Player A and Player B are playing a game where there is one pile of *N* marbles. Each player is allowed to take 1, 2, or 3 marbles from the pile on each turn, with Player A taking the first turn. A player wins if they take the last marble. For what values of *N* (the starting number of marbles in the pile) can Player A guarantee victory? How can Player A win in these cases? **Justify your answer.**

Problem 3
Player A and Player B are playing a game where there is one pile of *N* marbles. Each player is allowed to take any number of marbles that is a power of 2 (1, 2, 4, 8, ...); Player A has the first turn. A player wins if they take the last marble. For what values of *N* (the starting number of marbles in the pile) can Player A guarantee victory? How can Player A win in these cases? **Justify your answer.**

Figure 1: The first three problems in the task sequence.

Our analysis focuses on three groups' work on Problems 1 through 3 (Figure 1). The three groups in our analysis worked on these three problems for a total of 35 minutes, 29 minutes, and 45 minutes, respectively. Because our study focuses on students' generalization and justification practices, we transcribed the segment of each group's work on each of Problems 2 and 3 from the first time a group made a generalization or conjecture about the problem to the time when their work on the problem ended. We then analyzed each group's generalization processes and attempts to justify their conjectures, noting the degree to which each group formalized its reasoning using induction. We adopt the perspective that students' justification attempts offer some evidence of what they consider to be compelling arguments about winning strategies in combinatorial games, and in particular, of what aspects of PMI they are motivated and able to adapt to proving processes in this context.

Results and Analysis

In this section we provide a detailed description of one group's work on Problems 1 through 3 and briefly summarize the work of the two other groups in our analysis.

The Case of Group 1: Evidence of Process Pattern Generalization

Group 1, consisting of Bridget, William, Grace, and Ryan, used the names "John" and "Fluffy" in place of the letters A and B to refer to the two players. They used tables throughout the problem session to represent possible sequences moves in games, and gradually began to use these tables to represent branching cases that could occur within the same game.

After finding in Problem 1 that the first player can win by ensuring that the other player always receives a multiple of four marbles, the group moved on to Problem 2 and began categorizing possible starting positions as winning or losing for Player A. In the group's initial work on this problem, after identifying some examples of initial positions that are winning for Player A, Grace stated the conjecture, "So it's like -- basically, all the numbers except for the multiples of 4, because in that case, Fluffy would win." We interpret this as result pattern generalization, since Grace appeared to obtain this insight from a table of cases the group had considered, and because the group had not publicly justified all of its previous claims about winning positions for the first player.

The group chose to continue considering specific examples to gather evidence for this conjecture. Ultimately, the group returned to its conjecture and finalized it by writing it on the board: "if $N \equiv 1$, 2, or 3 (mod 4), then Player A will win (by generalization of P1). If $N \equiv 0$ (mod 4), then Player B will win." The group then debated whether to provide a written proof of this conjecture; while William remarked that "If we wanted to prove that, we could probably use induction or something," Grace indicated that this was not needed since they had already explained that their conjecture was true "by generalization of the first problem." We interpret this segment of discussion as indicating that the group saw an opportunity to formalize their argument using mathematical induction, but found such formalization to be unnecessary in this case, possibly because of the similarity between the reasoning used in Problem 2 and that used for the more specific Problem 1. We hypothesize that Problem 2 did not create intellectual necessity for PMI for this group; a proof by induction would not have done more to convince this group that their conjecture was universally valid.

On Problem 3, after testing the cases $N \leq 12$, the group correctly conjectured that Player A has a winning strategy if and only if N is not divisible by 3. The group then went on to write an argument justifying this conjecture:

> If 3 [does not divide] N, then Player A will win. If 3 [does not divide] N, then N ≡ 1 or 2 (mod 3), so Player A can leave Player B w/ a multiple of 3. If Player B has a multiple of 3, then B can only remove 1 mod 3 or 2 mod 3 marbles, leaving A w/ 1 mod 3 or 2 mod 3 marbles, so A can win.

Prior to the group's production of this argument, William had stated that each power of 2 is congruent to 1 or 2 modulo 3; this allowed the group to reason that if Player B receives a multiple of three marbles, then any move by Player B will reduce the number of marbles to a non-multiple of 3. In this argument we see evidence of process pattern generalization based on the group's work on specific examples: both the insight that a power of 2 cannot be a multiple of 3 (and that this is important in limiting what a player can do if given a multiple of 3), and the strategy of reducing the number of marbles to a multiple of 3. However, the argument as written does not explain why "A can win" after receiving a smaller number of marbles congruent to 1 or 2 modulo 3 (and one can envision this smaller number being outside of the range of specific examples that the group tested directly).

The Cases of Groups 2 and 3: Obstacles to Process Pattern Generalization

Like Group 1, Groups 2 and 3 correctly determined that in Problem 2, Player A has a winning strategy if and only if *N* is not a multiple of 4. Neither group used induction to ground claims that a first move for Player A would place Player B in a losing position; they instead referenced their prior work on Problem 1 and examples they explored in Problem 2. We hypothesize that the regularity of winning and losing positions in Problem 2 led both groups to the belief that a formal proof by induction was not essential for justification of their conjecture.

While both Groups 2 and 3, like Group 1, arrived at a correct answer to Problem 3, their attempts at justification differed significantly. In attempting to show in general that a multiple of 3 would be a losing position in this game, Group 2 did not take into account possible moves for the next player other than taking 1 or 2 marbles, even though they did account for other possible powers of 2 in the preliminary example work that led to their conjecture. Therefore, while Group 2 was able to render a partial explanation of how Player A could seize a winning strategy by taking 1 or 2 marbles if *N* is not a multiple of 3, their argument did not fully demonstrate that this first move would put Player B in a losing position. Group 3 attempted to prove its conjecture for Problem 3 using PMI, but in doing so, they attempted to establish values of *N* as winning or losing positions by proving the false claim that an integer *N* can be written as either a sum of an even number of powers of 2 or the sum of an odd number of powers of 2, but not both. They embarked upon this strategy despite the fact that expressing an integer as a sum of powers of 2 had not been a key part of their reasoning about specific examples that led to their conjecture.

Discussion and Implications

The results of our interviews are not necessarily indicative of students' ability to use PMI to generalize and formalize recursive reasoning. We did not require students to produce formal proofs during the interviews, so any attempts to use induction or other proof techniques reflected students' desire to confirm or formalize a result, or their sense that we wished for them to do so. In a future study we hope to ask groups of students to work on the same sequence of problems in one task-based interview, then ask them in another interview to write formal proofs of their results.

Nonetheless, we claim that observing students' work on combinatorial game problems provides useful insight about obstacles that may hinder students' efforts to make the cross-cultural translation between the empirical and recursive reasoning that often occurs naturally in exploratory mathematical activity, and the formal inductive justification accepted by the mathematics discipline. First, regularity in the structure of a problem may eliminate intellectual necessity for formal proof by induction. Second, our preliminary results suggest that students may have difficulty translating the recursive reasoning used in specific examples into a proof by induction; and in fact, they may use reasoning disanalogous to their prior reasoning when attempting a proof by induction. Finally, when students do successfully transfer their recursive reasoning into an induction argument, some work may be needed to impress upon students a sense of the importance of a base case, and the function of the structure of an induction proof in providing a foundation on which higher-order cases can rest on lower-order cases.

STUDENTS' UNDERSTANDING OF LINEAR ALGEBRA CONCEPTS UNDERLYING A PROCEDURE IN A QUANTUM MECHANICS TASK

Kaitlyn Stephens Serbin
Virginia Tech
ksserbin@vt.edu

Megan Wawro
Virginia Tech
mwawro@vt.edu

As undergraduate physics students solve problems related to quantum mechanics, they often have to draw on their conceptual understanding of both linear algebra and physics concepts. One concept that is prevalent in both of these disciplines is change of basis. In this study, we focus our analysis on physics students' mathematical conceptual knowledge of principles that underlies their use of a procedure on a quantum mechanics task. As students perform this task, they demonstrated understanding of change of basis and properties of orthonormal bases. We share examples of students' reasons for performing a change of basis and demonstrate how students seem to draw on their conceptual understanding of properties of orthonormal bases as they implement the procedure. We thus exemplify how physics students apply their mathematical knowledge in interdisciplinary contexts.

Keywords: Interdisciplinary studies, STEM / STEAM, University mathematics

Undergraduate physics students are commonly required to take a course in linear algebra, seen as several concepts and procedures covered in a linear algebra course are also addressed in physics courses, particularly quantum mechanics. Physics students have to make connections between concepts covered in both linear algebra and physics contexts. This may be challenging for students, given that concepts included in both linear algebra and quantum mechanics courses are sometimes used differently in the two different contexts. One such example is that bases are typically orthonormal in quantum mechanics contexts (McIntyre, Manogue, & Tate, 2012), which is generally not the case in linear algebra. Furthermore, a change of basis in a quantum mechanics context may be performed differently than a change of basis in a linear algebra context, such as through formulaic substitution of commonly used bases rather than a change of basis matrix. Since instructors want students to have a cohesive understanding of basis and change of basis across these interdisciplinary contexts, it is useful to explore how students reason about change of basis in a quantum mechanics context.

As students solve problems related to quantum physics, they often have to draw on their conceptual understanding of both mathematics and physics. In this study, we focus our analysis on physics students' mathematical conceptual knowledge that underlies their use of a procedure on a quantum mechanics problem. We address the following research question: How do students use their mathematical conceptual knowledge as they perform a quantum mechanics task?

Theoretical Framing

Conceptual and procedural knowledge are constructs commonly used by researchers to characterize students' understanding of mathematical concepts. Rittle-Johnson, Schneider, and Star (2015) have theorized that bidirectional relations exist between students' conceptual knowledge and procedural knowledge. These researchers asserted that procedural knowledge can support students' development of conceptual knowledge and vice versa. Particularly, conceptual knowledge can support students' flexibility in choosing appropriate procedures (e.g., Baroody, Feil, & Johnson, 2007). Crooks and Alibali (2014) identified two main types of conceptual knowledge, general principle knowledge and knowledge of principles underlying procedures. *Knowledge of principles underlying procedures* involves understanding the "connections among the steps in a procedure and between individual

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. steps and their conceptual underpinnings" (p. 367). In this study, we use Crooks and Alibali's (2014) construct of knowledge of principles underlying procedures to frame our analysis of students' conceptual knowledge of the mathematical concepts underlying their use of a procedure in quantum mechanics problem.

Brief Physics Background

Quantum mechanical systems and all knowable information about them are represented mathematically by normalized kets, symbolized in Dirac notation as $|\psi\rangle$. Kets mathematically behave like vectors, and a ket's complex conjugate transpose, called a bra, is symbolized as $\langle\psi|$. Spin is a measure of a particle's intrinsic angular momentum and is represented mathematically by an operator such as $\hat{S}_z$ (where the z indicates the particle's axis of rotation). In a spin-½ system, there are two possible results for the S_z measurement: $\pm\frac{\hbar}{2}$; they correspond to $|+\rangle$ and $|-\rangle$, which comprise a set of orthonormal basis vectors called the S_z basis. Any quantum state $|\psi\rangle$ is a linear combination of them: $|\psi\rangle = a|+\rangle + b|-\rangle$. In this study, we analyze the students' responses to the two interview questions presented in Figure 1. Interview question (a) asks students to determine the probability of obtaining $\frac{\hbar}{2}$ or $\frac{-\hbar}{2}$ in a measurement of the observable S_z on a system in state $|\psi\rangle$. This is calculated by $P_{\pm} = |\langle\pm|\psi\rangle|^2$, where $\langle\pm|\psi\rangle$ is an inner product between one of the basis kets and psi. Because $|\psi\rangle$ is written as a linear combination of the two vectors that comprise the z-basis, solving this problem requires no change of basis. The analogous information can be determined for other axes of rotation, such as y. To complete question (b), a change of basis is involved because the given state vector $|\psi\rangle$ is written in terms of the z-basis, but the prompt asks for the probability that the spin component is up along the y-axis. The two main approaches are to either change $|\psi\rangle$ to be written in terms of the y-basis (denoted $|\pm\rangle_y$), or change the y-basis vectors to be written in terms of the z-basis. In either change of basis approach, one would need to utilize the relations, $|\pm\rangle_y = \frac{1}{\sqrt{2}}|+\rangle \pm \frac{i}{\sqrt{2}}|-\rangle$.

Consider the quantum state vector $|\psi\rangle = \frac{3}{\sqrt{13}}|+\rangle + \frac{2i}{\sqrt{13}}|-\rangle$.

Calculate the probabilities that the spin component is up or down along the z-axis.

Calculate the probabilities that the spin component is up or down along the y-axis.

Figure 1: The interview questions analyzed in this paper.

Methods

Semi-structured interviews (Bernard, 1988) were conducted with 12 quantum physics students, of which eight were enrolled in a junior-level course at a large public research university (A) in the northwest United States, and four were enrolled in a senior-level course at a medium public research university (C) in the northeast United States. Students from these two universities were assigned pseudonyms of A# and C#. Both courses used a "spins first" approach, with McIntyre et al. (2012) as their course textbook. The interview questions were designed to elicit evidence of student understanding of linear algebra concepts used in their quantum mechanics course. We analyzed the students' responses to the two interview questions presented in Figure 1. A relevant follow-up question of particular interest was: "How do you see this problem relating to basis or change of basis?"

The data collected from these interviews include video recordings of the interviews and copies of student work. We transcribed the students' responses to these tasks and wrote descriptions of the procedures the students used and the mathematical concepts the students discussed as they explained their thought process and justified their choice of procedure. In writing these descriptions of the students' interview responses, we noticed the students commonly referred to mathematical concepts of orthonormal bases, inner product, and change of basis. We thus focused our qualitative analysis on students' conceptual understanding of these mathematical concepts underlying the probability procedure in this quantum physics context. We performed open coding (Miles, Huberman, & Saldaña, 2013) of the procedures the students used and the mathematical concepts they demonstrated an understanding of in their responses to the interview questions. We then wrote analytic memos (Maxwell, 2013) reflecting on how the students' understanding of linear algebra concepts seemed to support their use of the procedure.

Results

We present our results in two subsections. We first discuss the procedures the students employed to solve task. We then discuss the nature of the conceptual understanding the students exhibited as they performed this procedure and justified their procedure choice.

Students' Procedures for the Task Requiring a Change of Basis

In task (b), the students could either change $|\psi\rangle = \frac{3}{\sqrt{13}}|+\rangle + \frac{2i}{\sqrt{13}}|-\rangle$ to be written in terms of the y basis or change $|+\rangle_y$ (and $|-\rangle_y$for spin down) to be written in terms of the z-basis. Three out of twelve students used the former approach, but only one did so correctly. This student, A8, added the change of basis equations (given on a reference sheet) $|+\rangle_y = \frac{1}{\sqrt{2}}|+\rangle + i\frac{1}{\sqrt{2}}|-\rangle$ and $|-\rangle_y = \frac{1}{\sqrt{2}}|+\rangle - i\frac{1}{\sqrt{2}}|-\rangle$ to find $|+\rangle_y + |-\rangle_y = \frac{2}{\sqrt{2}}|+\rangle$. He then multiplied both sides of the equations by $\frac{\sqrt{2}}{2}$ to find $\frac{1}{\sqrt{2}}|+\rangle_y + \frac{1}{\sqrt{2}}|-\rangle_y = |+\rangle$, which is a z-basis vector written as a linear combination of the y-basis vectors. He then subtracted the given change of basis equations to find $|+\rangle_y - |-\rangle_y = \frac{2}{\sqrt{2}}i|-\rangle$ and multiplied both sides by $\frac{\sqrt{2}}{2i}$ to find $\frac{1}{\sqrt{2}i}|+\rangle_y - \frac{1}{\sqrt{2}i}|-\rangle_y = |-\rangle$. He then substituted $|+\rangle = \frac{1}{\sqrt{2}}|+\rangle_y + \frac{1}{\sqrt{2}}|-\rangle_y$ and $|-\rangle = \frac{1}{\sqrt{2}i}|+\rangle_y - \frac{1}{\sqrt{2}i}|-\rangle_y$ into $|\psi\rangle = \frac{3}{\sqrt{13}}|+\rangle + \frac{2i}{\sqrt{13}}|-\rangle$ and simplified the equation to find $|\psi\rangle_y = \frac{5}{\sqrt{26}}|+\rangle_y + \frac{1}{\sqrt{26}}|-\rangle_y$. To calculate the probability that the spin component is up along the y-axis, he computed $\left|{}_y\langle+|\psi\rangle_y\right|^2 = \frac{25}{26}$ by squaring the coefficient of $|+\rangle_y$, taking for granted the fact that ${}_y\langle+|+\rangle_y = 1$ and ${}_y\langle+|-\rangle_y$= 0 because the basis vectors are orthonormal.

For the calculation in question (b), ten students changed $|+\rangle_y$ to be written in terms of the z- basis, and all of them used the appropriate change of basis formula $|+\rangle_y = \frac{1}{\sqrt{2}}|+\rangle + i\frac{1}{\sqrt{2}}|-\rangle$. Seven of the ten students who performed the rest of the procedure found the conjugate transpose as ${}_y\langle+| = \frac{1}{\sqrt{2}}\langle+| - \frac{1}{\sqrt{2}}i\,\langle-|$ and substituted this into the probability formula $P_{+,y} = \left|{}_y\langle+|\psi\rangle\right|^2$ to find $P_{+,y} = \left|(\frac{1}{\sqrt{2}}\langle+| - \frac{1}{\sqrt{2}}i\,\langle-|)(\frac{3}{\sqrt{13}}|+\rangle + \frac{2i}{\sqrt{13}}|-\rangle\,)\,\right|^2$. They then distributed and used the orthonormality properties, $\langle+|+\rangle = 1$, $\langle-|-\rangle = 1$, and $\langle+|-\rangle = 0$ to simplify the equation to be $P_{+,y} = \left|\frac{5}{\sqrt{26}}\right|^2$, which gave a probability of $\frac{25}{26}$.

Students' Conceptual Knowledge of Linear Algebra Underlying These Procedures

As the students performed this procedure, they demonstrated conceptual knowledge of the linear algebra concepts of change of basis and properties of orthonormal bases. All of the students recognized a need to change the basis for this problem. They often explicitly acknowledged that they could not calculate this inner product without performing a change of basis. For instance, A13 claimed, "you can't just multiply out in, when they're [the vectors are] in different bases." As C6 described how this problem was related to change of basis, she claimed, "you can't do anything until you're in the same basis." The students each demonstrated conceptual understanding of why a change of basis was necessary in this task. Other students noted that performing the change of basis made the calculation simpler. For instance, in A8's change of basis procedure described above, changing the basis of $|\psi\rangle$ to express the ket as a linear combination of y-basis kets allowed him to use the simple procedure of squaring the norms of coefficients of y-basis kets. Students who used the second procedure discussed how changing basis makes the calculations simpler because they can use orthonormality property of the bases.

The students' motivation for selecting the procedure of changing the basis was the ability to take advantage of these properties of an orthonormal basis. A21 claimed it was necessary to change basis in order to make assumptions about $\langle +|-\rangle = 0$. C5 also suggested that a change of basis was necessary for the "inner products to be nice." The students demonstrated conceptual understanding of properties of orthonormal bases, which underlie their procedures for this task. Their procedures were particularly dependent on the fact that the y-basis and the z-basis are both orthonormal, which implies that $\langle +|+\rangle = 1$, $\langle -|-\rangle = 1$, and $\langle +|-\rangle = 0$.

Discussion

As the students used the change of basis procedure in this quantum mechanics problem, they demonstrated conceptual understanding of the orthogonality and normality properties of basis vectors and the associated inner product relations of $\langle +|+\rangle = 1, \langle -|-\rangle = 1,$ and $\langle +|-\rangle = 0$. The students seemed to draw on their understanding of the principles underlying this procedure as they performed the probability calculation and justified their choice of procedure. Their conceptual understanding of these mathematical properties seemed to support them in their choice of procedure and their implementation of it. Baroody et al. (2007) suggested that students' conceptual knowledge can supports students' flexibility in applying procedures. Our study further illustrates how students' conceptual understanding of linear algebra concepts can be useful in supporting their flexibility in performing procedures in quantum mechanics contexts.

In this quantum mechanics problem, the students' change of basis approaches involved employing several mathematical properties. However, their method for performing the change of basis though algebraic substitution is different from how they would perform a change of basis in a linear algebra course, which typically involves the use of a change of basis matrix. Physics students may experience challenges in using their understanding of linear algebra to solve problems in quantum mechanics contexts. Therefore, we suggest that future research can address how physics students transfer their understanding of change of basis across linear algebra and quantum mechanics contexts. Researchers can particularly focus on how physics students resolve differences they experience as they make connections across these disciplines.

"SOLVING VERSUS RELATING": PRE-SERVICE TEACHERS' CONFLICTING IMAGES OF FORMULAS AND DYNAMIC CONTEXTS

Irma E. Stevens
University of Michigan
istevens@umich.edu

Researchers have identified both the affordances of engaging students in symbolization activities and students' difficulties in meaningfully representing contexts through algebraic expressions/formulas. In a semester-long teaching experiment, two pre-service teachers demonstrated their conflicting meanings for formulas with their images of a context when engaging in a task about a dynamic geometric object. The two students could construct both normative formulas by reasoning with a context and descriptions of covariational relationships between quantities within the context, but both still struggled to relate their formulas and quantitative relationships to one another. This result highlights the importance of attending to what students' formulas mean to them, which for the students in this study, could be either a way of "solving" or "relating" quantities.

Keywords: Precalculus, Algebra and Algebraic Thinking, Cognition, Teacher Education - Preservice

Several researchers have identified students' difficulties with symbolization within formulas, equations, etc. and others have illustrated students' ability to construct their own representational systems (e.g., Izsák, 2003). To support pre-service teachers in working with their future students, it is important to start with understanding what they know and similarly, understanding where perturbations (i.e., cognitive conflict) might occur. In this study, I explore two secondary mathematics pre-service teachers' (heretofore, students') meanings for formulas, particularly focusing on the relationship between students' images of context (i.e., the quantities they construct within contexts) and their associated formulas. To do so, I draw on two main bodies of research: symbolization activity and covariational reasoning—reasoning involving how two quantities change in tandem with each other (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002). The research objective of this study builds on these researchers' findings through a teaching experiment with two students and is focused on learning about the mental operations involved in students' construction of formulas via reasoning with dynamic objects. Specifically, here, I focus on the students' meanings for an area formula for a parallelogram. The two students expressed conflicting meanings for a formula and its associated context. I describe these two students' meanings for their formulas and discuss the implications on students' symbolization activity based on their conflicting meanings and how they resolved them.

Background and Theoretical Perspective

In an effort to distinguish between terms used throughout the results section, I adopt Thompson and Carlson's (2017) definitions of constants and variables as students envisioning the following: a *constant* is an image involving a quantity as having a value that does not vary ever and a *variable* involves a quantity's value varying within a setting. I further define an *undetermined constant* as one in which the individual considering a quantity has not established a unit of measure, but anticipates needing to do so in order to produce a value (cf., *unknown* constant). The definition of variable relates to the notion of covariational reasoning proposed (i.e., the quantities co-varied are variables) and is also compatible with Küchemann's (1981) definition of a variable as a letter "seen as representing a range of unspecified values, and a systematic relationship is seen to exist between two such sets of values" (p. 104). Lastly, I emphasize that an individual using a letter (or any other marking) as a symbol for a constant, parameter, or variable requires the individual to re-present that

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

letter as a quantity or quantitative relationship within a situation. That is, a letter in itself is not a representation; the marking is the figurative material that results from an individual’s operations.

Methods and Task

This study was part of a semester-long teaching experiment (Steffe & Thompson, 2000) with two secondary mathematics pre-service teachers at a large public university in the southeastern U.S. The students were selected from a pre-calculus secondary content course based on their results of a modified version of the *MMTSM* assessment (Thompson, 2012) and a pre-interview showing that the students had differing ways of reasoning about quantitative relationships. This report focuses on a task that occurred in Lily’s hour-long teaching sessions 9-12 (of 12) and Dahlia’s teaching sessions 6-9 (of 10). As a result of open and axial coding of the video recordings and transcripts of the lessons and applying the definitions for constants and variables, I describe how Lily and Dahlia constructed and interpreted their conflicting images.

I use the *Moving Angles Task* to discuss students’ representational activity and construction of conflicting images. In this task, students were given the manipulative in Figure 1a and the prompt, “Describe the relationship between the area inside the shape (shape formed by two pairs of parallel lines) and one of the interior angles of the shape (up to a straight angle).” After initial discussions, both students received a sketch in a dynamic geometric environment (DGE) (Figure 1b) to support their exploration (which also included dynamic magnitude bars which are outside of the scope of this paper). The data was analyzed using generative and axial approaches (Corbin & Strauss, 2008) in order to construct models of the *mathematics of the students* (Steffe & Thompson, 2000). For a more detailed description of this task and insights into how this task has supported PSTs’ covariational reasoning with equations, see Stevens (2018).

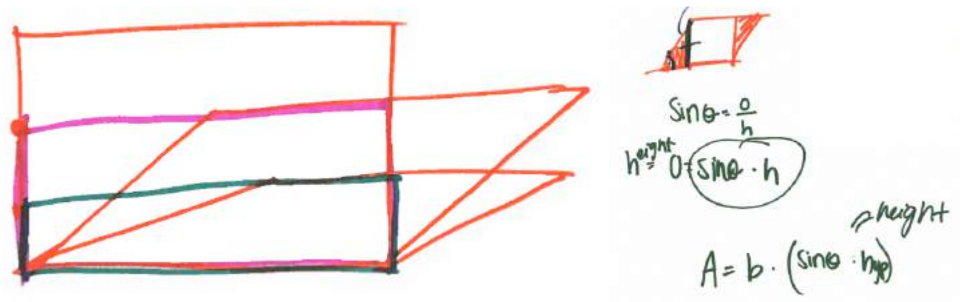
Results

Lily’s Conflicting Images

Lily originally focused on exploring the covariational relationships between angle measure (specifically for $\angle DAB$), height of the parallelogram, and the area of the parallelogram. After much deliberation, she concluded (as illustrated in Figure 2a) that equal changes in height corresponded with equal changes in area (i.e., “when the height was partitioned in decreasing equally, so was the area”), and in turning the angle clockwise from a right angle, the angle “decreases by decreasing amounts.”



(a) **(b)**

Figure 2: (a) Lily’s exploration of covariational relationships within a context (b) Lily’s reasoning with a static parallelogram

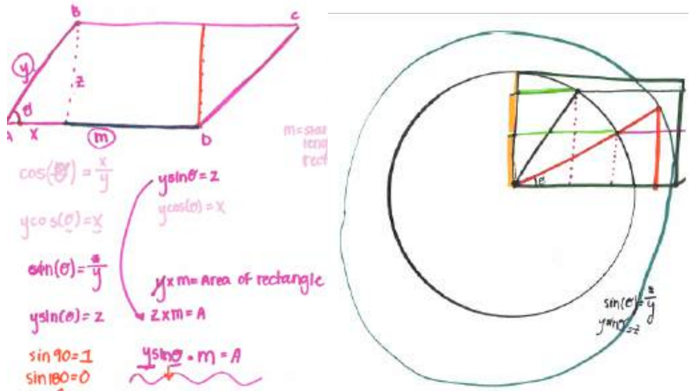
After her exploration, I asked Lily to “write an equation that represents the relationship that you’re talking about between the angle measure and the area of the parallelogram.” After several minutes, Lily drew a new parallelogram and stated that, “You can find this height [*of the parallelogram*] using sine and cosine” and produced the normative formula A=b(sin(θ)*hyp), where A=area of parallelogram, θ= m∠DAB in Figure 1b, and hyp= length of the hypotenuse in triangle in Figure 2b. In contrast to her drawing in Figure 2a, Lily said she did not see angle measure and height changing in her drawn parallelogram in Figure 2b. I interpret this description to indicate that Lily re-presented the symbols in her formula as undetermined constants of quantities she constructed from a static shape.

Lily indicated that her formula conflicted with her image of the relationships between quantities in the dynamic context, “Because I don’t know how to talk about it when I know this is true [*pointing to statement that from 0 to 90 degrees, angle measure increases so height increases so area increases*]. I don’t know how to relate it [*her statement*] to this part [*her parenthetical in her formula*].” She stated that the confusion stemmed from her understanding of her formula (Figure 2b) as “just solving, not relating,” where relating referred to seeing quantities (i.e., angle measure, height) as changing. In sum, to her, Lily, in constructing her formula, thought she was appropriately re-presenting a procedure for calculating area measures for static parallelograms but not the covariational relationships she constructed through her reasoning with the dynamic parallelogram.

Dahlia’s Conflicting Images

Like Lily, Dahlia identified a non-linear relationship between angle measure and area of the given shape, and she constructed a formula similar to Lily’s formula in Figure 2b using similar reasoning (Figure 3a). Unlike Lily, Dahlia also provided a unit circle meaning for sine and re-presented the segment corresponding to the hypotenuse of the right triangle in Figure 3a also as both a hypotenuse of a triangle and the radius of the circle (see Figure 3b). Moreover, she re-presented a relationship between *changing* quantities within her drawn parallelogram and formula; she described y as “not moving” and z and θ as “changing” in her figure and formula.

Nevertheless, Dahlia could not answer the question, “Why would we multiply a portion of the radius [*her description of* sin*(θ)*] by the radius [*her description of y*]?”. Thus, although Dahlia could construct a formula that re-presented varying quantities in a situation by reasoning with trigonometric relationships, her formula still conflicted with her image of the context. This conflict occurred because she thought that to calculate the area of a parallelogram, she would need to multiply the base length and height of the parallelogram together, but her formula indicated to her that the side length, h, of the parallelogram was also needed to obtain an area measurement. Thus, although Dahlia thought she appropriately re-presented her image of dynamic quantities in the context as a formula based on her reasoning with trigonometric ratios, she struggled to relate the symbols to her image of the context.



(a) **(b)**

Figure 3: (a) Dahlia’s formula for the area of a parallelogram with cosine related work dimmed for the reader (NOTE: m refers to AD, not the underlined segment in a different color) and (b) Dahlia’s diagram showing a unit circle approach for the sine relationship

Discussion and Implications

Researchers have often praised the symbolization activity of students developing their own symbols through representational activity, and this study is not an effort to discourage the use of contexts to support students’ meanings for formulas, equations, symbols, etc. Rather, this study indicates the importance of attending to the ways in which students’ symbolization activity re-presents their images of quantities and their relationships within given contexts. More specifically, Lily’s example indicates the importance of attending to students’ meanings for formulas (equations, functions, etc.) as ways to “solve for” or “figure out” values for constant quantities within static situations. This way of thinking about formulas was problematic for Lily even when she produced a normative formula because, for her, she was not re-presenting relationships between changing quantities with this formula. More generally, this view of formulas is problematic in students’ construction of variables because variables occur when a student re-presents values varying within a (dynamic) setting. Lastly, Dahlia’s example points to the importance of understanding students’ construction and role of units within their symbolization activity, particularly in regards to measurement contexts. By perturbing these meanings for formulas by attending to, for example, the role of units or the idea of a symbol as representative of a variable, students can accommodate their meanings for formulas to fit with their images of quantitative relationships in the context.

Palabras clave: Teorema fundamental del cálculo, Razonamiento, Método comparativo constante.

The first fundamental theorem of calculus relates differential and integral calculus, one of its important aspects according to Bressoud (2011) is that it shows the existence of two ways of calculating an integral: with the limit of a Riemann sum and by an antiderivative. Larsen, Marrongelle, Bressoud and Graham (2017) indicate that calculus is a barrier to the academic progress of many students and that there is a need for research that seeks to develop proposals for instruction to improve the understanding of its concepts. Therefore, with the idea of carrying out this type of research in the future, the present study seeks to identify the common interpretation of the first theorem of calculus and whether it is useful in solving contextual problems. Answering these questions will provide some elements to develop a proposal for instruction.

This study involved 18 students between the ages of 18 and 21 from engineering careers at a university located in Mexico City, who had completed a calculus course. The instrument was a set of three problems, in two, we propose contextual situations that can be solved by applying the first fundamental theorem of the calculus or by performing integration and derivation operations (one situation is about the ratio of change of the volume of water contained in a tank, with respect to time, where water falls to a variable ratio; the other is about the ratio of change of the volume of water contained in a cylindrical tank with respect to the height of water). In the last problem, the same type of situation is posed in abstract form: If $F(x) = \int_a^x f(t)dt$, obtain $F'(x)$, justify your answer.

The application of the instrument was done in a university classroom, participants were provided with the set of problems and paper sheets to write down their answers and were given 45 minutes to answer them. An analysis of students' responses to the problems was carried out using constant comparative method to form different categories, from which, one of the conclusions obtained is the following:

The common interpretation of the first fundamental theorem of calculus is that it establishes that integration and derivation are inverse operations, since in 71% of the answers of the shown problem (for which only 14 answers were given) used this argument. However, in 50% of these responses, mistakes are made by misusing notation when "cancelling" the inverse operations. This situation suggests that students, when applying the first fundamental theorem of calculus in the mentioned way, present a pseudo-conceptual behavior, (concept proposed by Vinner (1997)); since the way they proceed (making mistakes with the notation when "cancelling" the operations of integration and derivation when they appear together) seems to be linked to the algebraic representation of the situation ($\frac{d}{dx}\int_a^x f(t)dt$), not based on the concepts involved.

Palabras clave: Teorema fundamental del cálculo, Razonamiento, Método comparativo constante.

El primer teorema fundamental del cálculo relaciona el cálculo diferencial e integral, uno de sus aspectos importantes según Bressoud (2011) es que muestra la existencia de dos maneras de calcular una integral: con el límite de una suma de Riemann y con una antiderivada. Además, señala que se trata de un tema conceptualmente complejo. Larsen, Marrongelle, Bressoud y Graham (2017) indican que el cálculo es una barrera para el progreso académico de muchos estudiantes y que hace falta investigación que busque desarrollar propuestas de instrucción para mejorar la comprensión de sus conceptos, por lo que con la idea de realizar en un futuro una investigación de este tipo, se realiza el presente estudio buscando identificar cuál es la interpretación común que tienen los estudiantes sobre el teorema fundamental del cálculo y si ésta resulta útil al resolver problemas contextuales. Contestar estas preguntas aportará algunos elementos para desarrollar una propuesta de instrucción.

En este estudio participaron 18 estudiantes de entre 18 y 21 años de las carreras de ingeniería de una universidad ubicada en la ciudad de México, los cuales habían concluido un curso de cálculo. El instrumento fue una serie de tres problemas, en dos, se plantean situaciones contextuales que se pueden resolver aplicando el primer teorema fundamental del cálculo o realizando las operaciones de integración y derivación (una situación es sobre la razón de cambio del volumen de agua contenido en un depósito, respecto del tiempo, donde el agua cae a una razón variable; la otra es sobre la razón de cambio del volumen de agua contenido en un depósito cilíndrico respecto a la altura del agua). En el último problema, se plantea en abstracto el mismo tipo de situación: Si $F(x) = \int_a^x f(t)\,dt$, obtenga $F'(x)$, justifique su respuesta.

La aplicación del instrumento se realizó en un aula de la universidad, se les proporcionó a los participantes la serie de problemas y hojas de papel para escribir sus respuestas, y se les dio 45 minutos para contestarlo. Se realizó el análisis de las respuestas de los estudiantes a los problemas mediante el método comparativo constante para formar diferentes categorías, de donde, una de las conclusiones obtenidas es la siguiente:

La interpretación común de los estudiantes sobre el primer teorema fundamental del cálculo es que establece que la integración y derivación son operaciones inversas, pues en el 71% de las respuestas del problema mostrado (para el cual solo se tuvieron 14 respuestas) se utiliza dicho argumento. Sin embargo, en el 50% de estas respuestas se cometen errores al hacer uso inadecuado de la notación al momento de "cancelar" las operaciones inversas. Esto sugiere que los estudiantes al aplicar el primer teorema fundamental del cálculo de la forma mencionada, presentan un *comportamiento pseudo-*

conceptual, (concepto propuesto por Vinner (1997)); pues la forma en que proceden (cometiendo errores con la notación al "cancelar" las operaciones de integración y derivación cuando aparecen juntas) parece estar ligada a la representación algebraica de la situación ($\frac{d}{dx}\int_a^x f(t)\,dt$), no fundamentada en los conceptos involucrados.

In the present investigation, the aim is to characterize and analyze the role of those elements necessary for the construction of Cartesian ideas in secondary school students (13-15 years old). After a bibliographic review about the construction and interpretation of Cartesian graphs, it was found that those elements that characterize a graphical functional thought are determined by: covariation, variation and unification of a reference system (Clement, 1989; Caballero, 2012; Radford, 2008). The notion of co-variation is defined as the relationship between the simultaneous variations of two quantities (Ferrari, 2005), while the variation in our research is characterized as the quantification of a change, that is, the modification of state, appearance, behavior, condition of a body, system or object (Caballero, 2012). Finally, the unification of a Reference System refers to unifying the phenomenological space with the Cartesian space, resulting in the starting point of a movement (Radford, 2009a). This refers to the point from which it is possible to define positions, organize actions and interpretations.

According to the above, in the present investigation the following question is posed: what is the role of variation, covariation and the unification of a reference system in the development of Cartesian ideas associated with graphs? So, the objectives that are set are: to propose a didactic alternative to start the study of the notion of function / graph different from the strategy that is commonly approached within the school mathematical discourse: the equation-table-graph triad.

Likewise, to develop meanings in the students regarding the notion of function and graph, articulating the notions of variation, co-variation and frame of reference, with the support of educational technology such as graphing calculators and motion sensors.

This ongoing research is supported by the Theory of Objectification, which conceives teaching and learning as a single process that involves both knowing and being, where the objective of mathematical education lies in a political, social, and historical effort. and cultural aimed at the creation of reflective, ethical and critical subjects in historically and culturally constituted mathematical practices, and that reflect on new possibilities of those practices (Radford, 2019). Knowledge is developed in human activity, which is called joint work since it is a social form of joint effort through which individuals produce their means of subsistence while producing themselves as human beings (Radford, 2009b).

This research has a qualitative cut, since it seeks to analyze the productions carried out by a group of secondary school students (13-15 years old) in four guided activities that involve the articulation of the three notions previously reported, with the support of motion sensors in order to link them and arrive at Cartesian notions associated with a graph.

Currently the research is in process and an experimental instrument consisting of an activity where the articulation of the three notions is proposed has been developed. In this instrument, it is proposed by asking students to freely describe the movement produced by a cyclist when going down a hill that will be previously drawn. Another type of task within the activity will be to ask students to draw two hills with the same height but different gradients and they will ask themselves in which of them the cyclist will be able to descend faster and why.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

For the analysis of the students' productions, a multimodal analysis will be carried out in which the cognitive, body and perceptual resources used by the students are considered, that is, dialogues, body movements and their written representations will be analyzed (Vergel, 2016). This is expected to have results that allow a reflection on the importance of the three elements described to strengthen the construction of Cartesian ideas associated with graphs in basic level students.

Palabras clave: Gráficas cartesianas, variación, covariación, Sistema de referencia

En la presente investigación se pretenden caracterizar y analizar el rol de aquellos elementos necesarios para la construcción de ideas cartesianas en estudiantes de nivel Secundaria (13-15 años). Posterior a una revisión bibliográfica alrededor de la construcción e interpretación de gráficas cartesianas, se encontró que aquellos elementos que caracterizan a un *pensamiento funcional gráfico* están determinados por: la covariación, la variación y la unificación de un sistema de referencia (Clement, 1989; Caballero, 2012; Radford, 2008). La noción de co-variación se define como la relación entre las variaciones simultáneas de dos cantidades (Ferrari, 2005), mientras que la variación en nuestra investigación se caracteriza como la cuantificación de un cambio, es decir, la modificación de estado, apariencia, comportamiento, condición de un cuerpo, sistema u objeto (Caballero, 2012). Por último, la unificación de un Sistema de Referencia se refiere a unificar el espacio fenomenológico con el espacio cartesiano, resultando en el punto inicial de un movimiento (Radford, 2009a). Esto se refiere al punto a partir del cual es posible definir posiciones, organizar acciones e interpretaciones.

De acuerdo a lo anterior, en la presente investigación se plantea la siguiente pregunta: *¿cuál es el rol de la variación, covariación y la unificación de un sistema de referencia en el desarrollo de ideas cartesianas asociadas a las gráficas?* De manera que los objetivos que se plantean son: proponer una alternativa didáctica para iniciar el estudio de la noción de función/gráfica diferente de la estrategia que comúnmente se aborda dentro del discurso matemático escolar: la triada ecuación-tabla-gráfica. Asimismo, desarrollar significados en los estudiantes con respecto a la noción de función y gráfica, articulando las nociones de variación, co-variación y marco de referencia, con el apoyo de tecnología educativa como calculadoras graficadoras y sensores de movimiento.

Esta investigación en proceso se apoya en la Teoría de la Objetivación, la cual concibe la enseñanza y el aprendizaje como un único proceso que implica tanto el *saber* como el *ser*, donde el objetivo de la educación matemática reside en un esfuerzo político, social, histórico y cultural dirigido a la creación de sujetos reflexivos, éticos y críticos en prácticas matemáticas constituidas histórica y culturalmente, y que reflexionan sobre nuevas posibilidades de esas prácticas (Radford, 2019). El saber se desarrolla en la actividad humana, que se denomina labor conjunta ya que es una forma social de esfuerzo conjunto a través de la cual los individuos producen sus medios de subsistencia mientras se producen a sí mismos como seres humanos (Radford, 2009b).

Esta investigación tiene un corte cualitativo, ya que se busca analizar las producciones que realice un grupo de estudiantes de nivel Secundaria (13-15 años) en cuatro actividades guiadas que involucren la articulación de las tres nociones reportadas anteriormente, con apoyo de sensores de movimiento para poder vincularlos y llegar a nociones cartesiandas asociadas a una gráfica.

Actualmente la investigación se encuentra en proceso y se ha desarrollado un instrument experimental consistente en una actividad donde se plantea la articulación de las tres nociones. En dicho instrument se plantea por solicita a los estudiantes que describan de manera libre el movimiento que produce un ciclista al bajar por una colina que se les dibujará previamente. Otro tipo de tareas dentro de la actividad será la de solicitarle a los estudiantes que dibujen dos colinas con misma altura pero gradientes diferentes y se preguntará en cuál de ellas el ciclista podrá bajar más rápido y por qué.

Para el análisis de las producciones de los estudiantes se llevará a cabo un *análisis multimodal* en el cual se consideran los recursos cognitivos, corporales y perceptuales que utilizan los estudiantes, es decir, se analizarán diálogos, movimientos corporales y sus representaciones escritas (Vergel, 2016). Se espera con ello, contar con resultados que permitan una reflexión sobre la importancia de los tres elementos descritos para robustecer la construcción de ideas cartesianas asociadas a las gráficas en estudiantes de nivel básico.

Keywords: Calculus, Modeling, University Mathematics.

The findings of the research are shown from the perspective of mathematical modeling in the classroom, as a study process of phenomena or situations that could surface from everyday social and cultural contexts of the students, or from other sciences (Villa-Ochoa, 2010). To answer the question *how mathematical modeling of authentic problems contributes to the study on the concept of integral by university students,* we assume a mathematical model as a set of mathematical representations and relations for explaining, predicting and solving aspects of a phenomenon (Villa-Ochoa y otros, 2009a). An authentic problem is proposed (Kaiser y Schwarz, 2010) from the analysis of a simulation in GeoGebra of the download speed of a file, following the phases of ACODESA methodology. (Hitt, 2007).

The research was carried out with the participation of four students (aged 16-19) from a Colombian public university who passed the differential calculus course and had access to Aula Virtual GeoGebra. For the analysis of the data, the responses and written productions of the students in the Aula Virtual, and the recording of the responses to the structured interview (Goldin, 200) applied on the synchronic encounters were taken into account.

As an initial finding, the models built allowed to recognize the integral as the accumulated size of the file that has been downloaded until an instant of time t and was calculated as the area below the speed function graphic. Initially, the speed was simulated by a constant function, so the students resorted to the idea of inscribing a rectangle which base was the value of t and the height was the value of speed to find the size. Then, the speed was simulated by a lineal function with a slope of 0,1 for which the students divided the graphic into two regions and provided a model that represents the area below the curve. Afterwards, the speed was simulated by a sinusoidal function with a behavior similar to that generated by an internet connection, in which the speed increases or decreases, so the students considered the regions of the area they know and brought it neat the curve. Each student found a different model, by taking as a common significance that the area below the curve represented the size of the file until a particular time t.

Palabras Claves: Cálculo, Modelación, Matemáticas de nivel universitario.

Se presenta resultados iniciales de una investigación desde una perspectiva de la modelación matemática en el aula de clase, como un proceso de estudio de fenómenos o situaciones que pueden surgir de contextos cotidianos, sociales y culturales de los estudiantes o de otras ciencias (Villa-Ochoa, 2010). Para dar respuesta a la pregunta ¿Cómo la modelación matemática de problemas auténticos contribuye al estudio del concepto de integral a estudiantes universitarios?, asumimos un modelo matemático como un conjunto de representaciones y relaciones matemáticas para explicar, predecir y solucionar aspectos de un fenómeno (Villa-Ochoa y otros, 2009a). Se propone un problema auténtico (Kaiser y Schwarz, 2010), a partir del análisis de una simulación en GeoGebra del fenómeno de la velocidad de descarga de un archivo, siguiendo las fases de la metodología ACODESA (Hitt, 2007).

La investigación fue realizada con cuatro estudiantes de una universidad pública colombiana (16-19 años) que aprobaron el curso de cálculo diferencial, y que contaban con acceso al Aula Virtual GeoGebra. Para el análisis de los datos se tuvo en cuenta las respuestas y las producciones escritas de los estudiantes en el Aula y las grabaciones de respuestas a la entrevista estructurada (Goldin, 2000) aplicada en los encuentros sincrónicos.

Como resultados iniciales se tiene que los modelos construidos, permitieron reconocer la integral como el tamaño acumulado del archivo que se ha descargado hasta un instante de tiempo t, y fue calculado como el área bajo la gráfica de la función velocidad. Inicialmente la velocidad fue simulada por una función constante, por lo que los estudiantes recurrieron a la idea de inscribir un rectángulo, donde la base fuera el valor de t y la altura el valor de la velocidad para hallar el tamaño. Luego la velocidad fue simulada por una función lineal con pendiente 0,1 para el cual, los estudiantes dividieron la gráfica en dos regiones y dieron un modelo que representa el área bajo la curva. Posteriormente la velocidad fue simulada por una función sinusoidal con un comportamiento similar al generado por conexión a internet, en los cuales la velocidad aumenta o disminuye, por lo cual los estudiantes tuvieron en cuenta las regiones de área que conocen y las aproximaron a la curva, encontrando cada estudiante un modelo diferente, pero tomando como significado en común el área bajo la curva estaba representando el tamaño de archivo hasta un determinado tiempo t.

COMPARISON STRATEGIES BY QUOTIENT AND THE URN MODEL IN THE CHOICE OF PROBABILITIES

ESTRATEGIAS DE COMPARACIÓN POR COCIENTE Y EL MODELO DE URNA EN LA ELECCIÓN DE PROBABILIDADES

In this research, quotient strategies and their influence on decision-making in situations that involve the comparison of probabilities are analyzed. In order to achieve this, classical probability situations modeled with urns were designed. In each situation, two urns with simple extraction, involving or not proportional relationships, were proposed to third grade secondary school students. The analysis was carried out through the categorization of the results based on the relationships established between the components of the urns (favorable, unfavorable and possible cases). The study concluded that when comparing probabilities, students not only resort to the quotient (ratio): favorable case numbers among the number of possible cases to make their choice, but to others where they also include unfavorable cases.

Keywords: probability, problem solving

Background and the problem proposal

Proportional and probabilistic reasoning are closely related; both require quantitative and qualitative analysis, as well as inference and prediction of results. This statement follows from contrasting the definition of proportional reasoning by Lesh, Post and Behr (1988) with what Landín and Sánchez (2010) propose regarding the implications of probabilistic reasoning. In this way, both reasonings are not limited to numerical comparisons, and although some researchers have tried distinguishing these concepts from each other (see Hoemann and Ross, 1971), the work presented here does not focus on that distinction, but on incorporating them to extract and analyze those multiplicative strategies derived from comparison by quotient, considering as a means the resolution of situations modeled with urns.

The strategies used by students when solving probability situations modeled with urns, as Alatorre (1994) points out, have already been studied by researchers such as: Piaget and Inhelder (1951), Maury (1984, 1986), Lecoutre (1984), Fischbein et al (1970), and Thornton and Fuller (1981). However, although the authors refer to some indicators of why and how the selections were made, the uncertainty remains if other types of choices can be presented other than the ones they comment on or what other relationships the students establish, as well as what comparison mechanisms underlie in these strategies that can reveal their complexity, such as those derived from proportional reasoning that demand “the ability to recognize, to explain, to think about, to conjecture about, to graph, to transform, to compare, to make judgments about, to represent, or to symbolize relationships of two simple types ”(Lamon, 1999).

In the book for the secondary education teacher (Alarcón *et al.* 1994), as well as in works by Green (1988), Falk (1980), Aguas (2014), and Cañizares and Batanero (1997), situations with two urns have also been raised. Despite the fact that there are situations that can be modeled with them, the urns themselves are a rich model for working on probability or other topics in mathematics, as long as these are not seen as prerequisites for understanding it, but rather a context where they coexist and support each other. "use proportionality and a basic understanding of probability to make and test conjectures about the results of experiments and simulations" (NCTM, 2000, p. 248), leads to the development and strengthening of constantly interacting content. Thus, the "facility with proportionality develops through work in many areas of the curriculum, including ratio and proportion, percent, […] and probability" (NCTM, 2000, p. 212). Therefore, the present research consists of analyzing the quotients that arise when comparing probabilities. The strategies followed by secondary education students are classified in order to delve deeper into the processes they carry out to establish a result. It is proposed to identify what elements they consider when making their comparisons (favorable, unfavorable or possible cases), what types of choices they make based on the relationships established and what the particularities of these relationships are, which are fundamental for this study, because what is intended is to obtain indications of how the different quotients that they establish influence their decisions. The study is oriented by the following question and research purpose:

Research question: When solving probability situations, what are the quotients that secondary school students establish to make a choice?

Purpose: To identify, analyze and classify the strategies followed by third grade students of secondary education students when solving situations of classical probability contextualized with the urn model, focusing attention on those strategies that involve comparing by quotient to see how they influence the decision-making.

Method

The research is qualitative with an instrumental case (Stake, 1999) made up of a group of 35 third grade students from secondary education in Mexico City. Ten situations were designed, with and without proportionality, which involved the comparison of probabilities. The urn model was used to design the situations. From Lamon's (1993) classification, the problems posed correspond to those of *part-part-whole*, which Özgün-Koca (2009) includes in his study within those of numerical comparison, because most of the problems that were posed can be assumed as discrete sets where a *whole* corresponds to possible cases and subsets of that *whole* to favorable and unfavorable cases, respectively. For the implementation of the situations, three work sessions of 50 minutes were used. In each session, students solved three to four situations individually without instruction (prior or during implementation) of the resolution, which favored independent thinking and led to the identification and analysis of various strategies. In this paper it was interesting to illustrate those related to the comparison by quotient.

Theoretical Interpretative Framework

As a result of the analysis, an interpretative framework was constructed for the classification of the strategies derived from the quotient comparison that emerged from the implementation. Two types of comparisons were identified: a) additive — through a difference, and, b) multiplicative — through a quotient. The first implies an absolute thought, and the second a relative one (Lamon, 1999); the multiplicative one is interesting to illustrate in this paper. Table 1 shows sixteen expressions identified by comparing the elements of two urns by quotient, where F represents the number of favorable cases, D the number of unfavorable cases and $F + D$ corresponds to the number of possible cases. Subscripts 1 and 2, in F_1, F_2, D_1 and D_2 indicate the reference point, which states whether the favorable or unfavorable cases correspond to the first or second urn, respectively.

Table 1: Relationships that are established when comparing by quotient

Reference point F	Reference point D	Reciprocal of reference point F	Reciprocal of reference point D
Expression i	Expression ii	Expresion iii	Expression iv

$\frac{F_1}{F_2}$ with $\frac{D_1}{D_2}$	$\frac{D_1}{D_2}$ with $\frac{F_1}{F_2}$	$\frac{F_2}{F_1}$ with $\frac{D_2}{D_1}$	$\frac{D_2}{D_1}$ with $\frac{F_2}{F_1}$
Fraction: Part – Part		Fraction: Part – Part	
Ratio: When the antecedent is F and D and the consequent is F and D		Ratio: When the antecedent is F and D and the consequent is F and D

Fraction: Part-Whole. When the part is D		Fraction: Whole-Part. When the part is D	
Ratio: When the antecedent is D and the consequent is $F+D$		Ratio: When the antecedent is $F+D$ and the consequent is F	

In the comparison by quotient (see Table 1), considered as a fraction or ratio, they appear during the relationships established with the elements that make them up (*part-part*, *part-whole*, *whole-part* and antecedent-consequent), using strategies to compare them (see Table 2); where in the *part-part* relationship *a, b, c* and *d* are the parts; in the part-whole *a* and *c* are the parts and *b* and *d* are the whole; in whole-part *a* and *c* are the whole and *b* and *d* are the parts; in the antecedent-consequent relationship *a* and *c* are the antecedents and *b* and *d* are the consequents.

Table 2: Strategies to compare the relationships established in Table 1

1st Strategy: Fraction-ratio (part-part, part-whole and whole-part) with the use of:

Multiples: If multiplied $\left(\frac{a}{b}\right)\left(\frac{c}{c}\right)$; and $\left(\frac{c}{d}\right)\left(\frac{a}{a}\right)$, the expressions $\frac{ac}{bc}$ and $\frac{ac}{ad}$ are obtained, and as $bc = ad$ we can then establish the proportion $\frac{ac}{bc} = \frac{ac}{ad}$, which would be equivalent to: $\frac{a}{b} = \frac{c}{d}$. This indicates that the sets represented by a and b, and c and d are equiprobable.

Cross products: Given the ratios $\frac{a}{b}$ and $\frac{c}{d}$, when making the products ad and bc, equality is obtained as $ac = bd$, then the following proportion is established: $\frac{a}{b} = \frac{c}{d}$. This indicates that the sets represented by a and b, and c and d are equiprobable. Cross products are a particular case of using multiples to compare ratios or fractions.

Submultiples: By simplifying $\frac{a}{b}$, $\frac{m}{n}$ is obtained, and by simplifying $\frac{c}{d}$, $\frac{m}{n}$ is also obtained; then the following proportion is established: $\frac{a}{b} = \frac{c}{d}$, which indicates that the sets represented by a and b, and c and d are equiprobable.

Adding and subtracting fractions or ratios: Given the ratios $\frac{a}{b}$ and $\frac{c}{d}$, when subtracting $\frac{a}{b} - \frac{c}{d}$, the difference of $\frac{0}{bd} = 0$ is obtained; then the following proportion is established: $\frac{a}{b} = \frac{c}{d}$. This indicates that the sets represented by a and b, and c and d are equiprobable.

Adding and subtracting fractions or ratios in their decimal form: It is part of the fraction-ratio relationship, which allows for representation in decimal form to compare and make choices. By simplifying $\frac{a}{b}$, m is obtained, and by simplifying $\frac{c}{d}$, m is also obtained, where m is a decimal number; then the following proportion is established: $\frac{a}{b} = \frac{c}{d}$. This indicates that the sets represented by a and b, and c and d are equiprobable.

2nd Strategy: The relationship within. It is presented in an additive or multiplicative way.

Additive form: Given the ratios $\frac{a}{b}$ and $\frac{c}{d}$, if $a \pm (a)\left(\frac{m}{n}\right) = b$, and $c \pm (c)\left(\frac{m}{n}\right) = d$, or if $b \pm (b)\left(\frac{m}{n}\right) = a$, and $d \pm (d)\left(\frac{m}{n}\right) = c$, then the following proportion is established: $\frac{a}{b} = \frac{c}{d}$. This indicates that the sets represented by a and b, and c and d are equiprobable.

Multiplicative form: Given the ratios $\frac{a}{b}$ and $\frac{c}{d}$, if $(a)\left(\frac{m}{n}\right) = b$ and $(c)\left(\frac{m}{n}\right) = d$, or if $(b)\left(\frac{n}{m}\right) = a$, and $(d)\left(\frac{n}{m}\right) = c$, then the following proportion can be established: $\frac{a}{b} = \frac{c}{d}$. This indicates that the sets represented by a and b, and c and d are equiprobable.

3rd Strategy: Rule of three. A quaternary relationship is established where one of the four elements is unknown and the other three must be related to find its value. This value is compared with that obtained in another similar quaternary relationship.

To obtain percentages: Given the ratios $\frac{a}{b}$ and $\frac{c}{d}$, if $\frac{a}{b}$ is multiplied by 100 in order to obtain the percentage of a with respect to the percentage of b, it is considered 100%. Also, when $\frac{c}{d}$ is multiplied by 100 to get the percentage of c with respect to the percentage of d, it is considered 100%. If $\frac{(a)(100)}{b} = \frac{(c)(100)}{d}$, then the following proportion could be established: $\frac{a}{b} = \frac{c}{d}$, which would indicate that the sets represented by a and b, and c and d are equiprobable.

To obtain a, b, c or d: given the ratios $\frac{a}{b}$ and $\frac{c}{d}$, if $\frac{(cb)}{a} = d$ and $\frac{(ad)}{c} = b$, and d turns out to be a multiple or submultiple of b, then the following proportion can be established: $\frac{a}{b} = \frac{c}{d}$. This indicates that the sets represented by a and b, and c and d are equiprobable.

4th Strategy: The relationship between. It is presented in an additive or multiplicative way.

Additive Form: Given the ratios $\frac{a}{b}$ and $\frac{c}{d}$, if $a \pm (a)\left(\frac{m}{n}\right) = c$, and $b \pm (b)\left(\frac{m}{n}\right) = d$, or if $c \pm (c)\left(\frac{m}{n}\right) = a$, and $d \pm (d)\left(\frac{m}{n}\right) = b$, then the following proportion is established: $\frac{a}{b} = \frac{c}{d}$. This indicates that the sets represented by a and b, and c and d are equiprobable.

Multiplicative form: Given the ratios $\frac{a}{b}$ and $\frac{c}{d}$, if $(a)\left(\frac{m}{n}\right) = c$ and $(b)\left(\frac{m}{n}\right) = d$, or if $(c)\left(\frac{n}{m}\right) = a$ and $(d)\left(\frac{n}{m}\right) = b$, then the following proportion is established: $\frac{a}{b} = \frac{c}{d}$. This would indicate that the sets represented by a and b, and c and d are equiprobable.

If the previous relationships are not in proportion, then the sets represented by *a* and *b*, and *c* and *d* would not be equiprobable, therefore, it would be necessary to identify which of the two sets is more likely based on the cases (favorable, unfavorable or possible) that were considered and the relationships that were established to make the comparisons. In the aforementioned strategies, the relationships *within* and *between* are considered by Noelthing (1980) when working with mixing situations, and although this researcher only considers relationships *within* and *between* of a multiplicative nature, Alatorre (1994) extends them to order relations of an additive or subtractive nature, but she does not consider them as it is done in this study using quotient comparison, as she points out the differences without taking the basal amount into account, and from our perspective the *additive form* includes the basal amount when considering how many of how many. Quotient comparison is closely related to relative thinking, Lamon (1999) distinguishes this type of thinking as one where multiplicative structures are involved and differentiates it from absolute thinking where additive-type relationships are established.

Analysis of Results

For the purpose of this research, it is convenient to analyze the types of choices, the comparisons that are established, the strategies that are followed and the reference point that is considered in the comparison of probabilities, which is the meaning of the relationships that are given between the cases (favorable, unfavorable or possible). Table 3 illustrates the quantitative comparison by quotient and its implications in order to exemplify the monitoring of the strategies identified in the implementation.

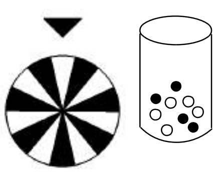
Table 3: Illustration of the type of choice, the strategy and the order relations identified in the quantitative comparison by quotient

Choice based on	Strategy (see Table 2)	Relationships (see Table 1)
Higher quotient; Lower quotient; or Equal quotient	1st Fraction-ratio (part-part)	Favorable-unfavorable v and vi Unfavorable-favorable vii and viii
	1st Fraction-ratio (part-whole)	Favorable-possible ix and x Possible-favorable xi and xii
		Unfavorable-possible xiii and xiv Possible-unfavorable xv and xvi

Consideration of favorable and unfavorable cases. The favorable and unfavorable cases of each set are compared by means of quotients (see expressions i, ii, iii, iv, v, vi, vii and viii in Table 1) and are chosen based on the highest, lowest or equal quotient. In the following, one of the strategies based on the choice of the highest quotient is exemplified.

Choice based on the highest quotient. *Strategy:* Fraction-ratio, part-part – with or without the use of submultiples and their representation in decimal form.

Order Relation: Favorable-Unfavorable.



Situation I. In a fair there are two games of chance: a roulette wheel and an Urn. You can spin the roulette wheel and bet to land on the white slot, or you can attempt to extract a white ball in urn mixed with black ones without looking. In which game is there a greater probability of winning? Explain how you determined your answer.

Student strategy. Example 1 (E1). Urn. There is a greater chance of winning at the urn. I was removing the median [half] to the colors of each game. In roulette they were the same colors and in the urn was a white ball rather than a black one and I saw that there was a better probability of winning.

$$\frac{7}{7}=\frac{3.5}{3.5}=1$$

$$\frac{5}{4}=\frac{2.5}{2}=1.25$$

$$\begin{array}{r} 1.25 \\ 2\overline{)2.5.} \\ 050 \\ 100 \\ 00 \end{array}$$

Figure 1: Student strategy. In example 1 (E1), the highest quotient is chosen. Quotient comparison (favorable-unfavorable) arriving at its decimal representation with the use of submultiples

In E1, a comparison of favorable and unfavorable cases is presented. To simplify the comparison of variables, submultiples are used and it ends with a decimal representation. In expressions v and vi (see Table 1), it is chosen based on a higher quotient, because the quotients in these expressions represent the number of favorable for each unfavorable. On the contrary, if expressions vii and viii are presented, the choices will be correct only if chosen based on the lowest quotient, which represents the number of unfavorable for each favorable. Hence, the significance of order relations: favorable-unfavorable or unfavorable-favorable.

Regarding the expressions i, ii, iii and iv of Table 1, correct choices would be provided if one considers the second quotient in i and iii; that is to say, this result is greater than the first quotient, whose elements are assigned the denominators of the comparative quotients. However, if it turns out to be less than the first, a correct choice is made if the set whose elements were assigned to the numerators is chosen. On the other hand, if expressions ii and iv are considered, the choice would also depend on the second quotient. If it turns out to be greater than the first quotient, the set that has remained in the numerators must be chosen. Yet, if it turns out to be less, a correct choice would be made if the set whose elements were in the denominators is chosen; this relates to the expressions i, ii, iii and iv, where the resulting quotients represent the number of favorable of a set for each favorable of the other, and in the same sense, the number of unfavorable of a set for each unfavorable of the other.

Consideration of unfavorable and possible cases. The possible and unfavorable cases of each set are compared by means of quotients (see expressions xiii, xiv, xv and xvi in Table 1) and the choice is made based on the highest, lowest or equal quotient. In the following, one of the strategies based on equal quotient is exemplified.

Choice based on equality of quotients. Strategy: Fraction-ratio, part-whole – with or without the use of submultiples and their representation in decimal form.

Order Relation: Unfavorable-Possible

Situation II. A teacher shows her students two black bags; the first bag contains 9 black and 6 white marbles, and the second bag contains 15 black and 10 white marbles. Which bag should they choose so that there is a greater probability that they will select a black marble on their first attempt? Explain the procedure you followed to make the choice.

Student strategy. Example 2 (E2). Any bag. Any bag has the same probability.

	Bag 1	Bag 1
White Marbles / Total Marbles	9 / 15	15 / 25
Probability	0.6	0.6

$$\begin{array}{r} .6 \\ 15\overline{)90} \\ 0 \end{array} \qquad \begin{array}{r} .6 \\ 25\overline{)150} \\ 0 \end{array}$$

Figure 2: Student strategy. In example 2 (E2), the equal quotient is chosen. Quotient comparison (unfavorable-possible) reaching its decimal representation without the use of submultiples

In E2, the comparison of unfavorable and possible cases in each set is presented. First, the cases of the first set were related and those of the second followed (see expression xiii of Table 1). It is important to note that in example 2 the decimal results obtained correspond to the probabilities of the unfavorable cases of each set. In expressions xv and xvi (see Table 1), it is chosen based on a higher quotient; this is because the resulting quotient determines the number of possible cases for each unfavorable one. Conversely, if expressions xiii and xiv are presented, the choices will be correct only if chosen based on the lowest quotient; this is because the quotient represents the number of unfavorable for each possible. In expressions ix and x, it is chosen based on a higher quotient; this is because they represent the number of favorable for each possible. On the other hand, if expressions xi and xii are presented, the choices will be correct only if chosen based on the smallest quotient; this is because the resulting quotient represents the number of possible for each favorable. It is noteworthy that expressions ix and x are the only ones that are used and considered in the 2011 Study Programs (SEP, 2011) to represent probabilities and make comparisons between them.

Final considerations

The results of this study concluded that with the probability of the event *A*, the students establish the quotient (ratio) $\frac{F}{P}$, determined by Laplace as the ratio of the number of favorable cases *F* to that of all the cases possible *P*. However, if they are presented with a probability comparison situation, they usually resort to other quotient comparisons where they also include unfavorable cases *D* such as: $\frac{D}{P}$ o $\frac{F}{D}$ or their reciprocals, and not necessarily the one established by Laplace. The research showed that these ratios led students to choices based on determining the urn with greater probability; hence, the importance of placing greater emphasis on quotient comparison strategies that result from comparing probabilities. The reference point is decisive for understanding the relationships that students establish and the interpretation they give to their quotients. For example, the interpretation of the quotient (ratio) $\frac{F}{D}$ is completely distinct from the one represented in the quotient (ratio) $\frac{D}{F}$, and in the same way, the interpretation is different $\frac{F_1}{D_1} > \frac{F_2}{D_2}$ to $\frac{F_2}{D_2} < \frac{F_1}{D_1}$. From a purely mathematical standpoint, these comparisons would have no greater difficulty, but from a pedagogical and didactic perspective of teaching and learning of probability, the change in the reference point when establishing the comparisons influences the treatment of the object of study and its interpretation. The incorporation of didactic orientations in the teaching materials for basic education curriculum is suggested, which includes an analysis of the strategies by quotient that the students can carry out when solving probability problems. A detailed analysis of the varied strategies presented by students would have a positive effect in the teaching and study of this branch of mathematics.

ESTRATEGIAS DE COMPARACIÓN POR COCIENTE Y EL MODELO DE URNA EN LA ELECCIÓN DE PROBABILIDADES

COMPARISON STRATEGIES BY QUOTIENT AND THE URN MODEL IN THE CHOICE OF PROBABILITIES

Maribel Aguas-Hidalgo

En esta investigación se analizan estrategias por cociente y su influencia en la toma de decisiones en situaciones que implican la comparación de probabilidades. Para ello, se diseñaron situaciones de probabilidad clásica modeladas con urnas. En cada situación se plantearon dos urnas con extracción simple, que implican o no relaciones de proporcionalidad, a estudiantes de tercer grado de educación secundaria. El análisis se realizó a través de la categorización de los resultados con base en las relaciones que se establecen entre los componentes de las urnas (casos favorables, desfavorables y posibles). El estudio arrojó que, al comparar probabilidades, los estudiantes no sólo recurren al cociente: números de casos favorables entre número de casos posibles para hacer su elección, sino a otros donde además incluyen a los casos desfavorables.

Palabras clave: probabilidad, resolución de problemas

Antecedentes y planteamiento del problema

Los razonamientos proporcional y probabilístico guardan estrecha relación; ambos requieren de un análisis cuantitativo y cualitativo, así como de la inferencia y la predicción de resultados. Esta afirmación se desprende de contrastar la definición de razonamiento proporcional de Lesh, Post y Behr (1988) con lo que Landín y Sánchez (2010) proponen respecto a las implicaciones del razonamiento probabilístico. De esta manera, ambos razonamientos no se limitan a comparaciones numéricas, y aunque algunos investigadores han intentado distinguir entre sí a estos conceptos (véase por ejemplo Hoemann y Ross, 1971); el trabajo que aquí se expone no se centra en distinguirlos sino en incorporarlos, para extraer y analizar aquellas estrategias multiplicativas derivadas de la comparación por cociente, considerando como medio la resolución de situaciones modeladas con urnas.

Las estrategias utilizadas por los estudiantes al resolver situaciones de probabilidad modeladas con urnas, como lo señala Alatorre (1994), ya han sido estudiadas por investigadores como: Piaget e Inhelder (1951), Maury (1984, 1986), Lecoutre (1984), Fischbein et al. (1970), y Thornton y Fuller

(1981). Sin embargo, aunque los autores refieren algunos indicadores del porqué y cómo se realizaron las elecciones, queda la incertidumbre si se pueden presentar otro tipo de elecciones distintas a las que ellos comentan o qué otras relaciones establecen los alumnos, así como qué mecanismos de comparación subyacen en estas estrategias y que pueden dejar ver la complejidad de las mismas, como las que se derivan de un razonamiento proporcional que demandan "la capacidad de reconocer, explicar, pensar, hacer conjeturas, graficar, transformar, comparar, emitir juicios, representar o simbolizar relaciones de dos tipos simples" (Lamon, 1999).

En el libro para el maestro de educación secundaria (Alarcón *et al.* 1994) así como en trabajos de Green (1988), Falk (1980), Aguas (2014), y Cañizares y Batanero (1997), también se han planteado situaciones con dos urnas. No obstante que existen situaciones que pueden ser modeladas con ellas, las urnas en sí mismas son un modelo rico para trabajar temas de probabilidad u otros de las matemáticas, siempre y cuando estos no sean vistos como prerequisitos para comprenderla, sino un contexto donde conviven y se apoyan mutuamente. "Utilizar la proporcionalidad y una comprensión básica de la Probabilidad para formular y comprobar conjeturas sobre los resultados de experimentos y simulaciones" (NCTM, 2000, p. 248), nos lleva al desarrollo y fortalecimiento de contenidos que interactúan de manera constante. Así, la "destreza con la proporcionalidad se desarrolla a través del trabajo con muchos temas del currículo: razón y proporción, porcentaje, […] y probabilidad" (NCTM, 2000, p. 212).

De esta manera, la presente investigación consiste en analizar los cocientes que surgen al comparar probabilidades. Para ello se clasifican las estrategias que siguen estudiantes de educación secundaria con la finalidad de profundizar en los procesos que llevan a cabo para establecer algún resultado. Es decir, se plantea identificar qué elementos consideran para hacer sus comparaciones (casos favorables, desfavorables o posibles), qué tipo de elecciones realizan con base en las relaciones que establecen y cuáles son las particularidades de estas relaciones, que para este estudio son fundamentales, porque lo que se pretende es obtener indicios de cómo los distintos cocientes que pueden establecer influyen en sus decisiones. El estudio está orientado por la siguiente pregunta y propósito de investigación.

Pregunta de investigación: Al resolver situaciones de probabilidad, ¿cuáles son los cocientes que estudiantes de educación secundaria establecen para hacer una elección?

Propósito: Identificar, analizar y clasificar las estrategias que siguen estudiantes de tercer grado de educación secundaria al resolver situaciones de probabilidad clásica contextualizadas con el modelo de urna, centrando la atención en aquellas estrategias que implican comparar por cociente para ver de qué manera influyen en la toma de decisiones.

Método

La investigación es cualitativa con un caso instrumental (Stake, 1999), conformado por un grupo de 35 alumnos de tercer grado de educación secundaria de la Ciudad de México. Se diseñaron 10 situaciones, con y sin proporcionalidad, que implicaron la comparación de probabilidades. Para el diseño de las situaciones se recurrió al modelo de urna. De la clasificación de Lamon (1993), los problemas planteados corresponden a los de Parte-parte-todo —que Özgün-Koca (2009) incluye en su estudio dentro de los de comparación numérica— porque la mayoría de los problemas que se plantearon pueden asumirse como conjuntos discretos donde un todo corresponde a los casos posibles y los subconjuntos de ese todo a los casos favorables y desfavorables, respectivamente. Para la implementación de las situaciones se utilizaron tres sesiones de trabajo, cada una de 50 minutos. En cada sesión los alumnos resolvieron individualmente de tres a cuatro situaciones sin instrucción (previa o durante la implementación) de la resolución, lo que favoreció un pensamiento independiente y conllevó a la identificación y análisis de diversas estrategias. En este documento interesó ilustrar las relacionadas con la comparación por cociente.

Marco teórico-interpretativo

Como resultado del análisis, se construyó un marco interpretativo para la clasificación de las estrategias derivadas de la comparación por cociente que surgieron de la implementación. Se identificaron dos tipos de comparaciones: a) aditiva —por medio de una diferencia— y, b) multiplicativa —por medio de un cociente—. La primera implica un pensamiento absoluto, y la segunda uno relativo (Lamon,1999); siendo la multiplicativa la que interesa ilustrar en este documento. En la Tabla 1 se muestran dieciséis expresiones identificadas al comparar por cociente los elementos de dos urnas, donde F representa el número de casos favorables, D número de casos desfavorables y F+D corresponde al número de casos posibles. Los subíndices 1 y 2, en F_1, F_2, D_1 y D_2 indican el punto de referencia, es decir, si los casos favorables o desfavorables corresponden a la primera o segunda urna, respectivamente.

Tabla 1: Relaciones que se pueden establecer cuando se compara por cociente

Punto de referencia F	Punto de referencia D	Reciproco del punto de referencia F	Reciproco del punto de referencia D

En la comparación por cociente (véase la Tabla 1), considerado como fracción o razón, se pueden presentar, durante las relaciones que se establecen con los elementos que las conforman (parte-parte, parte-todo, todo-parte y antecedente-consecuente), las siguientes estrategias para compararlas (véase la Tabla 2), donde en la relación parte-parte *a, b, c* y *d* son las partes; en la parte-todo *a* y *c* son las partes y b y d son los todos; en todo-parte a y c son los todos y b y d son las partes; y en la relación antecedente-consecuente a y c son los antecedentes y b y d son los consecuentes.

Tabla 2: Estrategias para comparar las relaciones que se establecen en la Tabla 1

1ª.- Estrategia: Fracción-razón (parte-parte, parte-todo y todo-parte) con el uso de: *Múltiplos:* Si se multiplica $\left(\frac{a}{b}\right)\left(\frac{c}{c}\right)$ y $\left(\frac{c}{d}\right)\left(\frac{a}{a}\right)$ se obtienen las expresiones $\frac{ac}{bc}$ y $\frac{ac}{ad}$, y si $bc = ad$ entonces se puede establecer la proporción $\frac{ac}{bc} = \frac{ac}{ad}$ que sería equivalente a: $\frac{a}{b} = \frac{c}{d}$. Esto significa que los conjuntos representados por a y b, y c y d son equiprobables. *Productos cruzados:* Dadas las razones $\frac{a}{b}$ y $\frac{c}{d}$, si al efectuar los productos ad y bc se obtiene la igualdad $ac = bd$, entonces se establece la proporción: $\frac{a}{b} = \frac{c}{d}$. Esto significa que los conjuntos representados por a y b, y c y d son equiprobables. Los productos cruzados son un caso particular del uso de múltiplos para comparar razones o fracciones. *Submúltiplos:* Si al simplificar $\frac{a}{b}$ se obtiene $\frac{m}{n}$, y al simplificar $\frac{c}{d}$ también se obtiene $\frac{m}{n}$, entonces se establece la proporción: $\frac{a}{b} = \frac{c}{d}$, lo que significa que los conjuntos representados por a y b, y c y d son equiprobables. *Suma y resta de fracciones o razones:* Dadas las razones $\frac{a}{b}$ y $\frac{c}{d}$, si al hacer la sustracción $\frac{a}{b} - \frac{c}{d}$ se obtiene la diferencia $\frac{0}{bd} = 0$, entonces se establece la proporción: $\frac{a}{b} = \frac{c}{d}$. Esto significa que los conjuntos representados por a y b, y c y d son equiprobables. *Suma y resta de fracciones o razones en su representación decimal:* Parte de la relación fracción-razón, y se llega a su representación en forma decimal para comparar y hacer la elección. Si al simplificar $\frac{a}{b}$ se obtiene m, y al simplificar $\frac{c}{d}$ también se obtiene m, donde m es un número decimal, entonces se establece la proporción: $\frac{a}{b} = \frac{c}{d}$. Esto significa que los conjuntos representados por a y b, y c y d son equiprobables.
2ª.- Estrategia: Relación dentro. Se presenta de forma aditiva o multiplicativa. *Forma aditiva*: Dadas las razones $\frac{a}{b}$ y $\frac{c}{d}$, si $a \pm (a)\left(\frac{m}{n}\right) = b$, y $c \pm (c)\left(\frac{m}{n}\right) = d$, o si $b \pm (b)\left(\frac{m}{n}\right) = a$ y $d \pm (d)\left(\frac{m}{n}\right) = c$, entonces se puede establecer la proporción: $\frac{a}{b} = \frac{c}{d}$. Esto significaría que los conjuntos representados por a y b, y c y d son equiprobables. *Forma multiplicativa*: Dadas las razones $\frac{a}{b}$ y $\frac{c}{d}$, si $(a)\left(\frac{m}{n}\right) = b$ y $(c)\left(\frac{m}{n}\right) = d$, o si $(b)\left(\frac{n}{m}\right) = a$ y $(d)\left(\frac{n}{m}\right) = c$, entonces se puede establecer la proporción: $\frac{a}{b} = \frac{c}{d}$. Esto significaría que los conjuntos representados por a y b, y c y d son equiprobables.
3ª.- Estrategia: Regla de tres. Se establece una relación cuaternaria donde uno de los cuatro elementos es desconocido y los otros tres deben ser relacionados para encontrar su valor. Este valor es comparado con el obtenido en otra relación cuaternaria similar. *Para la obtención de porcentajes:* Dadas las razones $\frac{a}{b}$ y $\frac{c}{d}$, si se multiplica $\frac{a}{b}$ por 100 para obtener el porcentaje de a respecto al porcentaje de b, considerado como el 100%. Y $\frac{c}{d}$ también se multiplica por 100 para obtener el porcentaje de c respecto al porcentaje de d, considerado como el 100%, si $\frac{(a)(100)}{b} = \frac{(c)(100)}{d}$, entonces se podría establecer la proporción: $\frac{a}{b} = \frac{c}{d}$, lo que significaría que los conjuntos representados por a y b, y c y d son equiprobables. *Para la obtención de a, b, c o d:* Dadas las razones $\frac{a}{b}$ y $\frac{c}{d}$, si $\frac{(cb)}{a} = d$ y $\frac{(ad)}{c} = b$, y d resulta ser múltiplo o submúltiplo de b, entonces se puede establecer la proporción: $\frac{a}{b} = \frac{c}{d}$. Esto significaría que los conjuntos representados por a y b, y c y d son equiprobables.

4ª.- Estrategia: Relación entre. Se presenta de forma aditiva o multiplicativa.
Forma aditiva: Dadas las razones $\frac{a}{b}$ y $\frac{c}{d}$, si $a \pm (a)\left(\frac{m}{n}\right) = c$, y $b \pm (b)\left(\frac{m}{n}\right) = d$, o si $c \pm (c)\left(\frac{m}{n}\right) = a$, y $d \pm (d)\left(\frac{m}{n}\right) = b$, entonces se puede establecer la proporción: $\frac{a}{b} = \frac{c}{d}$. Esto significaría que los conjuntos representados por a y b, y c y d son equiprobables.
Forma multiplicativa: Dadas las razones $\frac{a}{b}$ y $\frac{c}{d}$, si $(a)\left(\frac{m}{n}\right) = c$ y $(b)\left(\frac{m}{n}\right) = d$, o si $(c)\left(\frac{n}{m}\right) = a$ y $(d)\left(\frac{n}{m}\right) = b$, entonces se puede establecer la proporción: $\frac{a}{b} = \frac{c}{d}$. Esto significaría que los conjuntos representados por a y b, y c y d son equiprobables.

Si las relaciones anteriores no están en proporción, entonces los conjuntos representados por a y b, y c y d no serían equiprobables, por lo que habría que identificar cuál de los dos conjuntos tiene mayor probabilidad con base en los casos (favorables, desfavorables o posibles) que se consideraron y las relaciones que se establecieron para hacer las comparaciones. En las estrategias descritas anteriormente se encuentran las relaciones *dentro* y *entre* consideradas por Noelthing (1980) al trabajar situaciones de mezclas, y aunque este investigador sólo considera las relaciones *dentro* y *entre* de carácter multiplicativo, Alatorre (1994) las amplía a relaciones de orden y de carácter aditivo o sustractivo, pero no las considera como se hace en este estudio en la comparación por cociente, pues ella señala las diferencias sin tomar en cuenta la cantidad basal y desde nuestra perspectiva la *Forma aditiva* sí incluye esta cantidad basal al considerar cuántas de cuántas. La comparación por cociente está estrechamente relacionada con el pensamiento relativo, Lamon (1999) distingue a este tipo de pensamiento como aquel donde se involucran estructuras multiplicativas y lo diferencia del pensamiento absoluto donde se establecen relaciones de tipo aditivo.

