematics is that of Ernest (1989). Ernests' model posits that teachers' beliefs about what mathematics is impacts their beliefs about how students learn, how teachers should teach, and subsequently impact their enacted model of how students learn (e.g., their teaching practices and how they utilize classroom resources like textbooks). Ernest proposes three categories of epistemological beliefs that increase in their level of sophistication: instrumentalist, Platonist, and problem-solving. Individuals that hold an *instrumentalist* perspective believe that mathematics is a set of unrelated rules and facts. Instrumentalists view mathematical statements as mere consequences of a set of arbitrary mathematical rules. Math teachers that adopt an instrumentalist perspective might view math statements as "just a collection of disconnected formulas" to be memorized and reproduced that are ultimately disconnected from our experience in the world. *Platonists* hold the view that mathematics is a unified body of objective mathematical knowledge and that mathematics is discovered. This can be illustrated by the teacher who believes that that mathematical knowledge is highly interconnected, builds upon itself, and exists in an unchanging almost transcendent world of objective mathematical knowledge. A Platonist teacher might believe that the best way to communicate mathematical knowledge to their students is to expose students to math knowledge in a logically consistent way. The *problem-solving* perspective holds that mathematics is dynamic, expanding, and is a human invention. This perspective stems from the view that mathematics is essentially a human invention constructed from subjective experience in the world. Teachers that hold a problem-solving perspective might believe that mathematical knowledge is a construction used to describe individual experience of the world, that math is a language to describe the world around us, and that the best way for students to learn mathematics is to co-construct knowledge through discussion and interaction in the classroom.

Additional mathematics-specific theoretical models of epistemic cognition are similar to Ernest's (see Table 1). Felbrich and colleagues (2012) and Daepepe and colleagues (2016) also posit categorizations of teachers' epistemic dispositions that lie on a continuum of less to more constructivist (scheme-related, formalism, and process-related). Two of Blömeke's three categories are similar, with the third category, the application perspective, being somewhat unique in that it represents a teacher with the perspective that math is a tool that can be applied to accomplish various tasks.

Teachers' mathematical beliefs are also predicted to shape their perceived role in the classroom, intended outcomes, and enacted instructional practices. For example, Ernest's (1989) model predicts that teachers' epistemic beliefs inform their espoused and enacted models of teaching and learning mathematics as well as their use of classroom materials. Briefly, this model posits that teachers' constructivist epistemic beliefs are expected to correspond with teaching practices that subsequently support student learning.

Table 1: Four Developmental Models of Teachers' Beliefs about Mathematics.

Ernest (1989)	Instrumentalist	Platonist	Problem Solving	
Felbrich (2012)	Math is Static Science		Math is a Dynamic Process	Application
Blömeke (2008)	Scheme-Related	Formalist	Process-Related	
Daepepe (2016)	Absolutist		Fallibilist	



As it stands, the epistemic cognition frameworks reviewed here posit that teachers generally progress from less to more constructivist mathematical beliefs and that these views on the nature of mathematics shape teachers' espoused models for teaching and learning and their enacted practices. However, it should be noted that such developmental models of epistemic cognition concentrate on epistemic beliefs and are limited in that they do not consider the multi-dimensionality or context-sensitivity of epistemic cognition as proposed in the educational psychology literature (e.g., Hofer & Pintrich, 1997; Chinn et al., 2014). As such, we operationalized epistemic cognition to include multidimensional and philosophically informed models and cast a wide net for retrieving relevant information about the topic, despite there being no math-specific theoretical models that are widely used that take these perspectives.

Method

Inclusion criteria. This review investigates empirical research on epistemic cognition of instructors within the domains of educational psychology and mathematics education. Studies were selected if they examined *teachers'* thinking about mathematical knowledge and knowing that could be identified as satisfying one or more of the components of the operational definition outlined above. These components included beliefs about the nature of knowledge in mathematics, justifications of knowledge in mathematics, sources of knowledge in mathematics including teachers' perspectives on the acquisition of mathematical certainties (i.e., proof). We included articles, dissertations, reports, and book chapters published in English.

Search procedures. Relevant empirical literature was identified by searching online databases, PsychINFO and ERIC, with the following search command: "(teach* OR instruct* OR profess* OR faculty) AND (epistem* OR proof* OR prove OR proving OR (math* NEAR/6 belief*)) AND (math*)," no additional restrictions were placed on the search. This search resulted in a total of 810 items, of which a total of 30 texts met the inclusion criteria and were selected for this review after multiple rounds of screening (screening procedures available upon request).

The 30 papers were then coded to capture characteristics of the theoretical framing, study setting, participants, internal validity, and external validity (Cooper, 2016; codebooks available upon request). Papers were broadly categorized by whether they addressed one or more of the three main research objectives to (a) describe teachers' epistemic cognition about mathematics, (b) identify whether there is a relationship between epistemic cognition and teaching practices, and/or (c) identify whether there is a relationship between epistemic cognition and student learning outcomes. Some texts were applicable to more than one category.

Preliminary analysis. For this preliminary analysis, we recorded the direction of effects—we noted whether each study found that teachers held constructivist dispositions or not, and whether these dispositions were positively or negatively correlated with reform-based instructional practices or with student learning. We then tallied up the direction of effects across these studies. The secondary reference section presents a list of the articles cited in the review.

Preliminary Results

The empirical literature identified in this synthesis tended to centralize epistemic beliefs as the object of investigation. Of the 30 items reviewed, all 35 of them appeared to be explicitly focused on assessing static epistemic beliefs using developmental or multidimensional conceptions of epistemic cognition (rather than philosophically informed models that consider the context-sensitive nature of epistemic cognition). Study samples ranged from pre-service K-12 teachers, and in-service teachers of preschool up through undergraduate and graduate instructors. Of 30 texts, 12 were qualitative, 16 were quantitative, and 2 were mixed methods.

RQ1: What are teachers' epistemic dispositions towards mathematics?

We assessed sample means of teachers' beliefs about mathematics from quantitative studies to judge whether their epistemic dispositions towards mathematics were constructivist or not. Of the 17 studies presenting relevant means, 13 of them (76%) revealed that teachers on average held constructivist beliefs about mathematics knowledge and knowing. Qualitative findings were consistent, but suggest that these dispositions were context dependent.

RQ 2: To what extent are epistemic dispositions are associated with teacher instruction?

To answer the second research question, we tallied the direction of effects of correlations between constructivist epistemic dispositions and teachers' reform-based teaching practices. Of the thirty papers, only four of them reported such correlations, all of which (100%) were positive and significant.

RQ3: To what extent are epistemic dispositions associated with student learning?

To answer the third research question, we tallied the direction of effects of correlations between constructivist epistemic dispositions and student learning outcomes. Of the thirty papers, only two studies presented correlations between epistemic dispositions and student learning. Both correlations were positive, but only one was significant.

Significance

We sought to assess the empirical literature on mathematics teachers' epistemic cognition to describe their epistemic dispositions and identify potential relationships with their practice and student learning outcomes. A systematic review of 30 journal articles, book chapters, reports, and dissertations begin to suggest that teachers lean towards constructivist perspectives regarding mathematical knowledge and knowing. A few studies show that these constructivist dispositions are correlated with reform-based teaching practices. However, due to the very small number of studies linking such beliefs with specific teaching or student learning outcomes, we recommend that more research is needed to establish such links.

We also found that all of the literature identified in this search conceived of and measured epistemic cognition as a unidimensional, static construct. Future work should also build from epistemic cognition models that centralize the role of context and frame epistemic cognition as a situated process rather than capturing only static beliefs.

We also note that issues of race, gender, and class were all but absent from this body of literature. Existing research suggests that teachers' seemingly innocuous beliefs about the nature of mathematical ability are not gender-neutral (Copur-Gencturk, Thacker, & Quinn, 2019). Such evidence suggests that implicit racial and gender biases may belie the seemingly harmless beliefs about the nature of mathematics and mathematical knowing. Future research should explore potential relationships.

DISTRICT CERTIFIED CULTURALLY RESPONSIVE TEACHERS AND THEIR ELEMENTARY MATHEMATICS TEACHING PRACTICE: A MULTI-CASE STUDY

Casedy A. Thomas
University of Virginia
cat6hu@virginia.edu

This multi-case study examines how three elementary teachers, all certified by their school district in culturally responsive teaching (CRT) through professional development opportunities, implement mathematics teaching practices that support CRT. Furthermore, this study examines the CRT certification process in the focal district and the structures that support teachers in their enactment of CRT. Data were collected via interviews, questionnaires, observations, teacher journals, and other reportable data. The teachers' CRT practices in mathematics fell into four large quadrants aligning with the work of Hammond's (2015) Ready for Rigor framework. The findings expand upon the literature and provide us with a more informed understanding of what CRT looks like in elementary mathematics classrooms with teachers who have been certified in CRT from a district developed and applied certification model.

Culturally Relevant Education, Elementary School Education, Equity and Diversity, and Instructional Activities and Practices

Purpose & Theoretical Framework

The achievement of historically marginalized students has been an ongoing concern for stakeholders. Gay (2010) stated, "The achievement of students of color continues to be disproportionately low at all levels of education, and the need to change these dismal conditions is even more pressing" (p. xxvii). While addressing student achievement in mathematics education, Bonner (2014) emphasized how data from the National Center for Education Statistics (NCES, 2009), indicated that from 1990 to 2007 there was, "little progress in closing the persistent mathematics achievement gaps between certain groups" (p. 377). More recently, data from the National Assessment of Educational Progress (NAEP; 2017) reported that though there were not significant changes in racial and ethnic disparities from the previous years, the scores of White students remain higher on average than those of their Black and Latinx peers, indicating that while the achievement gap is smaller than it was in 1990, disparities are still prevalent. Although there are numerous reasons why such achievement gaps persist between students of color and their White counterparts in mathematics, including but not limited to, tracking/leveling, access to resources, institutional racism, and stereotype threat, research has shown that the achievement of historically marginalized youth is likely to increase when learners have positive mathematical identities (e.g., Borman & Overman, 2004) and cultural identities (e.g., Moll, Amanti, Neff, & González, 1992). Teachers play a significant role in forming student perceptions and fostering the development of such identities (Schoen, Cebulla, Finn, & Fi, 2003).

Thus, Gay (2010) stated, "Culturally responsive teaching is a means for unleashing the higher learning potentials of ethnically diverse students by simultaneously cultivating their academic and psychosocial abilities" (p. 21). Though the theoretical framework for CRT has informed the educational community for quite some time, scholars (e.g., Hammond, 2015) continue to discuss the challenges of operationalizing CRT in practice. Mathematics education in particular has produced limited research examining the teaching practices of culturally responsive teachers in pre-kindergarten through 12th grade (preK-12) (Thomas & Berry, 2019). Bonner (2014) offers three reasons for why this might be the case, including: 1) the majority of the works are specific to one population such as African American learners (e.g., Ladson-Billings, 1994); 2) there is a broad focus

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

on content and practice, making it non-mathematics-specific (e.g., Gay, 2010); and, 3) the works remain largely theoretical (e.g., Greer et al., 2009).

The purpose of this multi-case study is to examine CRT practices in elementary mathematics with three teachers who have been locally recognized and certified in CRT by their school district. Furthermore, the intent is to examine the CRT certification process in the focal district and the structures that supported the teachers in their enactment of CRT with historically underserved students, in their efforts to address the achievement gap. Though there is variability in how to define achievement gap (e.g., test scores, course enrollment patterns, cognitively demanding learning opportunities, etc.), this study is utilizing the terminology to emphasize the gap in standardized test scores, based upon how the focal district is operationalizing the construct and their desired outcome. This study is not about "gap gazing" rather language surrounding the achievement gap has been made explicit to describe the context within the district (Gutiérrez & Dixon-Román, 2011). This study is grounded in CRT both in theory and practice.

Methods

Research Questions

1. How do teachers become fully certified in CRT, and what structures support teachers in their enactment in the focal district?
2. How do three elementary teachers, who have been certified in CRT, implement mathematics teaching practices? How does the mathematics instruction support CRT?

Site and Sample

William County (pseudonym) is located in a southeastern state and it is known for its diverse student population inclusive of over 90 spoken languages. There are approximately 14,000 students enrolled in elementary schools in the district. In an effort to close the achievement gap in William County, district leaders created a CRT certification program for preK-12 teachers, administrators, and counselors. Since the program's enactment in 2016, 40 individuals have been certified across the district. The majority of the certified teachers are elementary, and to date, no secondary mathematics teachers have received certification.

I secured the consent of Skylar, Elizabeth, and Clay (pseudonyms). Skylar and Elizabeth are both Black women and Clay is a White man. Skylar and Elizabeth both teach at River Elementary (pseudonyms for school names) and Clay is at Ivy Elementary. The participants teach mathematics in different grades such that Skylar is pre-kindergarten, Elizabeth is third-grade, and Clay is fourth-grade. Their years of teaching experience range between five and 11 years. Additionally, their ages range from late-20s to late-40s. All of the teachers were part of the most recent cohort to receive certification. To incorporate multiple perspectives, I also draw upon the voices and the actions of district leaders.

Data Gathering Procedures

Mapping cultural reference points questionnaire. The first module of the district's CRT certification focuses on teachers recognizing their own cultural lenses. To inform my understanding of how the teachers are pushing themselves outside of their own cultural boundaries, I had them complete a questionnaire (Hammond, 2015) following the first interview.

Teacher journals. A key component of CRT examines how teachers react in the moment and how they use those experiences to inform their practices in the future, as seen in Bonner (2014). Following each observation, I asked the teachers to briefly reflect upon their own instruction using a journal protocol to gauge awareness.

Interviews. The first, semi-structured interview focused on the teachers' perceptions of their enactment of CRT in mathematics education and their experiences with the certification process. The second teacher interview focused on emerging themes surrounding the teachers' CRT practices and their perceptions of district structures.

Classroom observations. I observed the actions of the teachers inclusive of both how they gained knowledge of their students and how they used such knowledge to inform their teaching practices. I observed (and video recorded) the teachers (using protocol) for at least 10 full mathematics lessons (1.5 hours each; time of a unit). Data were collected using fieldnotes.

Other reportable events. Other reportable events in this study is multifaceted, including: informal, unstructured interviews and conversations that arose; various forms of artifacts such as assignments, student work, photographs, and the teachers' certification portfolios; and data points from involvement in community partnerships, division meetings, and school-wide meetings in public spaces.

Data Analysis

The information gathered from the questionnaire served as preliminary data that led toward the development of other methods; particularly, by helping to inform the observations. The journal reflections were re-read, and compared to the data for the corresponding classroom observations to analyze teacher awareness. Both interviews with the teachers were recorded and transcribed to allow for member checking. All fieldnotes were transferred into write-ups, and analytic memos were written intermittently to document emerging themes and inferences from data collection. Data sources were triangulated and re-read and re-coded to document emerging patterns and themes of CRT practices. I compared confirming and disconfirming evidence and continued to adjust my findings until all of the evidence was accounted for. Additionally, I engaged in peer debriefs and consulted with experts in the field about emerging themes and patterns, aligning with the theoretical frameworks to ensure trustworthiness.

Findings

District Professional Development & Structures

The focal district has enacted a CRT certification program inclusive of three professional development modules and three characteristics of focus for monthly cohort meetings. The three modules include: 1) recognizing your cultural lens, 2) engaging diverse learners, and 3) ensuring equitable parent participation. The characteristics of the CRT certification state that culturally responsive teachers: 1) acknowledge and incorporate the importance of cultural heritage of all students, while reflecting on their own personal cultural influences; 2) provide multi-cultural instruction and differentiation for relevance and rigor; and, 3) build positive learning partnerships with students and families. To receive certification, teachers have to demonstrate within their portfolios that they are working to enact CRT and present evidence of student achievement. The compilation of their work is also presented at a district-wide Equity Conference. Furthermore, district structures are in place with the purpose of continuing to influencing the teachers' learning and implementation of CRT. These structures are evidenced in the county's Equity Model that acts as a structural hierarchy of support (See Thomas (2020) for further discussion of the Equity Model and district-level support structures.).

CRT in Mathematics Classrooms

During my time working in the classroom with the teachers, it became evident that their conceptions of CRT were highly influenced by the work of Hammond (2015) and the *Ready for Rigor* framework. However, similarly to other works surround CRT, some of the components of each quadrant exemplified particular tenets that are more thoroughly captured in other literature (e.g., Gay, 2010; Ladson-Billings, 1994). The findings have been outlined in Figure 1. The quadrants are oriented to mathematically model the coordinate plane and the ways in which the teachers went about building CRT at the beginning of the school year. However, it is important to acknowledge that after the initial phase (of consecutive order), this is very much viewed as a continuous cycle without particular attention to order and the quadrants are not mutually exclusive. Furthermore, gaining knowledge has been placed at the center of this model.

Although mathematics teaching and learning are embedded throughout Quadrants 1-3, Quadrant 4 on information processing is most specific to mathematics education. All three teachers emphasized the importance of helping their students to first develop growth mindsets or mathematical mindsets (Boaler, 2016) when tackling challenging tasks that require cognitive demand and problem solving. Furthermore, in the domains for relevance, mathematical representations (Berry et al., 2017), and discourse, I examined how such standards-based practices (NCTM, 2000) were accompanied with CRT strategies to help students process information. The teachers viewed these as strategies for "stimulating brain growth to increase intellective capacity" (Hammond, 2015, p. 17). For sample excerpts and a thorough examination of the findings on CRT in practice as demonstrated in Figure 1 refer to Thomas (2020).

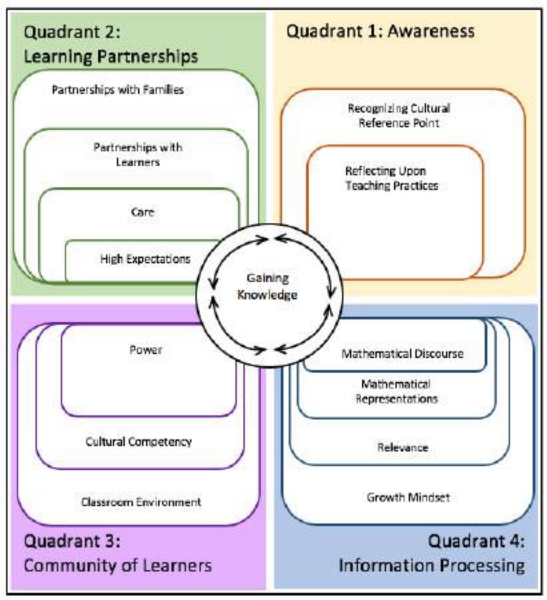

Figure 1: Findings of CRT in Elementary Mathematics Classrooms

Discussion & Significance

The study is significant because its findings expand upon the literature (e.g., Bonner, 2014; Thomas & Berry, 2019) and provide us with a more informed understanding of what CRT looks like in elementary mathematics classrooms. Furthermore, as indicated by Cai et al. (2017) there is a need in the field to link research and practice, and this study attempts to bridge that gap with CRT. This work is unique because the teachers are certified in CRT and supported by district structures in enacting CRT practices. This study continues to inform our understanding of how to operationalize CRT in mathematics, and it gives us insight into the professional development and support structures that may influence the implementation of such pedagogy.

DOCUMENTING MATHEMATICAL LANGUAGE: DISTINCTION-MAKING AND REGISTER-FITTING

David Wagner
University of New Brunswick, Canada
dwagner@unb.ca

Karla Culligan
University of New Brunswick, Canada
kculliga@unb.ca

This paper advances theory for language use in mathematics learning contexts. The theory arises from a cross-sectional longitudinal study of student language use in Grades 3 to 11, both in English first-language contexts and French Immersion contexts. We point to translanguaging and the language-as-resource metaphor to consider the goals educators have for documenting students' mathematical language. We problematize deficit-oriented assessment of mathematical language and differentiate between using language for distinction-making and for register-fitting. Both are important. We introduce a tool for documenting language repertoires to recognize students' language strategies, including distinction-making and register-fitting.

Keywords: Classroom Discourse, Communication, Cross-cultural Studies, Probability

The understanding of any mathematics is mediated by language. There is a reciprocal relationship between language and conceptualization: language repertoires are necessary to convey an idea, and the language used shapes the way people conceptualize. This reciprocity led us to to identify children's language repertoires in a range of contexts. Here we present a tool for documenting language repertoire and we explain how it helps us think about theory.

The research data from which we draw examples comprised a cross-sectional longitudinal study in English-medium and French Immersion instructional contexts in an Anglophone region in Canada. We worked with students in Grades 3, 6, and 9 in the first year, Grades 4, 7, and 10 in the second year, and Grades 5, 8, and 11 in the third year.

Second language acquisition literature has shown that people are generally good at picking up and using the language strategies employed by others in interaction (Ellis, 1997; Long, 1985, 1996, 2007; Swain, 2000, 2008)—in other words, people are naturals at learning language. We claim that first language acquisition works similarly—people pick up and use the language strategies used by others. To listen for students' language strategies (as opposed to students' ability to understand and then use the strategies we exhibit), we deemed it necessary to design mathematical tasks that do not have us saying or writing language strategies we foresaw students using. We found it possible to avoid the specialist language of prediction in our tasks by constructing a narrative context for our questions.

We introduced the game of Skunk with a narrative like this in each classroom: "I was picking strawberries in the forest. When my basket was quite full, a skunk wandered into the berry patch. I ran away so the skunk would not spray me. And I lost the berries in my basket." Participants had a pile of beans (representing the berries), a cup (the basket), and a bowl (home). When the researcher rolled the die and called out the number, participants put that number of berries in their basket. A 6 represented the skunk. When it was rolled, everyone would lose the berries in their baskets. If they had "gone home" (dumping their beans into their bowl) before the appearance of the skunk, their berries were safe. We played seven rounds.

The day after playing the game in the classroom, we interviewed groups of students and played again but, instead of the die, we used six cards bearing the numbers one to six (the skunk). The interviewer would not replace the cards into the deck until the deck was completely played out, at which time it would be reshuffled. Thus the participants experienced the difference between independent and mutually exclusive events in probabilistic situations. During the card game, the

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

interviewer would ask the participants to say why they made their choices about when to "go home." After the game, the interviewer would ask participants about specific things they had said earlier, asking for clarification on meaning. We had students work in pairs to encourage them to dialogue about their choices (e.g., "should we go home or stay in the berry patch?").

After transcribing the interviews, we collated students' language strategies for identifying certainty or uncertainty, organizing them into charts—one chart for each interview. The chart identifies each strategy and when it was used by referring to the turn number. A turn begins and ends with a change in who is speaking. The structure of the chart emphasizes who is the first person to use each language strategy and who uses it after that. We show one such chart here (Table 1), from an interview with four English-medium Grade 6 students. The strategies are presented in the order that they are used. For example, the first language strategy for uncertainty was Bal's use of 'probably' in turn 21. Bal used 'probably' again in turns 40, and 149. (Names are pseudonyms. "Int." refers to the Interviewer.)

Table 1: Grade 6 English group – expressions of certainty and uncertainty

Certainty	Certainty (continued)	Uncertainty
Simple Assertion		'probably'
1st user: Col (23, 44, 60)	…	1st user: Bal (21, 40, 149)
2nd user: Int. (49)		'it depends'
3rd user: Bal (62, 122,	'got to' / 'gotta'	1st user: Daz (22)
129)	1st user: Adi (260, 265)	2nd user: Adi (33)
'have to'	2nd user: Int. (262, 289)	'usually'
1st user: Int. (49, 81, 255,	3rd user: Daz (283)	1st user: Bal (25)
262, 279, 295, 297, 299)	4th user: Adi (284)	'you never know'
'sure'	'you know it's got to'	1st user: Daz (35)
1st user: Researcher (121)	1st user: Col (261)	2nd user: Bal (238)
'you know'	'has to'	3rd user: Int. (239)
1st user: Daz (197)	1st user: Adi (265)	'could'
2nd user: Int. (361)	'a rule'	1st user: Daz (35)
'probably'	1st user: Col (290)	2nd user: Int. (303, 305, 311,
1st user: Daz (197)	2nd user: Daz (291)	313, 317)
'I know'	3rd user: Int. (293, 295, 357)	'I/you think'
1st user: Col (226)	'can't'	1st user: Int. (30, 66, 69, 126,
'need to'	1st user: Int. (327, 329, 336,	128, 141)
1st user: Col (228, 294)	352, 361, 363)	2nd user: Col (41, 106)
2nd user: Daz (282)	'not allowed'	3rd user: Bal (105, 125)
'you know you're going to'	1st user: Bal (337)	'not sure'
1st user: Bal (238)	2nd user: Int. (338, 354, 361)	1st user: Int. (45, 47)
'you never know'	'impossible'	'I don't know'
1st user: Bal (238)	1st user: Col (340)	1st user: Daz (227)
…	2nd user: Int. (341, 344, 354,	'a chance'
	361)	1st user: Bal (304)
		2nd user: Int. (305)

Problematizing deficit assessments of mathematical language

We acknowledge that we found it hard to avoid deficit assessment even though it was our expressed intention to avoid it. For example, we expected students to use modal verbs to make distinctions in degrees of certainty—as we had found in earlier work (e.g., Wagner, Dicks & Kristmanson, 2015)—

ranging from negative root modality (e.g., 'it is not six') to positive root modality (e.g., 'it is six') and different levels of modulation in between.

However, we noticed that Adi, Bal, Col and Daz here did not use some common modal verbs. For example, after giving the students a chance to use the modal verb 'can't' on their own, the interviewer used it multiple times (starting in turn 327), even explicitly asking the students what it meant. But the students did not use it. It was clear that they understood it, because when asked about it they made distinctions between things that are 'not allowed' (Bal in turn 337) and things that are 'impossible' (Col in turn 340). If we were to rate their language use on a checklist, how would we assess their use of the word 'can't'? We can say they did not use the word. But it would be inappropriate to say they do not have the word in their repertoires. The fact that they did not use it does not mean they cannot use it. To illustrate further, we consider the word 'impossible'. If we had ended the interview a little sooner, before turn 340, we would not have known that it was in Col's repertoire. We can say that at least Bal and Col understand 'can't' because they responded well to questions using the word. They even demonstrated sophisticated understanding by making distinctions between impossibility due to logic and due to authority. Rowland (2000) has documented the language of this distinction.

Further, we see that Bal and Col responded with understanding to the word 'can't'. What can be said about the others in the group? We argue that it would be inappropriate to say that Adi and Daz did not understand 'can't'. While they did not use the word nor respond directly to the word being used, there was no reason for them to speak about it because Bal and Col already did so. We entered the research project with a principled decision to avoid deficit assessment. We found it difficult to avoid deficit approaches in our read of the data. Ultimately, our data gave us evidence to reject deficit assessments of language.

Translanguaging for distinction-making and register-fitting

Distinction is a word that appears multiple times in our theorizing above. Our stance of seeing language as resource (Martínez, 2017; Moschkovich, 2007, 2013; Planas & Setati-Phakeng, 2014; Ruiz, 1984) led us to appreciate the language work done by the students in our data across the ages. This led us to ask what goals we would promote for mathematics educators in relation to mathematical language. We settled on these three: (1) understanding mathematical concepts, (2) ability to use language to make mathematical distinctions, and (3) ability to sound knowledgeable (fitting the genre, the grammar, the lexicon)

We assume that all mathematics educators are interested in supporting students to develop understanding of mathematical concepts. With an interest in mathematical language, it is common to say that students should also be able to communicate their mathematics. This goal compels us to ask what it means to communicate mathematics. We differentiate between successful communication of an idea, which we call *distinction-making*, and using 'correct' language, which we call *register-fitting*. As shown by the students Adi, Bal, Col and Daz, and by the students in every other interview in our research from Grades 3 to 11, it is possible to communicate conceptual distinctions without using conventional language.

We claim that communicating mathematics successfully means being able to make mathematical distinctions in a way that others understand. We use the new theory of *translanguaging* here, introduced by García and Wei (2014), to challenge the neat boundaries people often imagine around languages. We aim to appreciate the range of language strategies people use, no matter how they cross lines of recognized languages (e.g., English or French), and variations within languages (mathematics registers, dialects, etc.).

For example, in relation to prediction, it is important to have language strategies that distinguish between certainty and uncertainty. This can be done with adverbs like 'certainly' and 'possibly.' Bal used adverbs—'probably' thrice, and 'usually' once. The distinction can also be made with adjectives, such as 'impossible' which was used by Col first in this interview. The distinction can be made with modal verbs as noted above and with a distinction between knowing and thinking, also noted above.

Further sophistication is possible with distinctions between levels of certainty (modulated certainty)—for example, Bal's adverbs 'probably' versus 'usually.' Other than that distinction we did not find modulated certainty in this group. For further examples we can point to data from a group of three Grade 9 French Immersion students. (We do not show the table due to space restrictions.) To identify a higher probability, Enk said 'plus de chance' (more chance) early in the interview (turn 14). Much later, Gyl said 'une bonne chance' (a good chance) (turn 127). To identify lower probability, Gyl said 'un sur trois chance' (one in three chance) early in the interview (turn 20) and 'une petite chance' (a small chance) later (turn 90).

In addition to making distinctions clearly, we have seen that mathematics teachers value students using 'proper' words 'properly'. We use the word *proper* in quotes because it can only refer to loosely defined expectations for standard lexicon ('proper' words) and standard grammar (words used 'properly'). This means that educators want to induct students into a community of mathematicians, who, presumably, use the words and grammar of the mathematics register—the specialized methods of communication used amongst the mathematically literate (Barwell, 2007; Halliday, 1974; Pimm, 2007). We see this *register-fitting* as different from distinction-making. However, there is a connection: as people move to using more conventional language it becomes easier for others to understand their meaning. For example, if we use language that you know and use, you will more likely understand us. This is the unitary force of language in Bakhtin's (1981) metaphor—the centripetal force (Barwell, 2014).

French Immersion contexts are especially interesting to us in terms of register-fitting because there are two explicit goals: learning mathematics and learning French. We suggest similar goals in first-language medium classrooms too: learning mathematics and learning to communicate mathematics, which would include both distinction-making and register-fitting.

Two of the four strategies used by students to modulate certainty in the French group used improper French: 'un sur trois chance' (turn 20), and 'une petite chance' (turn 90). We could criticize the students for using improper French (a deficit assessment). Alternatively, we could honor them for using the language strategies available to them to make the distinctions they intended to make. Strong language speakers are inventive with language to communicate their ideas. There are plenty of other examples of 'improper' language being used powerfully across the corpus of data in both French and English interviews.

But deficit views of 'proper' language are even more complicated. We consider the Francophone interviewer, who said 'c'est peut-être pas' ('it might not be') in turn 98. This too was successful communication in non-standard French (the speaker dropped the 'ne' in front of the verb 'est'). However, in oral French it would be weird to say the standard French 'ce n'est peut-être pas.' The interviewer was using standard oral French. We believe that anyone who has transcribed natural language data will have realized that people do not often speak in proper sentences.

Acknowledgments

This research was supported by the Social Sciences and Humanities Research Council of Canada, as part of a grant entitled "Students' language repertoires for investigating mathematics" (Principal Investigator: David Wagner).

Our research is a case study, qualitative, exploratory and descriptive, in which we analyze the free textbook for mathematics and consider, among other variables: the structure, the didactic situations, the expected learning, etc. The participants at the beginning of the research were seven teachers from a Primary School located in the municipality of Toluca: Two from first grade and one from second to sixth, with their students respectively. In the profile of the teachers we consider the following features: Gender, age, degree attended, professional training, institution that accredits their studies and professional experience

The information was obtained by applying a questionnaire to the teachers and another to their students. In the following we show an excerpt of them.

Questionnaire for the students	**Questionnaires for teachers**
ON THE POSSESSION OF THE BOOK When did you enter school this year, did you get a math book? ABOUT KNOWING THE BOOK AND ITS PARTS Do you like your math book? Why? What is the most interesting thing about your book or about math? ON THE USE OF THE MATH BOOK Do you use the math book in your math classes? (never, sometimes, always) In your math classes do you use the book as a whole class, at the beginning, at the end or homework? Does someone in your house help you solve the problems in the math book? ON THE WORK SEQUENCE WITH THE BOOK When you are presented with a challenge from the book: What do you do first? Next? In the end? Do you discuss with your classmates different strategies to solve it? Do you agree to solve it? Do you participate in group discussions? Do you communicate what you do? Do you always understand what others are saying?	The following questions are related to the free math textbook. How important is it to you in conducting math class? In relation to the didactic situations raised are: In relation to the didactic situations raised consider: When in class do you use it In relation to the mathematical concepts to build the didactic situations are: Do you use other books in your math class? What difficulties do you and the student face when using the new textbook: Didactic situations of the free textbook difficult to deal with. Do you consider that the textbook has defects? Which ones? Do you believe that parents can support students to carry out the activities in the textbook? Why? Are your students capable of producing their own ideas and procedures? YES NO Why? What is more important, the exercise or construction of the concepts? Why? Do students' ideas bring any new knowledge to you? Why? What do you consider before engaging your students in a new challenge? Have you solved all the challenges? Why? Are the challenges adjusted to the context and conditions of your children? But because? If they don't fit what do you do? Provide an example

Nuestra investigación, es un estudio de caso, de corte cualitativo, exploratoria y descriptive, dónde analizamos el libro de texto gratuito de matemáticas y consideramos, entre otras variables: la estructura, las situaciones didácticas, los aprendizajes esperados, etc. Los participantes al inicio de la investigación fueron siete profesores de una Escuela Primaria ubicada en el municipio de Toluca: Dos de primer grado y uno de segundo a sexto, con sus estudiantes respectivamente. En el perfil de los profesores consideramos los siguientes rasgos: Género, edad, grado que atiende, formación profesional, institución que acredita sus estudios y la experiencia profesional

La información la obtuvimos mediante la aplicación de un cuestionario a los profesores y otro a sus estudiantes. En lo siguiente mostramos un extracto de los mismos.

Cuestionario para los alumnos	Cuestionarios para los profesores
SOBRE LA POSESIÓN DEL LIBRO ¿Cuándo entraste a la escuela este año te entregaron un libro de matemáticas? **SOBRE EL CONOCIMIENTO DEL LIBRO Y SUS PARTES** ¿Te gusta tu libro de matemáticas? ¿Por qué? ¿Qué es lo más interesante de tu libro o de matemáticas? **SOBRE EL USO DEL LIBRO DE MATEMÁTICAS** ¿En tus clases de matemáticas utilizas el libro de matemáticas? (nunca, a veces, siempre) ¿En tus clases de matemáticas utilizas el libro toda la clase, al principio, al final o tarea? ¿Te ayuda alguien en tu casa a resolver los problemas del libro de matemáticas? **SOBRE LA SECUENCIA DE TRABAJO CON EL LIBRO** Cuando te presenta un desafío del libro ¿Qué haces primero?, ¿después? ¿Al final? ¿Comentas con los compañeros distintas estrategias para resolverlo? ¿Se ponen de acuerdo para resolverlo? ¿Participas en las discusiones grupales? ¿Comunicas lo que haces? ¿Comprendes siempre lo que los demás exponen?	Las siguientes preguntas están relacionadas con el **libro de texto gratuito de matemáticas**. ¿Qué tan importante es para Usted en la conducción de la clase de matemáticas? En relación a las situaciones didácticas planteadas son: En relación a las situaciones didácticas planteadas considera: En qué momentos de la clase lo utiliza: 5. En relación a los conceptos matemáticos a construir las situaciones didácticas son: ¿Utiliza otros libros en su clase de matemáticas?¿Qué dificultades enfrenta Usted y el alumno al utilizar el nuevo libro de texto: Situaciones didácticas del libro de texto gratuito difíciles de abordar. • ¿Consideras que el libro de texto tiene defectos? • ¿Cree que los padres de familia pueden apoyar a los alumnos a realizar las actividades del libro de texto? ¿Por qué? ¿Tus alumnos son capaces de producir ideas y procedimientos propios? ¿Por qué? ¿Qué es más importante, la ejercitación o construcción de los conceptos? ¿Por qué? ¿Las ideas de los estudiantes aportan algún conocimiento nuevo para ti?¿Por qué? ¿Qué consideras antes de involucrar a tus estudiantes en un nuevo desafío? ¿Haz resuelto todos los desafíos?¿Por qué? ¿Los desafíos se ajustan al contexto y condiciones de tus niños?¿Por qué? Si no se ajustan ¿Qué haces? Proporciona un ejemplo

Agradecimiento

Agradezco infinitamente a los profesores y estudiantes que contribuyeron en esta investigación.

WHAT MATTERS TO MIDDLE SCHOOL MATHEMATICS TEACHERS: RESULTS FROM A THREE-YEAR PROFESSIONAL DEVELOPMENT PROGRAM

Laura B. Kent
University of Arkansas
lkent@uark.edu

This poster session describes the results of a ranking activity from a three-year professional development (PD) program for middle level mathematics teachers. Not surprisingly, teachers in their first year of the PD program valued observing other teachers use questioning techniques with students and classroom observations more than any other of the seminar style activities. Some subtle shifts such as planning with other teachers and activities involving sorting student work were valued higher for year three teachers rather than year one and year two teachers. The results are consistent with the types of activities teachers desire in PD programs (Matherson & Windle, 2017).

The conceptual basis for the three-year professional development program involved two core components. The first component involves knowledge of content and students (Ball, Thames, & Phelps, 2008). The focus of the PD is exploring diverse student approaches to solving middle grades mathematics problems and serves the dual purpose of increasing middle school teachers' content knowledge and their understanding of students' thinking within specific mathematics content areas and topics. The second component of the professional development is examination of potential learning trajectories with the goal of planning and predicting student responses and questions that will promote productive mathematical discourse (Sztajn, Confrey, Wilson, & Edgington, 2012).

This study answers the following research questions:

1. What activities in professional development specifically focused on middle school mathematics do teachers value the most?
2. Are there shifts in what teachers value from year one participation to year three participation?

Data sources were part of a survey that was given to teachers at the end of each year of the three-year professional development program. The structure of the program involved three days of seminar style sessions in which teachers viewed videos of students solving problems, sorting student work, readings, discussions, planning problems to pose, and videos of teachers posing problems. Three of the four classroom embedded sessions involved sorting student work and then watching the host teacher orchestrate the sharing and questioning students. The fourth classroom embedded day involved planning problems and interviewing individual students.

Fifty-two teachers were asked to rank 10 professional development activities from 1 (most valuable) to 10 (least valuable). The 10 activities are: watching videos of students solving problems, predicting student solution strategies, observing in classrooms, interviewing individual students, sorting student work, planning with other teachers, learning about problem types, videos of classroom instruction, questioning techniques, and readings. The highest ranked activities of year one and year two teachers were questioning techniques and classroom observations. However, year 3 teachers ranked predicting student solution strategies and planning with other teachers highest, suggesting shifts in priorities over the three years of professional development.

TRANSLANGUAGING MOVES IN ELEMENTARY MATHEMATICS CLASSROOM NUMBER TALKS: UNDERSTANDING LINGUISTIC REPERTOIRES

Luz A. Maldonado Rodríguez	Gladys Krause	Melissa Adams-Corral
Texas State University	William and Mary	The Ohio State University

Keywords: Computational Thinking; Instructional Activities and Practices; Classroom Discourse

Mathematics education research advocates for practices that celebrate all students' mathematical reasoning and ways of knowing (Turner & Drake, 2016). For multilingual teachers, translanguaging theory opens up how mathematical knowledge is shared and understood in multilingual mathematics classrooms. Translanguaging, a dynamic view of language acquisition, posits that instead of viewing multilinguals as having separate language registers, we instead view their access to multiple linguistic repertoires in specific contexts (García & Kleifgen, 2010). Number Talks are a structured series of computation problems selected and sequenced and presented to elementary students in order to build mental computation and relational thinking (Bray & Maldonado, 2018; Parrish, 2010; Humphreys & Parker, 2015). This study investigated the translanguaging moves that revealed the mathematical thinking of multilingual elementary students while engaging in number talks.

We conceptualize a translanguaging stance in the mathematics classroom as the deliberate choice by teachers to create a space in which children's mathematical thinking and language practices are positioned as powerful resources during mathematics instruction (García, Ibarra Johnson & Seltzer, 2017). Further, we posit that Number Talks are a beneficial activity for mathematics instruction in multilingual contexts due to the open-ended nature of the activity. Students may share their thinking, unencumbered by language separation requests, as they share their mental computation, all while the teacher facilitates a discussion of ongoing analysis of the mathematical relationships that are revealed in students' strategies (Bray & Maldonado, 2018).

Six number talks that occurred in a 3rd grade two-way dual language classroom at a Southwest school were analyzed for this study. Of 23 students, 22 identified as Latinx (with families from Mexico, El Salvador, Honduras and Puerto Rico), and one student identified as both Black and White. Number Talks were video recorded and transcribed, and focused on multidigit subtraction, multiplication and division, and unit fraction multiplication. We used multimodal analysis (Jewitt, 2009) because it is particularly helpful to identify how bilingual learners use semiotic resources other than spoken language to participate (Domínguez, 2005).

Two themes emerged from analysis of the Number Talks: translanguaging teacher moves to facilitate the mathematical flow of ideas, and ongoing community mathematical knowledge building moves. Translanguaging teacher moves emerged at various points in the Number Talk, both to invite students into conversation, to scribe students' oral strategies, and to ask for further reflection and discussion. Community mathematical knowledge building occurred between students, and often began with a mathematical question or puzzlement. Our study highlights the need for opening up the ways in which multilingual students draw upon their linguistic repertoires to build community and individual mathematical knowledge.

USING TRANSLANGUAGING TO RE-EXAMINE AND DECONSTRUCT EARLIER FINDINGS ABOUT BILINGUAL MATHEMATICS EDUCATION.

Sitaniselao Stan Manu
University of the Fraser Valley
stan.manu@ufv.ca

In my 2005 doctoral thesis, I addressed the question of what is meant by individuals' growing mathematical understanding within a particular bilingual situation wherein those individuals use words with no direct or precise translation between English, a dominant Western language, and Tongan, an indigenous Pacific vernacular. As a result of that study, a defined number of structural categories of "language switching" were then identified which in turn provided a useful way of describing the pattern in which the studied bilingual individuals alternated between the two aforesaid languages. Since then, one remaining challenge is how exactly this type of *languaging* can be formalized and practiced.

This study employs the socio-linguistic theory of "translanguaging" as an alternative framework for analysing bilingual teachers' language acts and as a new lens that allows me as researcher to re-examine and deconstruct my earlier categorisations and findings about the role of the two aforesaid languages in bilingual individuals' mathematical discussions and teaching. This alternative view of "bilingualism" recognizes that bilingual individuals may have only one *language system*, not two, and that effective instruction would involve finding ways to help these individuals draw on all their linguistic resources, their full repertoire, when learning academic content in a new language.

This study also employs and thus continues to demonstrate the power of Pirie and Kieren's Theory (Pirie & Kieren, 1994), which, along with its associated diagrammatical model, were presented and discussed previously at a number of PME meetings. Of particular interest and a focus in this new study is how translanguaging as a process, which is said to be accessible through a bilingual's prior knowledge, may directly be related to Pirie-Kieren's innermost *Primitive Knowing* layer – the starting point or "base knowledge" for the growth of mathematical understanding. This is an important link in using translanguaging as an analytical lens in this study as well as in re-examining the results of my earlier research work.

Video recordings of bilingual mathematics teachers in two high schools in Tonga, which is a small island country in the South Pacific, were made in 2019. Several episodes of these bilingual teachers' classroom language use are included in this poster presentation to illustrate the results and findings of the study. The preliminary findings not only corroborate many aspects of my earlier research work but also offer a different perspective. For while the new study supports the view that translanguaging is a normal yet personal practice in this type of bilingual classrooms, it also recognizes that effective instruction involves identifying clues that can help students draw not only on their entire linguistic resources and repertoire, but also on their *primitive knowing*.

However, there appears to be no one-size-fits-all remedy to translanguaging. It varies among bilingual individuals in how it is deployed to facilitate learning or mathematical understanding. It also puts a damper on my desire to continue searching for an effective systematic pedagogical approach toward using two languages in a bilingual classroom environment. This new realization comes from viewing the language system that underlies what bilingual individuals actually speak as personal and unique, even when there is a commonly shared cultural identity (Otheguy, Garcia, and Reid, 2015), as is the case in Tonga. If bilingual individuals, like Tongans, are allowed the flexibility of translanguaging and thus access to mathematical terms and images in either language, such a dynamical practice would allow bilingual teachers and students alike to creatively interact and co-construct mathematical meanings (Manu, 2005).

ALTERNATIVES TO MATHEMATICS CLASS DISCUSSIONS: INCLUSIVE WAYS TO CONNECT AND EXPAND CHILDREN'S IDEAS

José Martínez Hinestroza
Texas State University
josemartinez@txstate.edu

Keywords: Classroom Discourse, Inclusive Education, Equity and Diversity

Teachers' efforts to orchestrate mathematics class discussions frequently result in the monopolization of the discussion by a few students (Webb et al., 2019). The purpose of this paper is to explore how a teacher learned to transform mathematics whole class discussions toward being more inclusive of multiple students. I report on a study where students' perspectives informed a teacher-researcher collaboration to develop these inclusive alternatives in a third-grade Spanish immersion classroom. I ask: How did a teacher make sense of students' perspectives on mathematics class discussions to develop alternative ways to socialize ideas? I argue that developing inclusive ways to connect and expand children's ideas involves learning about how students navigate class discussions and challenging unquestioned teaching practices.

Methodology

I followed a participatory research approach (Fals-Borda, 1987), where I collaborated with the teacher to make sense of students' perspectives on mathematics class discussions, and to develop inclusive ways to socialize students' mathematical ideas. Data sources included audio-recordings of focus groups with students, video-recordings of mathematics lessons, and audio-recordings of interviews and collaborative data analysis sessions with the teacher. I used a social semiotics analytical framework, which acknowledges that students' multiple ways of developing and contributing ideas is part of the multimodal nature of mathematical activity (O'Halloran, 2015). The teacher and I collaborated analyzing data to interpret relationships between the students' and the teacher's perspectives. These interpretations informed how we co-developed teaching strategies to transform class discussions. Interpretations also informed how the teacher flexibly and responsively approached students' interactions in her class.

Summary of Findings

Initially, the teacher considered her role in mathematics class discussions to involve distributing uniformly student talking time. In contrast, students valued opportunities to influence others' thinking, and they experienced mathematics class discussions as overcompetitive. For students, influencing others' thinking involved more than contributing ideas through spoken utterances.

The teacher flexibly and responsively drew on two teaching strategies to promote inclusive ways to socialize mathematical ideas. The group ambassador's strategy offered opportunities to develop initial ideas in a small group and then influence the work of a different group. Ideas circulated both within and across groups, thus serving one purpose typically reserved to class discussions. In the spotlighting gestures strategy, whenever the teacher noticed gestures that communicated relevant aspects of a mathematical idea, she directed the class attention to such gestures. Students observed the gestures, and adapted and incorporated them in their own mathematical activity. Spotlighting gestures helped children communicate ideas and make sense of others' ideas without the linguistic demands that class discussions frequently impose.

LEARNING THROUGH ACTIVITY (LTA) IN SUPERIOR EDUCATION: THE CASE OF THE HEINE-BOREL THEOREM

Rogelio Meana Chávez
Universidad Nacional Autónoma de México
alaskaroy93@ciencias.unam.mx

Juan Gabriel Herrera Alva
Universidad Nacional Autónoma de México
gabalva@ciencias.unam.mx

Keywords: Classroom Discourse, University Mathematics, Learning Trajectories, Heine-Borel Theorem.

The research program called Learning Through Activity (LTA) had its origins in Simon (1995). This research program has the objective of creating an integrated theory of conceptual learning, and the design of instructional mathematical activities through the use of Hypothetical Learning Trajectories (HLTs). Thus, this HLTs play a crucial role in the LTA program. This theoretical framework implements the constructivist theory of education, developed by Piaget (1970), as well as its applications in mathematics pedagogy by von Glasersfeld (1995).

In the last decades, the community of mathematics educators has become very interested in continuing to expand this theoretical framework, in an effort to incorporate social, cultural and psychological theories in the teaching-learning processes involved in a classroom context.

During this years, according to Stylianides & Stylianides (2009, 2018), research about teaching through this kind of activities has shown very promising results in the basic levels of education, and this being the case, HLTs as part of a mathematical teaching cycle have become one of the main referents about how to design activities to guide students learning according to the constructivist theory of education, for example (Leikin & Dinur, 2003; Simon, Kara, Placa & Avitzur, 2018; Stylianides & Stylianides, 2018). However, although HLTs seem to be a very promising way to approach mathematics pedagogy, there has been little research about their implementation in the higher levels of mathematical education (Simon et al, 2018).

In this Poster, we present a synthesis of a didactical proposal, based on the LTA program's approach, that includes a main HLT with the goal of guiding the student towards a proof of the Heine-Borel theorem, and other auxiliary HLTs, that will provide the student with the necessary tools to prove the theorem. We do this with the intent to investigate the efficiency of the LTA framework in the higher levels of mathematical education.

The proposed trajectories begin with the definition of open covers, and continue through some supporting theorems, such as the theorem that guarantees the compactness of closed subsets of compact sets, and the theorem that guarantees the compactness of any K-cell, before culminating in the proof of the Heine-Borel theorem, which states that any subset A, of the Euclidean space Rn, is compact if and only if A is closed and bounded.

The study is addressed to university students beginning their studies in the topology of Rn in the Faculty of Sciences of the "Universidad Nacional Autónoma de México" (UNAM), the most important public University of México. We based the mathematical part in Rudin (1986), and other classical texts such as Bartle (2011).

Lastly, this poster will also include a synthesis of a metric based on Toulmin's argumentative model that will be used to evaluate the knowledge acquired by the students through the learning trajectories. In the last years, this model has been used by several researchers in mathematical education to analyze non formal arguments, for example (Pedemonte, 2007; Simpson, 2015; Zazkis, Weber & Mejia, 2016; Herrera, Rivera & Aguirre, 2019).

MATHEMATICS TEACHER EDUCATORS AS CULTURALLY RESPONSIVE PEDAGOGUES: INTRODUCING A FRAMEWORK FOR "GROWING CRP"

Kathleen Nolan
University of Regina
kathy.nolan@uregina.ca

Lindsay Keazer
Sacred Heart University, United States
keazerl@sacredheart.edu

Keywords: Culturally Relevant Pedagogy; Mathematics Teacher Educators; CRP framework

Overview and Research Question

Research on culturally responsive pedagogy (CRP) in mathematics education and teacher education has focused on either preparing new teachers for diverse classrooms (e.g., Aguirre et al., 2012; Ukpokodu, 2011) or on taking a critical stance toward disrupting dominant/oppressive paradigms in mathematics classrooms (e.g., Gutiérrez, 2017; Willey & Drake, 2013). The tendency has been to focus on developing the CRP of prospective/practicing teachers (PTs) and/or the mathematics curriculum, rather than that of mathematics teacher educators (MTEs).

Our research responds to Averill et al.'s (2009) challenge to "critically reflect on [our] own culturally responsive practices, ideally in discussion with other practitioners, teacher educators, and students" (p. 181). We present a collaborative self-study of two mathematics teacher educators (MTEs) developing our own CRP. We address the question, "What do MTEs learn from attempts to grow and reflect on their own CRP?" In this presentation, we share our newly developed *MTE Framework for Growing CRP*. To date, no specific tool has been proposed for supporting and guiding the professional growth of culturally responsive teacher educators.

Conceptual and Methodological Framework

Our research takes a layered approach to collaborative self-study (e.g., Hamilton & Pinnegar, 2013; Hug & Möller, 2005) such that our individual self-studies in our respective institutions converge to a second layer of collaboration through conversations on how we enact our developing CRP. Our framework includes four key reflective questions, which we constructed from careful review of a few sources (see, for example, Aguirre & Zavala, 2013; Lingard & Keddie, 2013): (1) How do my pedagogical practices draw on my students' mathematical discourse and funds of knowledge? (2) How am I addressing concerns for balance between deep and rigorous mathematical knowledge with issues of culture, equity, social justice and language diversity? (3) What struggles and resistances do I experience as I attempt to disrupt dominant forms of pedagogy that my students express more comfort with? (4) How is my own identity and experiences of being a teacher interacting/integrating with key principles of what it means to be culturally responsive? In the framework, each key question is further clarified by sub-questions.

Data Collection and Significance of Study

Our collaborative self-study model includes individual journaling on the reflective questions of our self-study framework, and monthly meetings with each other for the collaborative layer. Data collection is ongoing with an aim of continually refining our framework for growing MTE CRP. In fact, the processes of applying, refining, and revising the framework itself help work toward the goal of growing as culturally responsive pedagogues. This poster brings to light ways that MTE collaborative self-reflection can support efforts to grow one's own CRP practice— in collaboration with other MTEs and also with one's students (PTs), making the framework available for use by other teacher educators who wish to reflect on their own CRP.

BEGINNING TEACHERS' EQUITABLE AND AMBITIOUS NUMBER TALKS

Byungeun Pak
Dixie State University

Number Talks (NTs) are instructional routines that offer students a participation structure for students to use mental mathematics to solve computational problems. Responding to a call for understanding ways teaching practices could be ambitious and equitable (Jackson & Cobb, 2010; Kazemi, Franke, & Lampert, 2009; Lampert et al., 2013), we investigate the structure of the routines and components of NTs as enacted by beginning teachers (BTs).

We analyzed the 21 videos of NTs by creating transcripts of the lessons. We then drew on Parrish's (2014) and Parker and Humphrey's (2018) descriptions of NTs to identify phases in NTs. We identified a structure of NTs: *introducing*, *collecting*, *idea sharing*, and *closing* phases. This structure was consistent across the data set. We then drew on Cazden's (2001) concept regarding the *initiate-respond-evaluate/feedback* (IRE/F) pattern that is prevalent in mathematics classrooms (Lawrence & Crespo, 2003) to parse transcripts initially coded as *idea sharing* into manageable units for analysis, called segments. We then characterized each of the segments by their function (e.g., sharing strategies, comparing ideas). We looked for patterns across these characterizations. We analyzed segments by attending to patterns of who was talking within each segment type as well as overall patterns of individual's talk throughout the duration of the NT. We then contrasted segments that contain a mathematical error with those that do not.

Our analyses suggest two findings. First, BTs followed a routinized structure across this set of NTs. Within that structure, we identified important variation within the *idea sharing* phase that have implications for ambitious and equitable teaching. Second, segments coded as *strategy plus, teacher strategy,* and *comparing* created more opportunities (as compared to segments coded as strategy) for multiple students to engage with mathematical ideas. Further, in these three segment types, students engaged in a variety of ways. In this poster, we focus on *strategy plus* segments to illustrate the potential for NTs to be both ambitious and equitable.

The recognizable structure of NTs across our dataset is notable. We see NTs as a type of transportable container through which BTs can develop an ambitious and equitable practice. NTs are transportable in the sense that their recognizable and reproduceable structure offer supports for BTs to engage in complex ambitious and equitable instruction. Though much current literature focuses on structures and routines to implement NTs, our analyses indicates that the structure itself does not inherently create ambitious and/or equitable NTs. We identified the *idea sharing* phase as a critical point for further development and investigation. It is here where we found distinctions between ambitious and/or equitable NTs related to the types of segments in which BTs engaged students.

THE INTERPLAY BETWEEN A VISUAL TASK AND ELEMENTARY STUDENTS' MATHEMATICAL DISCOURSE

Zachary Pearson
The Ohio State University
pearson.166@buckeyemail.osu.edu

Azita Manouchehri
The Ohio State University
manouchehri.1@osu.edu

This research was conducted by a fourth-grade teacher and doctoral student in mathematics education in conjunction with their advisor, a professor of mathematics education.

A growing body of research in mathematics education has highlighted the importance of recognizing mathematics learning as a socially mediated activity. Indeed, mathematics education researchers have increasingly focused on how classroom dialogue can facilitate students' creation of shared understandings. Aligned with this theoretical heritage, we recognize that human life and learning are inherently social and rooted in communication. We also recognize that student discourse is connected to student cognition and thus learning. Accordingly, this study relied on socio-cultural discourse analysis (Hennesy, et al., 2016, Mercer, 2010) both as a theoretical and a methodological tool to examine the nature of dialogue in one classroom in the context of students' collaborative work on one visual task. We ask, given the centrality of task selection to fostering discourse, how the use of a visual task, as an instructional tool, might affect students' peer-to-peer discourse practices?

Methods

The goal of this study was to identify specific discourse practices students utilized while collaborating on a visual mathematics task. A focus group of 4, fourth-grade students' interactions on one task was used as a data source for analysis.

The participants worked on a task (Boaler, 2017, p. 32) that asked them to work together to find patterns. Students were each nine to ten-years-old and represented a range of academic abilities. The group discussion was videotaped and transcribed.

Transcriptions were coded using Hennessy et al.'s Scheme for Educational Dialogue Analysis (SEDA) (Hennessy, et al., 2016). SEDA offers a scheme for analyzing discourse practices, specifically outlining different practices.

Findings

A total of 111 utterances were coded. Students most frequently conjectured and made their reasoning explicit by utilizing visual models presented in the task. Additionally, "Explicit reasoning" and "build on ideas of others" accounted for the majority of students' communicative acts during the discussions.

Group members exhibited different patterns of practice and adopted different roles. Despite differences in discourse moves, the majority of communicative acts consisted of students' conjectures and ensuing explanations using the task's visual models. Learners' comments frequently relied on the visuals with statements such as, "Look, (points to paper), there are triangles all over the place." Group members relied on the visual task as they considered proposed ideas, built on them, and utilized them in their own work.

In our on-going five-year naturalistic research, we analyze how math majors and future math teachers learn to use programming for mathematics investigation. Using the instrumental approach (Trouche, 2004) as a framework, we present some exploratory results on how the instrumental orchestration of an instructor (Bill) supports the activity of his students.

Rabardel (1995) describes how people, through their instrumental geneses, appropriate an artifact and turn into an instrument. Trouche (2004), proposed the concept of instrumental orchestration to refer to the teacher's organization: the arrangement and didactic use of artifacts in the class to steer the student's instrumental geneses. As an extension to this concept, Drijvers et al. (2010) consider three instrumental orchestration's components: (i) the *didactical configuration* – "an arrangement of artifacts in the environment; (ii) the *exploitation mode* – "the way the teacher decides to exploit a didactical configuration for the benefit of his or her didactical intentions"; and (iii) the *didactical performance* – which "involves the ad hoc decisions taken while teaching" (Drijvers et al., 2010; p. 215). Bill's data includes the course syllabus and the assignment guidelines; assessment grading rubric and 6 instructor interviews.

Bill's **didactical configuration** involved mathematical and social considerations and a web of ideas and actions that provide a creative structure for drawing connections between programming and mathematics (Buteau et al., 2020). The choice of programming technology and the general guidelines of their use was established in 2000 by the mathematics department at his university. Bill follows this didactical configuration.

The **exploitation mode** relates to his aims and the didactical design of the assignments, which involve modeling, problem-solving, simulations, and explorations; and where "mathematics is for programming", and "programming is used to do and understand mathematics". Bill provides his students with guidelines for each assignment including, in written form: worksheets guiding them through several steps or parts. For Bill, the mathematical content should be interesting for his students, related to computing and real-life phenomena. Bill's **didactical performance** aims at supporting and empowering his students while also taking into account and promoting the affective aspects (e.g. motivation, as well as creativity). He supports students by guiding their activity through individual interactions (in the lab mainly) or/and through collective interventions and discussions in lectures (Sacristán et al., 2020). In our on-going work, we analyze how the instrumental orchestration proposed by Bill, in particular the artifacts used in class, the design of the assignments and how he interacted with his students, support the development of his students' instrumental geneses of programming for mathematics. In the poster, we will illustrate the above in the case of a particular student in Bill's class.

TECHNOLOGY

RESEARCH REPORTS

THE EFFECTS OF A TECHNOLOGY COURSE WITH COLLABORATIVE DESIGN ON PROSPECTIVE TEACHERS' KNOWLEDGE AND BELIEFS

Jon D. Davis
Western Michigan University
jon.davis@wmich.edu

This study investigates the effects of a technology methods course containing a unique collaborative design experience on prospective elementary and secondary mathematics teachers' technological beliefs, computer algebra system (CAS) beliefs, and technological pedagogical content knowledge (TPACK). Overall gain scores on all three instruments were statistically significant. Moreover, gender and level (elementary vs. secondary) were statistically significant predictors of TPACK gain scores. However, the influence of level on TPACK gain score was different for female prospective teachers (PTs) than male PTs. Even in the case of low gain scores PTs displayed beliefs that were aligned with productive uses of technology in the classroom. PTs showed greater gains on knowledge subdomains associated with technological knowledge than on technology free subdomains (e.g., pedagogical content knowledge).