Análisis de los resultados

Por la finalidad que esta investigación persigue consideramos conveniente analizar el tipo de elecciones, las comparaciones que se establecen, las estrategias que se siguen y el punto de referencia que se considera en la comparación de probabilidades, es decir, el sentido de las relaciones que se dan entre los casos (favorables, desfavorables o posibles). En la Tabla 3 se ilustra la comparación cuantitativa por cociente y sus implicaciones, para ejemplificar el seguimiento de las estrategias identificadas en la implementación.

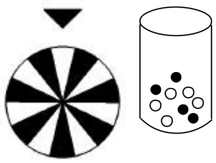
Tabla 3: Ilustración del tipo de elección, las estrategias y la relación de orden identificada en la comparación cuantitativa por cociente

Elección con base en el	Estrategia (véase Tabla 2)	Relaciones (véase Tabla 1)
Cociente mayor; Cociente menor; o Cociente igual.	1ª Fracción-razón (parte-parte).	Favorables-desfavorables v y vi Desfavorables-favorables vii y viii
	1ª Fracción-razón (parte-todo).	Favorables-posibles ix y x Posibles-favorables xi y xii
		Desfavorables-posibles xiii y xiv Posibles-desfavorables xv y xvi

Consideración de casos favorables y casos desfavorables. Se comparan por medio de cocientes los casos favorables y desfavorables de cada conjunto (véanse las expresiones i, ii, iii, iv, v, vi, vii y viii de la Tabla 1) y se elige con base en el mayor, menor o igual cociente. En lo que sigue se ejemplifica una de las estrategias con base en la elección del cociente mayor.

Elección con base en el cociente mayor. Estrategia: Fracción-razón parte-parte con o sin la utilización de submúltiplos y su representación en forma decimal.

Relación de orden: Favorables-Desfavorables.



Situ*ación II.* 1.- En una feria hay dos juegos azar: una ruleta y una urna, ¿en qué juego existe mayor probabilidad de ganar, en la ruleta si se apuesta a que al girarla se detenga en un sector blanco o en la urna si se apuesta a que en la primera extracción sin ver la bola será blanca? Explica como le hiciste para determinar tu respuesta.

Estrategia del estudiante. Ejemplo1 (E1). Urna 2. Hay más probabilidad de ganar en la urna. Pues fui sacando la mediana [mitad] a los colores de cada juego. En la ruleta eran los mismos colores y en la urna había una bola blanca más que negra y vi que había mejor probabilidad de ganar.

$$\frac{7}{7}=\frac{3.5}{3.5}=1 \qquad \frac{5}{4}=\frac{2.5}{2}=1.25$$

00

Figura 1: Estrategia del estudiante. Ejemplo 1 (E1) se elige el cociente mayor. Comparación por cociente (favorables-desfavorables)
llegando a su representación decimal con el uso de submúltiplos

En E1, se presenta la comparación de casos favorables y desfavorables. Para simplificar la comparación de variables se utilizan submúltiplos y se termina con una representación decimal. En las expresiones v y vi (véase Tabla 1) se elige con base en cociente mayor, porque los cocientes en estas expresiones representan el número de favorables por cada desfavorable. Por lo contrario, si se presentan las expresiones vii y viii las elecciones serán correctas sólo si se elige con base en el cociente menor, que representan el número de desfavorables por cada favorable. De aquí la importancia de las relaciones de orden: favorables-desfavorables o desfavorables-favorables.

En cuanto a las expresiones i, ii, iii y iv de la Tabla 1 se tendrían elecciones correctas si se considera, en i y iii el segundo cociente, es decir, si este resulta ser mayor al primer cociente se debe elegir el conjunto cuyos elementos se asignaron a los denominadores de los cocientes comparados. Sin embargo, si resulta ser menor al primero, se realiza una elección correcta si se elige el conjunto cuyos elementos se asignaron a los numeradores. Por otra parte, si se consideran las expresiones ii y iv la elección también dependería del segundo cociente, si resulta ser mayor al primer cociente se debe elegir el conjunto que haya quedado en los numeradores. Pero si resulta ser menor, se haría una elección correcta si se elige el conjunto cuyos elementos quedaron en los denominadores, esto debido a que en las expresiones i, ii, iii y iv los cocientes resultantes representan el número de favorables de un conjunto por cada favorable del otro, y en este mismo sentido, el número de desfavorables de un conjunto por cada desfavorable del otro.

Consideración de casos desfavorables y casos posibles. Se comparan por medio de cocientes los casos posibles y desfavorables de cada conjunto (véanse las expresiones xiii, xiv, xv y xvi de la Tabla 1) y se realiza la elección con base en su mayor, menor o igual cociente. En lo que sigue se ejemplifica una de las estrategias con base en la igualdad de cociente.

Elección con base en la igualdad de cocientes. Estrategia: Fracción-razón parte-todo con o sin el uso de submúltiplos y su representación en forma decimal.

Relación de orden: Desfavorables-Posibles.

Situación IX. Una profesora muestra a sus estudiantes dos bolsas negras; en la primera deposita 9 canicas negras y 6 blancas, y en la segunda deposita 15 negras y 10 blancas ¿qué bolsa deben elegir para que tengan mayor probabilidad de que en la primera extracción sin ver la canica sea negra? Explica el procedimiento que seguiste para realizar la elección.	*Estrategia del estudiante.* Ejemplo (E2). Cualquier bolsa. En cualquiera de las bolsas se tiene la misma probabilidad.

	Bolsa 1	Bolsa 2
Canicas blancas / Total de canicas	$\frac{9}{15}$	$\frac{15}{25}$
Probabilidad	0.6	0.6

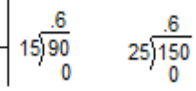

Figura 2: Estrategia del estudiante. Ejemplo 2 (E2) se elige el cociente igual. Comparación por cociente (desfavorables-posibles) llegando a su representación decimal

En E2, se presenta la comparación de casos desfavorables y posibles en cada conjunto. Primero se relacionaron los casos del primer conjunto y posteriormente los del segundo (véase la expresión xiii de la Tabla 1). Es importante señalar que en E2 se establece que los resultados decimales obtenidos corresponden a las probabilidades de los casos desfavorables de cada conjunto. En las expresiones xv y xvi (véase Tabla 1) se elige con base en cociente mayor; esto porque el cociente resultante determina el número de casos posibles por cada desfavorable. Por lo contrario, si se presentan las expresiones xiii y xiv, las elecciones serán correctas sólo si se elige con base en el cociente menor; esto debido a que el cociente representa el número de desfavorables por cada posible. En las expresiones ix y x se elige con base en cociente mayor; esto porque representan el número de favorables por cada posible. En cambio, si se presentan las expresiones xi y xii, las elecciones serán correctas sólo si se elige con base en el cociente menor; esto debido a que el cociente resultante representa el número de posibles por cada favorable. Es importante comentar que las expresiones ix y x son las únicas que se utilizan y consideran en los Programas de estudio de 2011 (SEP, 2011), para representar probabilidades y realizar comparaciones entre ellas.

Consideraciones finales

Con los resultados del estudio se concluye que, si se solicita la probabilidad del evento A, los estudiantes establecen el cociente (razón) $\frac{F}{P}$, determinado por Laplace como la razón entre el número de casos favorables F y el de todos los casos posibles P. Sin embargo, si se les plantea una situación de comparación de probabilidades, suelen recurrir a otros cocientes de comparación donde además incluyen a los casos desfavorables D como: $\frac{D}{P}$ o $\frac{F}{D}$ o sus recíprocos, y no necesariamente al establecido por Laplace. En la investigación se mostró que estas razones llevaron a los estudiantes a elecciones correctas con base en determinar la urna con mayor probabilidad. De aquí la importancia de poner mayor énfasis en las estrategias de comparación por cociente que resulten de comparar probabilidades. El punto de referencia es determinante para comprender las relaciones que los estudiantes establecen y la interpretación que le dan a sus cocientes. En este sentido, por ejemplo, la interpretación del cociente (razón) $\frac{F}{D}$ es totalmente distinta a la representada en el cociente (razón) $\frac{D}{F}$, y de igual manera es distinta la interpretación $\frac{F_1}{D_1} > \frac{F_2}{D_2}$ a $\frac{F_2}{D_2} < \frac{F_1}{D_1}$. Desde un punto de vista puramente matemático estas comparaciones no tendrían mayor dificultad, pero desde un sentido pedagógico y didáctico de la enseñanza y del aprendizaje de la probabilidad, el cambio en el punto de referencia al establecer las comparaciones influye en el tratamiento del objeto de estudio y su interpretación. Se sugiere la incorporación de orientaciones didácticas en los materiales curriculares de educación básica, donde se incluya un análisis de las estrategias por cociente que los estudiantes pueden llevar a cabo al resolver problemas de probabilidad. Se considera que un análisis detallado de las estrategias variadas que presentan los alumnos tendría un aspecto positivo en la enseñanza y estudio de esta rama de las matemáticas.

HIGH-SCHOOL STUDENTS' PROBABILISTIC REASONING WHEN WORKING WITH RANDOM INTERVALS

RAZONAMIENTO PROBABILÍSTICO DE ESTUDIANTES DE BACHILLERATO CUANDO TRABAJAN CON INTERVALOS ALEATORIOS

M en C Sandra Areli Martínez Pérez
Centro de Investigación y Estudios Avanzados del IPN

esanchez@cinvestav.mx

This work reports the results of a research aimed to know the probabilistic reasoning of high-school students when they deal with the notion of random intervals. An activity was carried out involving students between ages 16 and 17 who built random intervals through physical and computational simulations. The research question guiding this work was: Which reasoning do students exhibit when they estimate the probabilities of events related to the experience of creating random intervals from a frequentist approach? From the data analysis, partly based on the Grounded Theory, four categories were established. They suggest that the patterns observed in this work are likely present in situations demanding the frequentist approach to probability.

Keywords: Reasoning, Frequentist approach, probability, random intervals

Problem statement

The educational research on the probabilistic reasoning of students is a complex field since it involves an abundance of concepts, innovative instructional proposals, conceptions, misconceptions, and difficulties as well as a number of methodological approaches and conceptual frameworks (Jones et al., 2007; Chernoff & Sriraman, 2014). It has been recently stressed that educators and teachers must research and document the implementation of innovative approaches and materials in class to allow for a close integration of probability and statistics (Chernoff, Paparistodemou, Bakogianni, Petocs, 2016; Langrall, Makar, Nilson, Shaughnessy, 2017). It has been suggested to give probability teaching a modeling approach (Pfannkuch et al., 2016) starting from extra-mathematical situations or contexts of the natural or social reality. That is, modeling will allow students to acquire or create probabilistic concepts when solving problems emerged from real situations. For this supposition to be feasible, it is necessary to start with simple random situations that can be repeated under a set of well-defined conditions. Then, they will allow for the observation of patterns of outcomes. In our opinion, situations with coins, dice, urns, and roulettes can play a mediating role in the acquisition of probabilistic concepts and the fundamentals of modeling (Sharma, 2016). In this work, we assume the hypothesis that the situations based on random devices, with the aid of digital gadgets, can be mediators between abstract concepts and real situations. They can also be the support of fertile situations to contribute to the integrated learning of probability and statistics.

Traditionally, introductory high-school courses deal with probability and statistics separately. However, statistical analyses must include probabilistic reasoning since it allows to handle situations of uncertainty and variability intrinsic to the phenomena studied by statistics. Still, some approaches of probability teaching avoid developing reasoning on uncertainty and variability handling instead of promoting it and focus on more formal aspects (set theory), calculus (classic approach of probability), and technical elements (combinatorics). One way of including uncertainty and variability in probability classes is to organize situations and present problems that produce data following an unknown distribution. So, students have to analyze them to obtain conclusions, as in the estimation of the probability of events.

Saldanha (2016) and Prodromou (2016) argue that the study of samples of a distribution obtained through a digital simulation provides an adequate resource to link probability to statistics, especially from a frequentist approach. For that reason, we consider there should be research on how students reason when facing problems that link probability to statistics and that the frequentist approach of probability must be further studied.

Research question

Given that probability is studied in preuniversitary levels, it is important to explore the possibilities that technology offers to study its link to inference in high school. Particularly, this work explores the idea of introducing the notion of random intervals (RI). The aim is to set a background that helps reasoning on confidence intervals (CI), and so a research question was formulated:

Which reasonings do students show when they estimate the probability of events related to the experience of creating random intervals through a frequentist approach?

Background

The work presented here calculates probabilities from the frequentist approach of probability. So, we review some research that includes the frequentist approach of probability with technology and particularly focus on the work by Ireland and Watson (2009). The work explores the understanding of elementary-school students (ages 10–12) regarding the connection between theoretical probability and experimental probability (frequentist approach of probability) after students work with manipulatives (coins, dice) and the software ThinkerPlots. Ireland and Watson propose a framework to interpret the students' understanding as a continuum from concrete (experimental) to abstract (theoretical) in which manipulatives, the simulator, and the Law of Large Numbers are especially important. The findings lead them to conclude that it is necessary to explicitly teach the connection between theoretical and experimental probability; it is not enough for students to observe the behavior of the outcomes from simulations to achieve such connection.

Another study on the frequentist approach was that by Stohl and Tarr (2002). The authors report an instructional sequence with the aim of assessing how technological tools allow for and limit the development of the notion of inference from probabilistic situations. The participants were 23 students in sixth grade (ages 11–12) who worked in pairs and used the computational tool Probability Explorer to formulate and evaluate inferences during a 12-day teaching period. Among the conclusions, the authors state that the tasks designed in the context of games of chance and urns (one in the context of fishing in a lake) allowed the students to perceive relationships between empirical and theoretical probability as well as the role of the sample size in such relationships.

Conceptual framework

For the aims of this work, we have chosen concepts referring to two dimensions: content and cognition. From the first, content related to random intervals is presented and the same is done with probabilistic reasoning from the second.

Mathematical content relevant to the study

The content of this study refers to the estimation of probabilities through the frequentist approach of the probability of events related to the experience of generating random intervals. Then, some concepts on the frequentist approach of probability should be reviewed.

A repetitive phenomenon is that which can be repeated under a set of given conditions such that every repetition of the phenomenon is considered equivalent to its predecessors. Particularly, a random experience E is a repetitive phenomenon in which a characteristic is observed to change from one repetition to another and cannot be predicted; still, the set of all potential outcomes can be determined (sample space). Consider a random experience E and its sample space S while an event A is a subset of S. If experience E is repeated N times and n is the number of times event A occurs, then the quotient $n/_N$ is the relative frequency of A. The relative frequency of an event depends on N such that it varies as the values of N change. The most important characteristic of the relative frequencies of an event is that they converge in a given number as the number of repetitions grows indefinitely.

A random interval is defined as an interval in which at least one of the end points is a random variable, and so it gives rise to a family of intervals. Since we cannot assume that the students master the topic of distributions, the task design was carried out based on the experiment of drawing a ball from an urn containing 10 numbered balls from 0 to 9. If the random variable is the number printed on the ball, its distribution is the discrete uniform distribution taking the values $x = 0,1,2, \dots ,9$ and a probability $p = \frac{1}{10}$. Students are asked to observe the events of the type "E_C = the interval I_x contains number C, where C is any number between 0 and 9." Table 1 shows the probabilities of events E_C. These events are not mutually exclusive; hence the sum of their probabilities is higher than 1.

Table 1. Probabilities that the event E_c occurs

Event	E_0	E_1	E_2	E_3	E_4	E_5	E_6	E_7	E_8	E_9
Probability	$\frac{9}{45}$	$\frac{17}{45}$	$\frac{23}{45}$	$\frac{27}{45}$	$\frac{29}{45}$	$\frac{29}{45}$	$\frac{27}{45}$	$\frac{23}{45}$	$\frac{17}{45}$	$\frac{9}{45}$

Probabilistic reasoning

Batanero et al. (1996) define probabilistic reasoning as a mode of reasoning that refers to judgements and decision making under uncertainty; therefore, it is relevant to real life. This reasoning includes the ability to: identify random events in nature, technology, and society; analyze the conditions of such events and derive suppositions to make an adequate modeling; construct mathematical models and explore different scenarios and outcomes; and apply mathematical methods and procedures of probability and statistics.

Methodology

Participants

The participants of this research were 16 students between ages 16 and 17 from a public school in Mexico City who had never taken a formal course on probability. One of the researchers was the class teacher and conducted the activity.

Activity

The activity was created using the principles of design to support the students' statistical reasoning proposed by Cobb and McClain (2004). Those principles must consider five aspects: 1) central statistical ideas (in this work, we focus on population, sample, random intervals, relative frequency, probability, and law of large numbers), 2) the instructional activity (the questions were formulated to observe whether the students created a conception of the central ideas), 3) the classroom activity structure (it must start by pointing out relevant aspects, variables to consider and how they will be mediated, the topic to cover, the activity development, and the students' discussion on the data obtained), 4) computer tools used by the students (in this work, an applet was made using Fathom), and 5) the classroom discourse (it refers to the language used, which should cover the possible judgements that students make on the central ideas).

For the development of the activity, the following situation was presented to the students:

Two balls are drawn from an urn containing 10 balls numbered from 0 to 9. Consider the interval formed by the integer values found between the minimum and maximum of the values drawn (considering the end points). Which is the probability that the value contain number 8?

*Containing number 8 means that 8 is between the minimum and maximum values or it is one of them.

Technology

Biehler (2013) states that, if it is to be considered in statistics teaching, a digital tool should allow students to perform several actions as: quickly dragging and dropping variables in a graph to visualize distributions and relationships between variables; visualizing in real time how data and parameters change dynamically, affecting measures and related representations; and linking multiple data representations to informally observe statistical trends. Fathom allows for these actions and more.

The applet provided to the students (Figure 2) works as follows:

In an urn called *collection 1*, 10 balls numbered from 0 to 9 are placed. In *Sample of Collection* 1 is a sample of size 2, symbolizing the two values drawn from the urn with which the interval *[min, max]* is created. A measure, *belongs to*, is defined and consists in using the function *if* (*Si*) when number 8 is in the interval or *No* in the opposite case. A collection of measures in different sizes is taken and the tool *Summary* shows the number of *If* and *No* in a certain number of repetitions of the event. The plot shows the behavior of the relative frequencies.

Results and data analysis

For the analysis of the students' responses, we sought words or ideas that were common and placed them in codes. This response grouping process is proposed in the Grounded Theory by Birks and Mills (2015).

For instance, when they created intervals in the applet, students were asked what they observed in the plot. Some of the responses were "the dots are too scattered," "the dots generated by the data are too separated." They were placed in the code *scattering* since the students described how the dots in the plot were placed using the words "scattered" and "separated." Another type of response was "The plot is more constant when we placed more intervals." In these responses, the student observed that the dots in the plot (relative frequencies) were close to a constant value when many intervals were generated. These responses were placed in the code *Tendency to regularity*. Finally, in responses as "In the plot, the dots seem closer when we place more intervals and they are separated when there are fewer," we observed that students managed to see there was a difference when the number of intervals increased. These responses were placed in the code *Variability*. This analysis process was used to group the responses to all the questions in the activity.

The activity was divided in two parts; in the first one, the students carried out a physical simulation. To do so, they were given a bag with 10 balls numbered from 0 to 9. Each student obtained 10 intervals by drawing two balls without replacement. They wrote down the interval formed by the two values obtained $[x_{min}, x_{max}]$ on a table (Figure 1.a) and determined whether number 8 belonged to the interval.

b

Figure 1. a) Example of table filled in by students and b) group results.

Then, the students were asked to write down the relative frequencies of their classmates (Figure 1.b), and they were also asked about the probability that the interval contained the number 8. Some responded they had to obtain the mean or average (the best approximation), others expressed they had to pay attention to the one repeated the most (mode), and other students used the total relative frequency since they observed that 49 out of 160 intervals contained number 8. At the end of the physical simulation, the students were asked what would happen if they obtained 100 or 1 000 intervals to promote the use of the software. Three predictions were presented for this question: 1) proportionality (8/16)[1], which indicates that the number of favorable cases in 100 intervals must be proportional to 49/160; that is, approximately 30 in 100 intervals and 300 in 1 000; 2) approximation (3/16), where students propose a range of possible values around the proportional value of the frequency (values around 30 are suggested for 100 intervals while 300 are indicated for 1 000); and 3) the attention bias in favorable cases, in which only absolute frequencies, for instance, are said to "increase." The "approximation" responses are the most appropriate given that they take into account data on the relative frequency and predict a certain variability; attention bias is the response with the least quality.

In the second part of the activity, the students use an applet created in Fathom (Figure 2) by the authors and are explained how it works. Once they are familiarized with the software, the students are asked to create blocks of 5, 10, 20, … intervals, observe the corresponding plot, and write down their observations. Responses were classified in three codes, but it must be highlighted that the language used in their responses was mostly geometric and not probabilistic. They refer to the "dots" in the plot without providing any indication that they represent "relative frequencies:" 1) dispersion (5/16), they only say that the first dots in the plot are too separated; 2) a trend towards regularity (3/16), they only say that the "last" dots in the plot make a constant straight line; and 3) variability (4/16), they only deal with the separation between the dots at the beginning and their tendency to create a constant straight line at the end. The responses with the best quality are those classified in variability.

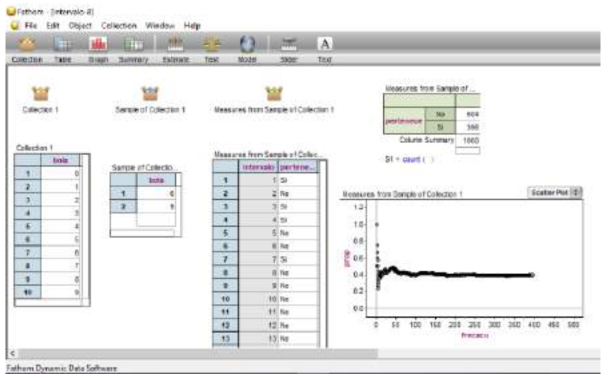

Figure 2. View of applet created by the students using Fathom.

Once the results of the applet were observed represented in the plot, the students were asked to tell the probability that an event contain the number 8. The responses to this question were classified in three codes: 1) relative frequency (8/16) when the students responded with the relative frequency that they obtained when they used the applet (considering 20, 100, and 1 000 tries); 2) approximation (6/16), when the students provided an interval or range within the relative frequency (as in "it is found around 0.306"). To know whether they were sensitive to the number of repetitions of the experiment (or number of intervals), the students were directly asked: What is the difference when there are a few and many intervals? The analysis of the responses led us to the codes above: 1) variability (7/16), 2) tendency to regularity (4/16), and 3) dispersion (1/16). Still, analyzing the responses according to the sense of their expressions, we proposed three additional codes: 1) geometric language (8/16) where they describe the behavior of the plot and not that of the relative frequencies, using terms as "dot," "straight line," or "constant" but not probabilistic terms; 2) variable probability (3/16), when they use the term probability in the same way as relative frequency, meaning that it changes as the number of experiments increases (for example "*The probability is more constant when the interval is greater*"); and 3) a priori probability (2/16), when, from their expression, we understand frequencies tend to a certain number ("*The more intervals there are, the better defined the constant is and also the probability we look for"* and "*The more dots there are, the closer we are to the probability*"). In these responses, students noticeably make a difference between relative frequencies and probability. Therefore, they are closer to the correct probability interpretation.

Finally, they are once again asked a prediction question: "If you had 1 000 intervals (without using the applet), how many of them would contain the number 8? Why?" The responses were classified in: 1) approximation (6/16), when students provide a range of 300 or say "*approximately around 300*;" 2) frequency (5/16), when they provide the frequencies obtained using the software; and 3) approximation to the value found using the software (4/16), when they say that they would obtain something similar to the result provided in the applet.

Discussion and conclusions

During the coding process, the synthesis of features present in several responses allow us to propose four categories that can provide a global notion of the progress and difficulties the students face in the process of conceptualizing not only the random intervals but also the probability in itself. They are:

Sensitivity to variability expressed in two ways. The first consists in accepting that, in prediction problems, it is impossible to accurately predict the number of favorable cases of an event in a series of repetitions of an experiment, but the relative frequency is known to be close to the probability. The second one consists in knowing that successive relative frequencies change greatly in a few repetitions of the experiment, while in the long run, they are stabilized around a constant. Our observations indicate that the activities using the software allow students to perceive variability. This is especially revealed when the simulation process is accompanied by the representation of the trajectory of the relative frequencies and also when, in prediction problems, several students do not provide exact values but intervals or ranges in which results can be found. This achievement is important since it is the basis to subsequently understand the law of large numbers.

No conservation of probability. It consists in believing that the probability of an event changes according to the implementations of the random experience. This phenomenon is similar to that of no conservation of the quantities described by Piaget (Gisnburg & Opper, 1988, p. 149). In the present case, the students do not use the term "relative frequency", preferring instead to use the term "probability." By doing so, they accept the notion that probability changes according to the number of experiments done. Although this is apparently a matter of terminology, it reflects the fact that the students are confused and do not conceive probability as a constant number related to an event.

Descriptive probability. It consists in believing that probability only offers information on the random experiences that have already occurred without reporting the future implementations of such experience. It is related to the previous category in that probability only describes a past state, and, when making new experiments, the state will change; therefore, probability will also change. Under this belief, there can be the misconception that probability does not allow for predictions. It is believed that the constant achieved when many experiments are repeated only occurs when a series of experiments are conducted. However, there is no assurance that the constant will be the same when carrying out other repetitions of the same random experience. This conception can be even more present in real random experiences different from games of chance; for example, social, medical, or weather problems.

Absence of a probabilistic language. It consists in describing a procedure or probabilistic result using non-probabilistic terms associated to a representation. In the students' responses to the question What is observed? Several students use geometric terms (dots, closeness/distance, constant, straight line) in the trajectories of relative frequencies without making any reference to relative frequencies and probability. The tendency to not use probabilistic terms to say what trajectories means raises the question of whether students understand the probabilistic meaning of trajectories of relative frequencies; that is, whether they interpret such representations as relative frequencies trending towards probability.

The four categories that emerged from the data of the exploration of the students' reasoning are more general to the particular situation of random intervals studied. They can also make sense in probability situations where there are problems to be solved through digital probabilistic simulations and a frequentist approach of probability. Indeed, in any situation where a computational simulation is used, it is suitable to consider and remember variability. In any preuniversitary teaching design, it should be considered that students can be at a stage where they do not accept the continuity of probability. They might also believe that probability only describes outcomes that have already occurred without any future consequences. Furthermore, care must be taken so that students interpret computational representations of probabilistic objects, as trajectories of relative frequencies, in probabilistic terms.

We also conclude that the use of technology was important because students managed to observe that relative frequencies in the plot generated by the applet converged in one value. Although they used geometric language, we think that better responses could be obtained by stressing what the constant and each point represent.

Finally, as a result of the analysis, we observed several ways in which the study can be improved to continue with another research cycle. Particularly, we have seen that the formulation of some questions should be improved, and more questions must be added to obtain further information on some aspects. For instance, it would be suitable to include an additional question to find to what extent do students who make geometric descriptions of the trajectories of relative frequencies understand the probabilistic background of the situation.

COVARIATIONAL REASONING PATTERNS OF HIGH SCHOOL STUDENTS IN PROBLEMS OF CORRELATION AND LINEAR REGRESSION

PATRONES DE RAZONAMIENTO COVARIACIONAL DE ESTUDIANTES DE BACHILLERATO EN PROBLEMAS DE CORRELACION Y REGRESION LINEAL

eleazar.silvestre@gmail.com

The topics of correlation and linear regression constitute a complex and subtle system of statistical and mathematical ideas whose teaching-learning raises numerous practical and theoretical problems. In this research paper, the patterns of reasoning that students exhibit, under the approach of informal inferences when they face problems of correlation and regression line are identified. To achieve this, activities were implemented in two stages: in the first stage, two problems (one of estimation and other of best-fit line) were applied to be solved using pencil and paper; the second stage incorporates the use of the Fathom software.

Keywords: Correlation, Linear Regression, Technology, Informal Inferences, Reasoning.

Background and Issues

Covariational statistical reasoning consists of the processes that allow subjects to perceive, describe and justify the relationships between statistical variables. These processes occur in two ways, on the one hand they occur in the subject's mind, and on the other, in the spoken or written discourse that occurs when relationships between variables are described or justified (Moritz, 2004). When the solid arguments or generalizations that students make are highlighted, based on the information they have, instead of only the representations they carry out, we speak of inferences; in this study we will refer to informal statistical inferences (without a formal instruction or explicitly formal procedure). Several authors have reported relatively recently, studies on informal inferential reasoning using the informal statistical inferences made by students as the premise (Ben-Zvi, 2006; Pfannkuch, 2005). For example, in the aforementioned Ben-Zvi work, the informal statistical reasoning of 5th grade students is analyzed and developed within a technological environment, reporting that the use of technological tools showed argumentative advantages in the way students presented ideas.

In this sense, we focus on covariational reasoning starting with informal inferences that students make, taking as reference some relevant clues about this type of reasoning. For example, Zieffler and Garfield (2009, p. 11) summarize some findings: often, students, 1) are significantly influenced by their personal beliefs regarding their covariational judgments; 2) they frequently assume that there is a correlation between two events that is non existent (illusory correlation) ; 3) they are liable to imply causal relationships when dealing with covariation tests; and 4) have difficulty reasoning about covariation when the relationship between variables is negative. Regarding the determination of the line of best fit, some studies, such as those by Casey (2014) and Casey and Wasserman (2015), show that: 1) it is necessary to induce students to convert the data collected in tables into a graphic representation (Dispersion diagram); 2) Students have difficulty observing the global trend of a data set when reading a scatter plot, because they focus their attention on isolated points and perceive the data as a series of individual cases, rather than considering them holistically (with invisible characteristics for isolated points); 3) Many students, when drawing a line of best fit, focus their attention on characteristic points such as the first or last, the highest or the lowest, or a subset of these.

Theoretical framework

This work uses the theory of Rubin, Hammerman and Konold (2006) on informal inferences reasoning seen as statistical reasoning that considers the dimensions of: *Aggregate*, *Signals and Noise*, and *Various Forms of Variability*. An aggregate vision involves the added characteristics of individual cases, that when seen together, enable properties to emerge that are different from those of the individual cases.. Signals and noise refers, on the one hand, to constant elements in statistics such as the mean or the best fit line (signals) and on the other to variable elements that serve to introduce variability around any signal (noise). The idea of considering the various forms of variability refers to the fact that when making judgments from a set of data, the variability that underlies the situation must be considered. Various studiesin the area of statistical education show that students at all levels have difficulties when reasoning about these ideas (Ben-Zvi and Garfield, 2004; Bakker *et al*., 2004).

Based on these ideas, we propose as a central objective of this research: To determine and characterize the reasoning patterns of high school students in the face of correlation problems and the line of best fit, as informal inferences.

Method

First stage of the study

Participants. The questionnaire was applied to a group of 30 high school students (16 to 18 years old) who were taking the subject of Statistics and Probability at the College of Sciences and Humanities, Plantel Vallejo, located in Mexico City. Two instructor-researchers, co-authors of this article participated in the application of the questionnaire; they provided worksheets containing the problems and guided the dynamics of the sessions, in particular clarifying doubts about the instructions of the activities without delving into the content.

Instruments and Execution. The questionnaire was applied to students who had not received formal and expository instruction on these topics. Two problems were chosen to report on, which are shown in Figure 1. The first priblem is an Estimation problem taken from Moore (1988) and which was modified to the present version. The second is a best fit line problem for which a scatter diagram of the variables Height and Weight is presented, in a situation in which they are directly correlated and with a linear trend. Given the diagnostic nature of the questionnaire, a didactic sequence was not elaborated as such, instead the students were given a series of problems that were solved individually during two sessions of 90 min each, only allowing the use of pencil and paper.

Estimation Problem

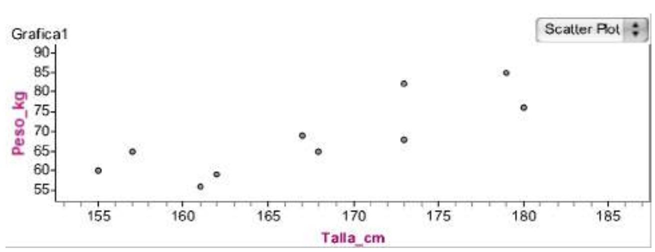
The Morales family is about to install solar panels at their home to cut down on heating costs. To better understand the savings that installing these panels can mean, the Morales have been recording their gas consumption for the last year and a half. The table shows the data with the average gas consumption and the average ambient temperature for each month:

Average Temperature (° C)	5.2	-9.8	-5.4	0.2	4.1	11.3
Gas Consumption (m^3)	17.6	30.5	24.9	21	14.8	11.2
Average Temperature (° C)	16.3	18.5	18.5	18	15.2	11.8
Gas Consumption (m^3)	4.8	3.4	3.4	3.4	5.9	8.7
Average Temperature (° C)	1.8	0.7	-10.4	1.8	17.1	10.7
Gas Consumption (m^3)	17.9	20.2	30.8	19.3	6.3	10.7

If the average temperature recorded in a month is 8 °C, what is the gas consumption expected by the Morales family in that month? Explain your answer:

Line of Best Fit Problem

The graph below shows the height and weight data for 10 high school students. Draw the line that you think best fits the data.



Explain the criteria you used to draw the line:

Figure1. Estimation and Best Fit Line Problem

Analysis Methodology. The analysis of the responses was carried out through a coding process (types of reasoning or inferences) of the responses, gradually refining through comparative analysis. Each researcher carried out an open coding of the data, generating codes that represent patterns of reasoning according to the similarities in the procedures and arguments declared by the students, which were then compared with each other. Comparison of these coding proposals resulted in a more consistent and abstract set of codes than the descriptions initially developed; this preliminary scheme facilitated inducing some central ideas of the students' covariational reasoning.

Second stage of the investigation

Participants. The activities were applied to a group of 40 high school students (20 couples) (16 to 18 years old) from the Colegio de Bachilleres Plantel 2, which is also located in Mexico City. Given the uncontrollable nature of the classroom, certain students were absent from some class sessions. Similarly, the two researchers involved in the first stage of the study participated in the experiment. In addition to guiding the class sessions, their participation included supporting the students in manipulating the Fathom software. As in the previous stage, the professor-researchers were prevented from delving into the thematic content.

Instruments and Execution. Again, for this report we have chosen two problems that we want to focus on: the first, which deals with the estimation of a response value, which was the same as in the first stage, only in this case the use of the Fathom software was incorporated as a tool for the student to be able to build a scatter diagram on and obtain the least squares line, to make the requested estimate. The second (figure 2) also deals with proposing the line that best fits the data, but the context of the situation was modified. Unlike the first stage, in this stage the students collected statistical data by measuring some of their own physiological attributes (namely, for the same student, the measurement of their height against that of their arm). In addition, they used the software to draw and manipulate a line that they considered best fit the data.

Line of Best Fit Problem

According to studies of the anatomy of the human body, there is a certain relationship between the height of people and the measurement of some parts of the body.

With the data of the measurement of the arms (from elbow to shoulder) and the height of your colleagues, which were collected in the first work session, and which are shown in the table, answer what is asked of you.

X (arm, cm)	30	33	35	36	32	38
Y (height, cm)	153	164	175	177	160	175
X (arm, cm)	34	31	35	29	28	38
Y (height, cm)	167	154	180	162	155	180

Figure 2. Problem of best fit line.

Analysis Methodology. The coding process of the data obtained in this stage was extended to the search for solid and consistent relations between the codes identified in both phases of the study; this process was carried out by investigating possible coincidences and patterns that we considered emerged with sufficient sense and coherence. Once the responses from the two stages of the study were coded, conceptual connections were identified between the proposed codes, to finally define the reasoning patterns as informal inferences made by the students.

Results

Analysis of the first stage of the study

During this stage, a system of codes representing the types of reasoning or inferences showing the student responses was developed, these codes are defined in terms of the arguments exhibited, that is to say the identification correlation between variables, use of all available data, or perception of the uncertainty that underlies the data. Some evidence of student responses is presented.

For the problem of estimation, a type of reasoning was defined as *Arithmetic Interpolation* (4/28 responses) representing the responses where the student takes a range of values in which the data of the given temperature (8 ° C) is included and with its corresponding gas consumptions, the student obtains the average to make the estimate. In this case the student uses data from the two variables, which we consider a slight statistical approach towards obtaining the arithmetic average. The response of the student E10 is presented as evidence in figure 3, where it can be seen that he chooses two temperature values (5.2 ° C and 10.7 ° C) among which is the data of 8 ° C - of which the estimate is requested - and with their corresponding gas consumption values (17.6 m^3 and 10.7m^3) calculate their average to give their estimated answer.

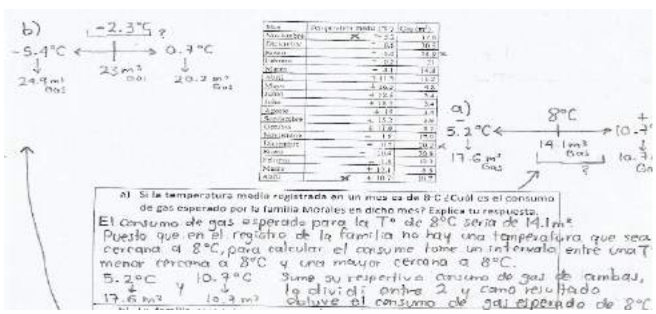


Figure 3. Student response E10. Arithmetic Code Interpolation

The following code we call *Proportional Arithmetic* (8/28) includes the answers where students look for a proportionality factor; choosing a pair of data (X-Temperature, Y-Consumption) and with the given temperature of 8 ° they form a rule of three, assuming that there is a proportional relationship between the variables. The student's answer E9 is shown as an example, in which he chooses the pair of values that correspond to the first month of the table (5.2 ° C, 17.6m^3) and with the value of 8 ° C he forms a rule of three.

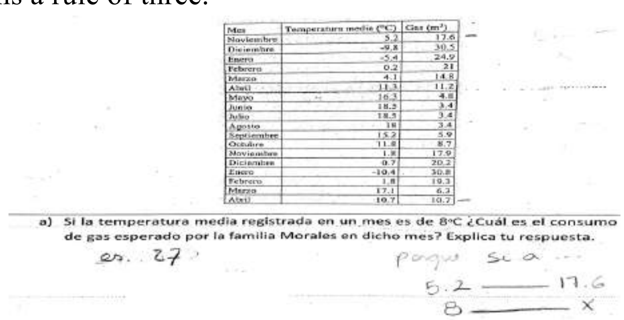

Figure 4. Student answer E9. Proportional Arithmetic Code

The *Arithmetic Reasoning Following A Pattern* (2/28) includes the answers where the students take as a reference the given temperature value (8 °) and try, from the data in the table, to “complete” this value by means of some arithmetic procedure, and once they get it they use that data in order to obtain their answer.

In the *Arithmetic Type Without Defined Pattern* (6/28) the students used some basic operations (addition, subtraction, multiplication and division; in one case the square root is used) but without being able to deduce a well-defined procedure.

In the *Perception Of The Trend* code (6/28) the student does not carry out any operation and only focuses his attention on the data in the table and his answers are based on a visual analysis of the trend of the data, in particular in the meaning of their behavior.

Finally, the code *Without Argument* (2/28) was defined, which represents those responses where the student only provides the result, without arguing or making their procedure explicit.

For the problem of drawing the line of best fit, two characteristic types of reasoning were found, the *Partition* code (6/21 responses) where the responses were classified in which the student draws the line or refers to the fact that their position must be such that passes through the middle of the cloud of points, following its direction, that is to say, traced diagonally, leaving the same number of points on one side and the other of the line, as shown in Figure 5.

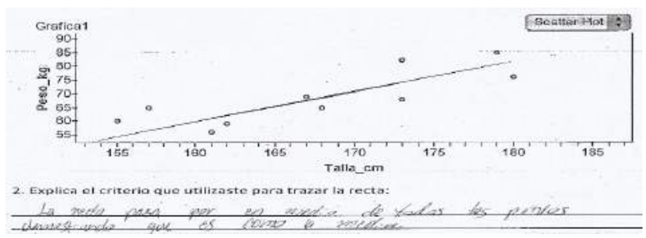

Figure 5. Student response E14. Partition Code

The *Belonging* code (15/21) includes the responses that show two types of behavior, on the one hand, those where the student draws or refers to the fact that the line must pass through as many points as possible or through all of them, and there are also the answers where the student draws the line insuring that it passes through specific points of the cloud, as in the answer shown in the following Figure, where it is argued that it must pass through two points (the lowest and the highest).

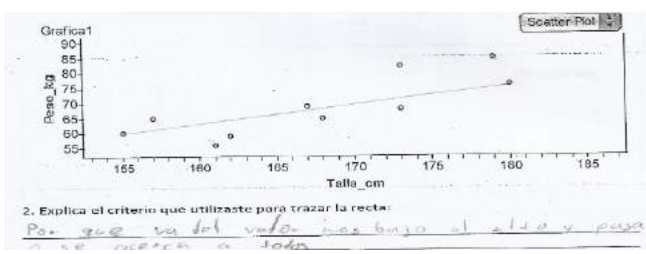

Figure 6. Student response E28. Membership Code

Analysis of the second stage of investigation

For the estimation problem, most of the identified reasoning was presented in the same way as in the diagnostic questionnaire, however, at this stage it stands out that the Arithmetic Interpolation code is absent in the students' responses and was replaced by the Use code of Software (3/15 pairs), in which the student uses the software to modify the position of a point in the cloud up to the given temperature value (8 ° C) and, following the trend of the data set, provides the estimated value of gas consumption. An evidence of this code is shown below:

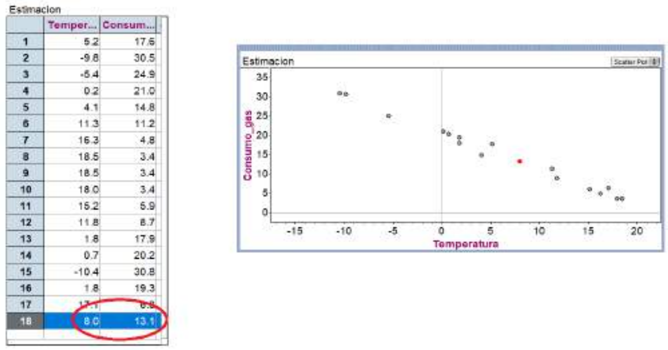

Figure 7. P4 partner response. Software Use Code

In the problem of the line of best fit, some students took the measurement of the arm (from elbow to shoulder) and with its corresponding height they formed a new bivariate database; It is from this set that the respective scatter diagram with which the students worked with was constructed.

The *Partition* and *Belonging* codes emerged with a frequency similar to that observed in the previous stage, with the exception of a new argument that we called *Closeness* (7/19 couples); The code includes the answers in which the students position the line with the help of the software in such a way that it is as close as possible to most of the points. The response of the pair of students P6 is included as evidence.

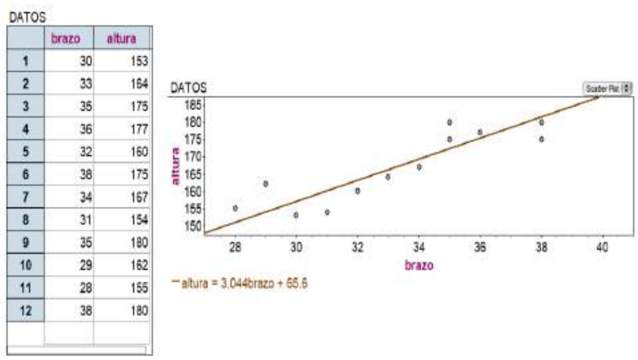

Figure 8. Pair answer P6. Closeness Code

A summary table of the analysis and initial coding is shown for the two stages of the study:

Table 1. Coding Process

Code	First stage	Second stage	Relative frequency	
Arithmetic Interpolation	✓		0.143	0.000
Use of Software		✓	0.000	0.200
Arithmetic Proportionality	✓	✓	0.286	0.267
Arithmetic Following a Pattern	✓	✓	0.071	0.267
Arithmetic Without Following a Pattern	✓	✓	0.214	0.267
Perception of the Trend	✓		0.214	0.000
No Argument	✓		0.071	0.000
Partition	✓	✓	0.286	0.211
Closeness		✓	0.000	0.368
Belonging	✓	✓	0.714	0.421

The next phase of the analysis was to compare the codes defined in the two stages of the study and to identify common covariational reasoning traits and some arguments raised in the second stage; the process of conceptualization of reasoning (inference) of student responses are described below.

Based on the inferences made by the students, conceptual connections were identified between the reasoning they exhibit, hence the codes *Perception of Tendency* and *Use of Software* (estimation problem) were reclassified in the reasoning pattern *Notion of Aggregate,* since in both students use the complete set of values that they are given to argue their responses; regardless of whether or not their results are normatively correct. On the other hand, the codes *Interpolation*, *Proportionality*, *Arithmetic following a pattern, Arithmetic without following a Patern* (estimation problem), *Partition* and *Belonging* (problem straight adjustment) will be reclassified as a *search for a signal*. The interconnection between these codes lies in the fact that the students infer that there must be a kind of clue to solve the problem, and they carry out a search in the data that was provided. It seems that the student suspects that there is a hidden pattern or structure in a subgroup of data (he does not use the totality of the data or contemplate the set of points) that will lead him to constant structures, absent of uncertainty or variation, that are familiar to him. Finally, the *Closeness* code (best fit line problem) was renamed as *Sense of Variability*, since features are perceived, albeit in a spurious way, that students infer a relationship between the fit model and the points of the cloud, in the scatter diagram. The *No Argument* code that was presented in the estimation problem, by not providing evidence of some type of inference made by the students, was not considered at this stage of the analysis.

Table 2. Process Conceptualization

Code	Informal Reasoning Pattern / Inferences
Perception of the Trend Use of Software	Notion of Aggregate
Arithmetic Interpolation Arithmetic Proportionality Arithmetic Following a Pattern Arithmetic Without Following a Pattern Partition Belonging	Search for a Signal
Closeness	Sense of Variability

Table 2 shows a summary of the conceptualization and definition of the identified reasoning patterns.

Conclusions

From our theoretical perspective, an informal inference is a type of reasoning that includes considerations in several dimensions (Rubin, Hammerman and Konold, 2006) and in specific study conditions. In our case a first dimension is the *Notion Added*, where a holistic perception of the problem situation over the contemplation of individual cases is privileged. In this sense, the initially defined codes, *Perception of the trend* and *Use of software*, present as a pattern that the students consider all the data they have available.On the one hand, they estimate the value of the requested response variable (gas consumption) by making a purely visual analysis based on the trend of the data set, that is, they argue their response based on the global behavior of the set of values. On the other hand, when they use Fathom, when constructing the scatter diagram and observing the trend of the point cloud again, they identify that there must be a certain relationship between the points, so they choose one and modify its position in such a way that the value matches the independent variable (8 ° C temperature) with that of the corresponding response variable (gas consumption), following the general "shape" of the cloud. Although it is true that in none of the above cases the response of the students is normatively adequate, it does allow us to appreciate that under certain circumstances they are able to perceive that in bivariate relationships it is necessary to consider the characteristics and behavior of the data as a whole and, based on this, infer the value of some particular point of interest.

Another dimension to consider is reflected with the pattern that we define as *Search for a signal* , where the answers show that given the difficulty represented by the uncertainty or the intrinsic variation in this type of problem, the students try to solve the situation in a familiar terrain for them or with which they feel comfortable, possibly for this reason they mostly use arithmetic procedures (rule of three, proportionality factor or additions and subtraction) to make the estimation; where they also only use part of the data. It is also the case of the best fit line problem, in which in the absence of the notion of uncertainty or of this aggregate view, they partially use the available data, referring to the linear function model as an alternative to fit a line to a distribution of points that presents a linear trend, considering only some of these points in their choice, ignoring the influence of all of these and their joint variation, and above all, defining two types of data: those that do or do not belong to the linear model that they choose to plot.

As a third dimension we propose, *Sense of Variability*, represented by the code that was initially defined as *Closeness*. In this pattern of reasoning, the answers that refer, albeit briefly, to the perception that there is some variation that underlies these types of problems and that that must be considered when proposing a line of adjustment for a set of points., just as the students did when plotting and arguing that the line should be positioned as close to most of the points as possible.

We trust that the identification of these reasoning patterns as the way in which students make informal inferences in the face of statistical association problem situations adds to the body of knowledge in the study of bivariate data, without neglecting the importance of exploring obstacles of learning, such as the apparent disconnection that the student has between the predictive or inferential nature inherent in the linear regression model and its identification as the line that best fits the set of points, as well as the difficulty to conceive the data set as an aggregate , that is, as a system in which they are linked to each other and have the property of being deviations from the same model.

PATRONES DE RAZONAMIENTO COVARIACIONAL DE ESTUDIANTES DE BACHILLERATO EN PROBLEMAS DE CORRELACION Y REGRESION LINEAL

COVARIATIONAL REASONING PATTERNS OF HIGH SCHOOL STUDENTS IN PROBLEMS CORRELATION AND LINEAR REGRESSION

Miguel Medina

eleazar.silvestre@gmail.com

Los temas de correlación y regresión lineal constituyen un sistema complejo y sutil de ideas estadísticas y matemáticas cuya enseñanza-aprendizaje plantea numerosos problemas prácticos y teóricos. En esta investigación se identifican patrones de razonamiento que exhiben los estudiantes, bajo el enfoque de inferencias informales cuando enfrentan problemas de correlación y regresión lineal; para esto se implementaron actividades en dos etapas: en la primera se aplicaron dos problemas (uno de estimación y otro de recta de mejor ajuste) para ser resueltos a lápiz y papel; en la segunda se incorpora el uso del software Fathom.

Palabras clave: Correlación, Regresión Lineal, Tecnología, Inferencias Informales, Razonamiento.

Antecedentes y Problemática

El razonamiento estadístico covariacional consiste en los procesos que le permiten a los sujetos percibir, describir y justificar las relaciones entre variables estadísticas; estos procesos se presentan en dos sentidos, por un lado ocurren en la mente del sujeto, y por otro, en el discurso hablado o escrito cuando se describen o justifican relaciones entre variables (Moritz, 2004). Cuando se destacan las argumentaciones sólidas o generalizaciones que los estudiantes realizan, a partir de la información con que cuentan, en lugar de solo las representaciones que llevan a cabo se habla de inferencias: en este estudio nos referiremos a las inferencias estadísticas informales (sin una instrucción formal o procedimiento explícitamente formales). Varios autores han reportado en fechas relativamente recientes, estudios sobre el razonamiento inferencial informal tomando como premisa las inferencias estadísticas informales que realizan los estudiantes (Ben-Zvi, 2006; Pfannkuch, 2005). Por ejemplo en el trabajo de Ben-Zvi mencionado, se analiza y desarrolla el razonamiento estadístico informal de estudiantes de 5° dentro de un ambiente con tecnología, reportando que el uso de herramientas tecnológicas mostró ventajas argumentativas en la presentación de ideas por parte de los estudiantes.

En este sentido, nos enfocamos en el razonamiento covariacional partiendo de inferencias informales que los alumnos hacen, tomando como referencia algunas pistas relevantes sobre este tipo de razonamiento; por ejemplo, Zieffler y Garfield (2009, p. 11) resumen algunos hallazgos: a menudo, los estudiantes, 1) se encuentran influenciados significativamente por sus creencias personales con respecto a sus juicios covariacionales; 2) suponen frecuentemente que existe correlación entre dos eventos que no lo están (correlación ilusoria); 3) son susceptibles a implicar relaciones causales cuando tratan con pruebas de covariación; y 4) tienen dificultad para razonar acerca de la covariación cuando la relación entre las variables es negativa. Sobre la determinación de la recta de mejor ajuste, algunos estudios, como los de Casey (2014) y Casey y Wasserman (2015), manifiestan que: 1) es necesario inducir a los estudiantes convertir los datos recopilados en tablas en una representación gráfica (diagrama de dispersión); 2) los estudiantes tienen dificultad para observar la tendencia global de un conjunto de datos cuando leen un diagrama de dispersión, debido a que enfocan su atención en puntos aislados y perciben los datos como una serie de casos individuales, en lugar de considerarlos de manera holística (con características invisibles para puntos aislados); 3) muchos estudiantes, al trazar una recta de ajuste, enfocan su atención en puntos característicos como el primero o el último, el más alto o más bajo, o en un subconjunto de estos.

Marco Teórico

Este trabajo toma ideas de la teoría de Rubin, Hammerman y Konold (2006) sobre inferencias informales vistas como razonamientos estadísticos que implican considerar las dimensiones de: *Agregado*, *Señales y Ruido*, y *Diversas Formas de Variabilidad*. Una visión de agregado implica que las características de los casos individuales, al ser vistas en conjunto, permiten que emerjan propiedades que son diferentes de las que tienen los casos individuales por sí mismos. Señales y ruido, se refiere por un lado a elementos constantes en estadística como la media o la recta de ajuste (señales) y por otro a elementos variables que sirven para introducir variabilidad alrededor de cualquier señal (ruido). La idea de considerar las diversas formas de variabilidad, se refiere a que al elaborar juicios a partir de un conjunto de datos se debe considerar la variabilidad que subyace en la situación. Diversas investigaciones en el área de la educación estadística manifiestan que estudiantes de todos los niveles presentan dificultades al razonar sobre estas ideas (Ben-Zvi y Garfield, 2004; Bakker *et al*., 2004).

Con base en estas ideas planteamos como objetivo central de la investigación: Determinar y caracterizar los patrones de razonamiento de estudiantes de bachillerato ante problemas de correlación y de recta de mejor ajuste, como inferencias informales.

Método

Primera etapa de la investigación

Participantes. El cuestionario se aplicó a un grupo de 30 alumnos de bachillerato (16 a 18 años de edad) que se encontraban cursando la asignatura de Estadística y Probabilidad y pertenecientes al Colegio de Ciencias y Humanidades, Plantel Vallejo, localizado en la Ciudad de México. Participaron en la aplicación del cuestionario dos profesores-investigadores coautores del presente artículo; proporcionaron hojas de trabajo que contenían los problemas y guiaron la dinámica de las sesiones, en particular aclarando dudas sobre la instrucción de las actividades sin profundizar en los contenidos.

Instrumentos y Ejecución. El cuestionario se aplicó a estudiantes que no habían recibido instrucción formal y expositiva sobre dichos temas. Se eligieron dos problemas para reportar que se muestran en la figura1, el primero es un problema de Estimación tomado de Moore (1988) y que se modificó a la presente versión. En el segundo problema, de recta de ajuste, se presenta un diagrama de dispersión de las variables Talla y Peso, en una situación en que están correlacionadas directamente y con una tendencia lineal. Dado el carácter diagnóstico del cuestionario, no se elaboró como tal una secuencia didáctica, sino una serie de problemas que fueron resueltos individualmente por los alumnos durante dos sesiones de 90 min cada una, permitiéndose únicamente el uso de lápiz y papel.

Problema de Estimación

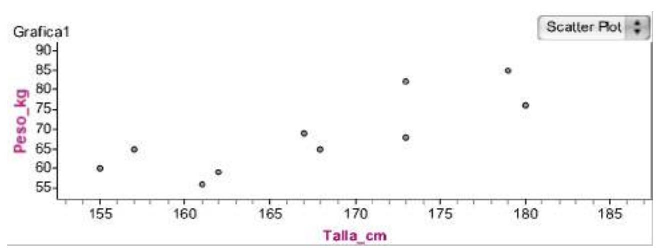
La familia Morales está a punto de instalar paneles solares en su casa para reducir el gasto en la calefacción. Para conocer mejor el ahorro que puede significar la instalación de dichos paneles, los Morales han ido registrando su consumo de gas durante el último año y medio. En la tabla se muestran los datos con el promedio del consumo de gas y de la temperatura media ambiental de cada mes:

Temperatura	5.2	-9.8	-5.4	0.2	4.1	11.3	16.3	18.5	18.5
Consumo de Gas (m^3)	17.6	30.5	24.9	21	14.8	11.2	4.8	3.4	3.4
Temperatura	18	15.2	11.8	1.8	0.7	-	1.8	17.1	10.7
Consumo de Gas (m^3)	3.4	5.9	8.7	17.9	20.2	30.8	19.3	6.3	10.7

Si la temperatura media registrada en un mes es de 8°C ¿Cuál es el consumo de gas esperado por la familia Morales en dicho mes? Explica tu respuesta:

Problema de Recta de Mejor Ajuste

La siguiente gráfica muestra los datos de la talla y el peso de 10 estudiantes de bachillerato. Traza la recta que piensas se ajusta mejor a los datos.



Explica el criterio que utilizaste para trazar la recta:

Figura 1. Problema de Estimación y de Recta de mejor ajuste

Metodología de Análisis. El análisis de las respuestas fue llevado a cabo mediante un proceso de codificación (tipos de razonamiento o inferencias) de las respuestas, refinándose gradualmente a través de un análisis comparativo. Cada investigador realizó una codificación abierta de los datos generando códigos que representan patrones de razonamiento según las semejanzas en los procedimientos y argumentos declarados por los estudiantes, que luego fueron comparados entre sí. La comparación de estas propuestas de codificación dio lugar a un conjunto de códigos más consistente y abstracto que las descripciones inicialmente elaboradas; este esquema preliminar facilitó inducir algunas ideas centrales en el razonamiento covariacional de los estudiantes.

Segunda etapa de la investigación

Participantes. Las actividades se aplicaron a un grupo de 40 estudiantes (20 parejas) de bachillerato (16 a 18 años) del Colegio de Bachilleres Plantel 2, que también se encuentra ubicado en la Ciudad de México; dada la naturaleza poco controlable del aula escolar, ciertos estudiantes se ausentaron de algunas sesiones de clase. De igual manera, en el experimento participaron los dos investigadores involucrados en la primera etapa del estudio; además de guiar las sesiones de clase, su participación incluyó el apoyar a los alumnos en la manipulación del software Fathom. Al igual que en la etapa previa, se evitó que los profesores-investigadores profundizaran en los contenidos temáticos.

Instrumentos y Ejecución. Nuevamente, para este reporte hemos elegido dos problemas en los que deseamos enfocarnos: el primero, que trata sobre la estimación de un valor respuesta, fue el mismo que en la primera etapa, solo que en este caso se incorporó el uso del software Fathom como una herramienta para que el estudiante estuviera en posibilidad de construir un diagrama de dispersión y obtener la recta de mínimos cuadrados, para realizar la estimación pedida. El segundo (figura2) también trata sobre proponer la recta que mejor ajusta a los datos pero el contexto de la situación fue modificado. A diferencia de la primera etapa, en esta los estudiantes recolectaron los datos estadísticos a través de la medición de algunos atributos fisiológicos propios (a saber, para un mismo estudiante, la medida de su talla contra la de su brazo); además, utilizaron el software para trazar y manipular una recta que consideraran se ajustara mejor a los datos.

Problema de Recta de Mejor Ajuste

Según estudios de la anatomía del cuerpo humano, existe cierta relación entre la talla (altura) de las personas y la medida de algunas partes del cuerpo.

Con los datos de la medida de los brazos (del codo al hombro) y de la altura de tus compañeros, que se recolectaron en la primera sesión de trabajo, y que se muestran en la tabla, contesta lo que se te pide.

X (brazo,cm)	30	33	35	36	32	38	34	31	35	29	28	38
Y (altura,cm)	153	164	175	177	160	175	167	154	180	162	155	180

Figura 2. Problema de Recta de Mejor Ajuste

Metodología de Análisis. El proceso de codificación de los datos obtenidos en esta etapa se extendió a la búsqueda de relaciones sólidas y consistentes entre los códigos identificados en ambas etapas del estudio; dicho proceso se realizó indagando posibles coincidencias y patrones que consideramos emergieron con suficiente sentido y coherencia. Una vez que se codificaron las respuestas de las dos etapas del estudio, se identificaron conexiones conceptuales entre los códigos propuestos, para finalmente definir los patrones de razonamiento como inferencias informales que realizan los alumnos.

Resultados

Análisis de la primera etapa de investigación

Durante esta etapa se desarrolló un sistema de Códigos que representan los tipos de razonamientos o inferencias que muestran las respuestas de los estudiantes, estos códigos se encuentran definidos en función de las argumentaciones que exhiben, es decir, la identificación de la correlación entre las variables, la utilización de todos los datos disponibles o la percepción de la incertidumbre que subyace en los datos. Se presentan algunas evidencias de las respuestas de los estudiantes.

Para el problema de estimación, un tipo de razonamiento se definió como *Aritmético Interpolación* (4/28 respuestas) que representa las respuestas donde el estudiante toma un intervalo de valores en el que se encuentra incluido el dato de la temperatura dado (8°C) y con sus correspondientes consumos de gas obtiene el promedio para realizar la estimación. En este caso el alumno utiliza datos de las dos variables, lo que consideramos un ligero acercamiento estadístico al obtener el promedio aritmético.

Se presenta como evidencia la respuesta del estudiante E10 en la figura3, donde se aprecia que elige dos valores de temperatura (5.2°C y 10.7°C) entre los que se encuentra el dato de 8°C –del que se pide la estimación- y con sus correspondientes valores de consumo de gas (17.6 m^3 y 10.7m^3) calcula su promedio para dar su respuesta estimada.

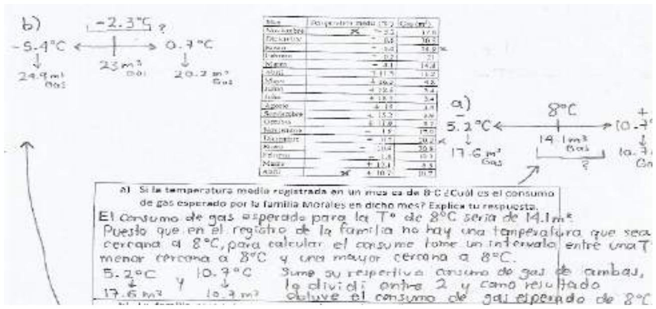


Figura 3. Respuesta estudiante E10. Código Aritmético Interpolación

El siguiente código lo llamamos *Aritmético Proporcional* (8/28) incluye las respuestas donde los estudiantes buscan un factor de proporcionalidad; eligiendo una pareja de datos (X-Temperatura, Y-Consumo) y con la temperatura dada de 8° forman una regla de tres, asumiendo que entre las variables existe una relación proporcional. Se muestra como ejemplo la respuesta del estudiante E9, en la que elige la pareja de valores que corresponden al primer mes de la tabla (5.2°C, 17.6m^3) y con el valor de 8°C forma una regla de tres.

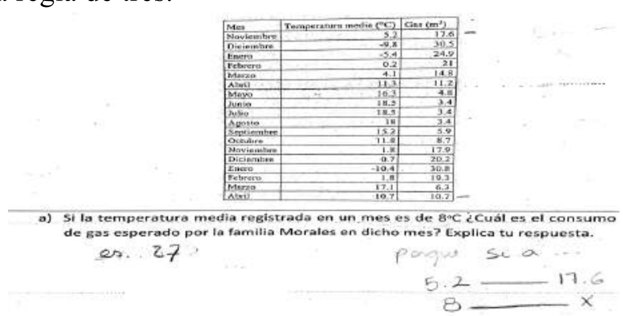

Figura 4. Respuesta estudiante E9. Código Aritmético Proporcional

El razonamiento *Aritmético Siguiendo Un Patrón* (2/28) incluye las respuestas donde los estudiantes toman como referencia el valor de la temperatura dado (8°) y tratan, a partir de los datos de la tabla, de "completar" este valor mediante algún procedimiento aritmético, y una vez que lo consiguen utilizan esos datos para obtener su respuesta.

En el tipo *Aritmético Sin Patrón Definido* (6/28) los estudiantes utilizaron algunas operaciones básicas (suma, resta, multiplicación y división; en un caso se utiliza la raíz cuadrada) pero sin que se pueda deducir un procedimiento bien definido.

En el código *Percepción De La Tendencia* (6/28) el estudiante no realiza operación alguna y sólo enfoca su atención en los datos de la tabla y sus respuestas se basan en un análisis visual de la tendencia de los datos, en particular en el sentido de su comportamiento.

Finalmente, se definió el código *Sin Argumento* (2/28) que representa aquellas respuestas donde el estudiante solo aporta el resultado, sin argumentar o hacer explícito su procedimiento.

Para el problema de trazar la recta de mejor ajuste se encontraron dos tipos de razonamiento característicos, el código *Partición* (6/21 respuestas) donde se clasificaron las respuestas en las que el estudiante traza la recta o hace referencia a que su posición debe ser tal que pase por en medio de la nube de puntos, siguiendo la dirección de ésta, es decir trazada de forma diagonal, dejando de un lado y del otro de la recta, el mismo número de puntos, como lo muestra la Figura 4.

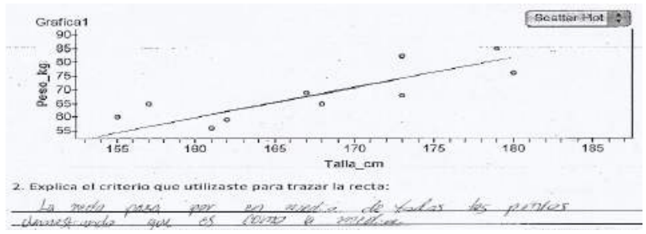

Figura 5. Respuesta estudiante E14. Código Partición

En el código *Pertenencia* (15/21) se incluyen las respuestas que muestran dos tipos de comportamiento, por un lado aquellas donde el estudiante traza o refiere que la recta debe pasar por el mayor número posible de puntos o por la totalidad de estos, y también están las respuestas donde el estudiante traza la recta cuidando que pase a través puntos específicos de la nube, como en la respuesta mostrada en la siguiente Figura, donde se argumenta que debe pasar por dos puntos (el más bajo y más alto).

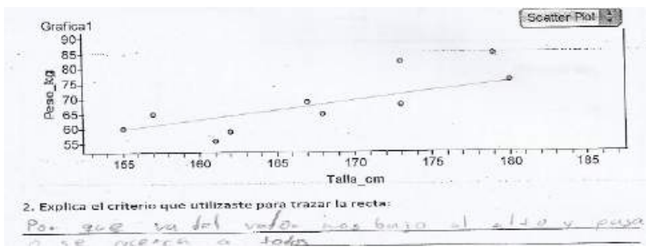

Figura 6. Respuesta estudiante E28. Código Pertenencia

Análisis de la segunda etapa de investigación

Para el problema de estimación, la mayoría de los razonamientos identificados se presentaron de igual forma que en el cuestionario diagnóstico, sin embargo en esta etapa destaca que el código *Aritmético Interpolación* se encuentra ausente en las respuestas de los estudiantes y fue sustituido por el código *Uso de Software* (3/15 parejas), en el cual el estudiante utiliza el software para modificar la posición de un punto de la nube hasta el valor de temperatura dada (8° C) y, siguiendo la tendencia del conjunto de datos, proporciona el valor estimado del consumo de gas. Una evidencia de este código se muestra a continuación:

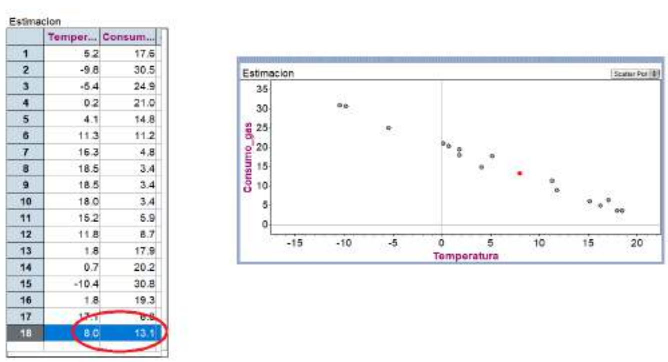

Figura 7. Respuesta pareja P4. Código Uso de software

En el problema de recta de mejor ajuste algunos alumnos se tomaron la medida del brazo (del codo al hombro) y con su correspondiente altura conformaron una nueva base de datos bivariados; a partir de este conjunto es que se construyó el respectivo diagrama de dispersión con el que trabajaron los estudiantes.

Los códigos *Partición* y *Pertenencia* emergieron con una frecuencia similar a la observada en la etapa previa, con la excepción de un nuevo argumento que denominamos como *Cercanía* (7/19 parejas); el código engloba a las respuestas en las que los estudiantes posicionan la recta con ayuda del software de tal manera que se encuentre lo más cerca posible de la mayoría de los puntos. Se incluye como evidencia la respuesta de la pareja de estudiantes P6.

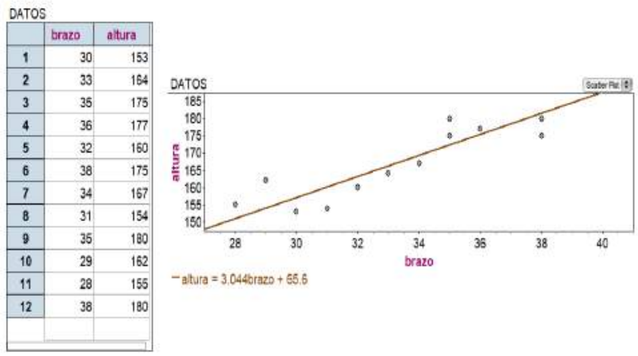

Figura 8. Respuesta pareja P6. Código Cercanía

Se muestra una tabla resumen del análisis y codificación inicial, para las dos etapas del estudio:

Tabla1. Proceso de Codificación

Código	Primera Etapa	Segunda Etapa	Frecuencia Relativa	
Aritmético Interpolación	✓		0.143	0.000
Uso de Software		✓	0.000	0.200
Aritmético Proporcionalidad	✓	✓	0.286	0.267
Aritmético Siguiendo un Patrón	✓	✓	0.071	0.267
Aritmético Sin Seguir un Patrón	✓	✓	0.214	0.267
Percepción de la Tendencia	✓		0.214	0.000
Sin Argumento	✓		0.071	0.000
Partición	✓	✓	0.286	0.211
Cercanía		✓	0.000	0.368
Pertenencia	✓	✓	0.714	0.421

La siguiente fase del análisis consistió en comparar los códigos definidos en las dos etapas del estudio e identificar rasgos de razonamiento covariacional comunes, así como algunos razonamientos que surgieron en la segunda etapa; el proceso de conceptualización de los razonamientos (inferencias) de las respuestas de los estudiantes a continuación se describe.

En función de las inferencias que realizan los estudiantes se identificaron conexiones conceptuales entre los razonamientos que exhiben, de ahí que los códigos *Percepción de la Tendencia* y *Uso de* Software (problema de estimación) se reclasificaron en el patrón de razonamiento Noción de *Agregado* pues en ambos casos los estudiantes hacen referencia a la utilización del conjunto completo de valores de los que disponen, para argumentar sus respuestas; independientemente de que sus resultados sean o no correctas normativamente. Por otro lado los códigos *Interpolación*, *Proporcionalidad*, *Aritmético Siguiendo un Patrón, Aritmético Sin Seguir un Patrón* (problema de estimación), *Partición* y *Pertenencia* (problema de recta de ajuste) se reclasificaron como *Búsqueda de una Señal*. La interconexión entre estos códigos radica en que los estudiantes infieren que debe existir una especie de clave o pista para resolver el problema, y realizan una búsqueda en los datos que se le proporcionaron. Parece que el alumno sospecha que existe un patrón o estructura ocultos en un subgrupo de datos (no utiliza la totalidad de datos ni contempla el conjunto de puntos) que lo llevarán a estructuras constantes, ausentes de incertidumbre o variación, que le son familiares. Finalmente se renombró al código *Cercanía* (problema de recta de ajuste) como *Sentido de Variabilidad,* ya que se perciben rasgos, aunque de manera espuria, de que los estudiantes infieren una relación presente entre el modelo de ajuste y los puntos de la nube, en el diagrama de dispersión. El código *Sin Argumento* que se presentó en el problema de estimación, al no aportar evidencias de algún tipo de inferencia realizada por los alumnos, no se consideró en esta etapa del análisis.

Tabla 2. Proceso de Conceptualización

Código	Patrón de Razonamiento /Inferencias Informales
Percepción de la Tendencia Uso de Software	Noción de Agregado

Cercanía	Sentido de Variabilidad

La tabla 2 muestra un resumen de la conceptualización y definición de los patrones de razonamiento identificados.

Conclusiones

Desde la perspectiva teórica que abordamos, una inferencia informal es un tipo de razonamiento que incluye consideraciones en varias dimensiones (Rubin, Hammerman y Konold, 2006) y en condiciones específicas de estudio. En nuestro caso una primera dimensión es la *Noción de Agregado*, donde se privilegia una percepción holística de las situación-problema por sobre la contemplación de los casos individuales. En este sentido los códigos inicialmente definidos, Percepción de la tendencia y Uso de software, presentan como patrón el que los estudiantes consideran la totalidad de los datos con que disponen; por un lado hacen la estimación del valor de la variable respuesta pedido (consumo de gas) haciendo un análisis puramente visual a partir de la tendencia del conjunto de datos, es decir que argumentan su respuesta con base en el comportamiento global del conjunto de valores. Por otro lado cuando utilizan Fathom, al construir el diagrama de dispersión y observar nuevamente la tendencia de la nube de puntos, identifican que debe existir cierta relación entre los puntos, por lo que eligen uno y modifican su posición de tal manera que coincida el valor dado de la variable independiente (8°C de temperatura) con el de la variable respuesta (consumo de gas) correspondiente, siguiendo la “forma” general de la nube. Si bien es cierto que en ninguno de los casos anteriores la respuesta de los estudiantes es la normativamente adecuada, si permite apreciar que bajo ciertas circunstancias son capaces de percibir que en las relaciones bivariadas es necesario considerar las características y comportamiento de los datos como un todo y, con base en esto inferir el valor de algún punto particular de interés.

Otra dimensión a considerar se ve reflejada con el patrón que definimos como *Búsqueda de una señal*, donde las respuestas arrojan que ante la dificultad que les representa la incertidumbre o la variación intrínseca en este tipo de problemas, los alumnos tratan de resolver la situación en un terreno familiar para ellos o con el que se sienten cómodos, posiblemente por esto utilizan en su mayoría procedimientos aritméticos (regla de tres, factor de proporcionalidad o sumas y restas) para hacer la estimación; donde además solo utilizan una parte de los datos. También es el caso del problema de la recta de ajuste, en el que ante la ausencia de la noción de incertidumbre o de esa visión de agregado, utilizan parcialmente los datos disponibles, haciendo referencia al modelo de la función lineal como alternativa para ajustar una recta a una distribución de puntos que presenta una tendencia lineal, considerando sólo algunos de estos puntos en su elección, ignorando la influencia de la totalidad de estos y su variación conjunta, y sobre todo, definiendo dos tipos de datos: los que pertenecen o no al modelo lineal que ellos eligen trazar.

Como tercera dimensión proponemos, *Sentido de Variabilidad*, representada por el código que se definió inicialmente como *Cercanía*. En este patrón de razonamiento se incluyeron las respuestas que hacen referencia, aunque de manera somera, a la percepción de que existe cierta variación que subyace en este tipo de problemas y que debe considerarse al momento de proponer una recta de ajuste para un conjunto de puntos, tal y como lo hicieron los estudiantes al trazar y argumentar que la recta debe posicionarse lo más cerca posible de la mayoría de los puntos.

Confiamos en que la identificación de estos patrones de razonamiento como la manera en que los estudiantes llevan a cabo inferencias informales ante situaciones-problema de asociación estadística abona al cuerpo del conocimiento en el estudio de datos bivariados, sin dejar de lado que es importante explorar obstáculos de aprendizaje como son la aparente desvinculación que tiene el estudiante entre la naturaleza predictiva o inferencial inherente al modelo de regresión lineal y su identificación como aquella recta que mejor se ajusta al conjunto de puntos, así como la dificultad para concebir al conjunto de datos como un agregado, es decir, como un sistema en el que están ligados unos a otros y tienen la propiedad de ser desviaciones de un mismo modelo.

TYPES OF ORCHESTRATIONS IN A CASE STUDY OF A STATISTICS CONSTRUCTIONIST TEACHING PRACTICE

TIPOS DE ORQUESTACIÓN EN UN ESTUDIO DE CASO DE UNA ENSEÑANZA CONSTRUCCIONISTA DE LA ESTADÍSTICA

This paper presents a case study that is part of a research studying how university statistics teachers integrate digital tools in their practice. The case study is of a teacher who claims to follow constructionist ideas for her teaching of statistics, using the R programming language. The teacher developed a series of activities with R, aiming to promote the understanding of statistical concepts. We observed 11 of her classes, in a three-week period. These classes were analyzed using as framework the notion of Instrumental Orchestration and Papert's construccionist principles. We identified four ways in which this teacher orchestrates her class and the constructionist elements present in them.

Keywords: University Mathematics, Data Analysis and Statistics, Technology, Programming and Coding

Introduction

For the study, at university level, of statistics and its advanced models, the use of digital technologies (DT) is necessary, due to the high computing and graphing requirements of the discipline. Additionally, mathematics education researchers point out that digital technologies can be used to rethink the teaching and learning of statistics concepts, by supporting students' statistical reasoning (Biehler et al., 2013) and facilitating access to the fundamental ideas of the discipline (Burrill, 2014).

In contrast, the results of a 2017 survey (Ruiz & Sacristán, 2019) of Mexican university statistics teachers showed that, although they use different digital resources in their teaching practice, most tend to limit their use to computation, graphing and visualization in practical sessions and/or in tasks, without changing their teaching, nor achieving what they themselves believe can be achieved using DT.

However, in the survey data, the responses of a particular teacher caught our attention: this teacher uses the R[1] programming language to engage her students in expressive exploratory activities to confront their intuitions regarding statistical concepts and practice. This teacher pointed out that she changed her use of technology in her classes after she became familiar with the constructionism paradigm (Papert, 1991), which we describe below. Thus, unlike most of the other participants in the survey (Ruiz & Sacristán, 2019), this teacher does not restrict the use of DT to perform calculations and draw graphs to solve tasks; rather, her aim is to promote conceptual learning in her students, through R-based programming. That is why we decided to conduct a case study of her practice, in order to identify how she integrates R, designs and implements activities using this language, in order to promote a conceptual learning of statistical ideas, and identify which of constructionist ideas are present in her practice.

For the case study, we used as a theoretical framework, the notion of Instrumental Orchestration (Guin & Trouche, 2002), derived from Rabardel's (1995) Instrumental Approach. In this regard,

Drijvers et al. (2009) note that the different forms of orchestration of teachers are related to their views of mathematics learning and teaching. Through the case study presented in this paper, we aim to identify the relationship between the studied teacher's view and her forms of orchestration, in particular, the research question were: What types of orchestrations can we observe in this teacher's practice? And what are the construccionist elements in those orchestrations?

Conceptual and theoretical framework

The construccionism proposal

The constructionist paradigm proposed by Papert (1991), follows the premise from constructivism that learning involves the construction of knowledge structures. Constructionism adds to that premise the idea that learning is facilitated when an individual consciously engages in the creation of a public entity – that is, of an object or product that can be shared with others (Papert, 1991). Thus, constructionism emphasizes the active role of the individual in the construction of their knowledge.

Sacristán et al. (2020) identified a long list of the principles and ideas that are part of constructionism. From their perspective, these are organized around four themes: (1) Epistemology, and conceptions of mathematical knowledge and of mathematics; (2) Conception of learning and of the role of the student; (3) Pedagogy and design; and (4) Computer programming and microworlds.

From a constructionist perspective, the use of DT artifacts in the classroom requires a rethinking of the teaching practices: emphasis is placed on inquiry and on the learner, instead of on a specific curriculum or on facts to be learned. For this reason, the use of the computer is conceived as an object-to-think-with (Martinez & Stager, 2013): Papert (1980b) believes that computers can provide environments to develop and work, especially through programming with powerful ideas and/or intellectual skills, that respond to one's own interests and needs. He also considers that the challenges that arise when programming can be learning opportunities.

Statistics education researchers (e.g., Chance et al., 2007) agree that the use of DT artifacts in teaching must be accompanied by changes in teaching style; they further point out that the teacher plays an important role in leveraging DTs to achieve such rethinking.

Instrumental Orquestration

The notion of Instrumental Orchestration was proposed by Guin and Trouche (2002) to take into account how a teacher directs and conducts his classes. It refers both to the different ways in which a teacher organizes and uses available artifacts, whether technological or not, and the teacher's performance during class seeking an effective use of those artifacts.

Drijvers et al., (2009) define instrumental orchestration as "the teacher's intentional and systematic organisation and use of the various artefacts available in a […] learning environment in a given mathematical task situation" (p. 482). It is composed of three elements: (i) the *didactical configuration* consisting of the arrangement of the artifacts, whether technological or not, and the learning setting; (ii) the *exploitation mode* which refers to the ways the teacher decides to carry out a given task, in order to exploit the proposed configuration; and (iii) the *didactical performance* , which involves the teacher's decisions and interventions taken while teaching in the chosen didactic configuration and exploitation mode (Drijvers et al., 2009).

The first form of instrumental orchestration mentioned in the literature (by Guin & Trouche, 2002) is the so-called *sherpa-student* orchestration, in which students carry out a task with an artifact (a calculator), while the work of one of them is projected and the teacher guides the actions of that student. In this orchestration, the didactical configuration is an arrangement that allows students to observe the projection while working on their own calculator, following the actions of the sherpa student. This mode of exploitation is determined by the teacher when guiding the sherpa student in his/her actions.

Trouche (2004) also distinguishes the *sherpa-at-work* orchestration, which has the didactical configuration described above and where the sherpa student is used to guide the work of the class in the exploitation mode. Other types of orchestrations identified by Drijvers et al. (2009) are: *technical-demo*, *explain-the-screen*, *link-screen-board*, *discuss-the-screen*, *spot-and-show*. In the exploitation modes of the first three orchestrations, the teacher has a central role; while the other orchestrations promote student intervention. On her part, Tabach (2011, 2013) distinguishes other types of orchestration: *monitor-and-guide*, *not-use-tech* and *discuss-tech-without-it*. In the *monitor-and-guide* orchestration, the teacher uses a learning management system to guide students to perform tasks similar to those of the *demo-technical* and *explain-the-screen* orchestrations. In the *not-use-tech* orchestration, technology is available but the teacher decides not to use it. The last form of orchestration proposed by Tabach (2013) is the *discuss-tech-without-it*, which corresponds to settings where it is not possible for students to have the technology element. Drijvers (2012) distinguishes one more type of orchestration, which he calls *work-and-walk-by*. In that orchestration, students work with a computer, either individually or in pairs, while the teacher walks between them to monitor their work and guide them when needed.

For Drijvers et al. (2009), teachers' different types of orchestration relate to their views on mathematical learning and teaching. For example, for one of his observed teachers it was important to achieve certain mathematical learning objectives, stressing the relationship between what happens in the technological and paper-and-pencil environments; thus, the type of orchestration that he used most was the *link-screen-board* one.

Drijvers et al. (2009) also point out that the *demo-technical* orchestration was the most prevalent among the observed teachers, because they "felt the need to familiarize students with basic techniques, in order to prevent technical obstacles from hindering the mathematical activities" (p. 6).

Based on these proposals, we analyzed the orchestration of the case study teacher. Next, we present the methodology of the study.

Methodology

As noted in the introduction, in 2017 we conducted a survey, using an online questionnaire, to get an insight into how university teachers use DT in their teaching of statistics. From the responses of 31 teachers, and interviews of three of them, the teacher, Mayra (pseudonym), was selected for a qualitative case study. As also noted, this teacher was chosen because she claimed to have a constructionist view of learning and teaching, which is why she uses technological tools in order to promote in her classes student-centered activities that will help them develop their conceptual learning (an appropriation) of statistical concepts.

We carried out an initial semi-structured interview with Mayra; observed 11 of her classes; and also had 6 conversations with her, in which she discussed details of her classes, the decisions she made and how her practice compares to other courses. All interviews (both formal and informal), as well as her classes, were recorded (audio for the interviews and video for the classes). We also analyzed the activities and assessments that she designed and implemented with her students.

The analysis of the data from the observations of her classes, focused on identifying the instrumental orchestration elements of her practice. Data from the interview and of her comments were used to complement the analysis of the classes and determine her vision of the teaching and learning of statistics and of the discipline itself.

The observation of the classes was divided into episodes when changes, in either the didactic configuration or in the mode of exploitation of Mayra's orchestration, were identified. We attempted to distinguish Mayra's types of orchestrations, using as reference those reported in the literature, and taking into account what Tabach (2013) pointed out, in terms of identifying whether an orchestration is a variant of another one, or a new orchestration.

In addition to that, guided by Papert's ideas (1980a, 1980b, 1991) and the synthesis of constructionist principles carried out by Sacristán et al. (2020), we attempted to identify the constructionist aspects in Mayra's classes.

Case study

Mayra's background, her teaching practice and her current activities design

Mayra is a biologist but has been teaching probability and statistical courses for 17 years, both at the undergraduate and graduate level. The topics covered in her courses have a strong practical orientation, as they address students of biology and environmental sciences.

DT resources always have been part of Mayra's teaching, because statistics needs them (for data processing, calculations and graphing). Initially, she used programs such as Excel, Statistica, and MiniTab, mainly to perform the calculations required in the formulas associated with a concept or statistical procedure. When using those resources, her classes used to have a traditional format, and only when necessary she showed students how to use those DT resources to perform calculations and get some results. The type of orchestration of those classes corresponded to the demo-technical one, where DTs were used to get a result that helped respond to a specific statistical problem.

When Mayra was introduced to the R programming language in 2007, she felt that her possibilities to statistically analyze the data of her professional practice were extended: "the window that opened to me when I got to know R, was precisely the possibility of adapting a set of analytical procedures to the data, and not the other way around".

A short time later, Mayra was introduced to the constructionist paradigm and was struck by the fact that learners did not need to be experts in programming to become creators of (increasingly complex) projects, be able to work independently and with, implicit or explicit, mathematical concepts. It was then that her view of statistics education changed and she decided to use R to develop a new way of teaching.

Thus, adopting the idea that students could construct their own knowledge, without the need of an excessively guided instruction but, rather, through a more construccionist pedagogy, Mayra designed a series of R-based activities so that students could explore data, using numerical, graphical and tabular records. In the course of several school cycles, Mayra refined the design of the activities: In her first proposals, the activities aimed to introduce the R programming language, so that later the students could use it for calculations and graphs; but in that case the tool was just integrated, without changing her teaching practice. The activities were then modified in order to explore statistical concepts (e.g. mean, standard deviation), or sets of concepts (included in the curricula) through different types of representations. For that, the activities present, through several parts, a particular problem involving a specific statistical concept. It should be noted that each activity leads the student to continuously explore and link the different types of representations, so that they can infer the result of an action, justify their decisions, explore the commands and propose different solutions. Mayra says: "The aim of the exercises became one that I had not been able to see[:] find in each of these thematic units, the essential concepts that they had to learn." She pointed out that her aim became to promote a more conceptual learning in her students through the activities that they had to solve, discuss and share. She explained that she is now aims to use DT resources, not to make easier what has always been done, but to rethink her teaching and change the usual roles in class of both teachers and students, as well as of technology.

Her activities with R are designed to be solved in class, in teams of two or three students. Through these activities, she aims to promote in students exploratory work with questioning and inference; in other words, students do a similar job to that of a statistical user. In this way, her activities coincide with what Papert promoted (1980a, 1980b): i.e., to use programming as an activity for students *to do* *math,* instead of learning about math. Thus, as Kynigos (2015) explains, whereas traditional school practices may impose an artificial picture of mathematics, by presenting the products of mathematical activity, the constructionist paradigm focuses on the mathematical activity and the expression of meanings through the use of and tinkering of representations in the form of digital artifacts.

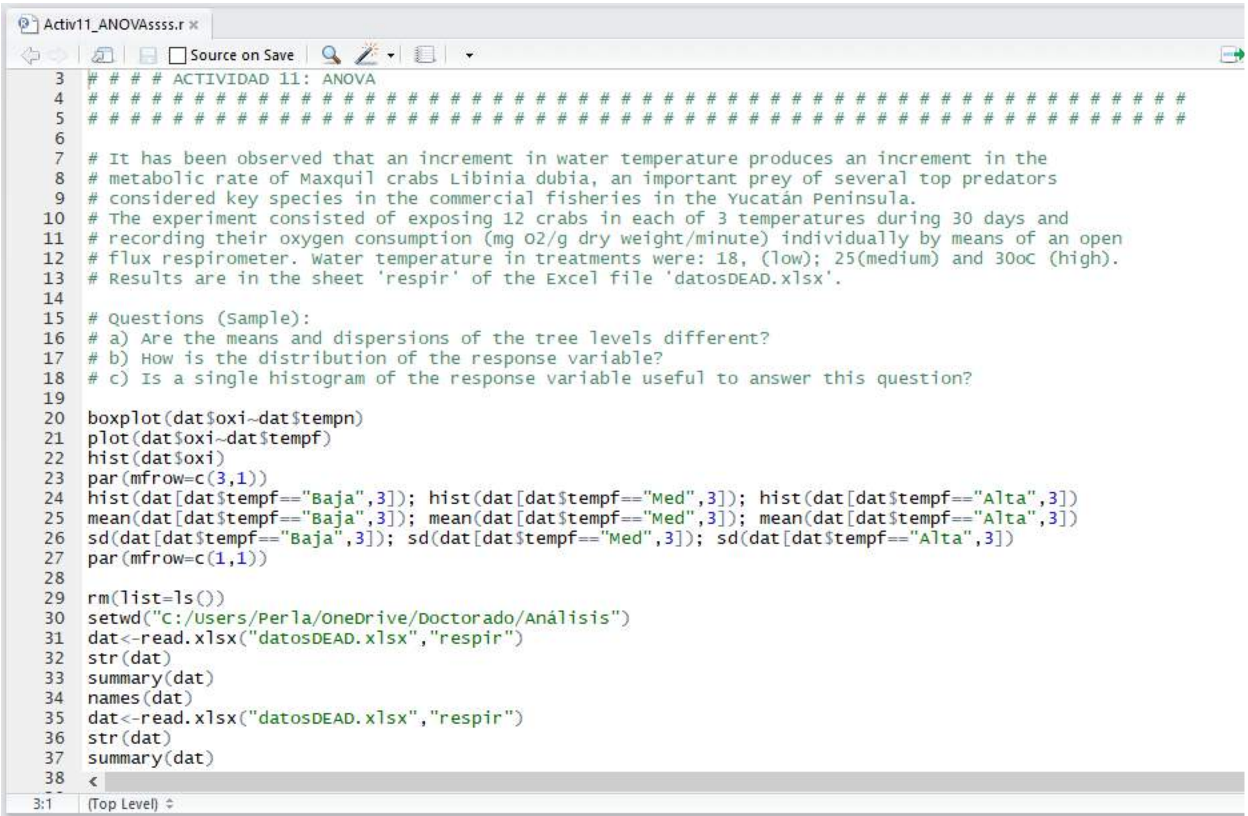

Figure 1: Script of an R-based activity on Analysis of Variance (ANOVA)

For example, one of Mayra's activities (see Figure 1) focuses on the analysis of variance (ANOVA) by presenting a real situation of the study of crabs under three temperature treatments. Some of the aims of the activity include exploring the components of the variance through the different representations and relating them to various elements in the ANOVA table (sum of squares, degrees of freedom, etc.); and familiarizing students with the F-distribution and the parameters that define it. The teacher explained that the purpose of this activity is for students to have to build representations themselves using R; that is, for

> students to have to use an ANOVA table... to look there for certain values that will help them give an answer [to the situation raised]. Do the same graphically, forcing them to relate what they are seeing on a graph to the numerical value; make them reflect on the magnitude of that difference, or on that variation, or on that number in terms of the problem, in general, [or] in terms of the units being used.

Although Mayra's approach focuses on students solving activities, we also observed some of her regular lessons (without technology), and others where group discussions of the activities (with technology) were carried out. In her regular lessons she presents a statistical concept or method and the symbology to be used. She also leads discussions on the relationships of that concept with others previously studied, and on relevant theoretical aspects. Mayra then assigns students an R-based activity to be carried out in teams of two or three students. When students complete the activity in R, or when Mayra needs to help them with their progress, she leads a group review of the activity.

Types of orchestration in Mayra's observed classes

Throughout our observations, of her regular lessons, the sessions where students carried out the R-based activities, and the group reviews of those activities, we identified four types of orchestrations in Mayra's practice, as presented below.

Discuss-tech-without-it orchestration. In her regular lessons, Mayra does not use technology; however, there are times when either she, or the students, refer to the R commands to talk about a concept or statistical process. For example, in an episode where the teacher asked for a reference value needed to interpret the F-value present in an ANOVA, under a null hypothesis, a student's answer was in terms of the R (qf) command used for calculating quantiles in hypothesis tests for the F-distribution. The teacher used this idea to discuss how R presents the results of an ANOVA. In this episode we observed the *discuss-tech-without-it* orchestration, where she explained how statistical processes in the R environment are presented and how R commands are used for expressing statistical ideas. In this orchestration, the didactical configuration corresponds to a traditional class arrangement, in which students follow the explanations of the teacher on the blackboard. In addition to this material artifact (the blackboard), the didactic configuration includes symbolic artifacts, such as graphic representations, symbols, and terms that denote certain statistical concepts and the contexts in which the statistical problems are presented (the problems are usually taken from real situations and data). The exploitation mode includes Mayra's explanations, using the blackboard for annotations and to illustrate concepts. Part of the exploitation mode relates to how Mayra's explanations are characterized, where she aims to discuss the relevance of a newly presented statistical concept and/or the approach of a particular method.

Although her regular lessons refer to the statistical content of the activities to be carried out by her students, these are not theoretical sessions with activities as a practical component; on the contrary: the discussions and contexts addressed in these regular lessons serve as a scaffolding for students, so that they can develop the activities in R. In this sense, the contexts of the proposed problems play an important role, and by referring to them, Mayra links her different types of class-formats. The orchestration of Mayra's regular lessons do not show constructionist aspects, since they are more instructionist (Papert, 1980b) ways of teaching, although she does promote student participation, so that students are not passive and they may benefit from what is discussed, which is fundamental for carrying out the R-based activities.

Work-and-walk-by orchestration. In classes dedicated to solving the activities, we observed the work-and-walk-by orchestration. Some of the artifacts involved in this didactical configuration are the resources shared in computer folders by the teacher, which include the designed activities as R-scripts and databases to be used with those activities. The symbolic artifacts include the (previously studied or newly presented in the lessons) statistical concepts. Other artifacts include the programming language, in particular the commands related to those statistical concepts. Following Papert's (1980a, 1980b) ideas, these artifacts become objects-to-think-with and for exploring the mathematical and statistical ideas.

The didactical configuration of this orchestration requires students to have access to the computer resources, and for the classroom setup to allow them to gather as teams on one or more computers. In classes that we observed, almost every student used their own computer. In the exploitation mode of the work-and-walk-by orchestration, the teacher promotes student teams to investigate, on their own, the R-based activity, looking for their own solutions, discussing them within each team and also with other teams; Mayra interacts with one team at time, seeking to: (i) emphasize important aspects and the relationship between the procedures/results of the activity and the theoretical concepts involved; and (ii) address students' particular doubts and difficulties.

How the teacher's aims for the programming activities are fulfilled, depends on how students are able to outline a solution proposal to the problem and refine it through different attempts, until reaching an appropriate response in terms of the given context. According to Mayra, the activities' approach generates a need for students to ask themselves "what do I want to do? What do I want to do it for? What is the information I'm going to get with that particular step, through that method?" Mayra states that when students fail an attempt, they need to find out the reason for such a result and that reflection exercise leads to a more profound learning than if they didn't make mistakes, where the result simply confirms their reasoning. These different roles of the teacher and students –the latter having an active role in their learning process– that involve collaboration and communication, are central constructionist aspects (as described in Sacristán et al., 2020) in this orchestration, which also includes other constructionist aspects such as: problem solving, exploration, the construction of new objects and/or ideas, the need to overcome obstacles and debug, etc..

One of the advantages of Mayra's proposed activities is that they are conceived and designed taking into account a problem from real biological/environmental practices (the students' study area), so that the context and the results of that problem become references for students. This helps articulate the explanations given in the regular lessons with what is done in the R environment. Sometimes, discussions that emerge during the activities are taken up in subsequent regular lessons to make connections between topics.

In Mayra's didactical performance, there are times when she decides to lead a plenary discussion of some proposed solution, of a result or of a doubt, either to facilitate the understanding of the concepts or to help the pace of the different teams in solving the problems.

Sherpa-at-work and link-screen-blackboard orchestrations. When Mayra leads classes to review the activities that were carried out, we observe a variation of the sherpa-at-work orchestration, in which a team of students participates to present their work. The didactical configuration consists of an arrangement where a team projects their work so that it can be shared with the other students. In the exploitation mode, the teacher selects a team of students to present and discuss how they followed the R-based activity guidelines, and their solutions to the problem –thus fulfilling the constructionist aspect of sharing and discussing "public entities" (Papert,1991).

The didactical performance in this orchestration includes the validation by the teacher of the different solution proposals, confronting the misconceptions and difficulties that arose in the activity, and the assessment of students' understandings of the concepts under study.

The review classes also involve the link-screen-blackboard orchestration. For example, during the review of an activity on the Additive Model, the first part focused on exploring the corresponding dataset and indicating its difference with datasets that were used in the T-test. In her explanations, she emphasizes how data needs to be arranged in order to perform the statistical method. She uses a whiteboard to show how data needs to be arranged, noting how subscripts can serve to distinguish between the numbering of a data observation and the treatment for each observation, and how this is reflected in the R t.test command inputs.

Conclusions

In this study we observed how Mayra, through her constructionist teaching approach, implemented activities, as promoted by Papert (1980a), to get her students involved in *doing* statistics through programming and by generating R-based representations, rather than learning *about* statistical concepts. Other constructionist aspects in Mayra's orchestrations were observed in her classroom dynamics and in the participants' roles (except in the regular lessons). In Mayra's three class formats, we identified four types of orchestrations. In the orchestration types presented in the research literature (Drijvers et al. 2009, Guin & Trouche, 2002; Trouche 2004, Tabach, 2011, 2013) there are few examples where teamwork is encouraged. Mayra's orchestrations involve much more varied aims and considerations than those illustrated in Drijvers et al. (2010). Also, while the demo-technical orchestration is the most frequently observed in the study by Drijvers et al. (2010), Mayra’s classes do not present this type of orchestration.

Pratt et al. (2011) state that immersion in the use of statistics software is important for teachers to gear student learning of statistical ideas, and helps them appreciate the role that DTs play in promoting understanding of statistical concepts and methods.

Mayra, using her own experience, generated activities that reflect a greater use of technology in the classroom. In this document we show a novel way to use the R programming language in the teaching of statistics, in which students have a much more active role in the construction of their knowledge.

TIPOS DE ORQUESTACIÓN EN UN ESTUDIO DE CASO DE UNA ENSEÑANZA CONSTRUCCIONISTA DE LA ESTADÍSTICA

TYPES OF ORCHESTRATIONS IN A CASE STUDY OF A STATISTICS CONSTRUCTIONIST TEACHING PRACTICE

En este artículo se presenta un estudio de caso que forma parte de una investigación con profesores de estadística de nivel universitario para estudiar su incorporación de herramientas tecnológicas digitales en su enseñanza. El estudio de caso corresponde a una profesora que dice adoptar ideas del construccionismo para su enseñanza de la estadística con el lenguaje de programación R. La profesora desarrolló una serie de actividades con R, para promover la comprensión de conceptos estadísticos. Observamos 11 de sus clases, en un periodo de 3 semanas. Sus clases se analizaron considerando la noción de Orquestación Instrumental y los principios construccionistas de Papert. Identificamos cuatro formas en la que esta profesora orquesta su clase y los elementos construccionistas presentes en éstas.

Palabras clave: Matemáticas de Nivel Universitario, Análisis de Datos y Estadística, Tecnología, Programación y Codificación Computacional

Introducción

La estadística que se estudia en el nivel superior, y sus modelos avanzados precisan del uso de tecnologías digitales, debido en gran parte a las elevadas necesidades de cómputo y graficación de la disciplina. Además, investigadores en educación matemática señalan que su uso puede aprovecharse para replantear la enseñanza y el aprendizaje de conceptos estadísticos, promoviendo el desarrollo del pensamiento propio de la disciplina (Biehler et al., 2013) y permitiendo que los alumnos accedan a las ideas estadísticas fundamentales (Burrill, 2014).

En contraste con lo anterior, los resultados de una encuesta que realizamos en 2017, con profesores de estadística de nivel universitario (Ruiz & Sacristán, 2019) mostraron que, si bien los profesores utilizan distintos recursos tecnológicos digitales (TD), en su práctica docente, la mayoría tiende a limitar su uso al cómputo, graficación y visualización en las sesiones prácticas y/o en tareas, sin cambiar su forma de enseñanza ni llevando a cabo lo que ellos consideran que puede lograrse al usar TD.

Sin embargo, de entre los resultados, nos llamó la atención una profesora que utiliza el lenguaje de programación R[2] para involucrar a sus alumnos en actividades expresivas de exploración para confrontar sus intuiciones sobre los conceptos y la práctica estadística. Esta profesora señaló que hubo un cambio en la forma en que usa la tecnología en sus clases a partir de que conoció el planteamiento del construccionismo (Papert, 1991), enfoque que describimos más abajo. Así pues, a diferencia de la mayoría de los encuestados (Ruiz & Sacristán, 2019), esta profesora no se restringe a utilizar las TD para realizar cálculos y obtener gráficas para resolver tareas, sino que su principal objetivo es promover un aprendizaje más conceptual por parte de sus alumnos a través de la programación con R. Por ello, la forma de enseñanza de esta profesora llamó nuestra atención, y decidimos hacer un estudio de caso de ella para identificar de qué forma integra R, diseña y conduce las actividades con este lenguaje, para fomentar el aprendizaje conceptual de ideas estadísticas y cuáles de las ideas construccionistas son parte de su práctica.

Para el estudio de caso, hemos utilizado como marco teórico, la noción de Orquestación Instrumental (Guin & Trouche, 2002), la cual se deriva de la Aproximación Instrumental de Rabardel (1995). Al respecto, Drijvers et al. (2009) señalan que las diferentes formas de orquestación de los profesores se relacionan con su visión sobre el aprendizaje y la enseñanza de las matemáticas. En la parte del estudio de caso, presentada en este documento, pretendemos identificar, en particular, la relación entre la visión de la profesora y sus formas de orquestación. Por ello, las preguntas de investigación que guían lo aquí descrito, es: ¿Qué tipo de orquestaciones se observan en la enseñanza de esta profesora?; y como sub pregunta ¿cuáles son los elementos construccionistas en esas orquestaciones?

Marco conceptual

La propuesta del Construccionismo

El paradigma construccionista propuesto por Papert (1991), parte de la premisa constructivista de que el aprendizaje implica una construcción de estructuras de conocimiento. La propuesta construccionista añade a esto, la idea de que el aprendizaje se promueve cuando un individuo se involucra conscientemente en la creación de una entidad pública –es decir, un objeto o producto que pueda ser compartido con otras personas (Papert, 1991). Así, esta propuesta enfatiza el rol activo del individuo en la construcción de su propio conocimiento.

Sacristán et al. (2020) identificaron una larga lista de los principios e ideas que forman parte de la propuesta construccionista. Desde su perspectiva, éstos se organizan alrededor de cuatro temas: (1) Epistemología y concepciones sobre el conocimiento matemático y sobre la matemática; (2) Concepciones del aprendizaje y el rol del estudiante; (3) La pedagogía y el diseño; y (4) La programación computacional y los micromundos.

Desde la perspectiva construccionista, el uso de artefactos TD en el aula requiere un replanteamiento de la forma de enseñanza, de manera que se hace hincapié en la indagación y en el aprendiz, no en un currículo específico o en hechos a ser aprendidos. Por esta razón, se promueve el uso de la computadora como algo con qué pensar (Martinez & Stager, 2013): Papert (1981) considera que la computadora puede proveer ambientes que permitan desarrollar y trabajar con ideas poderosas y/o habilidades intelectuales, que respondan a los intereses y necesidades de cada individuo, sobre todo a través de la programación. También considera que las eventualidades que surjan al programar, pueden ser oportunidades de aprendizaje.

Investigadores en educación estadística (e.g., Chance et al., 2007) coinciden que el uso de artefactos TD en la enseñanza debe ir acompañado de cambios en las formas de enseñanza; señalan, además,

[2] https://www.r-project.org/

que el profesor juega un rol importante en el aprovechamiento de las TD para alcanzar tal replanteamiento.

La Orquestación Instrumental

La noción de Orquestación Instrumental fue propuesta por Guin y Trouche (2002) para dar cuenta de cómo un profesor dirige y lleva a cabo sus clases. Se refiere tanto a las distintas formas en las que un profesor organiza y usa los artefactos disponibles, ya sean tecnológicos o no, así como al desempeño del profesor durante la clase para sacar provecho de dicha configuración.

La orquestación instrumental se define como la organización y uso sistemático e intencional de los artefactos a disposición del profesor en el aula, durante la realización de una tarea determinada en un ambiente de aprendizaje (Drijvers et al., 2009). Se compone de tres elementos: (i) la *configuración didáctica* que consiste en la disposición de los artefactos, ya sean o no tecnológicos, y del ambiente de aprendizaje; (ii) los *modos de explotación* que se refieren a las formas indicadas por el profesor para llevar a cabo la tarea dada, en busca de sacar provecho de la configuración propuesta; y (iii) el *desempeño didáctico* del profesor, incluye sus decisiones e intervenciones desarrolladas en el ambiente de aprendizaje (Drijvers et al., 2009).

La primera forma de orquestación instrumental mencionada en la literatura fue la llamada orquestación *alumno-sherpa*, en el cuál los alumnos desarrollan cierta tarea ayudados de un artefacto (una calculadora), mientras que el trabajo de uno de ellos se proyecta y el profesor, regula la intervención de dicho estudiante (Guin & Trouche, 2002). En esta orquestación la configuración didáctica consiste en un arreglo que permite a los alumnos observar la proyección y manejar su propia calculadora, siguiendo las acciones del alumno sherpa. El modo de explotación lo determina el profesor, indicando al alumno sherpa que acciones realizar.

Trouche (2004) también distingue la orquestación sherpa-en-el-trabajo, la cual tiene una configuración didáctica como la descrita antes y en cuyo modo de explotación se guía el trabajo de la clase a través del alumno sherpa. Otros tipos de orquestaciones identificadas por Drijvers et al. (2009) son: *demostración-técnica*, *explica-la-pantalla*, *enlaza-pantalla-pizarrón*, *discute-la-pantalla*, *indica-y-muestra*. Los modos de explotación de las primeras tres orquestaciones implican que el profesor tome un papel central, mientras que las siguientes orquestaciones promueven la intervención de los alumnos. Por su lado, Tabach (2011, 2013) distingue otros tipos de orquestación: *monitorea-y-guía*, *no-usa-tecnología* y *discute-la-tecnología-sin-ella*. En la de monitorea-y-guía, el profesor utiliza un sistema de administración del aprendizaje para guiar a los estudiantes o llevar a cabo tareas similares a las de las orquestaciones demostración-técnica y explica-la-pantalla. En la orquestación no-usa-tecnología, la tecnología está disponible pero el profesor decide no hacer uso de ella. La última forma de orquestación propuesta por esta autora, *discute-la-tecnología-sin-ella,* corresponde a escenarios donde no es posible que los alumnos dispongan del elemento tecnológico. Drijvers (2012) distingue un tipo de orquestación más, al que denomina como circula-mientras-trabajan (*work-and-walk-by*). En esa orquestación, los estudiantes trabajan con una computadora, ya sea individualmente o en pares, mientras el profesor circula entre ellos para monitorear su trabajo y guiarlos cuando es necesario.

Para Drijvers et al. (2009), las diferentes formas de orquestación de los profesores se relacionan con su visión sobre el aprendizaje y la enseñanza de las matemáticas. Por ejemplo, para uno de los profesores que observaron era importante alcanzar ciertos objetivos de aprendizaje matemático, vinculando lo que sucede en los ambientes tecnológicos y de papel-y-lápiz; así, utilizaba más frecuentemente la forma de orquestación enlaza-pantalla-pizarrón.

Drijvers et al. (2009) también señalan que la orquestación demostración-técnica era la más frecuente entre los profesores que observaron, debido a que éstos “sienten la necesidad de familiarizar a los alumnos con técnicas básicas, para prevenir obstáculos técnicos que inhiban las actividades matemáticas" (p. 6).

Es con base en estas propuestas, que analizamos la orquestación de la profesora estudio de caso. A continuación presentamos la metodología del estudio.

Metodología

Como se señaló en la sección de introducción a este artículo, en 2017 realizamos una encuesta, mediante un cuestionario en línea, para tener un panorama sobre cómo profesores de nivel superior utilizan las TD en su enseñanza de la estadística. A partir de las respuestas de 31 profesores, y de las entrevistas a tres de ellos, se seleccionó a la profesora, que llamamos Mayra, para realizar un estudio de caso de tipo cualitativo. Como también se señaló, esta profesora fue elegida ya que decía tener una visión construccionista del aprendizaje y la enseñanza, razón por la cual utiliza las herramientas tecnológicas de manera que en sus clases se da un papel primordial a la actividad de los alumnos; además, busca promover un aprendizaje más conceptual en sus alumnos (una apropiación de los conceptos estadísticos).

Se realizó una entrevista inicial semi-estructurada a Mayra, se observaron 11 de sus clases, y se tuvieron 6 conversaciones fuera de clase en las que Mayra comentaba detalles de la clase, de las decisiones que tomaba y algunos contrastes de su práctica con otros cursos. Tanto las entrevistas (formales e informales) como las clases, se grabaron (en audio las entrevistas, en video las clases). También se recolectaron las actividades y evaluaciones que Mayra había llevado a cabo con sus alumnos.

El análisis de los datos de las observaciones de sus clases se centró en la identificación de los elementos de su práctica que componen el modelo de orquestación instrumental. Los datos de la entrevista y los audios de sus comentarios se utilizaron para complementar el análisis de las clases y para determinar la visión de la profesora respecto a la enseñanza y aprendizaje de la estadística y de la disciplina misma.

La observación de las clases se dividió en episodios, según se identificara un cambio, ya sea en la configuración didáctica, o en el modo de explotación de la orquestación de Mayra. Tratamos de distinguir sus tipos de orquestaciones, a partir de las señaladas en la literatura, considerando lo señalado por Tabach (2013) para identificar si se trata de una variante de cierta orquestación o de una nueva orquestación.

Adicionalmente, se llevó a cabo una identificación de los aspectos construccionistas de las clases de Mayra, guiado por las ideas de Papert (1980, 1981, 1991), y la síntesis realizada por Sacristán et al. (2020) en donde se distinguen los principios construccionistas.

Estudio de caso

Antecedentes de Mayra, sus formas de enseñanza y su diseño actual de las actividades

La profesora Mayra es bióloga pero cuenta con 17 años de experiencia docente impartiendo cursos de probabilidad y estadística, tanto a nivel licenciatura como posgrado. Los temas abordados en sus cursos tienen una fuerte orientación práctica, ya que se dirigen a alumnos de carreras biológico-ambientales.

Los recursos TD siempre formaron parte de la enseñanza de Mayra, debido a que en estadística no se puede prescindir de ellos (para procesamiento de datos, cálculos y graficación). Al principio, usaba programas como Excel, Statistica y MiniTab, principalmente para realizar los cálculos prescritos en las fórmulas asociadas al concepto o procedimiento estadístico. Cuando utilizaba esos recursos, las clases mantenían un formato tradicional y cuando era necesario, mostraba cómo utilizarlos para realizar cálculos y obtener algún resultado. El tipo de orquestación de esas clases, correspondía a la *demostración-técnica*, donde las TD eran el medio para obtener un resultado a partir del cual responder a una situación estadística concreta.

La percepción de Mayra, al conocer el lenguaje de programación R en el año 2007, fue que se le ampliaron las posibilidades de analizar estadísticamente los datos de su práctica profesional: “la ventana que se me abrió cuando conocí R, fue justamente la posibilidad de adecuar un conjunto de procedimientos analíticos a los datos, y no al contrario”.

Poco tiempo después, Mayra conoció el planteamiento construccionista y le llamó la atención que los aprendices no necesitaban ser expertos en lenguaje de programación para convertirse en creadores de proyectos (cada vez más complejos), poder trabajar de forma independiente, y abordar, implícita o explícitamente, conceptos matemáticos. Fue entonces que su visión de la educación estadística cambió y decidió usar R para desarrollar una nueva forma de enseñanza.

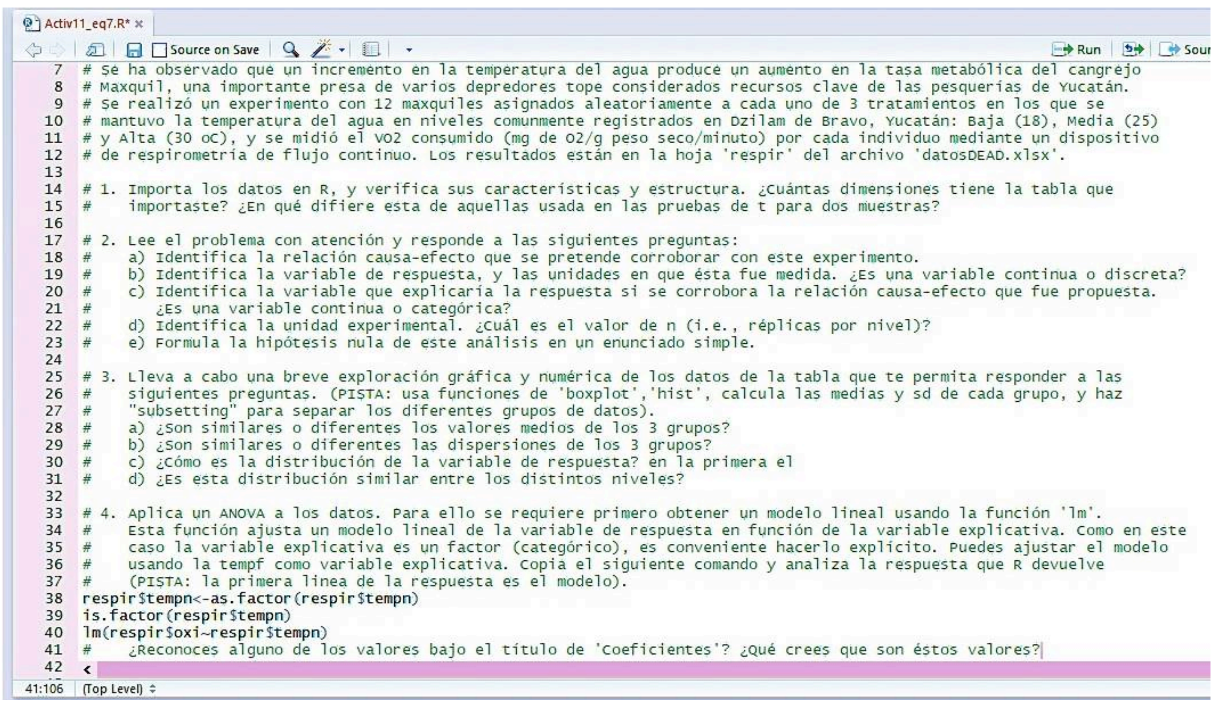
Así, con la idea de que los alumnos pudieran construir su propio conocimiento, sin necesidad de una instrucción demasiado guiada, Mayra diseñó una serie de actividades buscando una pedagogía más construccionista, basadas en el uso del lenguaje de programación R para la exploración de datos, por parte de los alumnos, usando los registros numérico, gráfico y tabular. Durante varios ciclos escolares, Mayra depuró y refinó el diseño de las actividades: En sus primeras propuestas, las actividades buscaban introducir el lenguaje de programación R, para que después los alumnos pudieran utilizarlo para obtener cálculos y gráficas; siendo ésta, una incorporación de la herramienta sin cambiar la forma de enseñanza. Luego las actividades se modificaron para explorar conceptos estadísticos (e.g., media, desviación estándar), o conjuntos de conceptos (incluidos en los planes de estudio) a través de distintos registros de representación. Para ello, las actividades plantean una problemática particular, cuya resolución se lleva a cabo por etapas donde se pone en acción un concepto determinado. Cabe mencionar que cada actividad lleva al alumno a explorar y vincular continuamente los distintos registros de representación, a tratar de inferir el resultado de una acción, a justificar sus decisiones, a explorar los comandos y a plantear distintas propuestas de solución. Al respecto Mayra comenta: “el objetivo de las practicas se convirtió en un objetivo que yo no había sido capaz de ver[:] encontrar en cada una de esas unidades temáticas, cuáles eran los conceptos esenciales que tenían que aprender.” Señaló como objetivo promover en sus alumnos un aprendizaje más conceptual a través de las actividades que resuelven, discuten y comparten. Explicó que busca ahora un uso de los recursos TD, no como auxiliares para hacer más fácil lo que siempre se ha hecho, sino para replantear su enseñanza y cambiar los roles usuales en clase tanto del profesor y los alumnos, como de la tecnología.

Sus actividades con R están diseñadas para realizarse en clase, en equipos de dos o tres alumnos. A través de dichas actividades, buscaba promover en los alumnos un trabajo de exploración, de prueba y error, de cuestionamiento e inferencia; en otras palabras, que realizaran un trabajo parecido al de un usuario de la estadística. De esta manera, coincide con las propuestas de Papert (1980, 1981) de utilizar la programación como una actividad para que los alumnos *hagan matemáticas* en lugar de aprender acerca de las matemáticas. Así, mientras que en la escuela tradicional se impone una imagen artificial de las matemáticas, con objetos acabados de la actividad matemática, la propuesta construccionista se enfoca en esa actividad matemática y en la expresión de significados a través del uso y re-creación de representaciones en forma de artefactos digitales (Kynigos, 2015).

Por ejemplo, una de las actividades (ver Figura 1) trata sobre el análisis de la varianza (ANOVA): presenta una situación real en torno a cangrejos sometidos a tres tratamientos de temperatura. Algunos de los objetivos de la actividad incluyen explorar los componentes de variación en los distintos registros y relacionarlos con diversos elementos en la tabla de ANOVA (suma de cuadrados, grados de libertad, etc.), además de familiarizarse con la distribución de F y los parámetros que la definen. La profesora explicó que el propósito de esta actividad es que los alumnos tengan ellos mismos que construir las representaciones y programar; es decir, que

> los alumnos [tengan] que ir a una tabla de ANOVA… a buscar ahí, ciertos valores que… [les permitan] dar una respuesta [a la situación planteada]… Hacer lo mismo gráficamente, obligarlos a relacionar lo que estaban viendo en una gráfica con ese valor numérico, hacerlos reflexionar sobre la magnitud de esa diferencia, o de esa variación, o de ese número en términos del problema en general, en términos de las unidades que estaban siendo utilizadas.

Si bien el planteamiento de Mayra se dirige hacia la resolución de las actividades por parte de los alumnos, también se observaron clases de tipo magistral (sin tecnología) y otras donde se hace una revisión grupal de las actividades (con tecnología). En las clases de tipo magistral se presenta un concepto o método estadístico y la simbología a utilizar. Se discuten las relaciones de este concepto con otros previamente estudiados y los aspectos teóricos pertinentes. Después, la profesora asigna a los alumnos una actividad en R, para realizarse en equipos de dos o tres alumnos. Al finalizar los alumnos la actividad en R, o en momentos donde la profesora requiere de uniformizar su progreso, se realizan las revisiones grupales de la actividad considerada.



```
# Se ha observado que un incremento en la temperatura del agua produce un aumento en la tasa metabólica del cangrejo
# Maxquil, una importante presa de varios depredores tope considerados recursos clave de las pesquerías de Yucatán.
# Se realizó un experimento con 12 maxquiles asignados aleatoriamente a cada uno de 3 tratamientos en los que se
# mantuvo la temperatura del agua en niveles comunmente registrados en Dzilam de Bravo, Yucatán: Baja (18), Media (25)
# y Alta (30 oC), y se midió el VO2 consumido (mg de O2/g peso seco/minuto) por cada individuo mediante un dispositivo
# de respirometría de flujo continuo. Los resultados están en la hoja 'respir' del archivo 'datosDEAD.xlsx'.

# 1. Importa los datos en R, y verifica sus características y estructura. ¿Cuántas dimensiones tiene la tabla que
#    importaste? ¿En qué difiere esta de aquellas usada en las pruebas de t para dos muestras?

# 2. Lee el problema con atención y responde a las siguientes preguntas:
#    a) Identifica la relación causa-efecto que se pretende corroborar con este experimento.
#    b) Identifica la variable de respuesta, y las unidades en que ésta fue medida. ¿Es una variable continua o discreta?
#    c) Identifica la variable que explicaría la respuesta si se corrobora la relación causa-efecto que fue propuesta.
#       ¿Es una variable continua o categórica?
#    d) Identifica la unidad experimental. ¿Cuál es el valor de n (i.e., réplicas por nivel)?
#    e) Formula la hipótesis nula de este análisis en un enunciado simple.

# 3. Lleva a cabo una breve exploración gráfica y numérica de los datos de la tabla que te permita responder a las
#    siguientes preguntas. (PISTA: usa funciones de 'boxplot','hist', calcula las medias y sd de cada grupo, y haz
#    "subsetting" para separar los diferentes grupos de datos).
#    a) ¿Son similares o diferentes los valores medios de los 3 grupos?
#    b) ¿Son similares o diferentes las dispersiones de los 3 grupos?
#    c) ¿Cómo es la distribución de la variable de respuesta? en la primera el
#    d) ¿Es esta distribución similar entre los distintos niveles?

# 4. Aplica un ANOVA a los datos. Para ello se requiere primero obtener un modelo lineal usando la función 'lm'.
#    Esta función ajusta un modelo lineal de la variable de respuesta en función de la variable explicativa. Como en este
#    caso la variable explicativa es un factor (categórico), es conveniente hacerlo explícito. Puedes ajustar el modelo
#    usando la tempf como variable explicativa. Copia el siguiente comando y analiza la respuesta que R devuelve
#    (PISTA: la primera linea de la respuesta es el modelo).
respir$tempn<-as.factor(respir$tempn)
is.factor(respir$tempn)
lm(respir$oxi~respir$tempn)
#    ¿Reconoces alguno de los valores bajo el título de 'Coeficientes'? ¿Qué crees que son éstos valores?
```

Figura 1: Guión de una actividad en R sobre Análisis de Varianza (ANOVA)

Tipos de orquestación en las clases observadas de Mayra

A lo largo de nuestras observaciones, tanto de las clases de tipo magistral, de las de resolución de actividades y de las de revisión, se distinguieron cuatro tipos de orquestación de Mayra, como se presenta a continuación.

Orquestación discute-tecnología-sin-ella. En las clases de tipo magistral de Mayra, ella no utiliza tecnología; sin embargo, hay ocasiones en que, ya sea la profesora o los alumnos, hacen referencia a los comandos en R relacionados con un concepto o proceso estadístico involucrado en la explicación. Por ejemplo, en un episodio donde la profesora preguntaba por un valor de referencia para interpretar el valor F obtenido en un ANOVA, bajo cierta hipótesis nula, un alumno dio su respuesta en términos del comando de R (qf) asociado al cálculo de cuantiles para la distribución F en pruebas de hipótesis. La profesora aprovechó esta idea para discutir la forma en que R despliega los resultados de un

ANOVA. En este episodio se observó la orquestación *discute-tecnología-sin-ella*, donde se explica el manejo de los procesos estadísticos en el ambiente de R y se utilizan sus comandos para expresar ideas estadísticas. En esta orquestación, la configuración didáctica corresponde al arreglo tradicional de una clase en la que los alumnos atienden la explicación del profesor, auxiliado del pizarrón. Además de este artefacto material (el pizarrón), en la configuración didáctica, se incluyen artefactos simbólicos, como las representaciones gráficas, los símbolos y los términos que denotan ciertos conceptos estadísticos y los contextos en los que plantea las problemáticas estadísticas (generalmente tomadas de situaciones y datos reales). El modo de explotación incluye las explicaciones de la profesora, usando el pizarrón para anotar e ilustrar. Parte del modo de explotación se relaciona con las características de las explicaciones de la profesora, las cuales buscan discutir la pertinencia de un nuevo concepto estadístico y/o del planteamiento de un determinado procedimiento.

Aunque las clases de tipo magistral hacen referencia al contenido estadístico de las actividades a desarrollar por los alumnos, no se trata de sesiones teóricas cuya componente práctica se encuentra en las actividades; al contrario: las discusiones y contextos abordados en esas clases de tipo magistral, sirven como andamiaje para los alumnos, para que puedan desarrollar las actividades en R. En este sentido, los contextos de las problemáticas planteadas juegan un papel importante, ya que la profesora conecta, a través de referencias a éstos, los distintos tipos de clases. En estas clases de tipo magistral de Mayra, no es posible señalar aún aspectos construccionistas en su orquestación, al ser más un modo más instruccionista (Papert, 1981) de enseñanza, aunque Mayra busca la participación de los alumnos, para que no estén pasivos y sus clases le son valiosas, ya que lo discutido es fundamento de las actividades con R.

Orquestación circula-mientras-trabajan. En las clases dedicadas a la resolución de actividades, se observó la orquestación circula-mientras-trabajan *(work-and-walk-by)*. Parte de los artefactos que componen esta configuración didáctica son los recursos electrónicos que la profesora comparte en carpetas con los alumnos, los cuales incluyen las actividades diseñadas en R y las bases de datos utilizadas. Entre los artefactos simbólicos se encuentran los conceptos estadísticos mismos (previos y los recién presentados en las clases de tipo magistral), además del lenguaje de programación, en particular los comandos que engloban dichos conceptos estadísticos. Estos artefactos constituyen entonces objetos con los cuales pensar y un medio para la exploración de ideas matemáticas, en particular, las estadísticas, siguiendo las ideas propuestas por Papert (1980, 1981). La configuración didáctica de esta orquestación requiere que los alumnos tengan acceso al recurso computacional y que el mobiliario del aula permita que se reúnan en equipo para utilizar una o varias computadoras. En las clases observadas, casi todos los alumnos utilizaban su propia computadora. Como modo de explotación, los alumnos realizan la actividad planteada en R, discutiendo entre ellos, en ocasiones también con otros equipos. Esta forma de orquestación, se centra en las actividades de los equipos de alumnos, permitiéndoles desarrollar sus propios intentos de solución. Mayra interactúa con un equipo a la vez, buscando: (i) enfatizar aspectos importantes y la relación entre los métodos/resultados de la actividad y los conceptos teóricos abordados; y (ii) abordar dudas y dificultades particulares de los alumnos.

El logro del objetivo de la profesora en las actividades de programación, se basa en la necesidad de los alumnos, de esbozar una propuesta de solución al problema e irlo refinando a través de distintos intentos, hasta alcanzar una respuesta que sea adecuada en términos del contexto dado. Siguiendo a Mayra, el planteamiento de las actividades genera en los alumnos la necesidad de preguntarse "¿qué es lo que quiero hacer? ¿Para qué quiero hacerlo? ¿Cuál es la información que voy a obtener con ese particular paso, en el procedimiento?" Mayra afirma que cuando los alumnos hacen un intento fallido, se enfrentan con la necesidad de encontrar el porqué de tal resultado y que este ejercicio de reflexión conlleva un tipo de aprendizaje distinto al obtenido en los intentos donde no se cometen errores, en los cuales el resultado ayuda a confirmar su razonamiento. El cambio en los roles del profesor y los alumnos, el rol activo de éstos últimos en su proceso de aprendizaje, la colaboración y la comunicación, son aspectos construccionistas ligados a esta orquestación (Sacristán et al., 2020). También se observan otros aspectos construccionistas relacionados con la resolución de problemas, la exploración, la construcción de nuevos objetos y/o ideas y la superación de obstáculos o depuración.

Una de las virtudes de las actividades planteadas por Mayra es que se desarrollan considerando una problemática asociada a la práctica biológica/ambiental (el área de formación de los alumnos), de manera que el contexto y los resultados obtenidos se convierten en referentes para los alumnos. Ello da pie a la articulación de las explicaciones dadas en la clase magistral y lo realizado en el ambiente R. En ocasiones, las discusiones surgidas durante las actividades son retomadas en clases magistrales subsecuentes para relacionar los temas discutidos.

En su desempeño didáctico, hay momentos en que la profesora decide hacer un discusión plenaria de alguna propuesta de solución, resultado o duda, ya sea porque tiene un interés particular para facilitar el trabajo o la comprensión de los conceptos o porque busca que el trabajo de los distintos equipos sea un poco más homogéneo.

Orquestaciones sherpa-en-el-trabajo y vincula-pantalla-pizarrón. Finalmente, Mayra conduce clases en las que se revisan las actividades realizadas. En ellas, se observa una variación de la orquestación sherpa-en-el-trabajo *(sherpa-at-work)*, en la cual participa un equipo de alumnos para presentar su trabajo. La configuración didáctica consiste de un arreglo que permita proyectar el trabajo de un equipo y que los demás alumnos lo observen. Como modo de explotación los alumnos de un equipo utilizan R para discutir sus respuestas a la actividad y seguir los planteamientos de la profesora – cumpliendo el aspecto de compartir y discutir "entidades públicas" que señala Papert (1991). El desempeño didáctico relativo a esta orquestación incluye la validación por parte de la profesora de las distintas propuestas de solución, la confrontación de las ideas erróneas y dificultades que surgieron en la actividad y la evaluación de la comprensión, por parte de los alumnos, de los conceptos abordados.

En las clases de revisión también se presenta la orquestación vincula-pantalla-pizarrón. Por ejemplo, durante la revisión de una actividad sobre el Modelo Aditivo, la primera parte se centraba en explorar el conjunto de datos e indicar la diferencia de éste con los conjuntos de datos usados en la prueba de T. Durante esta explicación, el énfasis estuvo en el arreglo de los datos para realizar el procedimiento estadístico. La profesora utilizó el pizarrón para representar los datos arreglados, señalando cómo los subíndices sirven para distinguir el número de dato y el tratamiento al que corresponde, y cómo esto se refleja en las entradas del comando t.test.

Conclusiones

En nuestro estudio se observó cómo Mayra, a través de una propuesta construccionista, puso en práctica actividades para que sus alumnos se involucraran en hacer estadística a través de la programación y generación de representaciones en R, en lugar de aprender acerca de sus conceptos, como propuso Papert (1980). Otros aspectos construccionistas en la orquestación de Mayra se observaron en la dinámica del aula, y en los roles de los participantes (excepto en las clases magistrales). En sus tres tipos de clases, se distinguieron cuatro tipos de orquestación de Mayra. En pocos de los tipos de orquestación presentados en trabajos previos (Drijvers et al. 2009, Guin & Trouche, 2002; Trouche 2004, Tabach, 2011, 2013), se fomenta el trabajo en equipos. Las orquestaciones de Mayra implican una planeación con intenciones y consideraciones mucho más variadas que las referidas en Drijvers et al. (2010). Por ejemplo, mientras que la orquestación-demo-técnica es la más frecuentemente observada en el estudio de Drijvers et al. (2010), en las clases de Mayra no se presenta este tipo de orquestación.

Pratt et al. (2011) señala que la inmersión en el uso de tecnología ayuda a los profesores a replantear el papel que las TD juegan en promover la comprensión de conceptos y métodos estadísticos. Mayra, por su experiencia propia, generó actividades que reflejan un mayor aprovechamiento de la tecnología en el aula. En este documento mostramos una manera novedosa de utilizar el lenguaje de programación R en la enseñanza de la estadística, en la cual los alumnos tienen un rol mucho más activo en la construcción de su conocimiento.

HIGH SCHOOL STUDENTS' MISCONCEPTIONS ABOUT SIGNIFICANCE TESTING WITH A REPEATED SAMPLING APPROACH

DIFICULTADES DE ESTUDIANTES DE BACHILLERATO SOBRE PRUEBAS DE SIGNIFICACIÓN A TRAVÉS DE UN ENFOQUE DE MUESTREO REPETIDO

In this paper, we address the following questions: What misconceptions do high school students exhibit in their first encounter with significance test problems through a repeated sampling approach? Which theory or framework could explain the presence and features of such patterns? With brief prior instruction on the use of Fathom software to generate empirical sampling distributions, 18 pairs of high school students participated in a series of lessons involving four significance test problems addressed by a repeated sampling approach. Based on the analysis of students' responses to the first problem, we identified four misconceptions about significance testing. A framework to explain the misconceptions is conjectured.

Keywords: Misconceptions, significance testing, empirical sampling distribution (ESD), verificationism, skepticism.

Sampling and inference are fundamental statistical ideas (Burril & Biehler, 2011). Statistical inference involves using a sample to make a claim about the population from which it has been drawn, quantifying the uncertainty in the process, then making decisions based on the information it provides. It arises from the necessity to evaluate experimental outcomes in any scientific domain. To fulfill this purpose, statistical inference relies on mathematical knowledge and thinking. This implies that the notions of sampling and inference are important components of statistical literacy and should be considered as candidates for compulsory topics in mathematics education curricula (Watson, 2006). However, the topic of statistical inference is usually not introduced until the university level, where it is compressed in an introductory course on statistics and probability. This is a concern, since teaching the wide scope of concepts that constitute statistical inference in just one semester often leads to poor understanding by students, who may only retain a set of terms and procedures.

A potential solution to this problem is to introduce the notion of statistical inference at different levels of education, with the degree of formality adapted to each level. Recent calls from the statistics education community to promote and advance the understanding of statistical inference (Pratt & Ainley, 2008) have spurred interest in exploring ways to introduce concepts related to statistical inference at the primary and high school levels. This research trend is consistent with the idea that Heitele, invoking Bruner, formulated 45 years ago: "…that any subject can be taught effectively in some intellectually honest form to any child at any stage of development" and that fundamental ideas "differ on the various cognitive levels, not in a structural way, but only by their linguistic form and their levels of elaboration" (1975, p. 187). Additionally, the rapid development of technological tools

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

in education have allowed for new ways of representing both mathematical and statistical ideas that make these ideas more accessible at pre-university levels (Biehler, Ben-Zvi, Baker, Makar, 2013).

The notion of significance testing is a critical element in the understanding of statistical inference, and is an application of an important principle of scientific thinking: "one does not have evidence for a claim if nothing has been done to rule out ways the claim may be false" (Mayo, 2018, p. 5). However, the idea of validating the outcomes of scientific research by searching for ways to demonstrate the falseness of the claims is contrary to intuition: According to Fischbein (1987), people's natural inclination is to look for confirmatory evidence. Given the importance of and difficulties in understanding the concept of significance testing, therefore, we contend that this concept should be introduced at the high school level, when students are capable of reasoning in a formal way. By developing an understanding of some pertinent components of significance testing earlier in their mathematical education, we propose that students would be in a better position to tackle problems involving statistical inference at the university and professional levels. Accordingly, we formulated the following hypotheses: 1) It is possible to design and implement a series of lessons for high school students that involve reasoning with and about significance testing. 2) The use of technological resources is key to the implementation of the former. 3) The understanding gained about students' reasoning in response to such problems may point to a better teaching approach for significance testing. Using these hypotheses, we formulated our research question:

What misconceptions do high school students exhibit in their first encounter with significance test problems through a repeated sampling approach using computational simulation? What intuitions may explain these misconceptions?

We are motivated to investigate students' reasoning about significance testing by the fact that on the one hand, significance tests are extensively used in a wide range of scientific research domains to evaluate the results of experimental outcomes (Haig 2016; Winch & Campbell, 1970), while on the other hand, many students and researchers have a tendency to misunderstand the objective of significance tests and to misuse the associated concepts and results (Cohen, 1994; Goodman, 2008; Morrison & Henkel, 1997). This tension has given rise to two contrasting reactions to the use of significance tests in experimental research: a) The development and refinement of concepts embedded in the test, as well as the ways they are used in experimental procedures (Mayo, 2018); b) a strong opposition to the use of significance tests and calling for their retirement from experimental research practices (Amrhein, Greenland, & McShane, 2019). This situation points to the need for a better understanding of the ways in which students reason about significance testing.

Background

One of the considerable challenges in the teaching of statistics at the college level is enabling students to rationally interpret the system of ideas that constitute significance testing (Castro-Sotos et al., 2009; Vallecillos, 1996). Batanero (2000) identified three main concepts involved in significance testing that students often misunderstand: 1) the nature of the test, 2) the nature of the *p*-value, and 3) the significance level. In their own study, Castro-Sotos et al. (2009) described two frequent misconceptions about significance testing: 1) it is viewed as a mathematical proof that establishes the truth of one of the two hypotheses, and 2) it is viewed as a probabilistic proof by contradiction: that is, if the null hypothesis is rejected, the *p*-value is the probability of making the wrong decision. Castro-Sotos et al. (2009) also detailed several misconceptions about the concepts of the *p*-value and significance level, including: a) the *p*-value is the inverse of the normative definition (the *p*-value represents the probability of the hypothesis being true, given the outcome of the sample); b) the *p*-value is the probability of a simple event (the *p*-value represents the probability of obtaining the observed outcome); and c) the *p*-value is the probability of the null or alternative hypothesis being true.

Lane-Getaz (2017) explored how early education may decrease the incorrect use (and possible abuse) of significance testing. The researcher examined learning outcomes related to statistical inference for social science students in an introductory course on statistics that incorporated randomization and simulation tasks. The study demonstrated progress made by the students during the course and highlighted several difficulties and misconceptions that could be tackled through instruction.

Other than the previous study, however, the following have not received much attention in the research on students' understandings and misunderstandings about significance testing: 1) students' reasoning about significance testing in the context of a classroom intervention, and 2) the use of digital resources to generate empirical sampling distributions (ESDs) as a support for learning about significance testing. Both are addressed in our current experiment.

Conceptual framework

Reasoning is any process whose objective is to determine the validity or plausibility of a proposition or result by means of certain premises (data or propositions). Mathematical reasoning, in a broad sense, can be elaborated at different levels of formality, given that premises can range from intuitions to firmly instituted axioms, and derivation processes can range from persuasive argumentations (examples, induction, analogies) to well-established mathematical and logical procedures.

Reasoning is accompanied by *sense-making*, which involves linking a new proposition or unexpected result to previous knowledge or beliefs held by the learner (Shaughnessy et al., 2009). Sense-making is supported by intuition which, according to Fischbein, "…expresses the fundamental need of human beings to avoid uncertainty" (1987, p. 28). Doubtful information and uncertain propositions prevent actions and reasoning. Intuitions are necessary to act and reason because they are considered to be true by the subject. While intuitions derived from perceptions of reality are generally correct, "mental representations, hypothetical ideas and solutions may be biased, distorted, incomplete, vague or totally wrong. To believe, however, at least temporarily, in such mental productions, a certain excess of confidence is required" (p. 28). In summary, in the reasoning process, people need to start from certainties, which is why they tend to trust their intuitions (beliefs or conceptions) more than what would be justified under objective evaluation. According to Fischbein, the excess of confidence in intuitions is a mechanism that allows reasoning to be carried out, but at the expense of the risk of spurious conclusions. Fischbein goes on to explain that people's cognitive mechanism for acting and reasoning in certain environments consists of producing a coherent structure (Gestalt) while preserving "facts and segments which fit together and to discard those which may disturb the unity" (p. 35). In particular, drawing from the psychology literature, Fischbein explains that people manifest a bias to confirmation and are reluctant to seek non-confirmatory evidence; when it does appear, they tend to ignore it. They also tend to not consider other plausible scenarios nor that the very same evidence can also account for alternative hypothesis. We can add that hypothetical deductive reasoning is a formal expression of the need to start from (assumed) certainties in a scientific and controlled manner. However, such reasoning requires maturity and practice, given that it does not usually appear in a spontaneous way in specific situations, even when subjects have reached the formal operational stage of development proposed by Piaget (Schmid-Kitsikis, 1983).

The logic of significance testing requires overcoming the cognitive tendencies described by Fischbein. Indeed, a null hypothesis is a hypothesis that one tries to reject, rather than confirm, as is often believed: for Fisher (…), the null hypothesis is "the hypothesis that the phenomenon to be demonstrated is in fact absent." An experimental outcome is deemed significant when the null hypothesis is rejected, and not significant when the null hypothesis is not rejected. A statistic is a function that assigns a number to each sample of a given size. In the simplest case (the one used in this study), this may be the proportion of an attribute in the sample. Significance testing is made possible by the ability to model the sampling distribution of the statistic under the assumption that the null hypothesis is true. It should be noted that in order to understand the role of the sampling distribution, one must apply hypothetical deductive reasoning. Once a sample has been drawn from the population and a statistic is calculated, a probability of the given event occurring or a more extreme value is computed, under the assumption that the null hypothesis is true. This probability is known as *p*-value. If the *p*-value is low (generally <5%), the null hypothesis is rejected, and the result is deemed significant.

A repeated sampling technique using software and random simulations allows students to construct an approximation to the sampling distribution of the statistic, which is usually referred to as an empirical sampling distribution (ESD). To simplify presentation, we define the following terminology as related to ESDs: assume that N samples of size k are simulated with H_0:P=θ, where θ is the probability of success. In this instance, success means selecting an element from the population that presents the feature R, and θ represents the proportion of elements of the population with the feature R. We define the statistic X as the "number of success cases in the sample" and use the notation ESD(N,k,P=θ) to denote an ESD of that statistic.

Method

Participants and data. The following results arise from data corresponding to responses provided by a group of 36 high school students to the first of four activities in a series of lessons on significance testing. Students were arranged in 18 pairs throughout the intervention, each with access to a computer equipped with Fathom. At the time of the intervention, the students were enrolled in their second year of high school (16-17 years old) and had not previously taken a course on statistics or probability. Activities were selected from statistics textbooks and then modified to align with the participants' school level and the repeated sampling approach. While solving the problems, each pair wrote a report that detailed their analysis and solution to the task; these reports constitute our main data source.

Instruments. The first problem of the series of lessons appears below; Table 1 summarizes the statistical data and the solution to the task.

> Coca-Cola's advertising campaign claims that the majority of people (more than 50%) prefer Coca-Cola to Pepsi. To corroborate this, an experiment was conducted, where 60 randomly-selected participants tasted both beverages in a blind test. Thirty-five of the participants preferred the Coca-Cola. Based on these results, would you accept the hypothesis that more than 50% of people prefer Coca-Cola to Pepsi?

Table 1. Data and solution to the first problem

Null Hypothesis (H_0)	N	Rejection freq.	*p–value*	Conclusion
$P = 0.50$	60	$X \geq 37$	$p = 0.126$	H_0 is not rejected

The intervention began with an introductory session aimed to enable students to use Fathom to generate ESDs. This was followed by a series of four lessons, each of which featured a problem involving significance testing. From the second lesson on, the lessons unfolded as follows: First, the instructor facilitated a discussion about students' solutions to the previous problem, inviting students to explain the motives and rationales behind their procedures; second, students were tasked with a new problem that gave them the opportunity to apply newly-gained skills and understandings about significance testing. Students worked on the problems in self-selected pairs and described their solutions on a worksheet. During this time, the instructor's role mainly involved posing questions to stimulate inquiry and helping students overcome technical difficulties (not to provide normatively correct answers).

We rely on principles of the grounded theory methodology (Birks & Mills, 2011; Glaser & Strauss, 1967/2008) for coding students' answers to the problems. This is a general research methodology in the social sciences (Holton, 2008) that involves constructing theories or frameworks through the gathering and analysis of data (as opposed to analyzing the data using an existing theoretical framework). As previously stated, the data analyzed in this study were students' responses to significance test problems. These responses were digitally transcribed, then analyzed in order to generate a set of codes and categories. Several misconceptions were identified using this procedure.

Results

Students' responses were analyzed and coded in three general categories: reasoning, hypothesis, and conclusion. In this report, we will only examine the four misconceptions identified in the first category (reasoning) exhibited in responses to the first problem. A more thorough analysis of the data can be found in García (2017); however, we consider the following evidence sufficient in exemplifying the identified misconceptions.

It should be noted that the descriptions of the emergent patterns use the authors' language and not necessarily the terminology students actually used when describing these ideas. Each identified misconception is a result of the constant comparative method, which allows for abstraction of the subtle differences in students' answers.

Misconception 1: *Majority in the ESD*. Students generate an ESD (500, 60, P=0.50, or similar) and identify the number of samples in which the statistic X takes a value greater than 30. If this number is greater than 250 (N/2), the null hypothesis is rejected, and if it is lower than 250 (N/2), then it is not. It should be noted that this procedure ignores information given by the sample and the significance level. This misconception is consistent with the belief that the ESD represents the population, or an approximation of the population. This misconception was the most frequent in the data, identified in 13 out of 18 responses, and can be exemplified by R6's answer:

> …we considered surveys in which we had at least 31 favorable cases for Coca-Cola, which was a total of 233 surveys… while surveys with 30 favorable cases, that is, 50% or less, represented 267 surveys… a quantity greater than 50%.

The pair concluded that it is not true that there is a greater preference to Coca-Cola over Pepsi and included Figure 1a in their response.

Figure 1: a) Majority in the ESD (pair R6); b) Mode (pair R13)

Misconception 2: *Mode*. Students generate an ESD (500, 60, P=0.50) and identify its mode. If this value is greater than 30, the null hypothesis is rejected, and if it is equal to or lower than 30, it is not. As in the previous case, this reasoning ignores both the observed outcome and the significance level, and is also compatible with the belief that the ESD provides some information about the probability of the null hypothesis being true: In other words, it is assumed that $p = frequency(H)$, where H is an independent variable. This misconception emerged in three responses. An example is provided by R13:

> …our most frequent value in the surveys was 28 people (out of 60) that liked Coca-Cola more, so we can see there are less than 50% that liked Coca-Cola the most.

The pair concluded that Coca-Cola's advertised claim is false and supported their argument with Figure 1b).

Misconception 3: ***Majority in the sample***. This is the only misconception in which students completely ignore the ESD and rely exclusively on the observed outcome (35/60 that preferred Coca-Cola). According to this line of reasoning, if the proportion of favorable to unfavorable outcomes is greater than 0.5, the null hypothesis is rejected, otherwise it is not. R2's response exhibits this misconception:

> …we can say that a majority is 51% or more, and the experiment's result showed that 35 out of 60 people preferred Coca-Cola, which is 59% of the total [(59% x 60) = 35.4]. Thus, we can conclude that they are not wrong in their conclusion.

The pair concluded that Coca-Cola's advertised claim is true, but unlike other students who participated in previous explorations of the task (Garcia & Sanchez, 2014), these students were unable to apply the ESD results generated with the software to support their argument.

Misconception 4. ***Extreme hypothesis***. In this case, $P > 0.5$ is taken to be the alternative hypothesis. Students arbitrarily establish a margin of error, M (e.g., 5% or 10%). Then, they pick a value for P such that $0.5 - M < P < 0.5$ and generate an ESD (500, 60, $P \neq 0.50$) to observe the values within the range of this distribution. If the value of the statistic at hand is in this range (which is the case for this problem), then the hypothesis $P > 0.5$ gets rejected. R10's response demonstrates this line of reasoning:

> …in general, we must take a greater number of surveys of the population so we can conclude that indeed more than 50% like or prefer Coca-Cola, because in these surveys there must be a range of around 10 values more and 10 values less around the expected value […] in the simulated survey, despite the percentage being lower than 50% (because P = 44%) and is expected to have a value of 26, we obtain results that go from 16 (the lowest value of X with a non-zero frequency) to 38 (the highest value of X with a non-zero frequency), from which we can see a greater value (for X) than in the original problem, which is why the 35 do not assure that most people like Coca-Cola.

As previously stated, these responses were provided to the first of the four problems in the series of lessons. It should be noted that the process of addressing students' ideas and solutions may have allowed them to gradually incorporate some previously absent but significant elements involved in significance testing, such as using all of the appropriate facts in the problem and determining if the observed outcome could be labeled as an outlier or not. Nevertheless, students were ultimately unable to provide solutions to this problem that were consistent with the logic of significance testing.

Conclusions and discussion

We propose an explanation based on Fischbein's (1987) theory about intuition for the first three observed misconceptions. According to Fischbein, intuition is related to people's tendency to avoid uncertainty and to look for confirmatory evidence. This idea, coupled with the traditional focus on proof in mathematics teaching, led us to propose a category in the context of our experiment called *naïve verificationism*, which consists of the belief that the objective of a significance test is to demonstrate the veracity of the null hypothesis. *Critical verificationism*, on the other hand, consists of the belief that the objective of the test is to compute the probability of the null hypothesis being true (or false). However, as students continue to participate in discussions about the problems and analyze solution strategies, they develop a kind of skepticism, which involves recognizing that it isn't possible to conclusively verify any hypothesis based on the evidence provided by a sample.

According to Fischbein (1987), people try to produce coherent structural schemata in which they can integrate their intuitions (certainties), beliefs (theories), and observations (evidence). Such structural schemata underpin the reasoning process—justifying the solution of a problem or explaining a phenomenon. In this sense, the misconception of mistaking an ESD with the population (or its approximation; Garfield & Ben-Zvi, 2008) is compatible with naïve verificationism, given that if the sampling distribution represents the population, then analyzing the ESD alone would be enough to verify the validity of the hypothesis. We interpret Misconception 1 (Majority in the ESD) as a manifestation of students' efforts to align the ESD, a new concept for our participants, to their expectations of verifying the null hypothesis. In a similar way, another way to create a structural schema is to believe that the ESD is a distribution in which each value for the statistic is taken as a possible hypothesis, with the frequency of each hypothesis (statistic) allowing for the computation of the probability of the truth (or falsehood) for each one; such reasoning demonstrates critical verificationism. The mode of such a conceived distribution would be the most likely hypothesis (statistic), and this is consistent with Misconception 2 (Comparing the mode of the ESD with the null hypothesis).

In Misconceptions 1 and 2, students do not assign a specific role to the information provided by the sample, given that their conception of the ESD makes this task an unnecessary one. These results show that the intended purpose and meaning of an ESD is not clear to students, despite their participation in activities in which they produced and interacted with different ESD's using physical and computational simulations.

In Misconception 3 (Majority in the sample), students do not ignore sample results as in previous cases, but create a simpler structural schema: they assume that because the information provided by the sample is the only information available when making a decision, it alone contains the key to the solution of the problem. Therefore, it is assumed that the proportion of favorable to unfavorable outcomes in the sample closely mirrors the corresponding proportion of the population. In this misconception, the information provided by the ESD is completely ignored, and therefore demonstrates naive verificationism. Shaughnessy (1992, p. 478) referred to two false conceptions that are related to this misconception: "people inadequately believe that there's no variability in the real world" and that "people often have an unjustified overconfidence in small samples." Nickerson (2000, p. 254) and, in a similar way, Castro-Sotos et al. (2009) report that one of the most common beliefs about significance tests among researchers and students is that "by rejecting the null hypothesis, a theory that predicts the falseness of the null hypothesis is established." Such a claim is compatible with naïve verificationism, because it responds to a desire of establishing the falseness of an hypothesis. This particular misconception emerged only in the first problem and was abandoned as students gained experience in generating and analyzing ESDs.

Furthermore, in Misconception 4 (Extreme hypotheses), students incorporate the idea of a margin of error by defining an interval on one side of the null hypothesis, with the opposite side representing the alternative hypothesis. An extreme hypothesis is selected in this interval. If the distribution generated by the extreme hypothesis captures the value of the statistic, there is no reason to reject the null hypothesis. That is, if the value of the statistic (in this case, 35) can plausibly occur in a more extreme ESD ($P < 0.5$), then the event is also plausibly occurring for the null hypothesis ($P = 0.5$) as well, and the null hypothesis should therefore not be rejected. In using such reasoning, students exhibit intuitions that are partially aligned with the logic of significance testing: for example, the idea of "taking more extreme values" is used when defining a p-value, and considering "what would happen if the hypothesis was…" demonstrates hypothetical-deductive reasoning that is used in the establishment of the hypothesis. However, such intuitions are not appropriately applied. An important feature of this line of reasoning is that it relies on an arbitrary, but well-intended criterion:

the null hypothesis is rejected when the statistic is not contained in a certain range of the simulated ESD.

In summary, the misconceptions that students exhibited in their solutions to the first problem correspond to the intuitive idea that the objective of a significance test is to verify the null hypothesis, or to estimate the probability that it is true. It is likely that a tendency to verificationism also explains some of the misunderstandings and misuses of ESDs evidenced even by experimented learners. This is why it is critical in the teaching of statistics to enable students to develop alternative reasoning schemes—that is, schemes based in reasonable skepticism.

FUNDAMENTAL STATISTICAL IDEAS IN PRIMARY, SECONDARY AND HIGH SCHOOL MEXICAN CURRICULUM: REFLECTIONS FROM THE INTERNATIONAL PERSPECTIVE

IDEAS FUNDAMENTALES DE ESTADÍSTICA EN PRIMARIA, SECUNDARIA Y BACHILLERATO EN EL CURRICULO MEXICANO: REFLEXIONES DESDE LA PERSPECTIVA INTERNACIONAL

Santiago Inzunza
Universidad Autónoma de Sinaloa
sinzunza@uas.edu.mx

In this article we analyze the fundamental ideas of statistics in the Mexican curriculum of basic and high school education, with the purpose of establishing relationships with some curricula and recommendations of organizations that promote statistical education. The results show that statistics are present from kindergarten to high school, as established by international recommendations; however, statistical inference is absent from the secondary school curriculum, including high school. The methodology of teaching in basic education gives importance to real contexts and to the posing of statistical questions to respond with the data, but in high school there is a greater emphasis on statistical procedures. Technology for data analysis and simulation is practically absent in the curriculum of all levels.

Keywords: Probability, data analysis and statistics, curriculum, technology

Study objectives

In the last three decades, statistics has had the greatest growth in the mathematics curriculum of basic education and high school in many countries, due to its importance as a methodological tool, but also due to the relevance of literacy and statistical thinking in modern society. In this way, organizations and researchers that promote statistics education have issued recommendations on the fundamental statistical ideas that should be in the curricula, as well as the teaching perspectives more according with the needs of literacy and statistical thinking of today's society.

In this context, it is pertinent to analyze the status and significance of statistics in pre-university educational levels in Mexico. It is interesting to analyze contents and didactic orientations, with the purpose of characterizing their teaching and contrasting with the recommendations and trends of the international curriculum.

Background

Holmes (2003) points out that in England since 1961, contents of data and chance were introduced in high school curriculum, in the late 1960s were extended to primary and secondary school. In the 1980s and 1990s the Curriculum and Evaluation Standards for School Mathematics (NCTM, 1989) and Principles and Standards for School Mathematics (NCTM 2000) were published in the United States, curricular documents in which data Analysis and Probability appears as an integral part of the Mathematics curriculum. Guidelines for Assessment and Instruction in Statistics Education (GAISE) (Franklin et al., 2005) was published in 2005 as a framework for statistics education from kindergarten to high school. Meanwhile, in 1992 in New Zealand, Statistics and Probability were included for the first time as a teaching area at all educational levels; in 2007 three main statistical areas were included in the eight levels of pre-university education: statistical research, statistical literacy and probability.

In Mexico, the Statistics and Probability appear for the first time in secondary education curriculum in 1975, and in the case of some high school programs since the end of the 1970s. The high school

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

curriculum consists of three components formative (basic, propaedeutic and professional). Statistics is part of the propaedeutic component, that is, it is not part of the basic table of subjects, but most educational institutions integrate at least one course of Statistics and Probability into their curriculum, either optional or compulsory.

Theoretical perspective

Statistical fundamental statistical ideas

In the search to define a set of fundamental statistics and probability ideas that must be learned by students before finishing high school, Burrill & Biehler (2011) propose the following themes:

1. Data.
2. Variability.
3. Distribution.
4. Representations.
5. Association and modeling between two variables.
6. Probability models.
7. Sampling and inference.

Guidelines for Evaluation and Instruction in Statistical Education

The Guidelines for Assessment and Instruction in Statistics Education (GAISE Report) (Franklin, et al., 2005) proposes a central teaching model based on solving statistical problems as a four-component research process: posing questions to answer with the data, collect the data, analyze the data and interpret results to answer the questions. The GAISE Report visualizes probability as a tool for statistics; in this sense, it is considered that the relationship between classical and frequency approach should be explored to compare theoretical probabilities and observed frequencies. Use probability to understand randomization in statistical work in the case of sampling and design of experiments.

Methodology

The methodology we have used is documentary in nature (Bardin, 2006). The sources of information were the most current official curricular documents. The contents, expected learning and didactic guidelines were analyzed to contrast them with the same entities proposed by Burrill & Biehler (2011) and Franklin et al., (2005). In each curriculum document, the presence of the fundamental ideas was reviewed in detail; Likewise, statements that inform about the contents, expected learning and didactic guidelines were analyzed in the text.

Results and Discussion

The study of statistics appears from the kindergarten, while the study of probability begins in the fifth grade of primary school. In basic education, both areas are included as themes in the mathematics subject, while at the high school are part of a subject by itself, generally called Probability and Statistics, or simply Statistics. In the lower grades of primary education, the importance to distinguish particular questions (referring to an element) from statistical questions (referring to a group) is pointed out. These teaching guidelines are in accordance with the recommendations of the GAISE report for the primary level. In grades 5 and 6, the notions of qualitative and quantitative variables are introduced, and the calculation of descriptive measures of center and dispersion of the data (mode, mean and range) appears for the first time. The guidelines suggest collecting data from the classroom and school context, and asking questions that require the use of such descriptive measures. The study of probability begins in the fifth year of primary school, beginning by the distinction of random and non-random experience, the idea of sample space and the determination of its elements through the use of tree diagrams. The expected learning consists of identifying chance games and carrying out experiments to record the results in tables of relative and absolute frequencies (frequency approach to probability).

Meanwhile in high school, the expected learnings in statistics emphasize again the collection and recording of data, and representations for the organization and interpretation of data; in this way, in addition to the bar and circular diagrams, histograms, frequency polygons and line graphs (time series) are considered. In the calculation of descriptive measures of the data, the mean, median, mode, range and mean deviation are considered. The instructional guidelines emphasize collecting data from school contexts such as the classroom or issues of interest to students that appear in the media. Teachers are directed to construct the graphs manually so that students understand how they are constructed. Instead, the use of spreadsheet to construct frequency histograms and polygons is suggested in an isolated and superficial way. Regarding probability, students are expected to carry out random experiments and record results as an approximation to frequency probability. It is further proposed that they determine the theoretical probability of a random experiment and of two mutually exclusive events using the rules of addition and multiplying probabilities.

Chance games and experiments are proposed in the didactic orientations where both are contrasted. In the second grade, the use of simulation of random phenomena by means of some software is proposed only as a recommendation, which is in full agreement with the recommendations of various authors and the international curriculum (Chaput, Girard and Henry, 2011; Burrill & Biehler, 2011).

In high school there is not unique curriculum; however, from 2008 there is a proposal for an official curriculum that we will take as a reference for the analysis. The course of Statistics and Probability I offers a review and deepening of the contents of the secondary school; the variance and standard deviation, quartiles, deciles and percentiles are added. An introduction to two-variable data analysis (bivariate data), which includes scatterplots, linear correlation, and simple linear regression. This topic is highly recommended in the GAISE Project and is one of the fundamental statistical ideas for high school (Burrill and Biehler, 2011) for its importance in developing multivariate thinking and prediction theory. In some countries such as Costa Rica and Chile this subject does not yet appear in the high school curriculum. In the course of Statistics and Probability II, the topics of sets, counting techniques and mutually exclusive events appear before calculating the theoretical and frequency probability; Bernoulli, Binomial, Normal and Poisson probability distributions and Bayes' theorem are included. Statistical inference is not part of the official curriculum, it is only considered in the case of CCH (a particular high school system offered by the National University) optionally in the last semester.

Regarding the use of technology in the statistics and probability teaching, there are superficial references in the all levels of Mexican curriculum. Its use is suggested for the simulation of random phenomena as a means of estimating theoretical probabilities, but there are no references for its use in the analysis and exploration of data, a situation that is widely recommended in the international recommendations and curricula of New Zealand, Spain, United States and other countries.

Conclusions

The study of the data is present from kindergarten to the high school, while the study of chance begins in the fifth grade of primary education, which is very similar to the international curriculum, thus claiming that the statistics and probability they have an important status in the education of citizens. However, there are some differences in some levels, particularly in the high school, where the absence of statistical inference in the official curriculum, -widely recommended in the international curriculum-, is observed.

The data collection, organization and representation of data, and descriptive measures of the data, constitute the backbone of the statistical content throughout all basic education and high school. Data collection techniques (surveys, observation, interviews, information consultation) are common at all levels, but increase in complexity in high school with a general description of random sampling methods and not random.

In the same way, graphical representations evolve from simple pictograms in kindergarten to bar and circle diagrams in primary school, to histograms, frequency polygons, and line graphs to visualize quantitative data. However, stem and leaf plots, box plots, and dot plots are absent in the curriculum, which are common in curricula from other countries. Descriptive measures begin with calculating frequencies in kindergarten, calculating mode in primary, and calculating mean, mean, mode, and mean deviation in high school, to expand standard deviation, variance, and correlation in high school.

For its part, probability in primary school begins with the study of notions of chance through simple random experiments and calculation of the frequencies of the results. In secondary education, the classical approach is introduced and its contrast with the frequency approach is promoted, this is an aspect highly recommended in the international curriculum. However, in high school that link between the two approaches is not encouraged and more emphasis is placed on the classical approach using combinatorial techniques.

Regarding teaching methodology, we observe a uniform trend in basic education, suggesting the use of real and meaningful contexts for students and the posing of statistical questions that must be answered with the data, which represents, in our opinion, an innovative trend, according to the perspective of development of statistical thinking. This trend is interrupted in high school, which focuses more attention on later stages of the statistical research cycle, such as data analysis.

The use of computer technology in data analysis and the simulation of random phenomena only has superficial references at all educational levels, which constitutes the greatest difference with the international curriculum. This is undoubtedly a pending subject, as is the absence of statistical inference in high school, which must be improved in the Mexican curriculum.