Keywords: technology, teacher beliefs, teacher knowledge

Technology plays an increasingly pervasive role in our everyday lives and that influence extends into school classrooms. Yet research suggests that technology is often used to support current educational practices instead of as a catalyst for change (e.g., Cuban, Kirkpatrick, & Peck, 2001). The mathematics education community has created an extensive body of research that has recognized the important role that both knowledge (e.g., Meagher, Özgün-Koca, & Edwards, 2011) and beliefs (e.g., Kim et al., 2013) play in shaping teachers' decisions around the use of technology in school classrooms. One particularly popular conceptual framework for thinking about the knowledge that teachers need to possess in these classrooms is technological pedagogical content knowledge (TPACK) (Mishra & Koehler, 2006). A variety of approaches have been used to promote TPACK among practicing and prospective teachers. One of the more popular approaches involves collaboration in the design of technology-infused lessons (e.g., Koehler & Mishra, 2005). This study examines the effect of a technology methods course containing a unique collaborative design environment on prospective elementary teachers' (PSETs') and prospective secondary mathematics teachers' (PSTs') beliefs about technology in general, beliefs about computer algebra systems (CAS), and their TPACK knowledge.

Background

TPACK is one of the most frequently used frameworks to conceptualize and research the knowledge that teachers who teach successfully with technology need to possess. A variety of interventions have been found to positively influence the TPACK of prospective teachers such as technology rich field experiences (Meagher, Özgün-Koca, & Edwards, 2011), collaborative design experiences (e.g., Agyei & Voogt, 2012), and engaging students in solving mathematics problems with technology (Meagher et al.). Wang, Schmidt-Crawford, and Yin (2018) reviewed 88 empirical studies and found that modeling of the integration of technological, pedagogical, and content knowledge in university courses and by practicing teachers was an effective way of increasing the TPACK of prospective teachers (PTs). Their synthesis also suggests that gaining experience teaching with technology, engaging in peer mentoring, and learning technological knowledge are important in developing PTs' integrated knowledge domains such as technological content knowledge (TCK).

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

An extensive collection of research has highlighted the connections between beliefs and teaching practices (e.g, Kim et al., 2013) and numerous studies have investigated teachers' beliefs with regard to technology. One way to conceptualize teacher beliefs regarding technology is what I refer to as the *role of technology in mathematics classrooms* which consists of a continuum with *doing mathematics* on one end and *learning mathematics* on the other end. Beliefs aligned with doing mathematics include the mastery principle (Fleener, 1995), "old school" (Erens & Eichler, 2015), and the restriction of CAS black box techniques (Doerr & Zangor, 2000). Individuals professing a learning mathematics position do not believe that students must learn fundamental ideas before technology; technology can be used as a tool to learn mathematical ideas (Lagrange, 1999). Proponents of a doing mathematics position argue that students should not use technology until they have learned the concepts or procedures that the technology can perform. An assumption hidden within this position, which is in contrast to the learning mathematics position is that students learn mathematics solely through paper-and-pencil work, not with technology. A belief that is aligned with the doing mathematics position is that even if technology is only allowed until students have acquired the paper-and-pencil skills they can still lose proficiency with these skills if technology is used too frequently, often described as technology becoming a "crutch" (e.g., Schmidt, 1999).

Beliefs are often connected to other personal characteristics. Tharp, Fitzsimmons, and Ayers (1997) found that practicing secondary teachers used technology more extensively in the classroom if they possessed less rule-based perspectives of mathematics. Teo and colleagues (2008) found that constructivist teaching beliefs of PTs were positively correlated with both constructivist and traditional use of technology while traditional teaching beliefs were negatively correlated with a constructivist use of technology. There is also an extensive body of research highlighting connections between gender and technology (e.g., Sanders, 2006).

Previous research has uncovered connections between TPACK and gender. For example, Bulut and Işiksal-Bostan (2019) found that male PSETs had significantly higher scores than female PSETs in TPK, TK, and TPACK. The relationship between TPACK and beliefs is mixed. For instance, Niess (2013) found that teachers' TPACK levels were occasionally connected to their beliefs. Similarly, Smith, Kim, and Mcintyre (2016) investigated the TPACK and beliefs held by four prospective middle grades teachers. Two of the teachers appeared to show relationships between beliefs and TPACK, where more student-centered views of mathematics teaching and learning were aligned with higher levels of TPACK for one teacher. More teacher-centered views of mathematics teaching and learning were aligned with lower levels of TPACK for another teacher. The results for the other two teachers were less clear.

This study builds on this extensive collection of research to investigate the effects of a technology methods course involving both PSETs and PSTs on their beliefs and TPACK. The technology methods course at the center of this study contains components that have been found to have significant impacts on the TPACK of PTs (Wang et al., 2018) as well as a previously uninvestigated collaborative design environment. This study was designed to answer three research questions.

1. In what ways does a technology methods course involving a collaborative design experience influence PTs' technological beliefs and CAS beliefs?
2. In what ways does a technology methods course involving a collaborative design experience influence PTs' TPACK and related knowledge subdomains?
3. Does a technology methods course involving a collaborative design experience differentially impact PTs' beliefs or TPACK knowledge depending on the gender or level (secondary vs. elementary) of participants?

Methodology

Frameworks

The TPACK framework (Mishra & Koehler, 2006) was used to understand the knowledge gained by PTs as a result of the activities comprising the technology methods course. This framework highlights the separate and interconnected nature of three different knowledge areas. By separate I mean that knowledge exists that is solely, technological, pedagogical, and content in nature that teachers must possess in using technology successfully in the classroom. For instance, purely technological knowledge comes into play when students "break" a pre-constructed technological document and the teacher must deploy his/her/their technological knowledge to diagnose and repair the problem. By integrated I mean that in addition to TPACK which involves the complex interplay of technological, pedagogical, and content knowledge there exist three other integrated knowledge types: pedagogical content knowledge (PCK); technological content knowledge (TCK); and technological pedagogical knowledge (TPK).

The learning by design framework (Koehler & Mishra, 2005) guided the construction of collaborative design experiences that PTs experienced in the technology methods course as the center of this study. The framework involves learning-by-doing and extended design work on authentic problems. Specifically, learning-by-doing involves two components: construction of lessons involving technology and the teaching of those lessons in middle school and high school classrooms. Authentic problems are those that teachers working in schools frequently encounter such as how to incorporate technology into a textbook lesson that does not currently contain technology or how to develop technology-rich activities that help students to develop conceptual understanding of important mathematical ideas. The course instructor often acts as a facilitator or problem-solving expert.

Context

The study took place in a large university in the midwestern U.S. that is known for its teacher preparation program. In the past, the technology methods course taught in the mathematics department, only enrolled PSTs, but the development of an Elementary Education Mathematics Major with a certification across grades K-8 necessitated the creation of another course focusing on technology use at the middle school level (grades 6-8) for these individuals. Since the development of the middle school mathematics technology course both courses have been taught at the same time and place and by the same instructor. The class met for two 100-minute sessions a week for 12 weeks. The course where the data for this study were collected was taught during the Spring 2019 semester. A total of five prospective elementary teachers (PSETs) and four PSTs were enrolled in the jointly-held course and chose to participate in the study.

PTs enrolled in both classes developed lesson plans and student activity sheets. The lesson plan involved components such as lesson objectives, places where students might struggle, how student struggles would be addressed, answers to lesson questions, and estimated time required for students to complete various lesson components. The student activity sheet involved a warm-up (if the PT chose to include one), activities and questions students were to complete, and oftentimes an exit ticket. The focus of the lesson was on conceptual understanding, the use of technology to help students learn the objectives of the lesson, the use of one or more high cognitive demand tasks (Stein & Smith, 1998), and the inclusion of at least one class discussion. All lessons taught in area classrooms involved middle school mathematics. The use of teaching experience with lessons involving technology has been found to positively affect prospective teachers' TPACK knowledge (Wang et al., 2018).

The class involved two different types of group lesson planning structures: brainstorming and refinement. Brainstorming involved the development of general ideas about a lesson without the creation of specific lesson elements. Refinement involved the presentation and critique of a student activity sheet. Brainstorming occurred if the PT was struggling to develop a lesson plan and student activity sheet while refinement was used if the PT had already completed a lesson plan and student activity sheet. PTs engaged in the development of lesson plans and student activity sheets individually, as part of a large group consisting of the entire class, and working with the instructor of the course. All of the PTs wrote a paper detailing the planning, enactment, and reflection regarding their lesson.

In addition to the presentations and brainstorming sessions, the PTs engaged in the following activities in the technology methods course: solving mathematics problems using technology; completing journal entries designed to make their beliefs regarding technology transparent to them; reading mathematics education articles involving technology and reacting to them; exploring the symbolic manipulation capabilities of CAS, the completion of a project involving the solution of an infinite class of optimization problems using graphical, tabular, and CAS capabilities; and considering how technology can be implemented in mathematics textbook lessons that do not currently use technology. Each PT created a lesson plan and student activity sheet which were either presented to the classroom for critique and refinement or began as brainstorming sessions for a total of nine lessons involving technology.

Instruments

A technology beliefs survey was administered to PTs on the first day of class and again on the last day of class. The beliefs survey was adapted from Schmidt (1999) in the following ways. First, the words calculator or calculators were replaced with technology. Second, items involving practicing teachers that referenced components of their work that were not applicable to prospective teachers (e.g., perspective of parents of their students) were removed. A frequently used TPACK questionnaire (Schmidt et al., 2009) consisting of 58 items measuring seven different knowledge domains was administered during the first day of class and again during the last day of class.

This questionnaire contains items in four different content areas: mathematics; literacy; science; and social studies. In addition to measuring TPACK (five items), the questionnaire also measures technological knowledge (TK) (seven items), content knowledge (CK) (three items), pedagogical knowledge (PK) (seven items), pedagogical content knowledge (PCK) (one item), technological content knowledge (TCK) (one item), and technological pedagogical knowledge (TPK) (four items). This TPACK questionnaire was used with the group of PSETs as this was the population for which the instrument was developed.

The questionnaire was adapted for PSTs (resulting in 44 items) by removing the CK, TCK, and PCK items related to literacy, science, and social studies and replacing them with similar items related to the students' minor degrees (e.g., history). Given the work that the PTs completed with CAS described earlier, I also administered a CAS beliefs survey (Lavicza, 2010) on the first day and last day of class to determine whether their beliefs regarding this powerful technology had changed as a result of the activities in the technology methods course. This survey, consisting of 20 items, was adapted as the original was intended for faculty teaching mathematics at the university level. For instance, the word *mathematicians* in the item, CAS enables mathematicians to work on problems more efficiently, was replaced with *students*. The technology beliefs survey, CAS beliefs survey, and TPACK questionnaire consist of Likert scale items that range from strongly disagree to strongly agree. None of the PTs were enrolled in another course that involved the use of technology during the Spring 2019 semester, but all were taking either foundational education courses or courses involving pedagogical components. Thus, there is a potential that the gains seen on the instruments with regard to pedagogy could be a result of these other courses. Three out of four of the PSTs were enrolled in mathematics content courses during Spring 2019, but this was a modern algebra course that did not highlight the connections between its content and school mathematics.

Analysis

I assigned a numerical score for each of the Likert scale items (strongly disagree – 1, disagree – 2, neutral – 3, agree – 4, strongly agree – 5). For each item of the technology belief survey and CAS beliefs survey, the differences between the first and last administration were calculated and the sum was found for each PT. Items that were negatively worded were reverse scored. The mean of the totals across the group of PSETs and the group of PSTs were found. All of the collected data were examined for trends. As there were different numbers of questions for the knowledge subdomains in the TPACK questionnaire, each PT's difference was divided by the number of questions that contributed to that difference for reporting purposes. The mean of these values was reported for each PT as an average gain value that enables comparisons to be made across different knowledge subdomains. The assumptions for the statistical tests (e.g., normality) were met and an alpha level of .05 was used for all statistical tests. The paired samples *t*-test was used to test for statistical significance for gain scores on each of the three instruments. Effect sizes were found by converting a *t*-value into an *r*-value (Rosnow & Rosenthal, 2005). A factorial ANOVA test was run on the gain scores for technological beliefs, CAS beliefs, and the TPACK questionnaire with gender and level (elementary and secondary) as independent factors.

Results

Overall, PTs scored higher on the second administration (M = 130.11, SD = 12.424) than the first administration (M = 110.22, SD = 4.324) on the technological beliefs survey and this result was statistically significant, $t(8) = -4.850$, $p = .001$, $r = .86$. In the factorial analysis, the independent factors of gender and level as well as the interaction were statistically non-significant. The changes in technological beliefs for PSETs and PSTs are shown in Table 1. The beliefs score changes for PSTs were greater than the score changes for PSETs. Three questions were common across both groups in terms of the greatest change between administrations of the technological beliefs survey. The first of these involved the belief that technology can damage students' paper-and-pencil skills and become a "crutch." A total of four out of nine of the PTs started out agreeing or strongly agreeing with this statement and shifted to disagreeing with this statement. The remaining five teachers either disagreed with the statement across both administrations of the survey or moved from disagree to strongly disagree. The second of these questions stated that students who use technology in high school mathematics classes learn mathematics better than those who do not use technology. Six out of nine of the PTs moved from disagree/neutral with regard to this statement to agreeing with it. The last statement involved prospective teachers' lack of confidence to teach mathematics involving technology. Six out of nine PTs agreed with this statement at the start of the class, but by the end of class they all disagreed with the statement.

Overall, PTs scored higher on the second administration (M = 69.89, SD = 8.42) than the first administration (M = 57.78, SD = 6.14) on the CAS beliefs survey and this result was statistically significant, $t(8) = -3.210$, $p = .012$, $r = .75$. In the factorial analysis, the independent factors of gender and level as well as the interaction were statistically non-significant. The changes in CAS beliefs for PSETs and PSTs are shown in Table 1. There were several low change scores in the table. For instance, Logan had no change on the technological belief survey, Liam had a CAS belief change of only two, and Madison had a change of -1 on the CAS belief survey. All of these PSETs possessed a number of initial beliefs that were aligned with an environment where technology is seen as a valuable tool to assist in the teaching of mathematics. For instance, Logan professed initial beliefs on 19 out of the 39 technological beliefs questions that were aligned with practices presented in the class. Across all PTs, two questions had highest gains from first to last administration: CAS promotes students' conceptual understanding; and CAS can be used to develop more engaging lessons.

Table 1: Changes in Beliefs for PSETs and PSTs

Prospective Teacher[a]	Technological Belief Change	CAS Belief Change
	PSETs	
Liam	26	2
Sophia	20	20
Amelia	13	6
Logan	0	15
Madison	14	-1
Mean	**14.60**	**8.4**
	PSTs	
Noah	12	6
Emma	40	23
Olivia	35	33
Mason	19	5
Mean	**26.50**	**16.8**

[a]All names are pseudonyms.

Overall, PTs scored higher on the second administration (M = 118.78, SD = 7.19) than the first administration (M = 102.44, SD = 12.78) of the TPACK questionnaire and this result was statistically significant, $t(8) = –4.599$, $p = .002$, $r = .85$. There was a significant main effect of gender on the TPACK gain score F (1, 5) = 14.12, p = .013, *,ω-2.=.15*. The main effect of level on the TPACK gain score was statistically significant F (1, 5) = 7.73, p = .039, *,ω-2.=.08*. Additionally, there was a statistically significant interaction between gender and group on TPACK gain score F (1, 5) = 59.904, p = .001, *,ω-2.=.67*. In other words, the influence of level on TPACK gain scores is different for female PTs than male PTs. Specifically, male PSETs had higher TPACK gain scores (M = 18.5, SD = 3.54) than females PSETs (M = 9.67, SD = 2.08). Female PSTs had higher TPACK gain scores (M = 33.00, SD = 2.83) than male PSTs (M = 7.50, SD = 4.95).

The knowledge gains by content subdomain for PSET and PST are shown in Table 2. For both groups the technology methods course appeared to have only a moderate influence on their content knowledge, technological knowledge, pedagogical knowledge, and pedagogical content knowledge. Both groups experienced the greatest knowledge gains in the TCK and TPACK areas. PSTs also experienced larger gains in the area of TPK.

Amelia experienced a loss of four in the area of TPK on the questionnaire. This occurred because on three of the five statements she moved from strongly agree to agree resulting in a drop of negative three. On the fourth statement in this area she had no change from agree while on the last statement she moved downward from agree to unsure. Mason also had a sum for a content subdomain (TK) that was negative. On four of the seven questions comprising this area, he had no change from agree or strongly agree on the initial and final questionnaire. On the three other questions, he moved from agree or strongly agree to unsure. Noah also had a sum of negative one in the knowledge subdomain of TCK that included one question. On this question, he moved from strongly agree to agree. In sum, despite decreases in change scores for some of the PTs that resulted in overall decreases the final rating on the majority of these statements was still in the agree category.

Table 2: Changes in Knowledge for PSETs and PSTs

Prospective Teacher	TK	CK	PK	PCK	TCK	TPK	TPACK	Total
				PSETs				
Liam	1	0	4	1	2	2	6	16
Sophia	0	1	3	0	2	3	3	12
Amelia	4	0	2	0	2	-4	4	8
Logan	1	1	6	0	0	5	8	21
Madison	1	1	2	1	0	3	1	9
Average Gain	0.2	0.2	0.49	0.2	**1.20**	0.36	**0.88**	13.20
				PSTs				
Noah	2	0	1	0	-1	2	0	4
Emma	7	1	12	2	1	5	7	35
Olivia	9	3	3	1	2	6	7	31
Mason	-4	0	1	0	2	6	6	11
Average Gain	0.61	0.33	0.61	0.75	**1.00**	**1.19**	**1.00**	20.25

Discussion

As a group, across all three instruments, PTs performed statistically significantly better on the second administration than the first administration. Thus, the collection of activities in the technology methods course appeared to positively influence PTs' beliefs and their TPACK. In general, where PTs displayed smaller changes in beliefs, their initial beliefs were already aligned with environments where technology was seen as an important tool in learning mathematics thus they had less room to change. This suggests that simply experiencing activities involving the use of technology to learn mathematics as all of the PTs did in previous courses can promote positive beliefs involving technology.

The PTs demonstrated less growth in CK, PK, and PCK as a result of the technology methods course than they did in the areas of TCK, TPK, and TPACK. This suggests that while topics regarding general pedagogical knowledge, content knowledge, and pedagogical content knowledge emerged during design work, teachers may not have perceived the work as occurring in these domains as the lessons were centered around the use of technology. That is, the PTs might have primarily seen the design work as involving technology. Indeed, on the technological belief survey one of the items of greatest change was their confidence in developing technologically based lessons. This result aligns with the work of Koehler and Mishra (2005) in which their collaborative learning environment resulted in greater connections among technology, pedagogy, and content. The differential gains on TK between PSETs and PSTs might have been a result of the particular lessons the groups developed. PSETs tended to create lessons involving technological applications that were already constructed while PSTs' lessons required them to learn and deploy more technological knowledge.

The PTs had limited work with CAS during the methods course as they used it to learn mathematics at the beginning of the course and solve optimization problems at the end of the course; none of the PTs created a lesson involving CAS. Nonetheless, they made statistically significant gains on this survey. This may have been due to a spillover effect involving the extensive design work in technology. Importantly, the technology methods course and its limited use of CAS resulted in a shift to envisioning the CAS as a tool to develop students' conceptual understandings much like the teachers Lagrange (1999) investigated. This is an interesting finding as PTs did not specifically use CAS in activities focused on conceptual understanding. This finding suggests that the collaborative design experiences and their focus on conceptual understanding affected PTs' beliefs in a different type of technology than where this work occurred.

As mentioned earlier, there were a few negative gain scores sprinkled throughout the results even though many of the PTs with these values were still agreeing with beliefs that were aligned with the use of technology to promote mathematics understandings and greater TPACK knowledge. These losses might have reflected a correcting of overly optimistic beliefs or knowledge as a result of deep engagements with technology during the collaborative design process.

Despite previous findings with regard to gender and technology (Sanders, 2006) this study found no relationship between gender and technological beliefs or gender and CAS beliefs. However, gender, level, and the interaction between gender and level were significant predictors of TPACK gain scores. Female PSETs had lower initial scores than male PSETs on the TPACK questionnaire overall. Thus, male PSET gain scores might have been lower than females because there was less room to grow. Female PSTs had the lowest initial TPACK scores among all both groups, about 20 points lower than female PSETs giving them more space to grow. PSETs had experienced more mathematics courses that incorporated technology and one more mathematics methods course than PSTs. These factors might have translated into higher initial TPACK scores. The higher TPACK scores among male students overall is similar to the findings of Bulut and Işiksal-Bostan (2019).

In sum, these findings illustrate the effectiveness of a technology methods course on PTs' beliefs and TPACK knowledge. The study is limited by its reliance on self-report data and the small sample size. In the future, I intend to examine other data (e.g., PT classroom enacted lessons involving technology) to move beyond self-report data in understanding the effect of the course on PTs' TPACK. Moreover, the study focused on the effect of the technology methods course as a whole on PTs' beliefs and knowledge and while the collaborative context was described in detail, the effects of this unique factor on PTs were not isolated. My future research intends to more carefully investigate the effects of this unique activity on PTs' beliefs and knowledge. The omnipresence of technology in today's classrooms necessitates that teachers be prepared to use it in ways that draw on its unique affordances and its potential to change mathematics instead of in ways that support traditional instruction (Cuban et al., 2001).

INVESTIGATING UNDERGRADUATE STUDENTS' GENERALIZING ACTIVITY IN A COMPUTATIONAL SETTING

Elise Lockwood
Oregon State University
elise.lockwood@oregonstate.edu

Adaline De Chenne
Oregon State University
dechenna@oregonstate.edu

Computational activity is increasingly relevant in education and society, and researchers have investigated its role in students' mathematical thinking and activity. More work is needed within mathematics education to explore ways in which computational activity might afford development of mathematical practices. In this paper, we specifically examine the generalizing activity of undergraduate students who solved combinatorial problems in the context of Python programming. We demonstrate instances of generalizing in terms of Ellis et al.'s (2017) framework, and we argue that some opportunities were facilitated and supported by the computational setting in which the students worked.

Keywords: Cognition, Computational Thinking, Programming and Coding

Introduction and Motivation

Computation is an increasingly essential aspect of science and mathematics, and researchers and policy makers within STEM broadly (Blikstein, 2018; NGSS Lead States, 2013; Weintrop, Beheshti, Horn, Orton, Jona, Trouille, & Wilensky, 2016), and mathematics education especially (e.g., Benton, Saunders, Kalas, Hoyles, & Noss, 2018; Buteau & Muller, 2017; Cetin & Dubinsky, 2018; Hoyles & Noss, 2015; Feurzeig, Papert, & Lawler, 2011), are making the case for more attention to be paid to computing in the field. Central to current interest in computing are questions related to whether and how computing might strengthen students' mathematical thinking and activity, including their engagement in mathematical practices. The question of whether such computing allows for transfer of content knowledge or practices is a source of debate, with some researchers making the case for and some against arguments that evidence of transfer exists (see Tedre & Denning (2016) for discussion). Acknowledging this debate, we investigate such questions with a qualitative exploration in which we demonstrate how computing may support students' engagement with a mathematical practice – generalization.

Our research question is: *In what ways did a computational setting support undergraduate students' generalizing activity on combinatorial tasks?* We hope that by providing qualitative interview data, we can gain some insight into how students engage in generalization in a computational setting. We see the paper as serving both a specific and a broader purpose. First, the paper is meant to highlight specifically how students engage in the particular practice of generalization with the use of programming (within the domain of combinatorics). Our results thus shed light on generalization as a practice, and they also illuminate implications for generalization within combinatorics. More broadly, this paper exemplifies of how students can make connections to and engage in mathematical practices within a computational setting.

Relevant Literature and Theoretical Perspectives

Literature and Theoretical Perspectives on Computation

In this paper we focus on *machine-based computing*, which we take to be the practice of developing and precisely articulating algorithms that may be run on a machine. We make two distinctions in this characterization. First, while computing can encompass many kinds of activity, we focus on activity that involves developing, articulating, and implementing algorithms. Second, while such algorithm

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

development could occur strictly by hand, we focus on activity that uses a machine. Further, we distinguish machine-based computing from engagement with technology more generally, which might include using computer algebra systems or dynamic geometry software – for us, machine-based computing involves not just using software, but engaging in algorithm design and implementation in some capacity. In our study, the specific machine-based computing in which our students engaged was programming in Python.

Mathematics education research has a history of using computers to enhance students' mathematical reasoning, beginning with Papert's (1980) introduction of Logo to help young children. Recently there seems to be an increasing amount of attention being paid to computation in education research, perhaps due in part to Wing's (2006, 2008) re-popularization of the term *computational thinking*. We have seen considerable attention paid recently toward examining the role of computing in mathematics education (e.g., Benton, et al. 2018; Buteau, Gueudet, Muller, Mgombelo, & Sacristan, 2019; Buteau & Muller, 2017; Cetin & Dubinsky, 2018; DeJarnette, 2019; Lockwood, DeJarnette, & Thomas, 2018; Lockwood & De Chenne, 2019).

We acknowledge that there is some discussion about whether or not computing can be effective in helping students engage in other practices and skills (e.g., Tedre & Denning, 2016). However, in spite of such debates, we think it is still worth investigating the degree to which computational activity might in fact support students' thinking and engagement in mathematical practices. Part of our reason for this is that we feel there are useful frameworks within mathematics education (such as Lobato's view of actor-oriented transfer) that may bring fresh perspectives toward questions of the role of computing in mathematics education. We draw on recent work by Lockwood et al. (2019), who interviewed research mathematicians in academia about their use of computing in their work. While these mathematicians suggested many benefits of computing, they also "framed computing as allowing for some other important habits of mind or practices related to their work" (p. 9). While these mathematicians did not name the practice of generalizing specifically, we view our work as building on these findings by Lockwood et al. The mathematicians reported in Lockwood et al.'s study shared their own beliefs and experiences, and we wanted to explore and demonstrate some of their claims with student data, offering insights into how students' engagement with computation can actually give opportunities for students to connect computing to the practice of generalizing.

Literature and Theoretical Perspectives on Generalization

Generalization is an essential aspect of mathematical thinking and learning, and there has been much work that has established the importance of generalization in mathematics education. Such work has included investigations into students' generalizing within algebraic contexts (e.g., Amit & Neria, 2008; Ellis, 2007a, 2007b, Radford, 2008; Rivera & Becker, 2007, 2008), and there has also been exploration into generalizing activity among undergraduates in areas like calculus, linear algebra, and combinatorics (e.g., Dubinsky, 1991; Jones & Dorko, 2015; Kabael, 2011; Lockwood, 2011; Lockwood & Reed, 2018). Researchers have also proposed theories about the nature of generalization, providing some categories and distinctions of generalizing activity (e.g., Ellis, 2007a; Harel & Tall, 1989; Harel, 2008). Together these studies provide rich insight into the nature of generalization in many settings. We contribute to this body of work by examining generalizing within the context of machine-based computing, and we hope to identify and understand specific ways that a computational setting might support students' generalizing.

Broadly, Ellis (2007a) followed Kaput (1999) and defined generalization as "engaging in at least one of three activities: a) identifying commonality across cases, b) extending one's reasoning beyond the range in which it originated, or c) deriving broader results about new relationships from particular cases (p. 444), and we similarly adopt that broad characterization. We also draw upon Ellis, Lockwood, Tillema, & Moore's (2017) Relating-Forming-Extending (R-F-E) framework of generalizing activity in characterizing generalization. Ellis et al. (2017) emphasize three different generalizing activities, which build upon a previous taxonomy that Ellis (2007a) had developed. In *relating,* students establish "relationships of similarity across problems or contexts" (p. 680), and so students make connections among situations they have encountered. In *forming*, students engage in "searching for and identifying similar elements, patterns, and relationships" within a single task (p. 680). Here, students may be attending to regularity and articulate some general pattern or relationship that they observe. In *extending, "*students extend established patterns and regularities to new cases" (p. 680). This might typically involve some increased abstraction (such as moving from numerical cases to arguments involving variables). Ellis et al. also discuss ways in which these generalizing activities are interrelated – for instance, relating and forming may help students start to identify some regularity, which can then facilitate their extending to more general cases. This categorization offers language by which to characterize generalizing activity that we observed in our students. We focus on instances of relating and forming in this paper.

Mathematical Discussion and Motivation for Focusing on Combinatorics

There are a couple of reasons that we focus on combinatorics in this paper. First, the computational setting is particularly well-suited for combinatorial problems, in the sense that some of the features of the programs (loop structures, conditional statements) serve to highlight important combinatorial concepts. We have articulated this phenomenon elsewhere, including demonstrating students' uses of conditional statements to reason about types of counting problems (Lockwood & De Chenne, 2019) and highlighting the computer's effectiveness in helping students verify solutions to counting problems (De Chenne & Lockwood, in press). We believe that combinatorial problems provide rich contexts in which students can solve mathematical problems in computational settings. In addition, combinatorial tasks are well suited to generalization, and researchers have previously explored students' generalizing activity on combinatorial problems (e.g., Lockwood, 2011; Tillema & Gatza, 2018). Our work builds on such studies by illuminating ways in which the computational setting supports generalizing within combinatorics. We thus aim to contribute both to work on generalization and work on combinatorics, building on our knowledge base of students' generalizing activity within the field of combinatorics especially. Finally, on the whole, combinatorial problems can be difficult for students to solve (e.g., Batanero, Navarro-Pelayo, & Godino, 1997; Lockwood & Gibson, 2016), and we see value in investigating ways to improve students' combinatorial experiences. In this case, by focusing on generalization within a computation setting, we gain insight into how students might understand and generalize ideas within the particular domain of combinatorics.

Methods

Data Collection

We draw on two data sources for this paper, both of which were part of a broader study investigating the role of computing in teaching combinatorial ideas. The broader study is ongoing and includes multiple paired and small group teaching experiments and one round of classroom implementation. We narrowed our focus to these two data sources for the sake of space and because they provide illustrative examples of relating and forming. First, we conducted a paired teaching experiment (in the sense of Steffe & Thompson, 2000) with two undergraduate students, Charlotte and Diana (all names are pseudonyms). They were chemistry majors recruited from a vector calculus class, and they participated in selection interviews, which indicated that they had not taken courses in discrete math, they were not familiar with combinatorial formulas, and they had no prior programming experience. Second, we share results from an individual interview with a computer science (CS) student, Allen. He was a CS major recruited from an introductory class in computer science. He indicated on a recruitment survey that he had not taken a class in discrete mathematics and that he had programming experience. In both cases, the students sat at a computer and worked on combinatorial tasks, writing in a Python coding environment while the interviewer asked clarifying questions. Charlotte and Diana participated in 11 total interview sessions during which they solved a variety of counting problems. Allen participated in 3 total interview sessions during which he wrote programs to list all outcomes of counting problems. In the final interview (from which the data in this paper is taken), we asked him only to solve a counting problem, and we then prompted him to explain how he would verify his solution.

Data Analysis

The data are part of a project in which we explored students' combinatorial thinking and activity within a computational setting, and we were not explicitly targeting generalization in this project. However, as we reviewed data it became clear that students were engaging in generalizing activity, and we wanted to examine that activity more systematically. For analysis, we surveyed both sets of data for instances that illustrated each form of generalization in the R-F-E framework. We particularly sought examples that would highlight the role of the computer and ways in which it supported students' generalizing activity. We identified a number of episodes of relating and forming in our data sets, and we chose the two episodes discussed in this paper as representative examples. Together we discussed additional generalizing in our data, and we articulated ways in which the computer in particular facilitated generalizing activity, which we elaborate in the Results and the Discussion and Implications sections.

Results

We provide two examples of students engaging in generalizing activity, and we focus especially on *relating* and *forming* within the R-F-E framework. We do not provide data related to extending in part due to space, and also because we hypothesize that the computer is particularly useful in supporting relating and forming, and students can then extend ideas and relationships by hand. We elaborate this point in the Discussion Implications section.

Relating

We demonstrate one particular sub-category of relating that Ellis et al. (2017) described: *relating objects*, which involves forming a relationship of similarity between two or more present mathematical objects. We demonstrate an instance of relating objects in which Charlotte and Diana connected back to work on a prior problem they had done (both sets of students engaged in more relating, but we do not have space to offer additional examples). We highlight the tendency of students to copy and paste, then edit, code from prior problems (we call this repurposing previous code), which we feel is a feature of the computer that particularly supported relating. On the one hand, repurposing code could seem just like practical, time-saving technique, but we argue that this is actually important for generalization for a couple of reasons. First, the code itself gives students a new aspect of the problem to which and from which they can relate. Because the code can be seen as encapsulating and representing a counting process, students can identify similarities between the representation of code on various problems. Our students drew on similar structures and features of code as they copied and pasted work from prior problems. For instance, at one point, Diana asked Charlotte, "Do you want me to copy this code from over here [a previous problem], since it's really similar?" This suggests that she perceived similarity between code they had written in the past and a current situation. Notably, the computer specifically facilitates that similarity by allowing such repurposing easily to occur. With very little effort, students get to duplicate and then adjust something they did previously. Such adjustments could be done by hand, but there is something about editing and adjusting real time that allows for efficiency. We also hypothesize that because copying and pasting reduces students' work load, it may incentivize their looking for similarity between solutions, thus encouraging generalizing activity.

As an example of relating, we offer an instance of Charlotte and Diana repurposing code. They had previously worked on a problem about enumerating people, *How many ways are there to rearrange 5 people: John, Craig, Brian, Angel, and Dan?*, reasoning about code in Figure 1a. This code counts arrangements of five people – the nested loops cycle iteratively through each element in the set People, and != (not equal) prevents elements from being repeated (more details about such problems are in Lockwood & De Chenne, 2019). We later asked: *Write some code to list and count the number of ways to arrange the letters in the word PHONE. How many outcomes are there? What do you think the output will look like?* As they started this problem, they had the following exchange.

```
arrangements = 0
People = ['John', 'Craig', 'Brian', 'Angel', 'Dan']

for p1 in People:
    for p2 in People:
        if p2 != p1:
            for p3 in People:
                if p3 != p1 and p3 != p2:
                    for p4 in People:
                        if p4 != p3 and p4 != p2 and p4 != p1:
                            for p5 in People:
                                if p5!=p4 and p5!=p3 and p5!=p2 and p5!=p1:
                                    arrangements = arrangements+1
                                    print(p1, p2, p3, p4, p5)
print(arrangements)
```

```
arrangements = 0
People = [P, H, O, N, E]

for p1 in People:
    for p2 in People:
        if p2 != p1:
            for p3 in People:
                if p3 != p1 and p3 != p2:
                    for p4 in People:
                        if p4 != p3 and p4 != p2 and p4 != p1:
                            for p5 in People:
                                if p5!=p4 and p5!=p3 and p5!=p2 and p5!=p1:
                                    arrangements = arrangements+1
                                    print(p1, p2, p3, p4, p5)
print(arrangements)
```

Figure 1a, 1b: Code for the People and PHONE problems

Charlotte: Okay. So, I feel like, yeah, basically just gonna be the same as this one because, I mean PHONE has five letters and this had five people. So, I feel like we can maybe just copy the same code.

Diana: Yeah, and then like edit it to be like PHONE.

The interviewer then asked her why their idea would work, and Diana said the following:

Diana: It works because there's like the same number of things that you're arranging. So, like you're arranging people here, there's five of them and then you're arranging letters here and there's five of them. And it's still the same as like you're not repeating any letter, so you keep the not equal to expressions. And, yeah.

Diana's comments highlight what she perceived as similar about the situation – they were still arranging five objects, and they still did not want to be able to repeat any object. So, she noted that they still wanted to maintain the same fundamental features of the code, which was the "not equal to expressions." They edited the code from Figure 1a just to have the letters P, H, O, N, and E instead of the people (Figure 1b). They ran the code, which correctly printed all 120 arrangements of letters in the word PHONE. The fact that they left much of their code the same as the People problem is noteworthy, as it suggests that they were attuned to the fact that some features of the code were or were not essential to solving the new problem. Notably, they did not change what they perceived as features that would not change their process or output (for instance, they did not re-name the set People, and they kept and p1 through p5 as their variables). That is, they recognized that the underlying structure was the same between the problems, but some other features, like the names of the set and variables, did not matter. This gives insight into what they deemed as relevant similarities or differences among the two problems.

To summarize, the computational setting afforded students with opportunities to repurpose code, and by doing so they related current situations to prior work. The computational representation of the code signified a particular counting process, and the computer's capacity to allow such code to be repurposed facilitated the students' generalizing activity of making connections among problems. We demonstrated one instance of this, but there were multiple examples throughout the teaching experiments of such activity. In this way, this example of relating within the computational setting lets us see one way in which computational settings could afford some unique opportunities for engagement in the practice of generalization.

Forming

Next, we offer an instance of forming. Ellis et al. (2017) distinguish between types of forming, and we focus on *searching for similarity or regularity* (searching to find a stable pattern, regularity, or element of similarity across cases, numbers, or figures), and *identifying a regularity* (identification of a regularity or pattern across cases, numbers, or figures). We share Allen's work on the Books problem, which states *Suppose you have 8 books and you want to take three of them with you on vacation. How many ways are there to do this?* Allen originally solved this problem incorrectly by finding the number of ways to arrange three of the eight books, 8*7*6 = P(8,3), rather than selecting three of the eight books, 8*7*6/6 = C(8,3). (We will refer to this correct answer as C(8,3), even though Allen did not yet know a closed form for it, and he could only find the value on the computer using his program.) After writing code that listed the outcomes of arranging the books, he noticed that outcome 132 appeared in the output after the outcome 123, and he realized that he had not been correct, stating "that would not be a good combo because it already appeared up here; it's just in a different order." He thus saw he needed to correct his solution, and to do so Allen wrote the code in Figure 2. When run, this code prints all three number combinations in ascending order, thus ensuring that each combination is printed exactly once, and it correctly outputs 56 as the total number of combinations.

```
count = 0

for i in range(1,9):
    for j in range(i+1,9):
        for k in range(j+1,9):
            count = count + 1
            print(str(i)+" "+str(j)+" "+str(k))
print count
```

Figure 2: Allen's code for the Books problem

While Allen's code correctly counted the number of outcomes of the Books problem, he did not initially offer any justification for a counting process or mathematical expression. However, he remarked that it was interesting that 56 = 8*7, which was his original answer of 8*7*6 divided by 6. So, he realized that a ratio of his answer over the correct answer was 6 (that is, P(8,3)/C(8,3) = 6). He wondered what would happen if the problem were selecting from only 7 books instead of 8. After extending his original (and incorrect) solution to seven books, P(7,3) = 7*6*5, he predicted that the ratio of P(7,3)/C(7,3) would be 5. (One potential rationale for this prediction is that he reduced the total number of books by 1 (from 8 to 7), and so he reduced his prediction by 1). Allen then decided to use the computer and his computational experience to explore these relationships more systematically. First, he adjusted the code from Figure 2 to count the number of outcomes for 7 books (rather than 8), yielding 35, and he computed the ratio of P(7,3)/C(7,3), yielding 6 (which contradicted his prediction of 5). Allen then adjusted his code to allow for him to explore more examples efficiently. In particular, he created a function that would let him explore multiple numbers of books within a range, from which he always selected 3 books. For each number of books, the program computed the ratio of his estimated guess (P(n,3) with the actual correct value that he found computationally (which is C(n,3)). Allen's code is displayed in Figure 3, and the output shows verified that the ratio P(n,3)/C(n,3) was 6 in each case (again, we write P(n,3)/C(n,3) for clarity, as Allen thought about this ratio as his original solution divided by the actual solution). We view Allen's initial exploration and creation of this function activity as an instance of forming, namely *searching for similarity or regularity*, as he was making predictions and looking for and expecting to observe patterns. Then, when he ultimately determined that the ratio was 6, we take this as an instance of *identifying a regularity*.

```
In [23]: def fun(book):
             count = 0
             for i in range(1,book+1):
                 for j in range(i+1,book+1):
                     for k in range(j+1,book+1):
                         count = count + 1
                         #print(str(i)+" "+str(
             return (book*(book-1)*(book-2))/cou

In [24]: for i in range(4,21):
             print fun(i)

         6
         6
         6
         6
         6
         6
```

Figure 3: Allen's identification of regularity via programming a function

Allen then decided to extend his work by changing the number of books being selected in his code; that is, rather than selecting three books, he wrote code to select four, five, and then six books. It is noteworthy that Allen had not yet provided justification for the constant 6, and so the decision to extend his work seems to stem from his desire to observe a pattern (thus we view this as an instance of forming). Further, the computer facilitated this forming activity by allowing him to adjust his previous code so other numbers of books were selected. For each of these new instances, he divided the answer from his original solution method by the actual answer, and he observed a constancy in each case. Essentially, Allen fixed an m and used his code to calculate $P(n,m)/C(n,m) = m!$ as n ranged for values of from $m + 1$ to 21, (again, he expressed this ratio as his original solution divided by the actual solution). The constant he found in each case represented the number of ways to arrange the books after the books have been selected. After finding values in cases three through six, he remarked "Okay, I think I found a really high-level relationship that is several layers." We asked him to elaborate, and Allen stated the following.

> Allen: So, this is the number of books. This is three books, four books, five books, six books. So, if that's the case, then with two books it should be 3. Three would be 6, four would be 24, five would be 120, and six would be 720… what I noticed is each time you go up, you multiply by the next number. So, 6 times 4 equals 24, which multiplied by 5 equals 120, which multiplied by 6 equals 720.

Allen went on to observe that "these are all factorials." Using this information, he constructed and justified a closed form for $C(n,m)$ (we do not include analysis of this data due to space).

To summarize this episode, Allen used his code to find a constant ratio between his (incorrect) original solution and the correct solution he computed. He then identified a pattern between these constants as the number of books being selected was increased. We observed *searching for similarity or regularity* when Allen identified the constant 6 in his work on selecting three books. Then, we observed *identifying a regularity* when Allen found a pattern among constants as the number of books selected increased. We argue that the computer was fundamental in this process, as Allen generated these constants by writing and implementing code. The computer, and the outcomes generated, seemed to afford Allen the opportunity to search for patterns and identify relationships. In Allen's case, he used the computer in two important but different ways. First, he used the computer to generate answers to problems he could not yet solve by hand (computing the correct number of combinations before he knew the closed form of $C(m,n)$). Second, he wrote a function to generate multiple cases, which allowed him to search for regularity in multiple cases efficiently. This episode thus sheds light on how the computational setting supported Allen in the specific generalizing activity of forming.

Discussion and Implications

In this paper, we have offered instances of students engaging in generalizing activities of relating and forming (in terms of Ellis et al.'s (2017) R-F-E framework) within the context of programming in Python. We have tried to make the case that in these cases the computer offered specific affordances for generalizing activity. These included copying and pasting to support relating, and generating correct solutions to multiple problems in order to support forming. While some of these activities would technically be possible by hand, the manipulation that the computer allows seemed to expediate this practice of generalization for the students. As an additional note, we mostly observed the computer being used to support relating and forming, and extending that we observed among students tended to be done by hand (students often extended formulas or expressions they had written by hand). We thus hypothesize that the computer may be most effective for supporting relating and forming, which then contribute to extending. More work is needed to explore whether and how extending arises explicitly via computational activity.

There is more to study specifically about the role of the computer (and specifically machine-based computing) in facilitating students' generalizing activity. We have focused on combinatorics, but such computing may elicit generalizing in other ways in other domains. Researchers could explore ways that the computer might facilitate other kinds of generalizing activity in other domains or in other kinds of problems. Further, we have focused on one perspective of generalization, drawing explicitly on Ellis et al.'s (2017) framework, but researchers could consider other possible framings of generalization to consider the computer's role in supporting students' generalization. In addition, our results demonstrate instances in which students engage in the practice of generalization. However, there are many other practices, and Lockwood et al. (2019) have suggested that other practices like proving or problem solving might closely be related to the kind of machine-based computing described in this paper. Thus, future research could be conducted on ways in which computing might support other mathematical practices.

MIDDLE SCHOOL STUDENTS' DEVELOPMENT OF AN UNDERSTANDING OF THE CONCEPT OF FUNCTION

Michael S Meagher	Jennifer Lovett	Allison McCulloch
Brooklyn College - CUNY	Middle Tennessee State University	UNC Charlotte
mmeagher@brooklyn.cuny.edu	Jennifer.Lovett@mtsu.edu	amccul11@uncc.edu

Middle school students (n=144) worked with an applet specially designed to introduce the concept of function without using algebraic representations. The purpose of the study was to examine whether the applet would help students to understand function as a relationship between a set of inputs and a set of outputs and to begin to develop a definition of function based on that relationship. Results indicate that, by focusing on consistency of the outputs the students, at a rate of approximately 80%, are able to distinguish functions from non-functions. Also, students showed some promise in recognising constant functions as functions, a known area of common misconceptions.

Keywords: Middle School Education, Technology, Representations and Visualization

Introduction

The concept of function is considered to be one of the most important underlying and unifying concepts of mathematics (e.g., Leinhardt, Zaslavsky, & Stein, 1990; Thompson & Carlson, 2017). Students have experiences with functions, or function behaviour, from the very earliest grades usually through pattern exploration. Study of functions continues up to and through high school with a formal treatment of functions as arbitrary mappings between sets. Indeed, in the Common Core State Standards for Mathematics function is given its own domain in grades 9-12 (Common Core State Standards Initiative, 2010).

Much of the lack of depth of knowledge of the concept can be attributed to the privileging of algebraic representations (function as algebraic rule) or graphical representations (function as graph that passes the vertical line test) and a consequent lack of focus on the general relationship (see e.g. Best & Bikner-Ahasbahs, 2012; Breidenbach et al., 1992; Carlson, 1998; Thompson, 1994). What might a group of students who have never encountered the concept of function learn by encountering it in a novel representation? Can they learn to think of a function as a relationship between inputs and outputs with some rules about the outputs rather than something that is defined by an algebraic rule? These are the questions that guided the current study.

Related Literature

Prior to secondary school, opportunities for study of functions are limited in scope (Best & Bikner-Ahasbahs, 2012; Carlson & Oehrtman, 2005; Vinner & Dreyfus, 1989) and focus mainly on pattern recognition and study of covarying quantities, most often related to an underlying linear structure (Blanton et al., 2015; Stephens et al. 2017, Ellis, 2011). For example, in Blanton et al. (2015) 6th grade students are given the tasks "People and Ears: The relationship between the number of people and the total number of ears on the people (assuming each person has two ears)" (p.520) to study the function type $y = x + x$ and "Age Difference: If Janice is 2 years younger than Keisha, the relationship between Keisha's age and Janice's age (Carraher et al., 2006)." (p. 521) to study the function type $y = x + 2$. In other words, the functional relationships typically encountered in elementary and middle school years are designed to prepare the (mathematical) ground for studying linear relationships (y = mx, y = x + b, y = mx + b) i.e. the privileging of algebraic representations begins early in the study of functions. Leinhardt et al. (1990), in a meta-study of research on function, and Mesa (2004), in a study of 24 middle grades textbooks from 15 countries, note the difficulty for students in apprehending the modern, abstract definition of function depending, as it does, on the mapping of one set of elements to another emphasising the difference between function and relation (many-to-one acceptable, one-to-many not acceptable); whereas, the work on function in early grades builds on the intuitive notion of a 1-1 correspondence and the historical development of function rested on covarying quantities.

Even in secondary school functions are typically introduced as very limited classes such as linear and quadratic, with attendant graphs and tables, with the result that students regularly consider functions to be mathematics objects solely defined by an algebraic formula (e.g., Best & Bikner-Ahasbahs, 2012; Breidenbach et al., 1992; Carlson, 1998) and have difficulty identifying constant functions as functions (Bakar & Tall, 1991; Carlson, 1998; Rasmussen, 2000). Instruction and curricular materials often emphasize procedures and algebraic manipulations when studying functions and research shows that students then have difficulty in understanding different representations and different contexts for functions (Carlson & Oehrtman, 2005; Cooney et al., 2010). At the heart of many student difficulties is a shallow understanding of the definition (Ayalon et al., 2017; Panaoura, et al., 2017). Students who have an algebraic view of function and who use procedural techniques to identify functions and non-functions struggle to comprehend a general mapping between sets (Carlson, 1998; Thompson, 1994).

Exposure to, and facility with, various representations of functions, i.e "flexible use of functions . . . within and between all kinds of representations and also between different functions" (Best & Bikner-Ahasbahs, 2012, p. 877), has been shown to be a critical component of a rich understanding of function (Best & Bikner-Ahasbahs, 2012; Dubinsky & Wilson, 2013; Martinez-Plandi & Tigueros Galsman, 2012). Furthermore, researchers have found promising results when using novel contexts and non-standard representations of functions such as dynagraphs, arrow diagrams, and directed graphs (Dubinsky & Wilson, 2013; Sinclair, Healy & Sales, 2009). The purpose of this study is to examine the effect of a specially designed applet on middle school students' ability to develop an understanding of the concept of function.

Methods

Context

Previous research (Meagher et al., 2019) has shown the promise of a vending machine representation as a "cognitive root" (Tall, McGowen, & DeMarois, 2000) for the study of functions. Thus, we designed an applet, *Introduction to Function,* (https://tinyurl.com/y2dramsb) as a mechanism for learners who have never encountered the concept of mathematical function and, therefore, do not associate the concept with any particular representation, to learn the basic elements of function. The goal was for the students to learn that a function is a relationship between of a set inputs that are matched with a set of outputs in a consistent and, therefore, predictable manner.

The *Introduction to Function* task is a GeoGebra book that consists of seven pages and has an accompanying worksheet. On the first two pages are two vending machines each of which consists of four buttons (Red Cola, Diet Blue, Silver Mist, and Green Dew). When a button is clicked it produces none, one, or more than one of the four different colored cans (red, blue, silver, and green), which may or may not correspond to the color of the button pressed (see Figure 1). The students are told that the first machine on each page is an example of something called a function, and the other is not a function, with their task being to identify what is the difference between the behaviour of the machines that makes one a function and the other not.

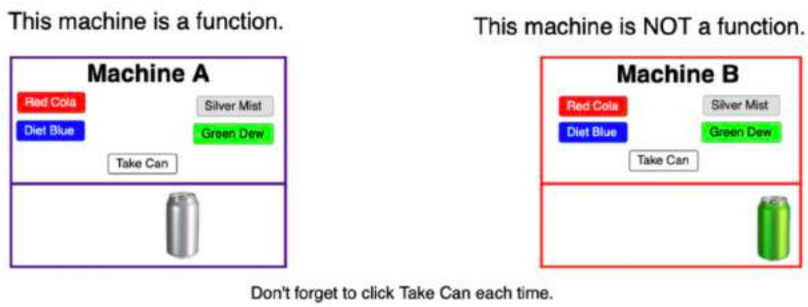

Figure 1: Screenshot of Introduction to Function

The machines on the first two pages work as follows:

This One is a Function		This One is Not a Function	
A	Red – Red Blue – Blue Silver – Silver Green – Green	B	Red – Red Blue – Blue Silver – Random Green – Green
This One is a Function		**This One is Not a Function**	
C	Red – Blue Blue – Red Silver – Silver Green – Green	D	Red – Red Blue – Random Silver – Silver Green – Green

Figure 2: Machines A – D

Note that Machines B and D are not functions because one of the buttons, when clicked, will produce a random can (i.e. not always the same result). Note also that in Machine C the colour of the output can does not correspond to the input button pressed, but that the non-matching can is consistently produced. After the first two pages there was a whole group discussion in which students discussed the first two pages, with the goal of consolidating their ideas.

The next four pages of the GeoGebra book consist of pairs of machines with the students being told that one of each pair is a function In each case there is a random element in the non-function. The machines work as follows:

	Which One is a Function?			
Page 3	E	Red Cola – red Diet Blue – blue Silver Mist – silver Green Dew – random color	F	Red Cola – silver Diet Blue – green Silver Mist – red Green Dew – blue
	Which One is a Function?			
Page 4	G	Red Cola – random color Diet Blue – random color Silver Mist – random color Green Dew – random color	H	Red Cola– blue Diet Blue – silver Silver Mist – green Green Dew – red
	Which One is a Function?			
Page 5	I	Red Cola – 2 silver cans Diet Blue – green Silver Mist – red Green Dew – blue	J	Red Cola – red Diet Blue – blue & random color Silver Mist – silver Green Dew – green
	Which One is a Function?			
Page 6	K	Red Cola – pair of random color Diet Blue – blue Silver Mist – silver Green Dew – green	L	Red Cola – green Diet Blue – green Silver Mist – green Green Dew – green

Figure 3: Machines E - L

On the worksheet, students are asked to note whether each machine is a function or not a function and how they know. After they complete these pages students are given the prompt: "Using the terms 'input' and 'output' write a definition for function based on your exploration of the machines."

Participants

The *Introduction to Function* applet was used in fifteen seventh grade classrooms. These classrooms were across two different states (one Northeastern state and one Southeastern state) and five different teachers for a total of 144 students who engaged with the task. These students engaged with the applet towards the end of their seventh grade year and had not yet learned about the definition of function or function notation.

Data collection and analysis

Students worked in pairs (N = 72) to engage with the applet on a laptop that screen captured their work. Data collected were their worksheets, which include their definitions, screen recordings, and audio recordings. For this study our analysis focused on the students' worksheets. All data was coded by three researchers. Any disagreements were discussed until any discrepancies were resolved.

For the definitions we coded for use of the terms input/output, attention to output, and focus (Author et al., 2019). In terms of input/output, each definition was read for use of those terms in the definition for example, "M49_M62: No matter what input the output is the same" and "M117_M118: A function is when you get the same output." In terms of focus, each definition was coded regarding whether the definition indicated a function was a relationship (or mapping), an object, or neither. We referred to this set of codes as focus, as they indicated how the students "saw" function. If the definition indicated that the function relates to the input and output then the definition was coded as a relationship. For example, "VM_M91_M96 The word function may mean when you input something, even though you may not get what you asked for, you will only get one type of it." The code "object" was used when the definition referred to a function as something, such as the button, or the machine.

Finally, definitions were coded according to whether or not they attended to output. In order for a definition to be coded as attending to output, the definition needed to refer to an output having a pattern, or being the same or consistent. For example, "VM_M54_M59: Function is when you put in the input and the output will never change / will always be the same."

Analysis of the student worksheets proceeded along two dimensions: classification of whether the pairs of students correctly identified the machines E through L as functions and the students' justifications for their classifications. For the pairs of machines E&F, G&H, I&J, K&L, since students were told one was a function and one was not, it was possible to simply count the classification. Of course, the percentages should mirror each other i.e. the number of "corrects" for machine E should match the number of "incorrects" for machine F.

The students' written justifications for their machine classifications were open coded using a constant comparative method to look for themes (Creswell, 2014). The final codes for students' justifications are shown in Figure 4. Justification codes were not mutually exclusive, as a justification could have been coded based on inconsistency as well as using the context of the vending machines.

Code	Description
Justification based on inconsistency of output	Students' justifications use phrases indicating an attention to the inconsistency of the outputs. Examples include: "different colors", "random", "it changes".
Justification based on consistency of output	Students' justifications use phrases indicating an attention to the consistency of the outputs. Examples include: "consistent", "constant", "pattern".
Justification uses the context of the machine	Students' justifications describe the relationships between inputs and outputs using the vending machine context. Examples include: "because it always gives the wrong drink", "it gives random colored cans"
Justification unclear	There is not enough detail in the students' written response to classify their justification.

Figure 4: Justification codes

Results

Identification of the Machines.

The first element of analysis was to tally whether the participants were able to correctly identify which of the machines E-L are functions. Recall that participants worked through machine pairs A&B and C&D being told that A is a function and B is not a function and that C is a function and D is not a function, and that the concept established was that the machine should behave consistently even if the colour of the output can does not match the colour of the button pressed. Students classification of the machines is shown in Table 1.

Machines	Non-function reason	% Correct
E & F	Machine E: Green Dew has random output	81.3
G & H	Machine G: all outputs are random	95.8
I & J	Machine J: Diet Blue output is Blue & random	86.1
K & L	Machine K: Red Cola output is 2 random cans	80.7

Figure 5: Participants' correct identification of functions

At a first level of analysis this shows that, broadly speaking, the pairs of students were able to correctly identify which machines were functions. The percentage of correctly identified functions for the first four pairs of machines was at least 80% and ranged from 80.7% to 95.8%.

It is interesting to note that for the pairs E&F, I&J and K&L the correct percentage is very similar (between 80% and 86%). The exception is the machine G&H pairing which has a much higher percentage of students identifying it correctly. This can be explained as follows: the primary identifying factor for a machine not being a function was the random behaviour of one of the buttons. However, one has to press a button often enough to be able to identify the behaviour as random. In the case of Machine G, all four buttons give random output and, therefore, the threshold to identify random behaviour is lower. Furthermore, Machine G comes first and, therefore, students can very quickly identify Machine G as not a function and not concern themselves too much with Machine H.

Looking more closely at the incorrect answers for the first four pairs of machines we see that it is often the same pairs of students getting incorrect answers. 10 of the 14 (71.4%) pairs of students who made a misidentification of the E&F pair misidentified at least one other machine, with 5 pairs misidentifying all of the first four sets of machines except the G&H pairing. Furthermore, of the 22 pairs of students that misidentified at least one machine, only seven of the 22 (31.8%) had their first wrong answer after the first pair of machines E&F and six of those seven misidentified just one of the pairs E&F, G&H, I&J and K&L.

The result for Machine L with 80.0% of participants identifying it as a function is a potentially significant result since researchers have shown that students exhibit difficulties identifying constant functions as functions (e.g. Carlson, 1998; Rasmussen, 2000). However, it may be that many students identified Machine K (output from Red Soda is two random cans) as not a function and concluded that Machine L must be a function.

Characterizing Students' Justification of Functions and non-Functions.

To better understand the ways in which students were making sense of the machines, we analyzed their justification for whether or not each machine was a function or non-function (see Figure 5). Those that were determined to be functions were justified based on consistency of the input/output relationship and those determined to be non-functions were described as such based on the inconsistency of this relationship. One notable exception to this is the 11 students that used the language of inconsistency to justify their choices for Machine F (Red Cola → silver, Diet Blue → green, Silver Mist → red, Green Dew → blue). All 11 of the students that described this as inconsistent, also determined the Machine was not a function. We see that these students could not overcome the cognitive dissonance of a machine giving them a different colour output can from the input button pressed, even if it did so consistently. For example, one student (M90) described Machine E (R→r, B→b, S→s, G→ random) as "more consistent" than Machine F (R→s, B→g, S→r, G→b) which "randomizes things." The very next pair of Machines in the applet had a similar design (Machine H: R→b, B→s, S→g, G→ r), and only one student determined this to be a non-function using the reasoning of inconsistency. This suggests that the students refined their meaning for such a justification to be aligned with situations in which a single output results in different outputs. Examples of students' justifications based on inconsistency are shown in Figure 7 below.

Machine	Justification based on consistency	Justification based on inconsistency	Justification unclear
E	5	54	13
F	45	11	17
G	2	68	2
H	62	1	8
I	54	6	12
J	2	59	9
K	4	54	11
L	58	1	10
M	38	2	15
N	34	1	14

Figure 5: Characterizations of students' justifications for each machine

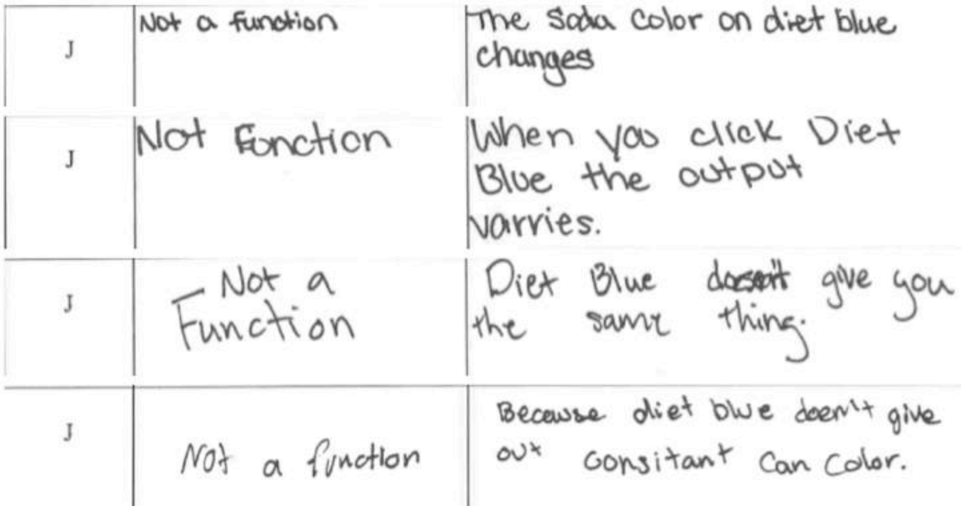

Figure 7: Examples of justifications based on attention to inconsistency of outputs

As is evident in the Machine F example above, the students' justifications provide insight to their misidentification of both functions and non-functions. For example, looking at the 13 pairs of students that misidentified Machine K (R→random pair) as a function it is evident that they either did not test the machine enough to see the random outputs that occurred when clicking Red Cola (e.g., "every color is functional, red produces 2 greens"), or they decided that since the rest of the buttons were consistent it was "close enough". For example, one pair wrote "mostly consistent" and another wrote "3 of the 4 function correctly." Furthermore, the inability to accept machines giving a different output from the button pressed, even if it does so consistently, persisted for a number of pairs. For example, Pair M17 & M20 said of machine J (R→r, B→b & random, S→s, G→g "The Blue one gives two but the others work."