IDEAS FUNDAMENTALES DE ESTADÍSTICA EN PRIMARIA, SECUNDARIA Y BACHILLERATO EN EL CURRICULO MEXICANO: REFLEXIONES DESDE LA PERSPECTIVA INTERNACIONAL

FUNDAMENTAL STATISTICAL IDEAS IN PRIMARY, SECONDARY AND HIGH SCHOOL MEXICAN CURRICULUM: REFLECTIONS FROM INTERNATIONAL PERSPECTIVE

Santiago Inzunza
Universidad Autónoma de Sinaloa
sinzunza@uas.edu.mx

En este artículo analizamos las ideas fundamentales de estadística en el currículo mexicano de educación básica y bachillerato, con el propósito de establecer relaciones con algunos currículos y recomendaciones de organismos que promueven la educación estadística. Los resultados muestran que la estadística está presente desde preescolar hasta bachillerato, tal como lo establecen recomendaciones internacionales; sin embargo, la inferencia estadistica está ausente del currículo de secundaria, incluso del bachillerato. La metodología de enseñanza en educación básica otorga importancia a contextos reales y al planteamiento de preguntas estadísticas para responder con los datos, pero en bachillerato se hace mayor énfasis en el cálculo estadístico. La tecnología para análisis de datos y simulación está prácticamente ausente en el currículo de todos los niveles.

Palabras clave: Probabilidad, análisis de datos y estadística, currículum, tecnología

Objetivos del estudio

En las últimas tres décadas, la estadística ha tenido el mayor crecimiento en el currículo de matemáticas de la educación básica y bachillerato de diversos países, debido a su importancia como herramienta metodológica, pero también por la relevancia que tiene la cultura y el pensamiento estadístico en la sociedad moderna. De tal forma, organismos e investigadores que promueven la educación estadística han emitido recomendaciones sobre los fundamentos y las ideas centrales de la estadística que deben estar en los currículos de cada nivel educativo, así como las perspectivas de enseñanza más acordes a las necesidades de alfabetización y pensamiento estadístico de la sociedad actual.

En este contexto, es pertinente analizar el estatus y significado que tiene la estadística en los niveles educativos pre-universitarios en México. Interesa analizar contenidos y orientaciones didácticas, con el propósito de caracterizar su enseñanza y hacer un contraste con las recomendaciones y la tendencia del currículo internacional.

Antecedentes

Holmes (2003) señala que, en Inglaterra, desde 1961 se introdujeron contenidos relacionados con datos y azar en cursos de bachillerato, a finales de la década de 1960, estos contenidos fueron extendidos a la escuela primaria y secundaria inglesa. En la década de 1980 y 1990 se publican en los Estados Unidos los Curriculum and Evaluation Standards for School Mathematics (NCTM, 1989) y Principles and Standards for School Mathematics (NCTM 2000), documentos curriculares en los que el eje de Análisis de Datos y Probabilidad aparece como parte integral del currículum de matemáticas. En 2005 se publica Guidelines for Assessment and Instruction in Statistics *Education* (GAISE Report) (Franklin et al., 2005), como un marco para la educación estadística desde preescolar hasta el bachillerato. Mientras tanto, en 1992 en Nueva Zelanda se incluye por primera vez la estadística y probabilidad como área de enseñanza en todos los niveles educativos. En 2007 se incluyen tres grandes líneas de contenido estadístico en los ocho niveles de la educación preuniversitaria: investigación estadística, cultura estadística y probabilidad.

En México, aparecen contenidos sobre estadística y probabilidad por primera vez en los programas de estudio de educación secundaria en 1975, y en el caso de algunos programas del nivel medio superior desde finales de la década de 1970. El currículo de bachillerato consta de tres componentes formativas (básica, propedéutica y profesional). La estadística es parte de la componente propedéutica, es decir, no forma parte del cuadro básico de materias, pero con base en su autonomía curricular, la mayoría de las instituciones educativas integran al menos un curso de estadística y probabilidad en su currículo, ya sea de manera optativa u obligatoria.

Perspectiva teórica

Ideas estadísticas fundamentales de estadística

En la búsqueda por definir un conjunto de ideas fundamentales de estadística y probabilidad que deben ser aprendidas por los estudiantes antes de concluir el bachillerato, Burrill & Biehler (2011) proponen las siguientes:

1. Datos.
2. Variabilidad.
3. Distribución.
4. Representaciones.
5. Asociación y modelación entre dos variables.
6. Modelos de probabilidad.
7. Muestreo e inferencia.

Lineamientos para la Evaluación e Instrucción en Educación Estadística

El reporte Guidelines for Assessment and Instruction in Statistics Education (GAISE) (Franklin, et al., 2005) propone un modelo central de enseñanza basado en la resolución de problemas estadísticos como un proceso investigativo de cuatro componentes: formular preguntas para responder con los datos, recolectar los datos, analizar los datos e interpretar resultados para responder las preguntas planteadas. En cuanto al enfoque de enseñanza y el contenido de probabilidad en el currículo, el reporte GAISE visualiza a la probabilidad como una herramienta para la estadística. En este sentido, se considera que se debe explorar la relación entre enfoque clásico y frecuencial para comparar probabilidades teóricas y frecuencias observadas. Usar la probabilidad para comprender la aleatorización en el trabajo estadístico en el caso del muestreo y diseño de experimentos.

Metodología

La metodología que hemos utilizado es de carácter documental (Bardin, 2006). Las fuentes de información fueron los documentos curriculares oficiales más actuales. Se analizaron los contenidos, aprendizajes esperados y orientaciones didácticas para contrastarlos con los mismos entes que proponen Burrill & Biehler (2011) y Franklin et al., (2005). En cada documento curricular se revisó con detalle la presencia de las ideas fundamentales; asimismo se analizaron en el texto, enunciados y declaraciones que informan sobre los contenidos, aprendizajes esperados y orientaciones didácticas.

Resultados y discusión

El estudio de la estadística aparece desde el nivel preescolar, mientras que el estudio de la probabilidad inicia en quinto grado de primaria. En la educación básica, ambos contenidos se incluyen como temas en la materia de matemáticas, mientras tanto en el nivel bachillerato los contenidos son parte de una materia por sí sola, denominada por lo general como Probabilidad y Estadística, o simplemente Estadística. En los grados inferiores de la educación primaria se señala la importancia de que los alumnos aprendan distinguir preguntas particulares (referidas a un elemento) de preguntas estadísticas (referidas a un grupo o colectivo). Estas orientaciones didácticas están concordancia con las recomendaciones del reporte GAISE para el nivel primaria. En los grados superiores se amplía el uso de representaciones de los datos a diagramas de barras y circulares. En los grados 5 y 6 se introducen las nociones de variables cualitativas y cuantitativas, y aparece por primera vez el cálculo de medidas descriptivas de centro y dispersión de los datos (moda, media y rango). En las orientaciones se sugiere la recolección de datos del contexto del salón de clases y la escuela, y el planteamiento de preguntas que requieren del uso de tales medidas descriptivas. El estudio de la probabilidad inicia en quinto año de primaria, se empieza introduciendo la distinción experiencia aleatoria y no aleatoria, la idea de espacio muestral y la determinación de sus elementos mediante el uso de diagramas de árbol. Los aprendizajes esperados consisten en identificar juegos en los que interviene el azar y realizar experimentos para registrar los resultados en tablas de frecuencias relativas y absolutas (enfoque frecuencial de la probabilidad).

Mientras tanto en secundaria, los aprendizajes esperados en estadística enfatizan de nuevo en la recolección y registros de datos, y un repertorio más amplio de representaciones para la organización e interpretación de los datos; de tal forma, además de los diagramas de barras y circulares, se contemplan los histogramas, polígonos de frecuencias y gráficas de línea (series de tiempo). En el cálculo de medidas descriptivas de los datos se contempla la media, mediana, moda, rango y la desviación media. Las orientaciones didácticas hacen hincapié en recopilar datos de contextos escolares como el salón de clases o asuntos de interés para los estudiantes que aparecen en los medios. Se orienta a los docentes a construir las gráficas manualmente para que los estudiantes comprendan cómo se construyen. En cambio, el uso de hoja de cálculo para construir histogramas y polígonos de frecuencia se sugiere de manera aislada y superficial.

En cuanto a probabilidad, se espera que los estudiantes realicen experimentos aleatorios y registren resultados como un acercamiento a la probabilidad frecuencial, se propone además que determinen la probabilidad teórica de un experimento aleatorio y de dos eventos mutuamente excluyentes utilizando las reglas de la suma y de la multiplicación de probabilidades. Se proponen juegos de azar en las orientaciones didácticas y experimentos donde se contrasten ambas. En segundo grado se propone el uso de simulación de fenómenos aleatorios mediante algún software solo como una recomendación, lo cual está en plena concordancia con las recomendaciones de diversos autores y el currículo internacional (Chaput, Girard y Henry, 2011; Burrill & Biehler, 2011).

En cuanto al nivel bachillerato no existen programas únicos a nivel nacional, sin embargo, a partir de 2008 hay una propuesta de currículo oficial por parte de la SEP que tomaremos como referencia para el análisis. El curso de Estadística y Probabilidad I ofrece un repaso y profundización de los contenidos de la escuela secundaria, se agregan la varianza y desviación estándar, cuartiles, deciles y percentiles. La novedad en este nivel es la introducción al análisis de datos de dos variables (datos bivariados), en el que se incluyen los diagramas de dispersión, correlación lineal y regresión lineal simple. Este tema es muy recomendado en el proyecto GAISE y es una de las ideas fundamentales de estadística para el bachillerato (Burrill y Biehler, 2011) por su importancia para desarrollar el pensamiento multivariado de los estudiantes e introducirlos a la teoría de la predicción. En algunos países como Costa Rica y Chile aún no aparece esta temática en el currículo.

En el curso de Estadística y Probabilidad II, aparecen los temas de conjuntos, técnicas de conteo y eventos mutuamente excluyentes previo al cálculo de la probabilidad teórica y frecuencial, distribuciones de probabilidad Bernoulli, Binomial. Normal y Poisson, probabilidad condicional y teorema de Bayes. La inferencia estadística no forma parte del currículo oficial definido por la SEP, solo es contemplada en el sistema de bachillerato CCH (sistema de bachillerato ofrecido por la Universidad Nacional), de manera opcional en el último semestre.

En cuanto al uso de tecnología en la enseñanza de la estadística y probabilidad en todos los niveles, apenas hay referencias superficiales en el currículo mexicano. Se sugiere su uso para la simulación de fenómenos aleatorios como un medio para estimar probabilidades teóricas, pero no hay referencias de su uso en el análisis y exploración de los datos, situación que es ampliamente recomendada en las recomendaciones internacionales y currículos de Nueva Zelanda, España y otros países.

Conclusiones

El estudio de los datos tiene presencia desde el nivel preescolar hasta el bachillerato, mientras que el estudio del azar inicia en el quinto grado de la educación primaria, lo cual guarda mucha similitud con el currículo internacional. Sin embargo, existen algunas diferencias en cuanto a lo contenidos en algunos niveles, particularmente en el bachillerato, donde se observa la ausencia de la inferencia estadística en el currículo oficial, ampliamente recomendada en el currículo internacional.

Los contenidos temáticos recolección de datos, organización y representación de datos, y medidas descriptivas de los datos, constituyen la comuna vertebral del contenido estadístico en educación básica y bachillerato. Las técnicas de recolección de los datos (encuestas, observación, entrevista, consulta de información) son comunes en todos los niveles, pero aumentan de complejidad en el bachillerato con una descripción general de los métodos de muestreo aleatorio y no aleatorio.

De la misma manera, las representaciones gráficas evolucionan desde los pictogramas sencillos en preescolar a diagrama de barras y circulares en la primaria, a histogramas, polígonos de frecuencia y gráficas de línea para visualizar datos cuantitativos. Sin embargo, se encuentran ausentes en el currículo gráficas de tallo y hoja, gráficas de caja y gráficas de puntos, que son comunes en currículos de otros países. Las medidas descriptivas inician con el cálculo de frecuencias en preescolar, cálculo de la moda en primaria, y el cálculo de la media, media, moda y desviación media en secundaria, para ampliar a la desviación estándar, varianza y la correlación en el bachillerato.

Por su parte, la probabilidad en la escuela primaria inicia con el estudio de nociones de azar a través de experimentos aleatorios sencillos y cálculo de frecuencias de los resultados. En la educación secundaria se introduce el enfoque clásico y se promueve su contraste con el enfoque frecuencial, un aspecto muy recomendado en el currículo internacional. Sin embargo, en el bachillerato esa liga entre ambos enfoques no es fomentada y se hace mayor énfasis en el enfoque clásico con uso de técnicas combinatorias.

En cuanto a la metodología de enseñanza observamos una tendencia uniforme en la educación básica, sugiriendo el uso de contextos reales y significativos para los estudiantes y el planteamiento de preguntas estadísticas que se deben responder con los datos, lo cual representa a nuestro juicio una tendencia innovadora y acorde con la perspectiva de desarrollo de pensamiento estadístico en los estudiantes. Esta tendencia es interrumpida en el bachillerato, que centra mas su atención en etapas posteriores del ciclo de investigación estadística, como es el análisis de los datos.

El uso de la tecnología computacional en el análisis de datos y la simulación de fenómenos aleatorios solo tiene referencias superficiales en todos los niveles educativos, lo que constituye la mayor diferencia con el currículo internacional. Sin duda esta es una asignatura pendiente, al igual que la ausencia de la inferencia estadística en el bachillerato, que se debe mejorar en el currículo mexicano.

REASONING ABOUT ASSOCIATION FOR CATEGORICAL DATA USING CONTINGENCY TABLES AND MOSAIC PLOTS

Sheri E. Johnson, Ph.D.
University of Georgia
sheri.johnson25@uga.edu

With the implementation of Common Core in most states, the pre-k-12 mathematics curriculum now contains a significant amount of probability and statistics, mainly situated in middle and secondary grades. Statistical association is a challenging concept, and secondary students are expected to use contingency tables to begin to reason about association of categorical variables. This requires proportional reasoning, which is a focus of middle grades mathematics and necessary for more advanced study but remains a struggle for even most adults. Researchers call for use of multiple representations to develop conceptual understanding, and I consider a traditional contingency table in addition to a mosaic plot to see how students reason through a series of tasks.

Keywords: Cognition, Data Analysis and Statistics, Representations and Visualization, Geometry and Geometrical and Spatial Thinking

Statistical skills develop over time and in order for all high school graduates to have statistical literacy, instruction should begin early and expand through middle and high school (Bargagliotti et al., 2020). Association can exist between variables that are quantitative, like a person's height in centimeters, as well as variables that are categorical, like a person's eye color. Association of two categorical variables is included in the eighth and ninth grade curriculum in most states. Statistical (in)dependence can be determined numerically or visually and it certainly requires proportional reasoning, which researchers have identified as a "major connecting idea" when reasoning with probability and statistics where it is important to help students make explicit connections between data and proportions (Watson & Shaughnessy, 2004).

When considering bivariate data that are quantitative, there are well developed and standard graphical methods to aid students in determining (in)dependence, namely the use of a scatterplot (Friendly, 1999). The widely accepted Cartesian plane serves as a structure to visualize the data and determine if a linear or other type of association might be present. When the data are categorical, a two-way contingency table is used, but a standard graphical display does not exist for considering association of categorical variables (Friendly, 1999). Bar graphs, either segmented or side by side are often used to display frequencies in contingency tables; however, a mosaic plot is a default display used in some statistical software. Researchers in Australia (Pfannkuch & Budgett, 2017) recently noted some promising results of students working with an interactive mosaic plot, which assisted students in appropriately applying proportional reasoning with problems dealing with probability, especially when considering independence. A mosaic plot is based on a unit square that is vertically divided in proportion to marginal frequencies of one variable and further divided into rectangular regions that are proportional in area to each of the joint frequencies (see Figure 1).

Mosaic plots are often non-numerical and can be used to understand what the displayed data implies quantitatively and determine independence. Visualization can aid engagement with meanings and concepts that are not readily available through symbolic representation and when information is displayed visually, we are able to "see" the story, picture a cause-effect aspect of a relationship, and vividly remember it (Arcavi, 2003). Visuals can "group together clusters of information that can be apprehended at once" (Arcavi, 2003, p. 218), and "visualization at the service of problem solving, may also play a central role to inspire a whole solution, beyond the merely procedural." (p. 224).

Figure 1. Contingency tables and corresponding mosaic plots.

Although elementary students are not likely to reason proportionally, previous studies indicate that younger students can reason correctly about association when only doubling and halving are required. The present study investigates how pre-k-12 students reason about association of categorical variables using contingency tables with and without mosaic plots.

Framework

Seminal work aimed to understand how students reason with complete contingency tables (Batanero, Estepa, Godino, & Green, 1996) provides the basis of my framework. Proportional reasoning requires the comparison of ratios and the use of all four cells in a multiplicative manner. I developed a framework which includes eight conceptions of reasoning with contingency tables (see Table 1), which are based on the five levels (L1-L5) identified by Perez-Echevarria (1990, as cited in Batanero et al., 1996).

Table 1 Graph Type and Variable Values for Different Items

Code	Description and features
N0	No cells in the table are used to decide about independence or association.
N1	No interior cells and one or more marginal cells are used to decide about independence or association.
L1	Localist-1: One interior cell in the table is used.
L2	Localist-2: Two cells in the table are used.
L3	Localist-3: Three cells in the table are used.
A1	Localist-4: All four cells in the table are used in an additive way.
P1	Proportional-1: All four cells in the table are used with proportional reasoning that compares risk (part to whole ratios). One conditional relative frequency is compared to another, focusing on the interior cells.
P2	Proportional-2: All four cells in the table are used with proportional reasoning that compares risk (part to whole ratios), and compares one conditional relative frequency to a marginal relative frequency.

P3	Proportional-3: All four cells in the table are used with proportional reasoning that compares odds (part to part ratios) and compares the odds for one category to another category for the same variable through subtraction or a ratio.

When considering the problems where the mosaic plots were provided, I used the same base codes and appended an additional code to indicate how the mosaic plot seemed to function. I considered whether the mosaic plot was a hindrance (M-), seemed to have no impact on the solution (M), or was helpful (M+).

Research Design

Since my interest is of the "how" and "why" nature, a qualitative, multiple-case study design is appropriate (Patton, 2005). I conducted think-aloud interviews (Charters, 2003) with seven participants that ranged in age from seven to 17 because I wanted to get a sense of ways that students across upper elementary, middle school and high school would respond to the same tasks. The reasoning about contingency tables of students in this age range has been underrepresented in past studies.

Each interview was semi-structured and used a protocol I develop based on the literature. The tasks all used the same context, but varied in the completeness of the contingency tables, numerical values of the frequencies, and whether there was an association among the variables. The words "association" and "independent" were used in the questions along with an additional explanation of their meaning. For the first part of the interview, I provided them with a series of problems with contingency tables and asked questions to ascertain their understanding of what the values in the tables represent. Then I introduced a mosaic plot by having them create one with a simple example. After verifying they could reason with it in conjunction with a contingency table, I presented two of the initial problems along with an accompanying mosaic plot. This study focuses on these two tasks. I concluded by asking them questions about the mosaic plot in general.

I recorded each interview with two video cameras, capturing both a close-up view of the student work as well as a broader view of the student to include gestures and facial expressions. Each of the seven interviews was transcribed and both an augmented transcript, noting participant actions, and a lesson graph, including notes of interesting moments, were created. The framework was used to code the data.

Results and Significance

The mosaic plot was never a distraction and was most often helpful. The two tasks considered in this study proved difficult for most students, and only two of the older students, Scott and Klaus, were able to provide comprehensive explanations for the tasks (Scott: Task 1 P2/P2M, Task 2 A1/P2M+; Klaus: Task 1 N)/P2M+, Task 2 A4/P2M+). These correct explanations occurred each time a mosaic plot accompanied the problem, but only once when it did not (Scott, Task 1). When the mosaic plot was provided, it improved all students' reasoning with the exception of this one problem Scott was able to solve without it.

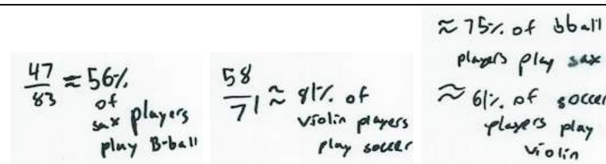
The younger students always showed improved reasoning when the mosaic plots were provided, but because of their limited proportional reasoning, they were not able to provide a completely correct solution and justify their reasoning. As the literature suggests, they were able to use numbers and benchmark fractions to reason about the data, but they conflated percentages with frequencies. Additionally, they did not have an understanding of the structure of a contingency table, often indicating the marginal frequencies for the rows and columns were a different group of people.

Some of the improvements in performance on the problem when the mosaic plot was included could be due to other factors like seeing the problem for a second time and working with different contingency tables between reasoning without and with the mosaic plot. However Scott and Klaus both verified they were looking at the mosaic plot and used it to solve the problem and overall, explanation and justification was more limited when there was no mosaic plot provided. Clear and complete explanations more frequently occurred when the mosaic plot was included. For example, when Scott was using the mosaic plot in the second task, he said, "just look at the mosaic, it's pretty clear" and provided a succinct explanation.

Interestingly, the mosaic plot seemed to help Klaus as he reasoned through the second task. With the contingency table alone, his additive understanding was apparent and he remained with his initial reasoning relying on the larger numbers. (see Figure 2).

Sport/Instrument	Violin	Saxophone	Total
Soccer	58	36	94
Basketball	13	47	60
Total	71	83	154

"The majority of soccer players play violin. And the majority of basketball players play saxophone."



"So, I don't think those percents mean anything in this situation."

Figure 2. (a) Klaus's work considering greatest numbers in comparison with smaller numbers in a contingency table and (b) computation of conditional probabilities.

Although he computed percentages that he could compare to reason proportionally, he did not recognize their usefulness. However, when he later reasoned with the mosaic plot accompanying the same problem, he clearly used the mosaic plot to compare the two categories and their proportions.

Conclusion

Overall, the mosaic plots appeared to be accessible, appealing, and useful to students. Scott claimed it allowed him to visualize the total as a whole and the percentages better than the table. In addition, all participants agreed mosaic plots were helpful and that having to draw it themselves helped them to understand it. Cici, the youngest participant mentioned it helped her to "memorize it a little more in your head."

Mosaic plots may be a useful representation for students when reasoning about (in)dependence of categorical variables. Future work might consider different aspects of contingency tables, how students understand and work with the constituent components, and how they reason across different representations.

STUDENTS' "MULTI-SAMPLE DISTRIBUTION" MISCONCEPTION ABOUT SAMPLING DISTRIBUTIONS

Kiya L. Eliason
Brigham Young University
kiya.eliason@gmail.com

Steven R. Jones
Brigham Young University
sjones@mathed.byu.edu

The sampling distribution (SD) is a foundational concept in statistics, and simulations of repeated sampling can be helpful to understanding them. However, it is possible for simulations to be misleading and it is important for research to identify possible pitfalls in order to use simulations most effectively. In this study, we report on a key misconception students had about SDs that we call the "multi-sample distribution." In this misconception, students came to believe that a SD was composed of multiple samples, instead of all possible samples, and that the SD must be constructed by literally taking multiple samples, instead of existing theoretically. We also discuss possible origins of this misconception in connection with simulations, as well as how some students appeared to resolve this misconception.

Keywords: Statistics, Sampling Distribution, Process and Object, Multi-sample Distribution

It is important to help pre-service mathematics teachers develop their own conceptual understanding of statistics content (Conference Board of the Mathematical Sciences, 2001), because their conceptual understanding impacts learning opportunities available for their students (Ball, Lubienski, & Mewborn, 2001). In statistics, one concept of critical importance is the sampling distribution (SD). It forms the conceptual basis of much of elementary statistics, including confidence intervals, hypothesis testing, and correlation testing (Lipson, 2003). Thus, if we want students to develop strong conceptual understandings of elementary statistics, it is essential to help our pre-service math teachers develop strong understandings of SDs, as well.

Much research aimed at conceptual understanding of SDs focuses on exploration activities in which students repeatedly sample from a population (Aguinis & Branstetter, 2007; Chance, delMas, & Garfield, 2004; delMas, Garfield, & Chance, 1999; Glencross, 1988; Mills, 2002; Peck, Gould, Miller, & Zbiek, 2013; Watkins, Bargagliotti, & Franklin, 2014). These simulations are meant to show the emerging properties of the SD that: (a) the shape of the distribution is approximately normal, (b) $\mu_{\bar{x}} = \mu$, and (c) $\sigma_{\bar{x}} = \sigma/\sqrt{n}$. However, some have realized that these same simulations might inadvertently be misleading (Watkins et al., 2014). It is beneficial for teacher educators to know what misunderstandings their students might develop from such simulations in order to use them most effectively. Our study seeks to build on this research by describing a previously undocumented misconception seen in pre-service teachers, which gets at the heart of what a SD even is. We also examine how this misconception might be resolved.

Background on the Sampling Distribution

Brief Recap of Sampling Distributions

Many types of statistical studies are based on using a sample to estimate or test certain population parameters, such as the population's mean (μ) or standard deviation (σ). Sampling distributions (SD) are what underlie the statistical methods used to do this. The basic idea of a SD is that, given a fixed sample size n, if all possible samples of size n are taken from the population, then the statistic of interest from all those samples creates a distribution in and of itself (Triola, 2010). For example, a SD for means is constructed by taking the sample means ($\bar{x}$) of all samples of the same size n from the population and putting them together to create a new distribution (see Figure 1). Note that there is a different SD for every sample size n that is chosen, because n is the same for all samples within a given SD. The Central Limit Theorem (CLT) then guarantees that a SD for means will always have the same mean as the population, $\mu_{\bar{x}} = \mu$, and a standard deviation given by $\sigma_{\bar{x}} = \sigma/\sqrt{n}$. If n is sufficiently large, often cited as $n > 30$ (e.g., Triola, 2010), the CLT states that the SD will be an approximately normal distribution. Similar properties hold for SDs for proportions. It is important to note that SDs are *theoretical* in nature, in that they do not need to be empirically constructed to be used in statistical analysis. The CLT guarantees those properties that are needed for statistical analysis.

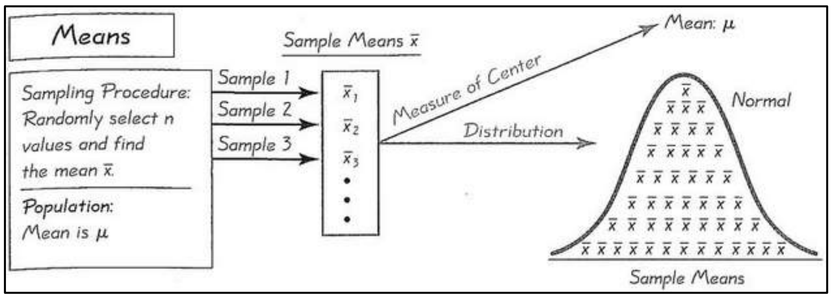

Figure 1: Creation of a Sampling Distribution, taken from Triola (2010, p. 281)

Brief Literature Review on Sampling Distributions

A common tool for teaching SDs and the CLT are simulations, in which physical enactment or computer software is used to create the results of many samples and to partially construct a SD. Using simulations to help students learn about SDs has been recommended as far back as the 1970s (e.g., Committee on the Undergraduate Program in Mathematics, 1972). Some have demonstrated that these simulations can give insight into otherwise theoretically intractable ideas (e.g., Mills, 2002; Simon, 1994). Yet other research has shown that simulations are insufficient by themselves. delMas et al. (1999) found that when students were allowed to experiment with simulations, their understanding did improve by a little bit, but not by as much as expected. They realized that the simulations alone did not force students to notice relevant features, and that activities needed to carefully scaffold student noticing (see also Chance et al., 2004). Lipson (2003) explained that there is a jump between an empirically constructed approximation to a SD using simulations and the actual theoretical SD. However, Lipson's focus was more on the influence that disconnect had on students' understanding of inference. In this paper, we examine how that disconnect directly impacts students' understanding of SDs themselves. Further, because simulated distributions are not perfect representations of the theoretical SD, Watkins et al. (2014) saw that students were sometimes misled by simulations. They observed students who incorrectly believed that the SD's mean got "closer" to the population mean as n increases. In fact, the CLT guarantees that $\mu_{\bar{x}} = \mu$ exactly, regardless of sample size. The misconception we discuss is related to what Watkins et al. observed, and might even be a root cause of it.

Taken together, this literature shows that simulations can be a useful tool in statistics education, so long as they are used carefully. We must be fully aware of potential pitfalls simulations might contain. We should continue to unpack possible issues in understanding SDs with simulations, in order to most effectively use simulations. This study adds a key, previously undocumented misconception, related to what a sampling distribution fundamentally is, that we observed in pre-service teachers who experienced this type of simulation activity.

Theoretical Perspective: Processes versus Objects

We view the concept of SDs as having a close connection to the theoretical notion of *processes* versus *objects* (Sfard, 1991, 1992). This lens gives valuable insight into possible SD misconceptions, and can help produce paths toward their resolution. In short, a process means an activity that can be conceptualized as being carried out, like imagining counting up to 1 million. It does not necessarily need to be enacted to be a process, but imagined. An object, then, is the encapsulation of such a process into a single cognitively entity. The "size" 1 million is a conceptual object, which can emerge out of imagining the process of counting up to 1 million.

SDs inherently deal with the *process* of repeated sampling. That is, one can conceptualize taking a sample and recording its sample mean (or proportion), and then taking another sample and recording its sample mean (or proportion), and so on. However, the full comprehension of SDs is to realize that this process can be encapsulated into a final result: the distribution of *all* sample means (or proportions). The SD is the *object* that results from the *process* of repeated sampling. We view simulations, through this lens, as essentially a representation of the *process* aspect of a SD. It permits the process to be quickly viewed over a large number of samples (as seen in Figure 2). However, in these simulations the *object* aspect of the completed SD is typically not reached. This limitation comes because such simulations usually do not depict when every sample has been represented exactly one time in the simulation, or at least represented in exactly equal proportion to every other possible sample. This matches Lipson's (2003) assertion that there is a jump from the empirically-simulated approximate SD to the actual theoretical SD. In this study, we examine how this issue led pre-service teachers to make incorrect conclusions about the fundamental nature of what a SD is.

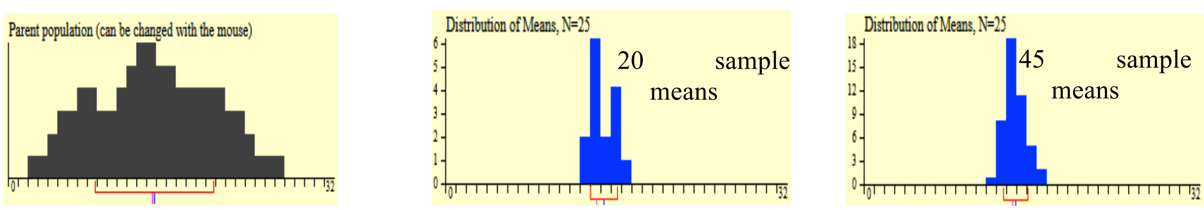

Figure 2: Example of a simulation (http://onlinestatbook.com/stat_sim/sampling_dist/)

Methods

This report emerged from a broader study we were engaged in regarding pre-service mathematics teachers resolving their misconceptions about confidence intervals. Students for the study were recruited from an undergraduate "Teaching Statistics and Probability" course for mathematics education majors, focused on conceptual understanding and on task exploration. The pre-service teachers had all completed a pre-requisite undergraduate statistics course, or AP statistics. In the education class we recruited from, the students used a simulation of repeated sampling, as discussed in the literature review, to develop the ideas of SDs.

The major purpose of the larger study was to understand how students might resolve misconceptions they held and to document the route they took in doing so. To recruit students for interviews, the students were given a quiz in their class regarding misconceptions on SDs and confidence intervals. Because the misconception we report on in this paper had not previously been documented, our specific misconception was not tested for, but emerged during the interviews while the students discussed other aspects of their understanding. From the quiz results, five students with varying levels of misconceptions about confidence intervals were selected to participate in two, hour-long interviews. We give the students the pseudonyms Danielle, Ethan, Corinne, Tiana, and Anna. During the interviews, the students were asked to explain how confidence intervals are constructed, to design their own hypothetical study that would use confidence intervals, and to discuss various aspects of SDs and confidence intervals. While conducting the interviews, the interviewer (Author 1) noticed a trend in terms of how all five students seemed to be talking about SDs. Thus, the interviewer began to follow up on this trend as well, and to make sure each student was asked about it. As the purpose of the larger study was to help students resolve misconceptions, the interviewer also attempted, impromptu, to document instances of students resolving this misconception during the interviews.

To analyze this trend, we went through all of the parts of the interviews where students made statements or gave explanations regarding SDs. In examining all instances of normatively incorrect statement or explanation, we realized they typically dealt with one main misconception about SDs. That is, most incorrect statements or explanations about SDs seemed rooted in the same misunderstanding. Once we singled out this misconception, we went back to the interviews to try to identify where the misconception came from in terms of prior knowledge or in-class activity. In doing so, we saw an important likely connection to the in-class simulation. Finally, as the interviewer had attempted, in the moment, to understand and document these confusions, we tracked the students' evolving conceptions of SDs over the interviews and looked for what was discussed in conjunction with changes in their understanding. This aided us in identifying what might help resolve the underlying misconception.

Limitations

There are some limitations to our analysis of this misconception. First, we had only five students in the sample, which is few. However, this report focuses only on documenting and discussing the misconception, rather than on establishing how common it is. Yet, since all five students in this study did share this same misconception, we posit that it is likely to be more widely shared. Second, this study was not originally designed to uncover this misconception, but it rather emerged from the data. Future work can be done to examine this misconception more systematically and to identify how common it might be among typical pre-service teachers.

Results

The Multi-sample Distribution Misconception

All five students suggested that to do statistics, one essentially uses a "sampling distribution" that contains *some* of the samples of size *n* from the population, as opposed to a completed sampling distribution of *all* possible samples. For example, consider Corinne's explanation.

> Corinne: If you took a bunch of samples and you found their means, you would get a sampling distribution.
> Interviewer: How many samples?
> Corinne: More than 30.

Corinne implied that if one has a certain amount of samples (i.e. "30"), then the distribution of those sample means *is* a SD. In another example, Ethan was describing how his hypothetical statistical study could be done. He seemed to imply that to obtain a SD, one would literally collect several samples in practice and compile them into a SD. The interviewer was initially unsure what he meant, and asked about how he imagined a SD.

> Interviewer: What's a sampling distribution?
> Ethan: The distribution of the means of your samples.
> Interviewer: How many?
> Ethan: Are you talking about in my thing [i.e. hypothetical study], or just in general? … [The SD is] the means of how many samples you take.
> Interviewer: But what if you only take one [sample]?
> Ethan: If you only take one sample then, [pause] I'm lost.

…
Interviewer: [The SD] is the distribution of the means of all your samples. Okay. All the samples that you take, or all the samples that you could take?
Ethan: That you take.

Here, Ethan explained that a SD is created by *empirically* collecting multiple samples during a statistical study. That is, he did not conceptualize a *theoretical* SD with the properties guaranteed by the CLT. In fact, at one point Ethan suggested that "all possible samples" really meant all the samples it was possible for someone to practically take. Ethan was not alone in believing one must collect multiple samples to empirically create a SD to do statistics. Most of these students described that to carry out their hypothetical study, they would need to take many samples to create a SD, as seen in the following statements.

Tiana: I want to take 30 samples of size 100.
Corinne: I would take 100 samples of size 30.
Ethan: I would get at least 200 samples just to be realistic.
Danielle: You take a large number of samples, like say 1,000, to get a sampling distribution of $\bar{x}$.

It is clear that these students were all thinking of a SD as a collection, not of *all* possible samples, but of several literally collected samples. We call the conceptualization of such a distribution of many, but not all, samples the *multi-sample distribution*, denoted *M-SD*. We consider it a misconception when the M-SD is seen as being *the* SD. We claim that the M-SD misconception is closely connected to perceiving only the *process* part of the SD. That is, the process of repeated sampling is understood, but it does not have a theoretically completed end of all possible samples that is the *object* SD. In this way, M-SD is not "wrong," but incomplete in a critical way. The students even seemed to understand that this process could continue, with more samples, to create a "better" M-SD, but they typically did not understand that the process has an end-result *object* that is the theoretical SD.

In conjunction with the M-SD misconception, the students in our study exhibited some misconceptions previously reported on in the research literature. For example, many claimed that $\mu_{\bar{x}} \approx \mu$ rather than $\mu_{\bar{x}} = \mu$ (cf. Watkins et al., 2014), as in the following excerpt from Corinne.

Corinne: [$\mu_{\bar{x}}$] is the mean of the means you sampled… In the real world, we never get to work with the distribution where μ and $\mu_{\bar{x}}$ are equal. We just get closer and closer [with more samples].

In fact, we believe previously reported misconceptions like this regarding $\mu_{\bar{x}}$ may really be a symptom of an underlying M-SD misconception. Note that the mean of the M-SD is technically $\bar{x}_{\bar{x}}$, as opposed to $\mu_{\bar{x}}$ because it is only a *sample* of sample means rather than the *population* of all sample means (where $\bar{x}$ refers to a sample and μ to a population). In this perspective, it is true that $\bar{x}_{\bar{x}} \approx \mu$ as the students claim. It is only in the SD of *all* samples where $\mu_{\bar{x}} = \mu$ exactly.

Possible Origins of the M-SD Misconception

During the interviews, the students described aspects of their thinking that matched with the simulation activity used in their class to discuss SDs. In the classroom activity, each student randomly selected samples from a population and computed the sample mean of them. The activity culminated in the students plotting their sample means together to create a visual representation of what is, essentially, a M-SD. This activity may have fostered M-SD thinking in the students. For example, in her interview, Tiana recounted this simulation activity and explained that she understood the image she saw – of the multiple sample means plotted together – as being *the* SD. Regardless of whether the instructor may have mentioned that the image was not the SD, the strong visual that represented the culmination of the simulation activity seemed powerful enough that she interpreted it as though she were seeing a SD.

By contrast, Corinne did recognize in her interview that there is such a thing as a distribution of *all* sample means. However, she discarded it as anything practically useful in doing statistics, explaining instead, as seen in her excerpt above, that "in the real world, we never get to work" with the actual SD. She explained that you could only use the actual SD "in something like manufacturing where you have data on every item or when you have a small population. But in that case it would be pointless because you could just do a census and know the population parameters." She explained that, practically speaking, in order to do statistics one would need to create the type of distribution seen in their class, that was made up of a collection of multiple sample means rather than all sample means.

Another root of the M-SD misconception may lie in classroom discussion of the CLT. One property of SDs given by the CLT is that if the common sample size for all samples is sufficiently large, often given as $n > 30$, then the SD is approximately normal. However, students may have confused this with believing that they need at least 30 samples for the (M)-SD to be approximately normal. The simulation activity may have inadvertently led them to focus on the wrong thing for "$n > 30$." In the simulation, the students saw that with each new sample mean added, the distribution began to resemble a normal distribution more. For example, when Ethan was explaining his hypothetical statistical study, he settled on wanting to collect 30 samples.

> Interviewer: Why is 30 a magical number to you?
> Ethan: The central limit theorem wants 30 [samples] for the sampling distribution to be normally distributed.

Notice that Ethan is justified in asserting that "30" is connected to the normality property given by the CLT. But, he did not appear to connect $n > 30$ as representing the *sample size* of each of those samples, as opposed to the *number of samples* needed to create a reasonably normal (M)-SD. This result is supported in the students excerpts from the previous section about wanting 30, 100 or 1,000 samples to make a sampling distribution.

Possible Resolutions of the M-SD Misconception

We defined the resolution of this misconception as recognizing that (a) the SD is a theoretical distribution from *all* possible samples and (b) that it does not need to be empirically constructed to be used. From our process-object perspective, the M-SD misconception essentially lacks the object component. Thus, resolution of this misconception is based on extending their process-oriented conception to include an object. Danielle, Ethan, and Corinne each gave some evidence of resolving this misconception. First, consider Danielle. One important part of her resolution of this misconception involved clearly distinguishing between sample size and number of samples.

> Interviewer: How many samples do we need to take before we can use the sampling distributions and assume that they are normal?
> Danielle: I think generally they say it's supposed to be like 35 or 30.
> Interviewer: Samples?
> Danielle: Yeah. That's the size of the sample [pause]. So wait, your question is?
> Interviewer: How many samples?
> Danielle: Oh, how many samples do we need to take. So, usually when we are using these types of things like our equations [refers to a formula sheet] we just take one sample!

Here, Danielle seemed to have realized the mismatch in thinking that multiple samples are needed to literally create an SD versus the fact that the statistical formulas use only one sample. Then, by thinking of just this single sample, she began to create for herself the ideas of a SD.

> Danielle: Any kind of sample you take is going to fall… somewhere. It is possible to get one that is farther away from the population mean… [Draws Figure 3]. If you were to take a sample, just one

sample, then it will fall somewhere along here in this range that is close to the population mean [gestures toward the middle a population distribution in Figure 3].

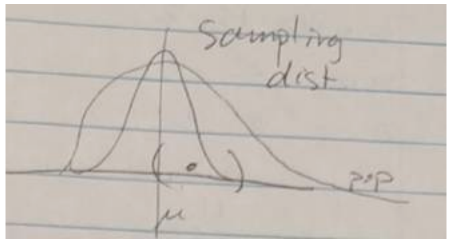

Figure 3: Danielle building on the simulation to now imagine all possible sample means

By reasoning with only a single sample, Danielle began to think more theoretically about where that single sample mean could be. In fact, this theoretical thinking seemed to help her imagine all possible samples, without having to literally collect all of them.

Danielle: So, if you could possibly take every single sample of that certain size and you were to be able to plot that, the sampling distribution would be normal and so we, since that concept is true, then we can just pull one sample point and it will be a point from somewhere on the sampling distribution.

We can see that Danielle had now conceptualized a SD as having all possible samples, and that it was theoretically, not empirically constructed. The single sample used in statistics was a member of this theoretical distribution. In fact, thinking of a single $\bar{x}$ more abstractly appeared helpful for some students in transitioning from the empirically-grounded M-SD to the theoretically-based SD. Corinne also used single $\bar{x}$'s to help make this transition.

Interviewer: What happens if someone only picks one sample? Let's make this the smallest possible $\bar{x}$ and this the largest possible $\bar{x}$. [Here the interviewer writes a number line and marks two points along it.]

Corinne: Without even knowing anything about this, most of them are going to be in the middle. So chances are that this one single [$\bar{x}$], it's here somewhere [gestures to the middle of the number line.]

Here, Corinne made an assertion about where a given $\bar{x}$ might be, without trying to create multiple samples. The interviewer tapped into this by then asking Corinne to imagine where all possible $\bar{x}$'s might fall along this number line. Corinne began to piece together where they might be, including that many $\bar{x}$'s would fall toward the middle. She eventually drew a SD similar to Figure 3. The interviewer asked about some of the specific properties of this new distribution.

Interviewer: Is μ the same as $\mu_{\bar{x}}$? [i.e. assuming all possible samples]
Corinne: I think at this point they are the same.
Interviewer: Why?
Corinne: Because at this point, if we have taken every possible sample, and take their means, and we are finding the mean of all those means, that is mathematically the same as finding the mean of all of those at once, which is finding μ.
…
Interviewer: So you are saying we can use just one sample [to do statistics]?
Corinne: But you're basing it off of information about all possible samples.

By leaving the empirical enactment from the simulation, Danielle and Corinne could begin to reason theoretically about where one $\bar{x}$ might lie, and then to where multiple $\bar{x}$'s might lie, to then where all $\bar{x}$'s might lie. This seemed to help them extend the *process* seen in the simulation to an imagining of a completed SD *object* with all possible $\bar{x}$'s being represented.

Discussion

We agree with the body of research that claims simulations are important for developing students' understanding of SDs (e.g., Mills, 2002; Simon, 1994). We also believe our study helps us better understand why simulation activities might be misleading in some ways, as noted by Watkins et al. (2014). Our process-object perspective suggests that simulations can only account for the process part of the conception of SDs, and cannot adequately portray the object part. We believe this is the reason for the possible disconnect Lipson (2003) described between the empirical simulation and the theoretical SD. If a simulation can only achieve the process component, the M-SD becomes a possible misconception students might develop. To be clear, we see the process component of a conception of SDs as essential, and simulations as a valuable way to develop the process component. That is, if one tried to simply create the *object* SD without first developing the process behind it, one might be left with a pseudostructural conception instead (Sfard, 1992; Sfard & Linchevski, 1994). In other words, the students might conceive of an SD object, but without understanding the underlying process that leads to it. Thus, we promote simulations as a useful way to develop the process, but claim that instruction must, at some point, move past the empirical simulation into a theoretical SD. Of course, simply "telling" students that there is a completed theoretical SD after observing a simulation might be insufficient to bridge the gap between process and object. Rather, it seemed important for some of our students who resolved the misconception to reason more theoretically about the distribution of a single hypothetical $\bar{x}$. This led to where multiple $\bar{x}$'s, and eventually all $\bar{x}$'s, might be distributed.

It was also important for our students to explicitly confront the difference between the sample size and the number of samples, which we believe is related to the misconception that $\mu_{\bar{x}}$ gets closer to μ as sample size increases (Watkins et al., 2014). As sample size increases, it is true that a M-SD will have an $\bar{x}_{\bar{x}}$ closer to μ. However, since a SD deals with all samples, *not* an increasing number of samples, it will always have $\mu_{\bar{x}} = \mu$.

Finally, we wish to emphasize that the M-SD misconception is not "wrong," but simply incomplete. In the spirit of perceiving misconceptions as useful building blocks, rather than faulty thinking that must be removed and replaced (see Smith, diSessa, & Roschelle, 1993/94), we find that resolving this misconception deals with adding on to what is already there, rather than taking away. Viewing the M-SD misconception in this light makes the path toward its resolution clearer, in that we can take the students' understanding as is and help them extend it to a completed *process-object* conception of SDs.

CONDITIONAL PROBABILITY IN EARLY CHILDHOOD: A CASE STUDY

PROBABILIDAD CONDICIONAL EN LA INFANCIA INICIAL: UN ESTUDIO DE CASO

Brigitte Johana Sánchez Robayo
Virginia Tech
brigsa1@vt.edu

Jesse L. M. Wilkins
Virginia Tech
wilkins@vt.edu

This study investigated the intuitive knowledge of conditional probability in one four-year-old child. Six clinical interviews were video-recorded for analyzing transcripts and expressions from the child. Findings from this research suggest that the child has a pre-operational intuition about change in sample space in non-replacement situations. He also seems to have an intuitive understanding of independent events. Furthermore, although his judgments are mainly subjective, he does use quantitative justifications, although, inconsistently.

Keywords: Cognition, Early Childhood Education, Probability.

According to Nikiforidou, Pange and Chadjipadelis (2013) and Antonopoulos and Zacharos (2013), the study of probabilistic thinking in preschoolers is very limited. Jones, Langrall, Thorton and Mogill (1997) list sample space, probability of an event, probability comparisons and conditional probability as four key constructs in probability thinking; however, while the first three constructs have been investigated by several researchers, they point out that there are few studies related to conditional probability in young children. As one of the key constructs in probability thinking, it would be worthwhile to identify how this construct first begins to develop in young children. In this way, we can better understand how to advance children's early probabilistic reasoning. Thus, we examined the following research question: How does a preschooler think about conditional probability? In this study we investigated the intuitive knowledge of one four-year old child in situations involving conditional probability and independence. The study focused on these concepts from an informal perspective.

Literature Review/Framework

Xu and Tenenbaum (2005) demonstrated that preschoolers might possess some intuitive notions of conditional probability despite having not reached the formal operational stage identified by Piaget and Inhelder (1975). Jones and Tarr (1997) validated a framework for assessing probabilistic thinking through a characterization of four levels in conditional probability and independence. Following are the first two levels briefly described:

- Level 1. Subjective: Students' judgments are based on their own construction of reality, looking for non-existent patterns and imposing their own system of regularity. Students believe past outcomes will always affect the future outcomes, and they "deny the existence of independence" (Jones & Tarr, 1997, p. 51). The level of subjectivity does not allow any meaningful attention to independence and conditional probability.
- Level 2. Transitional: Students in this level occasionally use quantitative information for making conditional probability judgments.

Some researchers (Nikiforidou & Pange, 2010, Nikiforidou, et al. 2013) highlight the importance of considering intuition when investigating children's probabilistic thinking. In this way, Fischbein (1975) argued that children have intuitive probabilistic knowledge. These intuitive notions are implicit forms of cognition beyond cognitive structures and conceptual systems. Fischbein (1975) categorized intuitions into pre-operational, operational and post-operational. Specifically, pre-operational intuitions can be influenced by subjective or perceptual considerations, and operational intuitions are basic intuitions that are expressed through formal rules of logic.

Methods

In this study we used a case study analysis to investigate notions of conditional probability in one four-year-old child, Mack. Six clinical interviews of 5 minutes each were conducted and video-recorded. Tasks designed as games were used in each interview. In these games, Mack was asked to predict the outcomes in different scenarios. Correct predictions were reinforced with tokens. We analyzed each of the activities focusing on Mack´s predictions and his reasons for providing his answers. After transcribing each interview, in the video records we identified Mack´s expressions, actions, and fluency in his answers. From these records, we selected the video-segments that met one of the following criteria: showed any justification given by Mack, revealed specific indicators of a particular kind of intuition, or showed specific features associated with his notions of conditional probability. For the chosen segments, we included descriptions of Mack´s actions associated with his verbal expressions in the transcriptions. Later, we organized the completed transcriptions into two non-disjunctive groups: those that enabled us to infer Mack's intuitions, and those that reveal different kinds of judgments.

Results

We describe the results from the interviews according to Mack's intuitions and judgements. We begin with a discussion of the BALLS situation. In this situation, we mixed two green balls and two red balls in a bag. We asked Mack to predict the color of the ball that he thinks will have the greatest chance of being chosen from the bag. He answered "red," giving the reason that it is his favorite color. He then chose a red ball without looking inside. After that, he recognized that there were two green balls and one red ball remaining in the bag. Here, we suggest a pre-operational intuition associated with the chance of selecting a green ball, because after reviewing the bag, he quickly predicted the selection of a green ball for a follow-up selection. He gave as his reason for this prediction, that he likes all the colors (subjective consideration).

His pre-operational intuition of chance is further confirmed in the next trial in which there was one ball of each color left. In this case, he predicted that the red ball would be chosen, arguing that red is his favorite color. Similarly, in a scenario involving two red and two green balls in the bag, he selected a red ball which was then replaced; when he was asked which ball had the greatest chance of being selected, he answered red again arguing that it was his favorite color. Then, the red ball was not replaced, and he predicted that a green ball would be more likely to be chosen, again arguing that he likes all the colors. In this case, the number and color of the balls were not confirmed as in the previous situation. In a subsequent scenario, we added one green ball to the two red balls and two green balls. In this case, Mack predicted the green ball again arguing that he liked all the colors. In summary, when the chance of choosing the different colored balls was equal, he predicted a red ball arguing that red is his favorite color; but, when the chance of choosing a green ball was greater, he selected that color, arguing that he likes all of the colors. These situations reveal that Mack has an intuitive recognition that the sample space changes. For example, after selecting some of the balls from the bag, he changed his decisions according to the remaining number of colored balls without checking which balls were left in the bag. Furthermore, these decisions reflect an intuitive notion of conditional probability as the probability of the subsequent choice of ball appears to be conditioned on the knowledge of the previous choice.

We now turn to a discussion of Mack's judgements in situations involving independent events. In the COINS tasks, Mack was asked to predict the resulting color (yellow or red) after flipping a coin.

He was asked to first toss the coin without making a prediction. The outcome was yellow. On the next toss, he predicted the coin to be red. In the third toss, he looked more confident in his guessing than previously. Then, the following discussion took place:

Interviewer (I): Now, which color do you think that you will get if you throw the coin?
Mack (M): Mmm, red
I: Why do you think is red?
M: Because it's my favorite color.
I: Ok, it's your favorite color, very nice, let's see
M: [tossed the coin and got yellow]
I: Yellow! Now, let's do it again. What color do you think you will get?
M: Red
I: Red again? Ok, why red?
M: Dark

Mack's choices in the coin tossing situation seems to reveal an intuitive recognition that previous outcomes do not affect subsequent outcomes. In a follow-up scenario, we used two coins that were flipped one immediately after the other. Mack was asked to predict the color he would get tossing the second coin once he had tossed the first coin; he answered yellow, and the reason that he said was "shine!" In different scenarios, the main justification of his predictions continued being "my favorite color!" when his predictions were red. However, he seemed to change his justifications when he had a clearer intuition about the possible chance of the outcomes, as in the BALLS situation. He also included subjective arguments like "because is dark," "I am sweety," and "because it's my mom's favorite color."

In the FIGURES situation (Figure 1), Mack was asked to predict from which piece of cardboard the figure was chosen (situation inspired by Lucas, Bridgers, Griffiths, and Gopnik, 2014). Covering the pieces of cardboard, we selected a diamond and asked Mack from which piece of cardboard the image was taken. He linked the selection of the color (red cardboard) with the red flowers in the interviewer's blouse. Repeating the experiment twice, he changed the kind of judgment in the second repetition:

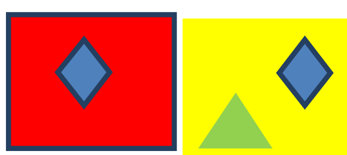

Figure 1. Pieces of colored cardboard

I: I take the blue diamond.
M: The yellow one.
I: Do you think it's from the yellow one?
M: (nodded)
I: Why?
M: Because there is more.
I: There is more what? There is more…
M: Shapes.

Although the quantity of shapes did not affect the chance, Mack´s attention moved away from subjective arguments to the quantity of shapes. In a similar situation in which there were two triangles on the yellow piece of cardboard and one on the red piece, Mack's first guess was that the triangle came from the yellow piece of cardboard, because "there is two of them." Although this was not technically a prediction because Mack was looking when we selected the triangle, he seemed to be appealing to the number of triangles as a justification for his choice. In, yet, another situation where two triangles were on the yellow piece of cardboard and three on the red piece, his judgements associated with the number of triangles became clearer. We took one triangle without letting him see where it came from:

I: I took this triangle from one of these two cardboards, what cardboard do you think this triangle came from?
M: Red.
I: Why do you think is red.
M: Because there is more.
I: There is more in red?
M: More triangles.

However, in a following task, the triangle was not replaced, and he expressed the same argument in selecting the red piece of cardboard when they were the same number of triangles in each one.

Conclusions

This study identified the intuitive knowledge of a four-year-old child in situations involving conditional probability and independence. Although the child does not have any formal knowledge about sample space, he has a pre-operational intuition about changes in the sample space in non-replacement situations. In other words, Mack quickly adapted his choices and justifications depending on the different options he had once the sample space changed. Additionally, as seen in the COINS task, Mack did not seem to consider past outcomes when making future predictions. These findings seem counter to Jones and Tarr's (1997) framework related to the lack of attention to independence and conditional probability for children who are in the subjective level.

Mack's judgments were mainly subjective as Jones and Tarr (1997) characterize for the subjective level and Fischbein (1975) characterizes for pre-operational intuitions. However, over the course of the interviews, Mack changed his judgments from subjective to quantitative without instructional interventions. Although his quantitative reasoning was inconsistent and sometimes irrelevant, notions of quantity did influence his decisions. The trajectory of Mack's judgments provides an intriguing situation for further research. In particular, when he felt more confident about the possible answer, he appealed to the quantity of objects to justify his predictions. It seems that Mack has an intuition about the likelihood of an object being chosen that is associated with the quantity of objects involved. This suggests that intuitions about chance in conditional situations associated with quantitative reasoning may be stronger than Jones and Tarr (1997) argue for the subjective level. Nevertheless, although Mack mentioned number of objects in his justifications, he did not associate such numbers in his predictions.

THE IMPACT OF SELF-COLLECTED DATA ON STUDENTS' STATISTICAL ANALYSIS

Karoline Smucker
The Ohio State University
smucker.37@osu.edu

Azita Manouchehri
The Ohio State University
manouchehri.1@osu.edu

Context plays a crucial role when students engage in analysis and interpretation of data, and is broadly recognized as one of the main elements that separate the studies of mathematics and statistics (Cobb & Moore, 1997). The ways that students engage with the environment surrounding data within a statistical task are of interest to researchers because of this. In this analysis of a teaching experiment with third grade students, interactions with self-collected wingspan data led to insights about graphs as students attended to individual values, but students varied in their willingness to use the data to describe/infer more broadly.

Keywords: Data analysis and Statistics, Measurement, Elementary School Education

When working with data, the context surrounding it plays an essential role in developing students' understanding. Context is one feature that can separate the study of statistics from the study of mathematics (Cobb & Moore, 1997). Watson (2009) posited that one of the goals of statistical literacy is for "students to be able to tell a story from a context with a distribution" (p. 33). With the potential for students' statistical investigations to involve the collection and use of survey or measurement data (Lovett & Lee, 2016; Makar, 2014), it is of particular importance to carefully unpack the impact of self-collected data (which may include the students themselves) on their statistical analysis. In this work, we investigated the ways that students in a third grade classroom engaged with context as they completed an activity involving wingspan data. The guiding research question included: how would the use of self-collected measurement data impact students' descriptions and their ability to infer based on their data collection and display?

Conceptual Framework

According to Watson (2007), a learner's ability to engage productively with context is one of the hallmarks of statistical literacy. When "meaningless or nonexistent" context is provided for data, students will often apply incorrect or inappropriate procedures, while when the context is "interesting, and relevant to students' worlds" they are more likely to use statistical ideas (Doerr & English, 2003, p. 111). However, when students engage with the context too personally, they may also make assumptions that are not supported by statistical evidence (Watson, 2007). Students may focus so closely on the story behind data that they prefer making conclusions based on their informal knowledge of the data's context over patterns in the data itself (Ben-Zvi et al., 2012; Biehler et al., 2018; Pfannkuch, 2011).

Within statistics, there are two broadly defined categories; descriptive and inferential. Descriptive statistics focuses on the "organization, summarization, and presentation" of data (Paparistodemou & Meletiou-Mavrotheris, 2008, p. 83). Inferential statistics looks at how patterns for a particular group could be viewed more broadly. Recently, research has focused on the importance of exposure to tasks which build inferential reasoning for students as young as the elementary grades (Makar, 2014; Pfannkuch, 2011; Watson, 2001). Graphical displays are an important part of both descriptive and inferential statistics. They can help students see the distribution of data more clearly, with distribution being defined as the overall picture of data based on expectation (center), variation, and shape (Watson, 2009). Watson (2007) concludes based on her longitudinal work with students in both the elementary and secondary grades that learners can benefit from opportunities to create their own displays and compare/contrast them with displays made by others to investigate their "success in telling the story of data" (p. 61). Despite this much remains unknown about the intricacies and impact of such an approach. This work looks specifically at the context of self-collected measurement data and how the nature of the data may have impacted elementary students' display creation and descriptions/inferences.

Methods

This research aimed to investigate the ways that a group of third grade students from a Midwestern State engaged in a task related to class wingspans. Using characteristics of a teaching experiment methodology (Steffe & Thompson, 2000), a focus group of five students were recruited to participate in the study. The wingspan task unfolded in three stages. First, the focus group were asked to measure each other's wingspans, and to consider reasons for observed differences. Second, the focus group collected measurements from the rest of their class and used these measurements to create displays individually or in pairs. Students had previously been introduced to bar graphs and pictographs involving categorical data but had not used them to represent quantitative data. Finally, participants presented their displays to the focus group. The purpose of this discussion was to consider the ways that different displays conveyed similar information, examine the overall distribution of class wingspans, and hypothesize about the distribution of wingspans for other classes or grade level groups. Video recordings of discussions, transcriptions of the activity, and student work served as data sources for analysis.

Data analysis consisted of three phases. First, video-data were segmented to isolate instances during which students seemingly contemplated the self-collected or personal nature of the data. These were broadly defined to consist of occasions where they referenced specific data values or general characteristics of specific groups (i.e. their class, other classes, other grades). The second phase of analysis focused on identifying ways that the context shaped students' interactions with the data towards description or inference. The third phase concentrated on analyzing the type of descriptions/inferences identified during the second phase of analysis.

Findings

The context of the physical measurement of wingspans impacted the ways that students engaged with the data in a descriptive sense. It led to a focus on individual students' measurements which both helped and hindered students' perceptions as they attempted to describe the data. Including self-collected data based on their own classroom seemingly led to an appreciation for how individual values fit within the data, but at times this focus on individuals appeared to inhibit students from looking at their displays more holistically.

Personalization of data

Locating self-based measurements amongst the data set was critical to enhancing students' understanding of the characteristics of displays produced. This approach to data reading seemed to have motivated them to both create and understand their graphs (Lovett & Lee, 2016). Finding one's own measurements in the display anchored their interpretations and descriptions of the overall data as depicted in this vignette (all names are pseudonyms):

> Julie: Everybody's was in the 50s but mine – but that kind of makes sense because I'm shorter than everybody.
> Researcher: Oh, so you think that maybe it's connected to your height?
> Katelyn: Yeah, because people say that if you're really tall then you have a big wingspan
> Julie: Yeah like Katelyn and Bob are the tallest people and they have the longest – um
> Bob: Wingspan

In both this and other instances, students referenced the data values of both themselves and others in the class. One wingspan, which was lower than all the others, is given an interpretation when Julie recognizes that the value represents her and makes a potential connection with height. This is pursued further by others who recognized that the higher wingspans also represent those in the group who are taller. In this way students were able to give some justification for the variation in the data and make a potential connection with height. Their prior experiences may have impacted this interpretation, as evidenced by Katelyn's statement about what "people say" about height and wingspan.

Interpreting based on individual measurements or personal experiences led to varying approaches to inference. When asked what the graph for another, unspecified third grade class might look like, students first believed that the graphs might be similar, as when Bob and Julie referenced their displays (Figure 1) and said, "It would look a lot like this/ours", or when Jeff said, "Most of them would be in the 50s". This provides evidence that some students viewed their data as representative of third graders in general. Others believed the graphs would look different, but for varying reasons. Abbie based her analysis on another specific class, saying, "If I were to measure Ms. Johnson's class, she has some really tall kids," leading her to conclude that they would have more values on the right side of the graph. Katelyn was unwilling to describe what a graph for another class would look like because they have "different people – one class could have all the tall people". In this case, envisioning specific classes led to inferences regarding a single case (Abbie) or an unwillingness to make any conclusion (Katelyn), characteristics that have been seen previously in young students with regards to informal inference (Ben-Zvi et al., 2012; Makar, 2014). Abbie's and Katelyn's observations also provide further evidence that students inferred a more general relationship between height and wingspan; for them, referencing height appears to be sufficient to justify potential variation in wingspan.

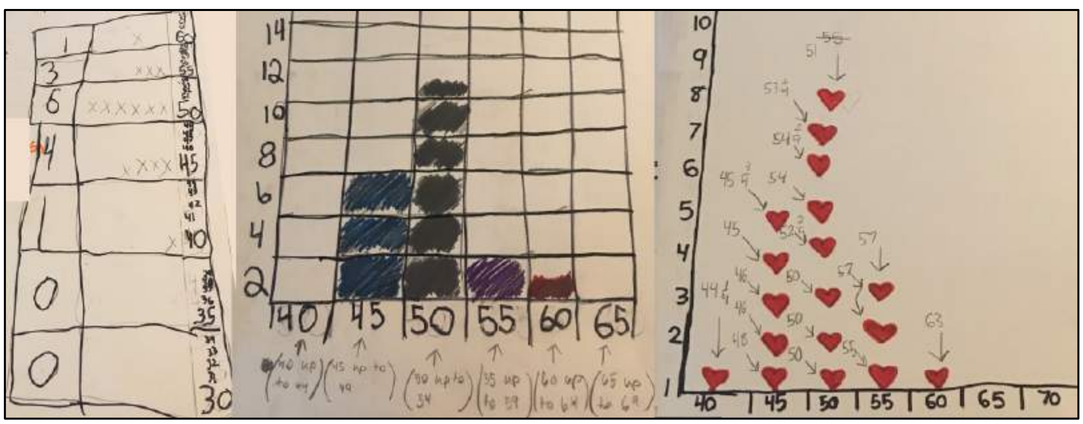

Figure 1: Jeff/Bob's display (left), Julie's display (middle), Katelyn's display (right)

Differences in Displays

The self-collected data were helpful for engaging students in interpreting their wingspans at an individual level, but the data collection and display creation process also led to some issues which kept students from seeking structural characteristics of the data. Students were intent on critiquing the format of others' displays (things like labels and titles), and characterized them as either correct or incorrect. This tendency can plausibly relate to the procedural and standalone nature of instruction on graph creation that students often experience (Friel et al., 2001). This led to a focus on minor discrepancies in students' data lists. Some values were left out accidentally by one or more of the participants, while other values differed slightly based on measurement. While this led to a discussion of measurement variability, students were also intent on tracking and noting these differences. Questions like, "Did you get John?" or "Which number is Maggie?" were common. When asked to compare their graphs, two students said, "They're all different". The following captures the difficulty students experienced in viewing and interpreting their displays holistically:

> Researcher: Look at these side by side and look at the shape. What do you notice?
> Abbie: Oh, it's the same
> Jeff: Oh they're the same
> Bob: It's the same thing
> Jeff: It's the same thing except these are pictures and those are like bars (pointing)
> Abbie: Wait wait wait!
> Researcher: What do you mean it's the same thing?
> Abbie: It's not the same thing – it's not the same thing
> Katelyn: It's not the same thing because Julie is missing a 40

Note that while students' graphs had similar structures (Figure 1), Julie's graph does not include a value in the 40-44 inch category, whilst the other two graphs do. Thus, an exchange that initially seemed to be moving students towards a discussion of the more general characteristics of their displays transitioned to a focus on an individual value. Discrepancies related to the self-collected nature of the data seemed to inhibit their ability to summarize the wingspan characteristics in this instance. Despite this, students did note some of the general characteristics of the data based on their displays. A consensus was reached that the "average" for the class was "50-55 inches" because it was "the highest" value amongst the data set. Thus, students' conception of "average" in this case appeared more closely aligned with ideas related to the formal ideas of "median" and "mode", a phenomenon previously reported by researchers who had considered students of the same age group (Makar, 2014; Mokros & Russell, 1995). Katelyn also noted during the discussion how the data "all go up and down", a reference to the unimodal shape of the distribution. Students determined that potential values could be anywhere between 40 and 65 inches, and believed this to apply to third graders in general. While some students envisioned that the graph for another class might look different in terms of "average", students also believed that the wingspans of another class would fall within this range, demonstrating awareness of reasonable variation between samples.

Discussion/Limitations

This research investigated how the use of self-collected measurement data would impact students' statistical analysis. The results suggest that positioning themselves within the data at times helps students distinguish relationships between values. However, the personal nature of the data, along with slight differences in representation due to measurement/sampling variability, at times kept students' attention on the differences between their graphs and the individuals represented by each element as opposed to aggregate characteristics of the distribution. However, the exploratory/preliminary nature of this study limits the scope of its conclusions. A future study comparing students engaged in tasks utilizing self-collected versus teacher-provided (not self-collected) data would be essential to gain further evidence of whether the characteristics observed in this study are truly related to the use of self-collected data.

DECISION-MAKING PROBLEM FOR INTERPRETING ALGEBRAIC INEQUALITIES

PROBLEMAS DE TOMA DE DECISIÓN PARA INTERPRETAR LAS INECUACIONES ALGEBRAICAS

Keywords: Inequalities, Constraints, Solutions, Number Line

The research about inequalities has reported that students treat them as equations; this parallelism also has an effect on the syntax that has a repercussion on the semantics of the literals used in algebra. The student often makes algebraic transformations without regard to the constraints of inequality. There are also conflicts with the type of solution, finally, variability can represent a problem from the treatment with the intervals, since it is related to the idea of multiple solutions.

We consider that the study of numerical inequalities and the variability of intervals are basic resources for the adequate use of linear inequalities. In the first, inequalities reflect the relationship that gives meaning to the use of signs of inequality by comparing quantities, while in the second they help to establish a relationship of dependency associated with the set of solutions.

We propose to develop this research as part of a reflective practice within a collective work that allows the student to "meet" with knowledge in a process of semiotic mediation and ethical collaboration, Radford (2020).

This ongoing research aims to develop the transit of the interpretation of the unequal sign from the numerical field, through the treatment of intervals and variability through the use of tables, to support the solution of linear inequalities associated with problem constraints for decision making, carrying out a treatment of variables as a generalized number.

To justify these relationships we will first use the model of the real line and the symmetry of the position of values, in particular, to make sense of the product by negative numbers, and then focus on the algebraic treatment of the inequalities and then make sense of the solutions over the previously used model. We would be developing this research with populations of high school students in Honduras and Mexico.

Palabras clave: Inecuaciones, restricciones, soluciones, recta numérica

Las investigaciones desarrolladas sobre las desigualdades han reportado que los estudiantes las tratan como las ecuaciones, este paralelismo también tiene un efecto en la sintaxis que repercute en la semántica de las literales utilizadas en el álgebra. El estudiante con frecuencia hace transformaciones sin tener en cuenta las restricciones de la desigualdad dominando la regla del despeje. También hay conflictos con el tipo de solución, por último, la variabilidad puede representar un problema a partir de un tratamiento con los intervalos, ya que está relacionada con la idea de múltiples soluciones.

Consideramos que el estudio de las desigualdades numéricas y la variabilidad de los intervalos son recursos básicos para el uso adecuado de las inecuaciones lineales. En el primero las desigualdades reflejan la relación que da sentido al uso de los signos de desigualdad comparando cantidades, en el segundo este contribuye a establecer una relación de dependencia asociada al conjunto solución.

Planteamos desarrollar esta investigación como parte de una práctica reflexiva al interior de una labor conjunta que permita que el estudiante se "encuentre" con el saber en un proceso de mediación semiótica y colaboración ética, Radford (2020)

Esta investigación en curso pretende desarrollar el tránsito de la interpretación del signo desigual desde el ámbito numérico, pasando por el tratamiento de intervalos y la variabilidad a través del uso de tablas, para sustentar la solución de las inecuaciones lineales asociadas a restricciones de problemas para la toma de decisiones, llevando a cabo un tratamiento de las variables como un número generalizado.

Para justificar estas relaciones usaremos inicialmente el modelo de la recta real y la simetría de la posición de valores, en particular, para dar sentido al producto por números negativos, para luego centrarse en el tratamiento algebraico de las inecuaciones y después darles sentido a las soluciones sobre el modelo previamente usado. Esta investigación la estaríamos desarrollando con poblaciones de estudiantes de educación media en Honduras y México.

The research reported here sought to answer the question: How do students' ways of thinking, about statistical concepts (data, distribution, variability, and sample) and process quality control techniques, changes while solving a Model Eliciting Activity [MEA] proposal? (Lesh, Hoover, Kelly, Hole & Post, 2000). Learning process quality control techniques is important for industrial engineering students because "these techniques are useful for identifying where, how, when and how often problems occur (statistical regularity)" (Gutiérrez-Pulido, 2005, p. 146).

We implemented a MEA proposal designed to identify the model's students generate in their problem-solving approach; which allows them to test the quality of their solutions, maintain productive thinking, in a short period of time and with a minimum of interventions (Lesh et al., 2000). In the activity, a discrepancy was raised between a pet food factory and a government institution due to anomalies in the weight of the product bags, hence the student is asked to write a letter to the editor of the magazine where the problem was reported. The letter should describe a method for verifying the packaging of the product. It was sought that with the models created the students would reinforce the concepts related to process control techniques, mainly descriptive techniques and control charts for variables.

Eighteen students participated in the activity, working first individually, and then in groups of three; at the end of the session, the participants share their work in a plenary session to the rest of their classmates. We qualitatively analyze the models and modeling process by reviewing voice and video recording from each session and categorized the level of understanding of the statistical concepts as described by Garfield & Ben-Zvi (2008).

A preliminary analysis of the models showed a change in the way concepts are thought of as data and dispersion. Students shift from perceiving data as individuals to data as a group. It was also noted that they began with a partial recognition of variation, and grew to think about the application of variation (Watson, Kelly, Callingham & Shaughnessy, 2003). Furthermore, students' ideas about concepts related to control techniques for variables were noted and need further refinement.

Palabras clave: Análisis de Datos y Estadística, Modelación, Matemáticas de Nivel Universitario

La investigación que aquí se reporta buscó responder a la pregunta ¿cómo cambia la forma de pensar acerca de los conceptos estadísticos (dato, distribución, variabilidad y muestra) y de las técnicas de control de calidad de procesos (carta de control de variables) de un grupo de estudiantes universitarios al resolver una propuesta de Actividad Provocadora de Modelos [APM]? (Lesh, Hoover, Kelly, Hole y Post, 2000). Aprender las técnicas de control de calidad de procesos es importante para los estudiantes de ingeniería industrial debido a que "son útiles para identificar dónde, cómo, cuándo y con qué frecuencia se presentan los problemas (regularidad estadística)" (Gutiérrez-Pulido, 2005, p. 146).

Se diseñó e implementó una propuesta de APM para identificar los modelos que los estudiantes generan en su proceso de solución; proceso que les permite probar la calidad de sus soluciones, mantener un pensamiento productivo, en un periodo corto de tiempo y con un mínimo de intervenciones (Lesh et al., 2000). En la actividad se planteó una discrepancia entre una fábrica de alimento para mascotas y una institución gubernamental por anomalías en el producto, por lo que se solicita al estudiante escribir una carta al editor de la revista donde se reportó la situación, en la carta debe describir un método para verificar el envasado del producto. Se buscó que los modelos creados los estudiantes reforzaran los conceptos relacionados con las técnicas de control de procesos, principalmente las cartas de control de variables.

La actividad se implementó con 18 estudiantes que trabajaron primero de manera individual, posteriormente en grupos de tres integrantes, los cuales finalmente presentaron su trabajo en una plenaria al resto de sus compañeros. Para analizar cualitativamente los modelos y el proceso de modelación se revisaron grabaciones de audio y video de la implementación, y se categorizaron niveles de comprensión de los conceptos estadísticos con base en Garfield y Ben-Zvi (2008).

En un análisis preliminar de los modelos se observó un cambio en las formas de pensar de los conceptos como dato y dispersión, que permitió pasar de pensar en cada dato de manera individual a concebir el dato como un grupo. Asimismo, se notó que comenzaron con un reconocimiento parcial de la variación y llegaron a pensar en la aplicación de la variación (Watson, Kelly, Callingham y Shaughnessy, 2003). Además, se advirtieron ideas de los estudiantes acerca de conceptos relacionados con las técnicas de control de variables que necesitan refinarse posteriormente a la implementación de la APM.

Agradecimientos

THE ROLE OF SIMULATION IN SOLVING PROBABILITY TASKS

Karoline Smucker
The Ohio State University
smucker.37@osu.edu

Keywords: Probability, Computational Thinking, Programming and coding, Problem Solving.

One of the key components of probabilistic thinking is attention to outcomes within a sample space (Chernoff & Zazkis, 2011). Researchers are also interested in the notion of computational thinking, including the use of simulation and programming (Weintrop et al., 2016). According to Lockwood and De Chenne (2020), coding can "facilitate mathematical learning" in combinatorics, an area with close connections to the concept of sample space. In addition, simulations can lead to solutions which are very close numerically to those found using theory. This study investigates how learners interpret these two solution types within a probability task.

Methods

Using a clinical interview methodology (Clement, 2000), a preservice secondary mathematics teacher engaged with a probability task. Greg (a pseudonym), was asked to determine the likelihood of obtaining 3 blue marbles in a situation where 10 marbles are drawn without replacement from a bag containing 50 green, 20 yellow, and 30 blue marbles (theoretical solution using hypergeometric distribution approximately 0.2812). The interview was video recorded and transcribed, and analysis focused on Greg's two solution strategies.

Preliminary Findings

Greg's first strategy was to think about different "possibilities", referencing the task's sample space. He listed different "configurations" that would be possible, saying, "I could go through and do this systematically by hand." Greg stated that it would take a long time to list all of these out and seemed perplexed about how he would actually get to some sort of numerical solution, but that it might involve permutations or combinations. He then stated that his next step "would probably be to run some sort of simulation," going on to describe how he would "code" the situation using random numbers, conditionals, and loops, and run 10,000 trials in Excel to get an idea of what the likelihood might be. According to Greg, "What that would do is it would give me some sort of framework to judge my work." His results from the simulation would allow him to check whether his theoretical approach was going "in the right direction". The researcher then asked whether he would consider giving the results of his program as his answer to the task. He said, "Yes and no." While he would give the answer as an approximation, he believed that to answer the question "fully" he would need to go back to his theoretical method which involved enumerating all the possibilities. It appeared that he viewed the simulation approach as a way to verify a potential theoretical solution, not as a true solution in its own right.

Discussion

This research suggests that learners may view experimental or simulated solutions to probabilistic tasks differently than those they arrive at using theoretical methods involving concepts like sample space. In this case, it appeared that a theoretical solution was valued more highly by Greg than one which utilized programming, and that his simulation was primarily useful as an approximation or verification tool. This brings up questions about what it means to "solve" a problem involving likelihood. However, these conclusions are extremely preliminary, based on one individual's responses. More research needs to be done to see if others respond similarly to solutions found using theory versus those obtained using simulation.

MATHEMATICS ANXIETY AS A MEDIATOR FOR GENDER DIFFERENCES IN 2012 PISA MATHEMATICS SCORES

Jennifer Cox
Indiana University
jennycox@iu.edu

Erik Jacobson
Indiana University
erdajaco@indiana.edu

Although gender differences in mathematics are smaller than they have been in the past, prominent voices still attribute these differences to a variety of fixed individual factors, such as genetic characteristics of men and women. We hold the alternative view that these differences can be ultimately attributed to malleable factors. From this vantage, societies could influence gender differences in mathematics by changing students' experiences in school. In this study, we built on prior work suggesting that mathematics anxiety causes lower mathematics scores. In particular, we found that mathematics anxiety entirely explains the gender differences evident in mathematics scores from the 2012 US Programme for International Student Assessment (PISA). Furthermore, we found that gender moderates the mediating role of mathematics anxiety: math anxiety is more detrimental for male than for female students. Because math anxiety is a malleable individual characteristic, we conclude that gender differences reveal more about gendered societal experiences than they do about innate characteristics of men and women.

Keywords: Gender and Sexuality; Equity and Diversity; Assessment and Evaluation; Affect, Emotion, Beliefs, and Attitudes

Headlines such as "Men in science think they are more intelligent than female counterparts, study reveals" (Richards, 2018) and "Study: 6-year-old girls say they are less 'brilliant' than boys. Why?" (Botkin-Kowacki, 2017) and "Why don't young girls think they are smart enough?" (Cimpian & Leslie, 2017) are not uncommon in the media today. Many researchers have challenged claims that "boys are better at math than girls" (e.g., Ding et al., 2006; Hyde et al., 2008). However, small average score differences between boys and girls on large-scale mathematics tests remain, particularly at the top of the score distribution, leading some to assume that girls are not as talented as boys in mathematics.

In this paper, we use the 2012 Programme for International Student Assessment (PISA) dataset to examine this small but persistent gender gap on mathematics exams. Although gaps analyses have been criticized for deficit thinking and not supporting individual students' mathematical identities (e.g., Gutiérrez, 2008), they often inform researchers and policymakers about necessary adjustments to educational systems. Lubienski (2008) notes, "It is dangerous for the mathematics education community to refrain from gaps analyses and allow others to speak in our place" (p. 352). Two recent cases illustrate this point. Mark Perry (2016), an economics professor at the University of Michigan Flint Campus used boys' and girls' average score differences on the mathematics portion of the SAT to assert that "closing the STEM gender degree and job gaps may be a futile attempt in socially engineering an unnatural and unachievable outcome" (para. 12). Likewise, Eric Rasmusen (2019), a professor in the highly-ranked Kelley School of Business at Indiana University, publicly and repeatedly agreed with an article entitled "Are Women Destroying Academia? Probably." In the article, differences in IQ scores were used to say that "geniuses" were most often men, and women's empathetic and emotional nature is the "enemy" of genius and, therefore, academia (Welton, 2019; see also Brice-Saddler & Paul, 2019). We find these views problematic because they frame female achievement in terms of fixed, innate characteristics.