It is notable that 80% of the student pairs used the language of the machine context in their justifications (see Figure 8 for examples). This suggests that having a realistic context in which to both think about and test their conjectures proved to be helpful in explaining their thinking.

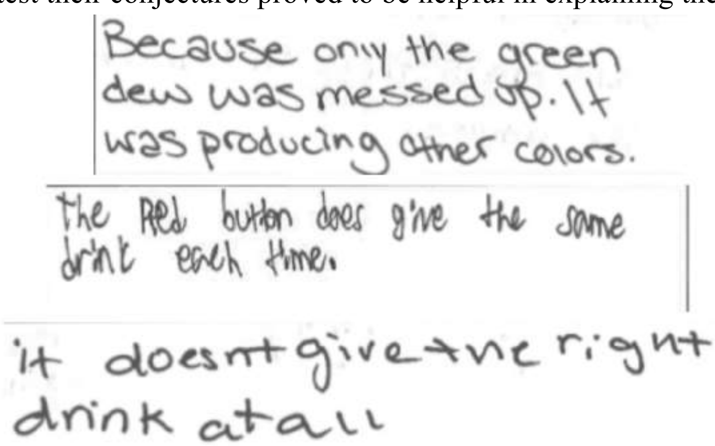

Figure 8: Examples of justifications that use the context of a vending machine

Definitions

One of the 72 pairs of students did not complete a definition on their worksheet. The remaining 71 definitions were coded using the codebook. In terms of the use of input/output 62 out of 71 (87.3%) definitions used the word input and 65 out of 73 (89.0%) definitions used the term output. Of course, the participants were asked to use these terms and, therefore, the result is not entirely surprising. Nevertheless, the result is promising in terms of establishing sets of inputs and outputs as a central aspect of the definition of function.

Perhaps the most interesting aspect of the activity was to examine the extent to which the participants would pay due attention to the outputs from the machines. Analysis of the definitions shows that 45/71 (61.6%) of the participants did pay attention to the output with definitions such as "When you input something, the output always will stay the same." However, 14/71 (19.7%) of participants, while paying attention to the output made an incorrect statement such as "Your input is your output and does not change."

In terms of focus, none of the participants described a relationship between inputs and outputs explicitly as a mapping between sets, and most definitions (43/71 (60.6%)) were coded as "neither object or relationship." A large number of participants' definitions (27/71 (38.0%)) were coded as "object" since they made explicit reference to the vending machine or the buttons of the machine. For example, "Whenever you input into the vending machine, you know the output which makes it reliable."

Conclusion

The purpose of this study was to explore whether seventh grade students who had not encountered the term function could use a specially designed applet to develop an understanding of a function as a relationship between inputs and outputs with some restrictions on the outputs. The non-standard representation of the *Introduction to Function* applet served to introduce the concept of function without algebraic representations. With the focus on the consistency, or otherwise, of the outputs the participants were able to correctly distinguish between functions and non-functions at least 80% of time. Some limitations of the study may be that the results were overdetermined by the discussion after the first two pairs of machines and that the participants might be seen to be simply playing a pattern recognition "game" with the rule "random bad, not random good." Therefore, more study would be needed to establish if the basic concept learned here transfers effectively to further study of function. However, even within this study, more than 60% used some appropriate language to describe the nature of the output in their definitions of function. In addition, contrary to a well-known misconception, participants may be able to recognise a constant function as a function.

In this project, we investigate how teachers develop the skills and knowledge to integrate makerspace technologies into mathematics lessons. Makerspaces are physical spaces that encourage creative design that often include emerging technologies such as 3D fabrication, coding, and robotics, and are being increasingly used to enhance mathematics instruction. Research suggests that for teachers to integrate any new technology into instruction, they must develop a specialized technological pedagogical content knowledge (TPACK), but little is known about how teachers develop TPACK for makerspace technology. We present emerging findings investigating how practicing mathematics teachers developed TPACK for makerspaces during a graduate technology course. Results suggest that despite similar experiences in the course, teachers varied significantly in their development of TPACK and integration of technology.

Keywords: STEM/STEAM; Teacher Education – Inservice/Professional Development; Teacher Knowledge; Technology

The issue of how teachers can integrate technology into their instruction in order to improve student learning of mathematics has been a focus of research for decades (Weglinsky, 1998), but continues to be a source of new questions (Cullen, Hertel, & Nickels, 2020). As new technologies are developed, researchers continue to wonder how these new technologies might impact students' mathematical thinking and learning. One emerging category of technologies which have the potential to transform student learning are those that are found in makerspaces.

Broadly considered, a makerspace is a physical space equipped with materials and technologies to encourage creative design (Cavalcanti, 2013). Some technologies currently found in makerspaces include 3D printers and other digital fabrication tools, robotics, microcontrollers (e.g., Arduino), as well as craft and circuitry tools. In this project, we investigate how teachers can develop technological and pedagogical content knowledge of makerspaces. This work looks "across cultures" as we investigate whether teachers can successfully integrate the "playful, growth- and asset-oriented, failure-positive, and collaborative" culture of makerspaces (Martin, 2015) into the context of their mathematics classrooms.

Introduction and Literature Review

Although makerspaces are relatively new, there is an emerging body of knowledge which suggests that they can be effective in improving student learning of mathematics. The use of makerspaces in mathematics instruction is informed by the cognitive theory of constructionism (Papert, 1980), which proposes that learning occurs by "actively constructing knowledge through the act of making something shareable" (Martinez & Stager, 2013, p. 21). Digital fabrication tools can expand constructionism to the creation of physical items. For example, students in a calculus class used 3D printers to create solids of revolution to create visual representations of integration (Propelka & Langlois, 2018). Some research has also suggested that makerspaces can be useful in developing

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

teachers' pedagogical content knowledge (Corum & Garofalo, 2019; Greenstein, Fernandez, & Davidson, 2019). However, little is currently known about how teachers can build on these experiences in makerspace to inform their own instruction.

A long-standing body of research suggests that teacher professional development is critical to the successful integration of technology (e.g., Weglinsky, 1998). Building on Shulman's (1986) description of pedagogical content knowledge, researchers have described an integrated technological pedagogical content knowledge (TPACK) which combines expertise in technology with understanding of how it can be purposefully used to enhance student thinking of content ideas (Koehler & Mishra, 2009). Previous research suggests that professional development can be effective in developing teachers' TPACK (e.g., Bos, 2011), but that this specialized knowledge can develop in uneven or unexpected ways (Polly, 2011). In particular, Niess et al. (2009) proposed a set of developmental levels for TPACK to describe teachers' integration of a new technology into their mathematics instruction (Table 1).

Table 1. Developmental levels for mathematics teachers' TPACK (Niess et al., 2009)

Level	Teacher Knowledge and Technology Integration
Recognizing	Teachers can use a technology, but cannot yet integrate it into teaching
Accepting	Teachers see benefits of a technology and may use it for a teacher-led demonstration of a mathematical idea
Adapting	Teachers can include student use of technology in a surface or instrumental way to support previously-learned mathematics ideas
Exploring	Teachers can integrate a technology for effective learning of new mathematics
Advancing	Teachers can integrate technology to expand boundaries of students' mathematical practices

Niess et al. (2009) emphasize that teachers must go through these developmental stages separately for different technologies, and that particular features of each technology might impact teachers' learning. However, no research has specifically investigated the development of teachers' TPACK for makerspaces (which we refer to as MakerPACK). In order to address this gap in the literature, we investigated how professional development (in the form of a graduate-level, makerspace-augmented mathematics instructional technology course) can impact teachers' MakerPACK. In particular, we explored the following research question:

> How does practicing teachers' MakerPACK develop through their engagement with makerspaces, and to what extent are they able to use their MakerPACK to develop makerspace-augmented mathematics lessons?

Methodology

To understand how teachers' MakerPACK develops, we designed a makerspace-augmented mathematics instructional technology course. Our goal in course design and implementation was both to develop teachers' MakerPACK and to investigate that development, including how teachers demonstrated their MakerPACK through the creation of mathematics lessons.

Course Development and Structure

Informed by current trends in makerspace technologies, five modules were created to develop students' technological knowledge of emerging technologies. These technologies included paper circuits, 3D fabrication, coding, robotics, and microcontrollers. The primary instructional method was open-ended guided exploration to model best practices when integrating makerspace-augmented lessons into a classroom. Examples of guided explorations include determining the volume of an origami balloon using non-standard measurement tools, deriving Ohm's Law, using iterative programming to draw various polygons, and creating a binary counter. Each module included open make time for teachers to explore the technology on their own and to develop their own mathematics lesson to highlight how this work could be incorporated into their own classroom contexts. Two of the authors with extensive experience in makerspace technology and mathematics education were lead curriculum writers.

Participants and Implementation

The makerspace-augmented mathematics instructional technology course was offered at a large public university in the Mid-Atlantic region of the U.S. A total of eight graduate students, all of whom were experienced mathematics teachers, completed the course in the Fall 2019 semester, with seven students agreeing to participate in the study.

Data Collection and Analysis

In order to assess the extent to which the makerspace-augmented mathematics instructional technology course supported students' development of MakerPACK, we collected the "lesson concepts" students developed throughout the course. These lesson concepts consisted of an educational object using a specified technology, a description of how the technology could be used to teach a mathematics topic, and a reflection on the design process. We used a comparative case study approach to examine similarities and differences among teachers' development of MakerPACK. A sample of teachers' lesson concepts (each using coding to teach a mathematical idea) were analyzed using the components of the "Mathematics Teacher Development Model" as described by Niess et al. (2009). Two of the authors assessed the lesson concepts independently and then compared their assessments. When the authors' individually assessments were not aligned, they reviewed the lesson concept together in order to come to a consensus. Three lesson concepts were purposefully selected to illustrate the different levels of MakerPACK as observed during the makerspace-augmented mathematics instructional technology course.

Results and Discussion

Data analysis of the codes from the "Mathematics Teacher Development Model" (Niess et al., 2009) revealed that these three participants varied significantly in their MakerPACK development. None of these teachers had prior experience with makerspaces, and all three had similar experiences in the makerspace-augmented mathematics instructional technology course, yet their lesson concepts revealed quite different views and uses of technology. Looking across the components, we noticed three distinct profiles of MakerPACK: Accepting (Jenna), Exploring (Kyle), and Advancing (Lauren).

Jenna: Accepting

Jenna created a Scratch animation and activity to demonstrate geometric transformations for use in an eighth grade class. Her lesson included tightly teacher-directed instructions and little student autonomy. Jenna struggled with identifying an application for coding within her curriculum, and she expressed concern that the use of technology would divert students' attention from learning mathematics. When Jenna encountered technical difficulties, she changed the content of her lesson rather than persevering to find a solution, and stated in her reflection, "I struggled to justify the amount of time and effort required to not make a lot of mathematical progress." Across multiple components, analysis revealed that Jenna was at an accepting level of MakerPACK since she was willing to use the technology in a teacher-centered lesson, but similar to participants described by Niess (2013), her "concerns overshadowed [her] enthusiasm for the use of [technology] in instruction" (p. 181).

Kyle: Exploring

Kyle created a Scratch animation and student project to learn about piecewise function for use in a precalculus class. His reflection expressed enthusiasm about a strong fit with his curriculum, and his project gave students multiple options and significant mathematical autonomy, using a rubric rather than specific instructions to provide guidance. We also note that Kyle's view of the challenges of using new technologies was different than Jenna's. Kyle identified his own difficulties in creating a Scratch animation that required him to use mathematics beyond the specified topic (e.g., converting, scaling), and he planned for how he would attend to these challenges when implementing the lesson concept with students. Data suggests that Kyle was at an exploring level of MakerPACK since he intended to give students autonomy in the classroom to explore new mathematical content; he "displayed indications of transforming [his] knowledge by more clearly integrating mathematics, pedagogy, and [technological] knowledge" (Niess, 2013, p. 188).

Lauren: Advancing

Lauren created a Python program and a programming experience related to the Pythagorean Theorem for use in an eighth grade class. Lauren intended to use technology to expand students' mathematical practices, as the technology provided motivation for determining a generalized solution method for determining the unknown side length of a right triangle. Lauren recognized that the value of incorporating technology into this lesson extended beyond the identified instructional goals. She reflected that her initial errors and the trouble-shooting process gave her additional interest and ownership of her program, writing, "I hope coding brings out the problem solvers in my students." Lauren's lesson concept suggests she was at the advancing level of MakerPACK, in that she used her integrated technological pedagogical content knowledge to "willingly explore and extend the mathematics curriculum" (Niess, 2013, p. 189).

These specific findings indicate that these three teachers' development of MakerPACK varied in terms of the value they perceived in using technology, the level of student autonomy in their lessons, and their response to technical difficulties in using the technology. These findings reflect the integrated nature of TPACK, aligning with previous research suggesting that technical expertise, pedagogical practices, and beliefs about technology are closely linked.

Conclusion

Despite these three teachers having similar experiences in the makerspace-augmented mathematics instructional technology course, our analysis of their lesson concepts revealed wide variation in their development of MakerPACK. We hypothesize that their development of MakerPACK was mediated by their beliefs about mathematics teaching and learning. In weekly reflections, Jenna often revealed frustration with the technology and a desire for more explicit direction. Kyle and Lauren, however, revealed a willingness to engage in productive struggle and a desire for mastery of the technology. This hypothesis aligns with research suggesting that development of TPACK is often mediated by teachers' beliefs (e.g., Smith, Kim, & McIntyre, 2016). Future research is needed to more closely understand the relationship between teachers' beliefs and TPACK, as well as how TPACK for makerspaces can develop.

INTEGRATING DIGITAL RESOURCES TO THE DOCUMENTATION SYSTEM OF A MATHEMATICS TEACHER IN A MEXICAN RURAL PRIMARY-SCHOOL

INTEGRACIÓN DE RECURSOS DIGITALES AL SISTEMA DOCUMENTAL DE UNA PROFESORA DE MATEMÁTICAS EN UNA PRIMARIA RURAL DE MÉXICO

Resources play an important role in how subjects act and think. Teachers, throughout their professional career, develop ways of teaching mathematics —articulated by the organization and type of activities that guide their class, the resources they use and their forms of intervention; these are modified when a new resource is integrated. In this paper we present evidence of this phenomenon using the case study of a teacher who, as a result of her participation in a professional development course that we implemented, integrated digital resources into her documentation work, destabilizing her previous forms of teaching.

Keywords: Elementary School Education, Technology, Teaching Tools and Resources, Teacher Education – In service / Professional Development

Introduction

Although, in this digital age, the integration of digital technological (DT) resources into the teaching of mathematics is a social and pedagogical necessity (Sunkel, Trucco & Espejo, 2014), there are deficiencies in some sectors of the Mexican basic education system (Enríquez & Sacristán, 2017, 2019). In fact, DTs are given very little importance in primary-school teacher training (as can be seen in the syllabus of the official primary-school teacher training programs –SEP, 2018). In this report we present part of a study that looks at how primary school teachers in a rural area of Mexico, and who took part in a professional development (PD) course, integrate digital resources into their mathematics teaching. The study uses the Documentational Approach to Didactics or DAD (Gueudet & Trouche, 2009, 2012), to investigate the following question: *When teachers integrate digital resources into their teaching practice, what changes occur in the design and implementation of their mathematics classes, that is, in their documentation system*[1]*?*

The Documentational Approach to Didactics (DAD)

The DAD studies teachers' practice and their professional development by looking at their interaction with the resources they use (select, adapt, review, reorganize) for teaching mathematics (Gueudet & Trouche, 2009, 2012). The resources they use, are integrated into a resource system (SR).The documentation work is the set of interactions of the teacher with their SR, "within processes where design and enacting are intertwined" (Gueudet & Trouche, 2012, p. 24) . This documentation work produces documents, which are composed of recombined resources and the usage schemes associated with them; a teacher's set of documents is their documentation system (Gueudet & Vandebrouck, 2011). Throughout a teacher's professional career, their documentation system evolves as they work and experiment with old and new resources. Thus, the teacher's documentation work reveals their professional development, that is, the evolution of their practice, knowledge and beliefs (Gueudet & Trouche, 2012).

[1] "Documentation system" is defined further below.

Methodology

This report is part of a larger research that has included: a diagnostic study to investigate teachers' previous training in the use of DT and their access to these resources; an intervention phase, where we implemented a PD course for the integration of digital resources for teaching mathematics, to teachers who had participated in the diagnostic study; and an inquiry phase into the documentation work of the participating teachers when integrating DT into their practice. In the study, 67 teachers from 10 primary schools in a rural region of the Mexican state of Oaxaca, participated in the diagnostic study; these teachers in their majority, had little training in the use of DT for teaching mathematics; their use of DT in their practice was scarce; and their access to digital equipment was limited –because schools lack hardware and school policies limit the use of what little is available (Enríquez & Sacristán, 2017, 2019). This information was considered, in the intervention phase, for the design of the PD course aimed at promoting the integration of DT for mathematics teaching. The 67 teachers who participated in the diagnostic study were invited to participate in the course and associated study; 15 of them accepted. The PD course lasted 5 months (6 hours per week). It was based on theoretical models on teacher knowledge (Shulman, 1986; Ball, et al., 2008, Thomas & Palmer, 2014). It was also based on the experiences of the EMAT program for teaching mathematics in middle schools (Sacristán and Rojano, 2009) and used some of its materials (the Logo software and accompanying didactic guidelines –Sacristán, 2005; Sacristán & Esparza, 2005).

The PD course. It consisted of 3 modules, each focused on studying a certain DT resource – respectively, miscellaneous applets and interactive apps, Geogebra and Logo. The tasks of each module were presented in 4 stages: (i) The study of the resource; (ii) the design of mathematics lesson plans integrating the digital resources studied in the course; (iii) the implementation of the designed classes; and, (iv) group reflections on the implementation experiences.

Data collection. In order to study the changes in the participants' documentation systems, we used: (i) initial interviews of the teachers, and subsequent ones after each implementation of their lessons using DT; (ii) the lesson plans designed by the teachers during the course; (iii) in-class observations of the implementations of the designed lessons; (iv) the teachers' presentations of their class experiences, which they shared, during the PD course, with their colleagues.

We now present data from a teacher, Nohelia, who was a participant in the study.

The case of Nohelia

Nohelia's profile. This teacher has a bachelor's degree in primary education, with a master's degree in the development of teaching competencies, and she has also taken various DP courses, including one in mathematics and computing. At the beginning of the study, she had 9 years of teaching experience, and was in charge of the 5th grade in a rural primary school; her school had a computer lab with 18 units, a portable video projector, and the old hardware from Enciclomedia (SEP, 2012) –a computer, an electronic whiteboard and another projector.

Changes in the documentation system (DS) of Nohelia

Based on the data from the initial interview with Nohelia, we determined her initial documentation system (DS) –the resources, and how she used them, for her mathematics lessons, before the study. This DS changed after she participated in the DP course, when she integrated the studied DT resources to her practice. Nohelia's initial DS included several documents —e.g., activities to introduce topics, or to strengthen students' knowledge (or to help her students overcome weaknesses)– each with specific resources. Her initial DS (see Table 1) structured her lessons in four stages: (1) a reviewing previous knowledge, (2) sharing knowledge with the whole group, (3) developing a new topic, and (4) assessment.

Table 1. The documentation systems (DS) of Nohelia

Stage	Activity	Aim	Resources	Teacher's actions
		Initial DS *(without DT)*		
1	Solve problems in teams	Assess and review previous knowledge	Official activities and guidelines; Printed materials. Internet. The children's settings. Stories.	Following the resolution processes
2	Share solutions (whole group)	Deal with weaknesses and reinforce knowledge	Children's solutions Videos and concrete materials Exercises and problems	Guides Sets exercises Uses resources Decides problems for M3
3	Solve problems individually	Promote an expected learning	Official activities and guidelines; Printed materials. Internet. The children's settings. Stories.	Guides Deals with difficulties Sets problems
4	Solve textbook tasks	Assess the learning	Textbook	Guides. Assesses. Closes theme.
		DS1: *"Capacity measures [of liquid containers]"* ***interactive app***		
1	Pose questions on liquid volumes (liter, milliliter)	Assess and review previous knowledge	Questions	Pose questions & assess answers
2	Solve in teams problems on capacity of liquid containers	Promote an expected learning	Bottles, pails. Worksheet.	Guides
3	Solve individually problems on capacity of liquid containers	Promote an expected learning	*"Capacity measures"* ***App.*** Official activities. Worksheet.	Guides Deals with difficulties
4	Solve textbook tasks	Assess the learning	Textbook	Guides. Assesses. Closes theme.
		DS2: *Heights of triangles with* ***GeoGebra***		
1	Build triangles in teams (to describe characteristics)	Assess and review previous knowledge	Tangram Geometry set Colored pens and paper	Assess students' descriptions
2	Recognize the height of a triangle (individually)	Assess and review previous knowledge	Geometry set Pen and paper	Guides Reinforces knowledge
3	Solve individually the GeoGebra activity on heights of triangles	Promote an expected learning	**GeoGebra** Official activities. Worksheet	Guides Deals with difficulties
4	Solve textbook tasks	Assess the learning	Textbook	Guides. Assesses. Closes theme.
		DS3: *Constructing polygons with* ***Logo***		
1	Team game (characteristics of regular and irregular polygons)	Assess and review previous knowledge	Polygon bingo game Polygon comparison table	Designed and showed a comparison table of polygon characteristics
2	Draw regular polygons (individually)	Promote an expected learning	Geometry set Pen and paper	Guides
3	Construction of polygons with Logo (in pairs & individually)	Promote an expected learning	**Logo** Worksheet	Guides Deals with difficulties

In Nohelia's initial DS, according to the initial interview, the following aims and resources (shown in italics) were included at each stage: **Stage 1** (reviewing previous knowledge) and **Stage 3** (developing a new topic) both focused on having children solve tasks, with the difference that in Stage 1, the aim was to make a *diagnosis* of children's knowledge, through their problem-solving activity work in teams; while in Stage 3, the Stage 1 *results* (another resource in itself) are taken into account for posing tasks on which students work individually. Nohelia designed the tasks using the following resources: (i) the *curricular aims of the study program*, (ii) *materials* from the Ministry of Education's *teacher activity books* (SEP 1994); (ii) *didactic guidelines* from the teacher activity books, or purchased or found on the Internet; (iii) fragments of stories, adapted to the context of the students, to motivate and interest them. The problems to be solved were presented as *printed materials* or projected on *slides*. Between Stages 1 and 3, in **Stage 2** (sharing knowledge with the whole group), the student teams' shared their solutions to the initial tasks, and the teacher guided the discussions and strengthened skills (e.g., arithmetic ones), through *exercises*, *videos* and *concrete materials*, before moving on to the individual problem solving activity (Stage 3). Finally, in **Stage 4** (assessment), she used the official *textbook* and *program of study* as resources for assessing the expected learning. Additionally, other resources that influenced her entire lesson plan were the *program of study, colleagues' experiences, courses* taken, and *didactic literature.*

That initial DS was modified as a result of the PD course, where Nohelia designed three lessons integrating, respectively, the use of some of the proposed digital resources, giving rise to a new DS for each class (see Table 1): In DS1, situations were proposed to find the quantity of milk comparing containers in three different scenarios, "at home", "in the stable" and in a "processing plant", using an interactive app called "Capacity measurements". In DS2, Geogebra was used to design –based on a task from the teacher activity book– triangles where a spider has to descend from one vertex to the opposite base in order to trace their heights. And in DS3, Logo was used to construct polygons. The DS1 and DS2 lessons were carried out by Nohelia in her classroom with a computer and projector, and the DS3 lesson, in the media room.

For each new DS, Stage 1 still had as purpose to review the previous knowledge needed for the new topic; however, instead of posing a task, children were asked oral and written questions, and given games to play. In Stage 2, instead of being one in which knowledge was shared, the teacher posed other tasks: for DS1, she asked children to compare containers of different capacities (liters and milliliters), similar to what is included in the interactive app; in DS2, she used complementary tasks to those posed in Stage 1, in order to review student's previous knowledge about triangles, particularly in terms of the heights the triangles; and in DS3, the teacher and students drew regular polygons on the blackboard in order to analyze their sides and angles. In Stage 3, the aim of developing the new topic was kept, using worksheets to pose tasks, the solutions of which were discussed as a whole group, but adapted in the following ways: in DS1 and DS3, the DT resources replaced those that the teacher originally used, in order to select, design and implement the tasks. In DS2, the DT resource (Geogebra) was used in combination with one of the original resources (a task from the teacher activity book). In DS3, the use of Logo led to study the content in another way, in terms of the Turtle Geometry context, which required thinking of the angles as turns; it was thus necessary to become aware that these did not correspond to internal angles. Finally, **Stage 4** continued to focus on children solving tasks from the textbook, in order to assess their learning (except in DS3, where Stage 4 was no longer carried out, because it was not possible to coordinate the Logo tasks with the curricular content).

Final remarks

In the case presented, we observed that the integration of digital resources, as well as the training (the PD course), generated modifications to the teacher's document system, causing: resources to be substituted, or used in combination to previous ones (i.e., in DS2); for the topic's tasks (and worksheets) to be designed ad hoc by the teacher, instead of taken from other sources; and for some activities that the teacher used to carry out (such as assessing the solutions to the tasks), being done by the software. Each digital resource presented new possibilities (in terms of implementation, knowledge and even motivation), as well as some limitations: The interactive app was easy to use and was adapted to the curricular content, although the learning tasks were restricted to what was proposed in it; GeoGebra was difficult to use, but allowed the teacher to design her own digital material, according to her interests and the curricular content; and Logo brought about more drastic changes to the initial DS of Nohelia, because it modified how the curricular content was approached.

These experiences show how the integration of digital resources into the DS of teachers is a complex but necessary task: it demands, in order to have meaningful DT integration, the collaboration of teachers, trainers, researchers and authorities, as well as access to hardware, with a development of teachers' pedagogical technology knowledge (PTK) (Thomas & Palmer, 2014), as we attempted to achieve through the PD course.

Los recursos juegan un papel importante en la manera de actuar y pensar de los sujetos. Los profesores, a lo largo de su trayectoria profesional, han construido formas de enseñanza de las matemáticas —articulados por la organización y tipo de actividades que guían la clase, los recursos que utilizan y sus formas de intervención— que se ven modificados cuando un nuevo recurso es integrado. Aquí presentamos evidencias de este fenómeno a partir del caso de una profesora quien, al participar en un curso de desarrollo profesional que implementamos, integró recursos digitales en su trabajo documental, desestabilizando sus formas previas de enseñanza.

Palabras clave: Educación Primaria, Tecnología, Herramientas y recursos docentes, Capacitación docente / Desarrollo Profesional

Introducción

Aunque, en esta era digital, la integración de recursos digitales en la enseñanza de las matemáticas es una necesidad social y pedagógica (Sunkel, Trucco & Espejo, 2014) se observan carencias en sectores de la educación básica en México (Enríquez & Sacristán, 2017, 2019). De hecho, el uso de tecnologías tiende a no ser casi considerado en la formación docente (e.g., ver el perfil de egreso para profesor de educación primaria –SEP, 2018). En este reporte presentamos parte de una investigación que indaga cómo profesores de escuelas primarias de Oaxaca participantes en un curso de desarrollo profesional (DP), integran recursos digitales en su enseñanza de las matemáticas. El estudio utiliza la Aproximación Documental de lo Didáctico o ADD (Gueudet& Trouche, 2009, 2012), para responder la pregunta: *Cuando los profesores participantes integran recursos digitales a su práctica docente, ¿qué cambios se dan en el diseño e implementación de sus clases de matemáticas, o sea, en su sistema documental*[2]*?*

La aproximación documental de lo didáctico (ADD)

La ADD estudia la práctica del profesor y su desarrollo profesional a partir de su interacción con los recursos que utiliza (selecciona, adapta, revisa, reorganiza) para la enseñanza de las matemáticas (Gueudet & Trouche, 2009, 2012). Los recursos se integran en un sistema de recursos (SR). El conjunto de interacciones y procesos con el SR, donde se articulan diseño y puesta en práctica, conforman el *trabajo documental* (Gueudet & Trouche, 2012) del profesor. A través del trabajo documental se producen, *documentos* integrados por recursos recombinados y esquemas asociados de utilización; el conjunto de documentos de un profesor es su *sistema documental* (Gueudet & Vandebrouck, 2011). A lo largo de la trayectoria profesional del profesor, su sistema de documentos va evolucionando, al trabajar y experimentar con viejos y nuevos recursos. Así, el trabajo documental del profesor da cuenta de su desarrollo profesional, es decir, de la evolución de su práctica, conocimiento y creencias (Gueudet & Trouche, 2012).

2 "Sistema documental" se define más abajo.

Metodología

Este reporte se enmarca en una investigación que ha,consistido en: un estudio diagnóstico para indagar las condiciones de formación de los profesores y de acceso a recursos digitales; una fase de intervención, donde se implementó un curso de DP a profesores participantes en el estudio diagnóstico, para la integración de recursos digitales en la enseñanza de las matemáticas; y una fase de indagación del proceso de integración de recursos digitales de los participantes, a partir del seguimiento de su trabajo documental. En el estudio diagnóstico participaron 67 profesores de 10 escuelas primarias de la región Mixteca del estado de Oaxaca, México, quienes carecían de formación sobre el uso de tecnología digital (TD) para la enseñanza de las matemáticas hacían uso limitado de TD en su práctica, y su acceso a equipo digital era limitado –debido a un pobre equipamiento de las escuelas y a políticas escolares que limitaban su uso (Enríquez & Sacristán, 2017, 2019). Esta información se tomó en cuenta para el diseño del curso, en la fase de intervención, de DP para la integración de TD a la práctica docente de matemáticas. Se invitó a los 67 profesores participantes en el estudio diagnóstico a participar en el curso y estudio asociado; 15 de ellos aceptaron. El curso de DP duró 5 meses (6 horas semanales). Se fundamentó en modelos teóricos sobre el conocimiento base del profesor (Shulman, 1986; Ball, et al.,2008, Thomas & Palmer, 2014). También utilizó la experiencia del programa EMAT (Sacristán y Rojano, 2009) y algunos de sus materiales (el software Logo y las guías didácticas para uso – Sacristán, 2005; Sacristán & Esparza, 2005).

El curso. Consistió de tres módulos, cada uno dedicado al estudio de cierto tipo de recursos TD – respectivamente, applets e interactivos diversos, Geogebra y Logo. Las actividades de cada módulo se desarrollaron en un ciclo de 4 momentos: (i) El estudio de los recursos digitales; (ii) el diseño de planes de clases de matemáticas integrando el uso de los recursos estudiados; (iii) la implementación de las clases diseñadas; y (iv) la reflexión grupal de las experiencias.

La recolección de datos. Para indagar los cambios en los sistemas documentales de los participantes recurrimos a: (i) entrevistas iniciales a los profesores, así como posteriores a la implementación de cada una de sus clases con TD; (ii) los planes de clase diseñados por los profesores durante el curso; (iii) observaciones de las clases diseñadas; (iv) las presentaciones de sus experiencias de clase, compartidas con sus colegas del curso.

Ahora presentamos datos de una profesora, Nohelia, participante en el estudio.

El caso la profesora Nohelia

Perfil de la profesora. Nohelia es licenciada en educación primaria con una maestría en desarrollo de competencias docentes, y ha tomado distintos cursos de DP, entre ellos de matemáticas y de computación. Al inicio del estudio, tenía 9 años de experiencia docente, y estaba a cargo del grado 5º en una escuela primaria rural, donde se cuenta con un aula de medios con 18 computadoras, un proyector portatil, y un viejo equipo de Enciclomedia (SEP, 2012) –computadora, pizarrón electrónico y otro proyector.

Los cambios en el sistema documental (SD) de la profesora Nohelia

A partir de los datos de la entrevista inicial a Nohelia, determinamos su sistema documental (SD) inicial –recursos y formas de uso para su clase de matemáticas— al principio del estudio. Este SD cambió a partir del curso, cuando integró los recursos digitales estudiados a su práctica. El SD inicial de Nohelia incluía varios documentos —e.g., actividades de orientación, o de reforzamiento (para ayudar a sus alumnos a superar debilidades) —cada uno con recursos específicos. Su SD inicial (ver Tabla 1) orientaba la totalidad de su clase, en cuatro momentos: (1) repasar conocimientos previos, (2) socialización de conocimientos, (3) desarrollo del tema y (4) evaluación.

Tabla 1. Los sistemas documentales (SD) de Nohelia con sus momentos (M)

M	Actividad	Objetivo	Recursos	Acciones del profesor
		SD Inicial *(sin recursos TD)*		
1	Resolución de problemas en equipo	Evaluar y repasar conocimientos previos	Fichero. Guía didáctica. Internet. Impresiones. Contexto de los niños. Cuentos.	Seguimiento a los procesos de solución
2	Compartir soluciones en plenaria	Atender debilidades y reforzar conocimientos	Procedimientos de los niños Videos y material concreto Ejercicios y problemas	Orienta Usa recursos Pone ejercicio Decide problemas para M3
3	Resolución de problemas (individual)	Favorecer el aprendizaje esperado	Fichero. Guía didáctica. Internet. Impresiones. Contexto de los niños. Cuentos.	Orienta Atiende dificultades. Implementa problemas
4	Resolución de tareas curriculares	Evaluar el aprendizaje	Libro de texto	Orienta. Evalúa. Cierra el tema.
		SD1: *Interactivo* *"Medidas de capacidad"*		
1	Planteamiento de preguntas (litro y mililitro)	Evaluar y repasar conocimientos previos	Preguntas	Valora respuestas
2	Resolución de problemas de capacidad (equipo)	Favorecer el aprendizaje esperado	Botellas, cubetas, hoja de trabajo	Orienta
3	Resolución de problemas de capacidad (individual)	Favorecer el aprendizaje esperado	**Interactivo** "medidas de capacidad". Fichas, hoja de trabajo.	Orienta. Atiende dificultades.
4	Resolución de tareas curriculares	Evaluar el aprendizaje	Libro de texto	Orienta. Evalúa. Cierra el tema.
		SD2: *Alturas de triángulos con* ***Geogebra***		
1	Armar triángulos en equipo (describir sus características)	Evaluar y repasar conocimientos previos	Tangram Juego geométrico Marcadores y papel	Valora descripciones
2	Reconocimiento de alturas del triángulo (individual)	Evaluar y repasar conocimientos previos	Juego geométrico Papel y lápiz	Orienta Refuerza conocimientos
3	Resolución (individual) de actividad sobre alturas de triángulos	Favorecer el aprendizaje esperado	**Geogebra** Fichero; Hoja de trabajo	Orienta Atiende debilidades
4	Resolución de tareas curriculares	Evaluar el aprendizaje	Libro de texto	Orienta. Evalúa. Cierra el tema.
		SD3: *Construcción de polígonos con* ***Logo***		
1	Juego (características de polígonos regulares e irregulares) en equipo	Evaluar y repasar conocimientos previos	Lotería de polígonos Tabla comparativa de polígonos	Crea y muestra tabla comparativa de características de polígonos
2	Trazo de polígonos regulares (individual)	Favorecer el aprendizaje esperado	Juego geométrico Papel y lápiz	Orienta
3	Construcción en Logo de polígonos (en binas e individual)	Favorecer el aprendizaje esperado	**Logo** Hoja de trabajo	Orienta Atiende debilidades

En el SD inicial de Nohelia, de acuerdo a la entrevista inicial, se conformaron cada momento con los siguientes propósitos y recursos (mostrados en cursivas): los **momentos 1** (repasar conocimientos previos) y **3** (desarrollo del tema) se centraban ambos en poner a los niños a resolver problemas, con la diferencia que en el Momento 1, se buscaba hacer un *diagnóstico* de lo que sabían los niños, trabajando ellos en equipos; mientras que en el Momento 3, tomando en cuenta los *resultados* del 1 (otro recurso en sí), los alumnos trabajaban individualmente. Nohelia diseñó los problemas a partir de los siguientes recursos: (i) los *objetivos curriculares* del *programa de estudio*, (ii) *actividades* de los "ficheros" de la Secretaría de Educación (SEP 1994); (ii) orientaciones o *guías didácticas* de los ficheros, compradas o halladas en Internet: (iii) fragmentos de *cuentos*, adaptados al contexto de los estudiantes, para motivar e interesarlos. Los problemas se daban *impresos* o proyectados mediante *diapositivas*. Entre esos momentos, en el **momento 2** (socialización de conocimientos), se compartían las soluciones grupales de los niños a los primeros problemas, y la profesora reforzaba habilidades mediante *ejercicios* (e.g., aritméticos), *videos* y *materiales concretos*, antes de pasar a la actividad de resolución individual de otros problemas (Momento 3). Finalmente, en el **momento 4** (evaluación), el *libro de texto* y *programa de estudio* fueron los recursos utilizados para valorar los aprendizajes esperados. Adicionalmente, hay otros recursos que influyen en la totalidad de la clase –

tales como el *programa de estudio, experiencias de colegas, cursos* que ha tomado, y *bibliografía didáctica*.

Ese SD inicial se modificó a raíz del curso de DP, donde Nohelia diseñó tres clases integrando, respectivamente, el uso de algunos de los recursos digitales propuestos, dando lugar a un nuevo SD para cada clase (ver Tabla 1): En el SD1, se plantean situaciones para hallar la cantidad de leche comparando recipientes en tres escenarios distintos, "en la casa", "en el establo" y en la "planta procesadora", usando el interactivo "Medidas de capacidad". En el SD2, se usó Geogebra para diseñar, basándose en una actividad del fichero, triángulos por los que debía descender una araña desde un vértice hasta la base opuesta para trazar las alturas. Y en SD3 se usaría Logo para construir polígonos. Las clases de los SD1 y SD2 las implementó Nohelia en su salón con una computadora y un proyector, y la del SD3 en el aula de medios.

Para cada nuevo SD, en el **momento 1** se mantiene el propósito de introducir los temas repasando los conocimientos sobre el contenido a trabajar; sin embargo, en lugar de plantear un problema, se hicieron preguntas orales, escritas y juegos. El **momento 2,** en lugar de ser uno de socialización de conocimientos, fue uno para plantear otras situaciones: para el SD1, comparar recipientes de distintas capacidades (litros y mililitros), de manera similar a lo propuesto en el interactivo; en el SD2, actividades complementarias a las del momento 1 para evaluar los conocimientos previos sobre triángulos, en particular sobre sus alturas; y en el SD3, trazos de polígonos regulares para analizar sus lados y ángulos. En los **momentos 3,** se mantuvo el propósito de abordar el contenido mediante hojas de trabajo para plantear problemas, para luego discutir las soluciones en plenaria, con algunas adaptaciones: en los SD1 y SD3, los recursos TD suplieron los que originalmente utilizaba la profesora para seleccionar y diseñar problemas. En el SD2 se combinó el recurso TD (Geogebra) con uno de los recursos originales (una actividad del *fichero)*. En el SD3, el uso de Logo llevó a estudiar el contenido de otra manera, en términos del contexto de la Tortuga, pensando en los ángulos como giros, y requirió percatarse que éstos no correspondían a los ángulos internos. Finalmente, los **momentos 4** continuaron siendo la resolución de tareas del libro de texto para evaluar el aprendizaje (excepto en el SD3, donde no se llevó a cabo momento 4, ya que no pudo adaptar la actividad Logo, al contenido curricular).

Comentarios finales

En el caso analizado, observamos que la integración de recursos digitales, así como la capacitación (el curso DP) generaron modificaciones al sistema documental de la profesora, ocasionando: que se suplieran recursos, o se combinaran (i.e., en el SD2); que las actividades de aprendizaje (hojas de trabajo) del tema no fueran retomadas de otras fuentes, sino construidas por la profesora; que algunas actividades, que la profesora solía llevar a cabo (como el evaluar las respuestas a los problemas), fueran realizadas por el software. Cada recurso digital presentó nuevas posibilidades (en términos de implementación, conocimientos e incluso motivación), así como algunas limitantes: El interactivo fue de fácil manejo y adaptación al contenido curricular, aunque las tareas de aprendizaje se restringían a lo propuesto en éste; GeoGebra resultó de difícil manejo, pero permitió el diseño de material digital propio, de acuerdo al interés de la profesora y al contenido curricular; y Logo originó cambios más drásticos al SD inicial de Nohelia debido a que modificó la manera de estudiar el contenido curricular.

Estas experiencias muestran cómo la integración de recursos digitales, al SD de los profesores, es una tarea compleja pero necesaria: para lograr una integración significativa de las TD, demanda la colaboración de profesores, capacitadores, investigadores y autoridades, requiriendo acceso a equipo digital y de desarrollo del conocimiento pedagógico tecnológico (PTK – Thomas & Palmer, 2014), como se intentó mediante el curso de DP.

Spatial reasoning is a high-impact topic as it strongly predicts interest in, appreciation of, and success in STEM domains and careers. Yet, spatial reasoning is often under-used, underdeveloped, and ignored in current grade-school curriculum and teaching. Framed by the perspective of embodied cognition, our study explores changes in elementary students' spatial reasoning skills after participation in either a short-term or a long-term robotics intervention. We administered measures of spatial reasoning elements before and after two differently structured robotics interventions to students aged 9-10 years: a short-term (N=11) and two long-term (N=48). Statistical analysis revealed significant improvements to several different elements of spatial reasoning in both groups. Our findings suggest that programming robots in either the short- or long-term leads to improvements in spatial reasoning.

Keywords: Programming and coding; STEM / STEAM; Technology

The purpose of our study is to report changes in elementary students' spatial reasoning skills after participation in either a short-term or a long-term robotics intervention. Spatial reasoning is a high-impact topic as it strongly predicts interest in, appreciation of, and success in STEM domains and careers (Casey et al., 2011; Lubinski, 2010; Mix & Cheng, 2012; Mix et al., 2016; Wai et al., 2009). Spatial reasoning is highly malleable, and can be learned (Julià & Antolí, 2016; Sorby, 2009; Uttal et al., 2013).Yet, spatial reasoning is mostly under-used, underdeveloped, and ignored in current grade-school curriculum and teaching (Newcombe, 2010). A few studies have investigated the positive effects of spatial reasoning and robotics interventions in schools (Coxon, 2012; Francis et al., 2016; Julià & Anatolì, 2016, Julià & Anatolì, 2018; Khan et al., 2014; Verner, 2004). Our current study builds on previous studies to further investigate the malleability of spatial reasoning with short-term and long-term robotics interventions.

Background Literature

What is spatial reasoning?

While there is considerable debate about what spatial reasoning is (see Uttal et al., 2013), we draw upon Bruce et al.'s (2017) definition of spatial reasoning as the ability to recognize and (mentally) manipulate the spatial properties of objects and the spatial relations among objects. Davis et al. (2015, p. 141) describe the emergent complexity of spatial reasoning skills as co-evolved and complementary nature of the mental and physical actions. The nature of these skills is entangled and emergent. Their description of spatial reasoning elements include ALTERING (*dilating/contracting, distorting/morphing, scaling, folding, shearing*), MOVING (*sliding, rotating, reflecting, balancing, sliding*), SITUATING (*dimension shifting, locating, orienting, pathfinding, intersecting*), SENSATING (*perspective-taking, visualizing, propriocepting, imagining, tactilizing*), INTERPRETING (*diagramming, modeling, symmetrizing, comparing, relating*), [DE]CONSTRUCTING (*de/re/composing, un/re/packing, re/arranging, sectioning, fitting*).

Context

This study is based on a multi-year design-based research project investigating how robotics influences spatial reasoning. The data reported here is based on quasi experimental results investigating if robotics interventions impact spatial reasoning. The first iteration of the design reported here was based on a week-long robotics academy with elementary teachers and Grade 4-5 students held at a university (15 hours). The second and third iterations of the design reported here were year-long classroom interventions at a local school (40 hours) in Grades 4-5. It is beyond the confines of this brief research report to describe the structures of the interventions in detail. However, Table 1 summarizes the sequence and spatial reasoning elements engaged in each task. Every robotics task of the short-term and the long-term intervention involved multiple spatial elements.

Table 1. Spatial Skills Found in the Intervention Task

	Altering					Moving					Situating					Sensating					Interpreting					[De]constructing

Methodology

Our study explores the following research question: Do elementary students' spatial reasoning skills improve after participation in either a short-term or a long-term robotics intervention? The data reported here is based on the quasi experimental pre- and post-test results collected before and after the interventions mentioned above. Participants in the short-term intervention included 11 Grade 4 students. Participants in the long-term intervention were from a different school and included 48 students total, whereby ten Grade 4 students completed the pre- and post-tests in 2017-2018. During the following school year 2018-2019, 19 Grade 4 students and 19 Grade 5 students respectively took the pre- and post-tests on spatial reasoning skills. The administration of the pre- and post-test instruments was similar for the short- and long-term interventions.

Description of pre- and post-test instrument. We developed an instrument that encompassed a broad range of spatial skills based on an amalgamation of established protocols. The spatial reasoning pre- post-test consisted of seven (different) task categories with 13 test items for the short-term intervention, and three additional test items for the long-term intervention. The short-term pre- and post-test included four Sorby drawing items, two paper folding items, two shape rotation items, two stereonet items, one building a 3D object from an image item, one moving a shape on a grid item, and one cross-section of a cube: isometric projection. The three additional items in the reasoning pre- and post-test of the long-term intervention included one more paper folding item, a block visualization/rotation item, and a pattern arranging item. Groups of three students were tested at a time. Each of the tests took approximately 45 minutes.

Analysis of results of short-term intervention. The data reported in this section details the Grade 4 results from the week-long intervention in 2016. The data consisted of one group of the same subjects at two different points in time (before and after the intervention). For such data, the Paired t-Test is an appropriate test to compare the means when the data is normally distributed (Huck, 2012; Mills & Gay, 2019). For data that is not normally distributed, the non-parametric Wilcoxon Signed-Ranks Test is more appropriate (Huck, 2012; Mills & Gay, 2019). To determine if that data is normally distributed, the Shapiro Wilks test is a suitable parametric test for a small sample size (Huck, 2012; Mills & Gay, 2019).

To compare spatial reasoning at the beginning and end of the week long robotics camp (15 hours) a paired t-test was conducted on the normally distributed Items 2, 3, 5, 10, 11, 12, and Total (pre- and post-test) and a Wilcoxon signed-rank test was used for the not normally distributed Items 1, 4, 6, 7, 8, 9, and 13 (pre- and post-test). All spatial reasoning test items saw improvement. There was a significant improvement for the Sorby drawing Item 2: $t(10) = -2.4$, $p < .05$; building a 3D object from a picture Item 11: $t(36) = -2.9$, $p = .05$, moving a shape on a grid Item 12: $t(11) = -2.4$, $p = 0.05$ and; the overall total: $t(11) = -3.05$, $p < .05$.

Analysis of Results of Year Long Intervention. To compare spatial reasoning at the beginning and end of the school year a paired t-test was conducted on normally distributed Items 1-16 (pre- and post-test) and a Wilcoxon signed-rank test was used on the non-normally distributed Items Total (pre- and post-test). The data combines the Grade 4 results from Year 2017-2018 and the Grade 4 and 5 results from Year 2018-2019. All spatial reasoning test items saw improvement. There was a significant improvement for the Sorby drawing Item 2: $t(47) = -2.4$, $p < .05$; paper folding Item 5: $t(47) = -3.4$, $p < .05$; rotation Item 9: $t(47) = -3.0$, $p < .05$; pattern arranging Item 16: $t(36) = -4.2$, $p < .05$, and; the overall total: $Z(-4.519)$, $p < .05$.

Discussion

In this study, we found how powerfully robotics interventions can improve spatial reasoning. We found similar results from both the short-term and long-term interventions. For the short-term significant results were observed in Sorby drawing, building a 3D object from a picture, moving a shape on a grid, and overall total score. For the long-term, significant results were observed in Sorby drawing, paper folding, shape rotation, pattern arranging and overall total score. The long-term intervention did not reveal a significant improvement to building 3D object from picture and moving along a grid. Perhaps this is because the students in the long-term study were already quite high in these two measures compared to the short-term group; there was not as much room to improve with these groups.

Previous studies also found improvements in spatial reasoning with robotics interventions. Verner (2004) reported improvements in three spatial reasoning skills: visualization, perception, rotation. Julià and Anatolì (2016; 2018) found improvements with spatial reasoning tasks. By drawing upon Davis et al.'s (2015) descriptions of spatial reasoning elements, we were able to provide a broader perspective of spatial reasoning than Verner (2004). Like Julià and Anatolì (2016; 2018), our instrument included paper folding, shape rotation, cube comparison and perspective taking. However, our test instrument also included Sorby drawing items, stereonets, building 3D objects from pictures, moving shapes on a grid and isometric projects. We not only looked at the spatial reasoning tasks as did Julià and Anatolì (2016; 2018), we also identified the spatial reasoning elements that were associated with each task. For example, visualization and imagining from SENSTATING were elements that appeared in every task and are integral to spatial reasoning as evident from most definitions (see Uttal et al., 2013).

Our identification of spatial elements within the tasks was important to show the compatibility of the test instruments with robotics. For instance, it may seem like the Sorby drawing item is completely different from programming a robot to move. However, the Sorby drawing item requires seven spatial reasoning elements: SITUATING (dimension shifting, intersecting), SENSATING (visualizing, imagining), INTERPRETING (diagramming), and [DE]CONSTRUCTING (de/re/composing, fitting). Francis et al. (2016) observed the engagement of these same spatial reasoning elements when students programmed robots to move.

Our findings complement our previous qualitative research which illustrated how spatial reasoning is engaged while building (Khan et al., 2014) and programming robots to move (Francis et al., 2016). These prior studies illustrated the complex and co-emergent nature of spatial reasoning which helped provide a basis for this current study that drew upon embodied cognition to investigate the results of *learning from action*. Our results provide some validation to Pouw et al.'s (2014) prediction that sensorimotor experiences are important for development of related concepts. In other words, this study along with our two previous studies (Khan et al., 2015; Francis et al., 2016) illustrate the power of sensorimotor experiences of robotics learning for improving spatial reasoning. Not only is spatial reasoning engaged, it also improves significantly.

As future work, we would like to explore how programming robots to move helps with learning mathematics. Spatial reasoning ability is correlated to mathematics achievement (Mix & Cheng, 2012) and computer programming is highly related to mathematics. Exploring connections could lead to unexpected and emerging insights for the teaching and learning of mathematics.

This paper shows the types of problems posed by of in service Mexican teachers in both paper-and-pencil and GeoGebra. The analysis and characterization of the posed problems were based on the model stated by Stoyanova (1998). According to the results, teachers can more easily pose problems in paper and pencil when dealing within a semi-structured situation. However, when using GeoGebra, they can more easily create problems within a free situation. These kinds of results indicate the necessity of professional development regarding the use of new technologies for mathematics teaching, where problem posing is fundamental.

Keywords: Problem posing, Technology, Teacher's knowledge.

Background

Problem posing is an important issue in mathematics teaching and learning. It is a useful mathematical activity because it helps evaluate content understanding, it encourages critical thinking, creativity and motivation, and it guides teacher's decision making. Furthermore, it is recognized that mathematics teaching and learning is modified in technological environments, therefore, problem posing is modified as well. In this regard, some researchers (e.g., Abramochivh & Cho, 2006; Fukuda & Kakihana, 2009, among others) have studied attitudes on the effect of problem posing in a paper-and-pencil environment versus the use of technology, in which they have identified, as a potential to pose appropriate problems, the possibility of direct manipulation of the mathematical object in technological environments.

In service teachers and future mathematics teachers usually are engaged in problem posing, but they are not aware of it. For instance, they pose problems when they adapt a problem from different sources and adequate it to the students' context. Crespo and Sinclair (2008) have stated that teachers should have similar experiences than those they want to set in their students. Therefore, problem posing should be present intheir teacher training and professional development. Thus, the research question that guided this study is: What kind of problems are posed by mathematics teachers in a paper-and-pencil environment, and which ones in a technological environment?

Theoretical Framework

According to Silver (1994, p. 19) posing mathematical problems, or just Problem Posing, is "the production of new problems and the reformulation of given problems. Therefore, posing a problem can occur before, during or after the solution of a problem". For González (2001), problem posing involves "to identify, create, describe and write a mathematical problem, individually or collectively, based on an initial situation–identified or created– by those involved in developing it" (cited in Rodriguez, García & Lozano, 2015, p. 103).

Regarding the classification of the type of situations in problem posing, Stoyanova (1998, cited in Christou, Mousoulides, Pittalis, Pitta-Pantazi, & Sriraman, 2005) has proposed three categories: *Free* *situations, are those* that have no restrictions when creating a problem. *Semi-structured situations*, are those in which a drawing, a graph or a part of a story is given to pose the problem. And, *Structured situations*, are those which specifically refer to reformulating an existing problem.

Problem posing is important to promote mathematical thinking. In this regard, Ayllón and Gómez (2014) recognize that creating problems increases mathematical knowledge, because it encourages students to create connections between their already acquired knowledge. Among the different perspectives on problem posing, this paper is mainly based on Silver's (1994) ideas and on the proposed classification by Stoyanova (1998), for both, task design and data analysis.

Method

This paper is part of a current research project. Here, we are reporting the work of five teachers (T1, T2,…, T5), one male and four females (ages 27-37), for which their full work has been identified. Of the five teachers, one teaches at a junior high school, two teach at a high school, and one teaches at a college.

Task Design

Five problem posing tasks were designed, based on Stoyanova's (1998) classification. In this report, only the first two tasks were analyzed: *Task 1* uses a *free situation* to ask the teachers to pose a problem, related to any mathematical area.. *Task 2* uses a *semi-structured situation* toask them to create a problem regarding a given geometrical drawing Both tasks are divided into two parts; paper-and-pencil problem posing and problem posing in a GeoGebra environment.

Data Gathering

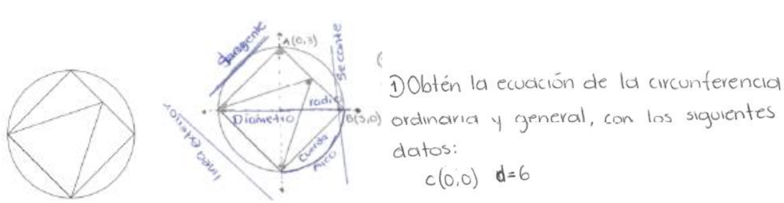
Data collection was carried out by means of a group interview in a workshop on problem posing, during three sessions. First, the five tasks were set to pose problems in paper-and-pencil (first part). Later, the same five tasks were used to pose problems using GeoGebra (second part. In the second part, each participant was given a GeoGebra file, to visualize and manipulate the given geometrical figure related to the semi structured situation. The sources for data analysis were the worksheets from each participant, the generated GeoGebra files and field notes.

Analysis and Results

Part 1: Problem posing in paper-and-pencil

Free situation. In Task 1 (creating a problem related to any mathematical area), the participants posed five problems. According to their answers, the following problems were posed: one geometry/calculus problem on optimization, one algebraic problem on second grade equations, two statistics problems on central tendency, and one financial mathematics on compound interest.

Semi-structured situation. For Task 2 (posing, based on a given figure, as many problems as they could), 38 problems were created, 37 Euclidean geometry problems and 1 problem on analytical geometry. Problems regarding Euclidean geometry are about areas (11), length (13), visualization of elements in the given figure, i.e., radius, diameter, chord, etc. (9), angles (2), and figure reconstruction using a ruler and a compass (2). As an example of the problems posed by the teachers, Figure 1 (right) shows the analytical geometry problem created by T4.



Find the circumference equation, ordinary and general, given that

Figure 1: Given figure (left). Problem posed by P4 (right)

Table 1 summarizes the total of posed problems in the first part, regarding the work on paper-and-pencil. Even though Task1 explicitly asks the teachers to pose one problem, the number of problems posed in Task 2 is higher. Which means that it was easier for participants to create problems when information is provided (semi structured situation) than when it is not (free situation).

Table 1: Summary, total created problems in paper-and-pencil

Task	Situation	Total problems
Task 1	Free	5
Task 2	Semi-structured	38

Part 2: Problem posing in GeoGebra

Free situation. In this type of situation participants created six problems (one of the participants created two). By their characteristics, these can be categorized as problems related to analytical geometry, Euclidean geometry, algebra and financial mathematics. Figure 2 shows the Euclidean geometry problem posed by T3, which involves the bisector.

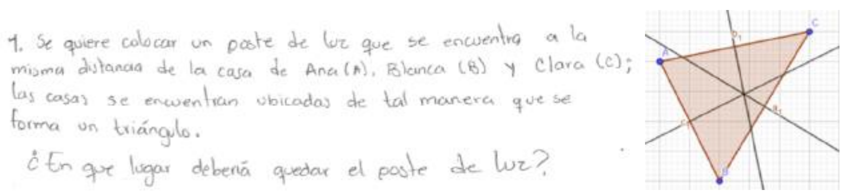


Figure 2: Problem Posed by P3 using GeoGebra

Semi-structured situation. This task involves a GeoGebra file. According to the results, 10 problems of this kind of situation were created when using GeoGebra referring to Euclidean geometry. The problems can be categorized as follows: 6 relating to areas, 2 relating to angles, and 2 to relating to length. Figure 3 (left) shows the given figure in this task (constructed in GeoGebra, and included in the given GeoGebra file used by participants) in which teachers based their problems. As an example, Figure 3 (right) shows the problems created by T5 using GeoGebra, the problem asks for measures of perimeter, angles, and the comparison of the areas of different figures involved, knowing that the observed square is 1 cm per side.

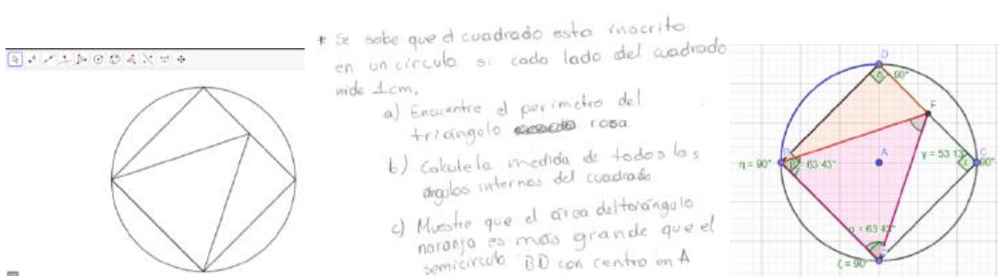

Figure 3: Given Figure (left). Problems posed by P5 (right)

Table 2 summarizes the problems posed by teachers during the second part. Based on the results, the number of problems created when using GeoGebra, in the semi-structured situation, decreases compared with the posed problems in paper-and-pencil (see Table 1). However, in both parts, the number of problems created in the semi-structured situation is higher than in the free situation.

Table 2: Summary, total created problems in GeoGebra

Task	Situation	Total problems
Task 1	Free	6
Task 2	Semi-structured	10

Conclusions

Regarding the free situation, in the first part, during the interview teachers expressed uncertainty about how to proceed to answer the task. This indicates the lack of experience of problem posing in their practice. Nevertheless, when they had the opportunity of using GeoGebra in the free situation, they interacted with the software in order to pose their problems by using it as a guide to explore the given figure, -see Figure 3 left,, or by including the use of GeoGebra as part of the problem.