Over the years, much scholarly work has been dedicated to understanding boys' and girls' mathematics score differences, and has produced clear evidence for a wide variety of contributing

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

factors. Nearly all of these factors—high-stress and timed environments, decreased curricular alignment, negative depictions in media—are related to high mathematics anxiety, which itself is a malleable factor. If educators can lessen mathematics anxiety in early grades, then more girls might increase their confidence in mathematics and subsequently pursue STEM careers. This can have a global effect, as Smith and colleagues (2015) note, because more women in STEM increases creativity and innovation. As we discuss below, researchers have also documented that mathematics anxiety affects a larger percentage of girls than boys and operates to reduce mathematics performance. Looking across these findings suggests the question that guided our research: *To what extent does mathematics anxiety explain the small but persistent gender gap in mathematics exam performance?*

Perspectives

Mathematics Gender Gaps Analyses

Researchers have found that girls outperform boys on many school measures, from grade point average to number of undergraduate, masters, and doctoral degrees in their postsecondary years (e.g., Carnevale et al., 2018). Although several researchers have found no significant gender differences on mathematics tests like state-mandated end of course assessments, National Assessment of Educational Progress (NAEP), and Pearson's Stanford Achievement Test (e.g., Ding, et al., 2006; Hyde et al., 2008), some suggest that there still might be a slight gap in scores at the higher end of the score distribution, specifically, on more challenging items that may not have been explicitly taught in school (e.g., Downey & Vogt Yuan, 2005, Lubienski & Ganley, 2017). For instance, a 2016 study by Stewart et al. found no overall gender difference for math calculation, geometric concepts, basic math concepts, and addition. The researchers did find a significant difference in solving "real-life complex math problems," which had multiple steps and required the test-taker to respond orally (p. 53). In addition, researchers have found significant score differences on the AP Calculus exam, the mathematics SAT, and the quantitative portion of the Graduate Record Exam (Niederle & Vesterlund, 2010). Cimpian and colleagues (2016) found that score differences on the Early Childhood Longitudinal Study were significant as early as first grade at the higher end of the distribution and widened throughout elementary school. Other researchers, even as early as Aiken's 1972 publication, have found little to no score differences for elementary-aged children—especially on curriculum-aligned tests, but find that a gap in scores expands in the high school years (e.g., Aiken, 1972; Casey et al., 2001, Hyde et al., 2008).

We first discuss factors that have been shown to contribute to boys' and girls' score differences on mathematics tests. A number of researchers note that timed tests can be particularly damaging to math-anxious students (e.g., Walen & Williams, 2002; Whyte & Anthony, 2012). Neiderle and Vesterlund (2010) suggest that, on average, boys are more competitive and confident than girls and use this competitive nature in high-stress test-taking environments. As mentioned, some scholars suggest that girls perform better on school-taught material (Downey & Vogt Yuan, 2005; Lubienski & Ganley, 2017) as well as tasks that involve computations and memorized procedures (Ganley & Vasilyeva, 2014). In other words, if the test is not aligned to curriculum to which they have been exposed, boys tend to score better. Others suggest differences in the ways girls and boys solve problems, with studies showing that, as early as 1st grade, girls tend to use concrete strategies like modeling and counting while boys use more creative problem-solving strategies (Fennema et al., 1998) Lubienski and Ganley (2017) state, "Girls' teacher-pleasing behavior is likely a consequence of gender socialization and […] is likely linked to later differences in mathematical problem-solving approaches, with girls following teacher-given rules more often than boys" (p. 74). In contrast, many researchers suggest that boys tend to have better spatial skills, which could improve scores on problems with measurement, space, and shape (e.g., Halpern et al., 2007; Lubienski & Ganley, 2017). Cimpian and colleagues (2016) found that teachers consistently rated girls' mathematical proficiency lower than boys with similar achievement and behaviors. Some researchers suggest that stereotype threats and negative depictions of girls and math in the media might deter girls from pursuing STEM courses and careers, with the "math is for boys" stereotype influencing students as early as 2nd grade (e.g., Cvencek et al., 2011; Gunderson et al., 2012). Halpern and colleagues (2007) believe sociocultural forces such as parent beliefs and expectations, teacher encouragement, and peer influences contribute to score differences. Van Langden and colleagues (2006) suggest that the more gender equality in a country, the smaller the score differences. They also posit that girls do better in math when they are in "integrated classrooms" instead of "differentiated systems," i.e., separate classes in which students are placed according to ability. In sum, competitive environments, timed tests, decreased curricular alignment, teacher-pleasing behaviors, less gender equity in a country, a "math is for boys" viewpoint—almost all factors mentioned—could be related to mathematics anxiety.

Mathematics Anxiety

Mathematics anxiety has been defined as "a feeling of tension and anxiety that interferes with the manipulation of numbers and the solving of mathematical problems in a wide variety of ordinary and academic situations" (Richardson & Suinn, 1972, p. 551). It differs from general anxiety and test anxiety; math anxiety can be exhibited in people who excel in testing situations in other subjects, and it can occur even during anticipation of interacting with numbers.

Dowker (2019) describes two dimensions of mathematics anxiety: cognitive and affective. The cognitive dimension closely relates to test anxiety and involves performance anxiety, worry, and "fear of failure." The affective dimension is often labeled as "emotionality" and refers to fear, nervousness, tension, and their related physiological reactions. Most importantly, the affective dimension occurs in the presence of numerical situations, with or without a test. Mathematics anxiety is not just correlated to performance deficits, but many researchers have suggested that mathematic anxiety has a causal relationship with performance deficits (e.g., Hembree, 1990; Ma, 1999). Ma (1999) describes two theoretical models that typically guide mathematics anxiety research: an interference model and a deficits model. In the interference model, mathematics anxiety disturbs the recall of prior knowledge and experiences, often causing lower scores; some scholars refer to this as the "debilitating anxiety model" (Carey et al., 2016). In the deficits model, researchers believe repeated poor performances produce increased levels of mathematics anxiety. In this model, lower scores are often attributed to poor test-taking skills and study habits. Several researchers have posited a bidirectional relationship between these two models, creating a vicious cycle of high mathematics anxiety and low mathematics scores (e.g., Carey et al., 2016; Dowker, 2019).

Working memory and the brain. Math anxiety has been shown to deprive people of their working memory, leading to lower scores, supporting Ma's interference model (e.g., Beilock & Willingham, 2014; Dowker, 2019). One might think that students with larger amounts of working memory could memorize every fact and formula and thus have lower levels of mathematics anxiety, but a counterintuitive result has been found. Children with high levels of working memory have a more pronounced negative relationship between math anxiety and math achievement (e.g., Beilock & Willingham, 2014; Dowker, 2019; Lubienski & Ganley, 2017; Lyons & Beilock, 2012; Maloney & Beilock, 2012). Dowker (2019) posits that those with higher levels of mathematics anxiety have more preoccupying thoughts and mental rumination, depleting crucial working memory resources. Consistent with Dowker's findings, Maloney and Beilock (2012) say, "Math anxious individuals tend to worry about the situation and its consequences. These worries compromise cognitive resources, such as working memory, a short-term system involved in the regulation and control of information relevant to the task at hand" (p. 404). In other words, students might be quite talented at memorizing formulas and procedures for use in normal classroom activities or homework, but the effects of mathematics anxiety might break down these rote procedures during stressful situations. Although other students might be able to solve the problem in a creative or novel way, students who have relied on rote memorization could further deplete their cognitive resources.

Neurologically, children with math anxiety show more activity in their right amygdala when performing mathematical tasks, and this area of the brain is known for processing negative emotions and fear (e.g., Beilock & Willingham, 2014; Chang & Beilock, 2016). When the right amygdala was active, there was a decrease in activity in the areas of the brain responsible for mathematical reasoning (Chang & Beilock, 2016). Psychologists at the University of Chicago refer to this as "working memory disruption," hypothesizing that students with higher working memory resources often use algorithms and problem-solving strategies with multiple steps, which are more susceptible to disruption during situations that induce anxiety (Ramirez et al., 2013). Further, Lyons and Beilock (2012) showed that the anticipation of doing math triggered the dorso-posterior insula in the brain, which is the area of the brain associated with bodily threat but also visceral pain; therefore, mathematics anxiety can be neurologically associated with physical pain.

Teacher, peer, and parent influences. Several researchers have noted how others might influence a student's level of mathematics anxiety. As early as 1959, Banks suggests that repeated failure, parents' and peers' unhealthy attitudes towards mathematics, and teacher insecurities can all contribute to students' negative associations with mathematics. Beilock et al. (2010) agree that mathematically anxious teachers at the elementary level impact students' mathematics achievement, especially when girls mimic the anxieties of their female teachers. Unfortunately, this can be a cyclical problem as the majority of elementary teachers are female, and a disproportionate number of preservice teachers have mathematics anxiety or worry that they will be unable to teach mathematics effectively. Brown and colleagues (2011) found this number to be 60% of preservice teachers, while Jackson and Leffingwell (1999) found that only 7% of preservice teachers in their study had only positive mathematics experiences in their K-16 schooling. Whyte and Anthony (2012) suggest that parents who suffer from math anxiety can transfer this to their children, and parents who give math a low status or, contrastingly, apply extra pressure to their children may contribute to mathematics anxiety as well.

Interventions to Decrease Math Anxiety

Some researchers have suggested that there is an optimal amount of mathematics anxiety that will positively affect performance. The graph is a curvilinear relationship, an inverted U-shaped curve. Cognitive reactions to mathematics anxiety might include "blanking out" or self-doubt, while an affective reaction might include the fear of looking stupid. Physical reactions for both dimensions might include perspiring, an increased heart rate, or nausea (Frieberg, 2005). In a 2010 study, researchers informed one group of participants that anxiety could help to improve performance but said nothing to the control group (Jamieson et al., 2010). When students took a practice Graduate Record Examination (GRE), the control group had more salivary alpha amylase (sAA)—an indicator of stress—than the test group. In addition, the group that was told anxiety improves performance had higher scores both on the practice test and on the actual GRE, taken 1-3 months later.

Jamieson et al. had a simple approach for lessening the impact of mathematics anxiety on high-stakes standardized tests like the GRE, but others have posited interventions to help with mathematics anxiety in everyday situations. In recent years, Ganley et al. (2019), have proposed the use of the Math Anxiety Scale for Teachers (MAST) to reduce the harmful effects of teachers' mathematics anxiety on students' learning. They note that teachers with high levels of mathematics anxiety avoid the subject, spending less time on mathematics lessons, especially in whole class discussions. Whyte and Anthony (2012) suggest promoting a positive classroom culture with effective teaching practices, such as having students share creative approaches to problem solving. They also suggest utilizing math fiction books, journal writing, and math autobiographies in the classroom. Researchers who noted the negative impact of timed tests (e.g., Walen & Williams, 2002; Whyte & Anthony, 2012) suggested providing ample time for assessments. Recently, Schaeffer et al. (2018) used an app to help mathematically anxious parents creatively interact with their children while discussing mathematics. After using the app for even a short period of time, parents reported feeling less anxious about math, and these results were maintained even two years after the study. This was an important finding, as parents' negative associations with math are often reflected in their children. Maloney and Beilock (2012), also note the importance of journal writing, saying that writing about emotions for 10-15 minutes before a test can boost the scores of students with mathematics anxiety. Lastly, students develop a negative relationship with mathematics when they are told there is only one right way to do a problem. When less emphasis is put on memorization and more weight is placed on creative problem-solving, students are less dependent on their working memory when working on mathematics problems.

Methods

Data for the present study come from the public release version of the 2012 US PISA data set. These data were selected because they are nationally representative, include trustworthy instruments measuring the focal constructs of our investigation (i.e., mathematics anxiety and of student achievement) as well as important covariates. More recent PISA data has not included the variables of interest. Participants were 4978 students aged 15 to 16 years old. The sample was 50.7% male, 52% White, 13.1% Black, 24.0% Hispanic, 4.6% Asian, 4.3% identified as multiracial, and 2.1% identified as other (n = 67, missing).

We used the PISA mathematics score as the dependent variable in our analysis. Because not all students answer the same questions when taking the PISA assessment, five plausible values are reported for each student instead of a single score. The differences between the plausible values for a specific student capture the uncertainty about the student's estimated math score. We completed the analyses described below with each of the five math scores, then used accepted methods to pool results (Rubin, 1987).

The first independent variable was a math anxiety instrument based on 5 rating items (e.g., "I often worry that it will be difficult for me in mathematics classes," "I get very tense when I have to do mathematics homework," "I get very nervous when doing mathematics problems," "I feel helpless when solving a mathematics problem," and "I worry that I will get poor grades in mathematics"). The composite score for the five-item math anxiety questionnaire was available within the PISA dataset. According to the technical report (OECD, 2014), the variable was transformed to an international metric with a mean of 0 and a standard deviation of 1 for all OECD countries that participated in the PISA 2012 (OECD, 2014). The internal validity of this multi-item construct was evaluated with Cronbach alpha = 0.88 and deemed to have good internal consistency. The sample mean was -0.104 and ranged between -2.370 and 2.550. By design, not all students answered each section of the survey. Thus, there were 1720 students with missing scores on the math anxiety measure. We used full information maximum likelihood estimator which is robust to missing data and this technique allowed us to include all students in the analysis. Self-reported gender was the second independent variable, and a summary of this variable is provided above. Finally, we used the PISA standardized index of economic, social and cultural status (ESCS) which summarizes occupational status, parent education, family wealth, home educational resources, and an index of possessions relative to each country context. The sample mean was 0.188 and ranged between -3.80 and 3.12 (n = 63, missing).

A mediation effect is said to occur when a mediating variable helps explain or account for the relationship between an independent and dependent variable. For example, in this study we wanted to know if the relationship between gender and mathematics score is mediated by math anxiety. A moderation effect occurs when a moderating variable influences the effect of the dependent variable on the independent variable. For example, gender is said to moderate the relationship between math anxiety and math scores if the relationship between these variables differed by gender. Moderated mediation describes a theoretical model that includes a variable that moderates the mediating effect of another variable on the outcome. In this study, we wanted to know whether the extent to which math anxiety accounts for the relationship between gender and math scores differs by gender—a moderated mediation model.

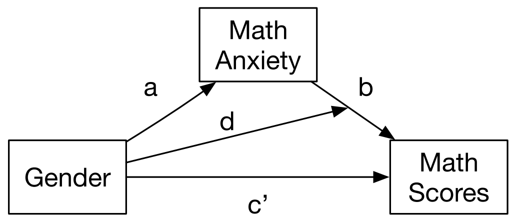

Figure 1: Conceptual model for moderated mediation.

As shown in Figure 1, the total effect of gender on math scores is the sum of the direct effect, c', and the indirect (or mediated) effect, a x b. The coefficient d describes how gender moderates the mediating effect of math anxiety on the relationship between gender and math scores. Following Shevlin et al. (2015) we operationalized moderated mediation by testing the path diagram in Figure 2 which includes an interaction term between gender and math anxiety. In this figure, the moderated mediation is investigated by examining coefficient d, which quantifies the gender difference in the math anxiety, math score relationship. We used lavaan, an R package, to estimate two structural equation models for (1) mediation and (2) moderated mediation for each of the five plausible values for the outcome variable. We used another R package (mice) to combine the results across the five models we estimated. We compared these models with a regression model that used gender and other covariates to predict math scores.

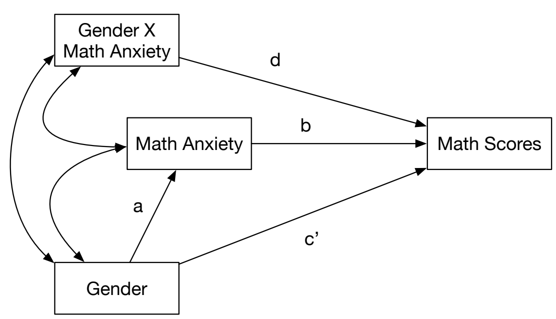

Figure 2: Path diagram used for analyzing moderated mediation.

Results

In the baseline regression model (see Table 1), we found a small (0.093), statistically significant (p < .001) relationship between gender and math scores in our sample after controlling for race and ESCS. The goal of our subsequent analysis was to understand how much of this relationship could be explained by mathematics anxiety. The second model shows that once anxiety is included as a mediating variable, the relationship between gender and math scores is no longer statistically significant (0.020, p = 0.42). Thus, in this sample, anxiety completely mediates the relationship between gender and math scores. The total effect is still the same (0.093, p < .001), but most of this effect is indirect via math anxiety (0.074, $p < .001$). The size of this effect can be quantified as the percent mediation: the indirect effect explains 80% of the total effect.

In the final model, the relationship between gender and math scores is not statistically significant (0.009, $p = 0.71$). In this model we can compare the indirect effects by gender. For males, the indirect effect is 0.085 ($p < .001$) and for females the indirect effect is 0.064 ($p < .001$). Moreover, the difference is statistically significant (.021, $p < .01$). We concluded that gender does influence the extent to which math anxiety explains the relationship between gender and math scores, and in particular, we found a stronger indirect relationship between these variables for male students.

Table 1: Regression and path coefficients for the baseline regression model and for the mediation and moderated mediation models.

	Regression Model	Mediation Model	Moderated Mediation
predicting Math Scores	β (SE)	β (SE)	β (SE)

Limitations

This study used cross-sectional data, therefore only associations—not causal relationships—can be investigated. Furthermore, mediation relationships depend on theory—not statistics. If the mediation model we presumed for this study is not accurate, then the results of the model are not meaningful (Maxwell & Cole, 2007). Finally, our conceptual model has anxiety causally preceding mathematics scores. Although we have argued in our review of the literature that this assumption is reasonable, not all scholars agree. Moreover, the data we used in this study cannot be used to settle this question because they are cross-sectional and non-experimental.

Discussion and Implications

The goal of this study was to better understand the influence of mathematics anxiety on the small but persistent gender gap in mathematics achievement. We applied moderated mediation to rigorously investigate these relationships, attending to missing data, and controlling for potential confounding variables at the same time. This rigorous method enabled us to accurately evaluate the associations between multiple variables in a large sample data set and draw robust conclusions.

Based on a large sample of 15-year-old students in the US, the results show that math anxiety entirely mediated the association between gender and math scores. In particular, the higher math anxiety of female students entirely explained female students' lower math scores. We also examined a moderated mediation model, in which we allowed the relationship between math anxiety and math scores to vary by gender. The results show that gender does moderate the mediation relationship between math anxiety and math scores. In particular, the anxiety of male students had a stronger negative association with mathematics scores than did the math anxiety of female students. Further, the moderated mediation finding suggests that although there are fewer male than female math-anxious students, the male students who have math anxiety may benefit more than similar female students from interventions because their experience of anxiety is more debilitating. Our results suggest that known interventions that decrease mathematics anxiety might be helpful in narrowing or eliminating the gender gap in mathematics achievement. For example, de-emphasizing rote memorization and encouraging creative problem-solving can lessen mathematics anxiety in early grades. As girls' mathematics anxiety has been linked to their math-anxious teachers in elementary grades, further studies using tools like the Mathematics Anxiety Scale for Teachers (Ganley et al., 2019) would be beneficial. In addition, it will be important to investigate math anxiety's relationship to other factors related to boys' and girls' score differences, such as high-stress environments, decreased curricular alignment, and negative depictions in media.

ELEMENTARY STUDENTS AND THEIR SELF-IDENTIFIED EMOTIONS AS THEY ENGAGED IN MATHEMATICAL PROBLEM SOLVING

Jenna R. O'Dell
Bemidji State University
Jenna.odell@bemidjistate.edu

Todd Frauenholtz
Bemidji State University
Todd.frauenholtz@bemidjistate.edu

In this study, we investigated two students', ages ten and eleven, emotions while they engaged in mathematical problem solving. During three task-based interviews, the students explored parts of the unsolved problem the Graceful Tree Conjecture. While they were engaged in the interviews, they self-identified the emotions of frustration and joy they were feeling using the Wong-Baker Scale. The students displayed the interplay of the emotions of frustration and joy or which we consider to be productive struggle. A descripted case of Georgia is included to describe her emotions while problem solving.

Keywords: Affect, Emotion, Problem Solving

Past researchers have documented that students experience both positive and negative emotions while engaged in mathematics (Hannula, 2015; O'Dell, 2017) and Else-Quest, Hyde, and Hejmadi (2008) and Williams (2002) have found an association between students having positive emotions during problem-solving and the development of mathematical understanding. However, much of the research completed on emotions have been documented through surveys and not while students are engaged in mathematical problem solving (Hannula, 2015).

O'Dell (2017) documented that when students are experiencing the emotion of frustration followed by the emotion of joy while the student is engaged in mathematical problem solving, they are experiencing productive struggle. Struggle is when "students expend effort to make sense of mathematics, to figure something out that is not immediately apparent" (Heibert & Grouws, 2007, p. 387). It has been acknowledged allowing students the opportunity to struggle is beneficial (Hiebert & Grouws, 2007; Kapur, 2010). Kapur (2010) said when students are allowed to struggle they are able to significantly outperform students of a similar ability who have not been granted the opportunity to struggle. Kapur further found when a student has engaged in productive struggle they are able to better transfer that knowledge to mathematical concepts to which they have not yet been exposed.

Warshauer (2015) and Zeybek (2016) stated researchers know productive struggle is beneficial but there is limited research on what productive struggle looks like. O'Dell (2017) has documented that productive struggle is the interplay of the emotions of frustration and joy, but we want to examine first how students express the emotions of joy and frustration, second how they self-identify their emotions of frustration and joy, and lastly if they self-identify as having more frustration during problem solving, do they then experience more joy.

With these ideas, the following questions guided our research study:

1. How do students display the emotions of joy and frustration while they are engaged in problem solving?
2. How do students self-identify the emotions of frustration and joy they experience while problem solving?

Theoretical Framework

To examine how students display and identify emotions, we draw on the concept of positioning theory (Van Langenhove & Harré, 1999). Positioning theory is "the study of local moral orders as ever-shifting patterns of mutual and contestable rights and obligations of speaking and acting" (van

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Langenhove & Harré, 1999, p. 1). Thus, positioning theory allowed us to examine how students position themselves through their engagement with the mathematics and the other participants. In mathematics education positioning theory has been used to examine social interactions (e.g., Turner, Dominquez, Maldonado, & Empson, 2013; Wood, 2013; Yamakawa, Forman, & Ansell, 2009) and researchers have identified that students' emotions are linked to their positioning (e.g. Daher, 2015; Evans, Morgan, & Tsataroni, 2006). Further, Wood (2013) used positioning theory to examine micro-level moment-to-moment interactions that allow a researcher to document the exact moment an identity was enacted. A person positions themselves through conversations, actions, and dispositions. Through the events and moment-to-moment interactions storylines are created. These storylines allow a researcher to document the exact moment a student displayed a disposition or in our case, an emotion.

Methods

The participants of the study were two students using the pseudonyms Luna and Georgia. Luna was 10 and in Grade 4 and Georgia was 11 and in Grade 5. The study took place on a university campus close to their elementary school in the Midwestern United States. The two students participated in three semi-structured, task-based interviews (Goldin, 2000). The interviews took place over three weeks and each interview lasted approximately 60 minutes. For the three interviews, the students explored an unsolved graph theory problem, the Graceful Tree Conjecture. This is a problem that has been used in previous studies that have documented students display productive struggle while engaged with the Graceful Tree Conjecture.

Graceful Tree Conjecture

During the three task-based interviews, the students explored the Graceful Tree Conjecture. The Graceful Tree Conjecture is an unsolved problem in graph theory that is accessible to young children. While the parts of the problem the students explored have been previously solved, the entire problem remains unsolved. The students explored different classes of tree graphs which are connected graphs without a cycle. This means all tree graphs contain one less edge than node (vertex). It is believed that all tree graphs can be assigned a graceful labeling. This means when the nodes are distinctly labeled 1 through *n* or the number of nodes in the graph. The edges are labeled with the absolute value of the difference between the two connecting nodes. If the edges are labeled distinctly 1 through *n*-1, the graph is labeled gracefully (see Figure 1 for an example of a graceful and non-graceful labeling). The Graceful Tree Conjecture states that all tree graphs can be labeled gracefully.

Graceful Labeling **Non-Graceful Labeling**

Figure 1: Example of Graceful Labeling and Non-Graceful Labeling

Overview of Task-Based Interviews

During the three task-based interviews, Luna and Georgia explored different classes of tree graphs in increasing sophistication (see Figure 2). We not only challenged the students to find a graceful labeling for the first four distinct graphs but to find a pattern or justification that would show they could label any graph in the given class gracefully.

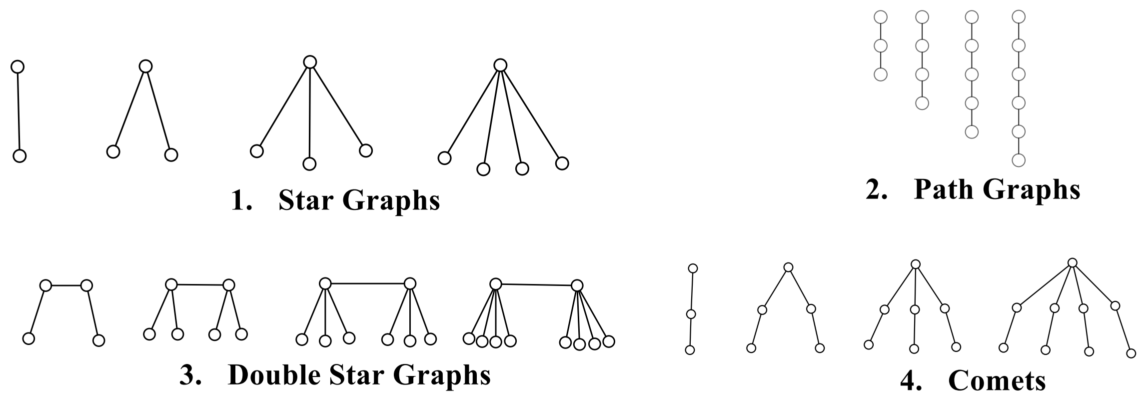

Figure 2: Graphs Students Explored in Increasing Sophistication

While the students explored the different classes of tree graphs, they were given a page on which to record labels for the first four distinct graphs in the class, a question that asked them to draw the next graph in the class, and statement to record their pattern. They were also given enlarged copies of each graph with numbered square and circle chips (see Figure 3 for an example of the students using the enlarged copy of each graph and numbered chips). The enlarged copies were given to the students so they could find solutions to the graphs without having to erase.

Figure 3: Example of enlarged copy of the graph and chips and image of how students self-identified emotions

During the first interview, the students were introduced to the meaning of the word conjecture, tree graphs, edges and nodes, what a graceful labeling was, and the Graceful Tree Conjecture. Next, they explored Star Graphs and Path Graphs. During the second interview, the students were reminded of the task, reviewed their solutions for Path Graphs, and explored Double Star Graphs. During the final interview, the students reviewed the problem, the Double Star Graphs, and explored Comets.

During each of the three interviews, the students self-identified their emotions or feelings using the Wong-Baker Faces (see Figure 3). Under the happy face, the words extreme joy was listed (we refer to this as level 6) and under the most upset face the words extreme frustration was listed (we refer to this as level 1). Students were instructed to move a chip to whatever they were feeling. An alarm sounded every three minutes as a reminder to mark their feelings.

Analysis

The task-based interviews were video recorded and the student work was collected. Next, the three interviews were transcribed using the program Transana (Woods & Fassnacht, 2016). This included the non-verbal actions, such as hand or arm motions, facial expressions, and the Wong-Baker level the students self-identified as. We then used a framework created by Else-Quest et al. (2008) and adapted by O'Dell (2017) to examine the emotions of frustration and joy the students displayed. Because of O'Dell's (2017) prior findings that the most common emotions students displayed were frustration and joy, we only examined the transcripts and video for those emotions (see Table 1 for modified framework).

Table 1: Analytic Framework

Emotion	Definition	Example
Frustration/Distress	Disappointment, discontent, displeasure	I am stuck. Man, this is confusing.
Joy/Pleasure	Delight, amusement, pride	I got it!

We examined the transcripts using the analytic framework and documented anytime an emotion of joy or frustration was displayed using Transana (Woods & Fassnacht, 2016). If the study displayed several statements or emotions of joy in a row, each individual statement or motion was documented as its own occurrence. We also document every time a student changed their self-identified emotion on the Wong-Baker Faces. Both authors both did this and discussed any discrepancies until we both agreed. Next, we created reports through Transana to account for each emotion and self-identified level displayed by the student.

Results

During analysis, we examined the emotions of frustration and joy the students displayed while working (see Table 2) and what level on the Wong-Baker Scale they marked. First, we will share the overall instances of frustration and joy, next we will give a description of Georgia during the third session to show how her emotion was displayed with her self-identified emotions, and lastly, we will share how the students self-identified on the Wong-Baker Scale.

Frustration and Joy

After analysis of the data, we used Transana to run reports of the instances of frustration and joy. We found 51instances of frustration and 92 instances of joy (see Table 2 for instances).

Table 2: Frustration and Joy Displayed by Interview

	Interview 1		Interview 2		Interview 3		Total	
	F	J	F	J	F	J	F	J
Georgia	6	12	5	16	22	19	33	47
Luna	2	10	13	18	3	17	18	45

Joy was typically displayed by both students when they made progress on the Graceful Tree Conjecture. Luna displayed joy, most commonly by verbal statements such as "I got it! So, I just have to figure out this pattern" when she found a graceful labeling. Another example of joy for Luna was, "that would be three. Yay!" with a big smile and saying "Okay, I have got to make sure I did this right." She also displayed joy when she was sharing her pattern verbally to one of the researchers and Georgia.

Georgia also displayed joy when she found a graceful labeling. Her joy was displayed more often by physical movement. One example is when she found a solution to a graph, she circled her arms around her head smiling and saying “my brain powers.” Another instance of joy she motioned her hands over her page and said: “Ta-da!” She often clapped her hands with excitement, danced in her seat, or made a fist of joy.

Frustration was typically displayed while attempting to find a graceful labeling for a specific tree graph, searching for a pattern in a class of tree graphs, and when we pushed the students to create a generalization for each specific class of tree graphs. Luna gave verbal statements in a similar way that she displayed joy. She often things such as, “That wouldn’t work” or “Wait, that wouldn’t work because the five is supposed to be there.”

Georgia again displayed her frustration more visually and kinesthetically. She would make faces of frustration, show frustration through her eye movements, leaning her body back in the chair, and toss chips down on the table when she got stuck.

Descriptive Case Study of Georgia

Georgia was a Grade 5 student. Her story from the third interview was chosen to be documented because she displayed the largest amount of frustration and joy. She worked on the Comet Graphs (see Figure 3). She began the session by identifying herself as a level five on the Wong-Baker Scale. Showing her joy of starting the interview session. The researcher then introduced the class of tree graphs called Comets. Georgia displayed joy by stating, “Those look really cool.” She began to attempt to label the first distinct graph in the class (see Figure 4 for her labelings) and displayed several signs of frustration. After making an angry face at the camera, she said (time is shown as minutes and seconds into the interview):

(6:15) I am trying to remember my line graph pattern.

She then continued to move chips around. Several seconds later she made a motion with her hands and gave a big smile showing joy. She asked:

(6:40) Is that graceful?

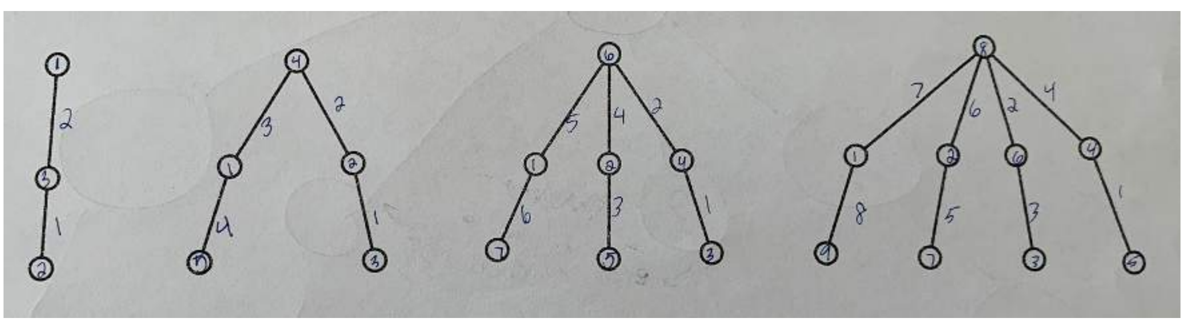

Figure 4: Georgia’s solutions to the first four distinct comet graphs

After deciding that it is and recording her solution, Georgia began to work on a graceful labeling for the next graph. The timer sounded and she moved down to level four on the Wong-Baker Scale. Georgia stated:

(7:27) I am feeling a little confused.

She continued to work and at nine minutes into the interview, she shook her head displaying clear signs of frustration. Georgia stated with a frustrated undertone:

(9:05) Wait, how would you label it gracefully? Like, how would you?

Georgia continued to work on the labeling and thirty seconds later she gave a sly smile and said:

(10:15) Got it!
(10:21) That is graceful right?

The researcher told her she was correct and the three-minute timer sounded. Georgia moved her tile to level 5 or second highest level on the Wong-Baker Scale and stated:

(10:31) I feel good!

Georgia then began working on the third distinct graph in the class. The next timer went off and Georgia moved down to level 4. She continued to work. At 15:23, Georgia tossed a chip with an angry look on her face showing a sign of frustration. Next, she said:

(15:23) I am stuck.

She continued to work making two more facial movements of frustration and several seconds later said:

(16:25) Ugg

The timer went off again, Georgia moved down to level 3. She said:

(17:12) This is confusing.
(17:31) So I was just doing it line by line trying to figure it out.

Georgia continued to move chips around looking for a pattern and making visual signs of frustration but no verbal signs. At twenty minutes in, the researcher told both girls they stuck at the same place. Georgia put a big smile on her face showing a sign of joy. She continued to work on finding a label but did not show any signs of frustration. The timer went off at 24 minutes and Georgia moved her level up to four.

At 26 minutes in, Luna found a graceful labeling for the third graph. Georgia examined Luna's paper, followed suit quickly, and stated she found a solution that was the same as Luna's solution. Both girls began working on the next graph, repeatedly saying, "I think I can" and laughing. Several minutes later, Georgia stated with frustration:

(37:16) Urg, this is where I got confused last time.

When the timer went off next, Georgia moved her level down to 3. She continued to work on her graph. She stated:

(38:41) Oh, wait, no, no, no. Four minus what equals five. Four. Five. Six
(39:03) So I want this to be four so two minus what equals four?
(39:16) Ten. Six.
(39:40) And I want my three to be here. Brain is working.

At 39:51, Georgia began clapping and smiling and then stated:

(39:52) This is my only hiccup. That is what my teacher says. That is my only hiccup.

She thought she had an almost graceful labeling but had one edge that did not have the proper number for a graceful label (she was missing a five). She continued:

(40:18) I know but, wait, wait, wait.

Georgia made an angry face and made a joke about not liking fives. The timer went off and Georgia moved her tile up to four and continued to move chips around. Two minutes later, Georgia exclaimed:

(42:19) Eight! Ah. One is always here and then it goes. Wooo (hands on her head). That is the second biggest number because that is the third biggest number.

She continued to work. Next, she said excitedly:

(43:19) Oh, I am so excited!

She found a solution to the fourth graph and after prompting from Luna, Georgia moved her tile to level six but said:

(43:45) It is kind of confusing because I have mixed emotions.

And then she moved her tile back down to level four. She examined her solutions looking for a pattern and stated:

(44:23) So this is one and then and then it counts by twos. This is the second biggest number. That is the biggest. That is the third biggest number. This is the fifth biggest number.

Georgia continued to examine her solutions and found a pattern to generalize that any Comet graph can be labeled gracefully (see Figure 5 for her generalization). She shared that the bottom row of nodes were odd numbers and the biggest, the middle row of nodes was one and the even numbers, and the center node was the second biggest number.

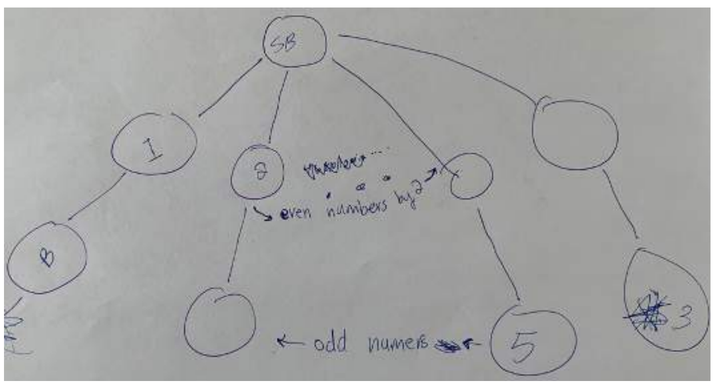

Figure 5: Georgia's generalization to Comet Graphs

Self-Identified Emotions

While the two students were engaged in the task-based interviews they self-identified their emotions of frustration and joy using the Wong-Baker Scale. The face of the most frustration we assigned a numeric value of one and the face with the most joy has a value of 6. Both subjects expressed familiarity with the scale from visiting the doctor's office. A timer went off every three minutes to remind them to mark how they were feeling and they were encouraged to move the tile to a new face if their emotion changed. We used Transana to run reports for every time the students self-identified using the tile and the Wong-Baker Scale (see Table 3)

Table 3: Frequency of tile movement on the Wong-Baker Scale

Level	Luna				Georgia			
	Day 1	Day 2	Day 3	Total	Day 1	Day 2	Day 3	Total
1	0	0	0	0	1	0	0	1
2	0	0	0	0	0	0	0	0
3	1	3	2	6	1	1	3	5
4	2	4	5	11	4	3	5	12
5	3	5	3	11	6	3	3	12
6	1	0	1	2	3	0	1	4

When either Luna or Georgia changed their tile to a higher level of frustration (lower number) on the Wong-Baker Scale they typically made some type of comment to discuss why they were moving down. The comment almost always had to do with them being “confused” or as Luna would say, “cornfused.” Neither student ever identified being more frustrated than a level 3 besides Georgia on the first day. This happened at the end of the session and with the tile movement Georgia stated, “I feel sad because we have to leave.”

Midway through the first interview, Luna decided that they should treat level six (extreme joy) as if they are experiencing similar feeling to riding a roller coaster and only move to that level if they felt that way. After that statement, there were only two more instances of extreme joy. Luna’s extreme joy came at the beginning of the third interview and said, “I feel good.”

Luna and Georgia tended to move their tile up when they were finding success on the graphs but that was not always the case. Several times both students would shift their tile higher when they reached a similar place on finding graceful labelings and were encouraged by the researcher to work together. Luna also tended to move her tile up at times while engaged in struggle and showing frustration but would not give a reason. For example, while trying to find a labeling for the third distinct Comet Graph she stated, while moving her tile up from three to four, “I am feeling better because” but did not give a reason. Both students never stated they reached extreme frustration besides, Georgia when she was sad they had to leave or even the level two. They also seldom reached level six of extreme joy.

Discussion and Conclusions

The results of this study are similar to Else-Quest et al. (2008) and O’Dell (2017) that students displayed both frustration and joy while engaged in mathematical problem solving. When O’Dell (2017) completed a similar study, she found students displayed more frustration than joy; however, we found the students to display more joy than frustration. Both studies still contained the oscillation between frustration and joy while engaged in problem solving. While Georgia and Luna were struggling through finding a graceful labeling they displayed several instances of frustration and when they found a successful labeling they displayed instances of joy. Other times they found joy in working together on the problem and through making jokes, such as “I think I can” while working.

When self-identifying their emotions, the two students repeatedly moved their tile to more frustrated when they stated they were “confused” and moved their tile toward joy when they found solutions. At other times we were not sure why they moved their tile toward joy while they were clearly still frustrated during the problem solving. Interestingly, they never—with the exception of Georgia being sad about the interview was over—moved to high frustration, level one or two. They only documented level three eleven times even though we documented 51 instances of frustration. The ratio of joy to frustration (levels 1-3 frustration and 4-6 joy) was 52 to 13. This demonstrated that even though the mathematical task was rigorous and an unsolved mathematics problem the students reported significantly more joy than frustration by a four to one ratio.

Overall, both of the students in this study were able to preserve through the struggle and frustration and were able to find joy and pride in their work on an unsolved graph theory problem. Unsolved problems are not typically included in elementary school but we found these problems to give students the opportunity to experience mathematics more similar to how mathematicians experience mathematics as a quest to describe patterns and relationships.

A CULTURE OF CHANGE: STUDENTS STORIES IN UNDERGRADUATE REFORM MATH

John Bragelman
San José State University
john.bragelman@sjsu.edu

Wesley Maciejewski
San José State University
wesley.maciejewski@sjsu.edu

A student's perceptions of, feeling towards, and beliefs about mathematics have long been known to be associated with their learning and performance in mathematics. But how might we observe and document changes in these attitudes and dispositions? How might a student's affects respond when the nature of mathematics changes? To answer these questions, we adopt a life stories theoretical perspective and read these stories through an affect lens. In so doing, we observe patterns of change in students' affects that correspond to milestones in their concurrent mathematics course. We present a vignette that illustrates one student's redemptive story of her transformation towards productive affects. Taken together, we suggest that curricula can be enacted in ways that afford such redemptive changes.

Keywords: Affect, Emotion, Beliefs, and Attitudes.

Introduction

In 2017, in the California State University (CSU) system, over 25% of entering, full-time freshman (16,628 students) were placed into a remedial mathematics sequence. Their stories within remedial mathematics courses were bleak, with students describing experiences of increased anxiety and negative dispositions towards mathematics (Maciejewski, Tortora, & Bragelman, under review). A change to this placement system was needed.

Later that year, the CSU Chancellor's office issued Executive Order 1110, which abolished remediation across its 23 campuses, leaving the institutions to individually determine reform of their general education mathematics curriculum for the 2018 academic year. San José State University embarked on a curricular redesign, Math 1, that emphasized four principles: an inclusive environment where students were no longer tracked by ability; content emphasizing contemporary mathematics rather than the traditional algebra sequence; a student-centered classroom experience; and a curriculum that also targeted non-cognitive components to support students' disposition towards mathematics (Maciejewski et al., accepted). In short, the reform targets multiple processes of the instructional dynamic (Cohen, Raudenbush, & Ball, 2003). In this work, we orient on the interactions between students and the reform curriculum by exploring students' change in affect towards mathematics as evidenced in their emergent life stories during Math 1.

Life Stories

We approach learners' experiences through a life narrative or life story methodology (McAdams, 1985, 2008; McAdams, 2018; McAdams & McLean, 2013; McLean et al., 2018. Indeed, "stories are the best vehicles known to human beings for conveying how (and why) a human agent, endowed with consciousness and motivated by intention, enacts desires and strives for goals over time" (McAdams, 2008, p. 244). They capture both consistent and inconsistent patterns over time (McAdams, 1985), such as a person repeatedly identifying as 'bad at math' across interviews or as a person describing what sequence of events led them to changing their major. Stories evolve over time, implying individuals' meanings attributed to important events may also change (Singer & Salovey, 2010). Last, stories are contextual (McAdams, 2013), suggesting stories are both created and discontinued within established cultural norms and traditions.

Affect and Stories

The affective domain in mathematics education encompasses varying concepts and theories and manifold approaches to its study (Goldin et al., 2016), and there is a clear alignment between life stories as a methodology and affect as a theoretical lens. Di Martino and Zan (2010) provide an entry point to examining students' affects towards mathematics through stories, with the Three-dimensional Model of Affect (TMA) having been developed from thousands of students' life stories with mathematics. We approach affect in this work through the TMA of Di Martino and Zan (2010); in particular, we restrict our attention to the categories of emotion and competence. Rather than approaching students' affect towards mathematics through more traditional life stories approaches (cf. McAdams and McLean, 2013), we explore students' change in affect by capturing multiple narratives across a semester of a reform introductory university mathematics course, in situ. Unlike Di Martino and Zan (2010), we explore change in affect across multiple narratives from each participant.

Method

In this multiple case study, we draw on empirical data collected during the first semester implementation of Math 1 in Fall 2018 at San José State University. The case study focus was twofold: an examination of students' mathematics experiences and affect in a reform general education mathematics course and an examination of a specific institutional implementation of a new curriculum (Yin, 2009). Within a life story methodology, qualitative methods were employed for the inquiry, most notably classroom observations and semi-structured interviews. Data was collected across two course sections of Math 1, and a subset of this data, ten students' stories about their mathematics learning experiences, is the primary unit of analysis here.

Setting and Participants

Under Executive Order 1110, incoming freshmen at San José State University are no longer required to take a basic skills assessment, which would normally have determined the starting point in their course sequence. Rather, multiple academic indicators are used to place students into the mathematics sequence appropriate for their degree focus. Math 1 served as the first of several mathematics courses for mathematics-intensive degree programs. However, students in non-mathematics intensive programs had the option to self-enroll in Math 1 as it satisfied their general education mathematics requirement. Of the 288 students enrolled in Math 1 in Fall 2018, 10 consented to the interviews.

The first author conducted three to four interviews across the semester, depending on students' availability, with a total of 53 interviews. Interview questions focused on personal background and school experiences, with an emphasis on school mathematics experiences both before and during Math 1. The first set of interviews was conducted during Unit 1, before the first assessment. The second set was conducted during Unit 2. The third set was conducted during Unit 3, and the fourth set, if availability allowed, was conducted in the last week of the semester, before finals. This work focuses on the participants who interviewed at all four time points, amounting to five participants in total.

Coding

Interview data was transcribed using an online transcription service, and the results were transferred into Microsoft Excel for coding. The interview data was separated into time points by participant, and each time point was broken into narrative utterances between interviewer and interviewee. Di Martino and Zan (2010) inform our coding for affect. Drawing on their descriptors for emotion and competence, we assigned codes of emotion (positive or negative) and competence (high or low) to narrative utterances, when applicable. Each time point was reduced to a single descriptor of affect dependent on the frequency of emotion and competence codes: more negative affect, less negative affect, less positive affect, and more positive affect. McAdams and McLean (2013) inform our coding for life story constructs.

Results

Table 1 displays participants' change in affect across a semester of Math 1. Participants' affect across the semester changes in relation to the reform curriculum and their perceived performance in the course. While changes in affect do not necessarily align with changes in perceived performance, emergent life stories seem to coincide with changes in participants' affect and perceived performance. Whereas we identify three types of changes in Table 1, we discuss one in this proposal due to space constraints.

	Entering Affect	Test 1	Affect After Test 1	Test 2	Affect After Test 2	Test 3	Affect After Test 3
Brian	more negative	30	more negative	50	less negative (**redemption**)	80	less positive
Alejandra	more negative	50	negative (**redemption**)	80	less positive	100	more positive
Becky	more positive	86	more positive	84	less positive (**contamination**)	78	less positive
Cici	more negative	32	more negative	34	more negative	56	less negative (**redemption**)
Frank	more negative	100	less positive (**agency**)	75	less positive (**contamination**)	91	less negative

Table 1. Affect and perceived performance across a semester of Math 1

Redemption - Alejandra's Story

Alejandra is the first in her family to attend college. While not required to take Math 1, she enrolled in it due to her more negative affect towards math, in her words, 'to start anew'. Her narrative suggests her negative perception of math developed in high school. Moving into Math 1, she struggles initially, as the course's focus on explanation and reasoning was difficult for her to understand. She explains that she felt lost with her first group. In her second interview, Alejandra describes how she felt during the first test:

> Alejandra: I did feel more confident, after the end. Right, I knew I failed this. After the end I felt like, I don't even know if I could say for certain I did it, wrong or right. Cause I was like, this answer ... you can answer the question, you can answer really simply even with equations or make it as complicated as you want to. At the end of the day, I guess you could say it was a flip of the coin.

In the same interview, she later describes her work with a new group, newly assigned after the first assessment, particularly one member, who has a noticeable impact on her understanding of the concepts.

> Alejandra: I think just surrounding myself with people who understand the material has made me understand that material more. The previous test, I think what happened was my group, we didn't talk about anything, so I was very confused, as were they.

Alejandra suggests the negative experiences of the first test and her first group pushed her to find what was missing for her success in the course. These narrative excerpts alone would not indicate a redemptive story; also necessary was her shift in performance and in her affect in the subsequent interviews. For example, in her fourth interview, she describes the end of her redemptive story:

Alejandra: I think when we were doing the disease population problem, and I was telling people where to move and stuff. And they'd be like, "I don't understand." And I would explain to them and in my head I was like, "You know this, like you're explaining to them. They're not explaining to you."

Alejandra experiences a change in perceived competence, part of her overall shift in affect across the semester. For her, Math 1 was the context for her redemptive story with mathematics.

Discussion

We highlight the theoretical underpinnings of our work as opening up potential new perspectives and approaches to understanding the development and evolution of students' affects towards mathematics. To assess change in affect, we could have used an established instrument with a pre/post design (e.g. the Mathematics Attitudes and Perceptions Survey (Code, et al., 2016)). However, any such instrument is inherently limited in scope: though they might capture the "first order" affects that bear on performance, say, they cannot capture the full lived experience of the students in mathematics. What's more, there are no objectively positive affects in mathematics, but rather productive affects; persistence during "effortful struggle", for example. A life story methodology captures these.

Participants' stories unfolded during a mathematics course that was intended to be a new mathematical experience, different from the traditional curriculum from high school. Our analyses demonstrate transformations of negative affects into productive ways of working with mathematics. This presents an opportunity: curricula can be designed and enacted to afford such productive transformations. The culture of a course can be a culture of change.

DISCOVERING SQUARE ROOTS: PRODUCTIVE STRUGGLE IN MIDDLE SCHOOL MATHEMATICS

Cindy Cattey
The University of Texas at San Antonio
ccattey1@saisd.net

Cody Patterson
Texas State University
codypatterson@txstate.edu

Using videos and transcripts from a lesson on square roots and follow-up conversations with students and teachers, we analyze factors that can facilitate episodes of productive struggle, including student and teacher dispositions, task features, and classroom conditions. We highlight choices and task features that honored student autonomy and maintained students' engagement in, and success with, the lesson. We also discuss students' equitable access to the mathematics of the lesson.

Keywords: Problem Solving, instructional activities and practices, and communication.

Background and Theoretical Framework

The phenomenon of productive struggle is a relatively new research focus in the study of classroom mathematical activity. Warshauer (2015) characterized productive struggle in terms of students' "effort to make sense of mathematics, to figure something out that is not immediately apparent" (Hiebert & Grouws, 2007, p. 287). Her findings suggest that teacher interactions with students in moments of productive struggle can either maintain or subvert the cognitive demands of tasks, thus strengthening or hindering student learning and understanding.

Sengupta-Irving and Agarwal (2017) discuss the implications of collective effort and decision making in persistence through challenging episodes, as well as indicators of these occurrences that allow educators to facilitate productive peer interactions. Granberg (2016) investigates the role of student observation and analysis of errors and mistakes in turning struggle into a productive event. She relates her definition of unproductive struggle to Schoenfeld's (1985) description of the behavior of novices, in which ideas are not revisited and knowledge is not reconstructed. Zeybek claims that tasks with high-level cognitive demands, specifically those which lend themselves to multiple approaches and allow for more than one correct answer, are essential to students' development of deep understanding (Zeybek, 2016).

In keeping with Harel's Necessity Principle (Harel, 2013), we hypothesize that students' acquisition of mathematical ideas is both more likely and more robust when animated by an intellectual need to understand a situation or solve a problem. Therefore, we conceptualize productive struggle as follows: we say that students are engaged in *productive struggle* when they autonomously attempt to use resources - including their own knowledge, knowledge of their peers and teachers, and physical resources such as technological tools - to overcome an intellectual obstacle, and when this process leads to the discovery or consolidation of a mathematical idea, technique, or problem-solving strategy.

Guided by this framework, we aim to address the question: *What student and teacher dispositions, task features, and classroom conditions are conducive to productive struggle?*

Study Method and Participants

This study was conducted at a two-week summer mathematics program for upper-elementary and middle school students in 2018. Our studied focused on one course which covered concepts of area, perimeter, and the Pythagorean theorem. The course was taught by an inservice seventh grade algebra teacher (Rita) and included seventeen students entering grades 6 and 7, two preservice

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

teachers (PSTs), and a doctoral student with experience teaching in special education programs. Sixteen students, Rita, and her three assistants (the two PSTs and the graduate student) participated in our study. Eight students were male and eight were female; all but one student belonged to ethnic minority groups.

The classroom was videotaped at all times, with a second camera used to capture episodes of small-group work. During breaks, we often conducted brief audiotaped interviews with Rita to capture her perspective on activity that had just occurred. After each day's class, Rita and her assistants completed written reflections and participated in a videotaped small-group debrief of the morning's events.

Throughout the program, we observed and recorded instances in which the entire class's activity met our criteria for productive struggle: that students are engaged in a sustained effort to overcome an intellectual obstacle; that students autonomously use resources to overcome the obstacle; and that the effort results in the discovery or consolidation of a mathematical idea, technique, or strategy. In this report, we present our analysis of one such instance, informed by observations from both students and teachers, in order to illuminate characteristics of a lesson and learning environment that can stimulate productive struggle.

Data Analysis

Our analysis of classroom, debrief, and interview transcripts focuses on an episode that occurred during the seventh day of the program. Following an activity on the Pythagorean theorem, Rita presented students with a planned sequence of problems on squares, square roots, and areas and perimeters of rectangles. Each time Rita presented a problem, students were asked to work out the problem on individual whiteboards at their seats, concealing their work until Rita prompted the entire class to reveal their answers. Students' work on the problems revealed some lingering confusion about the distinction between squaring a number and taking the square root of a number and the distinction between the area and the perimeter of a square; Rita and her assistants addressed these confusions as the class progressed through the tasks.

For the last problem in the sequence, Rita drew a picture of a square, labeled the area as "$A = 40$ cm^2", and asked students for the length of a side ("$l = ?$"). Videos of students' work revealed that most students approached this problem by observing that the length must be between 6 and 7 centimeters, then attempting to obtain increasingly precise approximations for the side length by iteratively selecting decimal numbers between 6 and 7, squaring them by hand, and using the result to decide whether to guess a higher or lower value for the side length.

Rita led a brief discussion of side lengths that students had tried so far. This discussion organically reverted to small group and individual work, with students attempting to refine approximations. During this process, a student discovered a bag of four-function calculators (with square root keys) behind the teacher's desk, and Rita encouraged students to use them to continue their work on the problem. The episode closed with a discussion of how the square root function on the calculator could quickly provide an approximation for the side length of the square, and why no terminating decimal value would yield an area of exactly 40.

We selected four students for one-on-one interviews at the end of the lesson based on the key roles they played in the development of the episode. During interviews, students had access to rulers, four-function calculators with square root keys, grid paper, and sheets of blank copy paper, as well as their personal electronic devices, when they were available.

In reviewing classroom and interview data, we conducted a thematic analysis (Braun & Clarke, 2006), coding themes in classroom discourse and in students' and teachers' descriptions of the episode that corresponded to elements of our framework for productive struggle or suggested factors that contributed to the episode's development. We organized our analysis according to the extended instructional triangle of Boerst and Ball (2007), which suggests we may gain insight by analyzing the work of students, work of teachers, mathematics in which students and teachers are engaged, and learning environment. We analyzed video and transcripts of the classroom episode, and then triangulated our observations with insights from our interview with Rita and the post-class debrief. We summarize the themes we identified in Table 1.

Table 1: Factors Supporting Productive Struggle in the Square of Area 40 Task

Student Factors	**Teacher Factors**
Curiosity about the value of an unknown quantity* Willingness to persist through lengthy calculations* Disposition to use tools strategically*+ Approximation sense: understanding when a guess is too high or too low; deciding when to move closer to one endpoint of an interval	Commitment to growth mindset (shared by Rita and assistants)* Commitment to probing rather than directing student thinking Disposition to enlist students in addressing each other's thinking Disposition to allow students to use technology to make work more efficient* Strategies for sustaining student motivation and engagement
Task Factors	**Learning Environment Factors**
Problem was "not too easy, not too hard"+ Problem came at the end of a sequence of tasks that gradually increased in difficulty* Problem addressed students' conceptions of perimeter and area* Problem rewarded sustained effort with successively more accurate approximations	Calculators were available in room, but not immediately visible* Classroom norms permitted students to move about the room and share ideas and approximations with each other
* Indicates an observation supported by teachers' comments during the interview or debrief + Indicates an observation supported by students' comments during post-task interviews	

Based on our observations as well as those of Rita and the assistants, the children's work on the Square of Area 40 task satisfied our criteria for productive struggle. Their work was productive in that it created learning opportunities that were realized in the collaboration among students and teachers: the co-construction of a process for interpolating a solution x to the equation $x^2 = a$, where a is a given real number, the consolidation of this process into the notion of the square root, and a discussion of how a calculator rounds the results of calculations and can appear to give a whole number output, even when the true value is not a whole number.

Teachers' discussions after the lesson revealed several student dispositions that contributed to the lesson's success in stimulating productive struggle. Foremost among these was genuine curiosity and excitement about the problem situation, as the doctoral student pointed out during the post-class debrief: "[the] question created so much engagement … intense discussion, action, like everybody's running around, digging in to get that exact number." Another factor was the students' willingness to persist through laborious pencil-and-paper calculations as they tested their guesses. During the episode, several students tested guesses that had three significant digits of precision. In the post-class debrief, the doctoral student recalled that "they were just … very excited, trying to be precise." Also important, in our own observation, was the students' strategic knowledge for approximation. For example, at least one student observed that since 40 was closer to 36 than to 49, her first guess for the side length should be closer to 6 than to 7. Students' approximation sense helped them obtain more accurate guesses for the square's side length, allowing them to obtain areas closer to 40 and bolstering their motivation to continue.

Both Rita and one of the PSTs spoke about the importance of helping students interpret struggle and temporary adversity through a growth mindset, so that students were not discouraged by temporary setbacks. Several choices by Rita and her colleagues bolstered students' sense of mathematical agency, and their disposition to encourage students to help one another through obstacles. This included heavy use of probing questions and tendencies to frequently have students describe their work in detail. We hypothesize that such facilitation moves by teachers can help students reinforce the conceptual content of a lesson for themselves and others, and allows them to enlist their peers as resources in pursuing a shared strategy.

Characteristics of the classroom environment also played a role in the episode's development. In their initial work on the task, students performed calculations by hand. Gradually, some students began to use the calculator functions of their phones to explore more efficiently; some students noticed this and questioned whether the use of calculators was contrary to class norms. The initial lack of calculators encouraged students to perform calculations by hand, which helped them become accustomed to the parameters and goals of the problem. However, the availability of calculators to only students with personal devices threatened to limit some students' access to the full depth of the task. The class set of calculators helped to resolve this, though some students still had access to more precise approximations.

Technology played an additional role in the resolution of the task: one student discovered that when she squared one of her estimates on her phone, the device reported that the square was 40. However, switching the phone to landscape orientation revealed more digits, showing that the value was equal to 40 to only thirteen decimal places. This helped the student to see that the device was automatically rounding values, even when it appeared to report a whole-number answer. Rita, noticing this insight, asked the student to share it with the entire class, again helping one student's access to the mathematics in the task become a resource for others.

Discussion

Granberg (2016) posits that when students are prematurely offered procedures for solving mathematics problems, the intellectual challenge of problem solving is lost, and students' inquiry into the nature of such problems is cut short. The Square of Area 40 task led to an episode of productive struggle in which students refined their conceptions of squares and square roots in an exploratory way without being guided to use a particular procedure or strategy. We hypothesize that the autonomy afforded to students during this activity strengthened their sense of agency as well as their understanding of the nature and purpose of the task. This sense of autonomy was a result of choices made by both students and teachers during the activity.

We hypothesize that the conditions we have described - student and teacher dispositions, task features, and classroom conditions - can be tailored to create a learning environment which facilitates productive struggle. These factors can further be considered in bringing productive struggle from a thing we strive to achieve into something that can be operationalized in creation of tasks to be facilitated in the research environment. However, some care is necessary to ensure that the benefits of productive struggle accrue to all students and that the knowledge and resources enjoyed by some students are marshalled for the benefit of the entire class. In orchestrating the lesson, Rita and her colleagues explicitly reinforced productive processing of adversity, encouraging students when they made mistakes or when their calculations did not turn out as anticipated. They also noticed some of the insights available to students with personal handheld devices and worked to draw other students into discussions about these insights. By attending to issues of equity, the teachers enhanced the lesson's effectiveness and deepened students' opportunities for learning.

EVERYDAY EXPERIENCES AND SCHOOL KNOWLEDGE OF MATHEMATICS. AN ENACTIVE APPROACH

EXPERIENCIAS COTIDIANAS Y CONOCIMIENTOS ESCOLARES DE MATEMÁTICAS. UNA APROXIMACIÓN ENACTIVISTA

Edda N. Jimenez de la Rosa y Barrios
Universidad Pedagógica Nacional
edda_jimenez@g.upn.mx

This text details the advances of a study based on the enactivist perspective of knowledge embodiment (Maturana and Varela, 1984; Varela, 2000). The purpose is to document the current knowledge about number, space and measuring, of children in a multigrade primary school located on a coffee plantation, where they also live and coexist with daily coffee-related activities. The recorded repertoire of these children's enacted learnings will be the foundation for teachers to propose situations that can help retrieve knowledge obtained beyond classrooms, through a corporal and sensitive experience. As Varela argues, this approach challenges the common classroom ethos and calls for a transformation of the research community's modus and values.

Keywords: Elementary Education, Embodiment and Gestures Studies, Rural Education, Concept of Number and Calculations.

Evidence derived from own experience and formal research has shown for years that children build knowledge (Resnick, 1989; Resnick & Greeno, 1990), which in most cases is not related to formal school learnings. This can be observed particularly among the contents in the field of mathematics prescribed by formal education and the skills that are acquired outside of it (Nunes, T., 1993; Padilla, 2015). In cases where out-of-school knowledge is documented, a distinction is made between this kind of knowledge and the one school code considers relevant to teach or learn within its boundaries. The idea that "real math" is learned only by interacting and appropriating the "true mathematical objects" presented by study programs, seems to underlie.

Our consideration, grounded on the ideas of the theory of enactivism, is that direct experience is a significant source of knowledge; that in the exchanges we experience via our actions, with and through our body, we produce experiences that may enhance or limit our conceptual understanding, while this last one also hinges on the different cognitive domains that we reach progressively.

Thus, girls, boys, youths, adults… we all build explanations and procedures which, from the formal perspective of the school institution, may be considered insufficient or not compatible with the criteria of "appropriate behavior", even if they constitute initial, provisional and effective explanations. When juxtaposed to time constraints, fragmented content, grading, planning, prescriptions, study programs, textbooks, and other formal devices that require attention at each school year, the students' knowledge, intuitions, incomplete procedures, affections, emotions, and interactions are interpreted as obstacles unrelated to school activity -more so with respect to mathematical content- and thus they are often avoided. Taking this into account, we assert that learning through concrete action is an approach of greater complexity, validity, and tradition.

The studies carried out by Piaget and his collaborators display how cognitive structures arise from recurring action patterns with a perceptual basis. Lozano, when referring to the enactivist approach, states: "The activities we carry out with different objects when interacting with the world result in cognitive structures such as mathematical concepts and categories" (2014:170). Knowing through concrete action is applicable to different fields, particularly in the field of mathematics as it is held in this research.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Purposes of the study

Identify and document -from an enactivist point of view- the understanding of numbers, space, and measure created by girls and boys from their own corporeal and interactive experience with their environment.

Work with the teachers of these children to build frameworks that integrate knowledge built from the corporeal, sensitive and interactive experience, linking it with the mathematical knowledge prescribed by the school while also making this last one more flexible.

Theoretical perspective

Even though the field of mathematical education is assisted by numerous theoretical perspectives that aid in analyzing what occurs inside and outside the classroom with respect to teaching processes and mathematical content learning, for our work we chose a theoretical reference based on the enactivist perspective (Maturana and Varela, 1984; Varela, 2000), which sustains that knowledge is built from the actions that we carry out in our daily experience and by the particular constitution of each individual, in a specific social and cultural context. This perspective of constructivist orientation conceives cognition in a broad sense, and therefore recognizes and addresses other dimensions -such as emotion, affection, and social interaction- in and for learning.

Lozano (2014:179) synthesizes substantial aspects of this approach: "Through enactivist ideas, individual learning is reconciled with social interaction, mind with body, reason with emotion, and knowledge with mathematical knowledge. Its concepts, as I understand them, allow for a broader perspective on learning and teaching mathematics, while taking its complexity into account ".

Enactivism, is separated from mind-body dualism and offers a theoretical perspective that coincides with what our experience and research work has shown us: knowing entails interacting with the world, starting from the individual story of each person and their context. Therefore, learning can only be conceived from the multiplicity of factors coexisting within it. Although more complex, this approach encompasses substantial dimensions that are omitted by other perspectives. Its understanding of perception, the fact that it does not recognize representations as a product of cognition, the relevance given to intuition, and its consideration of common sense (Varela, 2000:275), are significant disruptions that expand the perspectives regarding cognition understanding and analysis, and set it apart from the compartmentalized, formal, rigid and "disembodied" knowledge. We ponder that this approach will facilitate the creation of alternatives for students to regain interest in school mathematics content and in the knowledge about this subject produced by themselves.

Research method

Our work is a qualitative research, which process is thought of as a participant training space. The researcher joins as an apprentice and collaborator in both school and community activities, as well as with the teacher, the parents, and students. Consequently, there is no room for "observers", as the enactive approach holds that, as cognitive agents, we are active participants who enact in the world.

Context

The farm where the study is carried out, like others in the area, is located in a mountainous region of the state of Chiapas; the natural environment is exuberant, located in a rural area only connected to urban settlements through public transportation options that run a limited number of times a day. No public transportation gets directly to the farm. Internet connection is unstable to nil. Housing for workers and their families are equipped with basic drinking water services, electricity, a sanitary network, cement flooring. Health and education services are present. The elementary school is multigrade as a result of the limited number of students, while preschool is monograde.

Data Sources

Both the in and out-of-school activities deployed by the children of the farm constitute the sources. Recreational scenarios are designed to promote varied interactions where enacted knowledge can be deployed. Multilayered and semi-structured interviews are also carried out.

Analysis

We work through triangulation, with the purpose of complementing and enriching information collected through different activities and people. The criteria for analysis are in process of elaboration since they are put together from the previously mentioned scenarios.

Results

Up until now (February 2020) two visits have been made to the farm cumulating a total of three weeks living and sharing with the community -with the children, in particular- from Monday to Sunday. The following visits are designed to enhance participation and gradually foster an environment of confidence. Through these stays, the development of a wider perspective on the dynamics, roles, activities, needs, and complex knowledge required for the cultivation and harvest (*tapisca*) of coffee, as well as for orientation, recognizing harmful and edible plants -to name just a few domains- has been possible. Records of interviews and informal talks are being reviewed.

Discussion

We think it is fundamental that, since cognition is intimately related to action and actions occur in specific settings, learning has to be investigated in accordance to the situation in which it occurs. Knowledge in a specific location is associated with appropriate behavior or effective action in that location (Maturana, 1987:66). We believe that this perspective is promising for discovering new knowledge and that, through its formation, the active experience of the students can be brought out.

The conditions of multigrade groups are commonly perceived as deficient as they are associated with isolated communities with limited resources and even with indigenous populations. However, our approach highlights the opportunities that a multigrade classroom provides for the creation of knowledge in an enactive and collaborative environment. Associating age with school grade and defining the contents applicable to that entire group of individuals through it is not that reasonable. Even more so considering all the evidence that supports the case for making the students' approach to any knowledge more flexible. Multigrade, and its wide possibilities as a learning context, is a promissory area with great potential which, we believe, can be successfully articulated to the enactive approach.

EXPERIENCIAS COTIDIANAS Y CONOCIMIENTOS ESCOLARES DE MATEMÁTICAS. UNA APROXIMACIÓN ENACTIVISTA

EVERYDAY EXPERIENCES AND SCHOOL KNOWLEDGE OF MATHEMATICS. AN ENACTIVE APPROACH

Edda N. Jimenez de la Rosa y Barrios
Universidad Pedagógica Nacional
edda_jimenez@g.upn.mx

Se reportan los primeros avances de un estudio sustentado en la perspectiva enactivista, de corporización del conocimiento (Maturana y Varela, 1984; Varela, 2000). El propósito es documentar los conocimientos sobre número, espacio y medida, que tienen niñas y niños de una escuela primaria multigrado enclavada en una finca cafetalera, donde residen y conviven con la actividad laboral. El repertorio documentado de conocimientos enactados de esos niños, sustentará el acompañamiento para que sus maestros propongan situaciones que recuperen los conocimientos construidos más allá del salón de clase, mediante la experiencia corpórea y sensitiva. Este enfoque constituye, como sostiene Varela, un desafío a la cultura del salón de clases, y convoca a transformar el estilo y valores de la comunidad de investigadores.

Palabras clave: Educación primaria, Estudios de embodiment y gestos, Educación Rural, Concepto de Número y Operaciones.

Evidencias derivadas de la propia experiencia, así como otras basadas en procesos de investigación formal, han mostrado desde hace años que las y los niños construyen conocimientos (Resnick, 1989; Resnick & Greeno, 1990), que, en la mayoría de los casos, no tienen cabida en la escuela. En particular, esta situación se observa entre los contenidos de matemáticas prescritos en la educación formal y aquellos conocimientos que se aprenden fuera de ella (Nunes, T., 1993; Padilla, 2015). En los casos en que se identifica el conocimiento surgido más allá de la escuela, se establece una distinción entre ese conocimiento y lo que la cultura escolar considera relevante de enseñar o aprender en su territorio. Al parecer, subyace la idea de que las “verdaderas matemáticas” se aprenden al interactuar y apropiarse de los “verdaderos objetos matemáticos”, incluidos en los programas de estudio.

Nuestra consideración, sustentada en los planteamientos de la teoría de la enactividad, es que la experiencia directa es una importante fuente de conocimientos; que en el intercambio que tenemos con el mundo, a partir de nuestras acciones con y a través de nuestro cuerpo, producimos experiencias que posibilitan o limitan nuestra comprensión conceptual que, a su vez, depende de los diferentes dominios cognitivos que progresivamente alcanzamos.

Así, niñas, niños, jóvenes, adultos, todos, construimos explicaciones y procedimientos, que, desde la perspectiva formal de la institución escolar, pueden considerarse insuficientes, o no cumplen los criterios de un “comportamiento adecuado”, aunque para quien los genera constituyen explicaciones iniciales provisorias y efectivas. Frente a prescripciones de tiempo, contenidos fragmentados, graduados, planeaciones, procedimientos, programas de estudio, libros de texto y otros dispositivos formales que requieren cubrirse durante cada ciclo escolar, los conocimientos de los estudiantes, sus intuiciones, procedimientos incompletos, afectos, emociones e interacciones, particularmente respecto de contenidos matemáticos, se interpretan como irruptores, poco pertinentes a la actividad escolar, por lo que es preferible obviarlos. Ante esa situación, sostenemos que conocer a través de la acción concreta, es un planteamiento cada vez de mayor complejidad, vigencia y larga tradición.

Los estudios realizados por Piaget y sus colaboradores, mostraron en su momento cómo las estructuras cognitivas surgen de pautas recurrentes de acciones, con una base perceptual. Lozano, al referirse a la postura enactivista, plantea: “Las actividades que llevamos a cabo sobre los objetos al interactuar con el mundo dan lugar a estructuras cognitivas tales como los conceptos y categorías matemáticas” (2014:170). Conocer a través de la acción concreta, aplica a diferentes campos, particularmente en el campo de las matemáticas como se sostiene en este estudio.

Propósitos del estudio

Identificar y documentar desde un enfoque enactivo, los conocimientos sobre número, espacio y medida, que construyen niñas y niños a partir de su experiencia corporal e interaccional con su entorno.

Generar con los profesores de esos niños, andamiajes que incorporen los conocimientos que ellos han construidos a partir de la experiencia corpórea, sensitiva e interaccional, vinculando y flexibilizando el conocimiento matemático que se prescribe en la escuela.

Perspectiva teórica

Si bien en el campo de la educación matemática existen numerosas perspectivas teóricas para analizar lo que sucede dentro y fuera del aula con respecto a procesos de enseñanza y aprendizaje de contenidos matemáticos, elegimos como referente teórico la perspectiva enactivista (Maturana y Varela, 1984; Varela, 2000), que sostiene que el conocimiento surge de las acciones que realizamos en nuestra experiencia cotidiana y por la constitución particular de cada individuo, en un contexto social y cultural específico. Esta perspectiva, de referentes constructivistas, concibe la cognición en un sentido amplio, por lo que reconoce y aborda otras dimensiones -como la emoción, el afecto y la interacción social- en el y para el aprendizaje.

Lozano (2014:179) sintetiza aspectos sustanciales del enfoque: “A través de las ideas enactivistas, el aprendizaje individual se reconcilia con la interacción social, el cuerpo con la mente, la razón con la emoción y el conocer con el conocimiento matemático. Sus conceptos, desde mi punto de vista, permiten tener una perspectiva amplia acerca del aprendizaje y la enseñanza de las matemáticas, tomando en cuenta su complejidad.”

El enactivismo, se deslinda del dualismo mente-cuerpo y ofrece una perspectiva teórica que coincide con lo que la experiencia y el trabajo de investigación nos ha expuesto: conocer implica interactuar con el mundo, desde la historia de cada persona y su contexto, por lo cual el aprendizaje no puede concebirse sino a partir de la multiplicidad de factores que en él concurren. Aunque resulta más compleja, esta aproximación incorpora dimensiones sustanciales, que otras posturas omiten. Su concepción de percepción, el no reconocer a las representaciones como producto de la cognición, el dar relevancia a la intuición y ponderar del sentido común (Varela, 2000:275), son rupturas importantes que amplían perspectivas para la comprensión y análisis de la cognición, así como para diferenciarse de la concepción de conocimiento compartamentalizado, formal, rígido y “desencarnado”. Consideramos que esta aproximación contribuirá a generar alternativas para que los alumnos recuperen el interés por los contenidos escolares de matemáticas y por los conocimientos que sobre el tema, ellos mismos construyen.

Método de investigación

Se trata de una investigación de corte cualitativo, cuyo proceso se prevé como espacio de formación para los participantes. Quien investiga se incorpora como aprendiz y colaborador en las acciones de la escuela y la comunidad, con el maestro, padres y los alumnos. Siguiendo el enfoque de esta investigación, no hay cabida a "observadores", ya que la perspectiva enactiva sostiene que los agentes cognitivos somos activos participantes que enactamos en el mundo.

Contexto

La finca donde se lleva a cabo el estudio como otras de la zona, se encuentra en el área de montaña del estado de Chiapas; el entorno natural es exhuberante. En un área rural, comunicada con asentamientos urbanos a través de varias opciones de transporte público terrestres, en ciertos horarios del día, sin embargo, ningún transporte colectivo llega directamente a la finca. La conexión a internet, es de inestable a nula. En esa finca las viviendas para los trabajadores y sus familias, cuentan con servicios básicos de agua potable, electricidad, red sanitaria, piso de cemento, servicio de salud, y educativo. Por el número de alumnos, la escuela primaria es multigrado y la de educación preescolar, unitaria.

Fuentes de datos

Las diferentes actividades escolares o desplegadas en otros escenarios, por los niños de la finca, constituyen las fuentes. Se diseñan situaciones lúdicas para promover interacciones variadas donde sea posible desplegar conocimientos enactados. También se realizan enttrevistas a profundida y semiestructuuradas.

Análisis

Se trabaja mediante triangulación, con el propósito de complementar y enriquecer información recabada a través de diferentes actividades y personas. Los criterios para un análisis más fino, están en proceso de elaboración, ya que se construyen a partir de las situaciones que se generan.

Resultados

A la fecha (febrero 2020) se han realizado dos estancias en la Finca, un total de 3 semanas conviviendo con las personas de lunes a domingo, con las niñas y niños. Las siguientes estancias, presentando, ante la familia, participar e ir construir paulatinamente un clima de confianza. De ambas estancias se ha podido tener un panorama más amplio de las dinámicas, roles, actividades, exigencias y conocimientos complejos, que demanda el trabajo de cultivo y cosecha (tapisca) de café. Así como de los múltiples referentes que ponen en juego para orientarse, reconocer plantas dañinas y comestibles, por citar solo algunos dominios. Se cuenta con registros de entrevistas y pláticas informales que esttán en proceso de revisión.

Discusión

Consideramos fundamental que, dado que la cognición está íntimamente relacionada con la acción, y las acciones ocurren en lugares determinados, entonces el aprendizaje tiene que ser investigado en relación a la situación en la que ocurre. El conocimiento, en un lugar determinado, está asociado con la conducta adecuada o la acción efectiva en ese lugar (Maturana, 1987:66). Consideramos que esta persspectiva es promisoria para develar conocimientos y que mediante su construcción propiciar que se despliegue la experiencia activa de los estudiantes.

La condición de trabajo de los grupos multigrado en muchos espacios se valora como deficitaria porque se asocia a comunidades aisladas, con recursos limitados e incluso con población indígena. Sin embargo, nuestra postura reivindica las condiciones que ofrece un aula multigrado para la construcción de conocimientos de forma enactiva y colaborativa. Asociar una edad a un grado escolar y suponer por ello que eso determina los contenidos pertienentes para toda esa franja de individuos, es poco sostenible. Aún más si se cuenta con tanta evidencia que argumenta a favor de flexibilizar el acercamiento de los estudiantes a cualquier conocimiento. Multigrado, y sus amplias posibilidades como contexto de aprendizaje, es una línea promisoria y con gran potencial, que perfilamos, puede articularse con éxito al enfoque enactivo.

MOVING TOWARDS MEANING MAKING IN MULTIPLICATION: A PRELIMINARY REPORT OF AN INTERVENTION IN NUMBER SENSE

Rachel Lambert
UCSB
rlambert@ucsb.edu

tomynguyen@ucsb.edu

Rejecting pedagogies of deficit built around deficit mythologies about the mathematical potential of students with learning disabilities (Lambert 2018), this study will document an intervention designed to engage students in mathematical problem-solving and discussion, building student computational skills as well as number sense and participation in the mathematical practices. In this paper, we provide close analysis of the development of a fourth-grade student who demonstrated growth in participation and conceptual understanding of multiplication across the intervention.

Keywords: Equity and Diversity; Special Education; Number Concepts and Operations; Instructional Activities and Practices.

Research on the mathematical learning of students with disabilities has focused on medical deficits within children and prescribed behavioral mathematics teaching to remediate these deficits (Lambert & Tan, 2020). Locating the problem not within individual students, but within limited access to opportunities to make mathematical meaning, we designed an intervention for students with disabilities ages 8 through 11 significantly underperforming in multiplication and division and including students with disabilities. This intervention is designed to engage students in mathematical problem-solving and discussion, building both student number sense and participation in the mathematical practices. Our full study explores the growth of student strategic thinking, accuracy for multiplication and division, and participation in mathematical discourse. In this brief report, we focus on one student whose measurable math score did not increase during and after the intervention. While she displayed no measurable growth in her math score, she displayed growth in participation and strategy development. Our research question for this brief report focused on one student: How did one student participate in a mathematics intervention designed to promote student meaning-making and discussion? What shifts in participation are in evidence? What shifts in conceptual and procedural understanding of multiplication?

Schools in the US are being asked to provide intervention within Multi-Tiered System of Support (MTSS) in mathematics. However, interventions are often not aligned with classroom instruction based on Common Core State Standards, creating difficulties for students who must make sense of different approaches to mathematics. Our intervention using number strings is designed to align with a focus on meaning making in the curriculum. The intervention consisted of 8 sessions of number strings (Lambert, Imm & Williams, 2107) designed and facilitated by undergraduate tutors after 6 hours of professional development led by the first author. Each tutor was observed 2-4 times by a member of the research team and offered feedback. In addition, all tutors participated in a session in which they analyzed the participation of the students in their small group. Future analysis will focus on the teaching moves of the novice tutors.

A number string is a short (15–20-minute) daily instructional routine in which a teacher presents a carefully designed sequence of problems one at a time for children to solve mentally (Lambert, Imm & Williams, 2017). Instead of interventions that focus on direct instruction, number strings provide opportunities for students to engage in mathematical discourse, both in describing their own strategies and connecting with the mathematical strategies of others. Research on number strings has found that students participating in number string routines are able to adopt new strategies (O'Loughlin 2007) and make connections between conceptual understanding and procedures. Studies

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

on number strings have not previously focused on students with disabilities or students who are significantly underperforming in mathematics.

One issue in the assessment of students with disabilities is the difficulty of capturing growth that may be unusual in its learning trajectory or slower than peers. Van Geert and van Dijk (2012) describes the importance of moving beyond group-level data in understanding the variability for students that may exist at the level of strategies and engagement, recommending collecting data on inter-individual variability to better understand strategic change. We document conceptual growth through analysis of student participation and discourse, including attention to non-verbal communication. We used aspects of the coding scheme by Ing at al. (2015). A Complete Share was an answer that was accurate and explained in enough detail that we could confidently code the strategy. A Partial Share was either inaccurate or did not include enough detail that researchers could determine the exact strategy path of the student. We added the last two categories to track students who had nonverbal engagement in the problem. Nonverbal captured moments in which we could see evidence of nonverbal engagement, yet students did not verbally share in discussion (such as students counting on fingers). No Engagement was coded if the student did not demonstrate verbal or nonverbal engagement.

Methods

The study was situated in grades 3 – 5 at an elementary school in California. Demographics are as follows: 76.3% are Socioeconomically Disadvantaged, 14.4% are Students with Disabilities, 58.9% are English Learners, and 9.9% of students are Homeless. The majority of students at the school are Hispanic (88.3%) with the second largest demographic category being White students (7.5%). The full study included 12 student participants in 3rd grade, 6 students in 4th grade, and 18 students in 5th grade. 12 students had current IEPs, with an addition 4 students in the referral process. Each group met for 8 sessions, twice a week for 4 weeks. We collected two primary kinds of data: a) researcher-created multiplication and division paper and pencil assessments (Multiplication + Division CCSS CBM Math Assessment) with all students taking the assessment three times (pre, during and post intervention), and b) video records of the tutors teaching the number strings to document student participation and strategy development. In order to ascertain growth in student accuracy, we scored the MD-CBM before, during and after the intervention. After analysis of the first MD-CBM assessment, the first researcher met with the classroom teachers to decide the students who would be placed into the Tier 2 intervention. We assessed student use of strategies and participation in mathematical problem-solving and discussion through analysis of transcripts. Two authors each coded the small group we present in this paper, resolving any discrepancies. We will determine intercoder reliability for the final paper.