In the semi-structured situation, when using only paper-and-pencil teachers assumed geometrical properties, which allowed them to pose a higher number of problems than in the second part. When the situation involved the use of GeoGebra, it was observed that teachers did not take advantage of the software's capacities (i.e., its dynamic feature), GeoGebra was used only as a means for static visualization. This may have happened because only participants T1 and T5 had previous experience with GeoGebra. Furthermore, the problems posed by the teacher did not mention the use of GeoGebra in solving the problems. Thus, even when previous reports (e.g., Abramovich & Cho, 2006; Fukuda & Kakihana, 2009) suggest the potential of the use of technology for problem posing, our results show the necessity for teachers to develop specific knowledge for mathematics teaching with technology in order to pose problems in technological environments. Therefore, models such as TPACK (*Technological Pedagogical Content Knowledge*, Mishra & Koehler, 2006, 2009), or KTMT (*Knowledge for Teaching Mathematics with Technology*, Rocha, 2013), among others, should be included in teacher training and development.

Este trabajo muestra los tipos de problemas planteados por profesores Mexicanos en servicio de diferentes niveles educativos tanto en un ambiente de papel-y-lápiz como mediante el uso de GeoGebra. El análisis y clasificación de los tipos de problemas fue realizado mediante la categorización propuesta por Stoyanova (1998). De acuerdo con los resultados, por un lado, los profesores plantean problemas con mayor facilidad, en papel-y-lápiz, cuando se trata de una situación semiestructurada. Por otro lado, al hacer uso de GeoGebra, se les facilita el planteamiento de problemas cuando la situación es libre. Lo anterior indica la necesidad de que los profesores cuenten con mayor apoyo respecto al uso de las nuevas tecnologías para la enseñanza de las matemáticas; donde el planteamiento de problemas es fundamental.

Palabras clave: Planteamiento de problemas, Tecnología, Conocimiento del profesor

Antecedentes

El planteamiento de problemas es importante en la enseñanza y aprendizaje de las matemáticas, puesto que puede ser tomada como una herramienta que ayuda a evaluar la comprensión de los contenidos, estimula el pensamiento crítico, la creatividad y motivación, y promueve la toma de decisiones de los profesores. Además, es reconocido que la enseñanza y aprendizaje de las matemáticas se modifica en ambientes tecnológicos; por la tanto, también el planteamiento de problemas. De esta manera, algunas investigaciones (e.g., Abramovich & Cho, 2006; Fukuda & Kakihana, 2009; entre otros) han estudiado sobre las actitudes y efectos del planteamiento de problemas en ambiente de papel-y-lápiz frente al uso de tecnología; al respecto, identifican la manipulación de objetos matemáticos en entornos tecnológicos como un potencial para plantear problemas apropiados.

Los profesores y futuros profesores, por su parte, en diversas ocasiones crean problemas sin ser conscientes de ello. Es decir, en el momento en que adaptan un problema extraído de otra fuente para que sea adecuado al contexto de sus estudiantes, llevan a cabo el proceso de planteamiento de un problema. Crespo y Sinclair (2008), afirman que los profesores deben tener experiencias similares a las que pretenden inculcar a sus alumnos, por lo que el planteamiento de problemas debería estar presente en los años de su formación. Por lo tanto, la pregunta de investigación que guió el estudio es la siguiente: ¿Qué tipos de problemas plantean profesores de matemáticas en ambiente de papel-y-lápiz, así como con el uso de GeoGebra?

Marco Teórico

De acuerdo con Silver (1994, p. 19) el planteamiento de problemas matemáticos, o *Problem Posing*, como se le conoce en la literatura es "la generación de nuevos problemas y la reformulación de problemas dados. Por lo que, plantear puede ocurrir antes, durante o después de la solución de un problema". Para González (2001), plantear problemas consiste en "identificar, crear, narrar y redactar un problema matemático, en forma colectiva o individual, a partir de una situación inicial identificada o creada por la(s) persona(s) que la realiza(n)" (citado en Rodríguez, García & Lozano, 2015, p.103).

Respecto a clasificaciones de tipos de situaciones en el planteamiento de problemas, Stoyanova (1998, citado en Christou, Mousoulides, Pittalis, Pitta-Pantazi, & Sriraman, 2005), determina tres categorías: *Situaciones libres*, son aquellas que no tienen restricción alguna, sino que el creador decide el tema sobre el cual se planteará el problema. *Situaciones semiestructuradas*, se refiere a aquellas en la que se proporciona un dibujo, gráfico o parte de una historia sobre la cual se planteará el problema. Y *Situaciones estructuradas* las cuales tratan específicamente de reformular un problema ya existente.

De acuerdo con lo anterior, el planteamiento de problemas resulta importante para promover el razonamiento matemático. Al respecto Ayllón y Gómez (2014), reconocen que la invención de problemas provoca el aumento de conocimientos matemáticos, debido a que obliga a los estudiantes a crear conexiones entre los conocimientos ya adquiridos. Respecto a las diversas perspectivas reportadas en la literatura, con referencia al *problem posing*, el presente trabajo se basa principalmente en las ideas de Silver (1994) y en las clasificaciones propuestas por Stoyanova (1998), las cuales sustentan tanto el diseño de tareas, como el análisis de datos.

Método

Este trabajo es parte de un proyecto de investigación en curso. Del total de participantes, se da cuenta de sólo cinco profesores (P1, P2,…, P5), un hombre y cuatro mujeres (de entre 27 a 37 años) de quienes, hasta el momento, se tiene evidencia de su trabajo. De los participantes, dos imparten clases en nivel secundaria, dos en el nivel medio superior y uno en nivel superior.

Diseño de Tareas

Se diseñaron cinco tareas sobre el planteamiento de problemas, con base en la clasificación de Stoyanova (1998). Para efectos de este trabajo, se analizaron solamente las primeras dos tareas: La *Tarea 1*, dirigida al planteamiento de problemas por medio de una *situación libre*, solicita crear un problema del área de matemáticas de su preferencia. La *Tarea 2* se trata de una *situación semiestructurada*, en donde a partir de un dibujo geométrico se solicita plantear problemas relacionados con tal figura. Ambas tareas involucran dos momentos en el planteamiento de problemas: primero en papel y lápiz; segundo; en ambiente de GeoGebra.

Recopilación de Datos

La recopilación de datos se realizó mediante la implementación de un taller (entrevista grupal) dividido en tres sesiones. Primero se implementaron las cinco tareas referidas a plantear problemas en papel-y-lápiz (primer momento). Posteriormente, se utilizaron las mismas cinco tareas, para plantear problemas con ayuda del software GeoGebra (segundo momento). Para ello, cada participante contó con un archivo GeoGebra correspondiente, para visualizar y manipular la figura dada, para el caso de la situación semiestructurada. Para el análisis de datos, las fuentes de información fueron las hojas de trabajo de cada participante, los archivos GeoGebra y notas de campo.

Análisis y Resultados

Momento 1: Planteamiento de problemas en papel-y-lápiz

Situación libre. Para la Tarea 1 (inventar un problema del área de matemáticas de su preferencia), los participantes crearon un total de cinco problemas, uno por participante. De acuerdo con sus respuestas, fueron planteados: un problema sobre geometría/calculo (Optimización), uno de algebra (Ecuación cuadrática), dos problemas sobre estadística (Medidas de tendencia central) y uno de matemáticas financieras (interés compuesto).

Situación semiestructurada. En el caso de la Tarea 2 (inventar, a partir de una figura dada, ver Figura 1 izquierda, tantos problemas como pudieran) fueron creados 38 problemas. Los participantes crearon 37 problemas del área de geometría Euclidiana y 1 referente a geometría analítica sobre la ecuación de la circunferencia. Los problemas correspondientes a geometría euclidiana tratan sobre: longitudes (13), áreas (11), visualización de elementos de la figura dada e.g., radio, diámetro, cuerdas, etc. (9), ángulos (2) y recrear la imagen con ayuda del juego geométrico (2). Como ejemplo de los problemas creados, la Figura 1 (derecha) muestra el problema sobre geometría analítica creado por el participante P4.

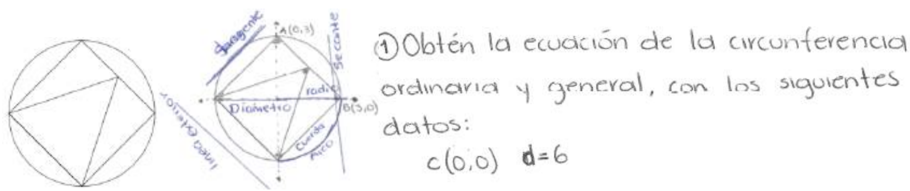

Figura 1: Izquierda, figura dada. Derecha, problema propuesto por P4

La Tabla 1 resume el total de problemas propuestos en el primer momento, referente al planteamiento de problemas en papel-y-lápiz. Si bien la Tarea 1 explicita crear un problema del área de su elección, el número de problemas creados en la Tarea 2 es considerablemente mayor, lo cual indica que para los participantes crear un problema resultó más fácil cuando se les provee de información (situación semiestructurada) a cuando no (situación libre).

Tabla 1: Resumen del total de problemas creados en papel-y-lápiz

Tarea	Situación	Total de problemas
Tarea 1	Libre	5
Tarea 2	Semiestructurada	38

Momento 2: Planteamiento de problemas en GeoGebra

Situación libre. En esta Tarea, los participantes crearon seis problemas (uno de los participantes creó dos). Por sus características, éstos pueden categorizarse como problemas de geometría analítica, geometría euclidiana, algebra y matemáticas financieras. La Figura 2 muestra el problema creado por P3; sobre geometría euclidiana, el cual involucra la mediatriz.

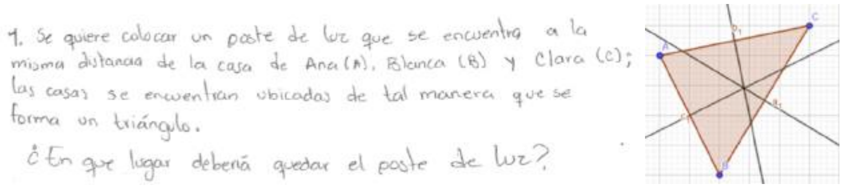

Figura 2: Problema propuesto por P3 con GeoGebra

Situación semiestructurada. En esta tarea se incluye un archivo GeoGebra. De acuerdo con los resultados, se crearon 10 problemas, todos referidos al área de geometría euclidiana. Por sus características, se pueden categorizar como problemas sobre: área (6), ángulos (2) y longitud (2). La Figura 3 (izquierda) muestra la figura dada (construida en GeoGebra) en la que cada participante se basó para crear sus problemas. Como ejemplo del tipo de problemas creados con ayuda de GeoGebra, la Figura 3 (derecha) muestra el creado por P5.

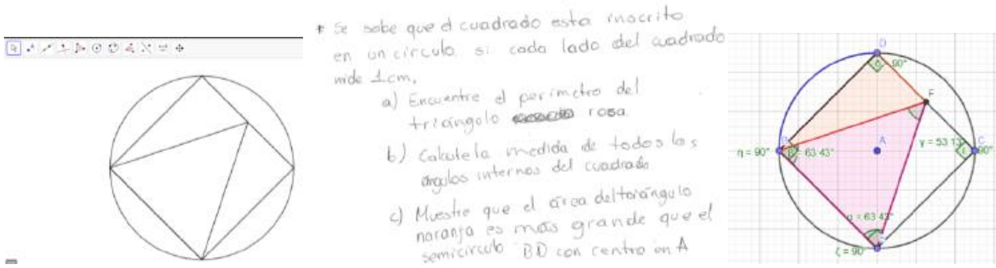

Figura 3: Izquierda, figura dada en GeoGebra. Derecha, problemas propuestos por el P5

La Tabla 2 resume el total de problemas propuestos en el Momento 2. De acuerdo con la Tabla 2, en GeoGebra, el número de problemas creados en la situación semiestructurada disminuye en comparación al ambiente de papel-y-lápiz (ver Tabla 1). Sin embargo, en ambos momentos, el número de problemas en la situación semiestructurada es mayor que en la libre.

Tabla 2: Resumen del total de problemas creados en GeoGebra

Tarea	Situación	Total de problemas
Tarea 1	Libre	6
Tarea 2	Semiestructurada	10

Conclusiones

Para la situación libre, en el primer momento, los profesores expresaron incertidumbre respecto a cómo proceder. Esto es indicativo de la poca experiencia sobre el planteamiento de problemas por parte de ellos en su práctica. Por otro lado, durante el uso de GeoGebra, la situación libre, les conduce a interactuar con el software, y de esta manera crearon los problemas, ya fuera que tomaran en cuenta GeoGebra como guía–al explorar–para la creación del problema, o bien sin necesidad de explorar, incluir su uso como parte del problema.

En la situación semiestructurada es notorio cómo los profesores, cuando trabajaron en papel-y-lápiz, asumen propiedades de la figura geométrica dada, esto les permitió plantear un número mayor de problemas. Cuando la situación involucra el uso de GeoGebra se observa que los participantes no explotaron la capacidad del software (e.g., su componente dinámica), sólo lo utilizaron como medio de visualización estática de la imagen, esto puede deberse a que únicamente los participantes P5 y P1 afirmaron haber utilizado GeoGebra en diversas ocasiones. Otra particularidad de los problemas propuestos es que no explicitan el uso de GeoGebra para resolverlo. En este sentido, aunque reportes previos (e.g., Abramovich & Cho, 2006; Fukuda & Kakihana, 2009) indican el potencial del uso de tecnología para el planteamiento de problemas, nuestros resultados muestran que, para ello, los profesores deben desarrollar conocimientos específicos sobre la enseñanza de las matemáticas con tecnología. Así, modelos como el TPACK (*Technological Pedagogical Content Knowledge*, Mishra

& Keohler, 2006, 2009), el KTMT (*Knowledge for Teaching Mathematics with Technology*, Rocha, 2013), entre otros, deben estar presentes tanto en el desarrollo profesional como en su formación inicial.

Studies have highlighted a multitude of beneficial student outcomes associated with the implementation of educational technology. However, there is a lack of understanding in both why and how preservice teachers intend to integrate technology into their future mathematics teaching. This small-scale study sought to examine preservice teachers' (N = 24) perspectives on technology integration within the context of elementary and middle school mathematics. The topics of primary interest in this study was preservice teachers' intended purposes of technology integration. Themes within responses to open-ended prompts were identified and interpreted through the lens of the SAMR model (Puentedura, 2006). Findings show that participants most frequently integrate technological resources in a way that augments a mathematical task. Implications for future research and teacher education are discussed.

Keywords: Technology, Preservice Teacher Education, Teacher Knowledge

The integration of technology into kindergarten through eighth grade (K-8) mathematics has been associated with a variety of benefits to students, teachers, and schools. Though various technological resources exist, particularly popular resources in K-8 mathematics are virtual manipulatives and mathematical games. Virtual manipulatives, defined as "an interactive, Web-based visual representation of a dynamic object that presents opportunities for constructing mathematical knowledge" (Moyer et al., 2002, p. 373), have been shown to increase K-8 students' conceptual knowledge of several mathematics topics (Reimer & Moyer, 2005; Suh & Moyer, 2007), positive attitudes toward mathematics (Lee & Chen, 2015; Sen et al., 2017), confidence in mathematics (Yuan et al., 2010), and feelings of competency (McLeod et al., 2013). K-8 students with disabilities have benefitted from virtual manipulative use as well, demonstrating increased rates of learning (Root et al., 2017), greater accuracy (Bouck et al., 2014), and faster independence (Bouck et al., 2017; Bouck et al., 2018). Mathematical games, such as those offered by Math Playground (https://www.mathplayground.com/), have been shown to increase K-8 students' achievement regarding multiplication (Kiger et al., 2012), adaptive number knowledge, arithmetic fluency, and pre-algebra knowledge (Brezovszky et al., 2019). Technological resources also benefit teachers and schools, as many are free to access, available for use outside of the classroom, and decrease in-class time spent distributing and gathering materials during lessons (Moyer et al., 2002).

Due to these benefits, it is imperative that preservice teachers (PSTs) are competent in technology integration upon degree completion. However, sufficiently preparing PSTs to integrate technology in their future classrooms has proven to be a challenging task for teacher education programs. A common approach implemented by teacher education programs has been adding the requirement of a stand-alone educational technology course – an approach that 85% of institutions have adopted (Kleiner et al., 2007). However, these courses often lack content-specific context and classroom practice opportunities, as just 32% of institutions provide learning experiences where PSTs deliver technology experiences within elementary classrooms (Rose et al., 2017) and many PSTs feel unprepared to effectively integrate technology on their first day of in-service teaching (Tondeur et al., 2012). Research has uncovered several factors that explain PSTs' feeling of unpreparedness, including insufficient access to technology (Dawson, 2008), lack of technology skills (Teo, 2009), negative attitudes toward technology integration, lack of confidence in their ability to integrate

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. technology, and the belief that their competence may be undermined due to students potentially having more knowledge about technology (Crompton, 2015). Gaining additional information regarding PSTs' perspectives on technology integration may prove beneficial to teacher education programs, current PSTs, and prospective PSTs.

This study sought to examine PSTs' perspectives on technology integration in K-8 mathematics. The aforementioned challenges associated with PSTs' integration of technology into K-8 mathematics inform the research question in this study: When prompted to select technological resources to enhance K-8 mathematics instruction after a two-day lesson about technology integration in K-8 mathematics, for what purpose do PSTs intend to use the selected resource?

Theoretical Framework

Puentedura's (2006) Substitution, Augmentation, Modification, and Redefinition (SAMR) model offered a theoretical perspective by which the intended purpose of a technological resource may be categorized. The SAMR model highlights four levels in respect to the impact that the integration of technology has on the design of a task within a lesson. Technology acts as a direct tool substitute at both the substitution and augmentation levels, but only provides functional improvement to the task at the augmentation level. The ability to significantly redesign tasks due to technology use occurs at the modification level, and technology use at the redefinition level allows for the creation of new tasks that would otherwise be inconceivable. Within the mathematics context of graphing functions, Dorman (2018) provided examples for each level of the SAMR model:

> At the substitution level, instead of printing off paper copies of the worksheet, an instructor could make the worksheet available online. At the augmentation level, students could complete the same questions on a Google Form, and the instructor could capture the answers for individual students to check for understanding. … At the modification level, … students could work in groups to analyze the different characteristic of functions as they graph them. Then, students could video record the characteristics and steps of how to graph functions. The video could be uploaded to a classroom website so that students can use it as a tutorial or study aid. At the redefinition level, students could create an online portfolio of all types of functions, and their graphs could include real-world applications that are modeled by the functions. (para. 3)

In this study, the SAMR model was utilized as a lens through which PSTs' intended purpose of mathematics technological resources were examined and through which PSTs' understanding of appropriate technology integration were interpreted.

Methodology

This study was conducted at a large university in the Northwest region of the United States. Participants (N = 24) were recruited from a K-8 Mathematics Methods course during the spring semester of 2020, which meets for two, 75-minute periods per week. All participants are PSTs majoring in elementary education which leads to licensure for teaching grades K-8. Participants were asked to respond to several prompts prior to, during, and following a two-day lesson about technology integration in K-8 mathematics. The design of the lesson was informed by Foulger et al.'s (2017) recommendations regarding teacher educator technology competencies and included: (a) an introduction to and exploration of mathematics technological resources; (b) modeling the alignment of K-8 mathematics content with both pedagogy and technology, and (c) collaborative activities in which PSTs designed mathematical tasks which utilized technological resources.

Open-ended prompts were posed to PSTs, including "Find one resource (include the URL) and answer the following questions: (1) For what grade level and CCSS [Common Core State Standards] would the resource be appropriate to use? (2) Explain how this resource might benefit a lesson." at the end of day two and (1) "Locate one resource (include the URL) and describe how you might use this resource to assess understanding in your future classroom." (2) "What do you think is the most practical application of technology in K-8 mathematics, and why?" after PSTs read Johnson et al. (2012) following the two-day lesson. The SAMR model was utilized to investigate the research question, with each response being coded as either substitution, augmentation, modification, or redefinition, according to PSTs' description of how the technological resource would be utilized.

Results

Of the PSTs recruited for this study, 19 consented that their responses may be analyzed for research purposes and 18 successfully completed both prompts. The recruited sample did not allow for an analysis based on demographic factors due to the fact that the vast majority of PSTs in the sample are White females in their third or fourth year of the elementary education program. Thus, demographic information was not gathered in this study.

Intended Purpose of Mathematics Technological Resources

The research question was examined with the following prompts: "Find one resource (include the URL) and answer the following questions: (1) For what grade level and CCSS would the resource be appropriate to use? (2) Explain how this resource might benefit a lesson." and "Locate one resource (include the URL) and describe how you might use this resource to assess understanding in your future classroom." Each response was coded according to the SAMR model based on the capabilities of the technological resource and PSTs' description of how the resource would be utilized in a lesson. In regard to the first prompt, the 18 PSTs who responded demonstrated a strong tendency to integrate technology into K-8 mathematics in a way that provides augmentation (n = 14). Four PSTs integrated technology in a way that modifies the task, while no PSTs described methods of integration where substitution or redefinition are utilized. Similar results were found in relation to the second prompt, in which PSTs favored augmentation (n = 14), while modification (n = 4) and both substitution and redefinition (n = 0) were less prevalent. It is worth noting that a total of 6 PSTs integrated technology in a way that modifies the task in response to at least one prompt.

The left side of Figure 1 displays the Pan Balance applet from the National Council of Teachers of Mathematics' (NCTM) Illuminations collection, which was selected by one PST as an opportunity to integrate technology to teach the commutative property, associative property, and distributive property. The PST supplied the equations located on the left side of Figure 1 and noted that this applet would benefit a lesson due to the visual representation of an equation being either equal to, greater than, or less than another equation. The affordances of the technological resource and rationale provided by the PST classify this instance of technology integration as an augmentation. Functional improvement is present, but a significant redesign of the task due to the integration of technology is not apparent.

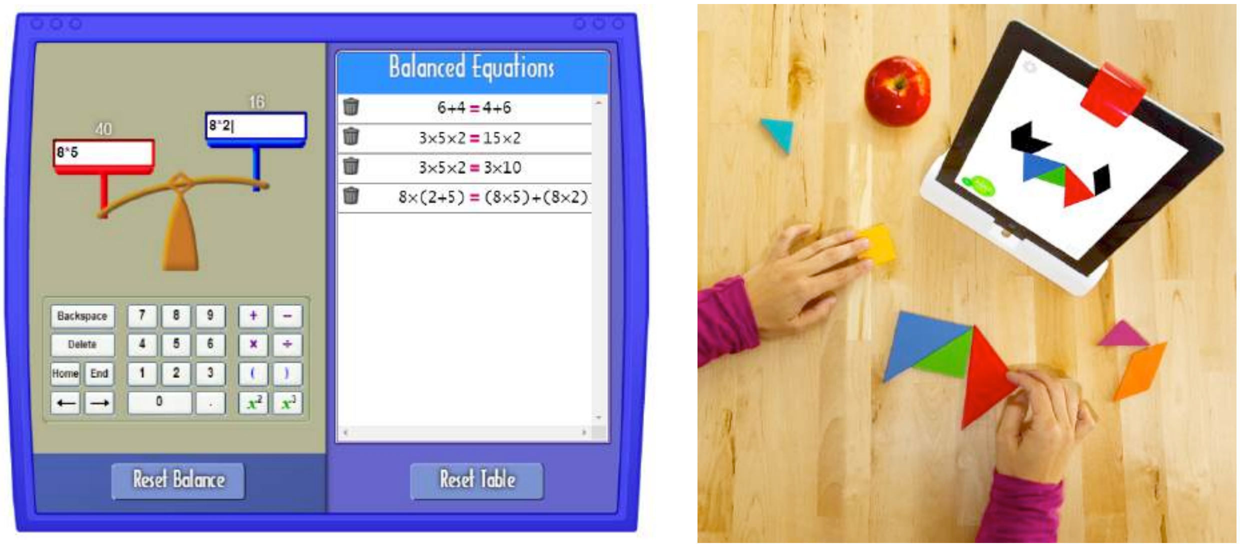

Figure 1: Augmentation - NCTM Illuminations' pan balance applet (NCTM, n.d.) and Modification - Osmo's tangram game (Osmo, n.d.)

The right side of Figure 1 presents the Tangram game to be used in conjunction with Osmo. Osmo, the red-colored device on the top of the tablet on the right side of Figure 1, utilizes the tablet's camera to scan the area directly in front of the tablet and then transfers that image to the tablet's screen. One PST selected Osmo as a technological resource to integrate into K-8 mathematics as a modeling task. The PST noted that Osmo allows for the concurrence of hands-on practice and technology integration in which students might explore the relationships between different shapes and construct/deconstruct various composite figures. The affordances of this game paired with the application described by the PST classify this method of integration as a modification task. The modeling task experiences a significant redesign via Osmo's Tangram game, though implementing this task is not entirely inconceivable without the utilization of the game via Osmo.

Discussion and Implications

Findings in regard to the research question are highlighted by PSTs' tendency to select and describe the integration of technological resources that augment a mathematical task. Similar results were found by Cherner & Curry (2017) when examining preservice English and social science teachers. While there is limited research of this topic within the context of mathematics education, this study uncovers a degree of understanding regarding PSTs' intended purposes of technology integration in a K-8 mathematics setting. These findings also have potential implications in regard to teacher education. The SAMR model was not presented to PSTs in the K-8 Mathematics Methods course, so it is possible that PSTs are simply unaware of the various degrees to which technology integration can impact the quality of a mathematical task. How might we encourage our PSTs to more frequently integrate technological resources in ways that modify and/or redefine the mathematical task? Future research is needed to examine the relationship of both the exposure to and discussion of the SAMR model to PSTs' design of mathematical tasks that utilize technological resources.

PROSPECTIVE TEACHERS' APPROACHES TO PROBLEM-SOLVING ACTIVIES WITH THE USE OF A DYNAMIC GEOMETRY SYSTEM

Daniel Ortiz May
CINVESTAV-IPN
daniel.ortiz@cinvestav.mx

Using digital technologies when working on problem solving tasks allows students to engage in different ways to explore mathematical concepts as well as analyzing multiple approaches that emerge while solving the tasks. For this study, it was important to document the extent to which prospective teachers become aware of the potential of a Dynamic Geometry System (DGS) as a problem-solving tool. To this end, six prospective teachers participated in a series of problem-solving activities meant to be approached by using a DGS. Even simple tasks offer ample opportunities to explore mathematical concepts when representing them within a digital medium, and in turn, the DGS' affordances influence the way participants pose mathematical propositions and validate them while solving and extending problems.

Keywords: Technology, Problem-solving, Geometry, Teacher Knowledge.

Introduction

The introduction of a technological element in the mathematics classroom modifies the way concepts are addressed, thus creating a perturbation within the teaching system. Laborde (2002), mentions two aspects that need to be considered when a certain technology is to be introduced in a learning environment: The domain of knowledge (how are mathematical objects interrelated through such technology? Which aspects are preserved, and which ones are modified?) and the teacher-student interaction (What is the purpose being considered when using that technology? Is the technology used for learning or is it used to support the teacher's discourse?). Technological tools such as Dynamic Geometry System (DGS) have the potential to open up multi-interpretations of mathematical knowledge (Leung, 2017), objects within the DGS do not appear as exclusively virtual to students, but become materialized (Moreno-Armella & Hegedus, 2009) and, therefore, subject to experimentation. One of the most notable outcomes from the study of mathematical objects in a dynamic environment is the emergence of alternative ways to justify mathematical relations (i.e. using *point dragging* to verify if a figure holds a geometric property in certain conditions). Santos-Trigo (2019) mentions that the use of digital technologies in learning environments demands addressing what new pedagogies are needed to frame mathematical working in which learners participate in the construction of mathematical knowledge. To this matter, problem-solving activities can be exploited with the systematic use of digital technologies, allowing teachers and students to examine mathematical tasks from different perspectives that include a plethora of concepts, resources and representations (Santos-Trigo, Camacho-Machin & Olvera-Martinez, 2018). However, teachers' perspective on the nature of mathematical knowledge and the role of digital technologies will define the ways in which students interrelate conceptual knowledge when solving mathematical tasks. Thus, teachers need to rethink the nature of mathematical activities in classroom when students solve problems using a DGS (Moreno & Llinares, 2018). For this study, six pospective teachers participated in a series of problem-solving activities with the support of a DGS. To this effect, the research question that guided this work was: What are some of the ways prospective teachers explore mathematical ideas when solving problems using a DGS?

Theoretical perspectives

Mediating tools are not epistemological neutral (Moreno-Armella & Sriraman, 2010). In a DGS, motion becomes a key element of mathematical representations. Therefore, a tool like a computer affects the cognition of the user, it reorganizes her ideas. In this way, the computer can no longer be considered as an agent that "does the task of the student” but provides students with a cognitive tool (Moreno-Armella & Sriraman, 2010). In a problem-solving environment, a DGS has the potential to enhance the use of heuristics like analyzing multiple particular cases, and fosters different problem-solving episodes like generate, explore and validate conjectures (Aguilar-Magallón & Poveda, 2017; Santos-Trigo & Moreno-Armella, 2016). These actions, however, are shaped by the subject’s expertise in using the tool. Throughout all problem-solving activities, it becomes important to pay attention to the transit in learners’ use of empirical approaches to the construction of geometric and analytic arguments to support results (Santos-Trigo, 2019). Santos-Trigo & Camacho-Machin (2013) proposed a framework to characterize ways of reasoning that emerge as result of using computational technology in problem-solving via four episodes: (a) comprehension episode, in which the solver needs to think of the task in terms of mathematical relations and how to use the DGS’ affordances to represent the problem (to generate a dynamic configuration); (b) problem exploration episode, where the tool is used to obtain empirically-generated conjectures; (c) search for multiple approaches episode, where students need to think of different ways to solve a problem in order to develop conceptual understanding of mathematical ideas; (d) Integration, a reflection of the different processes involved in the previous episodes.

Participants, methods, and procedure

The purpose of the study was to examine how high-school prospective teachers use a computational tool as a means of exploring multiple concepts derived from solving mathematical problems. Thus, this study is oriented to the analysis of cognitive processes exhibited by the participants and therefore, is of a qualitative nature.

Six prospective teachers participated in a problem-solving course as part of a master’s degree program at the CINVESTAV-IPN (Mexico City). They all had completed a university degree akin to mathematics and were attending the first semester of the program. The activities were conducted for 8 sessions of 3 hours each. The prospective teachers were encouraged to use a DGS (GeoGebra) as the main problem-solving resource. Firstly, they worked individually or in small groups and, subsequently, they presented their work to the group in plenary. Additionally, the participants were asked to prepare a report of their work in a text file and submit it to a google classroom platform. Data were collected through the information of the teacher’s reports and the video recordings of the sessions.

In this research report, I focus on the prospective teacher’s performance related to the following problem: Let ABC be a right triangle with perimeter 12. What are the lengths of the sides such that the triangle has maximum area?

It is important to note that, prior to the problem, participants worked on GeoGebra several construction problems collectively in plenary guided by the instructor. In this sense, they had knowledge about some of the DGS’ affordances.

Results and discussion

To present the results of this study, the participants’ work was structured around the problem-solving episodes described by the framework of Santos-Trigo & Camacho-Machin (2013). Also, it is also worth noticing the extent to which the use of a digital tool like GeoGebra modifies the way mathematical statements are stablished and validated (Santos-Trigo, Camacho-Machin & Moreno-Armella, 2016).

Comprehension episode. Most participants showed mainly algebraic procedures meant to find the function area $A,a.=,36a-6,a\text{-}2.\text{-}12-a..$ Subsequently, they didn't have any difficulties in finding that $,A\text{-}',a.=0$ if $a=12-6,\text{-}2.\approx3.515$, which is the measure of both legs of the right triangle with perimeter 12 such that its area is maximum. However, they were asked to represent the problem in a DGS. That is, they needed to construct a right triangle with perimeter 12 within GeoGebra. All of them showed the following procedure: define a slider a, and draw a circle with center A and radius a. Thus, the radius AB has side a. From B, trace a perpendicular line to AB. This line intersects a circumference with center B and radius $,12(6-a)\text{-}12-a.$ at point C. As a result, a right triangle ABC is obtained, such that its perimeter is always 12 (Figure 1).

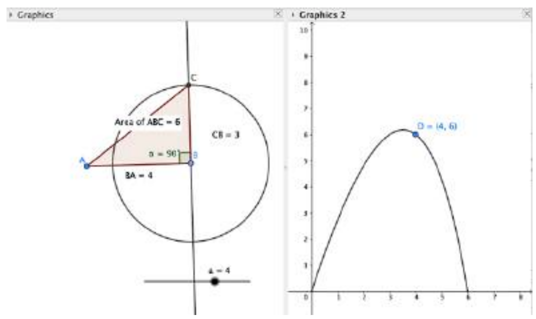

Figure 1: Dynamic configuration for Problem A

Exploration episode. How can the tool's affordances be used to find an empirical answer? Once the participants had a dynamic representation of the problem, they defined the point D: $(a, ,t\text{-}1.)$, where $,t\text{-}1.$ is the area of the triangle ABC. When moving the slider a, point D's trajectory can be visualized through the locus command. In consequence, the value of a can be adjusted so that (visually) point D is located at the vertex of the parabola.

Multiple approaches episode. The way this problem was been represented did not depend on the DGS' affordances, since the key aspect of the statement of the problem was approached in an algebraic way. Thus, participants were asked to re-interpret the given perimeter as a line segment of length 12 instead of a number. Using the coordinated axes, they traced AB with length 12 and placed a point C on the segment. In this way, AC is one of the sides of the triangle and by placing a point D on CB, segment AB will be partitioned into three segments. Are these segments always the three sides of a triangle with perimeter 12? It is important to see that this question does not appear when solving the problem by algebraic means, but in a digital medium, it is important to exploit the opportunities it offers to explore mathematical concepts. Figure 2 shows a triangle ACE such that $,AE.=,DB.$ and $,EC.=,DC..$ Whenever $,AC.>6$ (or more generally, $2,AC.>|AB|$) circumferences A and C will not intersect and, therefore, there will be no triangle. This is a crucial condition that must be stated when working with students because the motion of C must be limited in a way that ACE is always a triangle with perimeter 12 (or AB, in any case). Even though ACE is not necessarily a right triangle, it can be observed that when moving D, there is a position that results in angle AEC to be right. How to place point D such that the triangle is also a right triangle?

At this point, participants struggled to use an element of the dynamic configuration as a resource to obtain information about the mathematical relations involved. After working in small groups, two participants used the command *locus* to note that the motion of point E, because of moving D along BD, *seemed* to be an ellipse (Figure 3). What arguments could be used to support the validity of this conjecture? For different positions of *D*, it holds that $,AE.+,EC.=|CB|$, which means the sum of the distances from point *E* to *A* and *C* is always constant. Hence, point *E* moves on an ellipse with foci *A* and *C*.

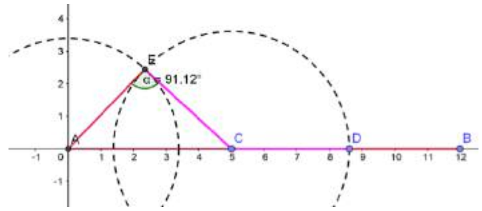

Figure 2. Drawing a triangle of a given perimeter

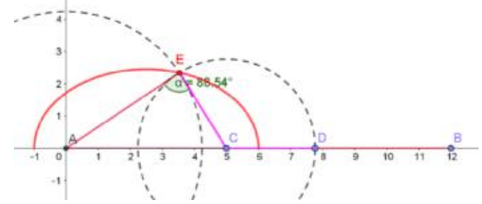

Figure 3. Locus of the point E as D moves along BC

Reflections on the problem. Two elementary forms of using loci within a DGS can be seen as crucial elements for concrete problem-solving strategies. On the one hand, the intersection of the ellipse and the circumference obtained in the analysis of the problem is a way of consolidating the heuristic of relaxing the conditions of a problem through an intersection point that unifies the solution of two subtasks (drawing a right triangle and tracing a triangle with a given perimeter). On the other hand, using a locus that represent a variation phenomenon can serve as a departure point for learners to make use of different geometric and algebraic resources to build and make sense of a robust dynamic configuration. The DGS also provides a scenario where mathematical discussions can be constantly extended. For instance, tracing the triangle considering AC as the hypothenuse rather than the side or restating the problem into considering an isosceles triangle instead of a right triangle with fixed perimeter.

Concluding remarks

In a digital medium, mathematical objects involved in the dynamic configuration of a problem become executable and react to the user's actions. This, in turn, allows the users to further extend their reflections or to find alternative approaches to the problem. In Problem A, the use of loci was underpinning in the formulation of conjectures and participants had to validate mathematical propositions stated in terms of the DGS affordances: what arguments can be stablished such that a certain property holds for the dynamic configuration when movable points are dragged? Prospective teachers were able to explore the concept of ellipse as a resource that can be useful in tasks related to the construction of triangles with a given perimeter. What is more, the concept of locus became a way to organize the use of problem-solving strategies such as solving similar simpler problems, simplify the conditions of the statement or solving many cases. As the activities developed, they became more prone to experiment with the tool and to find different solution paths that could open up for different kinds of mathematical discussions.

Teachers need to be exposed to environments where they can experience at firsthand how a digital technology affects the organization of mathematical ideas. When students use digital artifacts like a DGS, they rely on them to bridge the gap between mathematical ideas and their personal experiences through actions that can develop in the medium such as dragging or measuring attributes. If digital classrooms are to be successful, then teachers need to be fully aware of how these processes develop and relate to the generation of mathematical knowledge (Monaghan & Trouche, 2016).

DESIGNING FOR AN INTEGRATED STEM+C EXPERIENCE

In this paper we present an integrated design approach for bridging content between science, technology, engineering, math, and computational thinking (STEM+C). We present data from a design experiment to show examples of the kinds of integrated reasoning that students exhibited while engaging with our design. We argue that covariational reasoning can provide strong scaffolding in making integrated connections between the STEM+C content areas.

Keywords: Interdisciplinary Studies, STEM, Design Experiments, Computational Thinking.

To integrate math and science content, science materials often simply provide graphs while math materials often merely mention science terms for context. However, these efforts do not show the ways in which students' mathematical reasoning may influence their understanding of science, or how their scientific reasoning may influence their understanding of mathematical ideas. As English (2016) argued, in STEM integration there is a need for a more balanced focus on each of the disciplines, especially mathematics which is usually underrepresented. To illustrate this reciprocal relationship between mathematical and scientific reasoning, we looked for a design approach that could honor both math and science content. Specifically, our aim was to explore the research questions: (a) What kind of design integrates science and math for students? (b) What kind of reasoning do students display as they interact with this design?

Design Framework for Integrated Learning

First, we considered the power of covariational reasoning for bridging the two disciplines. Covariational reasoning is the mental coordination of simultaneous changes in two related quantities (Carlson et al., 2002). Mathematically, covariational reasoning has shown to be a strong building block towards the introduction of functions and graphing (Confrey & Smith, 1995). In terms of science, we considered that by engaging in covariational reasoning as they actively examine the interplay of variables in natural phenomena, students would develop deeper understandings of those phenomena than they might from exploring them only in terms of cause and effect relationships. To put it another way, there is a difference between reasoning about a cause and effect relationship, for instance, the depth of the rock affects its temperature, and reasoning covariationally about a relationship, for example, the temperature is changing as the depth of the rock is changing. This study of simultaneous change exhibited by covariational reasoning presented a promising route for supporting students' development of integrated forms of math and science reasoning.

We also considered the power of digital environments for designing simulations that dynamically model abstract mathematical and scientific concepts. We hoped that exploring a simulation would provide multiple trials and rapid feedback, supporting an inquiry environment (Meadows & Caniglia, 2019). Our goal was to encourage students to use the simulation to engage in inquiry practices such as questioning, developing hypotheses, collecting data, and revising theories (Rutten et al., 2012). This use of simulations to model and interact with data is also defined by Weintrop et al. (2016) as a form of computational thinking. They describe a taxonomy of computational thinking that includes practices such as Collecting, Analyzing, and Visualizing Data as well as Using Computational Models to Understand a Concept.

Finally, we gave careful attention to the design of tasks and questioning, aiming to shift students' attention to specific elements of the model and influence the nature of their interactions with those

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

elements. The questioning was organized to encourage students to explore specific relationships, such as “What have you observed about how the temperature and pressure change as Bob moves deeper underground?” Our goal was to prompt the students to engage in some of the Carlson et al. (2002) mental actions of covariational reasoning. These include coordinating the change of one variable with changes in the other variable (MA1), coordinating the direction of change of one variable with changes in the other variable (MA2), coordinating the amount of change of one variable with changes in the other variable (MA3), coordinating the average rate-of-change of the function with uniform increments of change in the input variable (MA4), and finally coordinating the instantaneous rate of change of the function with continuous changes in the independent variable for the entire domain of the function (MA5).

We also considered connecting the dynamic representations of relationships in the simulation with the graphing of those relationships. This connection was found to advance students’ conceptions of graphs of functions as a representation of coordinated change (e.g., Ellis et al., 2018). Students often fail to connect graphs with the covariational relationships they represent (Moore & Thompson, 2015), therefore, beyond simply describing and then having students graph these relationships, our goal was to ask them to use the simulation to collect data and graph these relationships. Our conjecture was that by engaging in these kinds of reasoning and practices as they interacted with our design, students would construct their own conceptual bridges in the context of an integrated STEM+C experience. In this paper, we present this design approach by providing an example using the phenomenon of the rock cycle, which is part of a larger collection studying science phenomena (e.g., Basu & Panorkou, 2019; Zhu et al., 2018).

An Example of Integrated STEM+C Design From the Rock Cycle

The earth science concept of the rock cycle describes the cyclical changes rocks experience due to the earth’s thermal energy. Like many natural phenomena, the rock cycle involves multiple variables. By identifying relationships such as the increase in temperature and pressure as depth below ground increases, we conjectured that covariation can be used as a link to integrate science and math. To encourage students to investigate for themselves how these quantities covary in the rock cycle, we developed the Bob’s Life simulation. The Bob's Life simulation (Figure 1) models the life of a rock named Bob near the sea on a volcanic island as he experiences different rock cycle processes and takes on different forms. The student controls Bob's depth in 1-km increments to investigate the behavior of the model. The simulation provides immediate visual feedback as the animation shows Bob moving and changing his form.

Though we used real geological data (e.g., Becerril et al., 2013) as a starting point to describe Bob’s path, these relationships are not always perfectly linear in the real world and can vary widely in real environments (e.g., de Wall et al., 2019). However, by sacrificing a certain amount of scientific realism, we were able to design the relationships between Bob's depth and the temperature and pressure to be piecewise linear functions with planned regions of friendlier numbers for students to graph. For example, in the Upper Crust environment we selected the numbers such that for each 1 km Bob moves down the temperature increases by 8 °C and the pressure increases by 1,000 kPa. This design choice maintains the scientific integrity of the model while creating an accessible data set for middle school students to investigate. The Bob’s Life simulation is thus a simplified model of real-world processes designed to have useful pedagogical features (Weintrop et al., 2016).

Students' Forms of Integrated STEM+C Reasoning

We focus on a whole-class design experiment (Cobb et al., 2003) in a middle school classroom and present episodes from a single pair of students, Laura and Michael, to illustrate examples of students' integrated reasoning as they interacted with our design. We adapted the Carlson et al. (2002) framework to identify episodes that illustrate students' covariational reasoning. We also remained open to students' use of other forms of reasoning, such as multivariational reasoning (Kuster & Jones, 2019) and computational thinking practices (Weintrop et al., 2016). At the same time, we examined how our design seemed to influence this reasoning by investigating the dialectic relationship between design and learning.

At the start of the design experiment, students were asked to freely explore the simulation. We included this free play to build students' interest and to encourage them to begin using inquiry practices (Rutten et al., 2012) as they interacted with the simulation and described what they noticed. During this time, we asked Laura about what she had noticed so far:

> Laura: I'd say, there's a rock named Bob, and you can control his depth. And if you go, the deeper you get, his form changes, his environment changes, his temperature, the pressure that's being put on the rock, the day, and the year change.

Laura's reasoning shows that the free exploration of the simulation offered a constructive space for her to both inquire into the behavior of the model and also to reason about how the rock's form, environment, temperature, and pressure change based on its depth. She coordinated changes in the variable she controlled, Bob's depth, with several other variables that were also changing simultaneously, illustrating MA1 reasoning. We would also argue that she exhibited multivariational reasoning since she was able to coordinate multiple variables at the same time.

After the free exploration, Laura was asked to use the simulation to investigate how the temperature and pressure change as Bob moves deeper underground. She responded that "the deeper you go, the more pressure's being put on it" and "the lower Bob goes in depth, the higher the temperature increases." Her responses show that she coordinated the direction of change of Bob's depth with the direction of change in pressure and temperature, engaging in both MA2 and multivariational reasoning. Immediately after giving the latter response, she used the simulation to illustrate by moving Bob several kilometers lower and pointing at the increasing number in the temperature readout. Laura's action shows that she used the simulation to understand what is changing and how it is changing in the model, illustrating a form of computational thinking.

Next, we asked students to collect data and graph the relationship between the variables. When asked to describe the numerical relationship in his graph (Figure 2), Michael said, "I got 1, as Bob moves 1 km deeper underground, the pressure increases by 1,000 kPa, because each km you go deeper, is 1,000 pressure compacted on Bob." Even though Michael's graph visually appears to be a falling line, his response shows that he viewed this as representing the increase in pressure as Bob moved deeper. This is evidence of MA3 reasoning as well as an indication that he might have been imagining his graph as an emerging record of this covariational relationship rather than a static shape (Moore & Thompson, 2015). This also shows that our design supported Michael in using computational thinking practices of collecting, analyzing, and visualizing data.

At the end of the experiment, students were asked to find intermediate values on their graphs. For example, we asked Michael to state the depth at which Bob would experience 4,500 kPa of pressure. Michael stated, "I think it's 4½ km underground." He explained that this is "Because 4 km underground is 4,000, and every .5 is 500, so if you do 4.5, that's going to be 4,500." Earlier, Michael had also observed, "1 km underground is 1,000, and if you add a .5 that's 500 more so that's 1,500." This shows that Michael had not only noticed that the pressure changed by a certain amount for each 1-km step, but that he had also used his graph to see that he could describe this relationship in terms of steps of .5 km. Michael's observation that "every .5 is 500" is an example of MA4 because it shows that he was reasoning about the rate at which pressure was changing for equal incremental changes in Bob's depth. It also shows that he used his graph as a second model to understand the relationships, illustrating computational thinking.

Conclusion

In response to RQ (a), we believe that this experiment has shown how our design approach can be used to develop integrated STEM+C instructional modules that have a more *balanced focus* (English, 2016) on each of the disciplines. This work supports our assertion that covariational reasoning can serve as a bridge to integrated STEM+C learning. Guided by the task design and questioning, students explored and explained the model's behavior in terms of both rock cycle processes and mathematical relationships. In response to RQ (b), the analysis of students' reasoning showed that they developed a sophisticated understanding of the science content which included identifying the factors that influence the rock cycle and constructing relationships between the involved variables. Students reasoned covariationally at various levels (Carlson et al., 2002) as they interacted with our design. We have also shown that students displayed multivariational reasoning (Kuster & Jones, 2019) and engaged in computational thinking practices (Weintrop et al., 2016). In the future, we plan to continue refining this integrated design framework with the rock cycle module as well as other modules that use covariational reasoning to build conceptual bridges between science and math. We also plan to explore other topics, such as probability and statistics, which might also be able to play the same bridging role that covariation plays in our Bob's Life simulation and investigation design.

Acknowledgments

This research was supported by a grant from the National Science Foundation (#1742125). The data presented, statements made, and views expressed are solely the responsibility of the authors. We would like to thank Jay Singh and Sowmith Etikyala for their help in module design.

INTEGRATED STEM EDUCATION THROUGH GAME-BASED LEARNING

Micah Stohlmann
University of Nevada, Las Vegas
micah.stohlmann@unlv.edu

Science, technology, engineering, and mathematics (STEM) education continues to garner focus and attention from teachers, students, researchers, policymakers, and businesses due to the vast importance of technology in the world. The integration of STEM subjects has the potential to make learning relevant and more engaging for students, which can increase their mathematical knowledge. In this paper, I focus on integrated steM education through open-ended game-based learning within a technological context. Integrated steM education is the integration of STEM subjects with an explicit focus on mathematics. The possibilities for integrating mathematics and technology through open-ended game-based learning has increased in recent years. Recommendations for future work will be discussed.

Keywords: Curriculum Enactment; Middle School Education; STEM

Interest, discussion, and work around technology integration in education continues to grow as advances in technology permeate our daily lives. The way that technology is integrated into the classroom is important in ensuring optimum learning outcomes for students. In game-based learning, technology integration should allow students to engage in more high-level thinking and have new experiences with mathematics that would be difficult without the technology. There is a distinction between how technology is used as an *amplifier* and how it is used as a *reorganizer* of mental activity (Pea, 1985). Technology as an amplifier enables students to perform more efficiently tedious processes that might be done by hand. This does not change what students do or think but does save time and effort and improves accuracy. As a reorganizer, technology is capable of effecting or shifting the focus of students' mathematical thinking or activity. This can enable students to do more higher-level thinking. A recent review of the literature suggests that the potential to integrate technology in a transformative way is not being met. For instance, researchers classified studies based on the ways in which technology has been integrated in mathematics education since 2009. The findings from this work indicated that the majority (61%) of the 139 studies were similar to an amplifier approach in that the technology was used as a direct substitute for traditional approaches with some functional improvement (Bray & Tangney, 2017). This result suggests that although innovative practices undoubtedly exist, the technology that could improve students' learning experience is generally not well implemented in the classroom (Hoyles & Lagrange, 2010). The purpose of this paper is to describe research done with middle school students (ages 11-15) and game-based learning to highlight productive principles for technology integration with mathematics.

Integrated steM Education Framework and Literature Review Integrated STEM Education

Researchers have noted that mathematics is often not emphasized in the integration of STEM subjects (English, 2017; Gravemeijer, Stephan, Julie, Lin, & Ohtani, 2017). In response to this, I have proposed that mathematics teachers and researchers focus on integrated STEM. Integrated STEM is the integration of STEM subjects that has an explicit focus on mathematics (Stohlmann, 2018). It is an effort to combine mathematics with at least one of the three disciplines of science, technology, and engineering, into a class, unit, or lesson that is based on connections between the subjects and open-ended problems. Further, integrated STEM education is an approach that builds on natural connections between STEM subjects for the purpose of (a) furthering student understanding of each discipline by building on students' prior knowledge; (b) broadening student understanding of each discipline through exposure to socially relevant STEM contexts; and (c) making STEM disciplines and careers more accessible and intriguing for students (Wang, Moore, Roehrig, & Park, 2011). There are three main ways in which integrated steM can be implemented by mathematics teachers: engineering design challenges, mathematical modeling with science contexts, and mathematics integrated with technology through open-ended game-based learning (Stohlmann, 2018). Each of the three approaches involves the integration of mathematics with a different science, technology, or engineering (STE) focus. In this paper, I focus specifically on mathematics integrated with technology through open-ended game-based learning.

Game-based Learning

Game-based learning has drawn international interest and has been reported as an effective educational method that can improve students' motivation and performance in mathematics (Byun & Joung, 2018; Wang, Chang, Hwang, & Chen, 2018). Students enjoy playing technology-based games whether it is video games or apps on their phones. However, when used in the mathematics classroom, game-based learning is often not implemented with best practices for teaching mathematics in mind (Byun & Joung, 2018). A meta-analysis was conducted to look at the overall effect size of game-based learning on K-12 students' mathematics achievement. Seventeen studies were identified that had sufficient statistical data from a time frame of the years 2000 to 2014. The overall weighted effect size was 0.37, which is a small effect size. There were 71 authors in the studies reviewed for the meta-analysis, with only five of these authors having a background in mathematics education. This research demonstrates the need for further studies on effective game-based learning approaches and best practices in mathematics education.

For example, most of the games used in the studies involved drill and practice (Byun & Joung, 2018). An example of one popular game includes students solving traditional, non-contextual practice problems in order to get more speed for a race car and attempts to take advantage of students' interest in videogames (Math-Play, 2019). However, in this type of game, students only receive feedback if the answers are correct or incorrect and do not receive support for improving their conceptual understanding. These types of games also emphasize that mathematics is about speed and focus on the memorization of ideas (Bay-Williams & Kling, 2015). Game-based learning for mathematics should move beyond drill and practice.

Another area that requires improvement in the implementation of game-based learning is for students to be able to work collaboratively or competitively. This has been suggested to be more effective than individual gameplay (Hung, Huang, & Hwang, 2014). A study in which this collaboration versus individual play was investigated involved 242 students with an age range of 11 to 15 years. There were four conditions in the study: collaboration and competition, collaboration control, competition control, and control. Overall, the game-based learning improved students' proportional reasoning, but the effects did not differ between conditions (Vrugte et al., 2015).

For game-based learning in integrated STEM, I refer to games in which the mathematics is integrated into the gameplay in a substantial way other than traditional practice problems. When structured well through open-ended problems, technology-based mathematics games may engage students in mathematics and help develop their conceptual understanding.

Methods

This study was structured as a teaching experiment (English, 2003). Nineteen students voluntarily enrolled in a five-week Saturday STEM program at a large urban university. The students were audio-taped and student work was collected including screenshots of the students' work in Desmos. Researcher field notes were also collected. Desmos is an online graphing calculator, but also has a suite of classroom activities available with some of the activities being game-based. In the lessons, students can share ideas and ask questions of one another. The principles that guide the Desmos' team lesson development include the following:

- Use technology to provide students with feedback as they work.
- Use the existing network to connect students, supporting collaboration and discourse.
- Provide information to teachers in real time during class (Danielson & Meyer, 2016, p. 259).

Little research has been conducted on these activities, but they have the potential to enable teachers to develop students' conceptual understanding. Research on how students develop conceptual understanding through technology integration tasks is important to investigate. The specific research question for this paper was the following. *How do students use and develop mathematical vocabulary while playing the Polygraph lines game?*

Results

In this paper I describe results from a Desmos game-based activity called Polygraph lines. I analyzed the data with an interpretative approach by looking at the ways in which students used mathematical vocabulary in the game. In this game, sixteen linear graphs are given. One student selects one of the graphs and the other student asks yes or no questions to determine which graph has been selected. Between games students are shown questions that other students ask. The teacher also is able to view and have a record of all questions asked in each game. Table 1 has the initial questions that were asked by 4 of the groups.

Table 1: Initial questions from polygraph lines

Group	1	2	3	4
Questions	-Does your line go through the origin? -Is your line vertical? -Is your line horizontal? -Is your line in quadrant 2 and 3?	-Does your line have a positive slope? -Does your line pass through the origin? -Does your line have a slope of 0 or undefined? -Does your line have an undefined slope? -Is the slope negative? -Does your line have a slope of 0? -Does your line have a slope greater than -2? -Is the slope of your line greater than or equal to 1?	-Is your slope positive? -Is the y-intercept positive? -Does it cross the origin? -Is your slope steep? -Is your line undefined? -Is your slope negative? -Is your line's linear equation zero or undefined -Is your line horizontal? -Is your line vertical?	-Is your line horizontal? -Is your line vertical? -Does your line intersect 2 quadrants? -Does your line intersect 3 quadrants? -Is your line positive? -Is it negative? -Does it go through the origin? -Does it pass through 3 squares?

After playing the game several times, the students discussed what quality questions to ask and strategies for asking the least amount of questions. Several questions appeared in common in the groups: "Is your slope positive?" "Is the slope negative?" "Is your line horizontal?" "Is your line vertical?" "Does your line go through the origin?" Groups also came up with questions of what quadrants the line crossed through, though not all groups used the term "quadrants." Through playing the game and subsequent discussions, students were able to make use of mathematical vocabulary including slope, positive slope, negative slope, horizontal line, vertical lines, origin, and quadrants. Desmos continues to develop their freely available activities, and further research is warranted on the effect of the games on students' mathematical understanding of linearity and motivation to learn mathematics.

Conclusions

It has been found that the use of puzzles and gamification in mathematics increases students' participation and engagement (Bryne, 2016). The research in this study provides early support for game-based learning done through integration with Desmos. This method can encourage students to develop mathematical understanding in an engaging game-based context. Through investigating technology game-based learning I have developed several important principles that should be incorporated to help make it more likely the game-based learning will be effective. First, the technology integration should allow for the creation of new tasks that would not be possible without the technology or for significant task redesign (Puentedura, 2006). Second, the tasks used should be worthwhile tasks. These tasks have no prescribed methods and there is no perception that there is only one "correct" strategy (Hiebert et al., 1997). Third, the tasks should be aligned with grade-level standards. Fourth, the tasks should enable students to work with multiple representations. Fifth, the technology should provide students feedback. Finally, the tasks should be open-ended and allow for discussion and multiple solutions (Stohlmann, 2019). When structured well, technology-based mathematics games can engage students in mathematics and help develop their conceptual understanding.

Too often middle school students perceive mathematics to be dull, irrelevant, and too difficult (Grootenboer & Marshman, 2016). Further research on game-based learning in the mathematics classroom can help to provide one way to address this problem. Students can play video games for hours on end though with the time going by quickly and the students persevering in problem solving. Bringing more game-based learning into the mathematics classroom has the potential to help more students be successful in mathematics.

The Hidden Village (THV) is a motion-capture video game for investigating how physical movements foster mathematical thinking and proof practices based on principles of embodied cognition. Analysis of the interactions of students in an all-Limited English Proficiency Title 1 high school geometry classroom revealed ways simulated enactment and collaborative gestural co-construction of mathematical ideas can bridge language barriers. These informed a redesign of THV to support both individual and collaborative play, as well as a collection of authoring tools for players to create their own content and upload it to an online database shared by users worldwide. Players, teachers and learners can implement custom directed movements that could foster deeper mathematical understanding and engagement for them and their peers.

Keywords: Technology; Reasoning & Proof; Geometry and Geometrical and Spatial Thinking

New technological interventions for learning mathematics are leveraging the embodied affordances of motion-capture technology to teach proportional reasoning (Abrahamson, 2015), algebraic reasoning (Ottmar et al., 2012), numerical training (Fischer et al., 2015), and geometric angles (Smith et al., 2014). As a design experiment (Brown, 1992), the development of *The Hidden Village* (THV) has been an iterative process of refining and extending its instructional application. THV is designed to help researchers better understand the grounded and embodied nature of geometric proof production by investigating how directed body actions, in combination with verbal prompts (i.e., pedagogical language), help students conceptualize the underlying mathematical ideas for geometric proof practices. Conducted in authentic classrooms, this type of *in situ* research exposes technologies like THV to dynamic environments in which "surprising occurrence[s]" emerge from students' collaboration and co-constructions to become sources for "ontological innovations" in the design process (diSessa & Cobb, 2004, p. 86). We present instances from gameplay of THV v.5, in which students renegotiated how the game was played, using a range of collaborative gestures and discussions to communicate shared understandings and present the newest revision, THV v.6.

Theoretical Background

Mathematicians use particular practices in their formulation of valid proofs. Research suggests that proof "is a richly embodied practice that involves inscribing and manipulating notations, interacting with those notations through speech and gesture, and using the body to enact the meanings of mathematical ideas" (Marghetis, Edwards, & Núñez, 2014, p. 243). Learners may derive new ideas and insights relevant to understanding and solving tasks based on their engagement in physical motions. Prior research shows that students' dynamic gestures reliably predict mathematical

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

intuitions and proof validity (Nathan et al., 2018), even when controlling for spatial ability, gender, expertise, prior geometry knowledge, and speech content. Playing THV has been shown to help foster the production of beneficial gestures that promote higher proof performance (Authors, date). As study of collaborative proof has emerged, a growing body of evidence is demonstrating that collaborative gestures, as social extensions of cognition, are relevant to learner-learner interactions in the processes of mathematical sensemaking (Walkington et al., 2019). Collaborative gestures are physically and gesturally taken up by multiple learners. These co-constructive activities often extend cognition by echoing ideas, mirroring each other's reasoning, alternating in co-constructions and jointly operating in the same problem spaces (Walkington et al., 2019; *see* Table 1).

Table 1: Categories of Collaborative Gestures (adapted from Walkington et al., 2019).

Echo	Simple Echo (SE)	One learner makes a gesture and then a second learner makes the same (or a very similar) gesture afterwards.
	Echo & Build (E&B)	The second learner must change or add to the echoed gesture in some way.
Mirror	Simple Mirror (SM)	One learner makes a gesture, and then a second learner makes the same (or a very similar gesture) nearly at the same time.
	Anticipation (A)	One learner is gesturing, and then a second person anticipates a gesture they are about to do (correctly or incorrectly).
Alternate	Alternate & Build (A&B)	One learner gestures their understanding, and then another learner follows up, building upon or extending their reasoning.
	Alternate & Redirect (A&R)	One learner gestures their understanding, and then another learner follows up with a different gesture and reasoning.
Joint	(J)	Multiple learners manipulate mathematical object(s).