Findings

This paper is a case study that focuses on one student (Inez) within one small group of 6 students in a fourth-grade class taught by undergraduate tutor Yola (all names are pseudonyms). Comprised of students with and without disabilities, the students in this small group had the lowest scores on multiplication in their class. Inez is Latina and classified as an English Learner, as well as a student of significant concern for her classroom teacher. The teacher noted that Inez rarely shared in math class and seemed to have significant issues with number sense. Inez appeared eager to participate in this small group, even when she did not share. She seemed particularly to enjoy talking to Yola.

In the first two sessions, Inez did not volunteer to answer questions. She shared twice when called on. Unlike her peers, she did not use her fingers to keep track as she skip counted. Instead, we could see her subvocalizing her counting and losing track. In discussions, we wondered if Inez needed support to help her keep track of her count. Starting in the second session, Yola passed out card stock arrays for the students. Inez began using these arrays to keep track of her counting. However, Inez seemed to need additional experience with the arrays. Initially, Inez counted each square as 2. For much of the first 6 sessions, Inez demonstrated her ability to count by 2s and 5s, but not other numbers. Inez appeared to prefer counting by 2s and 5s so much that she used this strategy to solve problems that neither 2 or 5 were factors. Asked to solve 9 x 5, she got the answer of 10 by skip counting by 2s, because "I thought it would be easier to count by twos." In discussions with Yola, we decided at the end of Session 2 that Inez needed to sit closer to Yola, who supported her in using her fingers or the array as a tool. Yola also spoke to Inez during turn and talks, which seemed to support Inez sharing in the small group. This shift seemed to mark a pronounced difference in engagement (Table 1) from a lack of engagement in the first two problems to a more sustained engagement in mathematical discussion in the subsequent sessions.

Table 1: Shifts in Inez's Participation in Mathematical Discussion

	Session 1	Session 2	Session 3	Session 4	Session 5	Session 6	Session 7
Complete Share	0	0	1	1	0	1	1
Partial Share	1	1	4	4	6	5	3
Nonverbal	0	3	0	2	0	0	1
No Engagement	5	1	1	0	0	0	0

Through close analysis of Inez's strategies across the 7 sessions (one session was not video recorded), we saw evidence that Inez developed her understanding of arrays. While in the beginning she did not count squares by ones successfully (by counting boxes as 2s or 5s), she was able to do so by Session 5. She also developed an understanding of the connection between skip counting and multiplication by groups. Twice, Yola represented Inez's skip counting numerically and connected that to the representation of the array. The first time Yola did so, Inez stopped, stared at the array and the skip counting represented next to it, and said, "What the heck?" The next session, Inez again counted an array by 2s, and then miscounted, getting an answer of 62 for 6 x 5. Yola listened to Inez's strategy, and then remodeled it on the array keeping track of the numbers. Inez again appeared to be provoked into disequilibrium by the tutor's representation of her strategy, saying, "I went really really far." Connecting visual and numerical representations of her own strategy appeared to make Inez's own thinking visible to her, thus allowing her to understand her own thinking as reflected by the tutor's representations.

While Yola seemed to make supportive moves to increase Inez's participation, as well as to model her thinking to make it visible, Yola described having significant difficulty understanding and representing Inez's strategies. While there were instances in which Yola pressed for explanation, there were more instances in which Inez shared an incorrect answer and Yola did not ask her to elaborate. In further analysis, we will determine which teacher moves within the number strings routine were most challenging for novices to enact. We suspect that pressing a student for further explanation when that student has a pattern of strategies that do not make sense to the teacher might be a particularly challenging teaching move to enact.

Discussion

Our intervention aims to increase the mathematics achievement of students with disabilities and students whose performance is significantly below grade level, but not with instructional practices that focus on memorization or procedural learning. Instead, we investigated the use of a number string to develop multiplication and division computation simultaneously with number sense. In this paper, we demonstrate how one student significantly below grade level in mathematics grew in her use of mathematical strategies and her engagement through participation in a number string routine.

Further analysis will include latent class modeling to determine growth patterns for particular subgroups of students. We also will document overall growth, using group averages as well as close qualitative analysis of strategy growth. Finally, we will analyze the teaching moves of the novice teachers to determine the effectiveness of the professional development we provided for tutors. We also plan to analyze how Inez's emergent bilingual status could better have been leveraged in her learning. Most importantly, we seek to better understand how to provide mathematics intervention for students who need more support engaging in meaningful mathematics.

GENDER DIFFERENCES IN ATTITUDES TOWARDS MATHEMATICS AND STEM MAJOR CHOICE: THE IMPORTANCE OF MATHEMATICS IDENTITY

Dalton Marsh
University of New Hampshire
ddm1002@wildcats.unh.edu

Sheree Sharpe
University of New Hampshire
sheree.sharpe@unh.edu

The building of a diverse and highly capable population of young people for careers in the science, engineering, technology, and mathematics (STEM) fields remains a critical issue in the United States. The researchers employed data from a nationally representative sample of high schoolers to better understand the relationships between students' learning experiences, attitudes towards mathematics, and STEM major choice. The focus of this paper is on how these relationships differ for males and females. The findings suggest that the underrepresentation of female students in STEM majors can be partially explained by a tendency for females to have less positive attitudes towards mathematics as compared to their male counterparts. Mathematics identity may be the most important attitude explaining this difference.

Keywords: STEM, Attitudes, Equity and Diversity, Gender

This research is part of a larger project aimed at better understanding factors that motivate U.S. students' decision to major in STEM fields and ultimately guiding efforts for broadening participation in STEM. The focus of this paper is on gender differences in attitudes towards mathematics and how these differences can help to explain why female students are underrepresented in STEM majors. Expectancy-value theory and data from the High School Longitudinal Study of 2009 were employed.

Theoretical Framework

The expectancy-value model of motivated behavioral choice (Eccles, 2009) holds that students' achievement-related choices (such as college major choices) are directly determined by the expectancy for success and the subjective value they attach to the tasks involved in those choices. Expectancy for success is similar to the notion of *self-efficacy* (Wigfield & Eccles, 1992). Subjective task values include the following three aspects: the relation of the task to one's self-image (*identity value*); the anticipated enjoyment from engaging in the task (*interest value*); and the perceived usefulness of the task for fulfilling personal goals (*utility value*). *Cost* is a fourth aspect of value that will not be examined in this study. Expectancies and values themselves are determined by various factors, including personal background characteristics and past learning experiences (Eccles et al., 1983). This model guides the research questions for the current study: (a) How are U.S. high school students' prior educational experiences, mathematics expectancy-value attitudes, and STEM major choice related? (b) How do these relationships differ for males and females?

Methodology

To answer these questions the present study employed data from the High School Longitudinal Study of 2009 (HSLS:09; Ingles et al., 2011). HSLS:09 is the most recent in a series of surveys administered by the National Center for Education Statistics (NCES) that follow nationally representative samples of young people as they transition from high school to postsecondary years. The first wave of HSLS:09's data collection began in the fall of 2009 with over 23,000 ninth-graders from 944 public and private schools throughout the United States. Sampling involved a complex, two-stage design in which eligible schools were first randomly selected and then students within those schools were randomly selected (Ingles et al., 2011). The students were followed up in the spring of 2011, when most were in the eleventh grade (Ingles et al., 2014) and a third time in 2013, after most had completed high school (Ingles et al., 2015).

Variables

The present study utilized variables from the base-year, first follow-up, and 2013 update of HSLS:09's public-use data file. Ninth-grade variables included mathematics achievement, STEM extracurriculars, and mathematics teacher support. Eleventh-grade variables included mathematics expectancy-value attitudes. The twelfth grade-variable was STEM major choice.

STEM major choice. STEM major choice was measured with a dichotomous variable indicating whether the student was planning to major in a STEM field at a postsecondary institution (reported in 2013 college update). Majors considered STEM included computer, physical, and natural sciences; engineering; mathematics and statistics; and military and science technologies/technicians.

Mathematics self-efficacy. Four items were used to measure students' confidence in their mathematics ability, including the degree to which they were confident that they can do an excellent job on tests and assignments; understand the most difficult material presented in the textbook; and master skills in their first follow-up mathematics course. All mathematics attitudes were standardized (mean = 0, SD = 1).

Mathematics identity. Two items were used to measure students' mathematics identity value, including the degree to which they agreed that they were a math person and other people saw them as a math person.

Mathematics interest. Five items were used to measure students' mathematics interest value, including the degree to which they agreed that their first follow-up mathematics course was enjoyable, a waste of time (reverse coded), and boring (reverse coded); that they were taking the classes because they enjoy math; and whether math was their favorite school subject.

Mathematics utility. Three items were used to measure student's mathematics utility value, including the degree to which they agreed that what they were learning in their mathematics course would be useful for everyday life, college, and a future career.

Mathematics achievement. Prior achievement in mathematics was measured using the ninth-grade algebraic reasoning assessment score. The assessment was developed by NCES using an item-response theory (IRT) design and standardized (mean = 0, SD = 1).

STEM extracurriculars. Extracurricular participating in STEM-related activities were measured by the number of mathematics or science related activities (clubs, summer camps, competitions, study groups) the student reported participated in from the base-year to the first follow-up.

Mathematics teacher support. Nine items were used to measure students' perceived support from their ninth-grade mathematics teacher. Some example items include the degree to which the student agreed that their teacher values and listens to students' ideas; thinks every student can be successful; and makes math interesting. This scale was also standardized.

Covariates. Covariates included student's gender (1 = female, 0 = male), race/ethnicity (1 = underrepresented minority [URM], 0 = white or Asian), and socioeconomic status.

Missing Data

Missing data were handled using multiple imputation. In total, five datasets were imputed for the analysis using Blimp 1.1 (Keller & Enders, 2018). The five datasets were analyzed and then the estimates and standard errors were averaged into a single set of results (Rubin, 1987). Multiple imputation has been shown to be robust against departures from normality and to provide unbiased results even for high rates of missing data (Enders, Keller, & Levy, 2018).

Analytic Plan

To analyze the relationship between the variables, the researchers used structural equation modeling (SEM; Byrne, 2011). The analysis was conducted in Mplus 8.2 with robust maximum likelihood (MLR) estimator and logit link. (Muthén & Muthén, 1998-2017). Figure 1 displays the path model. To asses model fit, the chi-square statistic (χ^2), comparative fit index (CFI), Tucker–Lewis index (TLI), and the root mean square error of approximation (RMSEA) were used. SEM literature typically considers CFI and TLI values greater than .95 and .90 to indicate excellent and acceptable fits, respectively. For RMSEA, values less than .05 and .08 are considered excellent and acceptable fits, respectively (Byrne, 2011). Design effect adjusted weights were applied to account for the nested structure of the survey (Hahs-Vaughn, 2005). As per Ingles et al. (2015), the raw weight adjusted was W3W1W2STU.

Results

The sample was comprised of 50.4 percent male and 49.6 percent female. The proportion of students who pursued STEM was 14.7 percent. Males chose STEM at a 19.4 percent rate compared to 9.9 percent for females. Whites and Asians chose STEM at a 17.5 percent rate compared to 11.2 percent for URMs. The (unweighted) sample size was N = 15,860 consisting of students who participated in the base-year, first follow-up, and 2013 update.

The SEM analysis began by testing the measurement model. The CFA indicated excellent fit of the measurement model: $\chi^2(217)$ = 2,898.685, CFI = .958, TLI = .951, RMSEA = .023. The CFA estimated that all four of the mathematics attitudes were significantly pairwise correlated ($p < .001$). However, examining variance inflation factors (VIFs) did not provide evidence of significant multicollinearity (VIF < 5). Next, the SEM model from personal background and educational experiences to mathematics attitudes was tested. This model also had adequate fit: $\chi^2(312)$ = 3,820.444, CFI = .951, TLI = .942, RMSEA = .022. Lastly, the full SEM model was tested. The above fit statistics are not available for models with categorical outcomes (Muthén & Muthén, 1998-2017). The pseudo R^2 for the logistic regression on STEM was .267.

Table 1 contains the estimates for the direct effects of personal background and prior educational experiences on mathematics attitudes. Table 2 contains the estimates for the direct, indirect, and total effects for the full path model, including the odds ratios (OR) for the direct effects on STEM major choice.

Table 1: Direct Effects for Paths from Educational Experiences to Mathematics Attitudes

	On Math Attitudes			
Predictor and Covariate	Self-Efficacy	Identity	Interest	Utility
Educational Experiences				
Math achievement	.23***	.39***	.24***	.11***
STEM extracurriculars	.14***	.14***	.15***	.10***
Math teacher support	.09***	.05**	.08***	.10***
Personal Background				
Female	-.25***	-.21***	-.11***	-.09***
URM	-.09	.07***	-.02	-.11***
SES	.33***	-.03**	.30***	-.11***

Table 2: Direct, Indirect, and Total Effects for Paths from Educational Experiences to Mathematics Attitudes and STEM Major Choice

	On STEM Major Choice		
Predictor and Covariate	Direct [Odds Ratio]	Indirect	Total

Educational Experiences			
Math achievement	.58*** [1.79]	.16***	.74***
STEM extracurriculars	.16*** [1.17]	.08***	.24***
Math teacher support	-.03 [0.97]	.04***	.01
Mathematics Attitudes			
Math self-efficacy	.11 [1.12]	—	—
Math identity	.31*** [1.36]	—	—
Math interest	-.01 [1.00]	—	—
Math utility	.16** [1.18]	—	—
Personal Background			
Female	-.77*** [0.46]	-.11***	-.88***
URM	-.09 [0.92]	.07***	-.02
SES	.33*** [1.39]	-.03**	.30***

Focusing on the first research question, Table 1 shows that the analysis found that higher mathematics achievement in ninth, participation in a greater number of STEM extracurriculars, and greater teacher support early in high school predicted more positive attitudes towards mathematics later in high school ($p < .001$ for all paths expect math teacher support on math identity which had $p < .01$). In turn, higher mathematics identity and utility predicted greater odds of majoring in STEM (OR = 1.36, $p < .001$ and OR = 1.18, $p < .01$ respectively).

For the second research question, Table 2 shows that after accounting for race/ethnicity, SES, prior educational experiences, and attitudes towards mathematics, females' odds of choosing a STEM major where half that of males (OR = 0.49, $p < .001$). From Table 1, the effect of female was negative on each mathematics attitude ($p < .001$ for all four), with the largest magnitudes on self-efficacy and identity. Thus, after accounting for personal background and prior educational experiences, female students tended to have less positive attitudes towards mathematics.

Discussion

This study provides evidence representative at the national scale for the expectancy-value model: higher mathematics achievement, greater participation in STEM-related extracurriculars, and more supportive mathematics teachers early in high school predict more positive attitudes towards mathematics later in high school, which in turn predict greater odds of majoring in STEM. The findings suggest that the underrepresentation of females in STEM in the U.S. can be partially explained by less positive attitudes towards mathematics with a sense of identity as a math person having the largest gender disparity. Given that mathematics identity was also the attitude most predictive of STEM major choice, this study supports the growing focus on identity in mathematics education research (see Graven & Heyd-Metzuyanim, 2019). Future work for this project is planned to better understand why female students' attitudes towards mathematics tended to be lower than that of males. Existing literature suggests that negative stereotypes about STEM professionals are partially responsible, including unattractive appearances and socially awkward personalities, which are typically at odds with female gender identity and cultural expectations (Eccles & Wang, 2016; Starr, 2018).

College Algebra students who struggle to pass the course could face delayed graduation or fail to obtain their degree. A key part to academic performance is self-regulated learning which includes self-efficacy and test anxiety as parts of motivation, as well as learning strategies. This study aims to investigate the change in motivation and learning strategies over the course of a semester and the relationship of this change to performance in College Algebra, as measured by final course grade. Test anxiety and self-efficacy were measured at the beginning and end of the semester using the Motivated Strategies for Learning Questionnaire. During the semester, self-efficacy decreased, and test anxiety increased. Moreover, the increase in test anxiety predicted performance. An important finding from the study was that the students who experience more stress on exams are the ones whose grades suffer the most.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Post-Secondary Education

Introduction

A large number of students take College Algebra each year in the United States. Generally, College Algebra fulfills a graduation requirement for non-math intensive majors and has historically been structured to prepare students for calculus (Gordon, 2008). While required for many students, only about 50% of students earn an A, B, or C in the course (Ganter & Haver, 2011). This could result in a graduation delay or failure to obtain a degree. With so many students unable to pass College Algebra, research is needed to investigate what occurs over the course of a semester to impact student performance.

A key aspect of academic performance is self-regulated learning (Berger & Karabenick, 2011; Pintrich & De Groot, 1990; VanderStoep, Pintrich, & Fagerlin, 1996). Students who are self-regulated learners utilize cognitive and metacognitive strategies to be successful in their learning. However, the knowledge of strategies is not enough; a student must also have the motivation to use them (Pintrich & De Groot, 1990; VanderStoep et al., 1996). Therefore, both motivation and learning strategies could be crucial to improving achievement in College Algebra.

This study aims to investigate the self-regulated learning of College Algebra students and answer the following research questions:

- What are the changes in College Algebra students' motivation and learning strategies over the course of a semester? And are the changes the same for all students?
- What is the relationship between the changes in motivation and learning strategies and performance in College Algebra?

While motivation and learning strategies are both important components of self-regulated learning, this paper focuses on two motivation components: self-efficacy and test anxiety. This controlled focus is due to test anxiety being a significant finding for both research questions, and self-efficacy is prevalent in the literature.

Literature Review

Over the last few decades, self-efficacy and test anxiety have been studied extensively. Self-efficacy is a key component in social cognitive theory and refers to "beliefs in one's capabilities to organize and execute the courses of action required to produce given attainments" (Bandura, 1997). Test anxiety is a multi-dimensional construct defined by Zeidner (1998) as "the set of phenomenological, physiological, and behavioral responses that accompany concern about possible negative consequences or failure on an exam or similar evaluative situation" (p. 17).

At the college level, many studies have examined how self-efficacy or test anxiety change over time but with mixed results. For two online courses, no statistically significant changes in self-efficacy (Hodges & Kim, 2010) and test anxiety (Chapman, 2013) were detected during the semester. Others found decreases in self-efficacy (DiBenedetto & Bembenutty, 2013) and test anxiety (Fournier, Couret, Ramsay, & Caulkins, 2017) in science courses. Some reported increases in self-efficacy in biology (Ainscough et al., 2016) and test anxiety for medical students (Kim & Jang, 2015) over the course of a semester.

Self-efficacy and test anxiety have also been studied in relation to academic performance at the college-level. Several studies found self-efficacy (Hodges & Kim, 2010; Roick & Ringeisen, 2018) and test anxiety (Gibbens, 2019; Hieb, Lyle, Ralston, & Chariker, 2015) to be statistically significant predictors of performance. However, these studies measured self-efficacy and test anxiety at a single time point, and change over time was not used as a predictor of performance.

Only two studies were found to look at change over time as a predictor of performance. Fournier et al. (2017) found a decrease in test anxiety was not a statistically significant predictor of performance, and DiBenedetto and Bembenutty (2013) found that the decrease in self-efficacy was negatively correlated with final course grade. In light of these mixed results and other studies, this paper sought to examine the change in self-efficacy and test anxiety for College Algebra students over the course of a semester, and if the observed changes impact the final course grade.

Methodology

This study was conducted at a public university in the northeast region of the United States. During the spring semester of 2017, six sections of College Algebra were included in the study with 166 out of 227 students (73%) consenting to participate. To measure the changes in students' motivation and learning strategies, the Motivated Strategies for Learning Questionnaire (MSLQ) was used; an instrument considered to be both valid and reliable for this population of undergraduate students (Duncan & McKeachie, 2005). The MSLQ consists of two sections, motivation and learning strategies, with 15 scales total. These scales can be used together or individually for a total of 81 survey items, each with a Likert-scale from 1 to 7.

The students were asked to complete the MSLQ during the third week of the semester (T_1) and again on the last day of classes (T_2). Students' final course grade was also collected. Changes in all 15 MSLQ scales were considered by final course grades using a MANOVA with the paired differences ($T_1 - T_2$) as a response variable and final letter grade as the factor. In order to investigate how these changes in motivation and learning strategies relate to the students' final course grade, multiple linear regression was performed using changes in MSLQ scales over time and final numerical course grade. Statistical analysis was conducted using the R software package. Familywise false coverage probabilities and error rates were controlled using an adjustment based on the multivariate *t*-distribution that is implemented in the emmeans (Lenth, 2019) and glht (Hothorn, Bretz, & Westfall, 2008) R packages.

Results

The MANOVA results indicate that final letter grade in College Algebra is statistically significant (Pillai Test Statistic = .888 and p-value < .0001). Post-hoc comparisons using a 95% familywise confidence level indicate that students who earn a final course grade of "D" or "F" are the only ones to experience statistically significant changes in the MSLQ scales. Students who earn a "D" in College Algebra on-average experience a decline in self-efficacy between 0.59 and 1.79 points. Students who earn an "F" in College Algebra experience a decrease in self-efficacy between 0.78 and 2.07 points on-average, and an increase in test anxiety by 0.67 and 2.25 points on-average. When controlling for familywise error rate, multiple linear regression analysis showed that test anxiety is the only statistically significant predictor of final course grade at the 5% significance level. For students that experienced a one-point increase in test anxiety during the semester, it is expected their mean final course grade in College Algebra will decrease by between 0.21 and 6.81 percentage points.

Discussion

The present paper examined the changes in motivation and learning strategies for College Algebra students over the course of a semester, and if the observed changes impacted the final course grade. During the semester, self-efficacy decreased while test anxiety increased; findings that are consistent existing research (DiBenedetto & Bembenutty, 2013; Kim & Jang, 2015). However, not all students experienced these changes. Students who earned a "D" or an "F" in College Algebra felt less capable of being successful in the course as the semester went on, similar to findings by VanderStoep et al. (1996). Additionally, the students who earned an "F" experienced increased worry and had a preoccupation with performance over the course of the semester, consistent with Fournier et al. (2017). This is an interesting result as the students who need the most support were the ones to experience negative changes in their motivation during a semester of College Algebra.

For this study, there was a relationship between the changes in motivation and learning strategies and performance for College Algebra students. As a semester goes on, the students who experience more and more stress on exams are the ones whose grades suffer the most. This is in contrast to work by Fournier et al. (2017) and DiBenedetto and Bembenutty (2013). Paired with the other results, students who end up earning an "F" in course experience increases levels of test anxiety along with decreased self-efficacy; this increase in test anxiety has a direct, negative effect on their course grade.

While there is ample research on both self-efficacy and test anxiety, the findings are not always consistent and vary from subject to subject. This highlights a need for continuing research on both motivation components. To improve the passing rates of College Algebra, additional research is needed to investigate how to improve self-efficacy and decrease test anxiety, especially for the students likely to earn a non-passing grade. With the key finding that test anxiety increases over the semester and significantly predicts performance, future studies could attempt interventions throughout the semester to curb anxiety.

MONOPOLIZING TEACHER ATTENTION: A CASE OF MULTILINGUAL LEARNERS' COMPETENCE EMBODIED IN SOCIAL FORMATIONS

Isaac T Nichols-Paez
Vanderbilt University
isaac.t.nichols@vanderbilt.edu

The rapid growth of multilingual mathematics learners in the US creates an urgent need for researchers and teachers to pay close attention to the complex social negotiation of resources in their classroom because these students are some of the most vulnerable to continual dehumanizing practices. Researchers and teachers need to understand how multilingual learns access resources but also how they manage the social risk of incompetence ascribed to students utilizing these resources. The current work presents an interaction as a case of the negotiation of resources, access, and competence during of a breakdown in the expectations of whom is allowed to make meaning of mathematics. Through the analysis, we see both how multilingual students are othered and excluded from mathematical discussion and how these students can reconstruct themselves as competent.

Keywords: Classroom Discourse, Marginalized Communities, Embodiment and Gesture, Learning Theory

Introduction

The rapid growth of multilingual mathematics learners in the US creates an urgent need for researchers and teachers to pay close attention to the complex social negotiation of resources in the classroom (Barwell, Chapsam, Nkambule, & Phakeng, 2016). Multilingual students are some of the most vulnerable to continual dehumanizing practices (Gutiérrez, 2018). Furthermore, their competence is constantly in question around both their mathematical conceptual knowledge and their language communications (Moschkovich, 2002), yet competence is a co-constructed phenomenon within classrooms (Gresalfi, Martin, Hand, & Greeno, 2009) meaning all students' power and identity play a major role in the formation of competence and incompetence of multilingual learners. In order to design and facilitate educational spaces that support multilingual learners, teachers and researchers need to understand how students manage both their access to resources but also the social risk of incompetence if/when resources are needed (c.f. Gibbons, 2003). As multiple students balance these two factors within the classroom system, they socially negotiate the resources present to assert power and reify their mathematical identity. The current work unpacks this negotiation by presenting a case where meaning-making resources are managed, and language incompetence is used to bar access. Within the case, I seek to answer the research questions: What role does language competence play in student-student negotiations of resources? and How are these negotiations embodied in students' social formations? My analysis breaks down how a dyad of 7th-grade students competes for resources, including the attention of a researcher-teacher, and negotiates each other's and their own competence around an educational digital narrative environment designed for single player. I discuss the implications of this type of negotiation in undermining educators' efforts to support all learners to make meaning of mathematics.

Literature and Conceptual Framework

Across a diverse array of approaches to research in mathematics learning, researchers increasingly recognize the themes of identity and power as urgent, especially where equity is foregrounded (e.g. Aguirre, Mayfield-Ingram, & Martin, 2013; Boaler & Greeno, 2000). These constructs are especially important as global immigration and language diversity in classrooms grow (Barwell et al., 2016). Mathematics plays a politically significant role in our society both as a gatekeeper to educational

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

success and in our culture overall (Gutiérrez, 2013), so the imprints left on students' mathematical identities, self-efficacy, and confidence from negotiations of power in math class greatly impact their lives. Multilingual learners must balance their need to draw on language resources with others' perceptions of their incompetence. This tension permeates their experiences of mathematics and school in general through discourse, both at the interactional level and through larger Discourses (Gee, 2004). Greater understanding of how narratives of incompetence are perpetuated and used to further alienate these students is a vital component of efforts to support teacher noticing of the power dynamics at work in their classroom and then to disrupt microagressions within those dynamics.

To unpack these dynamics, I present a conceptual framework of discourse understood as layers of the semiotic field that can be 'read' by participants in the class which are laminated together in interaction (c.f. Goodwin, 2017). I parse these layers into three forms of discourse to better understand student-student negotiations of resources and how they make use of different aspects of the semiotic field in those negotiations. The first form is the active communication, both verbal and nonverbal, among people within the classroom. In many ways, the active communication between the teacher and the students and amongst the students is the most important form of discourse because it encompasses all the in-the-moment teacher moves to scaffold student thinking (Cazden, 1988). Yet, another form of discourse exists, the historically situated narratives around the discipline, the classroom/school, the students, and the teacher, conceptualized as Discourses (Gee, 2004). These narratives permeate the classroom, framing interactions and relational identities as they are invoked, enacted, and inscribed. These two forms of discourse make up most discourse analysis approaches, but I argue for considering the institutional infrastructure in place around the classroom as an additional form of discourse. Key aspects of infrastructure are its seeming invisibility and also its deep relation to ongoing practiced (Star & Ruhleder, 1996). Together, these aspects of infrastructure generate a form of discourse which communicates what is normal and what isn't, what is allowable and what isn't, what is supported and what isn't. Each form of discourse plays a distinct role in the classroom, and understanding their relation allows us to understand the complexities of students' social negotiation and formation and the impacts of these on student learning and identity.

To understand each form of discourse, I build on different constructs within discourse analysis. I used two constructs to analyze in-the-moment, dynamic communication among individuals: footing (Goffman, 1981) and formations (Kendon, 1990). Footing provides a space to deeply examine roles of speaker and listener. Specifically, I employ Goffman's distinction between ratified and unratified participants. Ratified participants are those with the access and opportunity to fully engage in the social dynamics and enact any of the three roles of the speaker (animator, author, and principal). Unratified participants are persons present but expected not to engage directly with ratified participants. I use this distinction with Kendon's conceptualization of formations to analyze the embodied practices at work and the relational configurations of bodies, resources, and gaze. Formations are flexible patterns of physical arrangements of bodies during interaction that can be categorized, and F-formations, or formations where participants are facing each other, are a common one. By combining the principles of footing and formations, I present representations of bodies, people and objects, to understand and convey the direct communication and relational dynamics of social negotiation moment to moment.

Gee's Discourses (2004) provides a framework to understand the larger social, political, and historical contexts of the classroom within which interactions occur. Discourses are constantly at work in and through direct discourse where they are used and operated on to exercise power and manipulate positionality. By unpacking how students apply, perpetuate, or challenge different Discourses meaningful to the situation, my analysis in sensitive to Discourses role in social resource negotiation, specifically the Discourse of incompetence of (some) multilingual learners.

Finally to understand the role of infrastructure and its impacts on classroom interactions and social negotiations, I draw on conceptualizations of infrastructure as temporal and enacted through local practice (Star & Ruhleder, 1996). Star and Ruhleder (1996) characterize infrastructure with eight properties, two of which are especially significant in educational contexts. First, infrastructure becomes most visible upon breakdown, when the system does not function as it normally does. This property is especially important upon disruptions of the (classroom) system when new elements like digital games are introduced (c.f. Barab, Gresalfi, & Ingram-Goble, 2010). Another key feature is how infrastructure embodies standards which perpetuates what is 'expected' and what is 'normal.' In many ways, multilingual learners continuously grapple with both of these features of the infrastructure of 'normal school' in their daily lived experience. Unlike Discourses and moment-to-moment communication, infrastructure is an expression of the embedded norms within and assumptions of the classroom system. Important to note, both technological formations or socio-cultural formations play the role of infrastructure, and considering this social infrastructure is especially important in math classrooms (c.f. Yackel & Cobb, 1996) and multilingual learners (c.f. Langer-Osuna, Moschkovich, Norén, Powell, & Vazquez, 2016).

Data and Methods

The data for the current paper came from a multi-year design-based research study of how educational story games support students' mathematical engagement (XXX, 2017; XXX, 2016). The classroom of focus was within an ethnically diverse school serving a primarily low-income community (92% free and reduced lunch) and many multilingual learners (30% of the school population) located in a medium-sized city in the Southeastern United States. The classroom teacher, Ms. Lynn (pseudonym), was a seventh-grade mathematics teacher having seven years of teaching experience at the time of the study and in her second year of participation with the research team. The current work focuses on a class of thirty-two students, Ms. Lynn, and two to four researcher-facilitators in the room (including the author). The role of the researcher-facilitators was to support the teacher by assisting with both technical concerns and students' conceptual questions. Ms. Lynn implemented the game in a four-day unit on rates, ratios, and proportional thinking. I focus on a dyad of two students, X and LM. X was a female Latinx multilingual learner with Spanish as a first language and seemed socially active with other Spanish speakers but rarely in whole class discussions. LM was a female black student active in the class and seemed to have a positive relationship with Ms. Lynn and other students, including A, another multilingual learner.

While data collected for the larger project encompassed much for each of the four days, I focus on data of a focal dyad working on a single computer. I use video data collected from three sources. First, a standalone camera captured the table at which students were working. Second, a camera embedded in the computer provides a view from the computer's perspective to give both an additional angle and to show who is framed in front of the computer. Finally, a screen capture software records students' digital actions on the game. Audio is provided from both the computer microphone and a table microphone, but because of the proximity of another group, not all speech is captured, especially simultaneous utterances. Coordinating these different sources allows for a bird's eye view representation of the dyad's dynamic.

To analyze the interactions of this dyad, I first watched their complete progress through the four days selecting the focal case of social negotiation. I chose this interaction because it captured a breakdown in interaction when X attempts to participate and this creates an activation of a social infrastructure of other multilingual learners to "help" X. After bounding the focal interaction, I transcribed intelligible talk and noted the occurrence of any unintelligible talk and (when possible) the speaker. Next, I transcribed each participant's body language and then coordinated these multimodal transcripts in a single transcript. By coordinating this transcript with the video, I generated a series of bird's eye views of the relevant space using representations similar to those employed by Kendon (1990). These temporally discrete snapshots were created at significant changes in the dyad's formations during the interaction. Lastly, I analyzed these representations with both the video and transcript to contextualize the formation changes, document salient Discourses, and understand the enacted infrastructure.

Analysis

Overview

Evident from the first day and throughout the implementation, LM and X appear to be working together as a dyad against their wishes (at least in part). As directed by the teacher on the first day of gameplay, students choose partners to work on the game together with the condition that at least one person in the dyad reads English, the exclusive language within the game. LM and X seem to have been joined largely based on this latter requirement. Two other individuals are also the main actors within the interaction of focus, A and F. A is a female Latinx multilingual learner positioned as bilingual and a translator for multilingual learners, including X, within the class. A and three other multilingual learners sit at a table group, referred to here as G1, directly at the back of LM and X. F entered the classroom for the first time only a days prior and is a female Thai research assistant working in the class as a researcher-facilitator.

The scene starts with LM communicating frustration with a specific part of the game where students are pushed to solve unit rate calculations using a double numberline tool before moving on. LM attempts to engage both the teacher, Ms. Lynn, and G1 to little effect. F approaches and offers to help LM and X. LM expresses her confusion with this part of the game, and F provides scaffolds via clarifying and probing questions. Throughout this first part of the exchange, X seems to follow the interaction and, in a lull, makes a bid to participate in F and LM's meaning-making around the problem and the tool. Upon X's attempt (and the ending of segment 1), LM draws on A in G1 to aid in the interaction by translating. The start of the final segment is the inclusion of A. LM continues to engage directly with F to solve the problem and move forward in the game while X and A converse inaudibly in Spanish. As A finishes translating and returns to G1, LM figures out the answer to the problem and inputs it into the computer. F asks the question "Does 8 [the answer] make sense to you?" and as LM responds with "Yes," X points to the computer bidding for participation once again but this time to close the interaction.

During this time, LM is acting as both a pivot point for the formation and the arbiter for whom can join in it while X remains slouched toward computer gazing downward. F, a somewhat new resource to the environment, offers to aid the pair, and she and LM solidify the formation into an F-formation to include the three individuals (LM, F, and X) and the computer. F positions herself as a ratified listener and lets LM take up the role of ratified speaker. At the same time F is joining the dyad, X engages in sideplay (Goffman, 1981) with members of G1 from between F and LM.

As LM talks with F (the third picture of Figure 1), F constricts the F-formation around the computer, and this constriction seems to draw X into the interaction. She begins to follow the interaction between F and LM, and as LM pauses to think of an answer to F's main question, X makes a bid to participate by offering an alternative answer and looking to LM as a meaning making partner. X's attempt to connect with LM as partner is in stark contrast to the behavior of LM, who has yet to even look at X, let alone make eye contact. This difference is further expressed in the subsequent segment when LM reacts to this bid as a disruption and a violation.

This moment holds a lot of tension for the group, which can be seen in the contortion of their formation, and for the individuals, which can be seen in the LM's twisted body. Furthermore, highlighting these contortions helps us to see the breakdown of 'normal' within the scene which reveals the social infrastructure to 'support' multilingual learners. LM enacts this social responsibility for A to leave her formation and mathematics learning in G1 and 'deal' with X's constructed incompetence. Unpacking this further, X's constructed incompetence is twofold, combining both language incompetence and social incompetence, because she did not activate the infrastructure of G1 and A in the first place (unlike during the sideplay of segment 1). Following this fraught moment, LM turns her body back towards the remnants of the previous formation and makes a slight, but distinct, motion with her posture and elbow between X and F. In this microaggression, LM simultaneously recovers the formation with F capturing her attention, absolves F of responsibility to engage with X, and further positions X as a non-member of the formation and an unratified speaker.

An analytic finding problematizes Kendon's F-formations. Kendon defines F-formations as semi-static spaces of interaction where each participant has equal access to the resources within the formation. Presumably, unratified participants could not be included in F-formations because they would not have equal access. Yet in this instance, we see just that, an F-formation where an unratified participant attempts to contribute and is re-positioned out of the formation. In the final picture of Figure 1, the closeness of F, X, and LM seems to show resoundingly that they form a single formation, at least as how F and X enacts it. Yet in segment 2, LM's surprise at X's bid implies LM's enactment of the formation rendered X as virtually invisible, merely meant to engage in sideplay and animate others authorings. Such a finding pushes on Kendon's F-formation definition and brings up the question of whose formation is being described.

..	= short pause, 2-4 secs
…	= long pause, more than 4 secs
()	= inaudible
(words?)	= sounds like "words"
((actions))	= Speaker is performing "actions"
[ ]	= Simultaneous speakers, always comes in sets of at least, but not limited to, 2
-	= Latched talk (see Dressler and Kreuz's "=")
?	= Rising intonation
.	= falling intonation

Thick Dotted line	= formation
Solid line	= F-formation
Thin Dotted line	= gaze
-People-	
Complete white center	= unratified participate not included in formation (i.e. bystander)
Gradient with white center	= unratified participate in formation
Gradient with black center	= ratified participant in formation

MOTHER-CENTERED UNDERSTANDING OF MATHEMATICAL INTERACTIONS WITH CHILDREN: PURSUING POSITIVE INTENT

Sam Prough
University of Wisconsin-Madison
sprough@wisc.edu

How past research considers the influence of parents on their children's mathematical understanding does not often focus on the experience and intent of the parents themselves. In a cross-case analysis, I address how two mothers' experience shapes their mathematical positioning and the resulting interactions with their children in the subject. The attention on parents in mathematics takes on particular gendered roles, which is not often considered in research. There are more complex factors that shape how parents see and interact with mathematics. This study begins to show what alternative possibilities exist for engagement by U.S. parents in the content that still positively support children's early learning.

Keywords: Informal Education; Gender and Sexuality; Affect, Emotion, Beliefs, And Attitude

Objectives

Mathematics is taught and learned across a wide array of environments and situations, certainly not limited to the school classroom. Parents are often involved in early childhood mathematics learning through authentic engagement in everyday activities. However, across studies on parental influence on children's learning is the assumption of mother as a proxy for parent (Posey-Maddox, 2017). In research and media, mothers are frequently assumed to be doing the work of parenting. Maloney and colleagues (2015) claim that "parents are their children's first and most sustained teachers" (p. 1480). This statement coupled with the assumption of mothers doing the work of parenting implies that *mothers* are these first teachers. What is missing across literature on parents involved in mathematics learning is a focus of perspective on the parents and exploration of the parental (or specifically maternal) intentions.

The connections between parenting and mothering create additional tensions within the often-masculinized environment of mathematics. Mathematics is often framed as being for men and unwelcoming to women (e.g., Connell, 2010; Hottinger, 2016). Given the parallels between women and mothers (Arendell, 2000), potentially negative assumptions are made about mothers engaging with their children in mathematics. I explore the following questions: How does past experience in mathematics impact mothers' interactions with their child's early learning? What does this say about a mother's intent to support mathematical learning? Exploring the factors that direct mothers' action in mathematics provides a richer context for researchers in understanding parents' action in mathematical learning.

Background Literature

To understand how experience impacts mothers' interactions in mathematics requires an exploration of the larger context of motherhood expectations, parents' experience in mathematics, and the types of alternative activities parents can use to engage their children in early mathematical learning. The expectations within motherhood show what societal factors function to direct a mothers' actions in mathematical engagement. For example, adults in the United States believe that the more time women spend with their children, specifically giving their time to their children's development, the better mothers they are (Dillaway & Pare, 2008; Gorman & Fritzsche, 2002). These beliefs frame a societal expectation that mothers should be caring for and teaching their children, which mothers may identify as an obligation in their role as mothers.

Previous research that has studied parents' experience in mathematics has focused on the activities parents might do at home (e.g. Elliott & Bachman, 2018; LeFevre, Skwarchuk, Smith-Chant, Fast, Jamawar, & Bisanz, 2009) or the transfer of parental anxiety, affecting performance (e.g. Maloney et al., 2015). Research indicates a focus on authentic problem-solving (Pattison, Rubin, & Wright, 2016) and hands-on activities (Elliott & Bachman, 2018) in everyday tasks are common strategies for effectively engaging children in mathematical learning. While mathematical activity at home can be enriching for children, many parents do not recognize these problem-solving tasks as forms of mathematics (Goldman, 2005). Rich mathematics learning can happen at home, but much research on parents in mathematics is centered around how their anxiety impacts children's performance, often focused on mothers (e.g. Else-Quest, Hyde, & Hejmadi, 2008; Soni & Kumari, 2017). What is missing from this body of work is analysis from the perspective of mothers, to understand what has shaped their (gendered) experience and how they use it to create the best experiences for their children.

Theoretical Framework

I use positioning theory to frame mothers' experience in mathematics and how they represent themselves today in actions with their children. This theory uses experience and broader context to position people or be positioned as mathematical or not. Positioning theory thus becomes a way to understand the influences across cultural norms, history, experiences, and interactions with others (Harré & Van Langenhove, 1999). How mothers are positioned and position others will speak to a larger context of expectations for mothers in mathematics and what they do to still support their children in learning. Positioning oneself as mathematically able or not is frequently paralleled with concepts of power and agency (e.g. Kotsopoulos, 2014; Langer-Osuna, 2017). Using these themes of agency in positioning in mathematics education can support the agency mothers may have in positioning themselves to teach their children.

Methods

I use life history to capture the experience of my participants as a means to express the complexity of their experiences, informing their actions. Life history, an analysis of life stories, provides context to the situation and factors that make up the decisions of someone's life. "Life stories express our sense of self: who we are and how we got that way" (Linde, 1993, p. 3). This methodology supports a more intentional exploration of mothers and the reasons behind their mathematical interactions, which is frequently missing in mathematics education literature. Additionally, life stories can be characterized "as relational, as both personal and social, and as grounded in places" (Steeves, Clandinin, & Caine; 2013, p. 225). Life history offers a way to examine the connections to social and personal expectations more explicitly.

Two white, middle-class mothers, Ella and Corinne (names have been changed), who are roughly the same age, have young children, and spouses working in similar jobs, are the participants for this study. Their current life situations are similar, but their past mathematical experience and current interactions with their children differ in interesting ways. A comparison of their positioning in relation to their experiences demonstrates how mothers in different situations use available resources to provide the best mathematical opportunities they can for their children. Both participants were interviewed, with a focus on stories about their past mathematics experience and the current mathematical interactions they have with their children. Particular attention is given to the context of their stories, relating to feelings, relationships, and reflection. Interviews were audio-recorded and transcribed. A final meeting with each participant was made to go over their stories from the transcription, in order to confirm the stories best represented their experience. Interviews were then coded for themes around their positioning as mathematical thinkers, gendered roles as women and mothers, and the resultant activity they had with their children in mathematics.

Results

The difference in past experience and positioning of each mother frames how they see themselves today and ultimately engage with mathematics learning for their young children. While the specific activity differs, both mothers demonstrate attempts for positive and authentic engagement in activity. Ella came from a larger Midwest town, with an interest in reading and sports. The stories Ella shared continually related to her lack of confidence in her mathematical ability and in activity with mathematics today. In many stories related to her schooling, Ella described how teachers would put her on the spot to solve problems and she could not keep up with other students, never seeing herself as the smart one in class. Gendered roles from her past show how mathematics was understood and supported by her father, but not by her mother:

> My mom's like me, she was, my mom was probably fine with elementary school but when I got past that she was like "you have to ask your dad." And my dad, he's an engineer, so he's got a great math brain.

Ella frequently connected to her mother and her lack of fluency in mathematics problem solving. Her experience with her parents in gendered roles of mathematics support extended to how she expected her and her husband to divide work in supporting their children's learning, saying "I feel like when we got married it just like, we fall into certain roles." She claimed it was more likely that her husband would help their children with math and she could assist them in other learning.

The interactions Ella currently has with her daughter in mathematics are focused primarily on counting activities. She explained how her daughter learned to count higher than expected by stating, "we count a lot, at home. Like, she learned to count to 13 because every time we'd go up and down the stairs we would count the stairs." Ella's experience working directly with mathematics and her daughter is based on activities that have an authentic connection to their everyday lives. In moments where Ella wants more mathematical exposure for her daughter, she relies on resources in other areas, such as math-focused games from the library, and specific initiatives directed to her husband about helping in mathematics.

Corinne grew up in a small Midwest town, with a love of mathematics and learning, encouraged by her parents and supported by teachers. The stories Corinne shared related to her interest in math and dedication to engage her children in math at every available opportunity. Similar to Ella's experience, Corinne's parents had an influence on her mathematical positioning, but it was her mother who associated with mathematics and her father who was hesitant: "My mom was an accountant. So we already had like the math background and she pushed school, like school was a pretty high priority in my house. Like math just came very easy to me." The gendered roles of her parents' connection to mathematics, coupled with the positive positioning of Corinne as mathematical, supported Corinne's current activity with mathematics and her children. She is engaged often with her children in mathematical tasks and sees that as an important feature for parents who know math, connecting to a shared future role in teaching for her and her husband, where they both have mathematical backgrounds.

The activities Corinne uses to engage her children in mathematics have similar authentic connections to everyday life. However, Corinne feels comfortable asking her children questions in the moment and engaging in mathematics across any activity where a mathematical opportunity may present itself. She shared the following story about her youngest daughter:

> I was cutting up a banana for her and counting as I did it and I would pause and she would sometimes fill in the next number and I was like oh, okay you know way more than I thought you did, you can just count things.

Corinne's comfort in asking her children mathematics questions allows for opportunities to push for deeper connections in authentic settings, extending from counting to arithmetic and geometric reasoning.

Discussion and Implications

The experience and action of both Ella and Corinne demonstrate the impact of family and teacher positioning on a person's association with mathematics. Ella's association with her mother, who did not connect with math, and repeated interactions with teachers and peers that she was not learning math quickly enough have shaped how Ella characterizes herself today as uncomfortable with the subject. Corrine's past connections with her mother, who did connect with math, and the repeated affirmations by teachers of her success have shaped Corinne's continued positive associations with the subject. Literature on mathematical development in children often stresses the influence parents and teachers can have (e.g. Maloney et al., 2015; Pea & Martin, 2010). While this influence is apparent in how Ella and Corinne position themselves today, it also informs the influence of their mathematical activity with children. In this sense, mathematics interaction by parents can have a generational impact.

How Ella and Corinne interact with mathematics and their children today has marked differences, and reflects on their prior experience in the subject. Ella relies on outside or common resources, such as directives for her spouse or everyday tasks, to support engagement in mathematics for her daughter. She uses these elements as a way to counteract her positioning of uncertainty and discomfort with the subject. Corinne relies on authentic moments in everyday tasks to ask more math-specific questions of her children, divided equally with her mathematically-capable spouse. Her actions reflect similar exposure to the subject she received from her mother and repeated positioning by parents and teachers as mathematically capable. While there are variations in the kinds of activities Ella and Corinne choose, both reflect positive forms of mathematical engagement.

Ella and Corinne's interactions with children are based on authentic activity. As Pattison and colleagues (2016) suggest, this attention to authentic, at-home mathematics learning in diverse settings effectively supports mathematical reasoning. In both cases, the mothers are seeking out positive forms of mathematical engagement with their available resources and reflective of the positioning that they have. These interactions may have elements of difference, but they both rely on the use of everyday activity and are done with the best of intentions for their children. The cases of Ella and Corinne demonstrate alternative understanding of mothers' engagement with mathematics and recognition of context informing their interactions.

While there are limitations in the current study due to a lack of diversity in the participants, this study acts as a gateway to further exploration of parents (not just mothers) and their mathematical interactions. Literature that addresses Black mothers' perspectives in engagement to promote academic success for their older children (e.g. Jackson & Remillard, 2005; McGee & Beale Spencer, 2015) offer further validation to the possibilities of mothers' positive interactions in mathematics. Future work can strengthen connections between school and early childhood mathematics while alleviating the assumptions about mothers negatively impacting their children. Additional attention is needed to understand the complexity of experience and the factors that shape parents' positioning and resultant interaction with mathematics.

DIDACTIC PURPOSES AND FUNCTIONS OF SECURITY AND DOUBT IN MATHEMATICAL CONTENTS

FINES Y FUNCIONES DIDÁCTICAS DE LA SEGURIDAD Y LA DUDA EN CONTENIDOS MATEMÁTICOS

The security and doubt about mathematical facts (F) that a high school student experiences are examined. Rigo-Lemini (2009; 2013) has called those states 'epistemic states of conviction' (ESC) around F. It is argued that: i) the ESCs fulfill a didactic purpose, related to the satisfaction of certain epistemic needs and that ii) those ESC function as an alarm system that informs the person about the status of those needs and as a system that prepares the person to act accordingly.

Key words: Affect, Emotion, Beliefs; Research Methodologies; Cognition.

Background, Problem and Research Questions

The study focuses on phenomena related to security and doubt in mathematical contents F (eg, results of mathematical tasks or operations, solving tasks' strategies). Rigo-Lemini (2013) calls these states "epistemic states of conviction around F's", denoted as "ESC". Researchers have provided evidence that security and doubts about some F are present in school mathematics (Fischbein, 1987; Segal, 2000). Likewise, experts have suggested that, in certain cases, these ESCs adequately guide mathematical work, promoting advances in learning. However, in other cases, ESCs come to have unfavorable effects on the student's decisions and actions: for example, if a student doubts a mathematical concept or rule, it is very likely that he will not use it in a problem-solving activity (Fischbein, 1987; Foster, 2016). It would be highly desirable to understand the conditions under which the phenomena described above occur. However, experts acknowledge that the phenomena of conviction around F's have been little studied in the field of mathematics education (Fischbein, 1987; Foster, 2016; Inglis, Mejia-Ramos and Simpson, 2007; Segal 2000). So, to make didactic interventions focused on the ESCs, and well-founded, it is necessary to expand the current knowledge on this topic. In order to increase these understandings about ESCs in the field of mathematics education, this manuscript answers the following two research questions: What are the didactic purposes of the ESCs that a student experienced during the resolution of a mathematical task? And what functions did those ESCs perform?

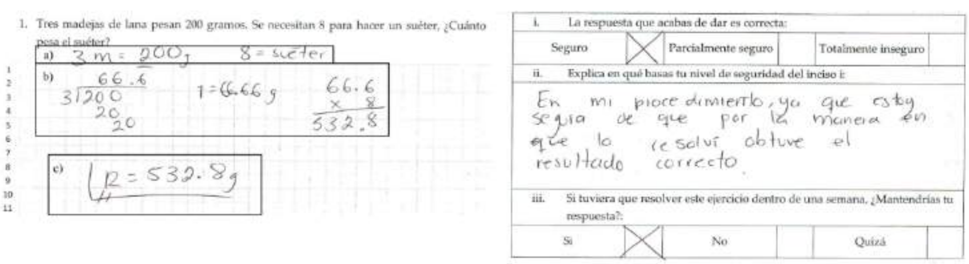
Methods and Methodology

The research adheres to the guidelines of the Grounded Theory (GT), in the version by Corbin & Strauss (2015). GT is a form of qualitative research that offers tools to build theoretical categories, based on empirical data, in order to develop explanations about the phenomena under study. For this reason, the GT does not start from a theoretical framework; it is about developing one. To elaborate these theoretical explanations, Corbin & Strauss (2015) suggest going to what they call *context analysis* (CA). In CA it is assumed that when people act or have some internal experience they are seeking to respond to events that are significant to them, in order to cover some unmet need or to maintain circumstances to preserve satisfied needs; these events are called *conditions*. From the conditions and from the actions or experiences that they promote, some result is usually derived, called *consequences*. In GT, explanations are constructed by applying the categories developed in the research and following the principles of CA. One of the objectives of the present investigation is to transcend the description to construct theoretical explanations; it was for this reason that GT was chosen. In addition to CA and other analytical techniques, microanalysis was applied, a tool that seeks to explore in depth the meaning of some pieces of data and that is usually used in early exploration stages.

What is reported in this manuscript is focused on a case study, about Hannia. She, like the five classmates who participated in the research (between 14 and 15 years old), were in third grade. The choice of subjects was made by the math teacher, who was asked to choose students with academic excellence. Empirical data was retrieved through a questionnaire, applied individually, that included 6 problems of missing value, 5 of them about proportional reasoning. At the end of each item students were asked to report the ESC they experienced (on a scale that included secure, partially secure, and totally unsecure) with respect to the answer given, and to explain in what reasons they based their level of secure. After the questionnaire, an unstructured interview was applied individually. Hannia was chosen because her questionnaire resolutions and her interview pronouncements and testimony provided valuable information on the nodal concepts examined in this investigation. In the following the case of Hannia is exposed; the data from the case is taken from the resolution that she offered to one of the tasks proposed in the questionnaire (the task of the skeins), as well as from her interventions in the interview.

Description of Security and Doubt Experiences around F's. Case Report

The researchers proposed Hannia the following task: Three skeins of wool weigh 200 grams. It takes 8 to make a sweater. How much does the sweater weigh? Three elements can be distinguished in Hannia's production: strategy approach (a), the operations carried out (b) and the resolution reached (c).



1. Tres madejas de lana pesan 200 gramos. Se necesitan 8 para hacer un suéter, ¿Cuánto pesa el suéter?

a) 3 m = 200 g   8 = suéter

b) 66.6 3|200 20 20   1 = 66.66 g   66.6 × 8 = 532.8

c) R = 532.8 g

i. La respuesta que acabas de dar es correcta:

Seguro	X	Parcialmente seguro		Totalmente inseguro	

ii. Explica en qué basas tu nivel de seguridad del inciso i:

En mi procedimiento, ya que estoy segura de que por la manera en que lo resolví obtuve el resultado correcto.

iii. Si tuviera que resolver este ejercicio dentro de una semana, ¿Mantendrías tu respuesta?:

Sí	X	No		Quizá	

Figure 1. Hannia's resolution

Although the strategy approach is not orthodox and despite omitting the reference to the quantities involved in each measurement space, Hannia's resolution is correct. Its resolution consists of two steps. In the first one, the unit value is calculated using the proportionality factor. In the second, she applied the external factor to the unit value (Cf. Vergnaud, 1985). The analysis of the episode, which is set out below, has been divided into three segments.

First Segment: Security in Strategy

In the questionnaire, Hannia explicitly stated her security in the strategy (See Figure 1). In the interview, when the researchers asked her "(. . .) What is your security about?" (311), she confirmed that security and expressed what it was linked to: "(. . .) I know that the procedure [strategy] that I carried out to solve it, I know it was correct ..., so that is what my security is based on" (312). By reporting that her security in the procedure is based on the fact that she "knows that it is correct", she reveals what she needs to experience that security: she needs to know that she did the right thing. She did not base her security only on supposing that her procedure was correct, or on believing, intuiting, or imagining it (Cfr. Villoro, 2002); to be sure, she demands to know that she acted properly.

But how did Hannia know that her procedure was correct? What reasons did she rely on? Although the guarantees on which she based her knowledge does not make them explicit, in the interview she hinted at some clues about what it means for her to trust. When the researchers asked her: "Hey, for you, what is it to be sure?" (317), she responds: "(. . .) Trusting what you did or what you said or what you do… that you do not regret what you have already done, you have to be focused" (318), "(. . .) be ... like ... zero nerves, relaxed, as sure haha with what you did, that you feel satisfied "(320); to this, the researchers ask: "Satisfied with what? (321) and she responds: "(. . .) satisfied with what you achieve or what you already did" (322). She immediately takes up the topic: "(. . .) Of what I have already done, [that I did] what they asked me to do, [and] what I did was good and therefore I am relaxed" (324), and then she assures: "(. . .) [when] (. . .) I don't follow a procedure that was taught to me, I feel more unsure of the result I obtained "(340). From this, it is plausible to suppose that 'doing what they asked' (324) or 'applying a procedure they taught' (340) are the reasons on which Hannia possibly based her 'knowing' that her strategy was correct.

Second Segment: Insecurity in Operations (carried out on a first attempt)

Following the chosen strategy, Hannia carried out the corresponding operations (See Figure 1). In the interview, she also outsourced the ESCs that she experienced during the execution of those operations and clarified what she based those ESCs on. Hannia comments that her security is based on the procedure performed, "(. . .) I know that the procedure I carried out to solve it, I know that the calculations I made were correct or well done, so my security is based on that" (312) and when asked her about how she knows that her calculations are correct, she expresses: "(. . .) I rectified them several times when I had already obtained the final result and I was able to make my conclusions and that's it" (314). By the type of response, it was considered important to ask if this is something that she usually does, to which she replied: "yes, when I don't feel very sure, or things like that (. . .) sometimes I do rectify my operations" (316).

As in the case of strategy, in the case of operations Hannia clarifies that she needed to know that they were correct in order to experience security, imposing on herself the epistemic need to know the correctness of the calculations to experience confidence. But, unlike the first, in this segment the student did specify the reasons on which her knowledge rested: in the verification of operations. In the interview, Hannia reveals that if she does not verify the calculations, she cannot know that they are correct and therefore she experiences insecurity around them. So, regarding her resolution of the task of the skeins, it is possible to suppose that in the first attempt, that is, in this second segment, Hannia felt insecure of her operations, because as she clarified, she verified them to be sure of the final result (314).

Third segment: Security in operations (performed on a second attempt) and security in the final result

Both in its production and in the interview, Hannia left no evidence of the rectification of operations. We assume that work was done mentally. Upon achieving the goal of 'rectifying the operations multiple times', she knew they were correct (met her epistemic need to know) and felt a security experience reporting in 312: "I know (. . .) That my calculations are correct, in that is based on my security". Supported by that security, she was already able to make her conclusions (314), that is, she was able to propose with confidence her final result, 'without regret' (318), concluding the exercise.

Theoretical Empirical Findings: Explanations on the Didactic Purposes and Functions of Security and Doubt about H's

From the above, it can be said that the overlapping of conditions that generated security (eg, about the strategy, or the operations) in Hannia included having achieved some *objectives* (eg, verifying operations, applying what they taught her), which it allowed her to satisfy her *epistemic need* to know that (her work was correct). As a consequence, security led her to *accept the results* that are the object of her security and to *continue with the mathematical work* in accordance with this acceptance trend. A consideration, in a sense symmetrical to the previous one, can be made regarding the insecurity that Hannia felt during her productions. The overlapping of **conditions** that generated insecurity (e. g, in operations) includes (among other factors) not having reached certain *objectives* (e. g, to verify), which prevented her from meeting her *epistemic need* to know that (her work it was well done). As a **consequence**, insecurity led Hannia *to distance* herself from the object of her doubt and led her *to carry out certain mathematical works* (in order to achieve her goals and satisfy her epistemic need to know). The categories corresponding to the conditions and those corresponding to the consequences that have been introduced in the framework of the investigation whose partial results are presented here have been highlighted with italics.

In accordance with this approach, the ESCs function as signals that inform the student whether or not an epistemic need is met. The study also reveals the effects of ESCs: when Hannia experiences security (epistemic need fulfilled), she generates a certain commitment to F and specifically directs her mathematical work towards F accordingly. When she builds an experience of doubt, in the face of unmet epistemic needs, she generates a distance or reluctance towards F and specifically guides her mathematical works in accordance with this trend.

We are then able to answer the first question, about the aims of ESCs in Hannia, or about the kinds of situations that her ESCs experiences allowed Hannia to face and resolve. A remarkable purpose of the ESCs in Hannia is that they allowed her to face and solve situations where epistemic needs are involved: when they are fulfilled, to preserve them and when they are not, to settle them.

And it is also possible to answer the second: What didactic functions did her ESCs play in solving these events? Her ESCs allowed Hannia to identify if her epistemic needs were met or not, functioning as an alarm system that keeps her informed about the status of those epistemic needs. Additionally, her ESCs also functioned as a system, coordinated with the previous one, that prepares her for action, that is, that drives her to carry out the corresponding mathematical works.

Final thoughts

Research based on GT methodology is not intended to establish generalizations; however, GT allows generating understandings that can be generalized, under certain restrictions, to similar cases that adjust to conditions analogous to those studied under GT (Corbin & Strauss, 2015; Reichertz, 2007). So, it is feasible to suppose that the explanations given here can be applied to cases analogous to those of Hannia. These explanations are novel and pertinent for research in mathematics education and for its teaching and may represent the basis for the gradual theoretical construction of a compendium of understandings on the phenomenon, empirically based, that allow, in the medium term, to make didactic interventions focused on the ESCs, well oriented and ethically responsible.

Se examina la seguridad y la duda en torno a hechos de las matemáticas (H) que experimenta una estudiante de secundaria. A esos estados Rigo-Lemini (2009; 2013) los ha denominado 'estados epistémicos de convencimiento' (EEC) en torno a H. Se argumenta que: i) los EEC cumplen una finalidad didáctica, relacionadas con la satisfacción de ciertas necesidades epistémicas y que ii) esos EEC funcionan como un sistema de alarma que informa a la persona sobre el estatus de esas necesidades y como un sistema que prepara a la persona para actuar en consecuencia.

Palabras clave: Afecto, Emoción, Creencias; Metodologías de Investigación; Cognición.

Antecedentes, Problema y Preguntas de Investigación

El estudio se centra en fenómenos relacionados con la seguridad y la duda en hechos de las matemáticas H (e. g., resultados de tareas matemáticas o de operaciones; estrategias de resolución de tareas). A esos estados Rigo-Lemini (2013) los denomina *estados epistémicos de convencimiento* en torno a H's', denotados como EEC. Investigadores han aportado evidencias de que la seguridad y las dudas en torno a algún H están presentes en la matemática escolar (Fischbein, 1987; Segal, 2000). Asimismo, los expertos han sugerido que, en ciertos casos, esos EEC orientan adecuadamente el trabajo matemático, promoviendo avances en los aprendizajes. Sin embargo, en otros casos los EEC llegan a tener efectos desfavorables en las decisiones y acciones del alumno: por ejemplo, si un estudiante duda de un concepto o regla matemática, es muy probable que no la utilice en una actividad de resolución de problemas (Fischbein, 1987; Foster, 2016). Sería del todo deseable comprender las condiciones en las que se dan los fenómenos antes descritos. No obstante, los expertos reconocen que los fenómenos de convencimiento en torno a H's han sido muy poco estudiados en el ámbito de la educación matemática (Fischbein, 1987; Foster, 2016; Inglis, Mejia-

Ramos y Simpson, 2007; Segal 2000). De modo que, para hacer intervenciones didácticas centradas en los EEC, y bien fundamentadas, resulta necesario ampliar el actual conocimiento sobre ese tema. Con el fin de incrementar esas comprensiones en torno a los EEC en el ámbito de la educación matemática, en este manuscrito se responde a las siguientes dos preguntas de investigación: ¿Cuáles son los fines didácticos de los EEC que experimentó una estudiante durante la resolución de una tarea matemática? Y ¿Qué funciones desempeñaron esos EEC?

Métodos y Metodología

La investigación se apega a los lineamientos de la Teoría Fundamentada (TF), en la versión de Corbin & Strauss (2015). La TF es una forma de investigación cualitativa que ofrece herramientas para construir categorías teóricas, fundadas en datos empíricos, con el fin de construir explicaciones sobre los fenómenos bajo estudio. Por eso, en la TF no se parte de un marco teórico; se trata de desarrollar uno. Para elaborar esas explicaciones teóricas, Corbin & Strauss (2015) sugieren acudir a lo que ellos llaman *análisis de contexto* (AC). En el AC se supone que cuando las personas actúan o tienen alguna experiencia interna están buscando dar respuesta, a sucesos o eventos que son significativos para ellas, con el fin de cubrir alguna necesidad no satisfecha o de mantener circunstancias para preservar necesidades satisfechas; a esos eventos se les denominan *condiciones*. De las condiciones y de las acciones o experiencias internas que propician, se suele desprender algún resultado, denominado *consecuencias*. En la TF, las explicaciones se construyen aplicando las categorías desarrolladas en la investigación y siguiendo los principios del AC. Uno de los objetivos de la presente investigación es trascender la descripción para construir explicaciones teóricas; fue por ello que se eligió la TF. Además del AC y de otras técnicas analíticas, se aplicó el microanálisis, herramienta en la que se busca explorar en profundidad, el significado de algunas piezas de datos y que se suele utilizar en estadios de exploración temprana.

Lo que se reporta en este manuscrito está centrado en un estudio de caso, el de Hannia. Ella, al igual que los cinco compañeros que participaron en la investigación (de entre 14 y 15 años), cursaban tercero de secundaria. La elección de los sujetos la realizó la maestra de matemáticas, a quien se le solicitó que fueran estudiantes con excelencia académica. Se recuperaron datos empíricos a través de un cuestionario, aplicado de manera individual, que incluía 6 problemas de valor faltante; 5 de ellos eran de proporcionalidad. Al final de cada reactivo se les pidió a los alumnos que reportaran el EEC que experimentaron (en una escala que incluía seguro, parcialmente seguro y totalmente inseguro) con respecto a la respuesta dada, y que explicaran en qué basaban su nivel de seguridad. Después del cuestionario se aplicó, de manera individual, una entrevista no estructurada. Se eligió a Hannia porque sus resoluciones al cuestionario y sus declaraciones en la entrevista brindaron información valiosa sobre los conceptos centrales que se examinan en esta investigación. En lo que sigue se expone el caso de Hannia; los datos del caso se toman de la resolución que ella ofreció a una de las tareas propuestas en el cuestionario (la tarea de las madejas), así como de sus intervenciones en la entrevista.

Descripción de Experiencias de Seguridad y Duda en torno a H's. Relato de un Caso

Las investigadoras le propusieron a Hannia la siguiente tarea: Tres madejas de lana pesan 200 gramos. Se necesitan 8 para hacer un suéter ¿Cuánto pesa el suéter? En la producción de Hannia se pueden distinguir tres elementos: el planteamiento de su estrategia (a), las operaciones realizadas (b) y la resolución a la que llegó (c).

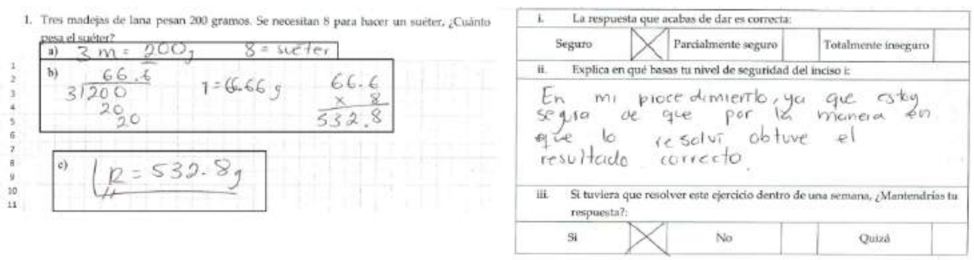

Figura 1. Producción Hannia

Aunque el planteamiento de la estrategia no es ortodoxo y a pesar de que omite la referencia a las cantidades involucradas en cada espacio de medida, la resolución de Hannia es correcta. Su resolución consta de dos pasos. En el primero calcula, mediante el factor de proporcionalidad, el valor unitario. En el segundo aplica el factor externo al valor unitario (Cf. Vergnaud, 1985). El análisis del episodio, que se expone en lo que sigue, se ha dividido en tres segmentos.

Primer Segmento: Seguridad en la Estrategia

En el cuestionario Hannia manifestó de manera explícita su seguridad en la estrategia (V. Figura 1). En la entrevista, cuando las investigadoras le preguntaron "(. . .) ¿A qué se debe tu seguridad?" (311), ella confirmó esa seguridad y expresó a qué estaba ligada: "(…) sé que el procedimiento [estrategia] que realicé para solucionarlo, sé qué pues fue correcto…, entonces en eso se basa mi seguridad" (312). Al reportar que su seguridad en el procedimiento está basada en que ella 'sabe que es correcto´, deja ver lo que necesita para experimentar esa seguridad: ella necesita saber que procedió de manera acertada. Ella no basó su seguridad sólo en suponer que su procedimiento fue correcto, o en creerlo, intuirlo o imaginarlo (Cfr. Villoro, 2002); para estar segura, ella se exige saber que actuó adecuadamente.

Pero ¿Cómo supo Hannia que su procedimiento era correcto? ¿En qué razones se apoyó? Aunque las garantías en las que sustentó su saber no las explicita, en la entrevista insinuó algunas pistas sobre lo que para ella significa confiar. Al preguntarle: "Oye y para ti ¿Qué es estar segura?" (317), ella responde: "(. . .) confiada de lo que tú hiciste o lo que dijiste o lo que haces… que no te arrepientas de lo que ya hiciste, tienes que estar como centrada" (318), "(. . .) estar… como que… cero nervios, relajada, como segura jaja con lo que tú realizaste, que te sientas satisfecha" (320); a esto se le pregunta: "¿Satisfecha de qué? (321) y ella responde: "(. . .) como de lo que logras o lo que ya hiciste" (322). En seguida retoma: "(. . .) de lo que ya hice, [que hice] lo que me pidieron, [y] lo que hice estuvo bien y por ello estoy relajada" (324), y después asegura: "(. . .) [cuando] no (. . .) sigo un procedimiento que me enseñaron sí me siento más insegura del resultado que obtuve" (340). De esto, es plausible suponer que el 'hacer lo que le pidieron' (324) o el 'aplicar un procedimiento que le enseñaron' (340) son las razones en las que posiblemente Hannia basó su 'saber' que su estrategia era correcta.

Segundo Segmento: Inseguridad en las Operaciones (realizadas en un primer intento)

Siguiendo la estrategia elegida, Hannia realizó las operaciones correspondientes (V. Figura 1). En la entrevista ella también externalizó los EEC que experimentó durante la ejecución de esas operaciones, y aclaró en qué basaba esos EEC. Hannia comenta que su seguridad la basa en el procedimiento realizado, "(. . .) sé que el procedimiento que realicé para solucionarlo, sé que pues fue correcto, o estuvo bien los cálculos que yo hice, entonces en eso se basa mi seguridad" (312) y al preguntarle sobre cómo sabe que sus cálculos están bien, ella expresa: "(. . .) los rectifiqué varias veces cuando ya había obtenido el resultado final y ya fue que pude hacer mis conclusiones y ya" (314). Por la respuesta, se consideró importante preguntar si eso es algo que ella suele hacer, a lo que ella respondió: "sí, cuando no me siento muy segura, o cosas así (. . .) a veces sí rectifico mis operaciones" (316).

Al igual que en el caso de la estrategia, en el de las operaciones Hannia aclara que necesitaba saber que eran correctas para poder experimentar seguridad, imponiéndose la necesidad epistémica de saber de la corrección de los cálculos para experimentar confianza. Pero, a diferencia del primero, en este segmento la alumna sí especificó las razones en las que descansó su saber: en la verificación de operaciones. En la entrevista, Hannia revela que, si ella no verifica los cálculos, no puede saber que son correctos y por tanto ella experimenta inseguridad en torno a ellos. Así que, respecto a su resolución de la tarea de las madejas, es posible suponer que en el primer intento, es decir, en este segundo segmento, Hannia se sintió insegura de sus operaciones, pues como ella aclaró, las verificó para estar segura del resultado final (314).

Tercer segmento: Seguridad en las operaciones (realizadas en un segundo intento) y seguridad en el resultado final

Tanto en su producción como en la entrevista, Hannia no dejó evidencia de la rectificación de operaciones. Suponemos que ese trabajo fue hecho de manera mental. Al lograr el objetivo de 'rectificar varias veces' las operaciones, supo que eran correctas (satisfizo su necesidad epistémica de saber) y sintió una experiencia de seguridad que reporta en 312: "sé (. . .) que mis cálculos son correctos, en eso se basa mi seguridad". Pertrechada en esa seguridad, ya pudo hacer sus conclusiones y ya (314), es decir, pudo proponer con toda confianza su resultado final, 'sin arrepentirse' (318), dando por terminado el ejercicio.

Hallazgos Teórico Empíricos: Explicaciones sobre los Fines y las Funciones Didácticas de la Seguridad y la Duda en torno a H's

De lo antes expuesto se puede decir que el imbricado de **condiciones** que generaron seguridad (e.g., sobre la estrategia, o las operaciones) en Hannia incluyó el haber alcanzado algún *objetivo* (e.g., verificar operaciones, aplicar lo que le enseñaron), lo cual le permitió satisfacer su *necesidad epistémica* de saber que (su trabajo era correcto). Como **consecuencia**, la seguridad la llevó a *aceptar los resultados* objeto de su seguridad y a *continuar con el trabajo* matemático en concordancia con esa tendencia de aceptación. Una consideración, en cierto sentido simétrica a la anterior, se puede hacer con respecto a la inseguridad que Hannia sintió durante sus producciones. El imbricado de **condiciones** que en ella generaron inseguridad (e.g., en las operaciones) incluye (entre otros factores) el no haber alcanzado ciertos *objetivos* (e.g., el de verificar), lo que le impidió cubrir su *necesidad epistémica* de saber que (su trabajo estaba bien hecho). Como **consecuencia**, la inseguridad llevó a Hannia a *tomar distancia* del objeto de su duda y la llevó a *realizar ciertos trabajos matemáticos* (con el fin de alcanzar sus objetivos y satisfacer su necesidad epistémica de saber). Se han resaltado con letras itálicas las categorías correspondientes a las condiciones y las correspondientes a las consecuencias que se han introducido en el marco de la investigación cuyos resultados parciales aquí se exponen.

De acuerdo con este planteamiento, los EEC funcionan como señales que le informan a la estudiante si una necesidad epistémica está o no solventada. El estudio también deja ver los efectos de los EEC: cuando Hannia experimenta seguridad (necesidad epistémica cumplida) genera un cierto compromiso con H y orienta específicamente sus trabajos matemáticos hacia H conforme a ello. Cuando construye una experiencia de duda, ante necesidades epistémicas insatisfechas, genera una distancia o reticencia hacia H y orienta específicamente sus trabajos matemáticos de acuerdo con esa tendencia.

Se está entonces en condiciones de responder a la primera pregunta, sobre los fines de los EEC en Hannia, o sobre el tipo de situaciones que sus experiencias de EEC le permitieron a Hannia afrontar y resolver. Un propósito destacable de los EEC en Hannia, es que le permitieron enfrentar y solventar situaciones donde están involucradas necesidades epistémicas: cuando están cumplidas, para preservarlas y cuando no lo están, para saldarlas.

Y también es posible responder a la segunda: ¿Qué funciones didácticas desempeñaron sus EEC en la resolución de esas incidencias? Sus EEC le permitieron identificar a la estudiante si sus necesidades epistémicas estaban satisfechas o no, funcionando como un sistema de alarma que la mantiene informada sobre el estatus de esas necesidades epistémicas. Adicionalmente, sus EEC funcionaron también como un sistema, coordinado con el previo, que la prepara para la acción, esto es, que la impulsa a la ejecución de los trabajos matemáticos correspondientes.

Consideraciones finales

Las investigaciones basadas en la metodología de la TF, no tienen la finalidad de establecer generalizaciones; no obstante, la TF permite generar comprensiones que se pueden generalizar, bajo determinadas restricciones - a casos semejantes que se ajusten a condiciones análogas a los estudiados bajo la TF (Corbin & Strauss, 2015; Reichertz, 2007). De modo que es viable suponer que las explicaciones aquí dadas se pueden aplicar a casos análogos a los de Hannia. Esas explicaciones resultan novedosas y pertinentes para la investigación en educación matemática y para su enseñanza y pueden representar la base para la paulatina construcción teórica de un compendio de comprensiones sobre el fenómeno, fundamentadas empíricamente, que permitan, a mediano plazo, hacer intervenciones didácticas centradas en los EEC, bien orientadas y éticamente responsables.

COMPARING TRANSFER AND NON-TRANSFER COLLEGE STUDENTS' MATHEMATICS PROFESSIONAL VISION

Sarah A. Roberts

This research focuses on the importance of attending to transfer students in mathematics departments at research universities. This study explores the development of professional vision among mathematics transfer students, through examining community, "student" skills, and students' future career aspirations. A bundle of three transitional mathematics course for transfer students offered concurrently at a four-year research university provided the setting, and we compared transfer students enrolled in bundle, non-bundle transfer students, and non-transfer students. Overall, students identified differences in their mathematical communities, their development as mathematics students, and their resources for career pathways.

Keywords: University mathematics; Affect, emotion, beliefs, and attitudes

The recent increase of transfer student enrollment mandated by many universities drives a need to understand how we can better prepare faculty to support this growing population of students. There is currently little research about how to support mathematics majors as they make the transition from two-year institutions to four-year institutions of higher education, even though there is general scholarship about transfer students (e.g., Melguizo et al., 2011). Understanding mathematics transfer students is important for three key reasons. First, the mathematics transfer population includes large numbers of underrepresented minorities, low-income, and first- generation college students (>50%), who start their college education at a community college—students who are often left out of the STEM pipeline (Carnevale et al., 2011). Second, we have seen a high level of attrition of transfer students from the mathematics major at our university, with just over half completing the major. It is important to understand whether retaining students in the major with the proposed intervention, a bundle of course to support transfer students helps. Third, transferring and adjusting to a four-year institution can be a complex process for students, requiring adjustments on many different levels (Laanan, 2001). In addition to a drop in GPA, transfer students often report feelings of alienation and isolation at their new institution (Laanan, 2001), with women and minorities majoring in STEM more likely to face this particular struggle (Espinosa, 2011). For these reasons, we studied how transfer mathematics students compared to non-transfer mathematics students enrolled in the aforementioned bundle of courses designed to support transfer students.

Framing

We use Lave and Wenger's (1991) *legitimate peripheral participation* and Goodwin's (1994) *professional vision* as a conceptual framework to consider mathematics transfer students' development along a novice to expert continuum of professional vision. In particular, our research question was: How do community college transfer students differ from non-transfer students enrolled in a bundle of support courses for transfer students in a mathematics department in terms of: (a) feeling that they are part of a community; (b) learning to be a college mathematics student; and (c) preparing for a future mathematics career?

Legitimate Peripheral Participation

We drew on Lave and Wenger's (1991) ideas of legitimate peripheral participation, as related to apprenticeships, and active participation in a community of knowledge. In particular, we were interested in how individuals engaged with one another to feel like they were part of a community.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Students learned content not simply by receiving factual knowledge, but within and engaged as part of a community of learners, developing facility with content and community (Lave & Wenger, 1991). As students learned to be college students and prepared for their future careers, they engaged in peripheral participation, which was full participation in the community of practice (Lave & Wenger, 1991). This allowed four-year mathematics students to engage in novice-expert relationships, being apprenticed into new skills and knowledge of expertise, such as becoming four-year university college students or mathematics professionals.

Professional Vision

Such novice-expert interactions as those previously described were organized for the development of professional vision (Goodwin, 1994). We drew on Goodwin's professional vision to understand the development of the professional vision needed for being a four-year student and a future mathematics professional, which he defined using three characteristics: 1) being perspectival; 2) being situated; and 3) being learned, because it was situated.

Research Methodology

This research took place in the context of a research university mathematics department and involved students engaged with at least one "bundle" course. Three mathematics courses made up the bundle: (1) special topics in mathematics (a course to develop problem solving and the expectations for upper level mathematics courses)—Course A, (2) group studies in mathematics (an academic and career advising course)—Course B, and (3) transition to higher mathematics—Course C. This third course served as a comparison course across all three groups of participants in the study, as it was a prerequisite for many mathematics courses that followed. Course C was an introduction to the elements of propositional logic, techniques of mathematical proof, and fundamental mathematical structures, including sets, functions, relations, and other topics. This was the second year of this study. In the first year of our study (Roberts et al., 2019), the mathematics department selected students into the bundle and placed all students into the same section of Course C. During the second year, reported here, students voluntarily selected into the bundle, and the mathematics department placed students into two separate sections of Course C.

Three groups of students participated in this study: transfer students who voluntarily chose to take the "bundle" courses (concurrently); transfer students who took only Course C; and non-transfer students who took only Course C. This allowed for comparative groups to understand how groups of students engaged with the content in the bundle courses.

We conducted and audio-recorded semi-structured focus groups (Yin, 2016; 40-60 minutes) and individual interviews (25-35 minutes) to understand how participants developed professional vision around being a mathematics major and mathematics professional. The interview covered the following: background information, three-course bundle, being a mathematics student, ways of thinking and doing mathematics, and preparation for a career in mathematics.

We used focused coding (Maxwell, 2005), applying three themes: community, being a student, and future as a mathematician, to code the interviews and focus groups. We then looked within and across each set of coded data and research question, looking for consistencies and inconsistencies. We also drew on data from our Year 1 data from the 2018-2019 school year, which was coded similarly and used the same conceptual framework but only examined bundle transfer student (See Roberts et al., 2019, for more information), to make longitudinal comparisons, to triangulate, and to look for further consistencies and inconsistencies.

Findings

We found that there were differences between bundle students, transfer students, and non-transfer students across the students we interviewed. We describe key differences in ways transfer and non-transfer students viewed community, office hours, and their future career opportunities.