Such multimodal discursive practices in communicating mathematics (e.g., Edwards, 2009; Hall, Ma, & Nemirovsky, 2015; Radford, Edwards, & Arzarello, 2009; Roth, 1994, 2001) often externalize representations of students' minds and help establish and maintain *intersubjectivity* in a shared problem space (Nathan & Alibali, 2007). The design of THV draws from the theory of *Gesture as Simulated Action* (GSA; Hostetter & Alibali, 2019), the theory that people gesture because they activate perceptual-motor processes in the brain when they think about--and therefore simulate--the spatial or motoric properties of an idea while speaking and thinking. In this way, gestures can reveal the spatial and motor correlates of abstract and generalizable mathematical thinking. THV also draws on Nathan's (2014) model of *action-cognition transduction*, in which learners' movements serve as inputs that can drive the cognitive system into related cognitive states much like the cognitive system can, reciprocally, direct the motor system to make specific movements in response to one's thoughts and goals. It is this bi-directional process, in which cognitive states give rise to physical actions and vice-versa that THV is designed to demonstrate. As an embodied intervention, THV elicits movements (i.e., directed actions) from its players with the intent of influencing their cognitive processes in ways that fostering mathematical insights in support of the proof process. The action-based intervention from game play not only helps elucidate mathematical ideas for learners (Nathan, 2014; Walkington & Nathan, 2017) by engaging mathematically relevant simulations, but it also offers novel, embodied design opportunities for education researchers and practitioners.

In cases of collaborative gesture, *intersubjectivity* is a key determinant in the amount of collaboration and co-construction between actors. Figure 1 presents a 3D model of collaborative gesture ecology. As individuals collect into groups, intersubjectivity increases as group members echo, mirror, alternate and jointly gesture. Collaborative game play of THV can facilitate transduction to help students communicate their ideas about mathematics.

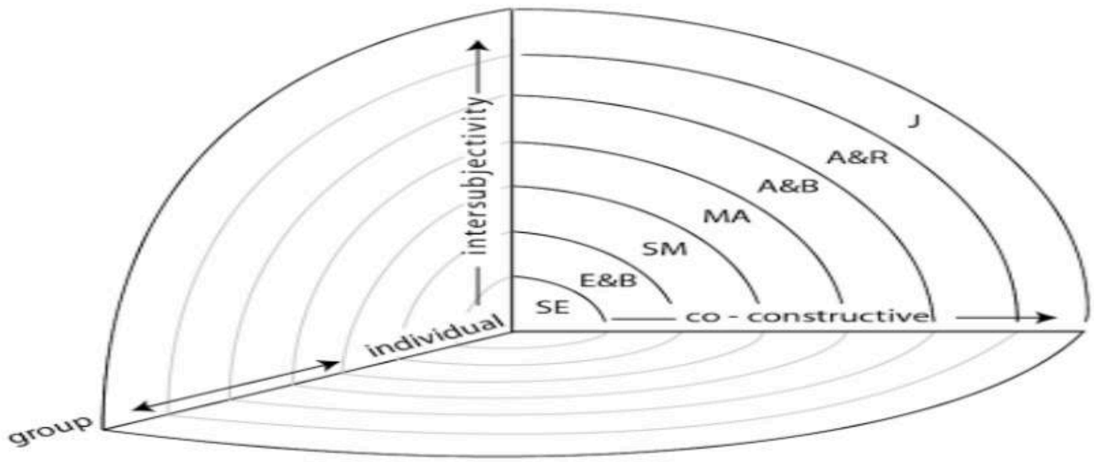

Figure 1: A 3D model of collaborative gesture ecology.

The Hidden Village

THV is a 3D motion-capture video game that delivers interactive math geometry curriculum in which each player mimics movements of in-game characters and then reads a geometry conjecture to determine if it always true or false. Each level of the game is comprised of 6 parts: Players meet members of the hidden village (Panel A), who implore players to perform movements (i.e., mathematically relevant directed actions detected by the MS Kinect; B). Next, players are given a math conjecture (C) and asked to indicate if the conjecture is true/false and why (D), followed by a multiple choice (E) and rewards and game achievement (F; *see* Figure 2).

Figure 2: The Hidden Village Game Play.

For example, in the triangle inequality conjecture (Figure 2, Panel C), a player will have performed the three movements (B) where they experience the arms extended laterally, then at an angle to the midline and then straight in front of the body. This series of movements is repeated 3 times. Next, they read the conjecture (C) and are prompted for an explanation (D). It is here that we video record their spontaneous representational and dynamic co-speech gestures that are hypothesized to contribute to their intuitions, insights and proof production. Then, players choose from among 4 multiple choices (E) before being rewarded by exposing a new portion of the Hidden Village map, a symbol, and energy strings to help power the ship (F).

Methods

Participants and Procedure

Over two days, we observed eight students in an all-LEP (Limited English Proficiency) Title 1 high school geometry classroom as they played THV v.5. Students' languages and ethnicities included Spanish from Central and South America, Arabic and French from North Africa, Hmong from Southeast Asia, and Chinese. Players were grouped as yoked pairs, alternating playing THV and observing game play of their partner.

Coding. Gameplay was audio and video recorded. The video clips were coded for whether participants made individual and collaborative gestures while validating the conjectures. Collaborative gestures were then coded by types identified by prior research (Walkington et al., 2019): echo, mirror, alternate, and joint (*see* Table 1).

Cases of Collaborative Gesture

Students, in light of the variability in English proficiency, dealt with the delivery of the game narrative, instructions, and mathematics in many ways, some unanticipated. In particular, many of the students used their bodies, objects in the room, and the bodies of other students to reason mathematically and formulate their justifications and proofs. To address comprehension and language production challenges, some students turned the dyadic game play into a collective activity where students contributed to each other's successful game play. They translated narratives and conjectures for each other and used directed actions to clarify and ground the math. Gestures traveled from the game to students and then crossed into different student groups as the movements simulated their mathematical ideas.

In this first transcript (*see* Figure 3), the students address the geometry conjecture: *The sum of the lengths of two sides of a triangle is always greater than the length of the third side*. In Figure 3 (below), students (S) engage in a discussion that leads to a series of collaborative gestures (panels A – F). Student 1 (S1, standing), turns to his partner, S2, to discuss the validity of the statement. S1 (*right*) listens to S2 (*left)* and *mirrors* (C) his gesture and then *builds* on the idea (D) in which S1 *anticipates* S2's gesture (E) before finishing *building* his explanation (F).

Figure 3: Embodied Collaboration – Mirror, Alternate and Build Gesturing.

S2: What are you doing? [Giggling]
S2: The sum of the length of two sides of a triangle is always greater than the lengths of the third side.
S1: The sum of the lengths of two sides of a triangle is greater than the length of the third side... No?
S2: Yes, because like the hypotenuse is the like, the greater one.

S1: Oh, yea, yea, yea.
S2: But if they add the other, the other side, then...
S1: The sum of the opposite angles...yea, so it is true.

In this next transcript (*see* Figure 4), S1 (*left*) and S2 consider the false conjecture: *If you double the length and width of any rectangle, then you exactly double the area*. S2 (a student from West Africa) explains the "doubling" of the sides to S1 (a student from Central America). S2's gestures extend a side (panel A), and S1 *echoes* the gesture (B). Then, S1 *builds* (C) upon the imaginary rectangle and that gesture is *echoed* by S2 (D), which is then *mirrored* by S1 (E), at which point they *alternate, build and redirect* gestures (F) as S1 gains insights about the relevant geometric relations.

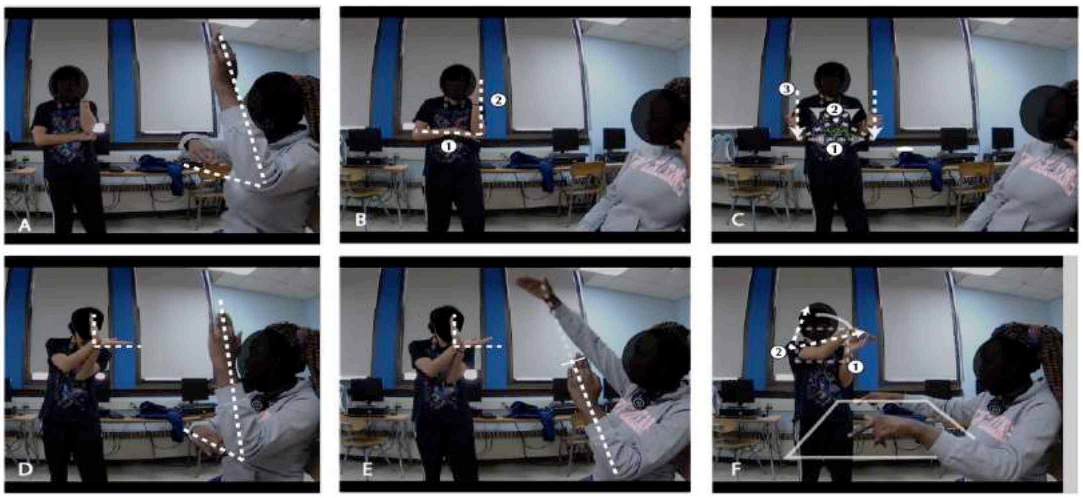

Figure 4: Embodied Collaboration – Echo, Mirror, Build, Alternate & Redirect Gesturing.

S1: So, the width of the rectangle... the area is...
S2: They, they multiplied it by 2 like if... if the length...
S1: So does it, does it have like, like this part?
S2: Let me show you the length – If the length was three
S1: Yeah
S2: They add another 3 and that becomes 6... If this one was 2, they add another 2 and that becomes 4.
S1: Oh...
S2: And they asking if the area, the area is like, like if that was a rectangle, the area is here, what is inside the rectangle?
S1: The angle?
S2: They asking if that would double, like if you...
S1: So... [Giggling]

In the final series (*see* Figure 5), S2 (*right*) asks for help translating words into Spanish and beckons S3 (*left*) over to interpret S1 (*center,* panel A). S3 translates S2's words in Spanish while *echoing* and *mirroring* the arm shape used by S3 (B & C) and replies "*Todo todo todo*" to S2 while adding several small circular motions between them (D). At this point, S3 *mirrors* S1's gestures (E) and then they gesture *jointly* (E) as they use a mutually shared discourse space. Finally, their discussion culminates in their convergence over a nearby tabletop to offload their ideas onto a workspace (F).

Figure 5: Embodied Communication – Echo, Mirror & Joint Gesturing.

S2: [Calls out to other Spanish speaking student for assistance]
S2: [to S3], can you explain to [S1] in Spanish what I mean? That, they double?
S3: Yea… What did it say?
S2: Like, here, this question, they double the length, and they double the, I don't know how to read in English...
S3: Oh.
S2: We talked about it... the width... [S1 and S2 engage in discussion in Spanish (Panels B – F)]

A Game for Collaborative Embodied Co-Creation

In effect, the students' collaborative co-constructive discussions while playing the original 8 conjectures in THV highlighted how varying levels of intersubjectivity combine to surpass language barriers and clarify concepts. Observations of students playing THV proved valuable for informing a redesign of THV. We learned that students may come up with novel movements that will help them understand the mathematical relations more clearly. Based on our observations, in the latest build of THV, students and teachers can now co-create the game characters' movements as ways to foster their own mathematical sensemaking and support the geometric reasoning of their classmates.

The conjecture editor allows players to co-create new levels of the game, including adding new conjectures and multiple-choice responses (*see* Figure 6). This content is stored and accessed via an external online database that allows users to share and play one another's content to support further collaborative, creative play, and learning. Additionally, players can collaboratively co-create new directed actions for a new conjecture using the Pose Editor (Figure 7), which is how THV "learns" to recognize new, user-generated poses. The process of creating and assigning movements is expected to deepen students' understanding of the embodied basis of geometric relations. When forming new poses (see Figure 7), each directed movement is comprised of 2-3 poses (starting, intermediate, and the target) that players design by posing the figure using pivots in the elbows and wrists. Once an individual pose is complete, players confirm or reset the figure. Once players have created all the poses (1), they can preview the sequence of directed action movements (2) in the form of a short GIF-like movie. Then can then set the matching tolerances (3) (i.e., % of allowable error for motion capture detection).

Figure 6: THV v.6 Conjecture Editor. Allows students to author their own content, including designing their own directed actions. Creating a New Conjecture (1) opens the Edit Conjecture (2) portal, where players name their team, name their conjecture, enter keywords, create a PIN, design a new icon, publish the conjecture to the online database repository, create their own directed actions, write the conjecture and devise 4 multiple choices for players to choose from and indicate which is correct.

A study that is currently underway in a set of ethnically and linguistically diverse, mixed ability high school geometry classes will assess how authoring conjectures and poses (i.e., directed actions) contributes to student learning. We hypothesize students making new content for the game will think, act, and talk through the ways that directed actions can foster mathematical insights and proof performance.

Figure 7: THV v.6 Pose Editor. The figure's limbs are posable via mouse movement. Figure can be rotated using a right-click drag or can be reset back to its origin (4). Being able to rotate the figure proved a critical for properly designing 3D directed actions.

Once students or teachers have created a collection of conjectures, they can cluster conjectures together in a game module (currently up to 8 maximum) for others to play (*see* Figure 8). Users can download individual conjectures or entire modules for their own use. As a tool for teaching, learning, and research, the conjectures within a module can be mixed and matched from any of the conjectures in the searchable database. Moreover, the module editor also allows the creator to customize a set of features for the module (e.g., offer hints, change the number of repetitions of the directed movements, etc.). This flexibility allows teachers to contour the game experience for their students. It also makes THV a flexible research tool. By making each feature of the game an option, investigators can create parallel versions of THV that only vary by a single variable, which is ideal for randomized controlled trials.

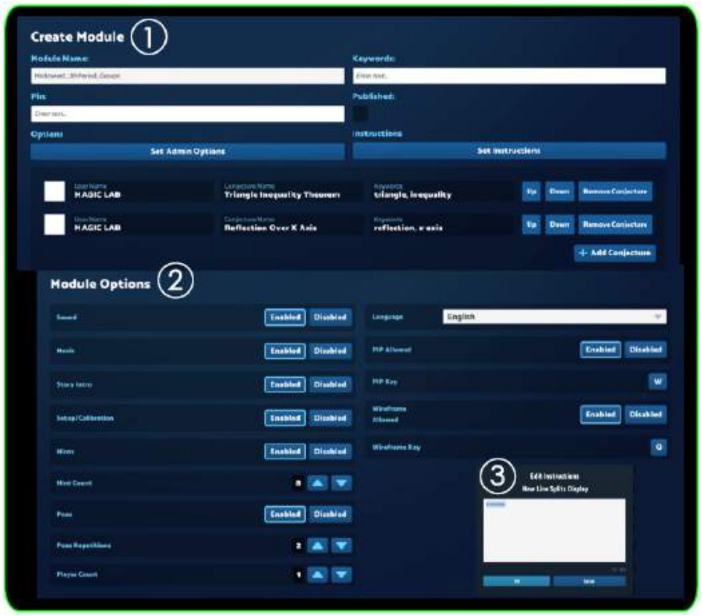

Figure 8: THV v.6 Module Editor. (1) Create a module, name the module, set the pin, customize the module (2) including: turning sounds, music, story, calibrations, hints, poses, number of players, language preferences, and scaffolding features. Players can add keywords (for easier search), publish to the database, and customize player instructions.

Discussion

Embodied principles of learning environment design offer some new opportunities for advancing students' mathematical reasoning. Embodied forms of reasoning offer a kind of Rosetta Stone that can bridge language barriers while supporting deep insights about the generalizable properties of space and shape. The co-construction of directed movements also allow students and teachers to institute more intuitive ways of embodying these mathematical ideas. The emergence of students' collaborative co-constructions inspired insightful ontological innovations in the redesign of THV. Our most proximate future goal is to elucidate how movements can embody spatial relations and transformations in geometry while empowering students to comfortably create their own content and instill confidence for deep, creative mathematics discourse. While THV currently focuses on high school geometry, the platform is applicable to other areas of mathematics that engage body-based forms of reasoning via simulation and metaphor (Lakoff & Núñez, 2000) as a path toward meaningful mathematical reasoning.

RANKING THE COGNITIVE DEMAND OF FRACTIONS TASKS

Sarah Kerrigan
Virginia Tech
stk123@vt.edu

Anderson Norton
Virginia Tech
norton3@vt.edu

Catherine Ulrich
Virginia Tech
ulrich@vt.edu

We report on and validate a system for ranking the cognitive demand of mathematical tasks. In our framework, task rankings are determined by the sequences of units and unit transformations students might use to solve each task. Using this framework, we ranked a set of 10 fractions tasks. We then interviewed 12 pre-service teachers to assess the validity of the ranking system. Results validate the task ranking system by demonstrating that increases in task ranking predict increases in the cognitive demand experienced by the pre-service teachers, as evidenced by their responses to the tasks. These results hold implications for instruction that maintains appropriate cognitive demand and future research that models students' mathematics.

Keywords: Cognition; Learning Theory, Number Concepts and Operations; Problem Solving.

In mathematics education, the cognitive demand of mathematical tasks has been categorized in terms of qualitative distinctions, such as procedures without connections and doing mathematics (e.g. Stein, Grover, Henningsen., 1996). In cognitive psychology, cognitive demand is quantified in terms of the number of action schemes a student might need to hold in mind in order to solve the task (Pascual-Leone, 1970). Here, we present a framework that accounts for the cognitive demand of mathematical tasks in terms of the sequences of units and unit transformations students might use to solve fractions tasks. Our framework integrates the math-specific construct of units coordination with the general cognitive construct of working memory.

The purpose of this study is to test a task ranking system based on our integrated framework. This purpose addresses one the major goals of PME-NA, "to further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof." We created task rankings based on the hypothesis that longer sequences of units/transformations would induce higher cognitive demand. To test the hypothesis, we applied a simple statistical test from 12 pre-service teachers' (PSTs) responses to 10 ranked fractions tasks. Results confirm that the task's rank predicts the cognitive demand experienced by PSTs, as evidenced by their behavioral (including verbal) responses to the task. Thus, our results validate the task ranking system and its underlying framework.

Theoretical Framework

Piaget characterized mathematics as a coordination of mental actions (e.g. Beth & Piaget, 1966). Mathematics educators who have adopted Piagetian perspectives on mathematical learning have attempted to account for the actions students rely upon to construct mathematical concepts (Simon, Placa, Avitzur, & Kara, 2018; Tzur & Simon, 2004). We are particularly concerned with the mental actions students use to construct and transform units.

Steffe (1992) originally defined units coordination as the distribution of one composite unit (a unit containing units of 1) across each of the units in another composite unit. For example, a student might conceptualize the product 5 times 7 as the distribution of seven units of 1 within each of five units of 1, simultaneously producing five 7s and 35 1s. However, units coordination can be understood more broadly as any coordination of mental actions used to construct or transform units. For example, the unit fraction 1/5 might be constructed by partitioning a whole into five parts; conversely, iterating one of those parts five times reproduces the whole. The coordination of this partitioning action and the corresponding iterating action establish 1/5 as a one-to-five relationship between the unit fraction and the whole (Wilkins & Norton, 2011)

Research on students' mathematics has identified several mental actions that undergird their fractions knowledge (Hackenberg & Tillema, 2009; Steffe & Olive, 2010; Ron Tzur, 1999; Boyce & Norton, 2016; Wilkins & Norton, 2011). In addition to partitioning and iterating, these mental actions include unitizing, disembedding, and distributing, as summarized in Table 1.

Table 1: Mental actions for constructing and transforming

Mental Action	Description	Fractions Example
Unitizing (U_n)	Taking a collection of n items or units, or a continuous span of attention, as a whole unit	Treating a rectangular bar as a whole unit, of 1
Iterating (I_n)	Making *n* identical, connected copies of a unit to form a new unit	Iterating 1/7 of a whole three times to produce 3/7 of the bar
Partitioning (P_n)	Creating *n* equal parts within a whole	Partitioning a whole bar into 15 equal parts
Disembedding (D_n)	Taking *n* parts out of a whole while maintaining their inclusion as part of the whole	Taking one part from a whole that has been partitioned into 9 parts, to make 1/9
Distributing ($T_{m:n}$)	Inserting the *m* units of one composite unit into each of the *n* units in another composite unit to produce a unit of units of units	Inserting three parts within each of the nine parts in 9/9 to make 27 parts in the whole

Working memory is a limited cognitive resource with special relevance in solving mathematical tasks (Bull & Lee, 2014; Swanson & Beebe-Frankenberger, 2004). Here, we adopt Pascual-Leone's definition: "working memory involves the process of holding information in an active state and manipulating it until a goal is reached" (Agostino, Johnson, & Pascual-Leone, 2010, p. 62). In our framing, in the context of solving fractions tasks, working memory involves holding in mind sequences of mental actions used to construct and transform units.

Methods

Task Ranking

We chose to focus on fractions tasks because of the wealth of literature on students' development of fractions knowledge and the mental actions that undergird that knowledge (Boyce & Norton, 2016; Hackenberg & Tillema, 2009; Steffe & Olive, 2010). The literature identifies unitizing, partitioning, iterating, distributing and disembedding as mental actions potentially available to students in solving fraction tasks. We used these five actions along with three types of units (whole units, composite units, and fractional units) as the atoms of fractions knowledge. The fraction tasks we used were modified from Hackenberg and Tillema's (2009) work. We report on a subset of 10 fraction tasks we ranked, listed in Table 2.

In order to determine how cognitively demanding a task might be for a student, we examined results from the literature that reported on students' prior responses. The literature we chose, and Hackenberg & Tillema (2009) in particular, included detailed accounts for the schemes and mental actions students seemed to use in solving the tasks. However, in some cases, we had to break down schemes and advanced ways of operating into the aforementioned atoms—simpler units and actions that undergird students' fractions knowledge. That is, we hypothesized potential solution paths for mathematical tasks using one unit/action at a time, without chunking them into larger structures, such as schemes.

Table 2: Fractions tasks

Task	Rank	Description
3	5	Imagine a cake that is cut into 13 equal pieces. You take 4 pieces. So, how much of the whole cake do you have?
4	7	Imagine you have 1/7 of a whole candy bar. So, could you use that to figure out how long 3/7 of the whole candy bar would be?
5	8	Imagine this [drawing a rectangle] is 5/9 of a whole candy bar. So, how could you make 1/9 of the whole candy bar from what you have?
6	10	Imagine a rectangular cake that is cut into 15 equal pieces. You decide to share your piece of cake fairly with one other person. So, how much of the whole cake would that person get?
7	10	Imagine you share a sub sandwich fairly among 17 people. Now each person shares their piece with two other people (three people total share each piece). So, could you figure out how much one little piece is of the whole sandwich?
8	12	Imagine you are at a party and a cake is cut into nine equal pieces. Two people show up to the party late and you decide to share your piece of cake with them. So, what fraction of the whole cake do the latecomers get together?
9	12	Imagine cutting off 2/5 of 1/3 of a cake. So, how much is that of the whole cake?
10	14	Imagine cutting off 1/4 of 5/6 of a cake. So, how much is that of the whole cake?
11	16/17	Imagine, you need 1/3 of a pound of sugar and all you have are bags of sugar that are 1/7 of a pound. So, how many 1/7 bags do you need?
12	16	Imagine I have 7/9 of a yard of ribbon, but every ninth it changes colors. My friend needs 2/3 of what I have, and she wants all of the colors. So, tell how much of a yard she has.

For example, consider Task 8. To solve this task, a student might start with the whole cake ($whole_1$) and partition it (P_9) into nine pieces (9), then disembed one of those pieces (D_1) to make their piece of cake ($whole_2$). The student could then partition (P_3) that piece into three pieces (3) and disembed one (D_1) of those to make a new piece ($whole_3$). Knowing two pieces are needed, the student could iterate that piece twice (I_2). The student still needs to name the fractional size of the small piece. To generate the relationship between the original whole cake and the small piece, the student could iterate (I_{27}) the small piece to exhaust the original whole. This process is captured in the graph shown in Figure 1. We refer to such graphs as unit transformation graphs.

Since our theory assumes that units and actions count towards the cognitive demand a student experiences when solving a task, both were counted when determining the rank of a task. This total sum of units and actions enumerated the cognitive demand of the task. In the unit transformation graph for Task 8 (Figure 1) there are six units (denoted by circles) and six mental actions (denoted by arrows), together giving a task demand of 12. All tasks were ranked using this same process and the ranks are reported in Table 2. Once all the tasks were ranked, we tested our theoretical ranking system through empirical evidence.

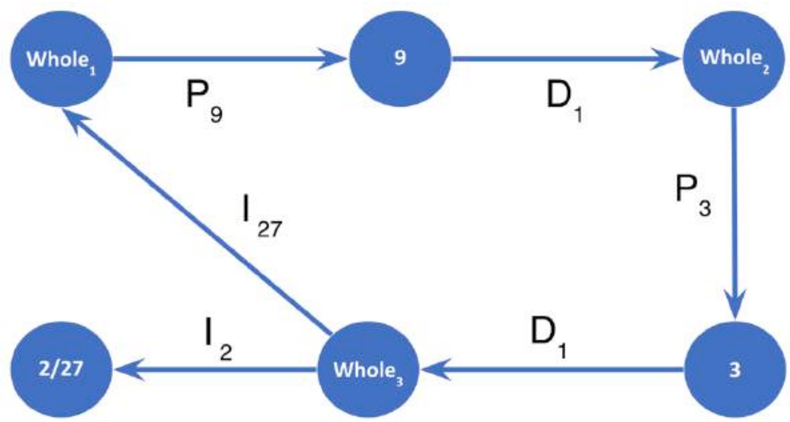

Figure 1: Graph of units and actions for Task 8

Data Collection

Participants were recruited from two sections of a mathematics for elementary school teachers content course taught by the same instructor at a large university in the mid-Atlantic United States. PSTs were selected for this study because they engage in metacognitive skills that enable them to express their thinking well; they commonly practice explaining their mathematics in the mathematics for elementary school teachers course. Moreover, they are mathematically mature enough to have constructed the mental actions required to productively engage with fraction tasks.

Twelve PSTs volunteered to participate in a 75-minute semi-structured clinical interview (Goldin, 2000). Each interview consisted of three parts: a units coordination assessment (Norton et. al, 2015), a working memory assessment (Morra, 1994), and a set of fraction tasks. This paper focuses on the final component of the interview. The PSTs were given the fraction tasks verbally one at a time and asked to solve them, initially without using figurative material. Sometimes follow-up questions were asked to probe a PST's thinking; sometimes PSTs were encouraged to use drawing to support their solution. A subset of tasks from Table 2 was selected for each PST, depending on our assessment of that PST's units coordinating ability and working memory. The tasks were always given in increasing order (top to bottom in Table 2), posing lower ranked tasks before higher ranked tasks. Each interview was video recorded with any written work collected using a Livescribe pen and notebook. The videos were selectively transcribed.

Data Analysis

Data analysis for this report consisted of two phases: coding for cognitive demand the PSTs experienced and a quantitative analysis of the task ranking system from the results of the coded cognitive demand.

Coding cognitive demand. Videos were analyzed for the purpose of coding the cognitive demand of each task, as experienced by each PST. We relied on video recorded behavioral data (including verbalizations) as indicators of this experienced demand.

Videos were analyzed one PST at a time with at least two of the three authors present. Experienced cognitive demand was coded as Low, High, or Over. The Low code was given when the PST was able to solve the task easily and confidently. Behavioral indicators included relaxed posture, providing an answer without verbal rehearsal or giving a fluent rehearsal of solution strategy. When a PST struggled but still had success engaging with the task, we assigned a High code. Behavioral indicators for a High code included asking for the question to be repeated during the solution process, expressing doubt throughout the task, unsure or repeated rehearsal needed to convince themselves of the task solution, and losing track of units during the solution process. The Over code meant that the

PST clearly was unable to assimilate the task or unable to resolve it without significant support from the interviewer or figurative material. This code often provided the easiest behavioral indicators with participants saying things like "Ah, it's just hard to do it in my head. Umm…" or "my brain is confused now."

The following pair of transcripts, from PST G provide an example of the difference between a Low code and a High code. The first transcript is for Task 6 (rank 10), and the second is for Task 8 (rank 12). In her response to Task 6, we see that PST G is quickly successful in solving the task with minimal rehearsal needed. Indeed, she seemed to have an answer ready (one-thirtieth) before saying anything, so that her verbalizations served as explanations to the researcher, rather than a necessary process in generating a solution to the task. The verbal run through of her solution process was succinct and confident.

Researcher: This is the next task [Task 6]. Imagine a rectangular cake that is cut into fifteen equal pieces. You decide to share your piece of cake fairly with one other person. So, how much of the whole cake would that person get?

PST G: [pauses for seven seconds and looks up.] You get one fifteenth of the cake and split that in half. My first thought was one-thirtieth…Of the cake, because…[makes splitting motion with hands in the air.] Splitting that in half, like if you were to split every piece of fifteen in half, then that would be like one thirtieth of the entire cake.

In comparison to Task 6, Task 8 seemed to induce additional cognitive demands for PST G, who required verbal rehearsal of her thought process to determine the answer to this new task. While she was successful in the end, throughout the solution processes there were several times she expressed doubt about a step or result. She would say things like, "Wait, that doesn't seem right," and "I don't know if that'd give you the same answer." She was eventually able to be successful on this task after attempting it twice. The fact that she was able to work through and solve the task despite some expressed doubt meant it did not qualify for an Over coding. However, Task 8 appeared to require substantial mental effort to produce a correct solution, indicating demand was High.

PST G: So, it's split up into nine equal pieces. So, then, you would split one ninth into…Two people come, but you still have a little bit? So, that… So, you would split that up into three. So, then I… Well, I guess you would do one ninth times two thirds to get how much they equal, like how much both their pieces would be. And then whatever that is, I guess it would be… two over… two eighteenths? Wait, that doesn't seem right. [pauses for five seconds] I feel like… I mean, I guess… You take those nine pieces, splitting that one ninth into thirds. But to find out how much two of those thirds are, you'd multiply one ninth by two thirds… Or no. You'd… you'd multiply the one ninth by one third, and then just do that twice? I don't know if that'd give you the same answer.

Researcher: Okay. Uh, let's… Maybe I can help you.

PST G: Okay.

Researcher: If you want me to be your calculator again, I'll do it.

PST G: [begins to draw on table with finger] So, you do one ninth, which divided by three, so you could times it by one third. So, then you'd have one over um… [pauses for five seconds.] Oh wait… [whispers to self] Three times nine, that's twenty-seven. Oh no, one over twenty-seven. And then you multiply that by two… to get two-thirds or to get two parts of the thing… So, then I guess… What's one over twenty-seven times two? Is that just two-twenty-sevenths? Okay.

Researcher: Nice, I like the way you reasoned through it. Yeah.

PST G: Okay. I was like, because I was thinking one over twenty-seven times two over one and I was like I guess that's just two, twenty-sevenths.

Quantitative analysis. The variable we measured was cognitive demand. This ordinal categorical data was coded as Low, High, and Over as described above. To test whether the task ranking system was valid, we only considered instances where a PST experienced a change in cognitive demand between two successive and differently ranked tasks. We excluded any cases where the same cognitive demand was experienced on successive tasks and instances where the demand changed within the same ranked task. For example, if Task 6 (rank 10) was coded as High but Task 7 (rank 10) was coded as Low, we did not count this as a trial. In fact, such instances were common and expected because PSTs might rely on their solution to the first task within a given rank to facilitate their solution to the second task of that rank. After excluding these cases, we were left with 21 trials. The trials are labeled in Table 3 with the number placed in the cell of the higher ranked task where the change occurred. Since our theory assumes an increase in task ranking predicts an increase in experienced cognitive demand, we consider a successful trial to be one where the change in cognitive demand increased for successively given tasks of increasing rank. There are 18 successful trials. The three unsuccessful trials occurring with PSTs F, G, and J, denoted in Table 3 with an asterisk (Trials 7, 11, and 17).

To test the validity of the task ranking system, we asked the following: What is the probability of 18 successes in a sample of 21 trails if the chance of changed cognitive demand is 50%. To answer this question, we used a binomial test with a p-value of 0.05. We assume the independence of observation needed for a binomial test holds across PSTs since each was interviewed separately and any discussion of the interview between PST outside of the interview setting was negligible. We also assume the independence of observation holds within a PTS's interview because of the novelty of the tasks and the exclusion of same ranked tasks from the trials. We analyzed the data using Microsoft Excel (version 15.33).

Results

Table 3 illustrates the cognitive demand of tasks as experienced by each PST. Green indicates Low demand, yellow High, and red Over. Two pairs of tasks, 6-7 and 8-9, have the same rank; if a PST was given both tasks of the same rank, we only consider the first of the same ranked task given to eliminate familiarity with the task as a confounding variable of cognitive demand. At a glance, we can see that the predicted trend of increasing rank with increased cognitive demand did occur. There are three PSTs (F, G, and J) for whom this pattern did not strictly hold outside of same ranked tasks. For PST F, the codes followed the pattern of Over, High, then Over again. PST G had a High code after two Over codes. Lastly, PST J had one High code in the middle of two Low codes before getting coded as Over. We attribute PST F's deviation from the predicted pattern to her initial assimilation of fractions in an unconventional manner (e.g., assimilating "three-sevenths" as one-third of 1/7) before adjusting this understanding in subsequent tasks as parts out of wholes. The switch from Over to High that PST G experienced was a case of persistence in trying to solve a task as she made use of new strategies used on previous tasks. For PST J, she experienced a perturbation with her scheme for "one-ninth" in Task 5 that led to an Over code but was resolved for subsequent tasks.

Table 3: Summary of cognitive demand by task and PST

Task	Rank	A	B	C	D	E	F	G	H	I	J	K	L
12	16							11*		15			
11	16/17												
10	14						8	10	13			20	
9	12												
8	12			3		6	7*	9	12	14	18	19	21
7	10	1											
6	10		2		4	5					17*		

5	8										16		
4	7												
3	5												

With 18 successes out of 21 trials, and a probability of success for a single trial of 50%, we obtained a p-value of 0.0006. This statistical result validates the task ranking system. In particular, it supports the hypothesis that increased length in sequences of units/actions required to solve fractions tasks predicts cognitive demand, as experienced by the PSTs and evidenced by their behavioral responses to the tasks.

Discussion

In validating the task ranking system with a simple statistical test, we have affirmed the hypothesis that informed it. In turn, the affirmation of this hypothesis demonstrates the utility of our framework—a framework that integrates the psychological construct of working memory (Pascual-Leone, 1970) with the mathematics education construct of units coordination (Steffe, 1992). Furthermore, it supports the Piagetian perspective of mathematics as a coordination of actions (Beth & Piaget, 1966), while recognizing students' mental actions as the source of their own mathematical power.

Other mathematics education studies have addressed cognitive demand (e.g., Stein, Grover, Henningsen, 1996) or have identified how students might rely on sequences of mental actions to solve mathematical tasks (Simon, Placa, Avitzur, & Kara, 2018; R. Tzur & Simon, 2004). We used unit transformation graphs to account for both: mental actions constitute the atoms of students' mathematical knowledge, as represented by the circles (unit constructions) and arrows (unit transformations) in our graphs. We enumerated cognitive demand by the number of circles and arrows in each graph. Although this characterization of cognitive demand aligns best with the psychological construct of working memory, it also relates to Stein and colleagues' (1996) categorization.

Stein and colleagues were especially concerned with maintaining high cognitive demand of instructional tasks, where high demand referred to aspirations of engaging their students in "procedures with connections" and "doing mathematics" (Boston & Smith, 2009; Stein et al., 1996). Unit transformation graphs might support such aspirational goals by informing teachers of ways they can help students manage the demands of mathematical tasks without reducing them to the lower categories of "memorization" or "procedures without connections." Within our framework, maintaining such demand would involve facilitating students' coordination of the mental actions involved in a task's solution by providing appropriate figurative supports, such as manipulatives and opportunities for student drawings. Such supports could allow students to offload demands on working memory, especially in long sequences of units/actions, without eliminating the demand for their coordination (cf., Costa et al., 2011).

Prior research has highlighted additional factors that contribute to cognitive demand. For example, Pajares (1994) demonstrated that self-efficacy and math anxiety can moderate the cognitive demands that students experience in response to mathematical tasks. Although we did not take such factors into account in our study, the complexities of teaching necessitate that teachers do. We recognize these complexities and intend unit transformation graphs as a tool teachers and researchers might use to manage them.

Ultimately, we see unit transformation graphs as a means of recognizing and empowering students' mathematics by explicitly accounting for their available mental actions and coordinations thereof. We might expand the program by relying on research that identifies students' mental actions in other domains of mathematics, such as algebra (e.g., Lee & Hackenberg, 2014) and covariation (e.g., Carlson et al., 2002).

Acknowledgments

We thank the Adaptive Brain & Behavior Destination Area at Virginia Tech for their support of this research. We also thank undergraduate researcher, Rachael Stryker, for her contributions to the project.

Incorporating video case study of mathematics teaching into professional development (PD) can provide opportunities for teachers to develop new ways of seeing teaching and learning and inform efforts to enact new instructional practices. However, more research is needed to understand how such PD can foster sustained teacher learning about high-quality instruction and materials. In this paper, we share the evolution of our analytic method that aims to reveal how secondary mathematics teachers learn while collectively analyzing video of mathematics teaching. We found that conceptualizing this PD within a community of practice, along with applying analytic tools from frame analysis and professional noticing, helped us recognize and describe the process of teacher learning in this setting. We plan to apply our analytic method to our full dataset to better understand how teacher learning in this context is happening over time.

Keywords: Teacher Education - Inservice / Professional Development, Teacher Knowledge, Research Methods

Teaching is a dynamic endeavor for each teacher; no two learning environments are identical. Each classroom is shaped by teacher and student interactions, including teachers' interpretations of and responses to students' thinking and problem-solving strategies. Teachers' decision making during these interactions provide opportunities for students to develop as problem solvers and effect mathematical thinkers (Schoenfeld, 2017). As educators, we can learn from classroom interactions, personal reflections, and collaborations with others in order to improve our own practice. Analyzing video case studies of mathematics teaching "can help [teachers] develop new ways of seeing teaching and learning and support their efforts to enact new instructional practices" (van Es & Sherin, 2017, p. 1).

However, teachers' opportunities to systematically develop and share ideas about teaching are limited (Ball, Ben-Peretz, & Cohen, 2014). Professional development (PD) has been shown to be key in supporting instructional shifts that deepen students' learning opportunities (Desimone, 2009). In our research, we designed a model of video-based PD for our work within professional learning teams (PLTs) of secondary mathematics teachers, bringing teachers together to collaboratively investigate video of mathematics teaching. One important aspect of our PD model is that it is grounded in the Teaching for Robust Understanding framework (TRU; Schoenfeld, 2017). The TRU framework details dimensions of high-quality instruction that support deep mathematical learning opportunities for students. Our goal is to understand (a) how discussions and activities used in the PD support teacher learning, and (b) the extent of teacher learning about high-quality instruction and instructional materials that can be used within mathematics classrooms.

Submitted to the Theory and Research Methods strand of PME-NA, this proposal describes the analysis process for the NSF-funded project *Analyzing Instruction in Mathematics using the Teaching for Robust Understanding Framework* (project number 1908319), or AIM-TRU. The project team consists of a research group of practitioners and mathematics teacher educators analyzing PLTs' investigation of video cases. Through our analysis process, we aim to demonstrate how our PD model can foster sustained teacher learning about high-quality instruction that contributes to shared professional knowledge across a diversity of school settings. As we worked to understand the impact of our PD model on teacher learning, we drew from and expanded on a collection of complementary conceptual and analytic perspectives, including communities of practice, frame analysis, and professional noticing. Thus, the purpose of this proposal is to share our analytic method and illustrate how we have been using it to understand how teachers learn in a community of practice as they collectively analyze video case materials.

Conceptual and Analytic Perspectives

Our conceptual model relies on understanding learning within a community of practice (CoP; Wenger, 1998). To understand learning in a CoP, we incorporate analytic tools from frame analysis (Bannister, 2015) and apply constructs from professional noticing (Jacobs, Lamb, & Philipp, 2010). In this section we describe each of these frameworks to articulate our process of investigating teacher learning within professional learning teams.

Communities of Practice

Wenger (1998) claims that people learn through their participation in specific communities, called communities of practice (CoPs), consisting of people with whom they interact regularly. CoPs are defined as groups whose members (a) are mutually engaged in an activity, such as analysis of video case studies of mathematics teaching; (b) are connected by a joint enterprise, such as fostering sustained teacher learning about high-quality instruction; and (c) have a shared repertoire of communal resources, such as the TRU framework.

According to Wenger (1998), communities of practice negotiate meaning collectively. This negotiation of meaning is represented by changes in participation which are reified to give form to the meaning through the three dimensions of the CoP outlined above. For our analytic process, we utilize frame analysis to identify these reified changes in participation, which manifest themselves as participants engage with "evolving forms of mutual engagement," "understanding and tuning their enterprise," and "developing their repertoire, styles, and discourses" (Wenger, 1998, p. 95). We consider changes within these three processes as evidence of learning within a CoP.

Frame Analysis

Bannister (2015) linked community participation with tools from frame analysis (Benford & Snow, 2000; Snow & Benford, 1988), to examine how teachers' participation patterns evolve around a community defined problem of practice (PoP). By employing the tools from frame analysis, Bannister sought to understand development within a group of teachers within common planning time to capture teachers' reification patterns and give insights related to member participation. The tools from framing analysis consist of framing tasks (Snow & Benford, 1988): diagnostic framing ("identification of a PoP and the attribution of blame" (p. 200)), prognostic framing ("a proposed solution to the diagnosed PoP that specifies what needs to be done" (p. 199)), and motivational framing ("a call to arms or rationale for engaging in ameliorative or corrective action" (p. 199)).

Bannister (2015) delineated the connections between the key concepts from frame analysis and processes of participation and reification in a CoP (see Figure 1). For example, a group of high school mathematics teachers (a CoP) collaborate weekly (shared repertoire) on developing interventions for struggling students (joint enterprise). As the teachers identify a PoP and specify possible causes (diagnostic framing), and discuss possible solutions (prognostic framing) by interacting each other and sharing their ideas (participation), the framings reify the community's ideas about who the struggling students are and what can be done to help them. Changes in framings within a community help to reify the changes in participation occurring within a CoP. These changes in participation and reification, are in turn, empirical evidence of learning occurring within a CoP.

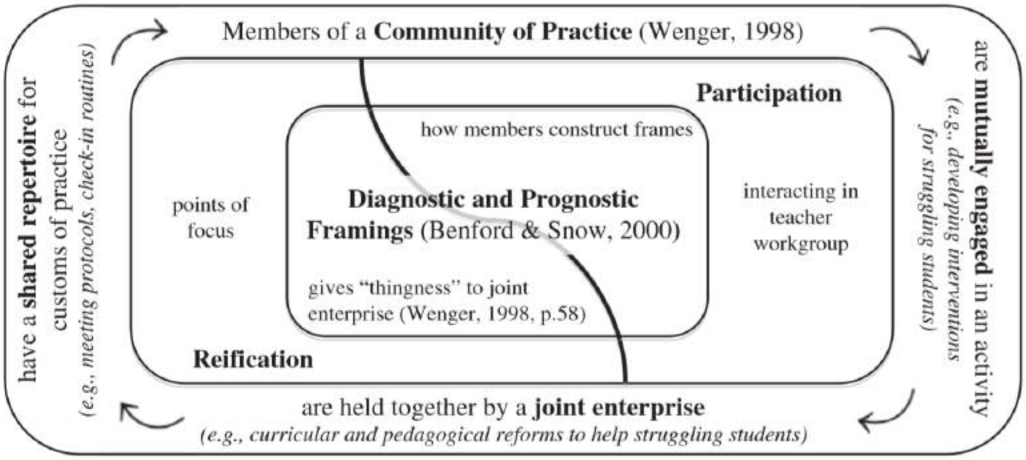

Figure 1: Connections between key ideas from communities of practice and frame analysis. (Bannister, 2015)

Professional Noticing of Children's Mathematical Thinking

To identify a PoP, we use the construct *professional noticing of children's mathematical thinking* to "begin to unpack in-the-moment decision making" (Jacobs et al., 2010, p. 173). Researchers argue that teachers need to first learn to productively attend to pertinent features of an instructional setting and be able to make mention of that which is noticed before they can make responsive instructional decisions (Jacobs et al., 2010; Superfine, Amador, & Bragelman, 2019). Thus, Jacobs et al. (2010) detail the components of professional noticing with three skills: "attending to children's strategies, interpreting children's understandings, and deciding how to respond on the basis of children's understandings" (p. 172). The premise of the framework indicates that in order for teachers to respond to student thinking, the other skills of attending and interpreting are occurring simultaneously to provide the teacher insight and knowledge about how to respond. Moreover, according to Thomas et al. (2015), anticipating how students might respond provides a firm basis of noticing. Therefore, the framework for professional noticing for children's mathematical thinking provides a foundation for us to apply frame analysis techniques to understand the ways in which teachers are learning within a CoP.

Methods

Participants

The participants of the study include eight practicing secondary mathematics teachers and two participant observers from the research team. The teachers volunteered to be part of a Professional Learning Team (PLT) with the goal of analyzing videos of mathematics classrooms to interrogate mathematics teaching and learning. Two of the eight participants are facilitators for the discussions; however, the two research members also engage and probe teacher thinking throughout the PLT meetings.

Context

Teacher participants who elected to participate in this PLT enrolled with the knowledge that they would be analyzing video case studies that are aligned with the TRU framework. Each set of video case materials utilized in PLT meetings was created to demonstrate a teacher implementing a formative assessment lesson (FAL) from the Mathematics Assessment Project. The Mathematics Assessment Project also uses the TRU framework as a way of characterizing powerful mathematics classrooms, defined by a focus on the mathematics, cognitive demand, equitable access to the mathematics, agency, ownership, & identity, and formative assessment (Schoenfeld, 2017). The TRU framework provides a necessary shared repertoire within the PLT for discussing the video case studies.

Participants attended four PLT meetings and analyzed three sets of video case materials. The first PLT session was used for teachers to better acquaint themselves with FALs and the TRU framework with the intent to build a shared repertoire among members. In the next three sessions the participants engaged in a guided analysis of video case materials. Each PLT meeting was two hours in length. The teachers engaged with mathematical content around applying properties of exponents and representing quadratic functions graphically. The facilitators followed a predetermined guide to keep each session consistent throughout the larger project.

Data Collection

Data was collected with the intent of understanding how teachers develop knowledge through engagement with the video case materials. The four PLT meetings were video recorded and each of the recordings were later transcribed to be analyzed. Materials from the PLTs were also collected to cross reference teacher conversation and build knowledge of their understanding. The materials include individual and group generated artifacts, solutions, and responses to question prompts.

Data Analysis

In order for us to understand changes in participation and reification within the CoP, we used frame analysis (Bannister, 2015) as an analytic tool. Our first level of analysis was to reduce the data into episodes of pedagogical reasoning (EPRs). Horn (2005) defines episodes of pedagogical reasoning as

> units of teacher-to-teacher talk where teachers exhibit their reasoning about an issue in their practice. …EPRs are moments in teachers' interaction where they describe issues in or raise questions about teaching practice that are accompanied by some elaboration of reasons, explanations, or justifications. These episodes can be individual, single-turn utterances, such as "I'm not using that worksheet because it bores the kids." Alternatively, these can be multiparty coconstructions over many turns of talk. (p. 215)

Using an EPR as our unit of analysis, we were able to systematically investigate teacher discussions. After collectively identifying each EPR, we analyzed the EPRs to determine what teachers were talking about and the nature by which they were having discussions.

After separating EPRs, we created descriptions or themes to characterize the essence of the conversation. These descriptions detail what the teachers were discussing. For example, two of our identified themes were *understanding one method of student strategies* and *using calculators to evaluate vs. expanding*. To apply frame analysis, we examined each EPR and the previously identified theme to determine the PoP which grounded the teachers' conversations. The PoP occurred when teachers identified an instance as troublesome, challenging, recurrent, unexpectedly interesting, or otherwise worthy of comment (Horn & Little, 2010); they are issues of practice that teachers encounter regularly. We identified the PoP through either explicit mentioning from participants or through prior participation or discussion. While we were stating the PoP in each EPR, we began to discover repetitive language emerging as we defined the PoPs. Therefore, we began to create descriptions of PoPs that could be used across the PoPs and revisited each previously analyzed EPRs to determine if they would also have our newly defined PoP. For example, we analyzed the two EPRs with different themes, labeled above, and determined that in both cases the PoP was *teachers anticipating student solution strategies.*

After identifying the PoP, we analyzed each EPR to understand the nature of the conversation through frame analysis. Incorporating the literature, we organized the definitions of framing tasks as detailed in Table 1.

Table 1: Definitions of Framing Tasks

Framing Task	Definition
Diagnostic Framing	Diagnostic framing is when teachers diagnose a PoP and attribute causality for the problem.
Prognostic Framing	Prognostic framing is when teachers discuss a solution or possible solutions for a PoP diagnosed or implicit from earlier conversations. This implies attribution of causality and solution(s) for the problem.
Motivational Framing	The motivational framing is the rationale for engaging in a particular action to attend to a particular PoP. This rationale should be more than just mentioning what the teacher thinks will change but include justification for why the proposed action will create change. This implies attribution of causality, solution(s) for the problem, and a rationale for why a solution or solutions would actually work.

We described the diagnosis, the prognosis, and/or the motivation with each EPR. The descriptions were generated by using the teachers' exact words or by interpreting the nature of the teachers' conversation. In some EPRs, we saw a progression of conversation from diagnosing the PoP, to prognosing a hypothetical solution, to detailing their motivation behind their prognosis. However, other EPRs were limited to only diagnostic discussions where the teachers did not provide hypothetical solutions to their identified PoP.

During the analysis process, we began to see patterns in our identified PoP and considered layering frame analysis with an additional analytic framework that would help us better understand what the teachers were talking about before we determined how they were talking about it. Through discussions, we realized that the PoPs contained themes aligned to the professional noticing of children's mathematical thinking framework. As a team we revisited the definition of each PoP to align them with the framework as an object of focus for the community's participation and reification. Figure 2 indicates how we visualize the noticing framework inside of a CoP. What and how the teachers notice throughout their engagement with video case studies can be evidence of changes in participation and reification.

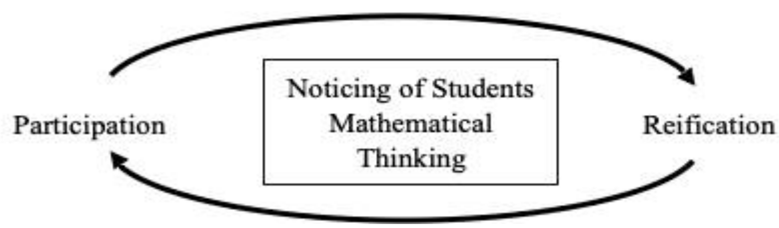

Figure 2: Noticing as a method to analyze changes in participation and reification.

Based on the professional noticing framework, to define our PoP, we categorized each EPRs' problem of practice as either attending, interpreting, or responding to student thinking. In our analysis, we also detailed the subject to what the teachers were either attending, interpreting, or responding. For example, the two EPRs, identified earlier regarding student solution strategies, were now coded as *Attending-Teachers anticipating student solution strategies*. However, using the definitions for attending, interpreting, and responding, we found some EPRs could not be characterized by one of these categories. In these instances, the teachers were not explicitly discussing students' mathematical thinking. However, because the context of their conversations is important for our larger research project, we categorized these as "other" and maintained the original description as the PoP.

Illustrative Example of our Analytic Method

In this section, we provide an illustrative example of our analytic method. We detail the processes of identifying an EPR and the PoP within the EPR, relating the PoP to the noticing framework, and identifying each EPR as a diagnostic, prognostic, and/or motivational frame.

For context, the participating teachers in this example were analyzing the video case of an Applying the Properties of Exponents FAL during the second PLT session (https://tle.soe.umich.edu/MFA/Applying_Properties_of_Exponents_1). While analyzing the video case, the teachers focused on a group of students discussing the problem $2^2 \div 2^3$. Two of the students in the group were trying to convince a third student how the properties of exponents could be used to simplify this expression. The following transcript is a teacher conversation in the PLT meeting about the situation in the FAL.

Louis: I think if I could rewind then ask a question, I might ask them or maybe prompt them
to do is maybe to think about it in terms of a different form. Because, from what I saw, it
was like a back and forth between computation and exponents. And I think if maybe the
students could maybe see it in the expanded form or another way it might, it might
prompt them to think about it in a different way.

Josh: Can I ask how you would go about doing that? Like, what would you ask them to
stimulate that conversation?

Louis: I think I would start at the beginning and I think it was where they were doing the
four divided by eight … it was two to the second divided by two to the third. That's what
it was. And that prompted them to do four divided by eight. And they got some, they got
some validation at the end, like he checked into the calculator and yes, in fact it was two
to the negative one power. So, I guess the question would be like, well why exactly does
that work? And then it would be, what's another way maybe we could write the initial
statement and then maybe that would help them along the way to the other ones.

Jackson: I agree. Have them write it in expanded form and then playing with it that way.

Lisa: I know for me, one of the things I would have, um, and I again, I don't know if this is
the right move, but being that it seems like the boy is a very visual person. Maybe he's
not really listening to these rules because he's not getting, he's not really seeing their
thinking. Uh, I know like I'm a very visual person. I need to see it written to really
understand it. So, I almost want to suggest to the girls like, can you just show, show him
what you're thinking? Can you show it on your whiteboards? And maybe then he'd have
like a better understanding for it.

We identified this teacher conversation as an EPR because it was an incident of teacher-to-teacher talk about a student who had not been building on other students' thinking or reasoning about $2^2 \div 2^3$ and were offering suggestions for improvement. We identified the PoP in this EPR as *providing opportunities to learn in different ways through multiple representations*. Evidence to support this description can be seen, in part, through one teacher's comment: "And then it would be, what's another way maybe we could write the initial statement and then maybe that would help them along the way to the other ones" (lines 13-14). Based on the professional noticing framework, we categorized the PoP as *responding to student thinking* because the teachers used what they learned about the student's understanding of the properties of exponents to pose hypothetical questions to students. As stated earlier, for teachers to respond to student thinking, they must first attend to student thinking. Evidence of teachers attending to student thinking occurs when Louis claims that he saw students using computation and expanding as methods of simplifying exponential functions (lines 2-4). We identified other hypothetical responses to student thinking by the teachers: Louis proposed probing student thinking by asking why their mathematics works (lines 12-14); Jackson suggests having students write the expressions in expanded form (line 15); and Lisa would ask students to make their thinking visible through the use of whiteboards (lines 20-22). In each of these instances, the teachers are sharing questions they would ask students in response to the analysis of their thinking.

We then analyzed the EPR to understand the nature of the conversation through frame analysis. The teachers diagnosed the PoP as *responding to student thinking: providing opportunities to learn in different ways through multiple representations*. They came to this diagnosis by focusing on one student who did not believe that one representation (the properties of exponents) was valid to illustrate the equivalence of expressions. The teachers' determination of the attribution for causality, or what caused the PoP in this EPR, was that the student did not build on other students' thinking. This is evidenced in Lisa's claim, "Maybe he's not really listening to these rules because he's not getting, he's not really *seeing* their thinking" (lines 17-19, emphasis added).

The teachers went on to provide a prognosis for this PoP. In this EPR, the teachers discussed prompting students to consider looking at the expanded form of $4 \div 8$ (line 9) written on the whiteboard (line 21) because it would be helpful for the student, who might be a visual learner, to see and understand the properties of exponents are valid to illustrate the equivalence of expressions. In the end, we coded this EPR as a motivational frame because the teachers went beyond the diagnosis and prognosis of the identified PoP by providing a rationale for their proposed action based on their assessment of the student appearing to be a visual learner (lines 17-22). The summary of our analysis for this illustrative example is organized and presented in Table 2.

Table 2: Sample Analysis

Category	Description
Problem of Practice	Providing opportunities to learn in different ways through multiple representations
Noticing Skill	Responding to student thinking
Diagnostic Framing	The student doesn't believe that one representation (properties of exponents) is valid.
Prognostic Framing	The teacher could prompt students to consider looking at the expanded form of expressions.
Motivational Framing	The student appears to be a visual learner, thus seeing expanded form might assist his belief in properties of exponents.

Discussion

Our analytic method stems from a need to understand how teachers learn in a CoP and, in turn, how to foster sustained teacher learning. In this paper, we elaborated how our analytic method is helpful to understand teacher learning within the PLT during their engagement with video cases. First, frame analysis enabled us to analyze what and how the teachers negotiated meaning in the PLT. Meanwhile, we saw that, during the teachers' interaction, they mostly talked about noticing their students' thinking. Thus, by adding the noticing framework to frame analysis, our team was able to categorize the PoPs in a consistent way. This consistent categorization of PoPs was beneficial to understand how the teachers could start to think about improving their own instruction. Taken together, within our analytic method, we combined frame analysis and professional noticing, which was conducive to our analysis of teacher conversations about FALs. Specifically, frame analysis played a major role while the noticing framework played a supporting role in our analysis process because we utilized the noticing framework after making use of frame analysis. If researchers or teacher educators apply the analytic method in their own context, it might be helpful to utilize an additional framework, like professional noticing, from the beginning of an analysis. By characterizing the PoP in a streamlined manner, patterns related to participation and reification will become more easily evident through analysis. Then, through analysis of the entire PLT data, using the identified PoPs, we will be able to discern if there are reified changes in participation.

Next Steps

In order to better understand teacher learning within PLTs of practitioners and mathematics teacher educators analyzing video cases, we first need to further investigate how teacher conversations and their framings are changing over time. These changes in frame will allow us to identify and describe the reified changes in participation that indicate learning in CoPs. Secondly, we need to look for patterns across EPRs in the remaining sessions of the PLT to verify that this analytic method is robust. Additionally, it will be necessary to determine how to interpret the EPRs we categorized as "other." Our initial understanding of this collection of EPRs is that they are about group dynamics or classroom norms. However, we will need to continue to look at this data, and the PLT sessions to find confirming or disconfirming evidence of this conjecture. Finally, future studies can build on our analytic method by connecting this data to the TRU framework in order to obtain a deeper understanding of our overall research questions around understanding (a) how discussions and activities support teacher learning and (b) the extent of teacher learning about high-quality instruction and instructional materials that can be used within mathematics classrooms.

We reflect on the limitations of our research group's prior methods for assessing covariational reasoning which primarily used graphical tasks found in extant literature. Graphical tasks dominate the literature on covariational reasoning, and through our use of these tasks we came to question the heavy reliance on them. Our concerns led us to ask the following: (1) What are the limitations of using tasks with graphs to assess covariational reasoning? (2) How can we improve assessment of covariational reasoning to accommodate students with nonnormative graphing schemes? We offer this piece as the beginning of a conversation to develop improved methodologies that attend to the ubiquity of students' nonnormative graphing schemes.

Keywords: Research Methods, Cognition, Precalculus, Calculus

The role of quantitative and covariational reasoning in the teaching and learning of mathematics has received increased attention in recent decades. Researchers have adopted numerous methodologies to investigate said reasoning, and, relatedly, they have developed a number of research-based tasks and instructional settings that afford such investigations. In our previous work, we drew connections between covariational reasoning and units coordination (Boyce et al., 2019). In this paper, we reflect on the relationships between our prior methods for assessing covariational reasoning, including how this influenced our data and claims regarding participants' maximum capacity to reason covariationally across settings. By sharing the analysis of our methods, we hope to spark a larger conversation that is important for a number of reasons.

First, reflection and review of research processes can refine our research and the quality of research in the field as a whole. Second, our research team consists of many newcomers to covariational reasoning research, including three first-year doctoral students—two of whom are the leading authors of this piece. This affords us the opportunity to start a dialogue between both novice and expert researchers concerning the interpretation and use of covariational reasoning frameworks in research. To further help facilitate such a conversation, we invited an expert on quantitative and covariational reasoning (the last author) to participate in crafting this paper. Third, in the sphere of covariational reasoning, there is a new generation of researchers who have started using the covariational reasoning frameworks that Thompson and Carlson (2017) developed over the past 30 years (Gonzalez, 2018; Stevens, 2019). By examining the evolution and contemporary usage of these frameworks, we can adopt a lens by which to identify previous works' contributions and limitations. Fourth, and most relevant to the present work, after reflecting on our methods we contend that extant

[1] Both leading authors contributed equally to the creation of this piece.

studies have often relied too heavily on graphical items to assess covariational reasoning. We offer specific suggestions on how to improve interview protocols to address this issue.

Previous Study Design and Current Research Questions

Our initial interview protocols for assessing a students' overall ability to reason covariationally were guided by Carlson and Thompson's work (Carlson et al., 2002; Thompson & Carlson, 2017), the Project Aspire covariation tasks (Thompson, 2016; Thompson et al., 2017), and the classic Bottle Problem (Swan, 1985). Project Aspire, led by Thompson, created a validated diagnostic assessment of secondary teachers' mathematical meanings. Their work included drafting a number of covariation items and then piloting them with teachers to determine the best items for reliably assessing covariational reasoning. While the initial covariation item pool included both graphical and non-graphical items, all non-graphical items were discarded for a variety of reasons. Because we drew inspiration from the Aspire instrument and Carlson et al.'s (2002) tasks, and the covariational reasoning literature sparingly highlights the importance of non-graphical tasks, it did not occur to us to include such tasks in our interview protocol.

While retrospectively analyzing our methods and resulting data, we hypothesized that assessing overall covariational reasoning with mostly graphical tasks limited our ability to model students' thinking. This hypothesis stemmed from our observation that some students correctly described relationships between two covarying quantities using words and gestures, but these same students failed to graphically convey their described relationships because of their nonnormative graphing schemes. In hindsight, it makes sense that graphical tasks have limitations given the growing body of evidence that a number of successful undergraduate students use nonnormative graphing schemes (Frank, 2017; Lee et al., 2019; Moore et al., 2019), which often involve meanings for graphs that do not entail covariational reasoning. Consequently, such student graphs do not provide data for a researcher to assess their covariational reasoning beyond an *in-the-moment* absence of it. Indeed, Saldanha and Thompson (1998) conveyed a similar sentiment when stating: "The results of this study lead us to believe that understanding graphs as representing a continuum of states of covarying quantities is nontrivial and should not be taken for granted" (p. 303). Building off Saldanha and Thompson's sentiment, recent researchers' characterizations of students' nonnormative graphing schemes, and our inference of a possible overreliance on graphing tasks to assess covariational reasoning both within and outside of our own work, we ask: (1) What are the limitations of using tasks with graphs to assess covariational reasoning? and (2) How can we improve assessment of covariational reasoning to accommodate students with nonnormative graphing schemes?

Theoretical Framework

Covariational Reasoning

Thompson's research in covariational reasoning stemmed from his interest in how "students conceive situations as composed of quantities and relationships among quantities whose values vary" (Thompson and Carlson, 2017, pp. 424–425). In Thompson's (2011) view, "Quantification is the process of conceptualizing an object and an attribute of it so that the attribute has a unit of measure, and the attribute's measure entails a proportional relationship (linear, bi-linear, multi-linear) with its unit" (p. 37). Quantitative reasoning, then, is a person's conception of quantities and the relationships between those quantities. Building off prior quantitative approaches to covariational reasoning (Thompson, 1988, 1993, 1994; Thompson & Thompson, 1992), Carlson et al. (2002) defined covariational reasoning "to be the cognitive activities involved in coordinating two varying quantities while attending to the way they change in relation to each other" (p. 354). For instance, a person can conceive of the volume and height of water in a bottle as varying simultaneously as the bottle is emptied by evaporation.

Carlson et al. (2002) associated mental actions (MAs) with indicative behaviors (both graphical and verbal) in their covariational reasoning framework (see Table 1). Levels of covariational reasoning were then defined in terms of these mental actions. We originally interpreted this framework to mean that someone who exhibits MA2 verbal indicators would also exhibit the corresponding MA2 graphical indicators. Carlson et al. (2002) clarified that a student can exhibit behavior associated with a specific mental action without engaging in the mental action itself, so we suspected someone might be able to perform a graphical behavior indicative of covariational reasoning but be unable to verbalize some covariational relationship. However, it did not occur to us that someone might verbally describe a covariational relationship at a much higher level than their graphical behavior would suggest. We will return to these ideas in our results section.

Table 1: Portion of Carlson et al.'s (2002) Covariational Reasoning Framework

Mental action (MA)	Indicative behaviors
MA1 - Coordinating the value of one variable with changes in the other.	Labeling the axes with verbal indications of coordinating the two variables.
MA2 - Coordinating the direction of change of one variable with changes in the other variable.	Constructing an increasing straight line. Verbalizing an awareness of the direction of change of the output while considering changes in input.
MA3 - Coordinating the amount of change of one variable with changes in the other variable.	Plotting points/constructing secant lines. Verbalizing an awareness of the amount of change of the output while considering changes in the input.

Thompson and Carlson (2017) refined the Carlson et al. (2002) framework to craft a more broadly applicable covariational reasoning framework. Instead of listing indicative behaviors for each level of covariational reasoning, their descriptions focused on students' abilities to envision and anticipate rather than construct, plot, or verbalize an awareness of something. In particular, their descriptions attend to the type of variational reasoning a student uses to envision how each quantity changes as well as the nature of the multiplicative object a student constructs between each quantity's values. Thompson and Carlson followed Saldanha and Thompson's (1998) usage of Piaget's notion of "and" as a multiplicative operator to derive the notion of a multiplicative object. An individual forms a multiplicative object by uniting attributes of two objects to form a new third object. For example, Frank (2017) described how an individual can consider the attributes 'red' (perhaps from an apple) and 'circular' (from a ring) independently, then unite them to construct a single red circle as a multiplicative object. The resulting object is multiplicative because it is simultaneously red and circular. In regard to variational reasoning, Thompson and Carlson built off the variational reasoning research done by Castillo-Garsow (2010, 2012) and adapted the distinctions made by Castillo-Garsow et al. (2013) between discrete, chunky continuous, and smooth continuous variational reasoning.

Thompson and Carlson (2017) outlined two different ways researchers could use their covariational framework. First, the framework levels could be used to characterize a person's covariational reasoning in a specific instance. And second, the framework levels could describe a person's capacity or ceiling for covariational reasoning across settings. For example, a graduate student in mathematics may display a gross coordination of values in describing how the miles driven in their car and the gallons of gas used by the car increased as their road trip continued. Nevertheless, the student may also possess the ability to envision smooth continuous covariation. In this report, we are primarily concerned with the second way of using the framework levels.

Nonnormative Graphing Schemes

Research has recently begun to detail the extent to which students' meanings for graphs diverge from the normative meanings privileged by the mathematical community (Moore et al., 2019). Roughly, there are two key components of a graph: a curve itself and the coordinate system in which the curve is plotted. To attend to the nuanced, nonnormative graphing schemes students use, we consider one construct for each component: (a) the type of *shape thinking* (Moore and Thompson, 2015) students engage in while reasoning about a curve and (b) the quantitative *frame(s) of reference* (Joshua et al., 2015; Lee et al., 2019) students use to construct an underlying coordinate system.

Shape thinking. In order to focus on the meaning an individual has for a graph, Moore and Thompson (2015) introduced the constructs of static shape thinking and emergent shape thinking. Static shape thinking involves attending primarily to the perceptual shape of a graph and inferring associations based on shape, rather than the underlying covariational relationship. On the other hand, emergent shape thinking involves conceiving of a graph as a trace or record representative of the underlying covariational relationship. Thompson (2016) reported that 29 of 111 written responses high school teachers provided to a version of the bouncy ball task were coded as representing static shape thinking (see pp. 449–450). If a nontrivial proportion of teachers are reasoning with static shape thinking, some students likely are as well.

Frames of reference. Joshua et al. (2015) defined a frame of reference as "a set of mental actions through which an individual might organize processes and products of quantitative reasoning" (p. 32). In particular,

> An individual conceives of measures as existing within a frame of reference if the act of measuring entails: 1) *committing to a unit* so that all measures are multiplicative comparisons to it, 2) *committing to a reference point* that gives meaning to a zero measure and all non-zero measures, and 3) *committing to a directionality of measure comparison* additively, multiplicatively, or both. (Joshua et al., 2015, p. 32, emphasis added)

Constructing a complete quantitative structure for a two-dimensional Cartesian coordinate system requires measuring two quantities at once, which is accomplished by simultaneously combining two frames of reference. Ultimately, then, a coordinate system is the result of the many mental actions involved in constructing and combining frames of reference (Joshua et al., 2015). As Lee et al. (2019) found, it is a nontrivial task to coordinate across multiple frames of reference/coordinate systems at once. This suggests that students who do not construct canonical coordinate systems may struggle to interpret the conventional meanings a graph is meant to convey.

Methods

After publishing preliminary results on the relationship between students' units coordination and covariational reasoning (Boyce et al., 2019), our group reflected on the tasks and methods we used to assess students' capacity for covariational reasoning. During this reflective process, we analyzed artifacts from our previous research—including videos of interviews, individual/group coding notes, and meeting memos. For example, we looked at spreadsheets in which two members of the team independently commented on each interview and assigned each student a covariational reasoning level. Over five months, we engaged in sustained group discussion for an hour and a half each week about the theory of covariational reasoning, the literature on graphing and quantitative/covariational reasoning, and how we determined the levels we reported in Boyce et al. (2019).

Prior to each weekly meeting, we spent extensive time considering these issues individually and in small groups. This helped ensure that all group members had a voice and that we were generating several distinct suggestions for improving our covariational reasoning assessment protocol and analysis. As we revised our analysis procedures, we looked back at previous student interviews to determine how these new procedures would affect our past assessments of students' capacity for covariational reasoning.

Results

Limitations of Graphical Tasks

In this section, we discuss our results through an analysis of the actions of a college calculus student named Shania. Specifically, we respond to our first research question by highlighting the limitations of using a graphical task to assess her capacity to reason covariationally. As previously noted, Carlson et al. (2002) remarked that a student might exhibit a behavior associated with a particular mental action or level of covariational reasoning but not reason in a way consistent with that covariation level. They wrote, "Some students have been observed exhibiting behaviors that gave the appearance of engaging in [advanced mental actions] . . . When asked to provide a rationale for their construction, however, they indicated that they had relied on memorized facts to guide their construction" (pp. 361–362). Put more succinctly, graphical activity can lead a researcher to overestimate a student's overall ability to reason covariationally. Shania, as we will demonstrate, is representative of the opposite: her graphing activity may have led us to underestimate her capacity to reason covariationally.

Shania attempted a variation of Thompson's (2016) Bouncy Ball task. The task scenario (with provided graphs shown in Figure 1) follows below:

> A ball is hanging by a 10-foot rubber cord, from a board that is 20 feet above the ground. The ball is given a sharp push downward and is left free to bob up and down. The graph on the left represents the ball's *displacement from its resting point* in relation to the *time elapsed* since the ball was pushed. The graph on the right represents the ball's *total distance* traveled in relation to the *time elapsed*. The information given is in the first second after being pushed. The final graph represents the ball's *displacement from its resting point* in relation to its *total distance traveled* since being pushed.

After Shania read the task, the interviewer asked, "What's happening to the ball based on that description?" The interviewer also provided Shania with a coffee cup to physically illustrate the ball's motion. Following some dialogue to clarify the initial dangling position of the ball relative to the board, Shania gestured up and down with the cup to demonstrate how she believed the bouncy ball would bob up and down after being first pushed down. Already, via gestures, Shania demonstrated signs of reasoning covariationally at the gross coordination of values level. Her movements suggest that she understood how the ball's displacement and the number of seconds elapsed changed together.

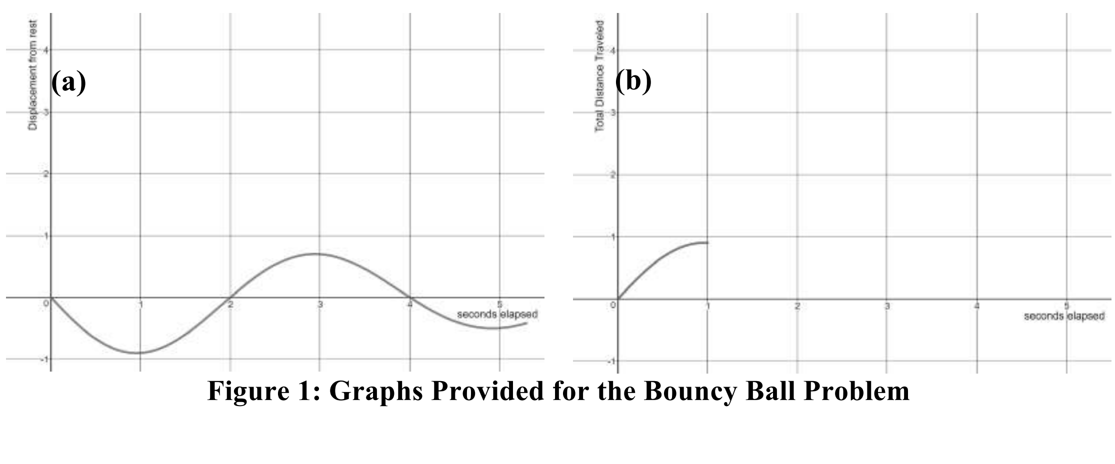

Figure 1: Graphs Provided for the Bouncy Ball Problem

Shania was then prompted to describe the *y*-axis label for the incomplete graph of total distance traveled with respect to time (See Figure 1b). After a brief conversation, the interviewer described how total distance traveled will always be positive. Shania agreed with this description and subsequently stated multiple times without prompting throughout the interview that, "The distance is always increasing." The interviewer then asked Shania to produce the remainder of the incomplete graph. In response, she drew a graph (Figure 2b) that seems to reflect the provided graph over the x-axis on the intervals where the displacement was negative. When describing her graph, Shania said that she thought of it as the derivative of the graph of displacement with respect to time (Figure 1a). But, when she described the relationship between different segments of her graph, she talked about the total distance traveled, rather than the displacement.

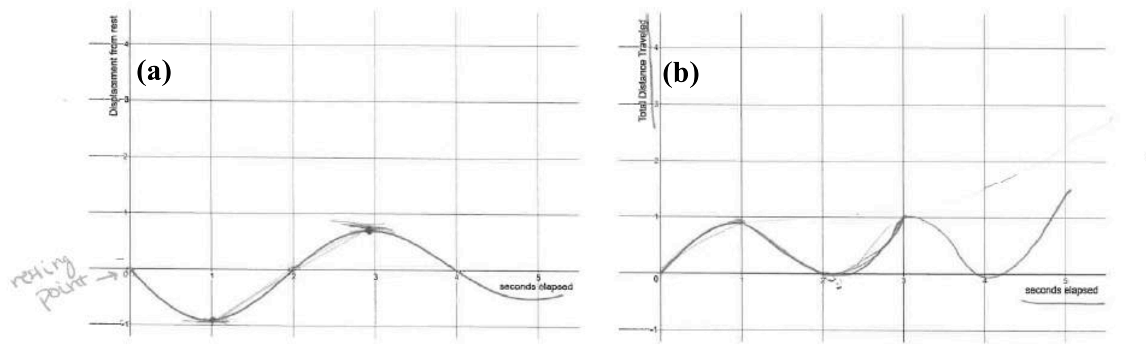

Figure 2: Shania's Work on the Bouncy Ball Task

The interviewer asked Shania why she thought the graph she was asked to produce was the derivative of the first graph. Shania responded, "I kind of saw, like, when we were doing the derivatives in class with sine and cosine and everything and then how sine is the opposite of cosine." The interviewer followed up and asked, "So it wasn't anything about the wording of the question that made you think derivative. Like, it was the memory of an oscillating shape?" To this, Shania responded, "yeah."

The summation of the interactions suggest Shania conflated three different sources to produce her graph: the graphs presented in her calculus course, the shape of the provided graph of displacement with respect to time, and her understanding of how total distance traveled must always be positive. Instead of attending to how the two quantities (total distance traveled and time) simultaneously vary, Shania intended her graph to represent a variety of concepts. We interpret this as significant evidence that Shania created her graph as a record that is intended to communicate a number of specific facts about the ball's movements. In other words, Shania was likely engaged in static shape thinking.

After the interviewer and Shania came to a joint conclusion that the task did not ask for a graph related to the derivative, Shania was given a second opportunity to produce a graph of total distance traveled with respect to time on a new piece of graph paper. Before producing her second graph, the interviewer asked, "What about that graph [Figure 1b] shows us the distance?" Shania responded by saying, "The distance is from here to here [draws an arrow going up parallel to y-axis on the new graph] since it's going up, increasing. And then our seconds were from zero to five." Here, Shania's language indicates that she was engaged in gross coordination of values due to her describing how the total distance traveled increases and how the time increases. Shania's original graph suggests that she did not envision how the two quantities were varying together. Instead, according to Thompson and Carlson's (2017) covariational framework, Shania would have most likely been classified at the precoordination level (a level beneath gross coordination of values).

As evidenced, nonnormative graphing schemes can cause underestimates of a student's capacity to reason covariationally. Frank (2017) demonstrated that in order to construct a graph as a record of quantities covarying, a student must conceive of a multiplicative object. Gross covariational reasoning, however, does not require a student to conceive of a multiplicative object. Thus, a gross covariational reasoner's graphing activity does not provide insight into their maximal capacity for reasoning covariationally. Subsequently, graphing tasks inhibit researchers' ability to assess some students' covariational reasoning capacity.

Improving Covariational Reasoning Assessments

We now transition to our second research question: *How can we improve assessment of covariational reasoning to accommodate students with nonnormative graphing schemes?* A reflective analysis of our own methodologies paired with a review of the literature has led us to one possible improvement that can be made: researchers could provide non-graphical tasks before—or possibly in place of—graphical ones. Although all interviewers in our prior study adhered to a general protocol, we noted in our analysis that one interviewer—the researcher who interviewed Shania—would often ask brief introductory questions to ensure interviewees fully understood the prompt before proceeding to any graphical tasks. Only upon retrospective analysis did the benefits of this practice become apparent. As detailed previously, the language and gestures Shania used to model the trajectory of the bouncy ball with a coffee cup provided strong evidence she was engaged in gross coordination of values. However, when she proceeded to the graphical component of the task, her tendency to engage in static shape thinking obscured evidence of this form of covariational reasoning. Further analysis and group discussion allowed us to see past her static shape thinking in our original study, but without data from the non-graphical introductory questions Shania's interviewer asked, we may have incorrectly assessed her covariational reasoning level.

The case of Shania highlights the importance of providing non-graphical means by which interviewees can engage in covariational reasoning. In line with this suggestion, Moore and Carlson (2012) noted that undergraduate precalculus students' graphical and computational solutions tended to match their emergent image of the problem's context as well as the quantitative structure they constructed for the problem. For example, Shania's gestures provided no evidence that her image of the problem incorporated the damping of the bouncy ball's displacement from rest as time passed. So, in line with Moore and Carlson's findings, it should come as no surprise that her graph of total distance with respect to time did not reflect this damping (see Figure 2b). Moore and Carlson (2012) contended that "It is critical that students first engage in mental activity to visualize a situation and construct relevant quantitative relationships prior to determining formulas or graphs" (p. 48). A simple way of supporting such mental activity could be to have a conversation with an interviewee about the situation and any relevant quantities. Even a short conversation has the added benefit of providing valuable data about the quantities an interviewee is constructing (as we have illustrated in the case of Shania). Another means for supporting the interviewee in constructing mental images of the quantities is to have them model the situation using gestures, like how Shania was instructed to model the trajectory of the bouncy ball using a cup. Of course, there are many other ways to aid interviewees in constructing an image and quantitative structure for the situation. We encourage researchers to be creative and design their pre-graphical tasks in ways that best align with their planned trajectory of tasks and intended methods of analysis.

The Invitation to Conversation

By reflecting on our prior research methods, we identified significant limitations of using predominantly graphical tasks to assess one's capacity for covariational reasoning across settings. Namely, students with nonnormative graphing schemes may be able to reason covariationally at higher levels in non-graphical settings. We suspect the primary difficulty for these students is modeling how two quantities covary in the *normative* Cartesian coordinate system privileged by the mathematical community. After all, even constructing a coordinate system—a prerequisite for creating or reasoning about a graph—requires constructing two frames of reference and then combining them. Not to mention, if the coordinate system a student constructs to model a covariational situation does not align with the normative Cartesian one, they may spend more time resolving perceived contradictions than demonstrating their capacity to reason covariationally. In sum, our analysis has revealed that graphical tasks can add considerable noise to a researcher's data for assessing students' covariational reasoning. If a researcher hopes to use graphs to assess covariational reasoning, we urge them to devise explicit methodologies for reducing or, at the least, acknowledging this noise.

Although we suspect experienced researchers have already begun to develop these types of methodologies (e.g., Johnson, 2015; Stevens & Moore, 2017), they are not yet explicitly outlined in the literature. We believe the community of covariational reasoning researchers, particularly novices, would benefit if experienced researchers shared the fine-grained details of their task design and analysis techniques. After all, such accounts are vital to communicating important considerations for conducting covariational reasoning research that may not yet be salient in the literature, such as the limitations of using graphical tasks. We call on researchers (ourselves included) to consider the role that non-graphical tasks should play in assessing covariational reasoning. To that end, we offer this piece as the beginning of what we hope becomes a larger conversation to develop improved methodologies that accommodate the ubiquity of students' nonnormative graphing schemes.

Cognitive Load Theory's Four Component Instructional Design (4C/ID) Model has been used in mathematics education but not confirmed as an instructional theory. Using the Factors Influencing College Success in Mathematics (FICSMath) project and confirmatory factor equation modeling, we empirically validated the model and created the 4C/IDMath Model. Instructional experiences of respondents completing the FICSMath survey were mapped to the theoretical components of the 4C/ID Model. The Mathematical Learning Task, Conceptual Understanding, Procedural Fluency, and Practice for Recall Components correspond to the Learning Task, Support, Procedure, and Part Task Components, respectively, from the original 4C/ID Model. The 4C/IDMath Model can be used to guide instruction in secondary precalculus and calculus courses to support transfer of learning to single variable college calculus.

Keywords: Research Methods, Design Experiments, Secondary-Tertiary Transition in Mathematics

Theoretical Perspective

Cognitive load theory (CLT) was introduced in the 1980s as an instructional theory based on well accepted aspects of human cognitive architecture (Sweller, van Merriënboer, & Paas, 2019). A major premise of the theory is that working memory load from cognitive processes is decreased when domain specific schemas are activated from long term memory. Comprehension, schema construction, schema automation, and problem solving in working memory often create high cognitive load. Hence, schemas transported from long term memory into working memory support learning and transfer of learning (Ginns & Leppin, 2019). One of the key developments from CLT has been the Four-Component Instructional Design (4C/ID) Model generated from evolutionary theorizing (Geary, 2008; Ginns & Leppink, 2019). Since its creation, the 4C/ID Model has been successfully applied to instruction that requires the learning of complex tasks. Van Merriënboer, Kester, and Paas (2006) defined a complex task as having many different solutions, real world connections, requiring time to learn, and as creating a high cognitive load. Based on this definition, the instruction and learning of mathematics is a complex task. For example, different solutions are algebraic, analytic, numeric, and graphic. Relative to real world connections, mathematics is one of the domains in the broader science, technology, engineering, mathematics (STEM) field and is regarded as the language of the sciences. Regarding taking time to learn and creating a high load on learner's cognitive systems, mathematics teachers deal with the tension between covering all the required standards and taking the time to teach for understanding. Teachers face challenging decisions about instructional approaches, materials, productive struggle, and the amount of classroom time spent on various standards. Better models for instruction that support transfer of learning could help teachers improve instructional decision making. Although the 4C/ID Model has been used in secondary mathematics education (Sarfo, & Elen, 2007; Wade, 2011), it has never been confirmed as a mathematical instructional theory. The purpose of this research report is to present an empirical confirmation of the 4C/ID Model, using data from the Factors Influencing College Success in Mathematics (FICSMath) project from Harvard University.

FICSMath Project

The Factors Influencing College Success in Mathematics (FICSMath) Project remains the largest and most recent national study of the secondary-tertiary transition in mathematics. Towards the beginning of the 2009 fall semester, college freshmen in single variable calculus courses across the United States (US) responded to questions on the FICSMath survey regarding educational experiences in their last high school mathematics course. Professors secured students' completed surveys until the end of the semester and recorded final grades for each student on their respective survey before returning them to Harvard University. A total of 10,492 surveys were collected, and from this sample 5,985 students had taken either precalculus (n=2,326), or any level of high school calculus (n=3,659) as their most recent high school mathematics course. The 4C/ID Model appears appropriate to use as a theoretical lens through which to view secondary preparation for college calculus because the components of the model explicitly consider instruction to support transfer of learning (van Merriënboer, Kester, Paas, 2006).

The 4C/ID Model

Van Merriënboer and other cognitive load theorists developed the 4C/ID Model in the early 1990s under the premise that instruction for complex tasks should be combined with methods that have been shown to enhance transfer of learning (Van Merriënboer, Kirschner, Kester, 2003;

Van Merriënboer, Clark, & de Croock, 2002). Transfer is required when prior learning must be recalled to support the learning of new tasks. Vertical transfer is required, for example, to transfer knowledge from the high school mathematics to college calculus. The model was not designed specifically for mathematics instruction, but generally for learning environments where complex problems are the basis of instruction and transfer of learning is the goal.

The 4C/ID Model employs human cognitive architecture from cognitive load theory (Sweller, 2008). The assumptions are that working memory is limited in space and duration while there appears to be no limit of either in long-term memory. The three sources of working memory load are assumed to be: (a) extraneous cognitive load coming from how the material is presented during instruction; (b) intrinsic cognitive load coming from element interactivity, or the interaction of the interconnected parts of the content; and (c) germane cognitive load, which sends and hooks new processed and encoded information into long term memory to be connected with existing schemas. Once information has been processed and connected within the learners' schemas in long term memory, it can then be brought back into working memory as a chunk of knowledge to help process more new content. Integration of new content into schemas makes learning more efficient as it lowers the demands on working memory and supports the learning of complex tasks.

Model Components

The 4C/ID Model incorporates four components: Learning Task, Support, Procedure, and Part-Task Components. These come from theorizing how to instruct a complex task to enable working and long-term memory to develop, retain, and recall comprehension, schema construction, schema automation, and problem solving. Figure 1 shows how Van Merriënboer, Kester, and Paas (2006) theorized the model. Each of these components needs attention during precalculus and calculus instruction. The neglect of any one of them could prohibit learning and/or transfer of learning. As such, the components are discussed specifically regarding the instruction of mathematics during the secondary-tertiary transition.

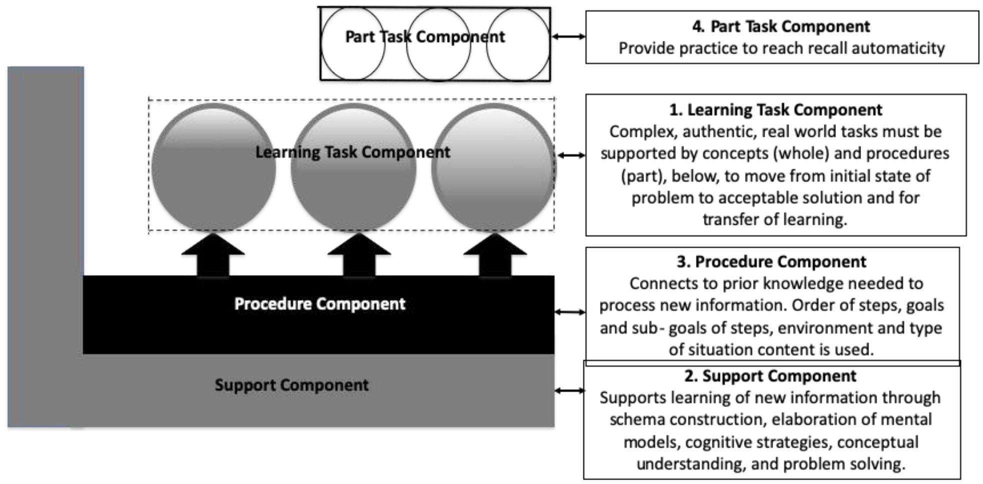

Figure 1: The theorized general 4C/ID Model (modified from van Merriënboer, Clark, De Crook, [2002])

1. The Learning Task Component is modeled to engage learners in meaningful problem-solving tasks. Working with real world problems, often integrated into mathematics to motivate learning (Beswick, 2010), requires mental processes to move from the initial state of the problem to an acceptable solution (van Merriënboer et al., 2003). Engagement in higher-level tasks during mathematics instruction increases students' engagement with mathematical ideas (Boaler and Staples, 2008). Such tasks include high element interactivity, which occurs because of the interacting parts of the mathematics that must be addressed during problem solving. Element interactivity is inherent in secondary preparation for college calculus because of the many interacting mathematical concepts involved in precalculus and calculus problem solving.
2. The Support Component undergirds the Learning Task Component and includes conceptual understanding, reasoning of new information, problem solving, and cognitive assessment (van Merriënboer, Clark, de Croock, 2002).
3. The Procedure Component integrates examples, hooks to previous learning or schemas from long-term memory, which supports the processing of complex ideas. These are important instructional practices in mathematics (Wade, Sonnert, Sadler, & Hazari, 2017; Wade, Cimbricz, Sonnert, Gruver, & Sadler, 2019). This is, first, because mathematics is abstract, and reasoning is required to understand abstract information (Russell, 1999). Another reason is that, when strategies are recalled from long term memory, it is common for mistakes in the problem-solving process to occur. Yet, with guidance, students can learn from their mistakes. This process is referred to as flawed reasoning and is believed to be an important part of learning mathematics (Russell, 1999).
4. The Part Task Component models instruction working towards students developing automaticity. This means that specific tasks from previous learning can occur with little effort, requiring little conscious monitoring and few cognitive resources (Feldon, 2007). The part-task component is included in the 4C/ID Model because there are times that instruction allows repeated practice of information to the point of automaticity. Depending on where the learner is in understanding whole concepts first, this can both benefit or hinder the meaningful learning of mathematics. For example, if a student has not learned the concepts but practices procedures, the result is often what Skemp (2015) refers to as instrumental understanding or rules without reason. The goal is relational understanding, which Skemp

(2015) defined as knowing what to do and why, which requires understanding concepts as well as procedures.

Research Question and Method

Can the 4C/ID Model be empirically validated for mathematics instruction for the secondary-tertiary level using data from the FICSMath Project and confirmatory factor analysis?

Confirmatory Factor Analysis Model

Freshmen respondents in single variable college calculus courses from large, medium, and small 2- and 4-year institutions from across the nation reported instructional experiences from their senior-level high school precalculus or calculus courses (n=5,985). The percent of missing value cases were small (between 1.3% and 4.9%), yet multiple imputation was computed to create a small number of copies of the dataset, with each having missing values suitably imputed. Each complete dataset was analyzed independently and estimates of parameters of interest were averaged across the copies to provide a single estimate (Royston, 2004). In the end, the model reported 6,146 cases, a 2.6% increase from the 5985 respondents included in the model. Then confirmatory factor analysis (CFA) was used to test the extent to which these variables related to the underlying constructs of the 4C/ID Model.

CFA is theory driven, so we began by analyzing the theoretical relationships among the observed and unobserved, or latent, variables (Schreiber, Nora, Stage, Barlow, & King, 2006). The observed variables (Figure 2 rectangles) are intercorrelated secondary instructional experiences reported by single variable college calculus students who completed the FICSMath survey. The unobserved variables (Figure 2 large ovals) are factors that account for correlations among the observed variables (Brown & Moore, 2012) that theoretically aligned to the 4C/ID constructs. We identified instructional experiences that provided: (a) complex mathematical tasks (Learning Task Component, n=4); (b) an overview of whole task mathematical concepts (Support Component, n=17); (c) support for the processing of mathematics, the use of algorithms, and graphing (Procedural Component, n=16); and (d) opportunities for practice (Part-Task Component, n=13). Figure 2 shows the number of observed variables that converged and survived CFA. The loadings to the right of the large ovals show the correlations between the components while loadings to the right of the rectangles show the correlations between the observed variables to each component. The small ovals connected to each rectangle on the left show the errors associated with the observed variables in the model. The loadings to the left of the errors show their correlations while one shows the correlation between the error for emphasis on vocabulary and the support component (discussed later).

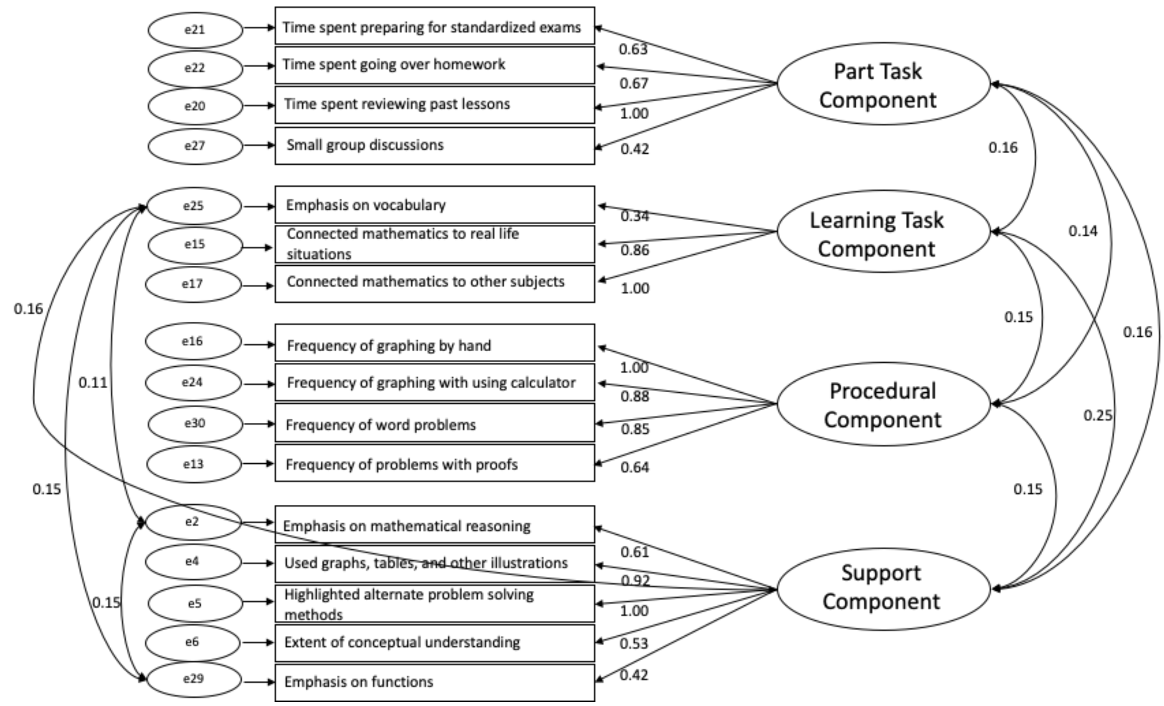

Figure 2: The 4C/ID *Math* Model Confirmed using Confirmatory Factor Analysis.

The large FICSMath sample size (n=5,985) allows assumptions of normality of data and increases the power of a hypothesis test. This large sample size, however, did limit some of the CFA measures that can be reported. For example, the chi square test, Normed Fit Index (NFI), and Tucker Lewis Index (TLI) are typically reported in CFA models, but these are preferable measures for smaller data sets. As shown in Table 1, the Comparative Fit Index (CFI) and the Root Mean Square Error Approximation (REMSA) confirm the components in the 4C/ID Model have meaningful relationships with the observed variables in the FICSMath dataset.

Table 1: Measures of CFA Reported, Accepted Cut-off Scores for Significance, Results of the 4C/ID Math CFA Model with Notes for Clarity.

CFA Measure	Cutoff for Significance	Model Value	Notes
Comparative Fit Index (CFI)	CFI > 0.90	0.907*	Compares the fit of a target model to the fit of a null hypothesis model.
Root Mean Square Error Approximation (RMSEA)	RMSEA < 0.08	0.050*	A parsimony-adjusted index. Values closer to 0 represent a good fit.

*Significant finding. (See Parry (no date); Brown & Moore, 2012).

Figure 3 shows a representation of the confirmed 4C/ID Model, now referred to as the 4C/ID*Math* Model. The constructs have been renamed to align closer with the field of mathematics education. These components are now:

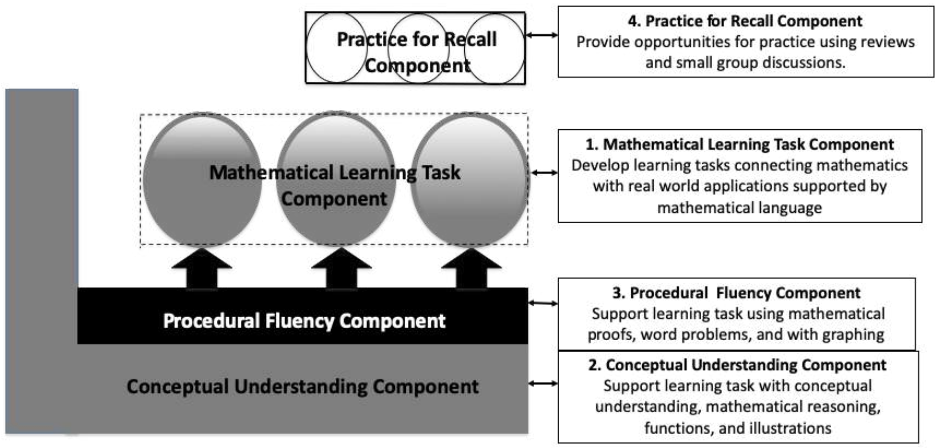

Figure 3: The 4C/ID*Math* Model for Secondary-Tertiary Mathematics (modified from van Merriënboer, Clark, De Crook, [2002])

1. The Mathematical Learning Task Component is the new name for the Learning Task Component. This is where whole tasks should be presented to avoid the transfer paradox. The transfer paradox is described as occurring when instruction breaks apart concepts to minimize the necessary time-on-task. This type of instruction has been shown to have a positive effect on short term retention for performance on tests, but not on transfer of learning (van Merriënboer et al., 2006).
2. The Conceptual Understanding Component is the new name for the Support Component. This name change aligns with what teachers who were identified as teaching for high conceptual understanding on the FICSMath survey concretely did to teach for conceptual understanding (Wade, Sonnert, Sadler, Hazari (2017). This study showed that teaching functions and mathematical reasoning was highly correlated with conceptual understanding.
3. The Procedural Fluency Component is the new name for the Procedure Component. Star (2005) presented thinking flexibly with mathematics as an indicator of deep procedural knowledge. To generate graphs, students must be able to think flexibly across the connections between equations and algorithms to points on various graphing planes. Mathematical proofs require meaningful connections across relevant mathematical relationships, which requires thinking flexibly with those relationships (Williams-Pierce et al., 2017).
4. Practice for Recall Component is the new name for the Part-Task Component. Van Merriënboer, Kester, and Paas (2006) stated that part-task practice may provide additional practice needed to develop knowledge elements that allow the learner to perform routine aspects at a high level of automaticity. In mathematics education, this is better understood simply as practice for recall.

Limitations and Future Work

One weakness of the study may be that the FICSMath Project is from 2009, yet this project remains the most recent national study on secondary preparation for college calculus success. Until the FICSMath project can be replaced by another large-scale national study, the national representation and sample size strength of the project warrants its continued use. Additionally, the 4C/ID*Math* Model is confirmed for students in the secondary-tertiary transition who took either precalculus or calculus as their last mathematics course before entering into single variable college calculus. More research is needed to confirm the model at different levels of mathematical instruction, such as for algebra or geometry. Lastly, how the 4C/ID*Math* Model actually predicts performance in single variable college calculus needs to be investigated. The focus of this paper was to confirm the 4C/ID Model and then modify it to be more user friendly for mathematics teachers.

Discussion

The theoretical perspective of the 4C/ID Model is that instruction of complex tasks should be guided by principles that reinforce learning and transfer of learning. The 4C/ID Model theorizes the Support Component as concepts that structure the learning of complex tasks and the Procedure Component as connecting prior learning, the order of steps and context for use. Both of these components undergird instruction of a complex task, which is represented as the Learning Task Component. The Part Task Component symbolizes the use of automatized information that requires little to no cognitive load in working memory. Van Merriënboer et al. (2006) state the 4C/ID Model was designed to focus instruction on whole tasks and claims breaking apart concepts to minimize time-on-task has a positive effect on short term retention for performance on tests, but not on transfer of learning. This was theorized as the transfer paradox. Skemp (2006) presented similar ideas in mathematics education through relational and instrumental understanding. Relational understanding comes from instruction that focuses on knowing what to do and why while instrumental understanding was conceived as instruction that focused on rules without reason. It was claimed that high school teachers often adopt a two-track strategy of instruction where they spend some time on drill and practice, providing for skills and facts, and some time on developing and integrating understandings (Skemp, 2006). Based on the 4C/ID Model, drill and practice can develop automaticity but does not reinforce learning for transfer. These similarities indicate the 4C/ID Model to be a good fit with mathematics education. The empirical confirmation of the 4C/ID Model using the FICSMath Project resulted in the 4C/ID*Math* Model for secondary-tertiary mathematics instruction. The 4C/ID*Math* Model confirms the importance of generating the learning task first then considering the concepts and procedures needed for learning and transfer of learning. Each of the components for the 4C/ID*Math* Model is discussed below relative to how this model can be used in precalculus and calculus secondary-tertiary mathematics instruction.

1. The Mathematical Learning Task Component represents complex tasks that must be considered as a whole to support transfer of learning. Instruction that breaks apart concepts to minimize time for learning has been shown to have a positive effect on short term retention but not on transfer of learning (van Merriënboer et al., 2006). Considering complex tasks and how to present the many interacting elements as a whole concept first is important, especially in mathematics where transfer of learning is critical. As seen in Figure 2, this component includes the emphasis on (mathematical) vocabulary item. The vocabulary item was originally mapped to the Support Component, but the CFA model was not valid. When the vocabulary item was moved to the Learning Task Component, the error associated with the item was too high. After correlating the vocabulary item error term with the Support Component, the 4C/ID Model converged. This correlation indicates the vocabulary term is essential to both, the Mathematical Learning Task and the Support Component. Tall (2004) stated real world representations require the sophistication of language to support abstract concepts in formal mathematics. After determining what standards and elements are to be instructed, focus should then be placed on the language required to present the content and how to connect the mathematics to real world applications and other subjects.
2. The Conceptual Understanding Component emphasizes conceptual understanding, mathematical reasoning, functions, illustrations, and alternate problem-solving methods necessary to support learning mathematical content. Wade, Sonnert, Sadler, and Hazari (2017) showed mathematical reasoning and emphasis on functions to be part of the construct

that described what teachers did to teach for conceptual understanding. This component aligns well with the field of mathematics education.

3. The Procedural Fluency Component demonstrates hooking previous learning, or schemas, from long-term memory to concepts presented in the Conceptual Understanding Component. Graphing functions and equations require modeling mathematics both by hand and, in the secondary mathematics classroom, the graphing calculator. Most secondary mathematics standardized exams, including AP exams, require the use of a graphing calculator but most single variable college calculus courses do not allow their use in class or on exams. This implies the importance of students understanding the mathematical procedures even if they have a graphing calculator available. Mathematical proofs, independent of the format, require justification from prior learning and are an important part of the secondary-tertiary transition. At the tertiary level, proofs tend to be longer, more complex, and require more mathematical insight than at the secondary level (Selden, 2011). Many students are not well prepared for the types of proofs they will be exposed to in college calculus (Bressoud, 2009). It could be that incorporating more proofs into secondary precalculus and calculus courses may reduce some of the transition struggles for students in college calculus.
4. The Practice for Recall Component illustrates that opportunities for practice using reviews and small group discussions are beneficial for developing automatic recall.

It is our hope that the confirmation of the 4C/ID Model, leading to the 4C/ID*Math* Model, brings this instructional framework into the purview of secondary mathematics teachers and mathematics professors who teach students in the secondary-tertiary transition. Better preparation for single variable college calculus is important because this is the first mathematics course that is commonly required in all STEM majors.

Acknowledgment

This research was supported by Grant No. 0813702 from the National Science Foundation. Any opinions, findings, and conclusions in this article are the authors' and do not necessarily reflect the views of the National Science Foundation. Without the excellent contributions of many people, the FICSMath project would not have been possible. We thank the members of the FICSMath team, the mathematics educators who provided advice or counsel on this project, and the many college students and professors who participated in the survey.

TEACHER QUESTIONING STRATEGIES IN SUPPORTING VALIDITY OF COLLECTIVE ARGUMENTATION: EXPLANATION ADAPTED FROM HABERMAS' COMMUNICATIVE THEORY

Yuling Zhuang
University of Georgia
yuling.zhuang25@uga.edu

AnnaMarie Conner
University of Georgia
aconner@uga.edu

Facilitating productive mathematical argumentation is challenging; it is critical to develop a specific guiding vision of practices to help teachers learn to teach argumentation. However, what counts as acceptable classroom-based mathematical argumentation remains an open question. In this study, building on Habermas' theory of communicative action, we developed two analytic frameworks to examine questioning strategies used to support the validity of collective mathematical argumentation. Habermas' three components of rationality allowed us to focus on fine-grained rationality components of teacher questioning as well as teachers' intentions of asking these questions. The theory of validity claims was used to capture different forms of validating argumentation. The frameworks may help teachers to be aware of the types of questions that they are asking when aiming at supporting valid argumentation.

Keywords: Research Methods, Classroom Discourse, Reasoning and Proof

Rationale and Purpose

Current research discusses many benefits of incorporating mathematical argumentation in classroom discourse (e.g., Nussbaum, 2008) and emphasizes the essential role of teacher questioning in facilitating collective mathematical argumentation — teacher and students (or a small group of students working independently) working together to determine the validity of a claim (Conner et al., 2014). Studies (e.g., Kazemi & Stipek, 2001; Kosko et al., 2014; Wood, 1999) have highlighted teachers' questioning as a pivotal factor shaping argumentative discourse and as strongly influencing students' engagement in productive mathematical argumentation. However, most of these studies placed more emphasis on documenting current situations or difficulties that teachers had in using questioning to regulate argumentative discourse than on developing effective ways to address some of these difficulties. For example, Sahin and Kulm (2008) analyzed types of questions two teachers used in two sixth-grade classes over two months. They found that the majority of questions teachers posed were factual, even when using a reform-based textbook, which included probing and guiding questions in the teaching guides. Scaffolding argumentation is not an easy task, and it is not clear precisely what actions of the teacher provide the desired results of argumentation. Further, no consensus exists in the field of mathematics education concerning the characteristics of successful argumentative discourse. Some researchers (e.g., Stylianides et al., 2016) have called for more research in the field to design practical tools for use in the classroom to address teachers' difficulties or particular learning goals in orchestrating argumentative discourse.

The goal of this study is to investigate how a beginning secondary mathematics teacher uses *rational questioning* as a didactical tool to support the validity of collective mathematical argumentation according to Habermas's (1984) theory of *validity claims*.

Theoretical Framework

Two concepts from Habermas' theory of communicative action are used in this study to investigate how teachers could support valid argumentative practices with a particular focus on teachers' questioning strategies. The first is Habermas' (1998) perspective on three interrelated components of rationality: epistemic (inherent in the control of validation of statements), teleological (inherent in the strategic choice of tools to achieve the goal of the activity), and communicative (inherent in the conscious choice of suitable means to communicate understandably within a given community). Boero (2006) advocated that Habermas' three components of rationality account for students' rational behavior in proving and argumentative activities. Corresponding to these components, students are expected to strategically choose tools to achieve a goal (teleological rationality) on the basis of specific knowledge (epistemic rationality) and communicate in a precise way with the aim of being understood by the classroom community (communicative rationality). Douek suggested that it was beneficial to develop argumentative discourse along the three components of rationality (i.e., epistemic, teleological, or communicative) and that the teacher should support students to meet the requirements of rationality, thus dialectically forming argumentation (Boero & Planas, 2014). In order to reach such aims, Douek further proposed the idea of using "rational questioning" as a method to “organize the mathematical discussion according to the three components of rationality” (Boero & Planas, 2014, p. 210). Following Douek's idea, we developed a Teacher Rational Questioning Framework (see Table 1) to classify types of rational questioning from teachers' perspectives to engage student participation in argumentation with different kinds of rationality (For more details, see Zhuang & Conner, 2018). We defined *rational questioning* as a question that contains at least one component of rationality. At times, for clarity, we call a question epistemic rational questioning if it contains an epistemic rationality component.

Table 1: Teacher Rational Questioning Framework

Components of Habermas' Rationality	Features	Examples
Epistemic Rationality (*ER*)	The questions intended to allow students to reason and justify their arguments; to clarify/challenge students when they gave unclear or incorrect responses.	Can you tell me why?
Teleological Rationality (*TR*)	The questions intended to allow students to show or reflect on the strategic choices that they used to achieve their arguments or ideas; to point students towards the specific means or tools.	How did you figure that out?
Communicative Rationality (*CR*)	The questions intended to allow students to communicate or reflect on the steps involved in their reasoning and arguments to ensure that their ideas can be understandable in the given community; to point students towards the correct use of mathematical terminology.	How would we write this correctly mathematically?

In terms of validation of argumentation, we adapted Habermas (1984) theory of *validity claims*, which proposed that three forms of validity claims exist: to truth, to rightness, and to sincerity (see Table 2). By adapting Habermas' theory of validity claims to collective argumentation in mathematics classrooms, we identified three parallel dimensions of validating argumentative practice (For more details, see Zhuang & Conner, unpublished).

Table 2: Validity Claims and Corresponding Validating Argumentative Practice

Validity Claims	Features	Corresponding Validating Argumentative Practice
Truth	Concern the way things are in the external world of objects and spatiotemporal entities, thus constituting a constative (fact-stating) speech act.	Argumentation results in correct mathematical conclusions (T). The truth of an argumentation was judged by the researcher's perspective according to shared mathematical theorems, axioms, and principles in the given mathematical classroom community.
Rightness	Concern the way things are in the social world of shared duties, norms, values, thus constituting a regulative speech act.	Argumentative practices conforming to the social norms (N-S) and sociomathematical norms (N-M) (Yackel & Cobb, 1996) in a given classroom social context.
Sincerity	Concern the way things are in the subjective world consisting of personal self-understandings, thoughts, intentions, feelings, thus constituting an expressive speech act.	We assume when the students engaged in the argumentation, they satisfied the sincerity of argumentation unless there is clear evidence demonstrating that the argumentative discourse deteriorates into oppositional or confrontational talk and interpersonal conflicts spill over into the intellectual content.

Further, Habermas (1984) argued that the acceptance of valid argumentation not only links to the referred mathematical objective world, to norms, but also to the use of language. If a speaker cannot present comprehensible and accepted language, then there is no way to establish a shared understanding through communication. This concern about the fundamental use of language gives rise to a new dimension for validating argumentation, which focuses on communicative validity of argumentation and the participants' intentions on reaching a shared understanding within an argumentative practice, that is: Argumentation is communicated by using appropriate mathematical language and representations with participants' intentions to reach a consensus or a shared understanding (*C*).

In this study, we adapted two developed frameworks on the basis of Habermas' theory of communicative action to investigate how rational questioning supports the validity of collective argumentation in a 9th-grade algebraic mathematics classroom.

Data and Methods

The participant, Jill (a pseudonym), was in her third year of teaching and was purposefully selected based on her good understanding of argumentation and willingness to support student engagement in argumentation. We video recorded two consecutive days of Jill's instruction per month, which translated into eight classes a semester. The primary data sources in this study included video recordings and transcriptions of two consecutive days of Jill's instruction, focused on factoring and expanding binomials with integer coefficients.

Each lesson was first divided into multiple argumentation episodes. An argumentation episode was located by identifying the final claim of an argument and the accompanying data, warrants, and data/claims supporting the final claim the collective attempted to establish. Therefore, if there were arguments or claims that supported or refuted the initial argument, these arguments were viewed as connected with each other and included in an episode of argumentation. The next step was analyzing all teacher questions within each chosen argumentation episode in order to identify and categorize rational questioning based on our Teacher Rational Questioning Framework (see Table 1). Each rational question was also categorized according to the valid argumentation analytic framework (see Table 2) to explore how teachers used rational questioning to support the validity of argumentative practices. The classification of teacher questioning started with developed frameworks, but we kept an open mind by using a grounded theory approach (Glaser & Strauss, 1967) to ensure the inclusion of additional themes that were not included initially in the framework. A simple enumerative approach was finally used to quantify rational questioning in order to explicate the patterns that emerged from the open-coding process.

An Example of Using Habermas' Frameworks

As an illustration, let us consider an argumentation episode on the second day where students had reviewed the greatest common factor and expansion of binomials with form $(x \pm a)(x \pm b)$ on the first day of the lesson. During this episode, the students were learning about factoring trinomials with integer coefficients in a small group:

Given $x^2 + \_\_\_ x + 12$, *what are the possible values for the blank?*

1 T: **All right, what do we think?** (Questioning without a rational component: *N*).
2 S1: It's six or nine.
3 T: Six or nine.
4 S2: Yup.
5 T: **Tell me why.** (*ER:* contains epistemic rational component).
6 S1: Tell her why S2.
7 S2: Why do I have to tell her. Oh. Um, okay, so couldn't, couldn't like...
8 T: **Hang on. I want to hear 6 or 9 explanations first.** (*N*)
9 S2: Oh gosh. Could you say the 9 explanation and I say 6 explanation?
10 T: **Tell me the 6 explanation.** (*ER*)

Interpretation. At the beginning of this episode, both students provided incorrect answers. Instead of giving direct corrective feedback, the teacher challenged students' arguments by asking them to provide an explanation of incorrect answers (Lines 5, 8 and 10). Thus, we coded these three questions as rational questioning that contains epistemic rational components (*ER*). These questions also illustrated that the teacher has a special role to play in trying to develop classroom social norms (*N-S*) to address expectations for student participation in argumentative practices through ongoing negotiations. In this context, students were expected to provide warrants, reasons, or backings to justify their claims. Thus, we coded these rational questions as facilitating the validity of argumentative practices in regard to classroom social norms.

11 S2: Okay. So, 6 times 2 is 12.
12 T: Yes, 6 times 2 is 12. That's true.
13 S2: Yeah, and then 6 might not work, 6 wouldn't work.
14 T: **Why not? Talk to me about why 6 might not work.** (*ER*)
15 S2: Because 6 plus 2 is 8 and you have to have 12 and so because [mumbling]
16 T: **Hang on, hang on. You are saying things that are on the very right track.**
17 **Think through it.** (*ETCR:* contains all three rational components).

Interpretation. Through the explanation of her arguments, S2 noticed that 6 was incorrect and worked towards the correct answer 8. However, she lacked the confidence to further articulate the justification in her thinking. At this point, the teacher encouraged her to explain her reasoning (Lines

16 to 17) which revealed again that students are expected to provide reasons to justify their claims (*N-S*).

S2: Okay. 6 plus 2 is 8 but yeah do not even know where 12 like, how are you supposed to like, do you know what I am saying it's like
S1: You can put 8 in here. That's the point.
S2: Yeah.
S1: So we are trying to find the line, what goes on the line up here.
S2: Yeah.
S1: You can put 8 but 6 times 2 is 12 and then 6 plus 2 is 8.
S2: So it's 8.
S3: Yeah.
T: **Yes. You are thinking about it in the right way. You said 8. That's okay. That's why I want you to think about it. Now does that make sense?** (*ETCR*)
S2: Yeah.

Interpretation. The student-student interactions (Lines 18 to 24) illustrated that pushing students to justify why their arguments hold served to support students to understand that the acceptable claims are based on mutual understanding and agreement on epistemic reasons. The question "Now does that make sense?" showed Jill's intention to provide students with opportunities to make sense of other students' epistemic, teleological and communicative requirements of argumentative practices (*ETCR*). It also pushed students to be able to learn from each other which promotes their productive disposition towards mathematics to reach a consensus or a shared understanding in argumentation (*C*).

T: **So does anyone come up with another number besides 8 that could go there? Anybody come up...S4, why could you do 7?** (*ER*)
S4:Oh gosh.
T: **You said you could do it. Why?** (*ER*)
S4:4 plus 3 is 7 and 4 times 3 is 12.
T: Very good. **Is there anything else?** (*TR*)

Interpretation. When S4 came up with answer 7, which was different than others, the teacher intentionally called on her to explain why this could work (Lines 30 to 31, *ER*), which established the expectations for students in the class to share their thinking, ideas, and solutions, even if they have answers that differ from other students' answers (*N-S*). At this point, the teacher's directive question served to help students understand what counts as mathematically different solutions (*N-M*). The final claims of this argumentation are 8 and 7 could work while 6 cannot. Notice that the answers provided here do not include all possible values. At the end of this episode, the teacher asked students to keep thinking of any other possible values that might exist (Line 35, *TR*). From the researcher's point of view, all the rational questions used in this episode also support the requirement of truth argumentation (*T*). Therefore, rational questioning can support multiple forms of validating argumentation.

Results

Based on our definition of argumentation episodes, Jill's two consecutive days of lessons contained 23 argumentation episodes. Within argumentation episodes, Jill asked 136 questions, and 81% (110/136) of questions involved rational questioning. According to our analysis, Jill used a variety of combined forms of rational questioning: some questions included two or three components of rationality and others only involved one. For the purpose of this study, we looked across epistemic, teleological, and communicative rational questioning and examined how different types of rational questioning were related to these components of validity of argumentative discourse. Table 3 gives the numbers in each type of rational questioning and how it related to engagement in valid argumentation.

Table 3: Rational Questioning Supports Validity of Collective Argumentation

Type of Rational Questioning	Number of Questions	Truth	Norms	Communication
Epistemic	46	27	45	9
Teleological	70	54	31	15
Communicative	32	22	17	15

Note. The number of questions in each category is not discrete; a question might be categorized in several categories.

The content of these lessons included multiple problem-solving mathematical activities to teach students how to factor and expand binomials with integer coefficients (see Figure 1), and the teleological (i.e., producing strategies to achieve the aim of the activity) was the most common rationality component among all rational questioning, in which over 60% (70/110) of rational questioning contained a teleological component. Most of Jill's teleological rational questions (54/70) were strategically goal-oriented to support students achieving the *truth* of arguments in regard to filling in an area model (e.g., "Alright now I have the inside of my area model filled out. How do I get the outside?") and finding the greatest common factor in each row and column of the area model so as to solve the problem (e.g., "What is the greatest common factor of the bottom row?"). Jill also intentionally used some teleological rational questioning to encourage other students to join the discussion: "Okay at this point we have two empty boxes. Somebody else, I want you to tell me how we find what goes into those two empty boxes that we have." By continuing to ask other students to respond to particular students' answers, Jill developed *norms* that every student in the class was expected to pay attention to what other students say and be ready to share solutions. On a few occasions, Jill wanted students to be able to use precise mathematics language to *communicate* their ideas and communicated this by asking them to be more specific about their solutions.

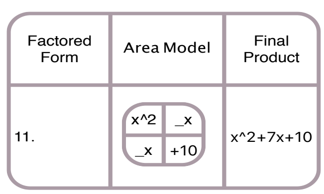

Figure 1: An Example of Task in Lesson One

Epistemic rationality followed as the second most common component of rational questioning (46/110). Jill used most of her epistemic rational questioning (45/46) to encourage her students to justify why their arguments hold (e.g., "You are correct; it's not three, but why?") or challenge her students to provide reasons for their arguments, especially when they gave incorrect answers. Epistemic rational questioning presses students to provide evidence to support the claims that contribute to the development of another *norm*: when engaging in argumentation, constructing a claim is not enough, you are expected to provide your reasoning for the claim. Through analysis we also noticed that not all epistemic rational questioning resulted in correct responses (27/46 prompted correct answers). Jill used sequences of epistemic rational questioning to make students' implicit ideas more explicit and help students to revise their incorrect answers (as shown in the example above). In this way, the teacher also supports the development of students' ability to form comprehensive and acceptable speech acts (i.e., *communication*) based on mutual understanding and agreement. This result provides empirical evidence to support Frank and colleagues' (2009) contention that a single specific question is not enough to elicit a complete explanation or justification; sequences of questions that concentrate on students' explanations are required.

Based on our analysis, 29% (32/110) of the rational questioning contained communicative components. In this unit, Jill's goal for students was apparently less focused on communicative rationality than on teleological and epistemic rationality. Most of the communicative rational questions (22/32) served to introduce graphic representation (the area model) to help students reason and to pull out correct answers (*truth*). For example, she asked, "If this is an area model, what could I call this [point at length] and what could I call this [point at width]?" Sometimes Jill intentionally asked students to rewrite a mathematical expression so that they could easily find the greatest common factor (e.g., "x^4, how do I rewrite this one?"). Occasionally, Jill wanted to highlight her expectations for students to use correct mathematical representations and ensure their representations can be understood in the given classroom community (i.e., *norms and communication*). An example of this type of question would be as follows: "Have I actually finished...I need to write it in the factor form. So tell me what to write."