Role of Community

There was a difference in the way that transfer students discussed the role of community compared the non-transfer students, especially those students who were enrolled in the bundle courses. This resonated with our Year 1 findings, where we found that students were very connected with other students in the bundle course. In our Year 2 findings, students in the bundle noted the role of the community. For instance, Megan shared, "[So,] the community I feel, like, it kind of empowered me a bit" (p. 6), when she was asked about the benefits of taking the bundle courses. Similarly, Talia, also from the bundle, explained, "[T]o reiterate, the community…I feel like I can always text someone, even if they're not in the same class. I can always message and be like, 'Does anyone, you know, wanna help?' Or whatever" (p. 21). These students felt like there was a strong sense of community in the bundle, where they could go to other students for help and draw on the collective wisdom of other students—there was collective professional vision situated in their bundle (Goodwin, 1994). However, Caleb, a bundle student, also mentioned that he had community through another outlet, a club sport, and did not need to draw on the community from other transfer students and the bundle. Therefore, this was not consistent with all bundle students. Additionally, not all transfer students mentioned that they felt that they were part of this community. For example, a non-bundle transfer student, Madison, explained, "I agree that there was community, but I also felt very excluded from it, so I didn't feel like I was part of that community. I did see that there was a community" (p. 17). For this student, there was an issue with being excluded from the community.

The non-transfer students also mentioned community, but this community did not appear to emanate from the courses, like it did with the bundle courses. Instead this community was from friends made externally from the courses or friends made within the courses but not with the help of the courses. In the bundle courses, the community appeared to be built from within the course—with the instructors helped to develop that community, as described below. Non-transfer student, Esther, described a group of friends she with whom had taken earlier mathematics classes and with whom she had studied previously. However, those students were not in Course C, so there was not a feeling of community, because she did not have interactions with any of those same students any longer. Bundle courses, in contrast, forced students to work together, which likely allowed most students to develop community.

Being a Student

Approaching faculty for support was the key component of being a student we explored in this study. Transfer students were the only students who mentioned visiting professors' office hours. Bundle students were the only ones who discussed their visits in detail. Others noted that these were resources for help in their mathematics course, but none of the other students we interviewed, besides the bundle students, discussed, in detail, attending office hours. Non-transfer students even went so far as to mention not going to office hours or not even interacting with faculty. This is notable, because office hours can be a useful tool for students to learn how to ask for help, especially for transfer students, who are more likely to change majors and leave universities. As we noted in our Year 1 paper, Course B required students to attend office hours. Talia, from the bundle, shared, "I think the first time I went to office hours last quarter, I was so terrified, but it kind of made me realize…how approachable people are" (p. 7). Even though going to visit professors was difficult at first, students found this valuable. As Talia explained, "And, so, now, I have no problem going to office hours if I need to" (p. 7). This was consistent with our Year 1 findings, where those students who were "forced" to go to office hours in the bundle were thankful for developing familiarity with the process and with getting to know faculty and TAs.

Future Career Opportunities

The Course B instructor, who was also a mathematics department advisor, was highlighted as key in sending out information to all student participants about future mathematics career opportunities. There was a key difference between transfer students and non-transfer students in their considerations about their future careers and what they had accomplished toward those careers by the time we had met for our interviews. Second year non-transfer students had already applied for internships, were participating in research on campus, had attended mathematics conferences off-campus, had secured funding, and had other such opportunities. Additionally, they seemed to feel like they had plenty of time to figure out their future plans. In contrast, transfer students were just beginning to learn about these opportunities, but they also felt the pressure to figure out their future more quickly as third-year students. Bundle students had, as part of their Course B coursework, weekly panels on graduate school, jobs in industry, and other opportunities, whereas, non-bundle transfer students were dependent upon weekly department emails, clubs, and reaching out for individual emails. Even so, bundle students asked for more, such as how to write in LaTeX, what K-12 careers might entail, and how to write cover letters for research internships (which those non-transfer students had already secured). We noted in our Year 1 findings that bundle students were similarly reaching out for more internship opportunities. The fact that non-transfer students had already applied for these placements supports this finding that more needs to be done to work with transfer students to level the playing field for future opportunities. Finally, because not all students had access to the bundle, we see that transfer students are missing out on Course B and this future career advising.

Discussion and Conclusions

There were three key differences between transfer students and non-transfer students in the bundle and non-bundle courses. First, the bundle course provided a community for transfer students to develop a mathematics community. Second, those transfer students in the bundle were more likely to attend office hours, which meant they were more likely to reach out for support in their coursework. Third, transfer students were more likely to be behind non-transfer students in their future mathematics plans; however, bundle students were more likely to have had exposure to more future possibilities. This bundle of courses offered transfer students with connections that helped them adjust to life as a mathematics student, as well as professional vision for their future mathematics careers.

SPONTANEOUS MATHEMATICAL MOMENTS BETWEEN CAREGIVER AND CHILD DURING AN ENGINEERING DESIGN PROJECT

Amber Simpson
Binghamton University
asimpson@binghamton.edu

Qiu Zhong
Indiana University
zhongqiu@iu.edu

Research studies support caregiver's involvement in their child's mathematical journey as foundational to their cognitive development and academic success as mathematical learners (e.g., Sheldon & Epstein, 2005). The purpose of this intrinsic case study was to understand how a caregiver initiated and/or continually engaged their child in spontaneous mathematical moments during the engineering design process. Through the analysis of approximately 13.5 hours of video data, we noted several ways in which Tonya guided, supported, and challenged Cindy through a shared endeavor of designing a remote-controlled delivery robot – questioning that promoted reflection and advanced Cindy's mathematical understanding, affording Cindy opportunities for decision making, and providing Cindy with the mathematical language to describe her approaches within the engineering design process.

Keywords: Caregiver as Educator, Informal Education, Mathematical Moments

Objective

Previous research suggests that interest and engagement in science, technology, engineering, and mathematics (STEM) can be triggered at a young age, and caregivers are considered to be one of the most significant influences in this development (e.g., Maltese & Tai, 2011). Additionally, the benefits of out-of-school learning experiences for youth is well documented and include positive dispositions toward STEM, greater likelihood of pursuing a STEM-degree and career, and development of interest and confidence in STEM (e.g., Bell et al., 2009; Denson et al., 2015). Engaging in teaching and learning of mathematics within home environments and other out-of-school contexts are framed as shared family experiences and tend to include budgeting, home improvement projects, games, proportions of ingredients when using recipes, and verbal exchanges during mealtime (e.g., Esmonde et al., 2012; Pea & Martin, 2010). As such, caregivers, regardless of their own experiences, are able to act as mathematics educators in engaging their child(ren) in mathematical moments (Sheldon & Epstein, 2005). In this study, these mathematical moments are defined as a spontaneous experience to engage with and/or explore mathematical ideas and concepts (Cunningham, 2015), and situated within a project aimed at developing, implementing, and refining a program for integrating engineering design practices with an emphasis on emerging technologies (i.e., making, DIY electronics) into home environments of families. Research has shown that participating in engineering design principles support students' application of mathematical concepts (e.g., Berland et al., 2014). Yet, we know very little of how such mathematical moments in the engineering design process arise in out-of-school learning contexts between caregiver and child. We address this gap in the literature by addressing the following research question – How does a caregiver initiate and/or continually engage their child in spontaneous mathematical moments during the engineering design process? We contend that caregivers and other family members should be recognized for their ability to enhance school mathematics within out-of-school learning contexts.

Perspective

In this study, we utilized a socio-cultural perspective, which views learning as active participation and engagement in cultural and social activities (Rogoff et al., 1993). More specifically, we employed Rogoff and colleagues' (1993) guided participation in which participation is guided, supported, and challenged from another in a shared endeavor; in this study, this other referred to the caregiver and the shared endeavor is the development of a robot (see below). As such, Rogoff (2008) defined participation as an interpersonal process in which individuals are actively observing and/or communicating with their words and hands. It builds upon the notion of zone or proximal development as it involves "not only the face-to-face interaction, which has been the subject of much research, but also the side-by-side, joint participation that is frequent in everyday life" (Rogoff, 2008, p. 60). Similar to Vedder-Wiess (2017), we contend that the caregiver's role within in the process of guided participation is through modeling and engaging in spontaneous mathematical moments with their child. Collectively, the caregiver and child are employing their knowledge and understanding of mathematics.

Methods

The larger research project was conducted between January to May. We met with caregiver-child dyads once a month for approximately 3 hours in length. This particular study is an intrinsic case study of a caregiver-child dyad (Tanya and Cindy) engaging in mathematical moments during an engineering design project developed and designed by the dyad (Stake, 1995). As stated by Cindy, "My project is a remote-controlled delivery robot to help people who can't get out of bed or are sick…I was thinking about someone in a nursing home." At the time of the study, Cindy was a third-grade student who aspired to be an artist.

Data Collection

The main source of data was video recordings of each monthly session and home video recordings of Tonya and Cindy working alongside a member of the team. Cameras were stationed as to capture the interactions between Tonya and Cindy, as well as interactions with facilitators and engineers who volunteered their time to assist the dyad. This amounted to approximately 11 hours of video data from the monthly sessions and approximately 2.5 hours of video data from the home visits.

Data Analysis

The analysis was conducted in two phases. During the first phase, both authors watched all the videos, individually looking for mathematical moments. We each noted the time range and provided a brief overview of the interaction in terms of engagement with mathematical ideas and/or concepts. Our goal was not to establish inter-rater reliability, but to capture identifiable mathematical moments, or ethnographic chunks, for further analysis (Jordan & Henderson, 1995). We met five times to discuss our observations as we acknowledged these identifiable moments to be influenced by our cultural understandings of and experiences with mathematics as a mathematics teacher educator and STEM education researcher, and science education doctoral student respectively. The final meeting focused on identifying specific moments that addressed the research question, which were transcribed verbatim and included non-verbal acts of communication. During the second phase, we individually read through the transcripts and noted the ways Tonya initiated and continually engaged Cindy in spontaneous mathematical moments. When we met to discuss, we were similar in our understanding of these spontaneous moments such as the manner in which Tonya posed questions to both initiate and advance Cindy's engagement as a mathematician. We also developed a shared language (i.e., agency).

Findings

We present two specific instances in which Tonya initiated and/or continually guided Cindy in spontaneous mathematical moments during the engineering design process. Both examples occurred during the last workshop when Tonya and Cindy are brainstorming how to construct the tray with the materials on hand. The first transcript begins as they are discussing the appropriate height for the tray once mounted on top of the rumba, which served as the base of the robot.

T: Okay. And so you were talking about the height of your stands and what you, you had said that- oh, well maybe you'll do it a certain way.
C: Yeah, in the middle of the three beds.
T: Okay. So what would that measurement be here? How would you figure out that measurement?
C: That would, wait…it would be all the beds to get all of it? No, it'd be the biggest height and then split that in half. So 32 in half is…
T: Are you trying to find the average?
C: Yeah.
T: So if you are going to take an average, you would take the three numbers. You would add them together and then you would divide them by three, if you're trying to get the average. Is that what you want? Or are you trying to do it one particular height to get to the person that…it's kind of your choice here.
C: No. I want it to be the average. So then it could get to anything. And it would either be a little too tall or a little too short. They [people in bed] would have to reach down a little bit or reach up, or like sit up.
T: Okay. So you think we should do the measurement or do you want to figure out the actual height?
C: I want to figure out the average.

The transcript highlights several things. One, Tonya provided Cindy with an opportunity to decide whether the average of the height of the three beds or the height of one bed was preferred (e.g., "It's kind of your choice here."). While Tonya more than likely knew the most appropriate approach within this context, she allowed Cindy to make her own decision (i.e., agency; Norén, 2015). Further, Cindy revealed her reasoning of why the average was appropriate in that the person in bed would have to reach down or up to gain access to food on the tray. Two, Tonya provided Cindy with the definition and language to describe the approach, which Cindy adopted as part of her language throughout the transcript (e.g., last line). Three, this example illustrates how Tonya was "with" Cindy in these moments as she gathered evidence of Cindy's thinking and made in-the-moment and intentional decisions regarding the project and Cindy's process and progress. This was often done through questioning.

In the next transcript, Tonya encouraged Cindy to find an alternative to converting inches to centimeters, which would be needed for her code.

C: *(Speaking into a tablet.)* Centimeters to inches.
T: *(Reaches across the table to grab a tape measure.)* Instead of using that, there's a way that you can figure it out using this. What do you think it is?
C: *(Grabs tape measure and pulls the tape from the housing. Smiles.)*
T: Yeah, you don't always need that. You can figure it out without just trying to get the quick answer.
C: Eight and a half. *(Let's go of the end of the tape and it retracts.)* I mean, no. *(Pulls the tape out again and seems to examine.)*
T: Yeah, that doesn't… Does that make sense to you? [Asking - How can 27 inches equal 8 centimeters?]
C: It said eight. *(Continues looking at the tape.)* Oh no, I get it. I get it. Sixty…sixty…sixty-eight and a half.
T: *(Takes the tape measure.)* These are decimals, so it actually would be 68 and six-tenths. When you're doing measurements, sometimes that tenth of a centimeter is going to make a big difference.

This mathematical moment was sparked through Tonya's question that pushed Cindy to think of another conversion strategy, namely, reading the tape measure. We also observed Tonya questioning the reasonableness of Cindy's first response of eight, indicating that 27 inches was the same as 8 centimeters. This question, as noted in the previous example, was intentional; it served a purpose as Cindy was encouraged to reflect upon her response (NCTM, 2014). Lastly, Tonya explained to Cindy the importance of accuracy and precision appropriate to this particular context (i.e., Mathematical Practice 6; CCSO, 2010).

Significance

The two examples presented here illustrated how one caregiver initiated and engaged their child in mathematical ideas and concepts that spontaneously arose within and throughout a self-identified engineering design problem. Tonya guided, supported, and challenged Cindy through a shared endeavor, designing a remote-controlled delivery robot (Rogoff, 1993). These spontaneous mathematical moments afforded authentic sense making between caregiver and child, which may be harder to attain in structured learning environments and other out-of-school contexts such as STEM-focused afterschool programs and summer camps (e.g., Vedder-Weis, 2017). For example, Cindy gained a different perspective and strategy of how to convert centimeters to inches; a strategy that was authentic and spontaneous to the design of the tray in this instance. Such mathematical moments were often initiated through questions for Cindy to explore within the design of the robot. These questions were not always answered orally, but addressed through physically engaging in mathematical ideas and concepts. Tonya further provided Cindy with a sense of agency in that Cindy was allowed to make mathematical decisions regarding the project. As such, we contend that this case highlighted how children can engage in mathematics in out-of-school learning contexts through the support and encouragement of caregivers. As a field, we should continue to think about ways to engage caregivers as mathematical partners, both within mathematics and STEM fields more broadly (e.g., engineering projects). As mathematical partners, researchers and educators should consider what is required for caregivers to actively and productively engage their children in spontaneous mathematical moments. Archer and colleagues (2015) made a similar argument in respects to science capital or the "level of scientific literacy and access to plentiful, high quality science-related cultural and social resources" (p. 15).

The purpose of this investigation was to examine connections between noticing and bias with a particular focus on how perceptions of race and gender may influence such noticing. Our primary research question was: How and to what extent does bias emerge within preservice teachers' professional noticing of children's mathematical thinking of differing races and genders? Results from this study indicate that bias most frequently occurs within the interpreting component of professional noticing, and that manipulating visual stimuli, such as adding a photo to a professional noticing vignette, influences manifestations of bias across race and gender.

Keywords: Teacher Education-Preservice, Equity and Diversity.

Equity concerns in mathematics have been of interest to researchers for a considerable period of time (Breshlich, 1941, DiME, 2007; NCTM, 2014). More recently, though, there has been renewal of interest regarding the support and flourishing of students from diverse backgrounds within mathematical contexts (Aguirre et al., 2017; Gutierrez & Dixon-Roman, 2011), and such differences in experiences are especially evident in STEM disciplines where students from non-dominant groups have received implicit and explicit messaging regarding their inclusion (or lack thereof) within such disciplinary settings (Goffney, Gutierrez, & Boston, 2018; Museus, Palmer, Davis, & Maramba, 2011). In some instances, inequities arise due to reduced expectations or lack of cultural considerations (Savage, Hindle, Meyer, Hynds, Penetito, & Sleeter, 2011; Zavala, 2014). We aimed to investigate *how and to what extent does bias emerge within pre-service teachers' professional noticing of children's mathematical thinking with respect to differing perceived races and genders?*

Conceptual Framework

Professional Noticing

Professional noticing (of children's mathematical thinking) (PN) has been of interest to mathematics educators for some time (Schack, Fisher, & Wilhelm, 2017; Sherin, Jacobs, & Philipp, 2011). The professional noticing framework incorporates three interrelated components, attending, interpreting and deciding (Jacobs, Lamb, & Phillip, 2010). Although the relationship and temporal ordering among these components is still being explored (Castro-Superfine, Fisher, Bragelman, & Amador, 2017), there appears to be some stability within the literature regarding the general nature of these components (Thomas, 2017). Specifically, *Attending* refers to the attention given to observable aspects of a mathematical context, *Interpreting* refers to the internal mediating and sense-making of that which is attended and *Deciding* refers to an intended response which is informed by some interpretation of a mathematical context.

Equity and Professional Noticing

There is emerging interest in connecting and studying aspects of equity in conjunction with PN (Jong, 2017). PN, as a practice situated within classroom contexts, is inherently braided with equity constructs and frameworks, and study thereof is appropriate and necessary. Jackson, Taylor, and

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Buchheister (2018) synthesized professional noticing with four dimensions of equity (i.e., access, achievement, identity, power) put forth by Gutierrez (2009; 2013) resulting in a framework for intersections between noticing and equity. Louie (2018), investigating relationships between equity concerns and noticing, makes a case that strict cognitive orientations of professional noticing (Schack et al., 2013) may overlook significant cultural dimensions of a mathematical moment. For example, PN may be focused upon equitable concerns such as power distribution and student positioning (Louie, 2018). Such practices are consistent with asset-oriented perspectives where students' backgrounds and their contributions are valued. Further, in the area of asset/deficit perspectives, Harper (2010) presents an anti-deficit framework of research on students of color in STEM by shifting questions to focus on assets. While subtle, the reframing of questions to be anti-deficit can empower how students of color are studied. These findings suggest that biases influence, to some extent, the manner in which teachers enact PN in the mathematics classroom. Thus, investigations of the nature and thresholds of such biases are necessary.

Methods

Measures

To examine emergence of bias (i.e., asset/deficit perspectives), an electronic survey was constructed. The primary element of this survey was an adaptation of a video-based professional noticing measure used by Schack et al. (2013) in their study of preservice teachers' professional noticing capabilities. Rather than using a video clip of a teacher asking a student to solve a story problem as the anchor for professional noticing enactment, we substituted a transcription of the video. Similar to Schack et al., preservice teachers (PSTs) were asked to respond to three prompts, except in this study, the picture was also visible – each aligned with a particular component skill of professional noticing: 1) "Please describe in detail what [Student Name] did in response to the problem" (*attending*), 2) "Please explain what you learned about [Student Name]'s understanding of mathematics" (*interpreting*), and 3) "Pretend that you are [Student Name]'s teacher. What problems or questions might you pose next? Provide a rationale for your answer" (*deciding*). Further, PSTs were prompted to provide some basic demographic data (i.e., gender, ethnicity, age, home state) as well as their familiarity with professional noticing. The transcript case names were *Margaret* (perceived white female), *William* (perceived white male), *Shaquan* (perceived African American male), and *Miguel* (perceived Latino male) (see Figure 1). We limited ourselves to these four cases as we wanted to maximize opportunities to examine differences across gender (i.e., male/female – William/Margaret) and race (i.e., African American/Latino/white – Shaquan/Miguel/William). While more cases would have allowed for additional comparisons (e.g., Latino Female/Latino Male), they would also have necessitated a much larger data set to ensure that each case had an adequate number of survey respondents. Note, a prior study was scored using the same asset/deficit scale, *without a picture* of a child that matches the perceived ethnicity and gender of the name, showed that bias tends to manifest significantly in only the interpreting stage of professional noticing (Thomas et al., 2019).

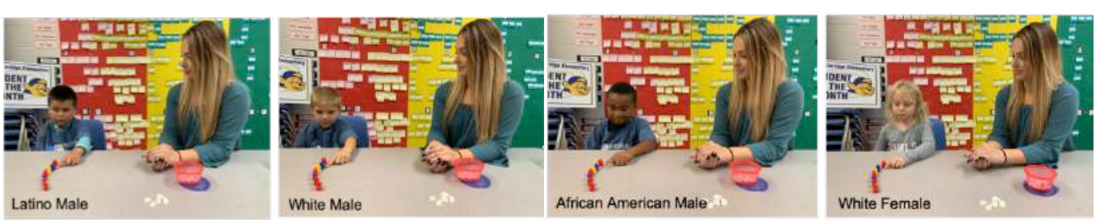

Figure 1: Case visuals

Participants

The electronic survey was fielded in teacher education programs across 18 states. Target respondents were PSTs who were in various stages of their respective teacher education programs. 315 PSTs initiated the survey, and incomplete surveys were discarded resulting in 170 completed responses with distribution across cases as follows: Margaret (n=44), Miguel (n=39), Shaquan (n=45), William (n=42). We used an electronic apportioning tool to ensure an approximately equivalent distribution of cases across respondents. Among the 170 participants, as one might expect of a preservice teacher sample, the largest gender and racial demographic was 18-24-year-old white females (59% of respondents)

Analysis

The asset/deficit perspective of the participant responses to the three questions were evaluated using a flow-process tool (AMSE, 1947) to determine the presence or absence of asset-oriented or deficit-oriented language describing the child's mathematical strategy. Each response was ascribed one of four different codes – asset, deficit, both [asset and deficit], and neutral. A previous study measuring equity in professional noticing, scored using the same asset/deficit scale, without a picture of a child (Thomas et al., 2019). Note, neutral responses contained no asset/deficit-oriented descriptions of the child's thinking/activity. Two raters used the flow process tool to calibrate with sample data, from a previous data set, until an 80% interrater reliability was achieved. The data from the current study were then blinded and combined into one list and scored independently by the two raters. Per previous studies of PN, rating differenes were resolved via discussion (Jacobs et al., 2010; Krupa, Huey, Lessieg, Casey, & Monson, 2017).

Findings

Adding the feature of a picture of a child produced similar results. The percentage of responses across perspectives with and without picture can be found in Table 1.

Table 1. Percentage of Responses Across Perspectives

		% With Picture	% Without Picture
Attending	Asset	19	6
	Deficit	4	5
	Neutral	75	87
	Both	2	2
Interpreting	Asset	38	31
	Deficit	13	27
	Neutral	24	12
	Both	25	30
Deciding	Asset	2	1
	Deficit	2	3
	Neutral	96	95
	Both	0	1

Delving more deeply into these data, we conducted chi-square tests to determine whether there are any relationships between case, survey type (picture, no picture), and bias categorizations (asset, deficit, neutral, both) (see Tables 3 and 4). Specifically, for each of the four cases, chi-square tests of independence were performed to test whether the different survey types were associated with a different distribution of attending, interpreting, or deciding bias categories. Furthermore, for each of the two survey types, chi-square tests of independence were performed for each noticing facet (attending, interpreting, deciding) to test whether each case was associated with bias categorization.

Table 2. Chi-square independence for each survey type between case and noticing component

Survey Type	Case vs. Attending	Case vs. Interpreting	Case vs. Deciding
No Picture	13.508 (9)	8.061 (9)	7.628 (9)
Picture	7.890 (9)	20.575 (9)*	5.719 (6)

Note. * $p < .05$, ** $p < .01$. Results are reported as χ^2 (df).

Table 3. Chi-square independence for each case between survey type and noticing component

Case	Survey Type vs. Attending	Survey Type vs. Interpreting	Survey Type vs. Deciding
Margaret	7.168 (2)*	9.025 (3)*	3.606 (3)
Miguel	0.935 (3)	4.826 (3)	0.781 (2)
Shaquan	2.430 (3)	1.204 (3)	1.506 (3)
William	7.294 (3)	14.629 (3)**	N/A

Note. * $p < .05$, ** $p < .01$. Results are reported as χ^2 (df).

A test of independence could not be calculated for the William case in the deciding component because all responses for this condition were categorized as "neutral". From these results, for picture survey, we see a significant association between case (Margaret, William, Shaquan, Miguel) and bias categorization within the professional noticing component of interpreting. Further, the Margaret case showed significant association between survey type and the attending bias categorization, and both the Margaret and William cases showed significant association between survey type and the interpreting bias categorization.

Discussion

The mere changing of names (e.g., Shaquan, William, Margaret, Miguel) does not appear to provoke the directly negative biases observed in other studies (Bertrand & Mullainathan, 2004; Hanson, Hawley, Martin, & Liu, 2016). Looking toward the relationship between bias and action, Rudman (2004) describes the relationship between individuals' implicit and explicit biases as connected but somewhat distant. As one's explicit biases exist consciously downstream of one's implicit biases, they are inherently more malleable by the individual. With respect to teacher noticing, implicit biases may (and likely do) influence teacher decision-making (i.e., deciding) and the situating of such biases appears to be within the interpreting component.

s.ringl@uky.edu

This study examined the spatial-scientific understandings of students from Kentucky (6th graders) and Nevada (8th graders). Quantitative data consisted of students completing a content survey as well as two spatial assessments at the conclusion of Earth-space instruction. Qualitative data involved student interviews concerning 2D Earth/Moon/Sun modeling. Findings showed Kentucky and Nevada students shared similar misconceptions regarding geometric motions, configurations, and spatial awareness to explain the physical phenomenon of lunar phases. Post data revealed significant differences in favor of Kentucky on lunar phases understanding related to the spatial domain of spatial projection (ability to visualize the Moon from multiple Earthly locations). Significant differences were also found in favor of Kentucky on the Geometric Spatial Assessment. No significant differences were found between students on mental rotation ability.

Keywords: Geometrical Spatial Thinking, STEM

Objectives

This research with middle level students from Kentucky (N=238) and Nevada (N=138) explored how well students from two geographically different locations understood lunar-related spatial-scientific content. The Next Generation Science Standards (NGSS Lead States, 2013) and Common Core State Standards-Math (National Governors Association, 2010) iterate the importance of student understandings related to spatial-scientific learning (i.e. scale, patterns, and geometric modeling). Previous research (Plummer et al., 2014, Black 2005) has linked increased spatial ability with an increased understanding of lunar phases. This study examined students' geometric spatial ability and how students developed and contextually applied this ability to their understandings concerning the phenomenon of lunar phases. The research question was: What geometric spatial factors might hinder or facilitate moon phase understanding? Factors could include students' understanding of scale of the Earth/Moon/Sun system, students' geographic perspective as they observe the moon, students' ability to recognize patterns, and students' aptitude to visualize in both 2D and 3D spaces.

Perspective: Spatial Reasoning and Scientific Performance

Students with high spatial reasoning tend to perform better on science assessments than students with low spatial ability; this has been found true on science assessments concerning chemistry, geoscience, physics, astronomy, calculus, and anatomy (Cole, Cohen, Wilhelm, & Lindell, 2018; Wilhelm, Toland, & Cole, 2017; Sorby, Casey, Veurink, & Dulaney, 2013). Wilhelm, Cole, Cohen, and Lindell (2018) argued that when spatial reasoning ability is advanced via an intervention or spatial experiences within a particular discipline, this spatial development should lead to improved understanding in other scientific disciplines. For example, in the Sorby et al. (2013) study, freshmen engineering students were separated into two groups (an intervention group and a comparison group) based on results of a mental rotation (MR) test. Students who scored low on the MR test were assigned to a spatial intervention course and those who scored above a passing cutoff grade were

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

assigned to a comparison group. Sorby et al.'s findings showed the treatment group's scores increased after the intervention as shown on a post MR test, and even more interesting, treatment students displayed ***transfer*** effects as displayed in increased calculus performance.

Other studies have shown correlations between spatial reasoning and science performance as well as gender differences on spatial reasoning assessments. Guillot et al. (2006) researched the relationship between visuo-spatial representation, MR, and functional anatomy examination results. Guillot et al. (2006) measured visuo-spatial skills using the Group Embedded Figures Test (GEFT; Demick, 2014) which contains 18 complex figures. The test taker must identify a simple form by tracing the simple form within the complex form. MR was measured using the PSVT-Rot (Bodner & Guay, 1997). Guillot et al. found that males scored better than women in GEFT and the MR test; however, this "gender effect was limited to the interaction with MRT ability in the anatomy learning process. The correlations found between visual spatial and MR abilities and anatomy examination results underscore the advantage of students with high spatial abilities" (p. 504).

Spatial Thinking in an Astronomical Context

People interact with many aspects of astronomy on a daily basis, often without noticing them. They develop their own ways of knowing and explaining astronomical phenomena from their conscious and unconscious daily glances at the Moon and sky. In reality, these ideas are more complex than most people realize. In order to understand many aspects of astronomy, developed spatial thinking ability is required. The necessary spatial thinking skills vary by astronomy topic, but studies show that spatial reasoning ability contribute to understanding of astronomy (Wilhelm, et al., 2018). Spatial reasoning ability, as stated earlier, has been linked to performance in both mathematics and science (Black, 2005; Lord & Rupert, 1995; Wilhelm, 2009; Wilhelm, Jackson, Sullivan, & R. Wilhelm, 2013). In terms of lunar phases, spatial thinking ability in the domain of mental rotation is particularly important (Wilhelm et al., 2018). Historically, males have shown an advantage in spatial thinking, particularly in the area of mental rotation. "Countering this view is substantial evidence that environmental influences, in the form of experience in spatial activities from an early age and explicit training can eliminate sex differences on spatial tasks" (Linn & Petersen, 1985; Casey et al., 1999). Thus, it is important that spatially rich curricular experiences be examined to better understand how we can foster the development of factors that encourage students' geometric spatial understanding of scientific phenomena such as lunar phases.

Methods

Study Design

In order to determine what geometric spatial factors hinder or facilitate middle level students' lunar phases understanding, we utilized a mixed methods design. Students were purposefully selected from two different geographic locations so that we might be able to determine if sky viewing in a mountainous terrain would affect students' ability to accurately note Moon motion, Moon rise/set times, and visualization of relative positions of the Earth, Moon, and Sun as compared to Kentucky students in comparatively flat terrain. Quantitative data included the Lunar Phases Concept Inventory (LPCI; Lindell & Olsen, 2002), the Geometric Spatial Assessment (GSA; Wilhelm et al., 2007), and the Purdue Spatial Visualization Test-Rotations (PSVT-R; Bodner & Guay, 1997). The LPCI is a 20 question multiple choice test that assessed eight science domains as well as four spatial domains. The PSVT-Rot was a 20-item multiple choice survey that assessed the level of mental rotation reasoning. The GSA was a 16-item multiple choice test that assessed the same spatial domains addressed by the LPCI, but outside of a lunar context. The qualitative data included semi-structured interviews, where four students were chosen by each teacher for the interviews. Teachers were asked to select the girl and boy with the highest and lowest spatial ability in their classes.

Participants

Participants were from two states, Kentucky and Nevada. Subjects were drawn from one public school in Kentucky with three 6th-grade teachers and their students (N=238). The teaching experience of the Kentucky teachers ranged from 6 to 16 years. The Kentucky teachers' Earth-space curricular unit is outlined in Table 1. Three 8th-grade teachers in a public school in Nevada participated along with their students (N=138). Their teaching experience ranged from 3 to 14 years. Nevada teachers taught their Earth-space curricular unit as shown in Table 1. Grade years were chosen based on the grade lunar phases content was required to be taught in each state (6th grade for Kentucky and 8th grade for Nevada). Both Kentucky and Nevada teachers implemented their units in approximately 5 weeks and both curricula asked students to keep a Moon journal. The main difference in the two curricula was Nevada's emphasis on eclipses which was embedded within lessons on phases and scaling. Kentucky lessons incorporated ***Stellarium*** (software) to examine views and motions from both Northern and Southern hemispheres.

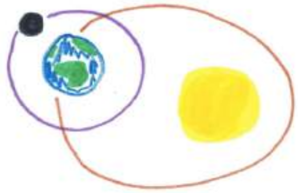
	Kentucky Curricular Unit	Nevada Curricular Unit
Lesson 1	***Can I see the Moon every night and why does it appear to change shape? -*** *Moon Journals* - Students keep daily Moon observation journals for 5 weeks.	***Ancient Civilization and the Moon***
Lesson 2	***How do I measure the distance between objects in the sky?***	***What's Up with the Moon? –*** Students record Moon observations for a month
Stellarium	Students observe the apparent motion of the Moon over the course of a day and compare this motion for locations in the Northern and Southern hemispheres.	
Lesson 3	***How can I say where I am on the Earth?***	***Earth's Moon Vocabulary***
Lesson 4	***How can I locate things in the sky?***	***Determining Hours of Daylight***
Lesson 5	***Why do we have Seasons?***	***Origin of the Moon***
Lesson 6	***What can we learn by examining the Moon's surface?***	***The Sun-Earth-Moon system and Eclipses***
Lesson 7	***What affects a crater's size?***	***Eclipses***
Lesson 8	***The scaling Earth/Moon/Mars NASA Activity***	***Scaling the Sun-Earth-Moon system and Solar and Lunar Eclipses***
Lesson 9	***Moon Finale*** - **Lunar Phases Modeling**	

Table 1: Kentucky and Nevada Curricular Units

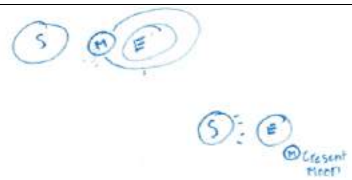
Results

Although both Kentucky (KY) and Nevada (NV) teachers asked their students to keep Moon journals for at least 4 weeks, a large portion of students in both locations failed to do so. As noted in Table 1, Nevada teachers placed a heavier emphasis on eclipses and taught this concept within lessons on phases and scaling. Qualitative interviews with high and low spatial ability NV and KY students showed similar ideas regarding geometric positioning of the Earth, Moon, and Sun for various lunar phases as well as how the Moon orbits the Earth. Table 2 illustrates representative samples of NV and KY high and low spatial ability students' geometric orientations and motions of the Earth/Moon/Sun system. Table 2 shows a High Nevada student modeling correctly the Moon's orbit around the Earth and the Earth's orbit around the Sun, and a High Kentucky student illustrating correctly the Earth/Moon/Sun geometry for New Moon and Waxing Crescent phase (although, neither representation is to scale). A Low Nevada student shows an incorrect understanding of the geometric configuration of a Waxing Crescent phase by demonstrating either an Earth blocking notion or an Earth's shadow misconception, and a Low Kentucky student revealed similar ideas to the Low Nevada student.

Table 2: Students' Geometric Spatial Orientations for Various Lunar Phases

High Nevada	High Kentucky
	


Low Nevada	Low Kentucky
	



Quantitative KY and NV survey results are shown in Figure 1 for the LPCI and the LPCI spatial domains: Geometric Spatial Visualization (GSV), Periodic Patterns (PP), Cardinal Directions (CD), and Spatial Projection (SP). Other results shown in Figure 1 are the PSVT-Rot test and the Geometric Spatial Assessment (GSA). Kentucky 6th grade students scored significantly higher on the SP domain items of the LPCI test and significantly higher on the GSA test than the 8th grade Nevada students. Test results showed KY and NV students had similar percentages of students holding classic misconceptions regarding cause of lunar phases explanations (object blocking (~10%), Sun's shadow (~25%), and Earth's shadow (~42%)).

	LPCI	GSV (7)	PP (5)	CD (5)	SP (4)*	PSVT	GSA*
KY (N=238)	36.97	46.22	42.77	22.44	49.37	39.68	43.88
NV (N=138)	36.45	41.51	47.1	21.3	41.12	42.71	40.13

Figure 1: NV and KY students post scores on the LPCI by domain, PSVT, and GSA (*p < 0.05)

Discussion and Conclusion

Regardless of geographic region, students held similar misconceptions concerning the causes of the lunar phases (i.e. object blocking, Sun's shadow, and Earth's Shadow); however, KY students scored significantly higher on the SP domain that concerns visualizing how the Moon appears from various Earthly perspectives on same day. KY students also scored significantly higher on the Geometric Spatial Assessment. The GSA is not in a lunar context and assesses all four spatial domains (PP, GSV, CD, and SP). Possible explanations for the differences could be due to the heavy emphasis on eclipses in the NV curriculum which could have confused students since they were also trying to comprehend/visualize cause of lunar phases.

PRESCHOOL-AGED CHILDREN'S EMERGENT DISPOSITIONS WITH RESPECT TO MATHEMATICS

Dr. James E. R. Beyers
The College of New Jersey
Beyers@tcnj.edu

Megan Sytsma
The College of New Jersey
Sytsmam1@tcnj.edu

Beginning to understand children's mathematical dispositions during the preschool years may be beneficial as early childhood experiences can predict student's achievement in subsequent educational settings (Fleer & Raben, 2005). Findings suggest that mathematical dispositions can be related to academic success in mathematics (Beyers, 2011a, 2012; Kusmaryono, Suyitno, Dwijanto, & Dwidayati, 2019; O'Dell, 2017). However, there are relatively few studies examining mathematical dispositions among preschool-aged children. However, it is critical to explore the nature of these dispositions and corresponding behaviors at this stage of development, because these behaviors may be directly related to mathematical gains in subsequent educational settings (Hofer, Farran, & Cummings, 2013). The current study aims to address the question of whether preschool-aged children demonstrate observable mathematical dispositions in a pre-kindergarten school environment.

The authors draw on a conceptual framework which includes three primary areas of mathematical dispositions: cognitive, affective, and conative dispositional functions (Beyers, 2001a). Within those three areas of dispositional functions reside 10 total dispositional functions[1], such as attitudes, beliefs, argumentation (Beyers, 2011b). The authors developed an observation rubric based on construct definitions and examples of dispositional functions in previous work. For example, within the affective dispositional function attitude, a child who has a positive attitude about mathematics may gesture gleefully or offer relevant verbal excitement when engaged in or about to engage in mathematical activity, when he or she had just previously not been excited. Conversely, a student's behavior might shift from excitement to a more apathetic state when a mathematical task or discussion is introduced.

The second author was a teaching assistant in an early childhood center. Math activities were done informally as part of games and more formally as part of instruction. The teaching assistant took copious field notes annotating her observations throughout the day. Any activity directly or indirectly involving mathematical content was highlighted in her field notes. Both authors then reviewed and coded a portion of the field notes together, and then the remainder independently. Evidence could have been of a verbal or non-verbal nature. Evidence was coded to reflect whether evidence of a dispositional function was present, and which dispositional function was observed. The authors achieved interrater reliability over .80.

The data show that some dispositions with respect to mathematics are present among preschool-aged children. There is evidence of dispositional functions from each of the three primary areas of dispositional functioning: cognitive, affective, and conative, but not all 10 dispositional functions within those three areas. Data include examples of the cognitive function argumentation, the affective function attitude, and the conative function persistence. Evidence for other dispositional functions, such as making connections, or beliefs about the nature of mathematics were not observed. It is possible that other functions were not observed because opportunities to engage or demonstrate those dispositional functions did not present themselves or those dispositional functions are not yet emergent. Further examination is warranted.

[1] For a complete discussion of the 10 dispositional functions (e.g., while engaging in mathematical activity, demonstrating a tendency to: make connections, make mathematical arguments, hold certain attitude or beliefs, etc…) please refer to Beyers, 2011b.

A PRELIMINARY MODEL OF INFLUENCES ON ADOLESCENTS' PERCEPTIONS OF USEFULNESS IN SCHOOL MATHEMATICS

Tracy E. Dobie
University of Utah
tracy.dobie@utah.edu

Rachel Francom
University of Utah
rachel.francom@utah.edu

Keywords: Affect, Emotions, Beliefs, & Attitude; Middle School Education

Students commonly question teachers about the *usefulness* of mathematics, and the Common Core State Standards in Mathematics encourages teachers to help students "see mathematics as…useful" (National Governors Association Center for Best Practices, 2010). In fact, perceiving a subject as useful can have numerous positive benefits for students including enhanced interest in a subject and improved course performance (Hulleman et al., 2010; Hulleman & Harackiewicz, 2009). However, adolescents use a range of criteria to evaluate whether something is useful (Dobie, 2019), and little is known about when or why these various criteria are employed. This research explores the question, *What factors influence the decisions adolescents make about what is or is not useful in the context of school mathematics?*

Expectancy-value theory highlights that one's goals and self-schemata influence perceptions of usefulness (Eccles & Wigfield, 2002), yet a black box remains regarding the mechanisms that mediate this relationship. The current research begins to build theory around influences on adolescents' perceptions of usefulness by drawing on data from interviews with 11-14-year-old students in two large cities in the United States. In particular, adolescents responded to card-sorting tasks depicting images of students engaging with varied mathematics content in a range of ways and described whether or not the mathematics seemed useful and why. Those responses were used to identify criteria adolescents used to make judgments about usefulness, and additional questions probed into the factors that influenced the criteria students applied.

Figure 1 illustrates a preliminary model unpacking the relationship between one's goals and self-schemata, and perceptions of usefulness. Emergent influences include whether usefulness was considered at the level of the subject (mathematics), specific topic (e.g., linear equations), or particular task (e.g., worksheet). Additionally, some adolescents attended to the form of engagement (e.g., individual vs. collaborative). Others considered the novelty of what they were learning, the usefulness of a specific practice (e.g., justifying thinking) or strategy (e.g., making graphs to represent data), or how engaging with the mathematics made them feel. These features attended to in turn influenced the specific criteria used to make judgments about usefulness, such as whether the mathematics applies to everyday life or enhances one's understanding of mathematics. Individual cases of students will be shared along with quotes to illustrate each factor in action. Future work will explore how different features influence the criteria applied, as well as the outcomes afforded by different pathways to perceiving mathematics as useful.

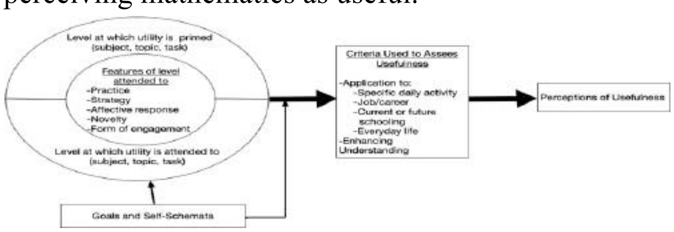

Figure 1: Influences on Adolescents' Perceptions of Usefulness

EXPLORING THE RELATIONSHIP BETWEEN MATH ANXIETY, WORKING MEMORY, AND TEACHER PRACTICES

Luke Duncan
Clemson University
lutherd@clemson.edu

Karen High
Clemson University
khigh@clemson.edu

Keywords: Affect, Emotion, Beliefs, Attitudes, Instructional activities and practices

Betz (1978) proposed that 68% of students in mathematics classes experience high levels of math anxiety. This is most unfortunate as it is a well-established fact that math anxiety is negatively correlated with mathematics performance (Ashcraft & Kirk, 2001; Ashcraft & Moore, 2009; Foley et al., 2017). This does not necessarily imply that math anxiety is an indicator of lower potential to succeed in mathematics. Arnsten (2009) and Diamond et al. (2007) have shown that moderate levels of anxiety can help focus attention and enhance working memory which is known to be a major factor in math competence. It has also been shown that the negative correlation between math anxiety and math performance is stronger for those with high working memory capacity (Foley et al., 2017). Though there has been much research on working memory and situational factors associated with math anxiety, there is not much research which synthesizes the data on working memory with classroom experiences relating to math anxiety. Furthermore, few studies on math anxiety include participants with a broad range of math anxiety levels.

In this study, we sample students in a year-long calculus course. We dig deeper into how students experience math anxiety and how they interpret past classroom experiences. The study utilizes tests for both math anxiety and general anxiety. Interviews are conducted in order to examine past classroom experiences and how these experiences helped to shape the students' belief of math anxiety. We use the interpretation framework developed by Ramirez et al. (2018) to explore the impact of classroom experiences on the development of math anxiety. Under this framework, we hope to discover ways in which the instructor can construct rigorous and engaging classroom activities which would ultimately fashion a favorable impression upon the student.

We also use the disruption account framework proposed by Ashcraft & Kirk (2001) to interpret the role in which working memory affects math anxiety and math performance. The interviews include various working memory tests along with written mathematical procedures. We hope to synthesize the information we gain from these activities with the data we collected for math anxiety and experiences in order to gain deeper insight into how we understand math anxiety.

PROBLEM POSING IN PARTITIVE AND QUOTITIVE DIVISION

Amanda Lake Heath
Middle Tennessee State University
alh2ei@mtmail.mtsu.edu

L. Jeneva Clark
University of Tennessee, Knoxville
dr.jenevaclark@utk.edu

Keywords: Modeling, Problem Solving, Number Concepts and Operations

Problem posing (Brown & Walter, 2005) can improve problem-solving (e.g., English, 1998), expand mathematical creativity (e.g, Voica & Singer, 2012), and provide instructors with valuable insight into student understanding (e.g, Silver, 1994). Problem posing can also give students ownership in learning and provide students with authentic modelling processes (Hanson & Hana, 2015). We aim to investigate problem posing with partitive and quotitive models of division. In quotitive division, the divisor is the number in each group. In partitive, the divisor is the number of groups (Neuman, 1999). Asking students to make the distinction between the two models of division has been shown to help students better understand place value (Bicknell, Young-Loveridge & Simpson, 2017), division with decimals (Okazaki & Koyama, 2005), division with remainder (Lamberg & Wiest, 2012), and the division algorithm (Silver, 1987).

Methods

In a 100-level math course at a private liberal arts university, which incorporated various problem posing tasks, students (n=38) were given the task "For 14÷2=7, write (a) one word problem that demonstrates a partitive model and (b) one that demonstrates a quotitive model." Students were then asked to create children's books that contained both models of division, to be donated to the Girls & Boys Club as a local outreach project. We seek to address: how do students respond when asked to pose problems demonstrating the two models of division?

Results

In the written task, 14 (36.8%) correctly demonstrated both models of division. We observed gaps in understanding and nuanced misconceptions, which inform teacher education. For example, students commonly provided partitive when asked for a quotitive model, provided problems not solved by 14÷2=7, and struggled with the concept that word problems from both partitive and quotitive models can correspond to the same equation.

Table 1: Summary of Student Response Themes

	Incorrect Model	Used Own Numbers	Rearranged Given Equation	Phrased as Statement
Part (a) [Partitive]	4 (10.5%)	5 (13.6%)	1 (2.6%)	15 (39.5%)
Part (b) [Quotitive]	14 (36.8%)	6 (15.8%)	10 (26.3%)	16 (42.5%)

Furthermore, we observed that all (14 of 14) students who drew an image with their response on part (a) provided a correct model. The analysis of the children's book task, which revealed what contexts the students chose, yielded themes of real-world relevance, fairness, and novelty. Future research includes exploring the impact of problem posing on problem solving in division and student perceptions of a course that utilizes problem posing tasks.

MODAL CONTINUITY IN DEAF STUDENTS' SIGNED MATHEMATICAL DISCOURSE

Christina M. Krause
University of California, Berkeley
University of Duisburg-Essen (Germany)
christina.krause@berkeley.edu

Dor Abrahamson
University of California, Berkeley
dor@berkeley.edu

Keywords: Deaf, Design experiments, embodiment and gesture, mathematical discourse

Despite numerous studies pointing to the delay in mathematical achievement of deaf and hard-of-hearing (DHH) students as compared to their hearing peers (e.g., Traxler, 2000; Pagliaro & Kritzer, 2013), only little is known about the peculiarities of mathematical learning processes of DHH learners. At the same time, studies both in psycholinguistics and mathematics education portray sign language (SL) as playing a key role in their individual and social processes of concept formation (e.g., Kurz & Pagliaro, 2020; Krause, 2019).

From both embodied and semiotic perspectives, the iconicity of SL signs may be relevant for mathematical thinking and learning: emerging from action, some signs carry and sustain enactive and/or depictive features of source sensorimotor forms, thus spontaneously schematizing individuals' situated enacted experience. As this, it becomes part of the modal hybrid of gestures and signs in signed discourse and thereby shapes the development of socially negotiated mathematical meaning. At the same time, the gestural expression develops from idiosyncratic gestures towards locally conventionalized signs that refer to the situated mathematical meaning. What is first action then influences a gestural representation of the action in a new mathematical context and eventually a gestural representation for a developing mathematical idea. Signed discourse thus facilitates modal continuity in the gestural modality from individual manual action to expression in social interaction, vice versa feeding into the individual's situated understanding. How modal continuity affects mathematical thinking and learning, we submit, is important for the theory and practice of mathematics education, both for DHH and for hearing learners. More broadly, theorizing modal continuity could illuminate the relationships between embodiment, representations, and language in processes of teaching and learning mathematics.

The poster reports on an ongoing design-based research project in which we develop a mathematical learning opportunity that considers sign language as a resource for learning mathematics. More concretely, we adapt a well-established embodied design—the Mathematical Imagery Trainer for Proportions (Abrahamson & Trninc, 2015)—with an eye on emerging manual movement patterns that foster a common ground for mathematical discourse in a way that is conducive to linguistic accuracy of (American) SL. In a two-step design, students first each develop sensorimotor schemes through solving a dynamic interaction problem, then explore in pairs a related mathematical problem, negotiating mathematical meaning in signed discourse. The poster will expand on the design's rationale and elaborate on the theoretical construct of modal continuity in light of data collected with Deaf and hearing students.

ADOLESCENTS' MATHEMATICS IDENTITIES IN A MATH CIRCLE

Rileigh Luczak
Michigan State University
luczakri@msu.edu

Keywords: Informal education; Affect, emotions, beliefs, and attitudes

Identity can be conceptualized as a function of participation in the various activities of communities of practice (CoPs), which are defined by mutual engagement, a joint enterprise, and a shared repertoire amongst its members (Wenger, 1998). An individual's mathematics identity development, then, is inextricably linked to their participation in the CoPs associated with the contexts in which they learn mathematics (Boaler & Greeno, 2000).

One such context is a Math Circle, a type of out-of-school mathematics program in which adolescents, guided by "mathematically sophisticated leaders, […] work on interesting problems or topics in mathematics […] through problem-solving and interactive exploration" (What is a math circle?, n.d.). The participants' participation in the Math Circle CoP is mediated through their participation in various activities of the CoP, where activity is defined as "a socially recognized and institutionally or culturally supported endeavor that usually involves sequencing or combining actions in certain specified ways" (Gee, 2014, p. 95). Therefore, identifying the Math Circle CoP activities is key to understanding (1) how these adolescents participate in the CoP and (2) how their participation affects the development of their mathematics identities.

I interviewed three City Math Circle (CMC) participants who had completed at least three years in CMC programs by Spring 2020. The interview addressed their current and past participation in CMC programs, what occurs in a typical CMC session, and their relationships with mathematics in different environments. I analyzed the transcripts using Gee's (1991; 2014) narrative structure, identified CMC CoP activities and the adolescents' participation therein using social practice analysis (van Leeuwen, 2008), and analyzed their participation in these activities using Wenger's (1998) modes of belonging.

The adolescents' descriptions of the CMC CoP activities were consistent with each other, and most activities involved both mathematical and social interactional components (i.e. program participants gave each other feedback [social interactional] on their problem solutions [mathematical] as part of the "sharing solutions" activity). Participation in such activities tended to be inversely related to how the adolescents participated in the mathematical and social interactional components of activities in other mathematics learning environments. For example, one adolescent who felt that "school mathematics" did not allow for collaboration with peers described the social interactional components of the CMC CoP activities in more depth than the mathematical components, where another who did not feel challenged by "school mathematics" described the mathematical components of the CMC CoP activities in more depth than the social interactional components.

These findings suggest that the development of these adolescents' mathematics identities due to their participation in City Math Circles programs is complementary to the development of their mathematics identities due to participation in other mathematics learning contexts. That is, through their voluntary participation in City Math Circles, an out-of-school mathematics program, these adolescents are developing their (mathematics) identities with agency they are not typically allowed in more institutionalized mathematics learning environments such as school.

TUTORING LAB ATTENDANCE AND TIME SPENT ON HOMEWORK: IMPACT ON STUDENT PERFORMANCE IN COLLEGE ALGEBRA

Yuliya Melnikova
Indiana University of Pennsylvania
yuliyamelnikova@gmail.com

Valerie Long
Indiana University of Pennsylvania
vlong@iup.edu

Courtlyn Adams
Indiana University of Pennsylvania
courtlynadams@yahoo.com

The aim of this research is to investigate how College Algebra students utilize a peer-staffed tutoring lab during a spring semester. Records of students' ID cards swipes as they enter the lab were analyzed to explore trends in attendance. In addition, the relationship between final course grades and the time spent studying math content using ***A****ssessment and* ***LE****arning* ***K****nowledge* ***S****paces (ALEKS), a web-based, adaptive learning system, was explored. The results found 79% of the students who used the tutoring lab made a D or better, a passing grade, versus 48% of the students who did not visit the lab. Also, for every 100-minute increase in time spent in ALEKS, a student's final course grade increased on average by 1%.*

Keywords: Post-secondary, Instructional activities and practices

While a large number of students take College Algebra each year, only 50% earn a C or higher (Ganter & Haver, 2011). Research shows that peer-tutoring has a positive impact on student performance in College Algebra (Xu, Hartman, Uribe, & Mencke, 2001), and time spent on homework out-of-class has a substantial effect on grades (Keith, Diamond-Hallam, & Fine, 2004). Based on this existing literature, this study aims to investigate 1) student attendance in a peer-staffed tutoring lab, 2) lab attendance's impact on final course grade, and 3) the relationship between time spent studying in ALEKS and final course grade.

During a spring semester, six College Algebra classes were included in the study. The students were expected to spend three hours each week completing homework assignments in ALEKS (with one-hour goals staggered throughout the week). The students could complete the time requirement from anywhere but were encouraged to attend a peer-staffed tutoring lab to work on homework. Lab attendance was incentivized by earning extra credit on the exams if a certain amount of time was met before each exam. Overall, students were encouraged to increase the time spent on studying math content in the lab and stagger that time throughout the week.

Lab attendance was collected through swipe-card access using students' university ID cards when students entered the lab. Total time spent working in ALEKS and final course grades were also collected for each student. The statistical software R was used for linear regression to model the relationship between final course grade and time spent working in ALEKS.

Among the 166 research participants, 57% attended the tutoring lab at some point during the semester. Half of the students who attended the lab came only once or twice during the semester with very few students coming on a weekly basis. During the week of exams, there were small peaks in lab attendance. Five to eight more students came during exam weeks, and there were 10 to 16 more swipes. Of the students who came to the lab, 79% made a D or better, a passing grade for the course. For the students who did not attend the lab, only 48% made a D or better. There was a positive relationship (r = 0.639) between final course grade and time spent studying in ALEKS. The r-squared value was 0.4083, so about 41% of the variance can be explained by the model. For every 100-minute increase in time spent in ALEKS, a student's grade will increase by about 1%. The preliminary results of this study point to the peer-tutoring lab having a positive impact on students' College Algebra course grades.

What impact, if any, do interesting lessons have on the types of questions students ask? To explore this question, we used lesson observations of six teachers from three high schools in the Northeast who were part of a larger study. Lessons come from a range of courses, spanning Algebra through Calculus. After each lesson, students reported interest on a Likert scale via lesson experience surveys (Riling et al., 2019). The average interest measures were then used to identify each teachers' highest and lowest rated interest lessons. The two lessons per teacher allows us to compare across the same set of students per teacher.

We compiled 145 student questions and identified whether questions were asked within a group work setting or part of a whole class discussion. Two coders coded 10% of data to improve the rubric for type of students' questions (what, why, how, and if) and perceived intent (factual, procedural, reasoning, and exploratory). Factual questions asked for definitions or explicit answers. Procedural questions were raised when students looked for algorithms or a solving process. Reasoning questions asked why procedures worked, or if facts were true. Exploratory questions expanded beyond the topic of focus, such as asking about changing the parameters to make sense of a problem. The remaining 90% of data were coded independently to determine interrater reliability (see Landis & Koch, 1977). A Cohen's Kappa statistic ($K=0.87$, $p<0.001$) indicates excellent reliability. Both coders then reconciled codes before continuing with data analysis.

Initial results showed differences between high- and low-interest lessons. Although students raised fewer mathematical questions in high-interest lessons (59) when compared with low-interest lessons (86), high-interest lessons contained more "exploratory" questions (10 versus 6). A chi-square test of independence shows a significant difference, χ^2 (3, N = 145) = 12.99, p = .005 for types of students' questions asked in high- and low-interest lessons. The high-interest lessons had more student questions arise during whole class discussions, whereas low-interest lessons had more student questions during group work. By partitioning each lesson into acts at points where the mathematical content shifted, we were able to examine through how many acts questions remained open. The average number of acts the students' questions remained unanswered for high-interest lessons (2.66) was higher than that of low-interest lessons (1.68). Paired samples t-tests suggest that this difference is significant $t(5)=2.58$, $p = 0.049$.

Therefore, student interest in the lesson did appear to impact the type of questions students ask. One possible reason for the differences in student questions is the nature of the lessons students found interesting, which may allow for student freedom to wonder and chase their mathematical ideas. There may be more overall student questions in low-interest lessons because of confusion, but more research is needed to unpack the reasoning behind student questions.

PROBLEM SOLVING DISPOSITIONS IN RURAL COMMUNITIES

Frederick A. Peck

Even as the mathematics education field has highlighted the importance of community-based resources, most of the attention has focused on local knowledges and practices. There has been comparably less attention paid to community-based dispositions. In ethnographic fieldwork in rural communities, we identified 5 community-based problem solving dispositions.

Keywords: Culturally Relevant Pedagogy, Rural Education

The mathematics education field has shown much interest in community-based, "everyday" practices (e.g., Civil, 2016). Research has documented the rich and varied ways that people understand and participate in the world (Lave, 1988). The field has also been interested in understanding disciplinary dispositions and advancing the notion that developing particular dispositions ought to be one goal of schooling (Gresalfi & Cobb, 2006). We bring these lines of inquiry together by sharing 5 community-based problem solving dispositions we found via ethnographic fieldwork in rural communities in the Rocky Mountain West.

Findings

We documented 5 CPSDs which were durable across data sources and communities: (1) *Self-reliance*: Community members were inclined to "do it themselves" or learn how to do it themselves. (2) *Resourcefulness*: Even as community members were disposed towards self-reliance, they were also inclined to seek out and use material and social resources to help them solve problems. (3) *Care/Helpfulness*: We found that community members were inclined to care for one another and accept care from others when faced with problems. (4) *Try something and iterate*: Community members were inclined to dive right in and "try" something. The notion of trying captures the willingness to attempt a particular approach, without full confidence that it will work. (5) *Practical wisdom*: Community member were inclined to use knowledge developed through experience, or which circulated and was taken for granted in the community.

Implications

We agree with scholars who argue that schools should not seek to replace community-based resources but rather should seek to *build with* and *strengthen* them. Our work has implications for this effort. For example, many classrooms are organized to purposefully restrict access to resources, especially during consequential activities such as testing. This seems to work against a community-based disposition of resourcefulness. Our work prompts us to wonder how schools might be reorganized to build with and strengthen this and other community-based dispositions.

Keywords: Algebra, Cognition, Problem Solving, Worked Examples

Worked examples consist of step-by-step derivations of problems, and are often provided to students as a way to learn the procedures for solving problems. An extensive body of literature has shown that worked examples can help students learn mathematics (e.g., Atkinson, Derry, Renkl, & Worham, 2000; Booth, Lange, Koedinger, & Newton, 2013; Sweller, 2006) but how the presentation of worked examples influence student learning remains unclear. For instance, new educational technology tools that demonstrate the dynamic process of solving algebraic equations (e.g., dragging 4 across the equal sign to initiate the inverse operations and divide both sides by 4 in $4x = 6$) may provide the opportunity to explore the potential benefits of dynamic worked examples.

To study how variations in worked example presentations influence learning, we varied the format of worked example presentations of algebraic equations in an online platform. Specifically, we compare the impact of viewing worked examples in animated dynamic presentations, traditional static presentations, and sequential line-by-line presentations. Within these variations, we also compare concise worked examples (e.g., Rittle-Johnson & Star, 2007), which display only the important steps of solving algebra problems, and extended versions, which display all steps in a derivation.

Our research questions are as follows: 1) *Do concise or extended worked examples lead to larger gains from pretest to posttest?* 2) *Do students show differential gains from viewing dynamic, static, or sequential worked examples?* 3) *If dynamic worked examples lead to higher learning gains, which form of dynamic worked examples are best for learning?* Currently twelve middle school teachers with a total of 146 students have completed this study and data collection is ongoing. Students complete a pretest on algebraic equation solving, six worked example-practice problem pairs, and a mirrored posttest in a 45-minute session. Our estimated sample of over 400 affords at least 80% power to detect small to medium effects of worked example length ($f = 0.13$) and presentation ($f = 0.15$).

Data analysis for this study will be conducted once all participants have completed the study in Fall 2020. To explore our research questions, a 2 (pretest vs. posttest) × 2 (concise vs. extended) ANOVA will be conducted to test the effects of work example length, and a 2 (pretest vs. posttest) × 3 (static, sequential vs. dynamic) ANOVA, and a 2 (pretest vs. posttest) × 2 (dynamic concise vs. dynamic extended) ANOVA will be conducted to test the effect of each worked example format on learning gains.

We expect that the results from this study will help the field better understand the best way to present worked examples. Results and implications will be presented at the PME-NA conference.

USING VIDEO ANALYSIS TO IMPROVE PRESERVICE ELEMENTARY TEACHERS' NOTICING SKILLS

Liza Bondurant
Delta State University
lbondurant@deltastate.edu

Appalachian State University
polingll@appstate.edu

Diana Moss
University of Nevada, Reno
dmoss@unr.edu

Prospective elementary mathematics teachers (PTs) were asked to analyze 28 videos of cognitive interviews. The purpose of this study was to determine if experiences analyzing videos would lead to improvements in PTs' professional noticing skills. Using a coding schema that reflected three levels of understanding (periphery, transitional, and accomplished), a frequency table was constructed that allowed PTs' use and understanding of a noticing framework to be analyzed. Findings indicate that experiences analyzing videos leads to improvements in PTs' professional noticing skills.

Keywords: Teacher Education - Preservice, Instructional activities and practices, Mathematical Knowledge for Teaching

Professional noticing, the skill of making complex, in-the-moment decisions regarding children's mathematical thinking has been introduced as a means to improve overall mathematics thinking and instruction (Jacobs, Lamb & Philipp, 2010). The research reported in this paper analyzed prospective elementary mathematics teachers' (PTs) use of the noticing framework, while promoting the exchange and enrichment of mathematics education research across learning environments. The research team consisted of three mathematics teacher educators (MTEs) who work at three different institutions, one in the south, one in the southeast, and one in the western part of the United States. Each MTE's unique experiences and perspectives enhanced the research study.

Theoretical Framework

Despite the fact that many teacher preparation programs require PTs to spend a significant amount of time observing classroom teaching and learning, researchers cannot make specific claims about what they learn as a result of these observations (Brophy 2004). Conducting observations may not benefit PTs, because they may not know what key features to focus on while conducting their observations. MTEs, using video recordings of teaching may provide an opportunity for PTs to develop their noticing skills (Berliner et al. 1988).

According to Barnhart and van Es (2015), without structured support, PTs' analyses of student knowledge typically focus on aspects of the classroom related to management rather than on students' mastery of the content. It is critical that mathematics teacher educators guide PTs in making instructional decisions that align with student understanding (Darling- Hammond & Bransford, 2005; Davis, Petish & Smithey, 2006; Zeichner & Liston, 1996). A body of research has found that PTs can learn to attend to, interpret, and make decisions on the basis of student thinking, skills related to analyzing teaching (Jacobs, Lamb, & Philipp, 2010; Mitchell & Marin, 2014; Santagata, 2011).

MTEs may use video to provide PTs with the knowledge and skills they will need to be effective mathematics teachers. Using videos as a teaching tool saves time, money, and provides PTs the opportunity to learn new skills and to craft their practice without placing real students at risk during the learning process. Star & Strickland (2008) found that viewing videos led to significant increases in PTs' observation skills, particularly in teachers' ability to notice features of the classroom environment, mathematical content of a lesson, and teacher and student communication during a lesson. This study aimed to explore the following question: In the context of a four-week online mathematics course for pre-service elementary teachers, does the experience of analyzing videos of

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

students' discussing their mathematical thinking lead to improvements in PTs' professional noticing skills?

The Instructional Activity

In an attempt to answer the research questions, a MTE at a regional public university located in southeastern United States used videos as an instructional strategy to study PTs' noticing skills. Fifteen female PTs in their second to fourth year of their studies to become elementary school teachers were a part of the study. Eleven of the PTs were White, three were Black, and one was Hispanic. Thirteen of the PTs were 20-25 years old, one was 42 years old, and one was 53 years old. PTs previously took between one and two math pedagogical content courses. PTs previous classroom experience includes 30 hours of focused observations in the areas of diversity, classroom management, and teaching strategies in a Survey of Education with Field Experiences course. They also have completed 10 hours of focused observations in diverse classroom settings related to classroom management along with small group teaching assignments in a Classroom Management course.

PTs were enrolled in an online course, Math Through Problem Solving. The study took place during Summer Session II. Therefore, the content of the course, which is typically taught over the course of a 15-week semester, was compressed into four weeks. The course focused on the following units: Number Theory, Fractions, Decimals, and Integers. One week was spent on each unit. In each unit, the first assignment was for the PTs to read the sections in the unit. The information from the book was also summarized in power points on a Supplemental Resources Page. PTs were required to take a Readiness Assurance Test (RAT) focused on the reading. Subsequently, PTs completed the unit homework assignments. Then, PTs took the unit test, there was a practice test to help them prepare for the test. Throughout the week PTs were asked to work on their cognitive interview video analysis assignment worth 10% of PTs' final grade. This sequence of assignments was repeated by PTs in each of the four units. Before the end of the course PTs were required to "pass", 80% or better, a Rational Numbers proficiency test that they have up to three attempts to pass. At the end of Unit 4, the PTs took a final exam.

The MTE developed the Cognitive Interview Video Analysis assignment to capture PTs' professional noticing skills. Over the course of the class the PTs were asked to watch and analyze 28 videos of cognitive interviews. The videos were focused on Number Theory (five videos), Fractions (eleven videos), Decimals (six videos), and Integers (five videos). The research team decided to focus their study on PTs' analysis of three videos, all focused on the concept of ordering, but completed across the span of the course. More specifically, the first video was focused on ordering fractions, the second video on ordering decimals, and the third video on ordering integers.

Before engaging in professional noticing, the PTs read the article A New Lens on Teaching: Learning to Notice (Sherin & van Es, 2003). In this article, the authors provide examples of how in-service teachers reflect on their teaching through noticing. Reading this article helps the PTs realize that noticing will help them make in-the-moment decisions and that there are a variety of ways to use noticing in their future classrooms.

The prompts that the interviewer asked the children in these three videos can be found in Figure 1. For each video, the assignment directions were:

> Post one (1) initial post where you answer each question below. Grading is based on effort (thoughtful and thoroughly explained answers) not accuracy. You are encouraged to read your peers' posts (you must make your initial post before being able to read others' posts) and post replies based on your reactions. Embedded in the book you will find the following video (there is a movie icon in the reading). Watch the video and then respond to each of the following prompts.

Attending:

- What did the student do?
- What strategies did the student use?
- Interpreting:
- What does this mean about the student's understandings or misconceptions of the mathematics?
- Deciding:
- Based on what you attended to and interpreted, what are the best steps to take next with this student?
- What questions would you ask this student?

The MTE structured the assignment as a discussion for three main reasons. For one, since the course was an online class, there are no opportunities to discuss the videos face to face. Secondly, the instructor wanted to be able to provide PTs with feedback about the expectations of the assignment as well as feedback and guidance for meeting those expectations. Finally, the MTE believed that PTs could benefit from seeing each others' responses and the MTE's feedback on their responses.

$\frac{1}{6}$ $\frac{1}{3}$ $\frac{1}{7}$ $\frac{2}{7}$ 1 $\frac{4}{3}$ $\frac{3}{10}$ $\frac{1}{2}$ $\frac{3}{6}$ $\frac{1}{2}$ 1.973 19.73 0.567 0.3 0.87 0.276 0.7 0.70 0.087 0.87 Fraction and Decimal Video Prompt: "For each pair, circle the larger of the two numbers. If they are equal, write =."

Figure 1: Image of the Tasks Presented to Students

Methodology

This paper reports on the integrated findings of an exploratory sequential mixed methods research design (Figure 2). In sequential exploratory design, qualitative data is first collected and analyzed, and themes are used to drive the development of a quantitative instrument to further explore the research problem (Creswell & Plano Clark, 2011). As a result of this design, three stages of analyses were conducted: after the initial qualitative phase, after the secondary quantitative phase, and at the integration phase that connects the two strands of data and extends the initial qualitative exploratory findings (Creswell & Plano Clark, 2011). In this paper the authors share the results of final integration phase of the research.

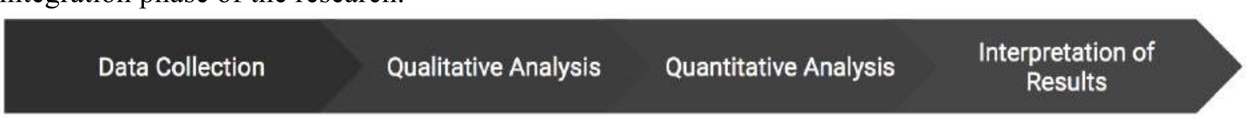

Figure 2: Exploratory Sequential Design (Creswell & Plano Clark, 2011)

The first goal of the coding process was to establish a standard exemplar response to the assignment for each video. To accomplish this goal, we, the team of three MTEs, each completed the Cognitive Interview Analysis assignment individually. Next, we met to discuss any discrepancies in the exemplar responses. We resolved any differences that existed and merged responses to create a standard exemplar response for each video. This task provided us with a standard exemplar to reference during coding. It also provided us with a thorough understanding of the content of the videos.

Next, we decided to use the coding scheme developed by Author (2019). The coding scheme is described in Figure 3. To analyze PSTs' responses, we used open coding (Corbin & Strauss, 2014) to determine the noticing level for each attending, interpreting, and deciding prompt in the Cognitive Interview Analysis assignment.

Noticing Level	Description
Periphery	Made general impressions (e.g. "Student understands the questions.")
Transitional	Highlighted noteworthy events, general impressions, but included why they believed something occurred (e.g. "The student used logic to reason through the problem."
Accomplished	Used evidence to elaborate on student understanding, made connections between the work and the next steps.

Figure 3: Coding Scheme for Professional Noticing

Prior to coding, all PTs names were removed and the responses were randomized in the spreadsheet to avoid any potential coding biases. The research team calibrated coding by discussing our inferences and interpretations of one PT's responses to each of the five items. Subsequently, each MTE independently double-coded all PTs' responses for two of the three videos, in a blinded format, to ensure the data from each video was analyzed by two MTEs. The percent agreement for the two raters across all items was 75%, suggesting substantial inter-rater agreement. Having computed a satisfactory percent agreement, we reconciled our coding through discussion of the data and the professional noticing framework coding scheme (Figure 3).

Findings

Through the lens of the noticing framework (Attending, Interpreting, and Deciding), the results of the study show patterns of growth related to the noticing levels of periphery, transitional, and accomplished. Once PTs' responses were coded using the scheme (Figure 3), the results of the noticing levels were analyzed for each of the three noticing assignments in the given semester (Comparing Fractions, Comparing Decimal Numbers, and Ordering Integers). The bar graph in Figure 4 shows the overall frequency of each response coded as periphery, transitional, and accomplished within each noticing assignment.

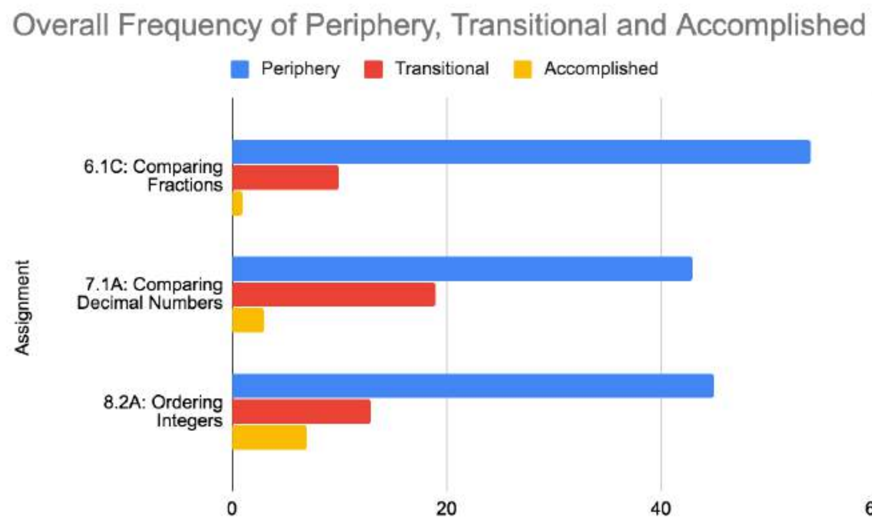

Figure 4: Overall Frequency of Periphery, Transitional, and Accomplished on each Assignment

Table 1 provides overall percentages of responses coded as periphery, transitional, and accomplished within each noticing assignment.

Table 1: Overall Percentages of Periphery, Transitional, and Accomplished

Assignment	Periphery	Transitional	Accomplished
6.1C: Comparing Fractions	0.83	0.15	0.015
7.1A: Comparing Decimal	0.66	0.29	0.046
8.2A: Ordering Integers	0.69	0.2	0.107

The percentage of responses coded as "periphery" decreased from 83% to 69%, whereas "transitional" increased from 15% to 20% "accomplished" increased from 1.5% to 10.7%, indicating that as the semester progressed, PTs' responses moved toward a transitional and accomplished level of interpreting student thinking. As seen in Figure 4, 54 of the PTs' responses were at a "periphery" level on the first assignment (Comparing Fractions) and only 1 PT response was at the "accomplished level on the first assignment. However, 45 PT responses were at the "periphery" level on the last assignment (Ordering Integers) and 7 PT responses were at the "accomplished" level on the last assignment.

These results indicate that the PTs have little experience with examining student mathematical thinking as seen on videos at the onset of this course. But, with practice, PTs' abilities to professionally notice improved as the course progressed. Based on experience and coursework, this seems to be a natural consequence of interacting with the ideas related to the framework. As shown in Figure 5, there is an overall increase of transitional responses in two of the three categories when considering Activity 7.1A. The attending percentage remained constant between Activity 6.1C and 7.1A. There is a slight decrease in transitional responses related to activity 8.2A but it is still down trending related to the introductory activity.

For example, one PT's response to the deciding piece of the framework changed over time. In the first assignment, the student offered the following suggestion, "And for both students I would ask the same questions the instructor did, and I would ask for more examples and review questions". Then, on a later video, the PT's level of sophistication changed and their response became, "What strategies are you using?", "How did you come up with that strategy?", "How did you figure out the answer?". As you can see, the later response is focused on conceptual understanding and is student-centered.

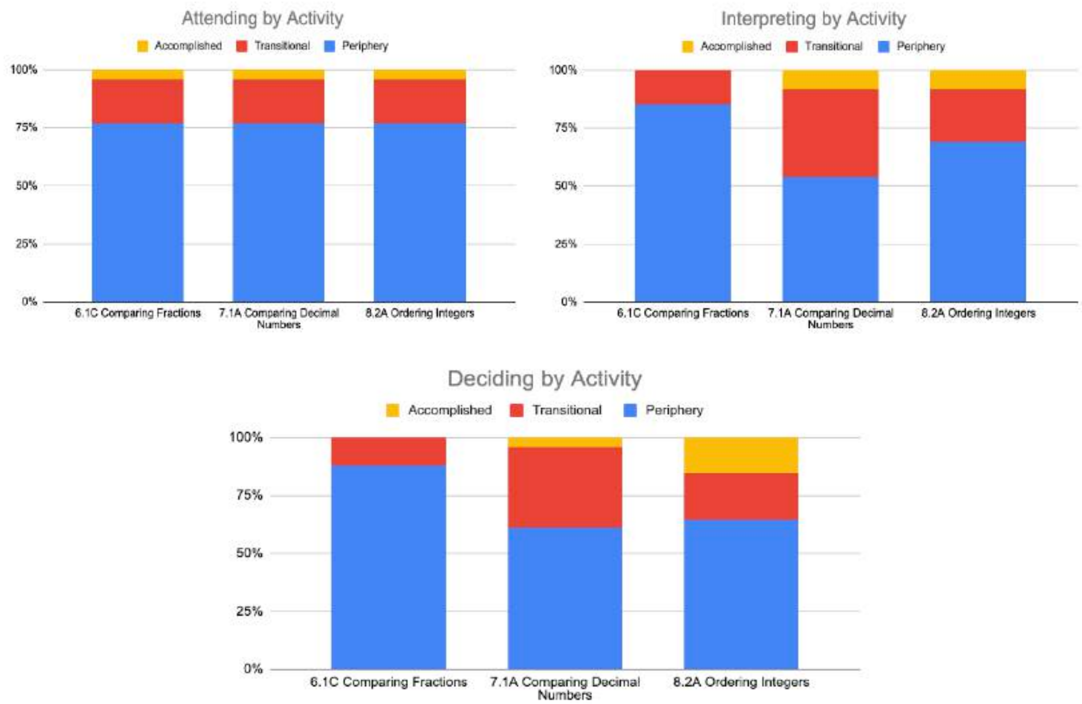

Figure 5. Percent Periphery, Transitional, Accomplished by Video

Three of the fifteen PTs did not complete all three assignments (chapters 6, 7, and 8). Therefore, their data were removed from the participant level analyses, resulting in n = 12. At the participant level, we (the MTEs) counted how many of the questions (out of the five questions) each PT answered at each noticing level for the three (comparing fractions, decimals, and integers) assignments. Next, we calculated the frequency and percent changes in the number of questions each PT answered at each noticing level from the first to the second, second to third, and first to third assignments. Finally, we found the average frequency and percent changes for all PTs.

We found a decrease in PTs' performance at the peripheral level during the course. All twelve PTs answered 49 questions at the peripheral level on the chapter 6 assignment. On the chapter 7 assignment all twelve PTs answered 43 questions at the peripheral level. All twelve PTs answered 40 questions at the transitional level on the chapter 8 assignment. The average number of questions that PTs answered at the peripheral level decreased by a frequency of 0.5, 0.25, and 0.75 from the first to the second assignment, second to the third, and the first to the third assignments, respectively. The average number of questions that PTs answered at the peripheral level decreased by 13.19, 0.69, and 19.44 percent from the first to the second assignment, second to the third, and the first to the third assignments, respectively

We found an increase in PTs' performance at the transitional level from beginning to middle and beginning to end of the course, but a slight decrease at the transitional level from the middle to the end of the course. Nine of the twelve PTs answered ten questions at the transitional level on the chapter 6 assignment. On the second assignment eight PTs answered fifteen questions at the transitional level. Seven PTs answered fourteen questions at the transitional level on the third assignment. The average number of questions that PTs answered at the transitional level changed by a frequency of 0.41, -0.17, and 0.25 from the first to the second assignment, second to the third, and the first to the third assignments, respectively. The average number of questions that PTs answered at the transitional level changed by 22.73, -2.27, and 4.55 percent from the first to the second assignment, second to the third, and the first to the third assignments, respectively.

We found an increase in PTs' performance at the accomplished level during the course. Only one PT answered one question at the accomplished level on the first assignment. On the second assignment two PTs each answered one question at the accomplished level. Five PTs answered six questions at the accomplished level on the third assignment. The average number of questions that PTs answered at the accomplished level increased by a frequency of 0.08, 0.33, and 0.42 from the first to the second assignment, second to the third, and the first to the third assignments, respectively. In most cases, the percent change could not be calculated because zero PTs initially answered at the accomplished level (causing a dividing by zero error in the percent change calculations).

Conclusion and Implications

This study, framed by research on noticing, the Coding Scheme for Professional Noticing (adapted from Van Es, 2011) was used to assess the development of PTs' use and understanding of noticing. Since PTs' noticing skills as they participated in the instructional activity was the focus of the study, the results are promising that the use of video to support PTs' understanding of student thinking may be a viable strategy for supporting growth. Preliminary findings indicate that through a deliberate scaffolding of course activities and projects, MTEs can help PTs develop their noticing skills.

Although many PTs' professional noticing skills improved, some PTs' skills did not show an overall increase, and few PTs reached the accomplished level. More research is needed to determine how to scaffold all PTs' skill development to the accomplished level. Analysis of the instructional activity indicates that prior to this course PTs have had little experience describing students' work, interpreting students' understandings, and then deciding how to proceed. PTs' initial interpretations seemed to rely on their own content understanding related to the task and limited the PTs in their ability to apply appropriate strategies to promote conceptual understanding for students. These results indicate the need for MTEs to spend more time reflecting on and discussing implications for teaching. Engagement in this work allowed us to see the PTs' reasoning so that we, mathematics educators, can improve our practice and our PTs' professional noticing skills.

COUNTERSTORIES OF PRESERVICE ELEMENTARY TEACHERS: STRATEGIES FOR SUCCESSFUL COMPLETION OF THEIR MATH CONTENT SEQUENCE

Master narratives exist in many forms within mathematics education. Preservice elementary teachers often are seen as having high levels of math anxiety while students in developmental mathematics are seen as being deficit in their mathematical understanding. This study uses counterstories to understand the experiences of two women of color, who are enrolled in math content courses for preservice elementary teachers. Students share strategies that they learned from one math content course in order to succeed in their math course sequence.