Conclusions and Implications

Drawing on two different concepts from Habermas' theory of communicative action, in this study we developed two frameworks focused on teacher questioning strategies to facilitate valid argumentative practices. Our definition and classification of *rational questioning* came from Habermas' three components of rational behavior. Many researchers (e.g., Boero, 2006; Cramer, 2015) applied this construct as a tool to analyze students' participation in argumentation; our study shows it could also be used to analyze teachers' ways of dealing with argumentation in the classroom. Habermas' theory of validity claims provides a tool to develop an analytic framework to capture "validation" of an argumentative discourse according to the three forms of validity claims. The two analytic lenses from Habermas' theory provide us with a more comprehensive perspective to shed light on teacher questioning that supports collective mathematical argumentation. Habermas' threefold perspective on epistemic, teleological and communicative rationality helps us to identify fine-grained rationality components of teachers' questions and how teachers' questioning is constrained in relation to the three components of rational behavior; the teacher's use of rational questioning to control the validation of argumentation is seen through Habermas' theory of validity claims.

Classroom-based argumentative discourse is a form of collaborative discussion, and classroom discussions are complex, messy (Frank et al., 2007), and sometimes the argumentation may not happen in the intended way. In order to facilitate productive collective mathematical argumentation, it is critical to understand what constitutes successful argumentative practice. We view rational questioning as a teaching intervention to enrich different levels of argumentation and help students to meet the requirements of rationality, thus dialectically forming productive collective argumentation. Our analytic framework for valid argumentation supports the analysis of classroom instruction related to argumentation and identifies different forms of valid argumentation. It considers students as mathematics learners to participate in argumentation throughout the grades and emphasizes the validity of argumentation as context-dependent. For future research, we should continue to find effective ways to support students' participation in appropriate local acceptance criteria for argumentation and study the role of teachers in regulating valid collective argumentation.

More importantly, in this study, we investigated the effectiveness of classroom-based rational questioning as a didactical tool to support validating argumentation, which responds to the call from the field to use theoretical ideas to design practical tools for teachers to use in the classroom. Our results indicated that although epistemic rational questioning may not always elicit correct or complete reasoning, it served as a way for teachers to set social norms that students were expected to provide reasons to justify their claims when engaging in argumentative activities. Through leading students to work towards a specific method or foreground a particular piece of mathematics for consideration, teleological rational questioning worked well in constructing correct claims. Further, by calling on a particular student to share a different solution, the class worked on what counted as a mathematically different solution, which facilitated the establishment of sociomathematical norms. Communicative rational questioning contributed to the development of students' communicative competencies by asking students to make sure their representations were correct and to use appropriate mathematical terminology to communicate ideas. Questioning focused on communicative rationality also cultivated norms that students were expected to ensure their use of mathematical language and representation can be understood in the given mathematical classroom community. Teacher questioning is one of the most frequently used ways of orchestrating students' reasoning and a key factor in promoting argumentation (Kosko et al., 2014). The fine-grained analysis of teacher questioning in regard to Habermas' three components of rationality served as a method to help us understand how collective argumentation could be initiated and sustained, which thereby contributes to the construction of the culture of rationality in argumentative discourse. This study only focused on general types of rational questioning; it will be interesting to examine what combinations of components of rational questioning appeared to be more supportive and which are less supportive of the validity of argumentation.

In summary, the findings of this study have implications for both theory and professional development in mathematics education. This study illustrates how an important theoretical construct from outside mathematics education can be interpreted and flexibly adapted to offer a new and promising perspective into the study of discursive practices that are related to mathematical argumentation. The frameworks provide a new perspective to understand the roles of teacher questioning in supporting mathematical argumentation. As for professional development, the types of questions provide information about how a beginning mathematics teacher used questions to support mathematical argumentation. In addition, the work of this study contributes to illustrate the link between theoretical and classroom-based research and can be applied in teacher professional programs as a means to develop teachers' awareness about using rational questioning to support the rationality and validity of argumentative discourse.

PSEUDO-EMPIRICAL, INTERNALIZED, AND INTERIORIZED COVARIATIONAL REASONING

Steven Boyce
Portland State University
sboyce@pdx.edu

In this brief theoretical report, I describe the process of the construction of units coordinating structures as the result of a non-linear progression from pseudo-empirical to internalized to interiorized mental activity, and I propose the utility of a parallel distinction between pseudo-empirical, internalized, and interiorized levels of covariational reasoning.

Keywords: Cognition, Number Concepts and Operations, Rational Numbers

Research with middle grades students suggests that the attributes of a quantity conceptualized by a student can lead to assimilation to schemes involving different units coordinating structures (Boyce & Norton, 2017). Similarly, I expect that when analyzing students' covariational reasoning, a critical aspect of their reasoning is *how* they assimilate attributes of objects as measurable and *how* they assimilate quantities as co-varying. In this paper, I propose utility of adopting distinctions between students' schemes for coordinating units (pseudo-empirical, internalized, and interiorized) to levels of covariational reasoning (Thompson & Carlson, 2017). I begin by providing background on scheme theory (von Glasersfeld, 1995).

Scheme Theory

A scheme consists of three parts: recognition of a situation, operations (mental actions), and an expected result (von Glasersfeld, 1995). Following von Glasersfeld (1995), I distinguish three types of schemes based on their activity: *pseudo-empirical, internalized, and interiorized* schemes. The "empirical" part of a pseudo-empirical scheme refers to an individual's need for an external object of attention to act upon; the activity portion of the scheme requires sensory-motor experience of an external transformation. What makes it "pseudo"-empirical rather than empirical is that the object acted upon is figurative material; the result of the scheme is not about the object itself. With an *internalized* scheme, perception of an act of transformation is still required, but the transformation can involve completely imagined representations (i.e., mental imagery). Representations of the results of internalized schemes can still involve external representations, but actions with these external representations involve communicating internalized reasoning rather than being a necessary aspect of one's reasoning. Both internalized and pseudo-empirical schemes involve mental activities that are experienced temporally; as part of a flow of experience of perceiving an object, acting upon it (mentally), perceiving the resulting object, and conceiving the results of the action. In contrast, an *interiorized* scheme does not require either internal or external representations for mental activity. Interiorized schemes are *anticipatory*, in the sense that the recognition of a situation, the mental actions, and the expected result of the actions of an interiorized scheme are experienced as synchronous, reversible, and necessary.

Although the process of interiorization is prefaced by stages of pseudo-empirical and internalized activity, constructing more advanced schemes is dependent upon individuals' lived experiences rather than following a strictly linear process, via psychological processes of *perturbation*, *abduction*, *assimilation*, *accommodation*, and *reflective abstraction*. Perturbation is the experience of a lack of stability or reliability of one's current schemes; often accompanied with emotive experiences of uncertainty or confusion (Piaget, 1970). Perturbation can be momentary and is most often closely tied to social interactions (communication with others about their mathematical reasoning can be viewed as a process of introducing and resolving perturbations involving interpreting others' semiotics; Steffe & Thompson, 2000). Perturbation can also be prolonged and invoke a powerful *intellectual need* for resolution (Harel, 2013) and involve internalized communication (Sfard 2007).

Abduction is a logical process of forming a hypothesis that, if true, would be experienced as satisfying an observation (Norton, 2008; Prawat, 1999). The process of assimilation is the result of a successful abduction of a modification of recognition of a situation or a modification of the recognition of a result that resolves a perturbation (most commonly an expansion of the recognition template, so that a scheme applies more broadly, von Glasersfeld, 1995). Typically accommodations involve a curtailing that is the reverse of the most common form of assimilation. Processes of assimilation and accommodation are thus intertwined, as assimilations lead to accommodations that lead to assimilations (von Glasersfeld, 1995).

Schemes can be thought of as recursive in the sense that the output of a scheme can become part of the activity of another scheme. I use the term *meta-scheme* to refer to processes that act on schemes (cf., Piaget, 1970). I thus consider the processes of assimilation and accommodation as meta-schemes. Schemes for internalization and interiorization of schemes are also meta-schemes whose input is a scheme itself. For the vast majority of situations, meta-schemes are enacted without meta-cognitive awareness, but learners also develop a meta-scheme of *reflective abstraction*. Reflective abstraction begins with reasoning about prior experiences, via *re-presentations* (mental recordings of prior experiences). Via processes of abduction, perturbation, assimilation and accommodation, these re-presentations can become successively more abstract. Reflective abstraction is thus an accommodation of an individual's meta-schemes to include more awareness, control, and flexibility. Due to limitations of working memory, reasoning about successively more abstract re-presentations of mental objects both requires and necessitates interiorizations of systems of mental actions on those objects as *conceptual structures*, which are systems of interiorized operations (Piaget, 1970; Norton & Bell, 2017).

Units Coordinating Structures

A units coordinating structure defines and regulates relationships between transformed *units* as possible, logically necessary, and reversible (Boyce & Norton, 2017). Here a *unit* refers to a size, and transformations include operations of partitioning and iterating as well as composing (putting one unit inside another unit) and disembedding (removing a copy of a unit from within a composite unit without modifying the composite unit). Such operations are constructed by students as part of their process of constructing sequences of counting numbers and reorganized to apply to fractions (Norton & Wilkins, 2012) and integers (Ulrich, 2015).

Individuals' schemes for rational number are thus characterized in part by their levels of units (Steffe & Olive, 2010), where the number of levels of the structure refer to the nestedness of reversible coordinations. The iterative fraction scheme requires assimilation with a units coordinating structure relating three levels of units (e.g., four 1/4 units within one and nine 1/4 units within 9/4). Assimilation of fractional situations with three levels of units allows a student who has constructed an interiorized iterative fraction scheme to *anticipate* iteration of an amount determined by partitioning before actually carrying out the partitioning with internalized or physical objects.

Need for Distinguishment of Covariational Reasoning Levels by Pseudo-Empirical, Internalized, or Interiorized Mental Activity

Note that with one exception, the descriptions of the covariational reasoning levels (depicted in Figure 1) refer to forming mental imagery, which I associate with internalized schemes. I propose theorized distinguishment of pseudo-empirical and interiorized covariational reasoning. I contend that to understand learners' development of covariational reasoning across levels requires understanding their pseudo-empirical, internalized, and interiorized reasoning within levels. For instance, whereas internalized continuous covariational reasoning (both smooth and chunky) might require assimilation with three levels of units, perhaps students assimilating with two levels of units can construct pseudo-empirical schemes for smooth continuous covariational reasoning. Consideration of this additional lens can help to inform the field of more specific learning trajectories and support the design of tasks engendering *perturbation*, *abduction*, *assimilation*, *accommodation*, and *reflective abstraction* that result in students' construction of more powerful covariational reasoning.

Framing mental imagery associated with levels of covariational reasoning as internalized activity of covariational reasoning schemes allows for other representations of internalized actions (such as imagery of zooming in or out on the graph of an emergent trace (Ellis, Ely, Singleton, & Tasova, 2018) that may require the same levels of units interiorized. More generally, it allows for identifying learning trajectories within and across levels of covariational reasoning that extend beyond descriptions of internalized mental activities to include focus on how students act upon standard and non-standard representations of graphs (Frank, 2018; Paoletti & Moore, 2017) and equations (Stevens, 2019) as part of analyses of covariational reasoning.

Level	**Description from (Thompson & Carlson, 2017, p. 440)**	**Proposed Distinguishment by Pseudo-empirical, Internalized, or Interiorized Reasoning**
Smooth continuous covariation	The person envisions increases or decreases (hereafter, changes) in one quantity's or variable's value (hereafter, variable) as happening simultaneously with changes in another variable's value, and the person envisions both variables varying smoothly and continuously	Interiorized: The person anticipates smooth and continuous covariation between two quantities without necessarily forming mental imagery. Pseudo-empirical: The person evokes reasoning about a smooth and continuous representation without envisioning covariation between two quantities.
Chunky continuous covariation	The person envisions changes in one variable's value as happening simultaneously with changes in another variable's value, and they envision both variables varying with chunky continuous variation.	Interiorized: The person anticipates chunky and continuous covariation between two quantities without necessarily forming mental imagery. Pseudo-empirical: The person evokes reasoning about a chunky and continuous representation without envisioning covariation between two quantities.
Coordination of values	The person coordinates the values of one variable (x) with values of another variable (y) with the anticipation of creating a discrete collection of pairs (x, y).	Interiorized: The person anticipates correspondence between two variables' values without necessarily forming mental imagery of their pairing. Pseudo-empirical: The person anticipates forming a new representation of discrete correspondences by which to reason about changes.

Gross coordination of values	The person forms a gross image of quantities' values varying together, such as "this quantity increases while that quantity decreases." The person does not envision that individual values of quantities go together. Instead, the person envisions a loose, nonmultiplicative link between the overall changes in two quantities' values.	Interiorized: The person anticipates binary correspondences between two variables' changes without forming mental imagery. Pseudo-empirical: The person identifies and reasons about representations of binary correspondences between two variables' changes.
Pre-coordination of values	The person envisions two variables' values varying, but asynchronously—one variable changes, then the second variable changes, then the first, and so on. The person does not anticipate creating pairs of values as multiplicative objects.	Interiorized: The person anticipates an asynchronous sequence of binary changes in values without forming mental imagery. Pseudo-empirical: The person identifies and reasons about representations of an asynchronous sequence of binary changes in values.
No coordination	The person has no image of variables varying together. The person focuses on one or another variable's variation with no coordination of values.	Internalized: The person forms an image of one variable varying. Pseudo-empirical: The person reasons about variation in one variable by relying on a representation.

LEARNING FROM TEACHING: A NEW MODEL OF TEACHER LEARNING

Yasemin Copur-Gencturk
University of Southern California
copurgen@usc.edu

Jessica Rodrigues
University of Missouri
rodriguesjm@missouri.edu

The development of a model that explains how teachers learn from teaching is critical for informing the design of quality professional development, which in turn can support teachers' effectiveness and student learning. This article reports the authors' effort to develop a model that brings together critical findings from existing research to unpack when and under what conditions teachers learn from teaching. Grounded in evidence drawn from research relating to teachers' learning and practice, the authors build a rationale for the Learning from Teaching (LFT) model, introduce each component of the model and propose two conditions that increase the likelihood of teachers' learning from their own teaching.

Keywords: Learning Theory, Mathematical Knowledge for Teaching, Teacher Education, Teacher Knowledge

Most people would agree that teachers continue to learn and improve their teaching throughout their career. Yet, when and under which conditions teachers learn from teaching are not clearly identified. Reviews of professional development programs pinpoint different attributes of professional learning opportunities that result in changes in teacher practices and improvements in student learning (cf. Blank, las Alas, & Smith, 2008; Borko, Jacobs, & Koellner, 2010; Darling-Hammond, Hyler, & Gardner, 2017; Desimone, 2009; Garet et al., 2011, 2016; Kennedy, 2016; Piasta, Logan, Pelatti, Capps, & Petrill, 2015; Santagata, Kersting, Givven, & Stigler, 2011). For instance, Darling-Hammond and colleagues (2017) identified in their review of professional development studies that the content focus was a characteristic of effective programs, whereas Kennedy (2016) found that programs with a content focus did not seem effective.

We suggest that this cycle of conflicting findings about what makes professional development effective can be interrupted by the development of a testable model of how teachers learn from teaching. Without such a foundational model that seeks to explain the key mechanisms underlying teachers' *learning from teaching*, researchers will continue to conduct assessments of teacher learning from various perspectives that yield conflicting findings. In alignment with our argument, Kennedy (2016) noted in her recent review that *"Education research is at a stage in which we have strong theories of student learning, but we do not have well-developed ideas about teacher learning"* (p. 973).

Thus, our intentions of the present article are (a) to contribute to the literature by bringing attention to the importance of developing a model of how teachers learn from teaching and (b) to share our theoretical Learning from Teaching (LFT) model that is informed by prior research and can be tested in future research. We conceptualize teachers' *learning from teaching* as adjusting, adding to, or changing instructional practices.

The Learning from Teaching (LFT) Model

Our model considers how teachers and students co-create the teaching context that shapes teachers' learning process (see Figure 1). Central to this model is that the *temporal links (i.e., time interval) between teaching actions and evidence of student learning* influences what can be learned from teaching. For instance, the model suggests that a teacher who does not attempt to capture students' learning (through formative or summative assessments) for a week will be unlikely to learn from his or her teaching because it will be challenging to pinpoint which teaching actions contributed to students' learning. We also identify teachers' problem-solving skills as the key mechanism for their learning. We argue that without problem-solving skills, teachers cannot learn from their teaching because they will not be able to identify what teaching action is causing students to learn or struggle.

Teachers and Students Co-Create the Teaching Context

As shown in the first part of the figure, our model highlights how characteristics of individual teachers and their students will co-create the teaching context. This teaching context will shape what teachers can learn from their teaching. What we suggest here is that each individual teacher has a somewhat different teaching context and encounters different teaching moments that influence the teacher's learning environment. Therefore, understanding how teachers, their students, and other contextual factors simultaneously create a potential learning environment that could be different for individual teachers is crucial.

This dynamic and yet individualized teaching context includes instances of teaching actions and evidence of students' learning. While many scholars focus on either teaching actions (e.g., improving the cognitive demand of tasks) or students' thinking (identifying instances of students' mathematical thinking as key to productive classroom discussions; Leatham, Peterson, Stockero, & Van Zoest, 2015), both are included in the LFT model.

Temporal Links Between Teaching Actions and Evidence of Student Learning

In the next part of the LFT model, we consider how the temporal links between teaching actions and evidence of student learning play a key role in whether teacher learning occurs. If the time interval between the teaching actions and evidence of student learning is too great, it becomes a difficult task for teachers to identify which of their actions is leading to student learning. Our argument is both supported by research suggesting that formative assessment, which includes teachers' informal assessment of students' learning throughout a lesson, can lead to student learning (Black & William, 1998) and data driven research (e.g., Farrell & Marsh, 2016a; 2016b). To illustrate our point, consider a dramatized example of two teachers who have identical teaching contexts (identical students, the same levels of knowledge and skills, identical beliefs, and the same teaching materials). Teacher A is not collecting any information on his students' understanding through questions or observations and is not frequently inviting students to share their ideas to reveal their thinking. In contrast, Teacher B is frequently "collecting data" from her students through observations, student participations, or questions to see whether her students are on track. Thus, we propose that because the time distance between the teaching actions and student input is longer for Teacher A, it becomes challenging for him to pinpoint what his students do or do not learn and identify what part of his instruction could potentially have contributed to this outcome. As illustrated in Figure 1, when the time distance between the teacher's actions and student learning narrows, the number of potential links decreases, which in turn helps the teacher identify how his or her teaching interacts with the students' learning.

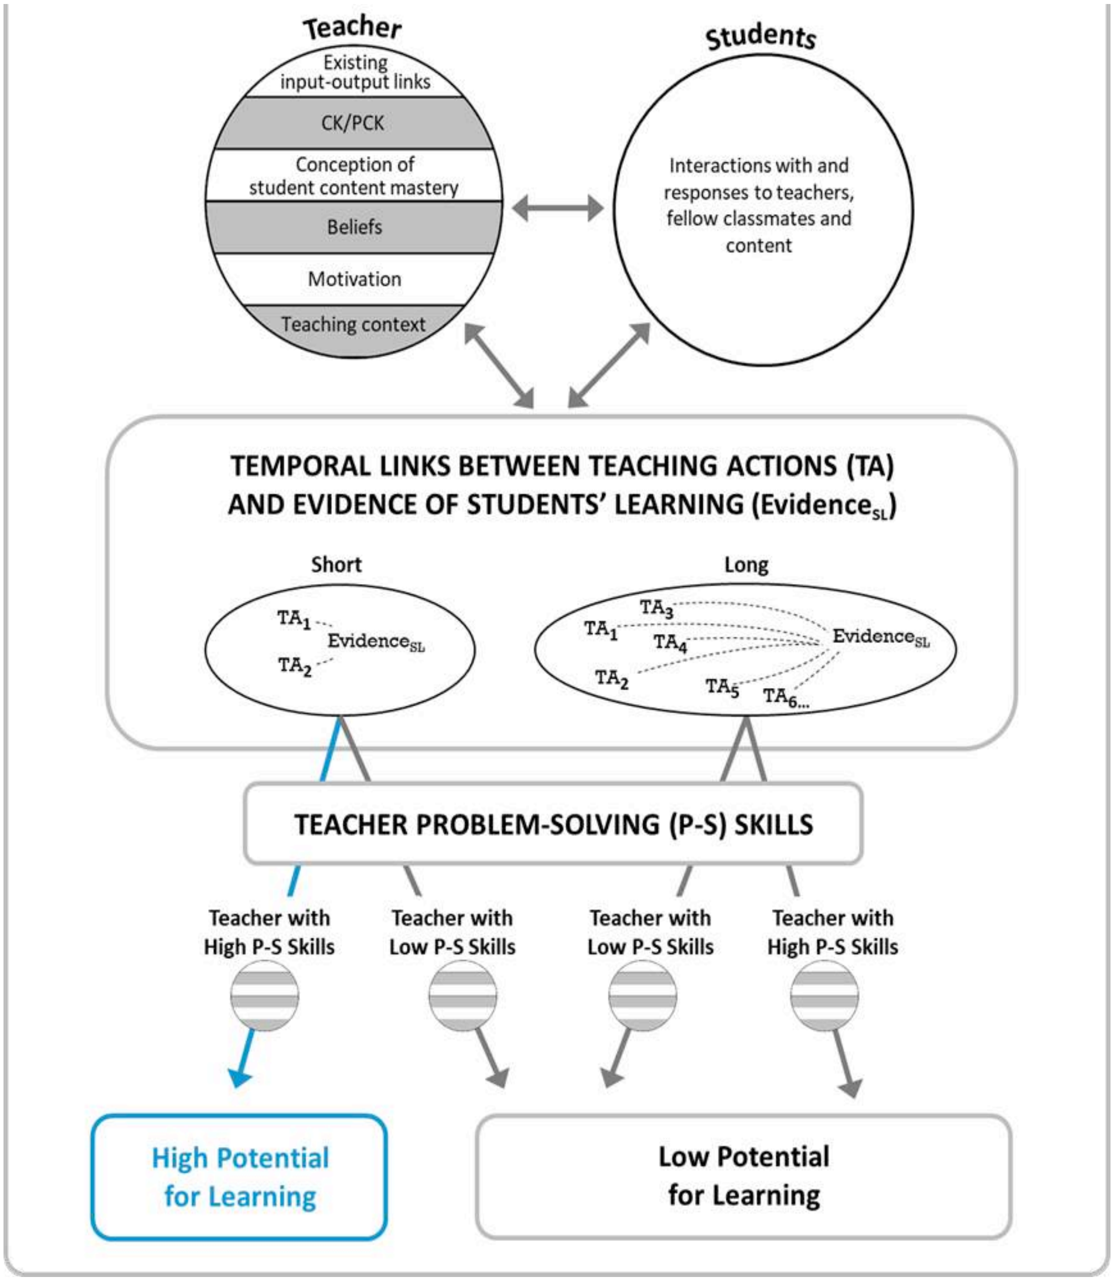

Figure 1. The Learning from Teaching (LFT) model.

Teachers' Problem-Solving Skills

We argue that problem-solving skills are key to teacher learning, and those who have developed problem-solving skills can learn on their own from teaching (Franke, Carpenter, Levi, & Fennema, 2001). As for any sorts of problems, dealing with them effectively requires developing a systematic approach to problem solving. That is why we have turned to one of the most successful strategies developed by Polya (2004) to help students develop problem-solving skills. According to Polya, problem solving involves four phases: (1) understanding the problem (why students learned or did not learn, what contributed to this outcome, what data we must have to find a solution, what other factors we need to take into consideration); (2) devise a plan (of all the potential strategies, knowing which one is more likely to lead to a correct solution); (3) execute the plan; and (4) look back (identifying whether the strategy was the right one and what can be generalized from this experience to other similar situations).

Understanding the problem is one of the first and most vital steps in solving any problem. It requires teachers to identify “the unknown, the data, the condition” (p. 28, Polya, 2004). Consider a teacher who wants to know whether his or her students have achieved the learning goal. What is *unknown* is what contributed to students’ learning or confusion. The *data* are the temporal links created during teaching or additional data, such as exit tickets, gathered on student learning. The *condition* is whether other factors in the teaching context and the available data are sufficient to determine what students learned or did not learn.

Devising a plan is the long journey that takes place after understanding the problem; it involves many unsuccessful trials. Indeed, this is why we created different learning paths, depending on teachers’ problem-solving skills. Teachers with strong problem-solving skills may think of a similar situation with similar unknowns and analyze how the current problem is related to similar problems solved before.

The third phase, *carrying out the plan*, is testing what is determined to be the reason for student learning. Executing the plan requires paying attention to the steps involved in the plan. For instance, if the plan is to use a specific manipulative (e.g., base-10 blocks) to help students understand the concept they are struggling with (e.g., the place-value system), then attending to the fact that mathematical ideas and representations (base-10 models) are clearly linked is the step required for correct execution of the plan.

The final step is *looking back*, which allows teachers to reexamine both the strategy and the result (e.g., whether modeling with base-10 blocks helped students understand what each digit means in the base-10 system). Checking whether the solution is supported by all the data collected helps teachers learn to analyze their teaching systematically to determine what works. Finally, good problem solvers generalize what is learned from a particular problem to solve similar problems by looking back at the same problem. Thus, we propose that only teachers with good problem-solving skills may change or adapt their existing conceptions because they collect data, devise a strategy, and evaluate their strategy by using evidence and reasoning.

Summary of the LFT Model

The LFT model suggests that teacher learning from teaching is situated in the teacher’s dynamic teaching environment and is jointly created by teachers and their students. Learning from teaching depends on the time distance between teaching actions and student learning evidence as well as on teachers’ problem-solving skills. In particular, two conditions increase the likelihood of teachers’ learning from teaching: (1) shortening the temporal links between teaching actions and evidence of student learning, because this limits the amount of potential actions the teacher can select to explain a certain outcome and (2) problem-solving abilities, because these allow teachers to use the information on hand systematically to find an answer to how particular teaching actions are linked to student learning. Teachers with problem-solving skills can work on the problem of teaching systematically and eventually find a correct answer to what is helping students learn or causing them to struggle.

DESIGN AND VALIDATION OF TWO MEASURES: COMPETENCE AND SELF-EFFICACY IN MATHEMATICAL MODELING

DISEÑO Y VALIDACIÓN DE INSTRUMENTOS DE MEDICIÓN DE COMPETENCIAS Y AUTOEFICACIA DE MODELIZACIÓN MATEMÁTICA

In this article, we share the design and validation processes of two instruments measuring aspects of the mathematical modeling process – one that measures competency and one that measures students' self-efficacy to do modeling. The study evaluates both instruments to establish their validity and reliability, using classical test theory.

Keywords: Measurement and Evaluation, Post-Secondary Education, Advanced Mathematical Thinking

Despite calls over recent decades to increase the number of graduates in STEM fields, these numbers have not grown sufficiently. Learning to apply knowledge in these majors implies integration of experiences leveraging design theories, scientific inquiry, technological literacy, and mathematical thinking (Kelley & Knowles, 2016). These goals can be realized through mathematical modeling. Modeling is of utmost importance for students pursuing STEM majors because modeling skills are of critical import to solving society's problems – whose solutions have global consequences. Today's students also take great interest in solving them (Eccles & Wang, 2016; Su, Rounds, & Armstrong, 2009). Further, research suggests that learning mathematics through modeling, as a pedagogical approach, has potential to increase student interest, proficiency in mathematics, robustness of mathematical knowledge, and self-efficacy for doing mathematics (Czocher, 2017; Czocher, Melhuish, & Kandasamy, 2019; Lesh, Hoover, Hole, Kelly, & Post, 2000; Rasmussen & Kwon, 2007; Sokolowski, 2015). Taken together, these factors are positively associated with persistence in mathematics and therefore in majors with high mathematics requirements. One aspect of incorporating more modeling in undergraduate mathematics classrooms is being able to demonstrate the efficacy of instructional interventions by measuring gains in students' modeling skills. This information would help refine programmatic innovations that focus on augmenting students' modeling experiences. Despite the need, there are presently no validated, reliable instruments to measure students' modeling skills available for undergraduates. In this article, we share two such instruments and their psychometric properties: one for modeling competencies and one for self-efficacy to carry out those competencies.

Conceptual Framework

For this project, we adopt a view of mathematical modeling as a cognitive process of rendering a non-mathematical problem about a real-world phenomenon of interest, such as those common to STEM fields, as a well-posed mathematical problem to be solved. It is a cyclic process realized as a suite of mathematical activities and cognitive processes (e.g., Kaiser, 2017). The mathematical problem can be expressed as an equation, a graph, a table, etc. The modeler solves the mathematical problem and interprets its solution in terms of the real-world context. The modeler validates and verifies each step of the process, evaluating whether the model correctly represents the situation and whether the solution makes sense (Czocher, 2018). Table 1 summarizes the conceptual framework,

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

called a mathematical modeling cycle (MMC) (Blum & Leiss, 2007; Czocher, 2016; Maaß, 2006), and also defines the competencies that constitute the modeling process.

Table 1 Modeling competencies

Competency	Description
Understanding	Forming an idea of the real World problema or identifying a real world phenomenon worth investigating
Structuring	Identifying (ir)relevant quantities and variables; making assumptions to simplify the problem
Mathematizing	Expressing relations among the variables using a mathematical representation
Working mathematically	Solving the mathematical problema, using techniques learned in mathematics classes
Interpreting	Interpreting the mathematical results with reference to the context of the real world problem
Validating	Evaluating whether the model represents the situation; verifying the analysis; establishing limitatinos

We operationalize self-efficacy *about* a task as an individual's self-assessed capacity to successfully carry it out (Bandura, 2006; Betz & Hackett, 1983; Hackett & Betz, 1989). In this study, self-efficacy is always evaluated with reference to a specified task. We operationalize the construct *self-efficacy for mathematical modeling* as an individual's self-assessed capacity to successfully carry out the interrelated competencies of the mathematical modeling process. In this way, we can, for example, consider a student's self-efficacy to identify the most important variables involved in estimating the spread of smart homes in the 21st century. The conceptual frameworks are compatible and we used them together to guide the design of the modeling self-efficacy and modeling competency scale items.

Methods

This study has a quantitative nature and is situated within the development of the two instruments, with the purpose of establishing evidence in support of their validity and reliability. The population under study was university STEM majors in the United States. The modeling self efficacy (MSE) instrument went through four rounds of design and testing. In each field test, we used a sample of STEM majors who participated in an international modeling competition called SCUDEM[1], which focuses on modeling with differential equations. In the first round of field testing, there were 6 related items for students to report their self-efficacy for the modeling competencies. In the second round, we created an additional item asking about *establishing limits* (a competency of *validating*, see Table 2, item 6) and we clarified previous items. We used pre- and post- forms of the MSE to measure change in students' self-efficacy from before to after competing. We found gains of moderate effect size $d = 0.545$ ($t(92) = -6.663, p < 0.001$). In the third round, we created a new item targeting *working mathematically* (Table 2, Item 4). Previously, this competency was excluded because it is traditionally the focus of mathematics instruction, and is complementary to modeling. In the third round, we measured statistically significant positive gains in self-efficacy for those participants who answered both the pre- and post-survey ($t = 4.202, df = 51, p < 0.001$). The final round was carried out concurrently with field testing of the Modeling Competency Questionnaire (MCQ), detailed be low. In each round, we carried out a principal component analysis (Abdi & Williams, 2010) to estimate variance and calculated Cronbach's α as a measure of internal consistency. Summary statistics are in Table 3. Our analyses, together with the instrument's construction based in theories of mathematical modeling, suggest that the MSE is unidimensional with high internal consistency, fase, content, and construct validity.

[1] The annual SCUDEM challenge is hosted by SIMIODE, https://www.simiode.org/scudem. SIMIODE is a professional organization of educators who advocate teaching differential equations from a modeling perspective.

Table 2 Final MSE instrument.

Rate your level of confidence by recording a number from 0 to 100 using the scale given below 0 10 20 30 40 50 60 70 80 90 100 Cannot do at all Moderately can do Highly certain can do.	Competencies
Create a differential equation model for the spread of smart home appliances in the United States during the twenty-first century.	Mathematize
In (1) identify the important variables leading to a reasonably accurate prediction.	Identify variables
In (1) make simplifying assumptions to reduce the number of important variables.	Make assumptions
In (1) select an appropriate numerical, graphical, or analytic technique to solve the resulting differential equation	Work mathematically
In (1) consult appropriate resources to check whether your model was reasonable.	Validate
In (1) list the real-life and mathematical limitations of your model.	List limitations
In (1) create a short presentation to convince a smart appliance manufacturer that they could rely on your model to develop their business plan.	Communicate findings
Given a differential equation which describes the rate of formation of material A, $A'(t) = \alpha A(t)^{\beta}$ and a data set of observations for time, t, amount of material A at each time t, you could estimate the parameters α and β.	Estimate parameters

Tabla 3 Summary of analysis of MSE

Round	N	Varience (ACP)	α	Round	N	Variance (ACP)	α
1	38	62.5%	0.822	3	198	61.5%	0.908
2	276	67.1%	0.917	4	226	69.0%	0.935

Design and testing for the MCQ was carried out in three rounds (feasibility, difficulty, and discrimination) with distinct samples drawn from a large, southwestern university in the United States. We imposed four restrictions on the design: (1) items should be drawn from authentic and relevant contexts (e.g., radioactive decay or analysis of a recycling program), (2) items should draw on knowledge from STEM content or everyday knowledge, (3) items should target the aspects of the modeling competencies, and (4) distractor choices should capture decisions and justifications common to students' reasoning. We created 118 multiple choice items belonging to 9 real-world situations, selected from instructional and research materials from STEM education. Mathematics content included arithmetic, algebra, calculus, and differential equations. For each item, we created one correct answer and four distractors that would appear reasonable to the students but would not help to model the situation. To establish content and construct validity, we invited two mathematicians who teach differential equations to STEM students and three mathematics education researchers who specialize in teaching and learning of mathematical modeling to evaluate the items for appropriateness, correctness, and aptness to the MMC. In the first round, 14 students answered the MCQs and gave us reasoning to justify their choices. We eliminated items that did not make sense to the student. In cases where a student selected a distractor but had sensible reasoning, we modified the item. In the second round, 78 students answered 63 items, distributed among two forms that balanced contexts and competencies. For each item, we calculated the mean difficulty. The majority (76%) of the items had moderate difficulty ($0.20<p<0.70$). We eliminated items outside this range as either too difficult or too easy, restructuring some of the too-difficult items. To analyze distractor efficiency, we calculated the proportion of students that selected each option. At least 5% of the students selected each of the 253 distractors (one item had 5 distractors). For 17 items, a distractor was selected more frequently than the correct answer. These items were flagged as potentially strong discriminators among students with varying levels of modeling competencies. After restructuring problematic items, we chose 30 items (15 items for each of 2 forms). The two forms were administered to a sample of $n = 314$ volunteers who participated in the SCUDEM competition, $n = 135$ responded to Form 1 and $n = 139$ responded to Form 2. For each item, we calculated the mean difficulty. Form 1 had mean difficulty 0.359 ($SD = 0.126$), with $0.177 < p < .0595$. Form 2 had mean difficulty 0.369 ($SD = 0.129$), with $0.147 < p < 0.580$. Four items were too difficult. We conducted another analysis of distractors and concluded that they were functioning adequately. We used point-biserial correlations (rPBIS) to conduct discrimination analysis. Only one item from Form 1 had a negative rPBIS; the remaining items had rPBIs > 0.20. We report the statistics Revelle's Omega Total (ω_T) as an estimate of internal consistency. This selection is appropriate in cases, like the MCQ, where the instrument is multidimensional and when those multiple dimensions contribute to the construct under investigation (Revelle & Zinbarg, 2009). Using the software package '`userfriendlyscience`' in R, we obtained $\omega_T = 0.59$ y $\omega_T = 0.63$, respectively, for Forms 1 and 2. The scales are approaching traditional estimates of 0.7.

Discussion

In this article, we have shared two instruments measuring mathematical modeling competencies and modeling self-efficacy. We also documented their design processes and their psychometric properties. The instruments are aligned with theories of mathematical modeling and have gone through several rounds of field testing. Future research will move into Item Response Theory as a means for constructing and calibrating parallel versions of the modeling competence questionnaire for use as pre/post or group comparison measures. In this way, the instruments can help to evaluate innovative educational interventions aimed at augmenting students' modeling skills. With such information, instructors, researchers, and academic units can improve modeling experiences for students and provide evidence of their efficacy. We are cautious but optimistic that the instruments can meet this goal as the evidence presented here suggests that both are reliable and valid for that purpose.

DISEÑO Y VALIDACIÓN DE INSTRUMENTOS DE MEDICIÓN DE COMPETENCIAS Y AUTOEFICACIA DE MODELIZACIÓN MATEMÁTICA

DESIGN AND VALIDATION OF TWO MEASURES: COMPETENCE AND SELF-EFFICACY IN MATHEMATICAL MODELING

Jennifer A. Czocher	Sindura Subanemy Kandasamy	Elizabeth Roan
Texas State University	Texas State University	Texas State University
Czocher.1@txstate.edu	s_k252@txstate.edu	Eaw109@txstate.edu

En este artículo, describimos el diseño y la validación de dos instrumentos – uno que mide la autoeficacia y otro que mide las competencias del proceso de la modelización matemática. La investigación consiste en la evaluación de ambas para establecer la validez y la confiabilidad utilizando técnicas de teoría clásica de validación.

Palabras clave: Valoración y Evaluación, Educación Postsecundaria, Modelización

A pesar de que una de las metas de la educación postsecundaria ha sido el aumentar el número de los graduados universitarios en las carreras de ciencia, tecnología e ingeniería, estos números no se han incrementado suficientemente. Para adquirir conocimiento útil, es necesario que el aprendizaje se fundamente en la combinación de la práctica y teoría de diseño, indagación científica, y en el pensamiento matemático (Kelley & Knowles, 2016). A través de la modelización matemática, se pueden lograr estas metas. Las habilidades de modelización matemática son de suma importancia al cursar carreras universitarias que requieren técnicas aplicadas a las matemáticas. También son importantes para resolver problemas sociales cuyas soluciones conllevan consecuencias mundiales y tangibles. La posibilidad de resolver los problemas sociales llama la atención de los estudiantes (Eccles & Wang, 2016; Su, Rounds, & Armstrong, 2009). Además, las investigaciones empíricas sugieren que aprender matemáticas a través de la modelización es beneficiosa para obtener una autoeficacia y un conocimiento matemático más robusto (Czocher, 2017; Lesh, Hoover, Hole, Kelly, & Post, 2000; Rasmussen & Kwon, 2007; Sokolowski, 2015). La modelización matemática, guiada por las innovaciones educativas, aumenta el interés, la competencia, y la autoeficacia de los estudiantes hacia las matemáticas (Czocher, Melhuish, & Kandasamy, 2019). Conjuntamente, esos factores también están asociados positivamente con la perseverancia en los campos disciplinarios que requieren las matemáticas. Para evaluar atentamente las intervenciones educativas y mostrar su eficacia, es necesario medir el aprendizaje. Esto ayuda a refinar programas que se enfoquen en las habilidades de la modelización matemática. A pesar de su necesidad tangible no existen instrumentos válidos ni confiables para evaluar las habilidades de modelización de los estudiantes universitarios. Aquí, compartimos dos instrumentos de medición y sus propiedades psicométricas: uno de competencias de modelización y otro de autoeficacia en realizarla.

Marco de Referencia

En este trabajo de investigación, se plantea el supuesto de que la modelización matemática es un proceso iterativo y cíclico que puede ser conceptualizado como un conjunto de actividades matemáticas y procesos cognitivos (e.g., Kaiser, 2017). El proceso comienza con un problema de la vida real – como los que son comunes en los estudios de ciencia, ingeniería o en la vida cotidiana – y desemboca en un problema matemático. El problema matemático se puede expresar como una ecuación, un gráfico, o una tabla de valores. El modelador resuelve el problema matemático y desde la solución matemática él interpreta el significado de los resultados al problema original planteado. El modelador valida y verifica cada etapa del proceso para evaluar si el modelo representa correctamente la situación real y si la solución tiene sentido (Czocher, 2018). La Tabla 1 presenta el marco de referencia que se denomina "ciclo de modelización matemática" (CMM) (Blum & Leiss, 2007; Czocher, 2016; Maaß, 2006) y define las competencias que constituyen el proceso de modelización matemática. Definimos la autoeficacia de realizar una tarea como la confianza de una persona en sí misma y en su capacidad para lograr resolver la tarea exitosamente (Bandura, 2006; Betz & Hackett, 1983; Hackett & Betz, 1989). En esta investigación, la autoeficacia siempre es evaluada con referencia al objetivo de la tarea. Definimos el constructo *autoeficacia de modelización matemática* como la confianza de una persona en sí misma y en su capacidad de realizar las actividades interrelacionadas que constituyen el proceso de modelización. De esta manera podríamos medir la autoeficacia de un estudiante para identificar las variables más importantes involucrados en estimar la propagación de hogares inteligentes en el siglo 21. El CMM y la autoeficacia son compatibles, y los utilizamos en conjunto para guiar el diseño de los ítems.

Tabla 1 Competencias de modelización.

Competencia	Descripción
Comprender	Formación de una idea de lo que debe ser el problema o identificación de un fenómeno de la vida real que merece investigación
Establecer estructura	Identificar los factores y cantidades reales relevantes y la información que se puede ignorar; imponer restricciones o supuestos para simplificar el problema
Matematizar	Expresar las relaciones entre las cantidades en una representación matemática
Analizar	Resolver el problema matemático, usando técnicas aprendidas en la clase de matemáticas
Interpretar	Observar y entender los resultados matemáticos desde el contexto del problema real
Validar	Examinar si el modelo representa la situación; verificar el análisis; establecer limitaciones

Metodología

La investigación es de naturaleza cuantitativa y se enmarca dentro de un estudio de desarrollo para establecer evidencia en apoyo de la validez y la confiabilidad de los instrumentos. La población bajo estudio consistió en estudiantes universitarios que estudian carreras en ciencias, tecnología, ingeniería, y matemáticas. A continuación, se documenta el diseño de los ítems. La evaluación del instrumento de autoeficacia se realizó en cuatro rondas de pruebas. En cada prueba empírica, usamos una muestra de estudiantes universitarios inscritos en un concurso internacional de modelización basado en lo que se llama SCUDEM (por sus siglas en inglés). El concurso se lleva a cabo cada año y es parte de una organización de capacitación que apoya a los profesores de matemáticas a quienes les gustaría enseñar los conceptos de ecuaciones diferenciales desde una perspectiva de aplicaciones y modelización matemática. En la primera ronda, eran 6 ítems relacionados con la autoeficacia de modelización. En la segunda, creamos un ítem (Tabla 2, ítem 6) y modificamos los ítems anteriores para mejorar su claridad. En la segunda ronda, también medimos el cambio de autoeficacia antes y después de participar en el concurso y constatamos una ganancia de efecto moderato, $d = 0.545$ $(t(92) = -6.663, p < 0.001)$. En la tercera, creamos un item nuevo de análisis matemático (Tabla 2, Ítem 4). Previamente fue excluido porque el enfoque eran las actividades complementarias de modelización. En la tercera ronda el instrumento midió el cambio positivo de autoeficacia ($t = 4.202$, $df = 51, p < 0.001$) de los participantes que contestaron las preguntas antes y después de participar en el concurso. En cada ronda de validación, realizamos un análisis de los componentes principales (Abdi & Williams, 2010), calculamos el Chronbach's α para estimar la consistencia interna, y medimos el cambio de autoeficacia antes y después de participar en el concurso. La Tabla 3 resume los resultados. Este análisis, en conjunto con su construcción basado en la teoría de modelización matemática, indica que el instrumento de autoeficacia es unidimensional con coherencia interna alta y tiene validez de diseño y de constructo.

Tabla 2 El instrumento final de autoeficacia.

Indica tu nivel de confiabilidad en cada uno de los escenarios siguientes, elegiendo un numero de 0 a 100 usando la siguiente escala: **0 10 20 30 40 50 60 70 80 90 100** **No puedo hacer. Tengo dudas… Con certeza elevada.**	**Competencias**
Crear un modelo de ecuaciones diferenciales para estimar la propagación de hogares inteligentes en el siglo 21.	Matematizar
En (1), identificar las cantidades importantes que aseguran una predicción razonablemente precisa.	Establecer estructura
En (1), establecer los supuestos que reducen la cantidad de factores importantes.	Establecer estructura.
En (1), elegir un método apropiado de tipo numérico, gráfico ó analítico para resolver la ecuación diferencial que resulta de (1).	Analizar
En (1) consultar a los recursos apropiados para verificar si el modelo matemático es razonable.	Validar
En (1) enumerar las limitaciones del modelo matemático, incluyendo restricciones de la vida real y restricciones matemáticas.	Validar
En (1), crear una presentación breve para persuadir un fabricante de aparatos inteligentes que podrían depender en tu modelo matemático para fomentar un plan de negocios.	Comunicar
Proporcionando una ecuación diferencial que modela la tasa de formación del material A, $A'(t) = \alpha A(t)^{\beta}$ y los datos de observaciones en tiempo t, la cantidad de material A por cada punto de tiempo t, podría estimar los parámetros α y β.	Establecer estructura

Tabla 3 El resumen del análisis del instrumento de autoeficacia de modelización

Ronda	N	Varianza (ACP)	α	Ronda	N	Varianza (ACP)	α
1	38	62.5%	0.822	3	198	61.5%	0.908
2	276	67.1%	0.917	4	226	69.0%	0.935

La evaluación del instrumento de competencias de modelización se realizó en tres rondas de pruebas con muestras distintas de una universidad de más de 40,000 estudiantes en los EEUU: viabilidad, dificultad, y discriminación. Para diseñar el instrumento tomamos en cuenta cuatro restricciones: (1) los ítems parten de contextos auténticos y relevantes (por ejemplo, la desintegración radioactiva o un programa de reciclaje). (2) Los ítems evocan conocimientos de matemática, ciencia, ingeniería, y sentido común. (3) Los ítems abordan aspectos de las competencias. Por ejemplo, un ítem aborda la competencia de establecer la estructura que se requiere al utilizar la habilidad de identificar cantidades importantes. (4) Los distractores son basados en las decisiones y justificaciones comunes al pensamiento de estudiantes actuales. Elaboramos 118 ítems de tipo selección múltiple (ISM) que pertenecen a 9 situaciones de la vida real elegido de materiales de cursos de matemáticas, física, biología, química e ingeniería. El contenido matemático incluye aritmética, álgebra, cálculo diferencial e integral y ecuaciones diferenciales. Por cada ítem, elaboramos una respuesta correcta y cuatro distractores que parecieran razonables a los estudiantes pero que no ayudaran a modelizar la situación. Para establecer la validez de contenido y la validez de los constructos, invitamos a revisar los ítems a dos investigadores matemáticos que se enfocan en la investigación de ecuaciones diferenciales y tres profesores universitarios de matemáticas que se especializan en realizar investigaciones sobre el aprender y enseñar la modelización. Aplicamos los cambios que sugirieron los expertos y eliminamos los ítems que resultaron no válidos. En la primera ronda, 14 estudiantes nos dieron su razonamiento para justificar sus elecciones. En el caso de que un estudiante eligiera un distractor y su razonamiento tuviera sentido, el ISM fue ajustado. Eliminamos los que no tenían sentido para los estudiantes. En la segunda ronda, 78 estudiantes contestaron 63 ISM en 2 versiones, equilibrando ítems de acuerdo a las distintas competencias de modelización. Por cada ISM, calculamos la dificultad media. La mayoría (76%) de los ISM tenían dificultad moderada (0.20<p<0.70). Eliminamos los ítems que eran demasiado fáciles (p>0.7) y restructuramos los ítems que fueron demasiado difíciles (p<0.20). Para analizar la eficacia de los distractores, calculamos la proporción de los estudiantes que eligieron cada opción. De los 253 distractores (62 ítems contaban con 4 distractores y 1 contaba con 5), El 5% de los participantes eligieron la mayoría de estos distractores. En 17 de los ítems, los distractores fueron elegidos más frecuentemente que las respuestas correctas. Estos fueron identificados de acuerdo con su potencial de discriminar entre estudiantes de distintas habilidades o como ítems que necesitaban ser reestructurados. Después de reestructurar los ISM según el análisis de distractores, elegimos 30 ítems (2 versiones de 15 ítems). Las dos versiones se administraron a una muestra de $n = 314$ voluntarios que participaron en el concurso SCUDEM, incluyendo $n = 135$ que contestaron a la versión 1 y $n = 139$ que contestaron a la versión 2. Por cada ISM, calculamos la dificultad media. La versión 1 obtuvo dificultad media de 0.359 ($SD = 0.126$), con $0.177 < p < .0595$. La versión 2 obtuvo dificultad media de 0.369 ($SD = 0.129$), con $0.147 < p < 0.580$. Cuatro ítems eran demasiado difíciles. Se realizó un análisis de detractores y concluimos que los distractores funcionaban adecuadamente. Para realizar el análisis de discriminación, usamos la correlación point-biserial (rPBIS por sus siglas en ingles). Un solo ítem de la versión 1 tenía rPBIS negativo. El resto tenían rPBIS > 0.20. Reportamos la estadística Revelle's Omega Total (ω_T) para estimar la consistencia interna. La selección fué apropiada en casos donde el instrumento era multidimensional y cuando múltiples dimensiones contribuían a predecir el constructo bajo investigación (Revelle & Zinbarg, 2009). Usando el paquete de software 'userfriendlyscience' del programa R, obtenemos $\omega_T = 0.59$ y $\omega_T = 0.63$ para la versión 1 y la versión 2, respectivamente. Las escalas se acercan al estimado tradicional 0.7.

Discusión

En este artículo, presentamos dos instrumentos de medición, uno de autoeficacia de modelización y uno de competencia de modelización. Así mismo, documentamos los procesos de construcción y diseño y las propiedades de ambos. Los instrumentos se alinean con las teorías de modelización y han pasado múltiples rondas de pruebas. Se planea emplear la Teoría de Repuesta al Ítems para componer versiones que sean paralelas para medir los cambios positivos de las competencias de modelización de los estudiantes con el propósito de evaluar programas educativos que se enfoquen en ensenar la modelización. Con esta información investigadores y docentes pueden mejorar las experiencias de modelización o proporcionar evidencia de su éxito. Estamos cautas pero optimistas que los instrumentos alcancen este objetivo ya que la evidencia expuesta aquí sugiere que los instrumentos son confiables y válidos para su propósito.

Agradecimientos

Este material se ha desarrollado gracias al apoyo de la donación No. 1750813 de la National Science Foundation. Además, estamos agradecidas a nuestras maravillosas colegas Alejandra Sorto, Monica Uribe, Gloria Velasquez y Alba Melgar por el apoyo brindado en la revisión del presente artículo.

GESTURE IN PROOF AND LOGICAL REASONING

Laurie D. Edwards
Saint Mary's College of California
ledwards@stmarys-ca.edu

Twelve doctoral students in mathematics took part in clinical interviews during which they were asked about their experiences with teaching, learning and doing proof. They were also asked to work together to find a proof for an unfamiliar conjecture. The students' discourse, including gesture, was analysed from the perspective of embodied cognition. In particular, a potential continuity between mathematical and everyday discourse was investigated, with a particular focus on epistemic conditionals, that is, "if-then" statements.

Keywords: Embodiment and Gesture; Reasoning and Proof; Advanced Mathematical Thinking; Cognition

Objectives of Study

In recent decades, researchers have investigated how the body in implicated in mathematical teaching and learning, challenging the paradigm that cognition is amodal and abstract, based solely "in the head." In addition, attention to embodiment has broadened the focus within mathematics education research beyond written symbols, images, and oral speech to include modalities such as gesture and other bodily movements (Edwards, Ferrara, & Moore-Russo, 2014; Hall & Nemirovsky, 2012). The purpose of this paper is to examine mathematical proof and logical reasoning from the perspective of embodied cognition (Edwards, 2011; Varela, Thompson, & Rosch, 1991), using data collected from clinical interviews with 12 doctoral students in mathematics.

The analysis presented here is based on the principle of cognitive continuity; that is, the proposition that there are not multiple different kinds of thinking, even within a domain like mathematics, but rather all thought is ultimately founded in embodied, physical experience (Johnson, 2012; Lakoff, & Núñez, 2000; Varela, Thompson, & Rosch, 1991). The implication is that even with "advanced" mathematical thinking, like that involving proof and logic, connections can be made with more everyday kinds of thinking and basic human experiences. As Johnson states, "we do not have two kinds of logic, one for spatial-bodily concepts and a wholly different one for abstract concepts. There is no disembodied logic at all. Instead, we recruit body-based, image-schematic logic to perform abstract reasoning" (Johnson, 2012, p. 181). The research reported her aims to delineate one way in which elements within the abstract domain of mathematical proof are connected to similar ones in everyday discourse.

Following Hanna (1990), we take proof to be:

> [A] finite sequence of sentences such that the first sentence is an axiom, each of the following sentences is either an axiom or has been derived from preceding sentences by applying rules of inference, and the last sentence is the one to be proved. (Hanna, 1990, p. 6)

Although this definition is appropriate for the end product of a process of proving, we also frame proof and proving as a specialized type of discourse, built on simple logical elements and constrained by agreements on validity generated within the mathematical community. In the current research, the specific focus is on logical statements that take the form of "if-then" statements; these statements can be seen as the building blocks of proofs. The central research question is whether the physical gestures that accompany these "if-then" statements when talking about proof are similar to those accompanying "if-then" statements in non-mathematical contexts. If so, then this would provide support for the notion of cognitive continuity between these two contexts.

Theoretical Perspective

The research was carried out utilizing the theoretical perspective of embodied cognition, making use of tools from cognitive linguistics and gesture studies. The theory of embodied cognition focuses on the bodily basis of thinking, that is, "on the ways in which complex adaptive behavior emerges from physical experience in biologically-constrained systems" (Núñez, Edwards, & Matos, 1999, p. 49; see also Varela, Thompson, & Rosch, 1991). Here, we focus not on specific mathematical content, for example, algebra or analysis, but on the mechanisms used by mathematicians to test and establish logical truth. Under Johnson's continuity principle, we propose that deductive proof and logic are constructed using the same basic conceptual building blocks as more mundane thought (Johnson, 2007).

Within an embodied cognition framework, mathematics is not seen as a transcendental, formal collection of rules and patterns, unrelated to everyday thinking and experience, but instead, as a human intellectual product, one which develops both historically as a discipline over time, and ontologically as it is constructed by an individual learner. It is socially-constructed, but not in an arbitrary way, being both constrained and enabled by the biological capabilities and physical situatedness of human beings. Embodiment does not deny the influence of social interaction and culture; rather it grounds it in shared biological constants (Hall & Nemirovsky, 2012; Nuñéz, Edwards, & Matos, 1999). As stated by Hall and Nemirovsky (2012), "We think of concepts (in mathematics but also in other domains) as forms of modal engagement in which bodies incorporate and express culture" (p. 212).

Prior Research on Proof

Prior research has been fruitful in its examination of the learning and teaching of proof, whether addressing the understandings and misunderstandings of novices, productive instructional practices and tools, or the thinking of advanced mathematicians (a selection of recent work can be found in Lin, Hsieh, Hanna & deVilliers, 2009). The current research builds on this foundation, particularly in seeing proof as a form of socially constructed knowledge and a specific form of discourse (Balacheff, 1991; Sfard, 2001). The current analysis adds the lens of embodiment and gesture studies in analyzing this discourse.

Prior Research on Conditional Statements

From the point of view of cognitive linguistics, mathematical or logical deductions ("if-then" statements) belong to a linguistic category known as conditionals (Dancygeir & Sweetser, 2005). Specifically, "if-then" statements represent the type called epistemic conditionals, because they reference a reasoning process, rather than a prediction or statement of fact. Two examples of epistemic conditionals are: "If the car is in the driveway, he must be home" and "If x is even, then x/2 is an integer" (p. 17). These kinds of conditionals involve what Danceygeir and Sweetser call a "metaphoric 'compulsion'" (p. 20) in which the speaker is "forced" to draw the given conclusion, either based on inductive reasoning ("the car is almost always in the driveway when he is home") or deductive logic (the mathematical definition of "even"). An analysis of how this metaphoric "compulsion" is grounded in early embodied experiences, providing a physical basis for the later construction of the notion of proof, can be found in Edwards (2017, 2019).

In addition to the linguistic analysis of explicit conditional statements by Danceygeir and Sweetser, recent research by Sweetser has examined gestures associated with spoken conditionals. In a study involving 402 video clips of talk shows, Sweetser and Smith (2015) found that conditionals were generally accompanied by a particular hand motion, specifically a movement along a transverse axis through gesture space, starting on the speaker's left and moving toward the speaker's right. The current analysis examined the gestures of mathematical doctoral students to see whether they also reflected this characteristic motion when orally stating epistemic conditionals. If so, then this would constitute evidence of the continuity between everyday uses of conditionals and their use in mathematical proof.

Methods

The research took the form of a qualitative study similar in format to a task-based clinical interview, recorded on audio and videotape. The participants, pairs of doctoral students in mathematics, were first interviewed about their specializations in mathematics, their experiences with teaching proof, and their ideas about whether there are different kinds of proofs. They were then presented with the conjecture below on a sheet of paper, and asked to work together to find a proof for it.

> Let f be a strictly increasing function from [0, 1] to [0, 1]. Prove that there exists a number a in the interval [0, 1] such that $f(a)=a$.

They were given 40 minutes to try to find a proof, during which the researcher left the room so that the participants could work without feeling self-conscious about being observed. During the third part of the interview, the students were asked to evaluate a visual "proof." The results presented here were drawn from the first part of the interview.

Participants

The participants were 12 doctoral students in mathematics, 9 men and 3 women, attending a research university in the United States. They were placed in pairs for the interviews based on their availability and schedules. They all knew each other as fellow students in the doctoral program, and two of the women, who worked together as a pair, were good friends. The time they had spent in the doctoral program ranged from less than a year to almost four years, and all had had experience in teaching undergraduate mathematics courses, although this experience did not involve much teaching of proof.

Context

The interviews took place in a small unused office with a blackboard at one end. The participants sat on chairs in front of the blackboard, facing the interviewer and the video camera. They were asked to use only the blackboard while working on the proof.

Data Collection

All sessions, lasting from 60 to 90 minutes each, were recorded on videotape and via digital audio, with the camera oriented to capture both the blackboard and the students as they sat or stood in front of it. A total of 6 hours and 55 minutes of video and audio were collected.

Analysis

The audiotapes were transcribed and annotated with brief notations of gestures as well as time spans of the use of different modalities by the participants. Specific segments of discourse containing gestures of interest were analyzed in more detail, utilizing the concurrent speech, written symbols, and drawn graphs to develop plausible interpretations consistent the context and with other research into gesture (Alibali, Boncoddo, & Hostetter, 2014; McNeill, 1992; Perrill & Sweetser, 2004).

Results

The analysis of the doctoral students' gestures when making conditional statements did indeed reveal the presence of the same left-to-right transverse gesture previously identified in non-mathematical contexts. Although the use of epistemic conditionals in speech was found throughout the video data, most instances occurred while the students were actively working on finding a proof; thus, their hands were often occupied with chalk or they were pointing to inscriptions on the board, meaning that "if-then" statements were often not accompanied by gestures. However, the transverse gesture did occur regularly in the data, approximately once in every ten instances in which an epistemic conditional was uttered. This occurred primarily when the students were talking to the interviewer, explaining a proof.

The example shown in Figure 1 illustrates three instances of this gesture form. In this example, the epistemic conditional that the student is expressing can be summarized as follows: "If you have a scalar function and a vector function, then the rule for finding their product is the same as the rule for finding the product of two scalar functions."

AC: Well, I guess, so, the other day they were trying to prove that, um, if you have some scalar function of T Int: Uh huh AC: —and some vector function of T,	 Figure 1a  Figure 1b	Left hand starts in horizontal C-shape ("bracket") facing upward on left side of body Left to right motion with left hand along transverse axis, ending in middle of body, with C-shape turning vertical
Int: Uh huh AC: —that the derivative of their product...	 Figure 1c  Figure 1d	Left to right motion with left hand along transverse axis, with left hand open and facing outwards. Left hand begins on left side of body and ends in middle of body.
is the same...		Rapid left to right motion with left hand along transverse axis. Left hand starts in loose horizontal C-shape ("bracket") facing upward on left side of body and ends in pointing gesture to the right.

	 Figure 1e  Figure 1f	
AC: ...product rule essentially that you know from just, you Int: (talking over): Uh huh.	 Figure 1g  Figure 1h	A complex motion in which the left hand begins by pointing downward, then is moved in a circle twice around the right hand while saying “you know,” ending up open and facing the speaker
AC: know from like scalar functions	 Figure 1i	Left hand moves to right and finishes in horizontal C-shape (“bracket”) on left side of body. This is the same shape and location as when the phrase “scalar function” was initially uttered.

Note: Underlined speech indicated the stroke or emphasized portion of the gesture

Figure 1: Student’s discourse about scalar functions

The sequence of gestures accompanying the student's speech is very rich, taking into account characteristics including hand shape and orientation, hand location, and movement of the hands through space. Consistent with other conditionals used in non-mathematical contexts, the sequence includes left-to-right motion along the transverse axis; in fact, this transverse motion occurs three different times, as shown in the pairs of figures above:

- Figure 1a – b: A relatively small left-to-right motion of the left hand, as AC begins by saying, "If you have some scalar function of T and some vector function of T." This sequence also includes a change in orientation of the left hand; when holding it on the left, AC uses an upward-opening (horizontal) C-shape as if "bracketing" or "holding" a scalar function. As she moves her hand to the right, she rotates her wrist so that when she says, "vector function," the C-shape is now vertical. She thus uses both hand shape and hand location to gesturally distinguish the two different kinds of functions.
- Figure 1c – d: A wider left-to-right motion of the left hand, as AC says, "the derivative of their product." In this case, the hand shape stays the same throughout, open and facing outward.
- Figure 1e – f: After saying "derivative of their product," AC pauses briefly, then makes a very rapid left-to-right motion of her left hand while saying, "is the same," starting with a horizontal C-shape and ending with a right-facing point.

As can be seen above, in addition to an overall left-to-right movement that occurs three times during the sequence, gestures are also used to mark or indicate specific mathematical objects, in a scheme that Calbris (2008) calls "two-entity opposition." Two-entity opposition occurs when either two locations in space or the two hands are used to denote or "mark" two related but distinct entities. In Figure 1, this happens when AC uses a horizontal "bracket" held to her left when saying "scalar functions" and then a vertical bracket held to her right when saying "vector functions." The terms "derivative" and "product" have the same hand shape but are marked by left and right hand locations, indicating two-entity opposition.

The discourse segment ends with AC discussing a "product rule" while using an iterative circular gesture during a pause in speech. This pause and rhythmic circular gesture may indicate that the participant is searching for her next words (Lucero, Zaharchuk, & Casasanto, 2014). She compares this product rule to a presumably familiar rule for scalar functions. Interestingly, the final gesture of the sequence, associated with the words "scalar function" has an identical shape and location as the gesture used the first time the words were uttered. This is an example of using specific hand shapes and locations in gesture space to "hold" a referent in discourse (Calbris, 2008; McNeill, 1992).

Discussion

Calbris (2008) has stated that in gesture space, the transverse axis can represent logico-temporal concepts, such as cause and effect, or before and after:

> A path in space or time is depicted by a left-to-right movement. But give that body symmetry allows this axis to account for splitting in two as well as two-entity oppositions, it can be used to oppose past and future, or precedence and successor, by locating the past on the left side and the future on the right side. (Calbris, 2008, p. 43)

In the current case, and in the research by Sweetser and Smith (2015), the transverse axis is used to indicate the premise followed by the conclusion of a conditional "if-then" statement.

The transverse axis of the body has been also called "the axis of reading and writing, pointing to the right in the Western world" (Calbris, 2008, p. 28). In this case, the motion of AC's gestures is consistent both with the placement of the "cause" (premise) on the left and the "effect" (conclusion) on the right, as well as the left-to-right order in which premise and conclusion are generally written in English. In the example given above, the left-to-right motion along the transverse axis is thus consistent both with how "if-then" statements are written in English, and with prior research and theory identifying this gestural motion with logical and conditional statements.

Taken in conjunction with related research (Edwards, 2010, 2011, 2017), we would argue that the examples above provide further evidence that proof and its building blocks, statements of logical deduction, are not abstract elements of disembodied rationality. Instead, we argue, these sophisticated forms of discourse make use of metaphorical mappings related to motion, and are supported by conceptual metaphors grounded in physical experiences.

Mathematical proof is thus seen as a specialized cultural product and a specific form of discourse, with particular constraints that distinguish it from everyday speech and make it more powerful for the purpose of exploring structure and patterns. Yet the form that this discourse takes is not arbitrary, but rather is grounded in embodied human experience. As shown above, there exists a continuity between the gestural grounding for the logical conditionals used in proof and those used in non-mathematical contexts. This kind of analysis is relevant to mathematics education because the conceptual sources that students draw from in constructing new mathematical knowledge may not correspond to the more sophisticated intra-mathematical sources that their instructors use (c.f., Núñez, Edwards & Matos, 1999). For example, students who are beginning to learn about formal logic often "import" expectations about conditionals from everyday speech, assuming that "if A, then B" implies "if not A, then not B" (Evans, Newstead, & Byrne, 1993). A better understanding of the cognitive roots of mathematical thinking may help in designing corrective instruction in such situations.

MAKING MEANING OF LEARNING TRAJECTORIES AMIDST MULTIPLE METAPHORS

Nicole L. Fonger
Syracuse University
nfonger@syr.edu

Amy Ellis
University of Georgia
aellis@uga.edu

In this theoretical report we focus on the issue of communicating learning trajectories (LTs) to researchers. There is great variation in the body of work on LTs including how researchers communicate what a LT entails, and the kinds of metaphors employed for making meaning of LTs. We elaborate possible affordances and limitations of different metaphors for LTs including "a garden path" and "growing flowers." This work has implications for how LTs are taken up by researchers, and also how LTs are leveraged to inform student-centered teaching practices.

Keywords: Learning Trajectories, Metaphors, Representations and Visualization

Learning trajectories are theoretical tools that elaborate transitions in students' processes of learning and goal-directed instructional supports. As a construct, learning trajectories can guide the design and study of teaching and learning by establishing predictions of how teaching and learning will unfold in tandem. Imagining, testing, and analyzing learning trajectories is core to the work of some design-based researchers, as are inquiries into how students learn mathematical ideas in response to instructional supports. Despite the integral nature of learning trajectories to some design-based research, the work of communicating such complex tools is challenging. Indeed, the domain of research on learning trajectories has grown and diversified in the approaches and theoretical orientations researchers take (e.g., see reviews by Empson, 2011; Lobato & Walters, 2017; and Fonger, Stephens et al. 2018).

This variation in theoretical orientation parallels what Simon (2009) articulated as a growth in the variety of theories of learning (and we might add, local instructional theories) being employed and developed in the field of mathematics education writ large. Amidst this growth, Simon recounts several challenges, including the need for researchers to engage in ongoing conversations to make theoretical choices transparent. In response to this challenge, we shed light on the practice of evoking visual metaphors for learning trajectories by considering the variation in both what learning trajectories communicate and how they are communicated in the research community.

Background and Major Issue

Variation in Learning Trajectories Research

One common definition for the construct of a learning trajectory (LT) is that it is a conceptual tool that links goals, instructional activities, and processes of students' learning (Simon, 1995). Learning trajectories vary widely in how they may (or may not) give evidence of students' mathematics with linked descriptions of the mathematical goals, learning activities, and/or the teacher moves that may engender such ways of understanding (cf. Lobato & Walters, 2017). As Empson (2011) elaborates, there has been a tendency for research reports in mathematics education to separate descriptions of learners' conceptions as evidenced on specific mathematical tasks, from the contexts, teaching, and tools, that might have engendered such learning (e.g., Steffe & Olive, 2010; Clements & Sarama, 2009). This focus on articulating students' conceptual trajectories on sets of tasks is a general trend in mathematics education research. Consider, for example, Hackenberg's (2014) research that details three epistemic algebra students' learning trajectories of fraction schemes and operations. In introducing these LTs, Hackenberg describes some ideas as to how the interviewer's questioning may have incited particular shifts in the students' reasoning on particular tasks. However, she

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

acknowledges that many open questions remain regarding the role of instructional support in such shifts in students' learning processes.

Despite this apparent trend in how LT are taken up, not all LTs are communicated with this same orientation and emphasis. Some LTs more explicitly attend to things like teacher moves or other contextual features influencing student learning as a way to developing local instructional theory. Stephan and Akyuz's (2012) research, for example, leverages LTs as a tool to build an instructional theory. In their approach, instructional supports for students' understanding of addition and subtraction included classroom mathematical practices as engendered through tools, gestures, imagery, and taken as shared activities.

Evoking Metaphors as a Tool for Communicating Learning Trajectories Research

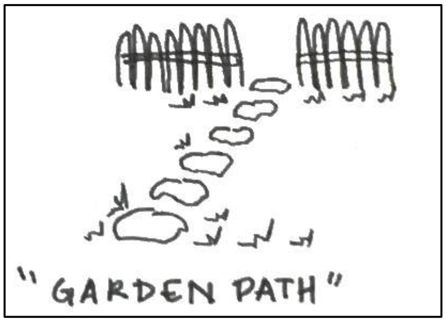
The challenge of conveying the simultaneity of change in students' learning and goal-directed instructional supports (as we believe learning trajectories as a research construct are primed to engender) may be a challenge of conceptual metaphor and related figural representations. Metaphors are essential to theory building and scientific inquiry (cf. Sfard, 1998). "Because metaphors bring with them certain well-defined expectations as to the possible features or target concepts, the choice of metaphor is a highly consequential decision. Different metaphors may lead to different ways of thinking and to different activities. We may say, therefore, that we live by the metaphors we use" (*ibid*., p. 5). Taking learning trajectories as the 'target concept' of our inquiry and theory building, we seek to understand the issue of communicating learning trajectories through an examination of the metaphors and meanings people make of them.

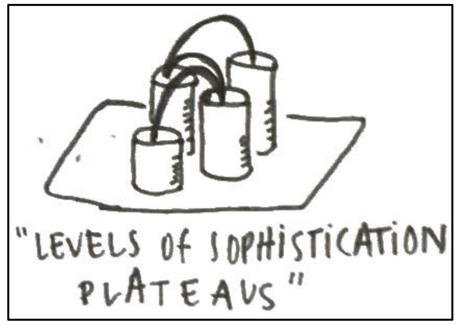
Different learning trajectories represent different things. Hence it is not always clear what types of information a particular learning trajectory might offer. Given this challenge, our inquiry into learning trajectories research is guided by the question of "What metaphors do researchers leverage in communicating learning trajectories?" We hypothesize that there is close link between what is communicated as a learning trajectory, and the conceptual and/or visual metaphor evoked in research.

Visual Metaphors for Learning Trajectories

Learning Trajectories Are Like "A Garden Path"

Sarama (2018) evoked the metaphor of a "garden path" to conceptualize learning trajectories, in which there are stepping stones that act as a developmental path to lead students through a gate—the goal state. From this view, learning trajectories must be interpreted by teachers and realized through social interaction around mathematical tasks. Indeed, the tight coupling of developmental progressions in children's thinking and sequences of tasks is evident in Sarama's research program (e.g., Clements & Sarama, 2014). Yet notice in Figure 1a, how the teacher, social interaction, and instructional activities are absent from the visual metaphor itself. Relatedly, Battista (2004) evoked the metaphor of "levels of sophistication plateaus" to characterize the "cognitive terrain" of learning processes for a learning trajectory (p. 186-187). In Battista's (2011) research, the sequence of tasks and ordered levels of sophistication in students' understanding are central to both what is conveyed in a learning trajectory and how it is communicated. Figure 1b offers a visual depiction of Battista's metaphor of "plateaus" of levels of understanding, which are complemented by narrative descriptions of related task type and instruction in his research.





(a) **(b)**

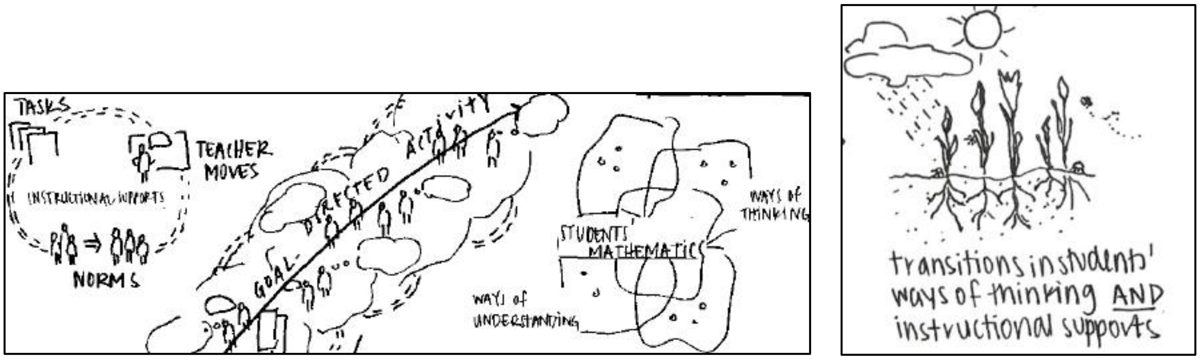
Figure 1. A visual depiction of (a) Sarama's (2018) "garden path" metaphor and (b) Battista's (2004) "levels of sophistication plateaus" metaphor for a learning trajectory.

It is notable that the aforementioned visual metaphors (garden path and plateaus, cf. Figure 1) evoke a sense of capturing the shifts or changes in how students understand mathematical ideas as measured by student outcomes on mathematical tasks. In these "conceptual trajectories" (cf. Empson, 2011), the role of instructional supports is not necessarily captured in the metaphor itself. Said otherwise, these approaches to learning trajectories afford great insight into the nature of students' conceptions and mathematical reasoning that are possible given certain task situations, with possible descriptive connections to instructional supports. However, the nature, character, and nuances of the instructional intervention, teacher-student relationships, time, and place, are often masked in the levels and path metaphors for learning trajectories. As a field, advancing understanding of student cognition and related curricular supports (e.g., sequences of task progressions) remain important, valued research agendas. Indeed, recent research has indicated that teacher's knowledge of students is an important predictor for improving student learning outcomes (Hill and Chen, 2018). However, learning and instruction are complex inter-related processes, with learning as a function of teaching (cf. Empson, 2011). If a goal of learning trajectories research is to convey a progression from lesser to greater sophistication in students' mathematical learning processes toward desired goal states, these metaphors provide little guidance for how instruction might engender change in students' learning that goes beyond a coupling of knowledge of students and related mathematical tasks.

Learning Trajectories Are Like "Growing a Garden"

In some of our own work on learning trajectories (Ellis et al., 2016; Fonger, Ellis, & Dogan, 2019; Fonger, Ellis, & Dogan, forthcoming), we frame learning trajectories as a networked relationship between transitions in students' ways of thinking and related instructional supports. In Figure 2a we offer a visual depiction of how students' mathematics (their ways of thinking and ways of understanding, ala Harel, 2014), transitions together with instructional supports (tasks, teacher moves, and norms) as guided by goal-directed activity (arrow). In our work, this conceptualization of learning trajectories was supported by evoking the metaphor of "growing a garden." Depicted in Figure 2b, the growing a garden metaphor captures the complex interplays between how a plant grows in response to environmental conditions such as soil, sun, and water. Evoking this metaphor for a learning trajectory accounts for changes in students' conceptions of mathematical ideas (i.e., the growth of a flower) together with the nature of instructional supports including but not limited to teacher moves, task design features, norms, student discourse, and student activity with artifacts and tools (i.e., the environmental conditions).

With these depictions, we intend to capture a more nuanced model of both what change in students' conceptions might look like, and how the learning environment (of which tasks are just one part) supported such change. We argue for treating learning trajectories as more than "just a bunch of flowers;" learning trajectories convey the transitions in the growth of the flower in relation to the supporting environment that evoked such change. This interpretation of a growing garden metaphor seems well-aligned to other research on learning trajectories (e.g., Stephan & Akyuz, 2012) that communicates the complexity of the interplay between the teaching and learning.



(a) **(b)**

Figure 2. Visualized Metaphors for Learning Trajectories as (a) a "growing garden", (b) Accentuating Transitions in Students' Mathematics and Instructional Supports

Discussion and Conclusion

To address the issue of what and how learning trajectories are communicated, we leveraged visual metaphors as a tool to make sense of two different approaches to learning trajectories research. In some approaches, learning trajectories are conceptualized as "a garden path", or "levels" wherein processes of students' learning and/or development as conceptual trajectories is foregrounded. Said otherwise, in a "garden path," characterizations of students' conceptual trajectories on sequenced sets of tasks is prominent. In another approach, learning trajectories are conceptualized as an interactive system of "growing a garden" wherein representations of goal-directed learning and instructional supports are taken together.

We invite conversation about the metaphors evoked in learning trajectories research as a way to address the issue of both what and how learning trajectories are communicated. We see a great need and opportunity to enrich the body of literature on learning trajectories (and learning progressions). In this report we argue that the use of interdisciplinary visual metaphors are productive for studying and representing learning trajectories. By articulating the metaphor(s) that guide our research, the products of learning trajectories research can become more explicit expressions of our theoretical assumptions about learning and teaching. Moreover, for researchers and practitioners concerned with learning trajectory based instruction (cf. Stzajn, Confrey, Wilson, Edgington, 2012), we hypothesize that by making theories of teaching (e.g., local instructional theory) more explicit in our communication of metaphors for learning trajectories, the field might improve the potential for learning trajectories to inform practice.

In close, by attending more seriously to the metaphors researchers evoke to communicate learning trajectories, the affordances and constraints of different approaches to learning trajectories becomes clearer. We intend for such elaborations to support the knitting together of a tapestry of research on learning trajectories that does not pit one approach against another, but that instead pushes for greater specification in the power of learning trajectories to advance research and inform practice as theoretical tools for research.

This theoretical discussion provides insight into an intersect of the mathematics education, cognitive psychology, and special education fields. To examine this intersect, the authors focus on how students identified with a learning disability develop actions on material when constructing and coordinating units. This theoretical frame considers results from several case studies in special education and cognitive learning fields, focusing on young students' number development, set in their subitizing activity and units construction/coordination. These results provide context and illustrate critical importance to their actions in light of neural differences and differences in their rate of development for future number and operation construction.

Keywords: Learning Theory; Number Concepts and Operations; Special Education; Cognition

Before children construct arithmetic units, they construct pre-numerical units, evident through a reliance on external representations, such as touching items while counting aloud or flashing four fingers sequentially or with manipulatives in patterned spatial arrangements (MacDonald & Wilkins, 2019). Children construct and reflect on their pre-numerical units to form internal or arithmetic units (Steffe & Cobb, 1988). To internalize units, children would need to step away from a reliance on perceptual material towards material that can stand in for the perceptual units they have constructed. These new pre-numerical units are described as figurative units and evidenced with fingers or counting words. Steffe (2017) estimated that about 40% of first graders do not yet use figurative units when counting and unitizing; this population remains at about 5-8% by third grade. By remaining reliant upon perceptual units, children are not yet able to develop mental operations grounded in their conceptual understandings. These same students are sometimes also identified as having a mathematics learning disability (LD) (Butterworth, 2011). Clements et al. (2013) explain that many children evidence precursors for an LD but are not yet identified, preventing them from receiving targeted mathematics interventions.

To consider how interventions could best be designed, we need to begin leveraging information pertaining to how young children construct pre-numerical units instead of focusing on deficits students with LD evidence (Butterworth, 2011). The purpose of this theoretical commentary is to shift from a deficit model towards a progressive model. In particular, we discuss students' actions and their possible progressions when *subitizing* (a quick apprehension of the numerosity of a small set of items - Kaufman, Lord, Reese, & Volkmann, 1949) and constructing units to determine how students' actions with visual patterns can best support early mathematics development. This, the aim of this theoretical commentary is to *examine aspects of number abstraction processes through students' subitizing activity and/or units construction/coordination.*

Theoretical Framework

To frame this theoretical commentary and consider this aim in the context of special education and mathematics education, we draw broadly from an intersection of cognition and learning and radical constructivist paradigms. In particular, we consider concepts that inform these paradigms: executive functioning (Clements & Sarama, 2019) and units construction and coordination (Norton & Boyce, 2015).

Executive Functioning

Executive functioning is evidenced through several processes that young children develop throughout their early childhood years (birth to third grade) (Clements & Sarama, 2019). These processes assist children in their ability to self-regulate their learning of mathematics and have been found to positively correlate with children's mathematics achievement (e.g., Best et al., 2011; Clements et al., 2016; Viterbori et al., 2015). In this commentary, we focus on attentional shifting and updating working memory.

*Attentional shiftin*g can explain mathematics strategy development through use of attentional mechanisms (Clements & Sarama, 2019). Attentional shifting is when children are able to shift their attention from perceived material to new perceptual material when developing problem solving strategies. This is evident when young children conceptually subitize (relying on conceptual processes when subitizing). For example, when a four-year-old child is shown five items arranged in a patterned spatial arrangement typical to the face of a die, MacDonald and colleagues (2016; 2019; under review) found children typically subitize two sets of two and one set of one. To segment and unitize, students would need to subitize two and associate this with a verbal word for two. By their attentional shifting between twos and ones, while attending to new information (what warrants attention) and not to other visual material (distractors), children are developing additive strategies (Clements & Sarama, 2019). Many students with LD experience attention differences compared to their peers that contribute to differences when learning mathematics.

When an individual manipulates and maintains information relevant for problem solving, Clements et al. (2013) explain this characterizes students' ability to *update their working memory*. Children engage in this when given multi-step problems, which require their working memory to be engaged and then updated with additional information. For example, when a five-year-old child is shown five items arranged in the same orientation described earlier, and then two additional items are added to this spatial arrangement, this child would be required to hold on to the five items while adding two additional items (possibly combining subitizing and counting). If a child considers the set of five items in isolation to the adding of two items, this child may struggle to construct units for these items, resulting in a counting all strategy. Students with LD struggle with some of these executive functions, pressing them to learn "tricks" grounded in procedural knowledge as they realize their peers are developing more sophisticated strategies for number and operation tasks (Hunt et al., 2019; see also Hunt & Silva, 2020).

Units Construction and Coordination

Units coordination and construction refers to the number of levels and type of units children can construct and bring into a situation (Norton & Boyce, 2015). Prior to units coordination, children use counting to construct *pre-numerical units* in their activity. For instance, children first rely on manipulatives (perceptual units) to construct a pre-numerical unit and determine the total amount through their counting activity. When pressed to step away from the perceptual units, children construct pre-numerical units with finger patterns (figurative units), pointing/tapping (motor units), and/or number words (verbal units) (Steffe & Cobb, 1988). Progressions from perceptual units towards verbal units provide evidence of children transitioning towards internalized actions (imagined external activity). When children interiorize units, these units are considered *arithmetic units* and allows children to operationalize number through their coordination of units (e.g., five is three away from two).

MacDonald and Wilkins (2019) found that one preschool student's subitizing related to her pre-numerical units construction. When developing conceptual processes to assist in her subitizing (e.g., two, two, and one is five; two and three is five), this preschool student constructed perceptual units and then figurative units to evidence her reasoning. Moreover, this student's units were represented with parallel actions (e.g., picking up two manipulatives simultaneously, flashing three fingers). Thus, counting and subitizing activity has been found to inform students of conceptual material that promotes their pre-numerical units construction.

The Intersect of Special Education, Subitizing, and Executive Functioning

Butterworth (2011) found students with LD encode numerosity information differently when subitizing compared to their normal achieving peers. In particular, Butterworth draws from decades of research to explain how young children typically develop *numerosity codes,* where individuals use a particular region of their brain to process sets of items over time and space. Fundamental to number understanding, numerosity codes have been found to evidence deficits in students identified with a LD and explains different types of subitizing activity (Butterworth, 2011). Butterworth explains that this neural difference fundamentally explains why students with LD rely mainly on rudimentary reasoning and strategy development with number (see also Hunt & Silva, 2020).

Hunt et al. (2016) compared findings from clinical interviews involving 21 upper elementary age students with LD with 23 students identified with a mathematics difficulty. Findings evidenced nuances to students with LD's partitioning (partitioning with no regard to equal parts, partitioning with regard to "halves", partitioning with regard to equal parts). When comparing students with LD to students with mathematics difficulties, Hunt et al. (2016) found that 30% of students with LD were able to partition with no regard to equal parts (10%) or with regard to "halves" (20%). Comparatively, students with mathematics difficulties did not rely on such rudimentary partitioning activity. Moreover, 70% of students with LD and 100% of students with mathematics difficulties partitioned with regard to equal parts. These differences suggest some students with LD partition in a very similar way to students experiencing mathematics difficulties, but may be developing their partitioning at a different rate than their peers. These different types of partitioning may also explain working memory differences that students with LD experience when given other tasks that do not provide external representations when working with complicated mathematics concepts. If a student with LD has not yet begun partitioning with equal parts, then solving symbolic fraction tasks may be too much for their working memory to manage. For instance, when solving tasks that only represent fractions as symbols, students may need to consider each symbol as a separate item (e.g., ¾ is considered as a 3 and a 4).

Given these different rates of development, students with LD may evidence seemingly puzzling ways of reasoning that, from a developmental and psychological stance, actually makes sense. For example, Hunt et al. (2019) found that one third grade student, Gina, relied only upon ways of solving number problems using procedures that she could not explain or make sense of. Interestingly, Gina was not perturbed when differences between her procedural number knowledge and physical actions did not align. Yet, when given novel rational number tasks for which she had no procedures for, Gina more readily connected her conceptual knowledge with her actions. Hunt et al. (2019) argued that students with LD are able to develop the same conceptual knowledge as their normal achieving peers, but may be doing so at a different rate. This is important because noticing differences between procedures and physical actions would not be a goal for Gina if procedures were not yet connected in her long-term memory and would make connections back to conceptual understanding difficult.

Conversely, another student, Stu, (Hunt et al., 2016) was also able to anticipate which strategies to use because he was engaged in a platform that supported him to successfully develop equi-partitioning (mental segmenting to form equal parts). In fact, he developed anticipatory types of strategies that allowed him to utilize mental actions so he was not dependent on his physical actions/material to solve problems. Opportunities to develop and abstract the actions that bring about number and rational number affords students with LD opportunities to access tasks that only represent number through symbols.

When considering how these differences evidence themselves in students' subitizing activity, we consider findings from Koontz and Berch (1996) who found elementary age students with LD had significantly slower response times when matching small (two and three) dot arrangements to number words. These findings suggest that young children with LD struggle to update their working memory because items were not processed in a parallel manner and these children struggled to inhibit distracting visual information. When considering this in relation to shifting attention it seemed young children were not yet able to inhibit distracting perceptual material and then shift their attention to primary perceptual material.

Finally, MacDonald et al.'s (under review) findings echo some of these findings, as one first-grade student, Diego, relies mainly on his unitization and iteration actions when solving subitizing and units construction tasks. Findings further indicate that Diego relies heavily on perceptually clustered items when unitizing and not yet able to construct figurative units. These findings also echo Butterworth's (2011) discussion, as he describes an unfinished amount of research examining relationships between students with LD's use of fingers and their numerosity code development.

Conclusion

To date, the research base remains an unfinished work when considering if and/or how students with mathematics difficulties develop separate, or different, understandings of part whole and what features of their diverse cognitive backgrounds (e.g., working memory or attentional processes) might interact with development (e.g., Hunt et al., 2016; Hunt et al., 2019a, 2019b; Hunt & Silva, 2020; Lewis, 2014; Lewis, 2017). In the absence of a convergence of evidence in the research literature, present research efforts document elements of students' diverse cognitive background thought to interplay with children's mathematical learning from an early point in their lives (Compton, Fuchs, Fuchs, Lambert, & Hamlett, 2012). These factors are then used in a predictive sense to explain "learning difference" as variations in certain norms that predict performance over time (Vukovic, 2012).

These findings suggest that students with LD are constructing and coordinating units with partitioning/segmenting activity at a different rate than other students. In fact, we wonder if these different rates of development relate to differences in their development of parallel processing activity, attentional mechanisms, and/or working memory resources. These developmental differences might evidence themselves in their subitizing activity and prevent them access to particular tasks in their early childhood years. To consider these differences more closely, we need to begin adopting new questions and theoretical perspectives, which allow us to work with intersections of mathematics education, special education, and cognitive psychology. Moreover, we need to consider how early actions students construct can explain these differences and inform intervention design that aligns with a wide variety of elementary age students' mathematics development.

This theoretical commentary examines theory driven discussions in Science, Technology, Engineering, and Mathematics (STEM) fields and mathematics fields. Through this examination, the authors articulate particular parallels between spatial encoding strategy theory and units coordination theory. Finally, these parallel are considering pragmatically in the Elementary STEM Teaching Integrating Textiles and Computing Holistically (ESTITCH) curriculum where STEM and social studies topics are explored by elementary students. This commentary concludes with questions and particular directions our mathematics education field can progress when integrating mathematics in STEM fields.

Keywords: STEM/STEAM; Elementary School Education; Learning Theory; Interdisciplinary Studies

Computational thinking (CT) has recently been making a larger presence in elementary classrooms, yet it is still not yet clear how CT relates to young children's mathematical reasoning or even how it can be defined. Feldon (2019) explains "computational thinking has been characterized as a foundational competency, akin to reading and arithmetic" (p. 1). Given this characterization, the instructional technology field has yet to define CT (Feldon, 2019; Grover & Pea, 2013, 2018). Margulieux (2019) examined findings that suggest relationships between students' spatial reasoning and their Science, Technology, Engineering, and Mathematics (STEM) achievement when outlining particular theories that explain CT achievement. Pragmatic delineation of CT in the K-12 standards of the Computer Science Teachers Association (CTSA Task Force, 2011, p. 10) broadly characterize CT as a "problem-solving methodology" that draws from reasoning present in mathematics education, such as "abstraction, recursion, and iteration." These learning constructs and types of reasoning echo K-12 mathematics reasoning, effective mathematics practices, and mathematics learning objectives. Thus, *the purpose of this brief research report is to consider theoretically how CT reasoning (framed through spatial reasoning) relates to mathematics reasoning (framed through units construction and coordination).*

To frame this theoretical commentary, we first draw from spatial encoding strategy theory to explain how students' engagement with visual and mental representations may explain CT achievement. Second, we draw from the units coordination learning theory to determine how young children may be drawing from mathematics reasoning in elementary grade levels. From this theoretical framing, we consider particular parallels between these theories to determine multifaceted mathematics reasoning, as integrated in CT activities. Through an integrated STEM-driven curriculum grounded in social studies, titled, Elementary STEM Teaching Integrating Textiles and Computing Holistically (ESTITCH) (Hawkman et al., under review), we frame the pragmatic aspects of these integrated activities, and we delineate parallels between particular CT and mathematics reasoning, objectives, and practices. Moreover, we include social studies topics to determine how

social artifacts leverage CT and mathematics engagement and what is gained with such an interdisciplinary instructional approach.

Theoretical Framework

This theoretical discussion is set in an emergent perspective paradigm (Cobb & Yackel, 1996), meaning we examine individuals’ construction of mental objects and actions before considering the meaning gained through their engagement with social artifacts. Therefore, we begin by articulating theories framed with cognition learning science paradigms (Attkinson & Shiffrin, 1971; Baddeley, 1994; Clements & Sarama, 2019) and radical constructivist paradigms (Glasersfeld, 1995; Norton & Boyce, 2015), before drawing on this emergent perspective (Cobb & Yackel, 1996) within the context of STEM curricula. This framework begins by discussing spatial encoding strategy theory (cognition learning paradigm) before drawing from units construction and coordination learning theory (radical constructivist paradigm).

Spatial Encoding Strategy Theory

Through a review of the literature and drawing specifically from Parkinson and Cutts’ (2018) findings, Margulieux (2019) proposed a spatial encoding strategy theory to explain the cognitive mechanisms related to individuals’ spatial skills and STEM achievement. Margulieux explains that both the encoding of mental representations and the identification of landmarks (non-verbal representations) help individuals develop strategies and spatial skills (e.g., orientation, relations, and visualization). *Encoding* (making sense of) mental representations is best characterized in the cognition learning sciences where (1) individuals “chunk” information to act on in their working memory (limited memory capacity – Baddeley, 1994) and (2) individuals draw from attentional mechanisms (a component of executive functioning processes – Clements & Sarama, 2019) to determine what feature of a representation warrants attention (Attkinson & Shiffrin, 1971). For instance, when young children are asked to use text or symbols to solve problems in STEM fields (e.g., develop a code to move a LEGO® robot), they would need to map their anticipated results to a mental model that they can manipulate (Parkinson & Cutts, 2018). Prior to this experience, we argue young children would need physical experiences to form this model.

Moreover, Margulieux (2019) proposes individuals’ mental representation construction partially depends upon individuals’ development of non-verbal representations. For instance, when individuals chunk encoded information of mental representations, they are required to determine critical features and relationships of non-verbal representations (Margulieux, 2019). Thus, for individuals to encode mental representations successfully, they need to engage with/construct non-verbal representations that form these mental models.

Units Construction and Coordination Theory

Units coordination and construction refers to the number of levels and type of units children can construct and bring into a situation (Norton & Boyce, 2015). We utilize units construction and coordination learning theories to frame students’ actions and establish transitions from their construction of *pre-numerical units* (physical material representing number) towards arithmetic units coordination. Children begin counting when first constructing pre-numerical units with which to use as material for future activity (Steffe & Cobb, 1988). These units are first constructed through children’s external activity before becoming internalized (imagined activity) and then interiorized (automaticity).

To transition from pre-numerical units construction to arithmetic units coordination, children engage in one of four actions: unitizing, partitioning, iterating, and disembedding. Once students can count on they are next able to *unitize* (taking an item, or collection of items, as a whole unit that can be further acted upon) and *iterate* (making copies of a unit) units to construct number sequences (1, 2, 3, 4, 5, 6 …) (Norton, 2016; Steffe & Cobb, 1988). Once number sequences are constructed, students are able to *partition* (break into equally sized parts) these number sequences with which to count on from (Norton, 2016; Steffe & Cobb, 1988). To coordinate two levels of units, students would need to both iterate and partition (reversible actions), but would not yet be able to use them simultaneously (Norton, 2016). For instance, through counting, students could unitize two composite units (e.g., 3 and 12) where there are able to iterate three in a "count by" sequence (e.g., three, six, nine, twelve).

Once students coordinate all three levels of units and are able to do so in an anticipatory manner, they compose reversible actions and develop what Piaget (1970) described as logico-mathematical actions (operations). These operations allow students to construct number as a mental object with which to *disembed* a whole into parts while remaining cognizant of the whole (i.e., 12 is understood as 4 sets of 3) (Norton, 2016; Steffe & Cobb, 1988).

The CTSA (2011) articulate objectives grounded in some of these actions "abstraction, recursion, and iteration" (p. 10). For instance, as children iterate units, they construct sequences and are more readily able to abstract these sequences. Moreover, through children's composition of reversible actions (e.g., iterating and partitioning), they are able to recursively make sense of activity in STEM fields, providing them strategy development for future success.

Intersection of CT and Mathematics Reasoning within Social Studies Activities

Much of the mathematics education literature (Sarama & Clements, 2009) has found relationships between young children's spatial reasoning and mathematics development. By considering Margulieux's (2019) spatial encoding strategy theory, we argue that children's "chunking" of features from representations occurs in CT and in mathematics activities. By setting these activities in Social Studies, we posit children are using social artifacts to determine what warrants attention, which provides culturally responsive learning opportunities. Thus, we first consider parallels between one of the two CT learning objectives (see table 1) before considering how these might evidence themselves in the ESTITCH curriculum where integration of social studies and STEM provide meaning to students' units coordination.

In table 1, we outline relationships between two CT learning objectives and how they relate to corresponding elementary mathematics objectives and practices. For instance, when considering children's ability to decompose systems of computational thinking tasks, we propose their reasoning would be similar when they apply properties of operations, generate patterns, and evaluate expressions. To meet both sets of objectives, we posit they would need reason abstractly and attend to precision. In particular, students would be required to have two or three levels of interiorized units (dependent on type of operation) and would be required to determine critical features of a visual representation that relates to the goal of the task.

On day five, part 2 in the ESTITCH curriculum, students use stories centered on immigration, migration, and forced relocation to determine what landmarks are present in their own histories and how might they be used to form a timeline. Through their timeline development, they create circuits coded to represent these landmarks and proportional length/time to represent relationships between these landmark events. Through these activities, students are representing time and length in a scaled model, which presses them to generalize particular patterns abstractly and attend to precision of these events. Moreover, students are constructing units based on features of cultural artifacts they value to coordinate in a linear format. These integrated activities are powerful because they draw from cultural artifacts that children can connect to their mental representations of experiences and development of relationships between units that form these relationships.

Table 1: Intersection of Computational Thinking, Mathematics Standards and Mathematical Practices

Computational Thinking	*Operations and Algebra*	*Mathematical Practices*
Decomposition: Break down a task into minute details.	Apply properties of operations as strategies to multiply and divide (3.OA.B.5). Generate a pattern that follows a given rule. Identify features of the pattern not explicit in the rule itself (4.OA.C.5).	Reason abstractly and quantitatively (MP2) Attend to precision (MP6).
Pattern Generalization and Abstraction: Filter out information to solve a certain type of problem and generalize information.	Identify arithmetic patterns and explain them using properties of operations (3.OA.D.9). Write simple expressions, and interpret numerical expressions. Analyze patterns and relationships (5.OA.A.2).	Look for and make use of structure (MP7). Use appropriate tools strategically (MP5).

To emphasize the mathematics in this unit of study, an educator could have students construct visual models of decimals to represent time in such a proportional manner. For instance, if ten meter sticks represented one whole unit (one second), students could explore proportional relationships with smaller portions of a second with base-ten blocks (one centimeter in length) to explore coding with milliseconds. This type of precursor activity allows students opportunities to develop proportional relationships with physical models before requiring them to draw from mental models of the same relationships (MacDonald et al., 2018).

Conclusion

By considering the intersection of students' reasoning associated with STEM and mathematics fields, we are more able to emphasize mathematical reasoning in curricula development while utilizing theories that focus on students' mathematics reasoning. Moreover, as theory and associated curricula begins to emerge in the STEM fields, more questions surrounding theory and curricula need to be considered. For instance, how do STEM activities afford and/or constrain students' mathematics reasoning? What trajectories in STEM are present for young children in prekindergarten classrooms as they transition to elementary classrooms? How might students with particular learning disabilities evidence STEM reasoning development in elementary classrooms and how might this relate to their access to mathematics in schools? Only through such multi-faceted theoretical frameworks and questions will our field continue to progress in a technology-driven society.

WHOSE PROBLEM, WHOSE PRACTICE? NEGOTIATING THE FOCUS OF RESEARCH-PRACTICE PARTNERSHIPS WITHIN SCHOOL MATHEMATICS

Charles Munter
University of Missouri
munterc@missouri.edu

Cassandra Quinn
University of Missouri
cdquinn@mail.missouri.edu

Phi Nguyen
University of Missouri
phinguyen@mail.missouri.edu

At the core of productive research-practice partnerships is a mutual commitment to addressing problems of practice, which must be jointly negotiated, working through differences in perspective, status, and authority across partners. But what is less clear is how to account for and navigate the influence of broader accountability policies in the framing of those problems, as their application can lead to "manufactured" problems specified around state standardized testing outcomes. In this conceptual paper, we reflect on recent encounters with school district personnel, some of whom we were interested in fostering research-practice partnerships, to describe an ethical dilemma of whether and how, in our position as researchers, to invite potential partners to take up more "authentic" problems of practice.

Keywords: research-practice partnerships, design experiments, equity and diversity, systemic change

Late in 2017, the lead author and a small team of researchers were meeting with leaders of a small, rural district in the midwest U.S. in hopes of initiating partnership work around a common problem of interest. That fall, they had conducted a series of interviews with leaders and teachers, attempting to learn about the mathematics-related problems with which the district was wrestling and how individuals in the district framed those problems (Benford & Snow, 2000). From the outset, the researchers had expressed interest in developing a partnership rooted in district challenges rather than imposing ideas stemming from their own research agenda (Penuel, Fishman, Cheng, & Sabelli, 2011). At this meeting they were sharing what they had learned through the interviews, inviting district personnel's responses, and listening for opportunities to endorse and offer help with a challenge of mutual interest. Toward the end of the near-hourlong meeting, the lead author (CM) invited the group to take a step back and articulate, in broad terms, their aspirations for mathematics learning in the district, to which a school administrator (A) responded:

CM: Thinking broadly, what- what are your goals for the children of [your community] in mathematics?
A: Short term, for at least *my* building, by the time they get to fifth grade, their fifth-grade scores are not- not good. Like, at *all*.
CM: So, Ok-
A: And a lot of it was number sense even starting in the third grade, so, like, when third graders are struggling with number sense, that's obviously coming from us too, so- I mean, that's not very narrowed down, but-
CM: But, I want to suggest that you, kind of, immediately went to *test* scores.
A: Well, because data shows if there's progress or not.

In this exchange, the administrator suggested that the grades 3-5 intermediate school may be insufficiently supporting students in developing number sense ("that's obviously coming from us too"), but what was most troubling for the administrator—and what defined the broader mathematics goal—was improvement on state standardized test scores. Munter, failing to hide his disappointment with that framing, lamented that the administrator "immediately went to test scores" when invited to think broadly about children's mathematics learning.

Negotiating Problems of Practice

Over the last decade, there has been increasing attention to and support for research-practice partnerships (RPPs) in education as a means of bridging the "research-practice divide" (Coburn & Stein, 2010), as evidenced by grant competitions (e.g., the Institute of Education Science's Researcher-Practitioner Partnerships in Education Research program; the Spencer Foundation's Research-Practice Partnership Grants Program) or special issues in research journals (e.g., Herenkohl & Herenkohl, 2019; Penuel, Cole, & O'Neill, 2016; Penuel & Hill, 2019). One frequently employed definition for such partnerships is that they are "long-term, mutualistic collaborations between practitioners and researchers that are intentionally organized to investigate problems of practice and solutions for improving district outcomes" (Coburn, Penuel, & Giel, 2013, p. 2). Indeed, a consistent commitment across the growing body of work through/on RPPs in education is that they begin with *problems of practice* "as encountered by participants in an activity system, rather than with researchers' goals for the improvement of teaching and learning" (Penuel, 2014, p. 100).

Increasingly, there are also accounts in the literature of the messiness and tensions that can arise as researchers and practitioners negotiate the problems they might collaboratively address (e.g., Desimone, Wolford, & Hill, 2016; Henrick, Muñoz, & Cobb, 2016; Penuel, Coburn, & Gallagher, 2013; Vakil, McKinney de Royston, Nasir, & Kirshner, 2016). Penuel and colleagues (2013), in particular, have highlighted the roles that status (e.g., from university affiliation or role as practitioner) and authority (e.g., from positions of leadership in a district) play as problems are identified and defined and as decisions about which solution strategies to pursue are made. And Vakil et al. (2016) have stressed how hierarchical relationships between researchers and practitioners can persist, especially when dimensions of researchers' positionalities are left unexamined. Such work helps to foreground the ethical issues that underly the formation and work of research-practice partnerships. As Bang and Vossoughi (2016) have reminded us, "we must take seriously the question of 'Who does the design and why?' (Engeström, 2011, p. 3)," the answers to which are "also deeply bound up with the *how and where* of design, demanding a focus on process and the genesis of relations as well as the places within which they are made, live, and unfold" (p. 179, italics in original).

Whose Problems? Whose Practice?

In some ways, the episode with which we began this paper matches descriptions of partnership negotiation in the literature, as the researchers and practitioners were likely entering the conversation with different values, interests, and perspectives, and differences in authority and status were undoubtedly shaping the interactions. But we have come to view the question of "Who does the design and why?"—and concomitantly, "Who does the *problem framing* and why?"—as likely implicating entities not at the negotiating table. Specifically, for us, the school administrator's pointing to "fifth grade scores" as a primary object of concern invokes a much broader set of reforms and accompanying discourse that are rooted in neoliberal principles (Croft, Roberts, & Stenhouse, 2016) and reduce the role of K-12 students to data production for the benefit of adults' regimes (McDermott, 2013). And, although a host of local stakeholders are arguably complicit in building and maintaining this system, more broadly, it is imposed by legislators, policymakers, and other "silent partners" who, with *their* authority, impose constraints within which school leaders and teachers identify goals and problems.

Given the potential influence of this broader frame, we can ask whether the problems of practice that district leaders articulate are *real* or *manufactured*. When we say "real," we refer to challenges that exist in pursuit of an extensive aim of education, such as the pursuit of truth (Dewey, 1938) or the practice of freedom (Freire, 1970), which seek to prepare students for a "whole life, not simply an economic existence" (Noddings, 2007, p. 26). And by "manufactured" (Berliner, 1995) we refer to challenges that exist only as a result of the imposition of standardized test-based metrics of proficiency and "adequate progress" (U.S. Department of Education, 2002; 2015), which offer no direct benefits to the laborers "at the bottom"—public school children (Munter & Haines, 2019). Based on experiences like the opening scenario, we became curious which kinds of challenges are most salient in school districts, and whether there might be patterns in relation to community contexts.

Patterns in Problems of Practice

To answer those questions, we investigated the mathematics-related challenges identified by mathematics leaders across the U.S. state of Missouri. We sampled 50 districts, ranging from rural to urban contexts, and in each one interviewed the district leader most directly responsible for mathematics instruction (Munter, Nguyen, & Quinn, 2020). In each interview, we invited leaders to describe their biggest mathematics-related challenges, what they perceived to be the cause(s), and what, if any, initiatives they were pursuing in response. Two of the leaders reported that their districts did not have any mathematics-related challenges, and nine described initiatives they were pursuing, but without specifying any problems motivating their efforts. For the present discussion, we focus on the other 39, among whom three main types of problems emerged: student outcomes (n=30), student experiences (n=6), and equity (n=3).

As we have alluded to above, we found some of these problems of practice to be *real* (challenges that exist in pursuit of expansive educational aims) and others manufactured (challenges that exist only as a result of the imposition of standardized test-based metrics of proficiency). Of the 30 leaders who articulated problems related to student outcomes, two pertained to internally established indicators of course taking patterns; all of the other 28 were focused on externally established indicators, primarily state standardized test scores. It is possible, of course, that some districts were facing challenges with ensuring all of their students were being supported in learning mathematics. However, their identification of low test scores as, itself, the problem and not merely a symptom, suggests that the bulk of district leaders we interviewed articulated manufactured problems of practice.

Of the remaining nine leaders, three articulated challenges related to issues of equity and six described challenges related to how students experience school mathematics. Because they look past the surface of standardized test scores, it is possible that these problems of practice are more genuine. For example, six leaders centered students' classroom experiences, with one describing a challenge of providing a cohesive school experience, and five describing challenges related to supporting student engagement (i.e., enjoying mathematics, seeing its usefulness, or engaging in sensemaking). For example, one small metropolitan district is working on supporting student engagement by adopting a workshop model, with the intention that through collaborative activities, mathematics experiences will be more authentic for students. And the three leaders' descriptions of problems related to equity may signal a concern about real problems in differences in opportunity (Da Silva, Huguley, Kakli, & Rao, 2007; Flores, 2007). However, it is also possible that even these problems are, to some extent, manufactured. For example, a district may be concerned about student engagement or cohesion only as a means of improving state test scores. Similarly, leaders' equity concerns may be defined by and limited to "achievement gaps"—narratives that are framed by externally established, standardized test-based metrics and often reinforce deficit narratives of students of color (Martin, 2009).

Additionally, as reported elsewhere (Munter et al., 2020), we found that leaders from districts outside of metropolitan areas were more likely to describe problems of practice related to outcomes. This suggests that the "*where* of design" (Bang & Vossoughi, 2016) indeed matters, as small, rural, districts may be suffering the differential impact of accountability policies, and more often attending to manufactured problems.

An Ethical Dilemma

It is at this point in our consideration that we reach an ethical dilemma. In our position as university-affiliated researchers, with the hierarchy and status that accompanies whatever "academic expertise" we are perceived to have (Penuel et al., 2013, p. 247), if we are convinced that the problems with which a great number of our potential partners are concerned are manufactured (i.e., that they are accepting a frame from the broader neoliberal agenda), who are we to tell them that their problem is not real? After all, even if the problem *is* manufactured, how they experience its implications are likely very real. Then again, who are we to withhold those insights? If we "honor" the problem they have identified, we risk (being complicit in) perpetuating a system of sorting and ranking that does not enrich the lives of students, particularly those who are most vulnerable in institutions of schooling. And, if we simply walk away from a potential partnership because we are unwilling or uninterested in taking up what we view to be a manufactured problem, whatever assistance we might have had to offer is squandered.

We have not reached a clear resolution of this dilemma. We do, however, take inspiration from Freire (1970) in assuming that the question is not *whether* to engage in fostering partnerships, but *how* to do so in liberating ways—which may require further reflection and analysis with respect to how to ethically pursue problems of practice that are increasingly "real," including how we can respectfully acknowledge and affirm practitioners' very real institutional pressures and demands while advocating for problem frames that more explicitly target inequity and students' experiences in school mathematics.

Acknowledgments

This work was funded by a University of Missouri Research Board grant. Thanks to Cara Haines, Rebecca Bruton, Emily Hornbuckle, and Susan Ramirez for their contributions, and thanks to school district personnel for allowing us to interview and partner with them.

FALA FRAMEWORK: A LEARNING PROGRESSION FOR NOVICE TEACHERS' USE OF FORMATIVE ASSESSMENT

Carolyn Mitten
Westmont College
cmitten@westmont.edu

Keywords: Learning Trajectories, Assessment and Evaluation, Teacher Knowledge

Formative assessment has been identified as one way that teachers can gather critical information about a student's level of understanding in order to make informed instructional adaptations that meet the needs of all students (NCTM, 2000; Shepard et al., 2005). Over several decades, research has shown the potential of formative assessment to effectively improve student achievement (Black & Wiliam, 1998; Kingston & Nash, 2011). Despite its potential, issues in preparing teachers to implement formative assessment practices has kept its potential from being realized (Schoenfeld, 2015) and many teachers have limited understanding of its use (Shepard et al., 2005).

In order to better understand how to prepare teachers to use formative assessment, a trajectory describing how teachers develop formative assessment knowledge and practice is needed. The Formative Assessment Levels of Appropriation (FALA) framework evolved from a larger qualitative research study on the evolution of formative assessment knowledge and practice of novice teachers from teacher preparation through their third year of teaching. Grounded in activity theory, the FALA framework describes the levels of appropriation (Grossman et al., 1998) for the five aspects of formative assessment defined by Black & Wiliam (2009). Table 1 provides an example of the framework for one aspect of formative assessment—clarifying intentions and criteria for success.

Table 1: Levels of Appropriation for Clarifying Intentions and Criteria for Success

Level 1	Level 2	Level 3	Level 4	Level 5
No conceptual understanding and/or not used in the classroom	Identifies learning goals/criteria by name, but does not understand purpose of learning goals/criteria (e.g., equates with standards) and does not engage students with them.	Understands that learning goals/criteria as targets for performance and may share them with students, but does not impact student learning and instructional decisions.	Understands learning goals/criteria and their relationship to student learning progressions. Makes connections to instructional decisions but may have limited experience applying to practice.	Understands the purpose of learning goals/criteria in shaping student learning and frequently makes instructional adaptations based on student progression towards learning goals. Evidence of student engagement with goals/criteria.

To create each level of appropriation, a typological analysis approach (Hatch, 2002) was used to code course data over three semesters of a course on the use of formative assessment for teaching mathematics. The data was first chunked by individual assignment posts and coded by its reference to one of the five aspects. Next, data for each aspect was read through and examples of the five levels were coded based on Grossman & Smagorinsky's (1998) general definitions of each level of appropriation. All levels were re-read and summarized as one to two sentence generalizations. A secondary coder worked with the primary researcher on coding a sample of the data until an inter-rater reliability level of 81% as met (Miles & Huberman, 1984).

A THEORY-METHODOLOGY FRAMEWORK FOR CONCEPTUALIZING A CULTURALLY RESPONSIVE MATHEMATICS/TEACHER EDUCATION

Kathleen Nolan
University of Regina, Regina, CA
kathy.nolan@uregina.ca

Keywords: Culturally Responsive Pedagogy; School Mathematics; Theory-Methodology

Overview

The research described in this presentation asks the question of how school mathematics and mathematics teacher education might be reframed through critical and culturally responsive pedagogies through the introduction of a new theory-methodology framework. By synthesizing perspectives offered by Ethnomathematics (EM), Critical Mathematics (CM), Indigenous Education (IE), Language Diversity (LD) and Equity-based (E-b) approaches to research in mathematics education, a new (disruptive) form of culturally responsive pedagogy (CRdP) is being conceptualized. CRdP is *pedagogically* informed by the EM-CM-IE-LD-E-b collective; it is *theoretically* informed by Nancy Fraser's three-dimensional approach to social justice and participatory parity; and it is *methodologically* informed by discourse analysis. Grounded in a conceptual approach to responding to the study's question, the research (and this presentation) offers a comprehensive approach to challenging teacher education practices and navigating toward socio-economic, cultural and political justice/parity for all mathematics learners.

Theory-Methodology Framework

CRdP is being conceptualized by building on existing and highly relevant research in the field of mathematics education— research which views the education of mathematics teachers through diverse theoretical/philosophical lenses, including those of Culturally Responsive Pedagogy (CRP) (see, for example, Aguirre & Zavala, 2013; Nicol et al, 2013); Ethnomathematics (EM) (e.g., Presmeg, 1998; Rosa & Orey, 2011); Critical Mathematics (CM) (e.g., Ernest et al, 2016); Indigenous Education (IE) (e.g., Lunney Borden & Wiseman, 2016; Sterenberg, 2013); Language Diversity (LD) (e.g., Barwell, 2018; Chronaki & Planas, 2018) and Equity-based (E-b) (e.g., Gutiérrez, 2012; Herbel-Eisenmann et al, 2012) approaches. The socio-critical work of Nancy Fraser (Fraser, 2009; Lingard & Keddie, 2013; Meaney et al., 2016) is central to the research, with the design of CRdP framed through the three dimensions of Fraser's theory of social justice: distribution (socio-economic justice), recognition (cultural justice), and representation (political justice), revealing how school mathematics may be reframed through the EM-CM-IE-LD-E-b collective. As a means of grounding Fraser's three dimensions in a research method, I draw on a critical discourse analytic (CDA) approach (Wodak & Meyer, 2009). The six-question CDA framework that I have developed to interrogate research texts and to construct CRdP, along with initial results of its application, will be outlined in this presentation.

Significance of the Work

In acknowledging the culture of mathematics, of mathematics classrooms and of students' lives and communities, the research is an innovative and productive response to the call to educate teachers in critical and culturally responsive pedagogies. In doing so, the research serves to strengthen communication and connections between the fields of teacher education, mathematics education research, and curriculum cultural revitalization in multi-cultural contexts.

A CONCEPTUALIZED FRAMEWORK FOR ASSESSING FACTORS THAT MAINTAIN AND LOWER COGNITIVE DEMAND DURING TASK ENACTMENT

Joshua M. Ruk
Western Michigan University
Jzf5431@wmich.edu

The National Council of Teachers of Mathematics (NCTM, 2014) has called for the use of cognitively demanding tasks. When using such tasks it is not only important that a task start out as cognitively demanding, but also that high cognitive demand is maintained during the task enactment; unfraternally, cognitive demand is often not maintained (Stein & Lane, 1996). To better understand this phenomenon, Stein, Grover, & Henningsen (1996) identified seven factors that help maintain, and six factors that lower cognitive demand during task enactments (Fig. 1). These factors have been used by numerous researchers who looked to understand what the maintenance of cognitive demands looks like (e.g. Hong & Choi, 2018; Lunt, 2011). But, the studies that use these factors don't discuss *how* they use the factors. They don't explain if they were just looking for the existence of the factors, or if they were coding the degree to which factors were applicable. As such, there is no reliable way to measure or compare what the maintenance of cognitive demand looks like within and across studies. The Instructional Quality Assessment (IQA; Boston, 2012) is a tool that could be used to help us to do this, but the IQA takes all 13 factors related to the maintenance of cognitive demand, and puts them on a single rubric with a four point scale. As such, it does not provide much detail about what each of the individual factors that maintains or lowers cognitive demand looks like during a task enactment.

To address the need for a tool that can provide a detailed analysis of how cognitive demand is maintained during task enactments, I conceptualized the **R**eorganized Factors that **U**ndermine or **K**eep Cognitive Demand (RUK). Looking at each factor individually, I found that many of the factors that lower and maintain cognitive demand are similar, and can be considered two ends of a continuum. This is true for nearly every factor, as can be seen by the continuums of the RUK (Fig. 1). For each continuum, the RUK provides a four point scale (available by contacting the author) to aid in the quantification of the factors that lower and maintain cognitive demand. By viewing these factors as two ends of a continuum, the RUK provides an efficient way to create a detailed analysis of what the maintenance of cognitive demand looks like during a task enactments. Additionally, the RUK provides a medium that can be used in subsequent research to allow *how* cognitive demand is maintained to be compared across different studies.

Factors that that maintain cognitive demand	Factors that lower cognitive demand	Factors combined on the RUK continuum
1) Tasks were built on students' prior knowledge	1) Task is inappropriate for the students	To what extent were students prepared to engage with this task?
2) Tasks were of the appropriate amount of time	2) Students are given too much or too little time to work on a task	To what extent was the amount of time students were given to work on this task appropriate?
3) High-level performance was modeled	3) The focus of the tasks shifts to finding a correct answer	To what extent are solution strategies discussed and important mathematical ideas and concepts uncovered?
4) The teacher sustained pressure for explanation and meaning	4) Lack of accountability	To what extent were students held accountable for explaining their thinking/reasoning?
5) Tasks had proper scaffolding	5) Challenges become nonproblems	To what extent did the teacher or more capable peers give away solution strategies in an attempt to help other?
	6) Classroom management problems	To what extent do classroom management issues occur during this task?
6) Student self-monitoring		To what extent can students provide evidence for their claims or explain their thinking?
7) The teacher drew conceptual connections		To what extent did the teacher draw conceptual connections?

Figure 1: Factors that Maintain and Lower Cognitive Demand (Derived from the work of Stein, Grover, & Henningsen, 1996) and their relationship to the RUK.

Emerging research has shown how student engagement with educational robots (e.g., Dash) can be associated with application and learning of mathematical concepts (e.g., Zhong & Xia, 2020). Yet, less is known about student learning in non-formal contexts (e.g., after-school programs) in contrast to formal learning environments (Pattison et al., 2016). The purpose of this proposal is to describe our varying, yet complementary analytical perspectives in understanding the complex nature of mathematical learning in a non-formal STEM environment. The project studied here – to design, build, and test an electronic vehicle – was not developed with an explicit mathematical goal(s) or objective(s). Thus, we intend to make the mathematical learning process visible through our emerging analytical perspective. Our proposed poster in the Theory and Research Methods strand will address a gap in the literature regarding how robotics can foster the application and learning of mathematics in a non-formal STEM learning environment (Karim et al., 2015), as well as address the PME-NA theme of looking across different cultures of mathematics and other disciplines (e.g., engineering). For context, data consisted of 24 days of audio/video recordings of two students, each equipped with a chest-mounted camera (i.e., GoPro) to capture their individual and collaborative points of view.

Our units of analysis are mathematical moments, or spontaneous experiences to engage with and explore mathematical concepts (Cunningham, 2015), that emerged as students collaborated in a non-formal STEM learning environment. To observe the growth of mathematical understanding in these moments, the Pirie-Kieren theory (1994) was used as an analytical tool. This theory perceives understanding as a dynamic, leveled but nonlinear, recursive process and describes eight levels of actions for mathematical understanding. By tracing the participants' growth of understanding along these potential levels, we can ascertain a global sense of the mathematical thinking and learning occurring during these moments. To complement the Pirie-Kieren theory and to capture details of the learning process, we apply additional frameworks to reveal perseverance pathways as the students navigated mathematical obstacles (DiNapoli, 2018) and their emotions as in-the-moment affective states (Middleton et al., 2017). We will detail our analysis of a mathematical moment through these three frameworks to make visible the learning that occurred in this non-formal STEM learning environment (e.g., the concept of variable through programming and engineering activity).

We argue that the overlay of multiple complementary perspectives on the same piece of data helps make visible the mathematics occurring in spaces where it may be hard to see otherwise, as well as provide triangulation of claims about student cognition and affect. This approach of aligning different views on an activity may be productive for other researchers as well. Ultimately, this work is a step towards understanding how non-formal environments can support mathematics learning and points of connection between non-formal and formal spaces.