Keywords: Instructional Activities and Practices; Affect, Emotion, Beliefs, and Attitudes; Equity and Diversity

Master narratives about preservice elementary teachers' (hereon labeled as PSTs) relationship with mathematics often paints a story that PSTs have high levels of math anxiety both during their teacher preparation program and also beyond as in-service teachers (Gresham, 2007). In particular, of all college majors, female elementary PSTs show the highest levels of mathematics anxiety (Beilock et al., 2010). Math anxiety can often be debilitating, leading to feelings of helplessness, tension, or panic, and can affect PSTs' experiences and success in their math content courses. "Mathematics anxiety affects learning and causes individuals to perform at lower levels than their capabilities" (Brown, Westenskow, & Moyer-Packenham, 2012, p. 366). It has been recommended that mathematics teacher educators incorporate strategies in the PSTs' math content classes that can help students alleviate their anxieties and to help PSTs succeed in their future courses and ultimately in their careers (Vinson, 2001). In fact, Johnson & vanderSandt (2011) showed that taking a math content course in the freshman year of college can contribute to reducing math anxiety in PSTs.

Another master narrative that can apply to PSTs is the deficit perspective that often comes with being required to complete developmental math courses. Developmental mathematics courses "target underprepared students with the purpose of improving their abilities to handle college-level material and succeed in college" (Bettinger, Boatman, & Long, 2013, p. 94). Oftentimes these courses focus on what students *do not* know and attempt to remediate topics in arithmetic and algebra. According to Sitomer (2014), a deficit view of students in such courses is problematic because it does not distinguish between different ways of knowing mathematics, seeks to blame instead of finding solutions, and does not acknowledge that the mathematical experiences of students might differ in significant ways from the mathematical experience of those who "define" the content of mathematics courses. Valencia (2015) argues that many remedial programs fail because they are quick fixes based on a deficit view, placing the burden of acquiring the needed knowledge on marginalized students and their families without much support for accomplishing learning. Oftentimes the coursework does not align with future courses that specific majors, like liberal studies majors, will need to take. Gutiérrez (2008) contends that in order to move away from the negative view of student achievement gap, more research should be done to investigate effective teaching and learning environments for marginalized students.

These master narratives are important to dismantle. Larnell (2011) defines *identity infiltration* where students who often continue to hear the master narrative can begin to replace their experience with that of the master narrative. This can be troublesome for PSTs. If a PST believes that math anxiety is a fixed feature of being an elementary teacher or believes that they are deficit in their

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

mathematical knowledge, this can be transferred onto their future students (Vinson, 2001). Therefore, we need to understand strategies that help students to succeed. The research questions that this paper addresses are: 1) What are the counterstories of two PSTs who enrolled in a support course? 2) What strategies do PSTs utilize to succeed in their math content course sequence? 3) How does a mathematics support course support students to forge new mathematical identities?

Theoretical Framework

This study uses a Critical Race methodology (Solórzano & Yosso, 2002) to understand the ways that two students experienced their math content courses as part of their teacher preparation. We chose this methodology because it focuses on the stories and experiences of marginalized students, viewing these experiences as sources of strength. Solórzano and Villalpando (1988) define those who are marginalized as having "less access to opportunities and resources [and] experience different barriers, obstacles or other forms of individual and societal oppression than those at the center" (p. 212).

PSTs who are also placed into developmental mathematics face more obstacles than those students who are placed in a traditional, introductory mathematics course. First, PSTs are expected to deeply understand, engage with, and convey deeper conceptual understandings of mathematics than a student taking, say, a pre-calculus course. Elementary teachers must balance the challenges of not only understanding mathematical content, but they must have a level of specialized content knowledge (mathematical knowledge that may not be familiar to mathematicians), paired with pedagogical content knowledge (knowledge of how the content interacts with students and within teaching) (Ball, Thames & Phelps, 2008). Second, more underrepresented minority students are placed in developmental mathematics courses (Bahr, 2010) which is problematic because such remediation often places barriers to access to higher levels of education (e.g., receipt of financial aid, extended time to degree), which effectively places many underrepresented students on the periphery of educational opportunities and advancement (Valencia, 2015).

In this study we specifically focus on counternarratives of the second and third authors. *Counterstories* "serve as a method of telling the stories of those people whose experiences are not often told" (Solórzano & Yosso, 2002, p. 32) and can be seen as a tool to challenge the dominant stories of marginalization. "Storytelling has been used to provide a venue for the marginalized to voice their knowledge and lived experiences" (Rodriguez, 2010, p. 493). Solórzano and Yosso (2002) argue that stories can build a sense of community among marginalized populations, giving voices to those who may be overshadowed by the dominant stories within education. Because schooling privileges some students and not others, understanding a student's narrative can aid in understanding the way that those students who are under-supported within our educational system experience mathematics and also find ways to support their learning and success. As scholars, we need to understand how students who may be marginalized in our educational system "make sense of their own experiences and how they feel empowered to act to learn mathematics" (Zavala, 2014, p. 62).

Methods

This study took place at California State Polytechnic University, Pomona, a large public university on the West Coast of the United States. The second (Hazar) and third (Samantha) authors enrolled as freshmen in Math 1900 (described in the next section) at the university Fall 2018. Both students enrolled as Liberal Studies majors, preparing themselves to complete a Bachelor's degree supporting elementary school teaching. Hazar is in the fourth and final course of the mathematics content sequence while Samantha is enrolled the third course. Students who are deemed as needing extra support enroll in Math 1900 and then move onto the three-course math sequence. Students that do not need extra support enroll directly into the three-course math sequence which covers numbers and operations, algebra, statistics, and geometry. Hazar identifies as a first-generation, Lebanese-American woman. She is the first in her family to attend public schooling in the United States. She is 20 years old and plans to finish her multiple subject credential with the goal to ultimately get a masters degree. Samantha is a 19-year-old woman who identifies as a Hispanic woman with Native American heritage, focusing on early childhood education. She would like to one day open a pre-school.

The Quantitative Reasoning Course

Based on a statewide change in the California State University (CSU) system in Fall 2018, developmental mathematics coursework could no longer be offered, and instead general education courses needed to be modified to provide support for students who would have been placed in developmental mathematics courses. Because research has shown developmental mathematics courses hinder student graduation, this change was implemented to help students complete general education mathematics in their first year, shortening their time to degree completion and to lower dropout rates. When a student enrolls at a CSU, they are suggested to take specific courses that provide the right level of support. Through an algorithm that utilizes multiple measures, such as high school GPA, cumulative high school math GPA, SAT score, and whether or not students took math their senior year, students are placed into their math courses.

Math 1900 was a newly designed course, developed by author one, to fulfill the CSU mandate. As a credit-bearing course, the quantitative reasoning course was specifically designed to support students who are enrolled in the liberal studies sequence aiming to become elementary teachers. Previously, these students would have been asked to enroll in two developmental mathematics courses focusing on algebraic skills before starting the liberal studies course sequence. The course was structured around three factors designed to: 1) help students alleviate their mathematics anxiety by focusing on course reflections, strategies, and growth mindset, 2) provide students with opportunities to have authority in their learning and self-regulation of their ideas, and 3) engage students in the eight standards for mathematical practice.

Analysis

This study focuses on the storytelling of these two students during their fourth semester in the liberal studies program. Both students responded to reflection questions asking them to relate their experiences in the math content courses they have taken. In particular, they were asked to reflect on their relationship with math coming in as a freshmen, their perspectives on teaching mathematics, how they attempt new problems or content areas, strategies they have developed along the way to support their success, and their sense of belonging in the liberal studies program. Through constant comparative methods, we pulled the following themes from the narratives: minoritized experiences in mathematics, change in relationship with math, relying on peers for deeper learning, and looking to oneself for validation.

This study, like all, has its limitations. First, the second and third authors, the participants of this study, were students in the first author's course. This may lead to some bias in the responses of the students. However, these students discuss their experiences after taking several math courses in the liberal studies math sequence, reflecting back on their overall experience. Second, the course has only run for two years, and therefore, much is to be learned, yet about its long-term implications for other students. However, it is worthwhile to gain an understanding of how it is addressing PSTs' needs in the moment.

Findings

Through their reflections, Hazar and Samantha related their experiences in the content sequence for liberal studies. In particular, the two students described how being in Math 1900, specifically, helped them to feel confident in their math abilities and to persevere in the subsequent course sequence. Both students indicated that their peers who did not start in Math 1900 struggled in their coursework when placed in the next class. From their narratives, both students discussed how they felt minoritized in previous math experiences, strategies that they have used to be successful, which include discussing their past and current relationship with mathematics and teaching mathematics, relying on peers for deeper learning opportunities, and relying on themselves to validate their work.

Minoritized Experiences in Math

Both women described being minoritized racially or because of their gender in their high school educational experiences, while Hazar also felt minoritized because of her learning disabilities. Both Hazar and Samantha went to schools that had a high proportion of Asian students. Samantha indicated that she was a Hispanic female attending school with a predominantly Korean population of students. She felt that because she was Hispanic, her peers automatically thought that she would not perform well in mathematics. Hazar attended nine different elementary schools, and felt that this caused gaps in her education. When she attended high school, she had a similar experience to Samantha:

> As a middle eastern woman I had less in common with my peers. Our school had a reputation of being academically advanced…Students felt the need to be competitive, and outperform one another instead of lift each other. I felt a need to prove my abilities, not only to my peers, but also my teachers. I did not feel as comfortable raising my hand, and asking questions. I had the fear of being thought of as stupid, or unintelligent. I wouldn't have the confidence to raise my hand or ask the teacher to slow down. On the first day of classes, I felt the need to stay after class and explain I had ADHD, and admitting that I may need extra guidance to perform at the same levels of my peers.

Hazar felt the pressure to perform at her high school, and felt that her lack of consistent learning in elementary school paired with her learning disability contributed to how people thought of her. Samantha described how in high school, she was told that because she was female, she was not good at mathematics. "I had always been told that my brain simply did not function in a mathematical standpoint…I was told that because I am a woman, I would not be as good at math as a male. I noticed that many times, the teachers would pair us with a male partner."

In contrast, both students described how they did not feel this way in their Math 1900 course. For example, Hazar reflected on how she felt when she walked into the class for the first time.

> When I walked into Math 1900, I was taken back to how female dominant the class was. I was heard, and felt that people cared about what I had to say…I was surrounded by a group of diverse and powerful women (and men) who had similar high school experiences to me. I thrived in Math 1900. It was the first time I felt my mental disability was not a crutch. I was able to embrace my differences, and got to be up and moving, and talking. I was no longer subjected to sitting down and lectured at. I am the first generation within my family to be born and raised in the United States. I have had to navigate the education system, which is very different than education in Lebanon. When coming to Cal Poly, specifically Math 1900, I was surrounded by a group that shared the same experiences I have had.

Samantha also indicated that her experience in college was different than in high school, "we were embraced for our differences and told that we were capable regardless of race or ethnicity."

Changes in Relationship with Math

Hazar and Samantha had relationships with math prior to starting college. Samantha particularly had a high level of anxiety when it came to her relationship with math.

> I did not believe that I would be able to pass a college level math class nor understand it. I was most likely one of the most pessimistic human beings ever when it revolved around math. Throughout my pre-college years, math was truly one of my biggest struggles…although I was excited to finally learn math in which I would be passionate about, I could feel my heart beating out of my chest as I entered into my first ever college class.

Samantha was very insecure about her ability to perform in the set of courses she was expected to pursue as a liberal studies major. She realized that her biggest fear was that she felt that if she could not comprehend the basics of mathematics, how would she be able to teach children? Before college, Hazar felt that mathematics gave her "a lot of anxiety and stress". While she enjoyed math in her early years, she felt that she started to fall behind in high school because she lacked the basic understanding of concepts. She feels that mathematics is important and is something that is used regularly in everyday life, however, she felt a lot of pressure to perform prior to starting college.

Both students described ways that their relationship with math changed after starting the liberal studies program. Samantha described learning about growth mindset in Math 1900 and decided that it might be worth it to change her perspective of mathematics and her ability to learn.

> I began to learn and grow faster than I could have ever imagined. Astonishingly, I finally understood math to the point where I could educate my peers during study review. Never have I walked out of a class with such confidence…Now, I am able to use critical thinking to attempt to comprehend [math] rather than [searching] the internet immediately…[the class] offered me multiple strategies of comprehending different forms of math.

Her relationship with mathematics started to change and her confidence grew. Hazar also indicated seeing similar changes.

> I relearned foundations of math that helped me to understand it better. I was no longer blindly doing problems and hoping I was doing it right. I understand what I am doing, and why I am doing math the way I am. And the moment I don't understand a topic, I've gained the confidence to raise my hand and ask for clarification. I had many misconceptions about math, I thought it was independent, and all memorization…I genuinely want to know and learn more. It has increased my appreciation for teaching…As cliché as it sounds, math is really fun and I want my students to get the appreciation of it earlier than I did.

Both women found a way to relate to mathematics again. Samantha found that changing her mindset provided her the opportunity to engage in mathematics more than she did in high school. She recognized that now she was learning mathematics in order to teach, and therefore found joy when she was able to explain to others. Hazar recognized that with support to understand basic foundations of mathematics, she was able to understand and gain more confidence. She reflected on a moment when she was selected to present her explanation for how to add two fractions:

Peer Interactions

Samantha and Hazar distinguished that interacting with peers was an essential strategy that they learned from Math 1900 that helped them succeed and persevere in the subsequent math sequence. As noted above, Hazar had always been in classes where she sat in rows, faced forward, and was lectured at. Both students indicated that because group work was a daily routine in Math 1900 and that they were expected to change group members regularly, they were able to create a bond with their peers. Samantha and Hazar found it extremely rewarding to be able to help their peers. Hazar stated

> More than anything, I learned how to think critically, which is very important as a Liberal Studies major. I even took a different approach to how I help my peers. I wanted to create an encouraging and positive setting, but I couldn't do that by saying "no that's wrong". Just changing my verbiage ended up being a learning curve, and I have gone a long way. I now see dozens of students and tutor them at my school's Learning Resource Center…It gave me confidence I didn't know I had.

At the end of her first year, Hazar had gained so much confidence through working with others, that she decided to apply for a position as a tutor for the first two math courses in the sequence. She has now been tutoring for almost a year, and finds the experience very rewarding.

Both Hazar and Samantha started group study sessions outside of class. They found that by being able to practice teaching concepts in front of one another, they were able to clarify their language and understanding of the material. For example, Samantha indicated that by becoming close with her classmates through groupwork in class, she was able to develop closer bonds with her peers and feel comfortable meeting outside of class to study and develop their mathematical understanding. "We were able to…develop the proper communication skills and be able to know the process to overall work through problems with one another…[which I used] not only my math courses, but my other courses in general."

In particular, Hazar indicated that because of her widespread interactions with peers in Math 1900, she felt she finally found her calling.

> I knew I was meant to be a teacher because I have never bonded so instantly with any group in my life. We are like-minded and have similar goals. I've met some of the most encouraging and uplifting people I will ever meet. I made a mistake on a worksheet and I said "I'm stupid" and the whole table responded "No you're not" so instantly. Teaching is exactly what I want to do, and I've never been so excited to start my future.

While both students indicated that the type of group work they experienced in Math 1900 was not the same in the subsequent math courses, they decided to carry on the tradition. For both students, their interactions with peers was a strategy that they took into their future math classes. For example, Hazar mentioned how she volunteers and shares her work with her peers, even though her instructor had not expected her to, because she understood the value of learning from peers. Samantha continues to meet with peers outside of class, even if they are not in the same course section, "with the community [from Math 1900], we still have study sessions, coffee dates, a hand to hold onto, and overall encouragement when we are feeling down."

Validating their Own Work

Hazar and Samantha both indicated the value of struggle in their Math 1900 course. Hazar described scenarios when in Math 1900, the instructor never explicitly answered her questions and instead would ask her to think through her reasoning.

> I found it important to have a professor that allows you to struggle and make mistakes. [My professor] was patient, she didn't give us all the answers right away. She gave a lot of time to communicate and troubleshoot within our groups. If I asked for help she would ask me to go through the work I had out loud, and upon doing so I would naturally answer my own question.

Hazar indicated that this strategy of asking "why?", "what?", or "how?" helped her immensely in her subsequent math courses. She does so for questions like: "Why did I convert fractions to decimal in this word problem? Why are we using base 5? In ⅚ why, is 5 part of the 6? What does the 3 represent in 532, and what is its relation to the other numbers?

Samantha described a similar takeaway from that course. She recalled that for the first time she was genuinely asked to explain her reasoning behind how she did specific problems.

> [My professor] instigated the challenge of questions such as "*why* do we do this that way?" or "*how* did you get that outcome?" This ultimately helped me to find the deeper meaning to why or how I got an answer which is an important aspect to becoming an educator.

Samantha recalled a moment when she was presenting at the board and when she was asked by her professor how she arrived at her answer, she "[stared] at the numbers scribbled all over the board for what seemed to be hours, I finally…said 'I do not know.' This taught me that children will ask why and how, and an answer is a necessity." Samantha understood that in future courses and her transition to becoming a teacher, she needed to rely on herself to validate her own work.

Discussion

In this study, we discussed the counterstories of two women enrolled in their math sequence for future elementary teachers. Both women described how their previous high school experiences positioned them as inferior to their peers in their mathematics courses. Their experience in Math 1900 was transformational to these experiences; they were able to create and utilize strategies in their subsequent math courses that promoted their success while also creating more positive mathematical identities. The master narratives that PSTs struggle with high anxiety and also that developmental math students are deficient in math understanding are being challenged through their experiences. An essential take-away from the findings is that the two students felt a sense of community in their Math 1900 class (e.g., did not feel minoritized, felt like they were part of a team). On the first day of class, all students in the course contributed towards a classroom set of norms, which were followed all semester. Part of the list was that students were expected to hold authority of their learning, to give respect to others, and to provide positive feedback to others. This could also contribute to why both women experienced a change in their relationship with mathematics and the joy they found working with others. Students were expected to be creative and to work on problems together, requiring them to only ask questions once the entire group needed help. Positive experiences for PSTs can contribute to positive attitudes towards mathematics (Kalder & Lesik, 2011). Part of the design of the course was to be transparent in the rationale for why the instructor did what she did, revealing underlying reasons to classroom decision making of the content and the mathematical practices.

Hazar and Samantha may have found purpose and utility in the mathematics they were learning because it was the first time they saw how it could be connected to their field. Anderson (2007) argues that an important feature of mathematics identity is to be able to *imagine* how mathematics fits into a student's broader life. Students in developmental mathematics courses often find that the math they learn is not connected to their career goals or futures and therefore do not feel motivated to learn the material (Cawley, 2018). Hazar and Samantha found a transformative change to enjoying mathematics and wanted to better understand it once they saw its purpose: to teach future children. Because the class was built around the standards for mathematical practice, students were constantly asked to make sense of problems and persevere in solving them while also constructing viable arguments for the conclusions they reached in problems and to critique the reasoning of others in their group. Both women found the strategy of asking themselves *how* and *why* they chose certain ways to work on problems to be a positive learning strategy that they carried forward. They also found that asking for help from others supported their learning. These strategies appeared to increase their confidence to engage with and present their mathematical work.

It is important to provide the supports early on for students in order to help them succeed. Different from developmental math, this course was grounded in math content that was purposeful for future teachers, intentional in the design, provided an early intervention for students to build confidence, connected to mathematical practices, and created positive learning experiences for students to have continued success.

Reasoning about fraction magnitude is an important topic in elementary mathematics because it lays the foundations for meaningful reasoning about fraction operations. Much of the research literature has reported deficits in preservice elementary teachers' (PSTs) knowledge of fractions and has given little attention to the productive resources that PSTs bring to teacher education. We surveyed 26 PSTs using a set of 9 fraction-comparison tasks. We report the frequency of complete strategy-arguments and the perspectives (ways of reasoning) used for each item. We further examine incomplete strategy-arguments, noting substantial evidence for productive seeds of reasoning. Using data from interviews with 10 of these PSTs, we identify evidence suggesting these seeds are, in fact, productive in that they provide foundations for further development. We argue that this type of research is needed in order to further mathematics teacher education.

Keywords: Number Concepts and Operations, Rational Numbers, Teacher Education-Preservice

The mathematics education research community is concerned with the mathematics content knowledge of preservice elementary teachers (PSTs; Thanheiser et al., 2014). The research literature has tended to characterize PSTs' mathematics content knowledge as poor (Graeber, Tirosh, & Glover, 1989; Green, Piel, & Flowers, 2008; Putt, 1995; Tsao, 2005; Thipkong & Davis, 1991; Widjaja, Stacey, & Steinle, 2011; Yang, 2007). A synthesis of the literature reveals that there is insufficient research that seeks to make sense of PSTs' conceptions, or that views their conceptions as resources for further learning (Thanheiser et al., 2014; Whitacre, 2013). The literature on PSTs' knowledge of fractions is a prime example of such characterizations (Olanoff et al., 2014). Researchers have found PSTs to be inflexible in their reasoning about fractions, relying heavily on standard procedures, while at the same time having difficulty justifying such procedures and difficulty relating fraction operations to contexts (Olanoff et al., 2014).

Preservice elementary teachers may not typically reason flexibly about fractions when they come to teacher education (Ball, 1990; Yang et al., 2009), but how far are they from doing so? We operate from the assumption that PSTs possess fundamental mathematical resources with which to reason productively about fraction magnitude, but they may not have had sufficient opportunities to exercise such reasoning. In that vein, we analyzed 26 PSTs' responses to fraction-comparison tasks in order to identify the variety of ways of reasoning that they might bring to such tasks. In keeping with our perspective, we went beyond tabulating correct responses and coding for strategies. We also examined how PSTs reasoned through comparisons that they ultimately answered incorrectly or incompletely. Even in these cases, we find evidence of PSTs reasoning about fractions in productive ways. In interviews with 10 of the PSTs, in which we provided low-level support and encouragement, we investigated which strategy-arguments for comparing fractions were readily learnable depending on their current knowledge.

This research highlights the valuable prior knowledge and the potential for growth in PSTs' knowledge of fractions. We believe our findings offer a fresh perspective that contrasts with the vast majority of literature on this topic by highlighting the strengths of PSTs that can be leveraged into effective reasoning strategies for fraction-comparison tasks.

Background

Knowledge Framework

We have found Smith's (1995) framework useful for categorizing PSTs' ways of reasoning about fraction magnitude (Whitacre & Nickerson, 2016). It consists of four *perspectives*, which are categories of comparison strategies: Transform, Parts, Reference Point, and Components. Below, we briefly describe each perspective.

The *Transform* perspective involves use of procedures such as converting to a common denominator or converting to a decimal. These strategies involve transforming one or both fractions in some way in order to facilitate the comparison (e.g., comparing 6/7 and 7/8 by converting to a common denominator and then recognizing that 49/56 is greater than 48/56).

The *Parts* perspective involves interpreting fractions in terms of parts of a whole. This approach works especially well in certain cases, such as when comparing fractions that have the same numerator or same denominator. For example, 3/4 is greater than 3/5 because 1/4 of a whole is larger than 1/5 of the same-sized whole. Thus, three larger parts are greater than three smaller parts.

The *Reference Point* perspective involves reasoning about the magnitudes of fractions on the basis of their distance from reference points, or *benchmarks* (Parker & Leinhardt, 1995). In particular, Reference Point strategies relates to the number line. For example, to compare 7/8 and 6/7, a student may notice that 7/8 is 1/8 away from 1, whereas 6/7 is 1/7 away from 1. Since a distance of 1/8 is less than a distance of 1/7, 7/8 is closer to 1, and therefore larger.

The *Components* perspective involves noticing additive or multiplicative relationships in the numerators and denominators of the given fractions. For example, in order to compare 13/60 and 3/16, a student may notice that $13 \times 5 = 65 > 60$, whereas $3 \times 5 = 15 < 16$. Thus, 13/60 is greater because the numerator is larger relative to the denominator.

Our coding scheme for fraction-comparison strategy-arguments represents a revised version of that of Smith (1995). Length limits prevent us from providing operational definitions for each strategy-argument here. See Whitacre and Nickerson (2016) for a similar coding scheme.

Previous Research

We note three points that concern us about the state of the literature regarding PSTs' mathematical knowledge: (1) The body of literature tends to emphasize deficiencies, rather than to regard PSTs' prior knowledge as a productive resource (Thanheiser et al., 2014; Whitacre, 2013). This emphasis runs the risk of promoting low expectations of PSTs' abilities to learn. (2) There are few articles that provide specific, qualitative descriptions of PSTs' mathematical thinking that could provide useful information from which to design instruction. The work of Thanheiser (2009) is a notable exception. (3) There is a tendency to overgeneralize about the mathematical thinking of PSTs, rather than to recognize the variety in their thinking.

We view PSTs as sense-makers who are ready and able to improve their mathematical knowledge. Unfortunately, there is scant literature that helps the field to understand *how* PSTs' knowledge of fractions can be improved (Olanoff et al., 2014). Thanheiser et al. (2014) assert that the field of mathematics teacher education needs studies that document successful approaches to improving PSTs' content knowledge and that illuminate the processes by which such changes can occur. We agree. In particular, the field needs studies that find value in PSTs' prior knowledge and that demonstrate how PSTs can and do use that knowledge as they learn, because "The key to turning even poorly prepared prospective elementary teachers into mathematical thinkers is to work from what they *do* know" (Conference Board of the Mathematical Sciences [CBMS], 2001, p. 17). In the literature on K-12 students' mathematical thinking and learning, much attention has been given to students' mathematical conceptions and to the productive ways in which they make use of their prior knowledge as they learn new mathematics (e.g., Carpenter et al., 2015; Clements & Sarama; 2014;

Fuson et al., 1997). Unfortunately, such a perspective has rarely been applied in the literature concerning PSTs' mathematical thinking and learning (Thanheiser et al., 2014; Whitacre, 2013). In this study, focusing on the challenging topic of fraction magnitude, we examined how PSTs made use of their prior knowledge, including to develop new strategies, when comparing fractions.

Theoretical Framework

This study is informed by the notion of the *zone of potential construction (ZPC)* (Norton & D'Ambrosio, 2008; Steffe, 1991). The ZPC refers to the range "determined by the modifications of a concept a student might make in, or as a result of, interactive communication in a mathematical environment" (Steffe, 1991, p. 193). In the case of our work, to say that a strategy for comparing fractions is in a learner's ZPC is to say that the learner can hypothetically extend or reorganize her current schemes or mental operations to compare fractions in this new way.

Informed by the above literature, together with our previous experience, we expected PSTs to approach the fraction-comparison tasks primarily by drawing upon Parts and Transform reasoning. In particular, we expected them to be able to apply Parts reasoning to compare fractions in cases of a common denominator or common numerator. We did not expect many PSTs to compare complements initially, but we conjectured that doing so might be within their ZPCs. We expected many PSTs to default to Transform procedures, such as converting to a common denominator, in cases in which there was not a common numerator or common denominator in the given fractions.

Method

The research questions that we address are the following: (1) How do elementary PSTs reason about a set of fraction-comparison tasks? (2) What productive seeds of reasoning are evident in their responses? (3) Given the opportunity to explore a set of fraction-comparison tasks in an interview setting, which strategy-arguments are PSTs able to construct, and how do these relate to their current ways of reasoning?

This study took place at a large, public university in the Southeastern United States. The participants were a cohort of 26 PSTs in an elementary mathematics methods course. They were senior-level Elementary Education majors enrolled in a credential program.

Collection of Survey Data

Participants were given a fraction-comparison survey early in the semester (prior to instruction related to fractions). The cover page had nine pairs of fractions and asked the PSTs to mentally decide which fraction in the pair was greater or whether the two fractions were equal. The subsequent pages revisited each of these nine comparisons, asking participants for a "Description of Method" and a "Justification" for each comparison. We chose this format in order to encourage the participants to exercise their number sense, although they were free to approach the tasks in any way that they chose.

The same survey was administered at the end of the fraction unit. In both cases, time to complete the survey was limited to 25 minutes. We note that some participants left items toward the end of the survey blank. It is possible that more attempts would have appeared on later items if there had not been a time limit, or if participants had been given significantly more time.

Analysis of Survey Data

Note: We do not assume that the participants performed all of their work mentally and then reported that work in writing. In fact, some participants explicitly noted that they changed some answers. Whenever a participant gave one answer on the cover page but gave a different answer when describing or justifying their method, we regarded the latter response as the final answer.

Whitacre and Nickerson (2016) used a modified version of Smith's (1995) framework to code fraction-comparison strategies. In this study, we further developed that coding scheme to capture the wider variety of strategies that we observed. Two authors separately coded every response for perspective and strategy. The data were coded in batches (e.g., data from 8 participants) and inter-rater reliability was checked after each batch. By coding in batches, we were able to make revisions and additions to the coding scheme along the way and to code each subsequent batch with an updated scheme. This approach also enabled us to identify any interrater reliability issues early and to clarify our interpretations. Overall, the authors initially agreed on the perspective for 91% of the participants' responses and agreed on the specific strategy for 89% of the responses. Consensus was reached through further discussion of the disagreements until the authors were satisfied with the final coding decision.

In addition to coding for a perspective and specific strategy-argument, we also focused on comparisons that fell short of being complete strategy-arguments, yet demonstrated what we judged to be productive seeds of reasoning. Thus, all comparisons were coded into one of five categories: (a) complete strategy-argument and correct solution, (b) complete strategy-argument with minor errors, (c) incomplete strategy-argument with productive seeds, (d) incomplete strategy-argument with no apparent productive seeds, and (e) no strategy-argument evident. Incomplete strategy-arguments were given credit for productive seeds if the characteristics of the work, together with the perspective, were consistent with a complete strategy-argument (i.e., the participants' reasoning was headed down a productive path but stopped short of the complete argument). We believe that this approach to the study of PSTs' mathematical thinking provides a more comprehensive picture than that which has typically been reported in the literature.

Collection of Interview Data

Prior to the fraction unit in class, PSTs were invited to participate in one-on-one interviews. In contrast to the typical interview style in which the interviewer refrains from providing any form of support, these interviews were designed to allow for minimal support. The purpose of the interview design was to investigate which strategy-arguments were in participants' ZPCs. Thus, we specified in the interview protocol allowable types and levels of intervention. The intervention strategies that interviewers used included emotional encouragement, requests to solve a comparison task in a different way, requests or encouragement to continue down a path of reasoning, and offering counter arguments or pointing out evidence that was relevant to determining whether a solution was correct or incorrect. Ten of the 26 PSTs participated in these video-recorded interviews. The first and second author each interviewed five of the participants. In these interviews, PSTs were given nine fraction-comparison tasks that each mapped closely to the nine comparisons on the survey, but with different components (see Table 1).

Analysis of Interview Data

To analyze the interview videos, we targeted comparisons in which participants activated a productive seed in their work. We first identified comparisons from the videos that demonstrated use of productive seeds, we then wrote short narratives on what transpired in each case, and finally chose representative cases that highlight successful progressions in reasoning from productive seeds with low-level support. In our analysis, we applied three criteria as evidence that a strategy-argument was within a participant's ZPC: (1) the PST had not previously used that strategy-argument, as determined from pre-assessment and interview data; (2) the PST produced the strategy-argument during the interview with no more than minimal intervention from the interviewer; (3) the PST later used the same strategy-argument independently.

Table 1: Fraction-comparison Tasks from the Survey and Interview

Item	Survey Comparisons	Interview Comparisons
1	2/8 vs. 3/8	4/6 vs. 5/6
2	3/4 vs. 3/5	5/8 vs. 5/9

3	6/7 vs. 7/8	7/8 vs. 8/9
4	14/13 vs. 13/12	11/10 vs. 12/11
5	8/24 vs. 13/39	6/24 vs. 13/52
6	13/60 vs. 3/16	17/42 vs. 8/23
7	7/28 vs. 13/50	4/20 vs. 11/56
8	2/7 vs. 12/43	5/12 vs. 30/71
9	35/832 vs. 37/834	25/287 vs. 28/290

Results

Survey Results

We summarize the survey results in terms of three themes: (a) PSTs know what they were expected to learn in school, (b) when encouraged to do so, PSTs explore different perspectives and strategies, and (c) PSTs exhibit productive seeds for reasoning about fraction comparisons.

First, unsurprisingly, we find that the participants tended to use Parts and Transform strategies. As expected, those two perspectives are most familiar to PSTs, and they were the perspectives most commonly used. Figure 1 tabulates the number of instances of strategy-arguments for each perspective, broken down by item. Parts was a common perspective across items involving smaller, easier fraction comparisons. Transform was also a common strategy perspective across most of the items, with many PSTs frequently converting both fractions to a common denominator explicitly or using cross multiplication. Components strategies occasionally appeared on the later items, but were predominant on the last item with many PSTs noting the common difference of two in that comparison. Reference Point strategies were rare. Strategy arguments coded as "Other" were not developed enough to code, and comparisons coded as "None" had no work shown (either a simple answer or completely blank).

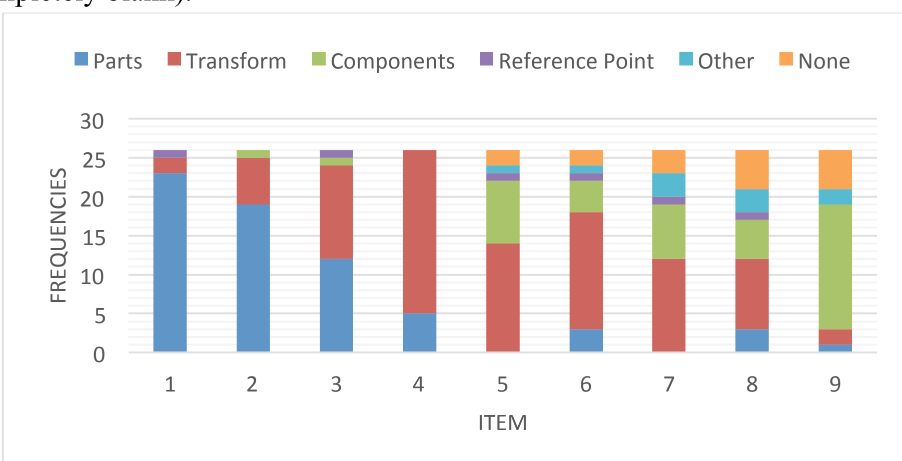

Figure 1: Perspectives used by comparison item

Second, in contrast to descriptions in the literature, the participating PSTs did exhibit flexibility in their reasoning about fraction magnitude. Recall that the instructions for the survey asked participants to first make comparisons mentally and that the numbers chosen for the comparison items lent themselves to different strategies. Nonetheless, the participants could have defaulted to converting to a common denominator for every task. They did not. Instead, PSTs used an average of 5.5 distinct strategies across the 9 tasks, and they averaged 3.73 distinct strategies that were accompanied by complete arguments. Of the 26 participants, 20 used five or more distinct strategies. All of the participants used at least three distinct strategies.

Third, we see substantial evidence of productive seeds of reasoning. The comparisons items ranged from easy to difficult for the participants, especially given that they were instructed to make their judgments mentally and that the survey was administered under time constraints. Each participant was given a correctness score for each item: correct answers scored 1 point, and incorrect answered scored 0 points. The mean total score was 5.96 (of a maximum of 9 points) with a standard deviation of 1.66. The average number of correct answers accompanied by complete arguments was 4.38 with a standard deviation of 2.17. Thus, the participants answered most items correctly, but there was substantial room for improvement in correctness and especially in producing complete arguments.

Candidate responses to be coded for productive seeds were those that did not constitute complete arguments. Of the 87 incomplete arguments, 39 (approximately 45%) included evidence of productive seeds. (There were another 6 responses with no written work provided, and there were 17 items left blank, which may have been due to time constraints.) Thus, even in cases of incomplete arguments, the participants often reasoned about fraction comparisons in productive ways. This result indicated the potential for the interview participants to construct new strategy-arguments with minimal intervention during the interviews.

Interview Results

Due to length constraints, we focus here on the interview participants' responses to the third comparison item, 7/8 vs. 8/9. This item was intended to invite PSTs to consider the complements of the given fractions (i.e., 1/8 vs. 1/9) and to construct a strategy-argument based on comparing complements (e.g., 1/9 is smaller than 1/8, so 8/9 is larger than 7/8 because it is closer to whole). Indeed, 8 of the 10 interview participants were able to construct a complete argument that involved comparing the complements and reasoning from a Parts perspective. Most participants did not compare complements initially. Instead, they began with a more familiar strategy such as converting to a common denominator. They then compared complements in response to an interviewer's request, such as to try to find a "different way" of making the comparison. Alternatively, the interviewer followed up on something that the participant had mentioned (e.g., the possibility of thinking in terms of "parts" or "pies"). Given such requests and encouragement, 80% of the participants constructed a complete Comparing Complements strategy-argument, supporting the correct conclusion that 8/9 was greater than 7/8. By contrast, only 1 of the 10 participants had compared complements for the corresponding item (6/7 vs. 7/8) on the pre-survey. On the post-survey—without assistance and free to choose any strategy they wished—7 of the 10 interview participants used comparing complements for 6/7 vs. 7/8.

Thus, we see evidence that the strategy of comparing complements was in the ZPCs of the majority of the interview participants. This was especially the case for those who took the size of the parts into account in comparisons involving a common numerator (5/8 vs. 5/9 in the interview). Those who explained that 5/8 was greater than 5/9 because eighths are larger than ninths (using Parts: Denominator Principle) appeared to be ready to reason in terms of complements for 7/8 vs. 8/9, even if doing so was novel and somewhat challenging. For example, Jane used the Denominator Principle to correctly compare 5/8 and 5/9. When she was posed 7/8 and 8/9, she noted that "the numerators are each one less than the denominator" and that eighths were larger than ninths. However, she was not immediately sure what conclusion to draw. She made rectangular area drawings of 7/8 and 8/9. Her drawings were sloppy and actually made 7/8 appear to be greater. However, despite her drawing, Jane reasoned that the missing piece from 8/9 must be smaller than the missing piece from 7/8, and therefore 8/9 was greater. Even after constructing a complete strategy-argument, Jane expressed doubt, so the interviewer invited her to explore the idea further. She created her own example, using 1/2 and 2/3, which bolstered her confidence in this new way of comparing fractions.

The two participants who did not construct a complete strategy-argument involving complements during the interview conspicuously ignored piece size in their reasoning. Both focused on the number of parts, rather than their size, when thinking in terms of Parts (and otherwise relied on converting to decimals). For example, Kimmy described 5/8 as missing 3 pieces and 5/9 as missing 4 pieces, without making any mention of the size of said pieces. As best we can tell from the data, even with interviewer probing, the size of the pieces did not enter into her reasoning. Like Jane, she noticed that both 7/8 and 8/9 were "missing one piece," but unlike Jane, she was unable to arrive at a complete strategy-argument using complements.

Discussion

We have begun the fine-grained work of identifying strategy-arguments for comparing fractions that are within the ZPCs of some PSTs, depending on their current ways of reasoning about fractions and given low levels of intervention. This finding is encouraging. Our work also reveals substantial diversity in PSTs' reasoning about fraction comparisons—a theme that is underemphasized in the literature. In the absence of documented distinctions, the literature might encourage mathematics teacher educators to treat all PSTs as if they think similarly.

We have shown that certain, nonstandard strategy-arguments, such as Comparing Complements are readily learnable by some PSTs, given their current ways of reasoning. Note that we are not distinguishing PSTs based on supposed ability. Our data do not speak to their mathematical abilities in general, and we do not claim that some of our interviewees were more mathematical capable than others. Instead, we are concerned with how they were thinking about fractions at the beginning of the course, in relation to the progress that they were able to make during the interview. Those PSTs who took the size of the parts into account when reasoning in terms of Parts were able to compare complements with lows levels of interviewer intervention. Those PSTs who consistently ignored the size of the parts did not appear to be readily able to construct Comparing Complements on the day of the interview. However, later on, having first constructed Parts: Denominator Principle, they may have become able to do so. Thus, in making claims about PSTs' ZPCs, these are limited to what was readily learnable *during the interview*.

Conclusion

In our review of the research literature concerning PSTs' knowledge of fractions, we pointed our three problems with the emphasis on negative generalizations. We frame our contributions in response to these problems: (1) Whereas the emphasis on deficiencies runs the risk of promoting low expectations of PSTs' abilities to learn, our approach is concerned with documenting learning and identifying the conditions under which it is readily achievable. (2) Whereas literature that emphasizes deficiencies fails to provide useful information from which to design instruction, our approach identifies PSTs' particular conceptions (in the form of strategy-arguments, in this case) and charts the terrain of viable reorganizations. (3) Whereas generalizations about deficiencies in PSTs' content knowledge fail to distinguish PSTs from one another, our approach focuses on the diversity of reasoning that can be found among PSTs. This research has illuminated our own understanding of PSTs' reasoning about fraction comparisons and has helped to inform instruction in the courses that we teach.

This line of research values PSTs' prior knowledge and identifies desirable mathematical understandings that are readily learnable, given favorable conditions. In this way, we identify PSTs' particular conceptions and chart the terrain of viable reorganizations. Once they move beyond default approaches like converting to a common denominator, we find considerable diversity in the mathematical thinking of PSTs, and we discover what they are ready to learn.

DIDATIC-MATHEMATICAL KNOWLEDGE AND COMPETENCE OF PROSPECTIVE SECONDARY SCHOOL MATHEMATICS TEACHERS ON LINEAR VARIATION

CONOCIMIENTOS Y COMPETENCIAS DIDÁCTICO-MATEMÁTICOS DE FUTUROS PROFESORES DE MATEMÁTICAS DE SECUNDARIA SOBRE VARIACIÓN LINEAL

In this paper we describe an educational proposal for prospective secondary school mathematics teachers in Mexico, whose aim was to contribute to the development of their didactic-mathematical knowledge about linear variation through mathematical tasks, the development of the competence of identifying primary mathematical objects and the reflection on hypothetical cases of teaching. The proposal is supported within both the Onto-semiotic Approach (EOS) and the Mathematics Teacher's Didactic-Mathematical Knowledge and Competence model. The proposal follows a design research methodology based on EOS. The results show the complexity related to the development of the competence of identifying primary mathematical objects, they also highlight the influence that competence has on the development of the epistemic and cognitive facets of prospective teachers' didactic-mathematical knowledge on linear variation.

Keywords: Teacher Education - Preservice; Mathematical Knowledge for Teaching; Middle School Education; Precalculus.

Introduction

Linear variation is an important mathematical topic that goes transversely trough the mathematics curriculum in Mexico, it is taught from the fifth year of primary education, becomes a central topic in secondary school (SEP, 2017), and its teaching continues in the upper secondary and higher educational levels.

The teaching of variation is essential because variation is a fundamental notion for the study of physical phenomena that can be observed in nature and found in people's daily experiences. These phenomena have the characteristic of being dynamic, that is, they involve processes that are constantly changing. Therefore, the teaching of variation should support students to make estimations, comparisons, and models that allow to explain the phenomena of change and solve problems demanded by their milieu (García & Ledezma, S / F; Caballero & Cantoral, 2015).

Despite the importance of teaching variation, particularly linear variation, the mathematics curriculum often promotes a static and limited teaching of this mathematical content in secondary school. In this regard, authors such as Bojórquez, Castillo, and Jiménez (2016), Panorkou, Maloney, and Confrey (2016), Thompson and Carlson (2017), and Vasco (2006) highlight that the variational thinking of students is not explicitly considered in the curriculum of mathematics in the elementary and secondary school. Also, they declare that mathematics textbooks are not formulated from a variational point of view and point out the notion of variable magnitude is missing in teaching of mathematics, despite the fact that they constitute a necessary basis for the learning of calculus at later educational levels. Instead, a static teaching of function as a correspondence rule is fostered, without any connection to variation.

Since curricula and textbooks are the primary materials available to secondary school mathematics teachers, and considering these documents foster a limited approach to the teaching of linear variation, it becomes highly important that Mathematics Education provide concrete guidelines to support teachers to broaden their perspective about teaching linear variation.

It is particularly important that, in an early stage, teachers incorporate to their professional practice more enriched strategies for teaching linear variation than the ones suggested in mathematics curriculum. Consequently, it is pertinent to intervene in the initial teacher education, as Godino, Giacomone, Batanero and Font (2017) argue: "mathematics teacher education […] demands attention from the Mathematics Education, since the development of students' basic thinking and mathematical skills depend essentially on this education"(p. 91).

It is noteworthy that there is little research that provides specific orientations on how to strengthen didactic and mathematical teachers knowledge on linear variation in teacher training programs, despite the fact that different researchers have reported difficulties of mathematics teachers and prospective teachers in relation to notions closely linked to linear variation, such as function (Wilhelmi, Godino & Lasa, 2014, Amaya, Pino-fan & Medina, 2016) and proportionality (Balderas, Block & Guerra, 2014).

To address this problem, we designed, implemented, and evaluated a didactic proposal for the teaching of linear variation. We called it *formative proposal* because it is aimed at prospective mathematics teachers. The main goal was to enrich didactic-mathematical knowledge of prospective teachers on linear variation and to initiate them in the development of their competence for identifying primary mathematical objects related to this mathematical notion. The proposal was theoretically supported on both the Onto-semiotic Approach (EOS) and the Mathematics Teacher's Didactic-Mathematical Knowledge and Competence model (DMKC). It was followed a qualitative design research methodology that integrates some of the EOS theoretical tools. The formative proposal included the design of a sequence of didactic activities which included mathematics tasks and several questions and situations to prompt didactical reflections. To design the formative proposal we took into consideration the work of Herrera-Garcia (2020), who characterized several meanings of linear variation pertinent for teaching in secondary school (as a visual representation on the number line, as a graphical representation on the Cartesian plane, numerically as proportional variations of corresponding magnitudes, and as an algebraic formula).

This paper we describe both the stages of the methodology followed to design the formative proposal and the structure of the didactic sequence designed. In addition, we discuss some of the results obtained by its experimentation with prospective secondary school mathematics teachers. We also present part of the analysis of some of the prospective teachers 'productions corresponding to the second activity of the sequence, which allowed us to establish important relationships between the development of the teachers' competence of identification of primary mathematical objects and the development of their didactic-mathematical knowledge.

Theoretical Frame

We support the formative proposal on theoretical tools from the Onto-Semiotic Approach (OSA) to mathematical knowledge and instruction (Godino, Batanero & Font, 2007), as it provides important elements to elaborate an instructional design and methodological tools that allow guide its development and evaluating its implementation. To design the proposal, we used two fundamental theoretical notions (Godino, Batanero & Font, 2008): *institutional meaning* of a mathematical object (the system of mathematical practices shared into an institution to solve a same type of problems) and the typology of *primary mathematical objects*: *situations* (problems, exercises, etc.), *concepts* (given by definitions or descriptions), *languages* (terms, algebraic expressions, graphs, ...), *procedures* (techniques, algorithms, operations), *arguments* (statements to validate or explain) and Propositions (statements about concepts).

Mathematics Teacher's Didactic-Mathematical Knowledge and Competence model (DMKC)

Given the need for theoretical tools to characterize and evaluate the teacher's didactic-mathematical knowledge and skills, the Mathematics Teacher's Didactic-Mathematical Knowledge and Competence model (DMKC) has recently been developed within the EOS (Godino, Giacomone, Font and Pino-fan, 2018). This model emerged as an extension of the Mathematics Teacher's Didactic-Mathematical Knowledge (DMK) model (Godino, 2009) and has been enriched by Godino and collaborators based on the EOS theoretical tools in several investigations (Pino-Fan & Godino, 2015; Pino-Fan, Godino & Font , 2015). In this model, it is considered that the mathematics teacher must have knowledge conserning of mathematical notions they teach (Pino- Fan & Godino, 2015). In addition, the teacher must have a didactic-mathematical (or specialized) knowledge of the different facets or dimensions that intervene in instructional processes: epistemic, ecological, cognitive, affective, mediational, and interactional. In this work, we consider only two facets: epistemic (didactic-mathematical knowledge about mathematics itself) and cognitive (knowledge about how students learn mathematics) (Godino, Giacomone, et al., 2017).

In addition to this, the DMKC model states that the prospective teacher must also develop a series of *didactic-mathematical competences* that allow him to face the problems of teaching mathematics. In particular, in this work we were interested in the competence of *ontosemiotic analysis of mathematical practices*, which, according to Godino, Giacomone, Batanero and Font (2017) consists in the identification of the network of primary mathematical objects and processes involved in mathematical practices, which allows the teacher to understand the progression of learning, manage the processes of institutionalization and evaluate the mathematical skills of their students. It is important to declare that we considered necessary, among all the elements contemplated in the competence mentioned above, the identification of primary mathematical objects in the mathematical practices carried out when addressing the didactic sequence, therefore, we call it in this paper *competence of identifying primary mathematical objects*.

Method

Methodological approach

We followed the methodology for design research proposed by Godino, Rivas, Arteaga, Lasa and Wilhelmi (2014), which integrates elements of both the design-based research methodology and Didactic Engineering within the theoretical tools of EOS. The methodology consisted of four stages; preliminary study (stablishing the institutional meaning of reference on linear variation), design of the didactic trajectory (elaborating didactic sequence by designing mathematical tasks using the primary mathematical objects related to the meanings of linear variation, the creation of GeoGebra applications and the design of tasks to prompt didactic-mathematical reflections), implementation of the didactic trajectory (implementation of the didactic sequence) and retrospective evaluation or analysis (the development of the above described competence and the epistemic and cognitive facets of the DMKC model).

Context and participants

The formative proposal was implemented with nine prospective mathematics secondary school teachers, who were in the eighth semester of Bachelor in a public institution in Mexico that provides programs for secondary school teachers initial education. The experimentatio was carried out in four sessions with a total duration of 15 hours. The designer of the formative proposal also served as the instructor.

Data Collection Instrument

The main instrument to collect the information was the sequence of didactic activities, which is made of five didactic activities with specific tasks for prospective teachers, supported by digital applications with GeoGebra according to the content of each activity. The activities started with a situation of variation in extra-mathematical context, some situations corresponded to linear variation and others did not, in order to help prospective teachers to distinguish when a situation corresponds or not to a case of linear variation. The didactic activities were printed on paper and given to each participant, who were designed with the letter "E" and a number from 1 to 9. The participants were asked to write their answers with different colored pen according to the working modality: black for individual work, red for teamwork and blue for group work.

Structure of the didactic sequence

Each of the activities is organized in three parts, addressing the following aspects: mathematical knowledge, didactic-mathematical knowledge, and the competence of identifying primary mathematical objects. In each of these three parts of the didactic activities different work modalities were considered: individual, team of three people and group discussion.

Part I: *Mathematical work*. This part of the sequence is intended for solving mathematical tasks aimed at enriching the meaning of linear variation of future teachers. For this, situations of linear variation and non-linear variation were proposed in various contexts, such as the relationship between the biological age of a dog and the years lived by him; the relationship between a person's weight (kg) and its height; filling and emptying of cylindrical containers. In these contexts, it was sought that future teachers manage to characterize linear variation based on the proportional relationship between the corresponding variations of two variable magnitudes in different forms of language: dynamic number lines in GeoGebra, Cartesian graphs, tables of values and algebraic expressions.

Part II: *Identification of the primary mathematical objects involved in the mathematical practices developed in Part I*. In the first didactic activity, it was sought that the future teachers express what they understood by three of the primary mathematical objects. To do this, they were asked the following questions: What is a mathematical concept for you?, What is a procedure for you?, What is a property / proposition for you?, adapted from the work of Giacomone (2018). It is important to mention that future teachers were not instructed in the use of EOS, but through group discussions they were guided so that, in a consensual way, they characterized those mathematical objects based on their initial ideas. Having established what is meant by that three mathematical objects, they were asked to identify those used in solving the mathematical tasks of Part I in each of the activities.

Part III: *Analysis of the answers given by hypothetical high school students*. This last part consists of the analysis of answers supposedly provided by students when addressing linear variation problems, with the aim that the prospective teacher analyzed the student's mathematical practice, determined whether or not it is correct and created strategies to guide and provide feedback to the student.

Data analysis and discussion

After the implementation of the five activities that integrated the didactic sequence, we carried out the analysis and interpretation of the answers provided by the prospective teachers. Below, we present some answers corresponding to the first two didactic activities of the sequence, which we interpreted from the perspective given by the theoretical referents chosen.

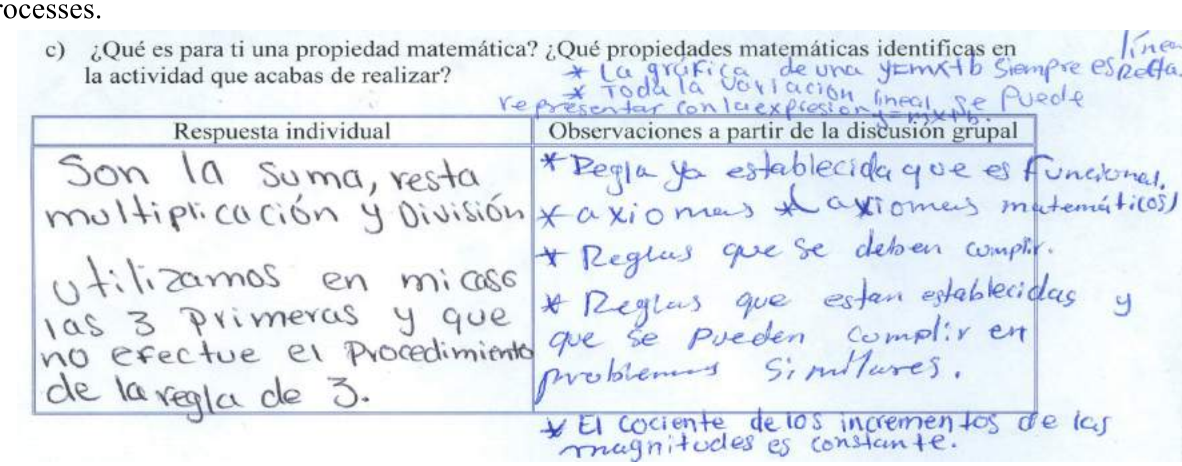
Identification of primary mathematical objects in the mathematical practices

An essential part for developing the competence of identifying primary mathematical objects both in their own and in their students' mathematical practices, is to have a wide perspective about the diversity of mathematical aspects involved in solving a mathematical task, that is, to understand each of the six primary mathematical objects. In this work, due to time constraints, we decided to limit the competence of identifying primary objects to the following three objects: procedures, concepts, and properties.

In the first didactic activity, the future teachers carried out the mathematical tasks of Part I, aimed at expanding their mathematical knowledge on linear variation. Then, in Part II, where future teachers were to explain what a concept, property, and procedure is, the following was found. The future teachers had no problem explaining what a *procedure* is to them and it was relatively easy to identify procedures such as the calculation of basic operations (addition, subtraction, multiplication, and division) in their practices. In the group discussion, the instructor asked questions in order to guide future teachers to recognize other types of procedures, so it is important to highlight that group interaction was essential for the identification of a wider variety of procedures, such as the "rule of three", the clearances of a variable, and the calculation the proportionality constant.

The mathematical object *concept* was a little more difficult to characterize by some teachers. For example, E8 expressed that a mathematical concept "is the problem with which we are working to find a solution", this suggests that for him a concept is the problem to be solved. Furthermore, E8 failed to use the notion he expressed to identify concepts in his own mathematical practices. On the other hand, the future professor E7, defined a concept as: "the meaning of a word" and identified term, equation, and magnitude as concepts in the work carried out in part I. Some of the concepts identified by future teachers individually are slope, proportionality, line, terms, proportionality constant, algebraic expression, and magnitude.

In contrast to the above, it was more difficult for future teachers to explain what a *property* is. For example, E5 expressed that a property "is a mathematical axiom" and E4 wrote that "it is an already established rule that is always functional". Both provided the algebraic expressions "$y = mx + b$" y "$K = \Delta y/\Delta x$" as examples of properties involved in part I of mathematical work, which might suggest that for them the properties have to be expressed algebraically. Other future teachers failed to provide examples of properties. On the other hand, E8 did not explain what a property was, but did mention addition and subtraction as examples. It is important to highlight the enrichment in the answers during the group discussion (this corresponds to the epistemic facet of didactic-mathematical knowledge). In the bottom of the right column (Figure 1), in blue, it can be seen that E8 takes up the ideas of its peers and adds some examples of properties, such as: "The quotient of the magnitudes' increases is constant." This highlights the importance of interactions during mathematical instruction processes.



c) ¿Qué es para ti una propiedad matemática? ¿Qué propiedades matemáticas identificas en la actividad que acabas de realizar?

* La gráfica de una y=mx+b siempre es recta. línea
* Toda la variación lineal se puede representar con la expresión y=mx+b.

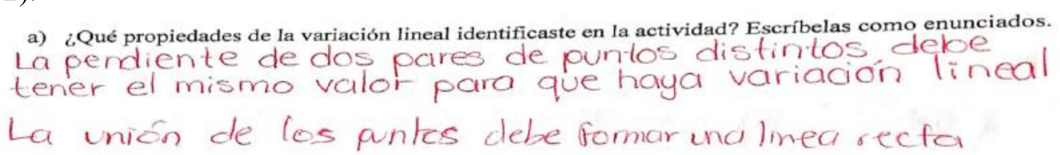
Respuesta individual	Observaciones a partir de la discusión grupal
Son la Suma, resta multiplicación y División utilizamos en mi caso las 3 primeras y que no efectue el Procedimiento de la regla de 3.	* Regla ya establecida que es funcional. * axiomas * axiomas matemáticos * Reglas que se deben cumplir. * Reglas que estan establecidas y que se pueden cumplir en problemas similares.

* El cociente de los incrementos de las magnitudes es constante.

Figure 1. Enrichment of E8 answer after group discussion

Explaining what a concept and a property is was a difficult task for future teachers, as has already been reported by other researchers such as Giacomone (2018), Giacomone, Godino, Wilhelmi and Blanco (2018), Burgos, Giacomone, Beltrán-Pellicer and Godino (2017), Burgos, Godino, Giacomone and Beltrán-Pellicer (2018b) and Burgos, Beltrán-Pellicer, Giacomone and Godino (2018a). The recognition of these objects in mathematical practices is a competence that needs time to be developed, partly due to the difficulty of understanding what these primary mathematical objects are. However, the tasks proposed in the didactic sequence were motivating elements to initiate them in the development of that competence.

Gradually, in subsequent activities, future teachers were able to more consistently identify concepts, procedures, and properties in the mathematical practices carried out in the mathematical tasks about linear variation, which also highlights the development of the epistemic facet of their didactic-mathematical knowledge. In Activity 2, which dealt with the relationship between the weight and height of a person, expressed in a numerical table, prospective teachers identified new concepts and new properties of linear variation when creating a Cartesian graph and reflect on some the points obteinded from the table. For example, E5 said: “The slope of two pairs of different points must have the same value for linear variation. The union of the points should form a straight line” (Figure 2).



a) ¿Qué propiedades de la variación lineal identificaste en la actividad? Escríbelas como enunciados.
La pendiente de dos pares de puntos distintos debe tener el mismo valor para que haya variación lineal
· La unión de los puntos debe formar una linea recta

Figure 2. E5 and E1 answer during teamwork

Furthermore, prospective teachers showed changes in the type of guidance they would give to students in the hypothetical teaching situations. Initially, their orientations were limited to and inclined towards manipulating algebraic expressions. After the mathematical work and the tasks aimed to identifying primary mathematical objects in Activity 2, they analyzed in more detail the hypothetical answer of a high school student (part III), who made a graph (Figure 3) with data on weight and height provided by the Mexican Social Security Institute, and stated the situation corresponded to a linear variation situation.

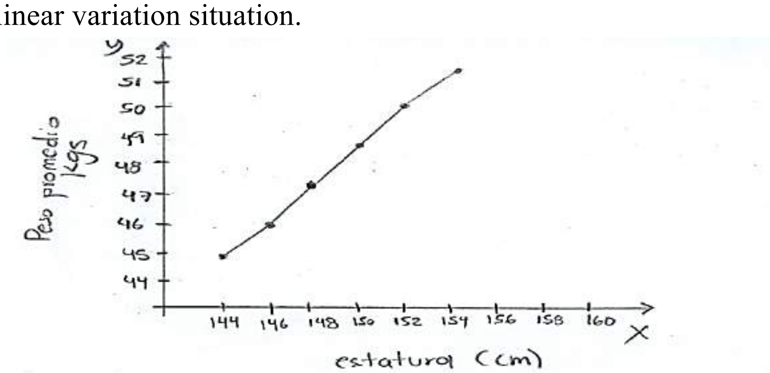


Figure 3. Graph drawn by a hypothetical high school student

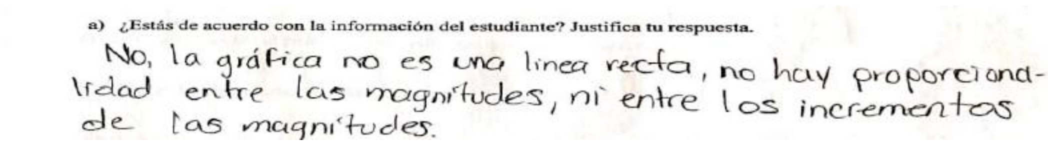
Regarding the student's answer, the future teachers were asked: a) Do you agree with the student's answer?, B) What arguments would you give to reinforce your point of view and give feed back to the student?, And c) How Would GeoGebra help you to provide feedback to the student? In evaluating the student's answer, the future teachers used the primary mathematical objects identified in their own mathematical practices (Figure 2). For example, E1 (Figure 4) analyzed the graphical representation through the properties of linear variation that emerged in part I of this activity. He states that "the graphic is not a line because there is no proportionality between the magnitudes, nor between the magnitudes' increases". E1 evaluated the student's answer and concluded it is not correct; being able to make this assessment corresponds to the epistemic facet of didactic-mathematical knowledge.

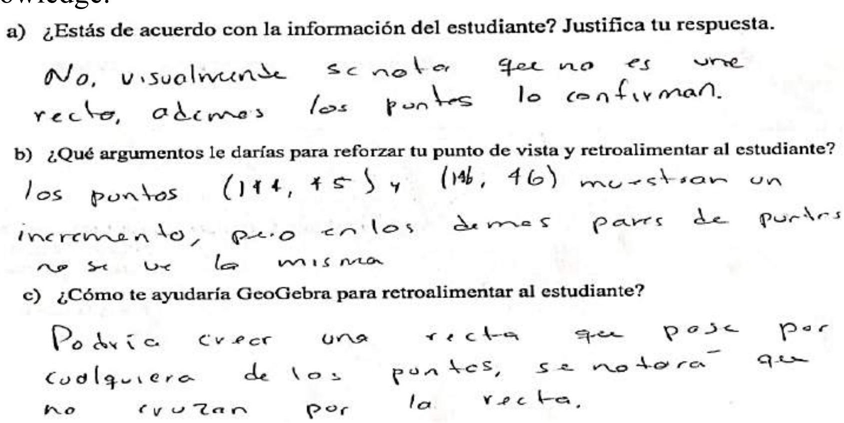


a) ¿Estás de acuerdo con la información del estudiante? Justifica tu respuesta.

No, la gráfica no es una linea recta, no hay proporcionalidad entre las magnitudes, ni entre los incrementos de las magnitudes.

Figure 4. The future teacher E1 argues using properties of linear variation

We can find another example of the enrichement of future teachers didactic-mathematical knowledge in the answer of E9 (Figure 4) to the same situation, who first expresses that "visually the graph is not a line". Then, to provide feedback to the student, he proposes to choose pairs of points and identify that there is no constant variation. In addition, he states that GeoGebra would help the student by creating a line that would show that it does not cross all the points. These reflections of E9 on how it would orient a student, show the enrichment of the cognitive facet of its didactic-mathematical knowledge.



a) ¿Estás de acuerdo con la información del estudiante? Justifica tu respuesta.

No, visualmente se nota que no es una recta, ademas los puntos lo confirman.

b) ¿Qué argumentos le darías para reforzar tu punto de vista y retroalimentar al estudiante?

los puntos (144, 45) y (146, 46) muestran un incremento, pero en los demas pares de puntos no se ve la misma

c) ¿Cómo te ayudaría GeoGebra para retroalimentar al estudiante?

Podría crear una recta que pase por cualquiera de los puntos, se notara que no cruzan por la recta.

Figure 5. Prospective teacher E9 provides feedback to the student using GeoGebra

In the examples shown above, it can be identified that future teachers progressed in their professional knowledge, both mathematical and didactic-mathematical, since they provide arguments and orientations (in some cases using GeoGebra) based on different procedures, and properties of linear variation, which allowed them to assess whether or not the situations posed to them and to the hypothetical students correspond to situations of linear variation in different forms of language (algebraic, graphic, numerical and verbal). That is, the formative proposal allowed future teachers to enrich their specialized knowledge of mathematics, since they could identify in their own mathematical practices primary objects related to linear variation, and then, based on them, they could argue why some hypothetical responses of students were incorrect and propose feedback strategies for the student regarding the study of linear variation.

Conclusions

After analyzing the answers of future teachers, we concluded that the competence of identifying primary mathematical objects was a challenging task for them, as documented in studies such as that of Burgos et al. 2017. On the other hand, their answers suggests that they were able to gradually carry out more detailed analyzes of both their mathematical practices and the mathematical practices of the hypothetical students, since they showed a greater diversity of primary mathematical objects in the reflection tasks (parts II and III of the activities).

In the implementation of the activities, time was devoted to the discussion of ideas and the comparison of the answers given, this generated a very rich moment of exchange opinions and allowed prospective teachers to reflect on other mathematical objects that they had not identified by their own, so group discussions allowed them to enrich their initial answers.

A very important aspect that must be highlighted is that, initially, the didactic-mathematical reflections that the prospective teachers generated regarding the tasks set out, used to be very limited and lacking arguments. Subsequently, by working on the activities and the tasks set out to initiate them to develop the competence of identifying primary mathematical objects, they generated more detailed responses, which included the use of primary mathematical objects. This helped them to propose more detailed strategies to guide the students based on argumentation related to properties and procedures of linear variation previously identified in the part I (mathematical work). This highlights the importance of the development of this competence for their teaching practice, since it prompts prospective teachers carry out analysis of mathematical practices that take into account the diversity of primary mathematical objects related to the teaching and learning of a specific mathematical content.

CONOCIMIENTOS Y COMPETENCIAS DIDÁCTICO-MATEMÁTICOS DE FUTUROS PROFESORES DE MATEMÁTICAS DE SECUNDARIA SOBRE VARIACIÓN LINEAL

DIDATIC-MATHEMATICAL KNOWLEDGE AND COMPETENCE OF PROSPECTIVE SECONDARY SCHOOL MATHEMATICS TEACHERS ON LINEAR VARIATION

Karina Jaquelin Herrera García
Universidad de Sonora
jaquelin_herrera@hotmail.es

María Teresa Dávila Araiza
Universidad de Sonora
maria.davila@unison.mx

Se describe una propuesta formativa para futuros profesores de secundaria en México, cuyo objetivo fue enriquecer sus conocimientos didáctico-matemáticos sobre variación lineal a través de tareas matemáticas, del desarrollo de la competencia de identificación de objetos matemáticos primarios y de la reflexión sobre casos hipotéticos de enseñanza. La propuesta se enmarca en el Enfoque Ontosemiótico (EOS) y en el modelo de Conocimientos y Competencias Didáctico-Matemáticos del profesor de matemáticas; además, sigue una metodología de investigación de diseño fundamentada en el EOS. El análisis de los resultados muestra la complejidad inherente al desarrollo de la competencia de identificación de objetos matemáticos primarios, pero resalta su impacto en el desarrollo de las facetas epistémica y cognitiva del conocimiento didáctico-matemático sobre variación lineal de los futuros profesores.

Palabras clave: Preparación de Maestros en Formación; Conocimiento matemático para la enseñanza; Educación secundaria; Pre-Cálculo.

Introducción y problemática

El estudio de la variación lineal abarca transversalmente el currículo de matemáticas en México; inicia en quinto año de educación primaria, se vuelve central en la escuela secundaria (SEP, 2017) y está presente en los niveles educativos medio superior y superior.

La enseñanza de la variación es importante porque ésta es una noción fundamental para el estudio de fenómenos físicos que se pueden observar en la naturaleza y que se encuentran en las vivencias cotidianas de las personas. Dichos fenómenos tienen la característica principal de ser dinámicos, es decir, involucran procesos que están en constante cambio. En este sentido, la enseñanza de la variación debe favorecer que los sujetos realicen estimaciones, comparaciones y construyan modelos que permitan explicar fenómenos de cambio y resolver situaciones que demande su entorno (García & Ledezma, S/F; Caballero & Cantoral, 2015).

A pesar de la importancia que tiene la enseñanza de la variación, particularmente la variación lineal, el currículo de matemáticas suele promover un estudio estático y limitado de este contenido matemático en la escuela secundaria. Al respecto, autores como Bojórquez, Castillo y Jiménez (2016), Panorkou, Maloney y Confrey (2016), Thompson y Carlson (2017) y Vasco (2006) destacan que el pensamiento variacional de los estudiantes no se desarrolla explícitamente en los planes de estudio de educación básica y que los libros de texto de matemáticas no están formulados desde un punto de vista variacional. Además, argumentan que no se promueve el estudio de magnitudes variables, a pesar de que constituyen una base necesaria para el estudio del cálculo en niveles educativos posteriores; en su lugar, se realiza un estudio estático de la función como regla de correspondencia, sin relación con la variación.

Dado que los planes de estudio y los libros de texto son los materiales principales que tienen a su disposición los profesores de matemáticas de secundaria, y en estos documentos es limitado el tratamiento propuesto para la variación lineal, es pertinente apoyar a los docentes en el desarrollo de una perspectiva más amplia de la variación lineal que oriente su práctica en el aula, de manera que la enseñanza de este tema no quede restringida a un enfoque estático y algebraico.

Particularmente, es importante fomentar de manera temprana que los profesores incorporen a su práctica docente tratamientos didácticos más enriquecidos para la variación lineal que aquellos planteados en el currículo. En este sentido, es pertinente intervenir en la etapa formativa de los profesores de matemáticas, como afirman Godino, Giacomone, Batanero y Font (2017), "la formación didáctica de los profesores […] reclama atención por parte de la Didáctica de la matemática, pues el desarrollo del pensamiento y de las competencias matemáticas básicas de los alumnos depende, de manera esencial, de dicha formación." (p. 91).

Es importante resaltar que son pocas las investigaciones que orientan de forma concreta sobre cómo fortalecer el conocimiento matemático y didáctico sobre variación lineal en programas de formación de profesores, a pesar de que diferentes investigaciones han reportado dificultades en los profesores o futuros profesores de matemáticas con relación a dos nociones estrechamente vinculadas a la variación lineal, la función (Wilhelmi, Godino & Lasa, 2014, Amaya, Pino-fan & Medina, 2016) y la proporcionalidad (Balderas, Block & Guerra, 2014).

Para atender esta problemática, se diseñó, implementó y evaluó una propuesta didáctica para el estudio de la variación lineal, a la que denominó propuesta formativa por estar orientada a futuros profesores de matemáticas. El objetivo de dicha propuesta fue enriquecer conocimientos didáctico-matemáticos de los futuros profesores sobre variación lineal e iniciarlos el desarrollo de la competencia de identificación de objetos matemáticos primarios relacionados con dicha noción matemática. La propuesta se fundamentó teóricamente en el Enfoque Ontosemiótico (EOS) y en el modelo de Conocimientos y Competencias Didáctico-Matemáticos del profesor de matemáticas (CCDM), y siguió una metodología cualitativa de investigación de diseño que integra las herramientas teóricas del EOS. La propuesta formativa incluyó el diseño de una secuencia de actividades con tareas matemáticas y de reflexión didáctica, para lo cual se caracterizaron diferentes significados de la variación lineal (como representación gráfica en rectas numéricas, como representación gráfica en el plano cartesiano, como representación tabular con variaciones proporcionales y como representación analítica) pertinentes para la educación secundaria. Tales significados se detallan ampliamente en Herrera-Garcia (2020) y ponen de manifiesto la diversidad de propiedades, procedimientos, representaciones, etc., que se pueden estudiar sobre la variación lineal desde un punto de vista variacional, y que es esencial que los profesores de secundaria conozcan para que puedan favorecerlos en el aula.

En este escrito se describirán a grandes rasgos las etapas de la metodología seguida para el diseño de la propuesta formativa y la estructura de la secuencia didáctica diseñada. Además, se discutirán algunos de los resultados obtenidos al implementar la secuencia didáctica con futuros profesores de matemáticas de secundaria, ilustrando con el análisis de las respuestas correspondientes a la segunda actividad de la secuencia, las cuales permiten establecer relaciones importantes entre el desarrollo de la competencia de identificación de objetos matemáticos primarios y el desarrollo de conocimientos didáctico-matemáticos de los futuros profesores.

Referentes teóricos

Para formular, implementar y valorar la propuesta formativa se tomó como referente teórico el Enfoque Ontosemiótico del Conocimiento y la Instrucción Matemáticos, EOS (Godino, Batanero & Font, 2007), pues aporta elementos significativos para elaborar un diseño instruccional y herramientas metodológicas que permiten estructurar su desarrollo y valorar su implementación. Fueron centrales para el desarrollo de la propuesta, por un lado, la noción de *significado institucional* de un objeto matemático, que se entiende como el sistema de prácticas matemáticas compartidas en una institución para resolver un tipo de situaciones problema y, por otro lado, la *tipología de objetos matemáticos primarios* que componen el significado de un objeto matemático (Godino, Batanero & Font, 2008): *situaciones problema* (problemas, ejercicios, tareas, etc.)*, conceptos-definiciones* (introducidos mediante definiciones o descripciones)*, lenguajes* (notaciones, expresiones, gráficos, etc., representados de manera escrita, oral, gestual, gráfica, tabular…)*, procedimientos* (técnicas, algoritmos, operaciones)*, argumentos* (enunciados para validar o explicar) *y proposiciones* (enunciados sobre conceptos).

Modelo de Conocimientos y Competencias Didáctico-Matemáticas del profesor (CCDM)

Ante la necesidad de contar con herramientas teóricas que permitan caracterizar y evaluar los conocimientos y competencias didáctico-matemáticos del profesor, se ha desarrollado recientemente al seno del EOS el Modelo de Conocimientos y Competencias Didáctico-Matemáticos del profesor de matemáticas (CCDM) (Godino, Giacomone, Font y Pino-fan, 2018). Este modelo surge como una ampliación del modelo de Conocimientos Didáctico-Matemáticos del profesor de matemáticas (CDM) (Godino, 2009) y ha sido enriquecido por Godino y colaboradores en diversas investigaciones (Pino-Fan & Godino, 2015; Pino-Fan, Godino y Font, 2015) con base en las herramientas teóricas del EOS. En este modelo se considera que el profesor de matemáticas debe tener conocimiento común y ampliado del contenido, es decir, conocimientos sobre las nociones matemáticas que se estudian en el nivel donde se desempeña y sobre contenidos correspondientes a los niveles posteriores (Pino-Fan & Godino, 2015). Además, el profesor debe tener un conocimiento didáctico-matemático, o especializado, de las distintas facetas o dimensiones que intervienen en el proceso educativo: *epistémica*, *ecológica*, *cognitiva*, *afectiva*, *mediacional* e *interaccional*. En este trabajo se consideraron únicamente las facetas *epistémica* (conocimiento didáctico-matemático sobre las matemáticas mismas) y *cognitiva* (conocimiento sobre la manera como los estudiantes aprenden las matemáticas) (Godino, Giacomone, et al., 2017).

Aunado a esto, el modelo CCDM plantea que el futuro profesor también debe desarrollar una serie de *competencias didáctico-matemáticas* que le permitan hacer frente a los problemas de enseñanza de las matemáticas. En particular, en este trabajo se puso el interés en la *competencia de análisis ontosemiótico de prácticas matemáticas*, que, según Godino, Giacomone, Batanero y Font (2017) consiste en la identificación de la red de objetos matemáticos primarios y procesos intervinientes en las practicas matemáticas, que permite al profesor comprender la progresión de los aprendizajes, gestionar los procesos de institucionalización y evaluar las competencias matemáticas de sus alumnos. Es importante declarar que en este trabajo se consideró únicamente, de entre todos los elementos contemplados en esta competencia, la identificación de objetos matemáticos primarios puestos en juego en las prácticas matemáticas realizadas al abordar la secuencia didáctica diseñada, por ello, se hará referencia en este trabajo a la *competencia de identificación de objetos matemáticos primarios*.

Consideraciones metodológicas

Se siguió la metodología para investigaciones de diseño propuesta por Godino, Rivas, Arteaga, Lasa y Wilhelmi (2014), que retoma elementos de la investigación basada en el diseño y de la Ingeniería Didáctica y los articula con las herramientas teóricas del EOS. La metodología consistió de cuatro etapas; *estudio preliminar* (determinar el significado institucional de referencia sobre variación lineal), *diseño de la trayectoria didáctica* (diseño de tareas matemáticas a partir de la elección de objetos matemáticos propios del significado de variación lineal, la creación de aplicaciones de GeoGebra y el diseño de tareas de reflexión didáctico-matemática que integraron en la secuencia didáctica), *implementación de la trayectoria didáctica* (implementación de la secuencia didáctica) y *evaluación o análisis retrospectivo* (del desarrollo de la competencia descrita y las facetas epistémica y cognitiva del modelo CCDM).

Contexto y participantes

La propuesta formativa se implementó con nueve futuros profesores de octavo semestre de Licenciatura en Educación secundaria con Especialidad en Matemáticas de una institución formadora de profesores en México. Se realizaron cuatro sesiones de trabajo con una duración total aproximada de 15 horas. La diseñadora de la propuesta formativa fungió como instructora.

Instrumento recolección de información

El instrumento principal para recopilar la información fue la secuencia de actividades didácticas, la cual se conformó por cinco actividades didácticas con tareas específicas para los futuros profesores, apoyadas en aplicaciones digitales diseñadas con GeoGebra acordes al contenido de cada actividad. Las actividades iniciaban con una situación problema de variación de contexto extramatemático, algunas eran de variación lineal y otras no, con el propósito de ayudar a los futuros profesores a identificar cuándo una situación problema corresponde o no a un caso de variación lineal. Las actividades didácticas fueron impresas en papel y entregadas a cada participante, a quiénes se designó con la letra "E" y un número del 1 al 9. Se dio la instrucción de escribir las respuestas con pluma de diferente color según la modalidad de trabajo: negro para el trabajo individual, rojo para el trabajo en equipo y azul para el trabajo grupal.

Estructura de las actividades de la secuencia didáctica

Cada una de las actividades se organizó en tres partes, atendiendo los siguientes aspectos: el conocimiento matemático, el conocimiento didáctico-matemático y la competencia de identificación de objetos matemáticos primarios. En cada una de estas tres partes de las actividades didácticas se consideraron diferentes modalidades de trabajo: individual, en equipo de tres personas y discusión grupal.

Parte I: *Trabajo matemático*. Esta parte de la secuencia se destinó a la resolución de tareas matemáticas orientadas al enriquecimiento del significado de variación lineal de los futuros profesores. Para ello, se propusieron situaciones de variación lineal y de variación no lineal en diversos contextos, como la relación entre la edad biológica de un perro y los años vividos; la relación entre el peso (kg) de una persona y su estatura; el llenado y vaciado de recipientes cilíndricos. En estos contextos se buscó que los futuros profesores lograran caracterizar la variación lineal a partir de la relación de proporcionalidad entre las variaciones correspondientes de dos magnitudes variables en diferentes formas de lenguaje: rectas numéricas dinámicas en GeoGebra, gráficas cartesianas, tablas de valores y expresiones algebraicas.

Parte II: *Identificación de los objetos matemáticos primarios involucrados en las prácticas matemáticas* desarrolladas en la parte I. En la primera actividad didáctica se buscó que los futuros profesores expresaran qué entendían por tres de los objetos matemáticos primarios. Para ello, se les plantearon las preguntas siguientes: ¿Qué es para ti un concepto matemático?, ¿qué es para ti un procedimiento?, ¿qué es para ti una propiedad/proposición?, adaptadas del trabajo de Giacomone (2018). Es importante mencionar que a los futuros profesores no se les instruyó en el uso del EOS, sino que a través de discusiones grupales se les guio para que, de manera consensuada, se caracterizaran dichos objetos matemáticos a partir de sus ideas iniciales. Una vez establecido qué se entendería por los tres objetos matemáticos mencionados, se les pidió que identificaran aquellos que intervinieron en la resolución de las tareas matemáticas de la Parte I en cada una de las actividades.

Parte III: *Análisis de respuestas dadas por estudiantes hipotéticos de secundaria.* Esta última parte consistió en el análisis de respuestas supuestamente proporcionadas por estudiantes al abordar situaciones problema de variación lineal, con el objetivo de que el futuro profesor analizara la práctica matemática del estudiante, determinara si era o no correcta y creara estrategias para orientar y retroalimentar al estudiante.

Análisis de datos y discusión de resultados

Tras realizar la implementación de las cinco actividades que conformaron la secuencia didáctica, se realizó el análisis e interpretación de las respuestas obtenidas. A continuación, se presentan algunas respuestas correspondientes a las primeras dos actividades didácticas de la secuencia, las cuales son interpretadas desde los referentes teóricos elegidos.

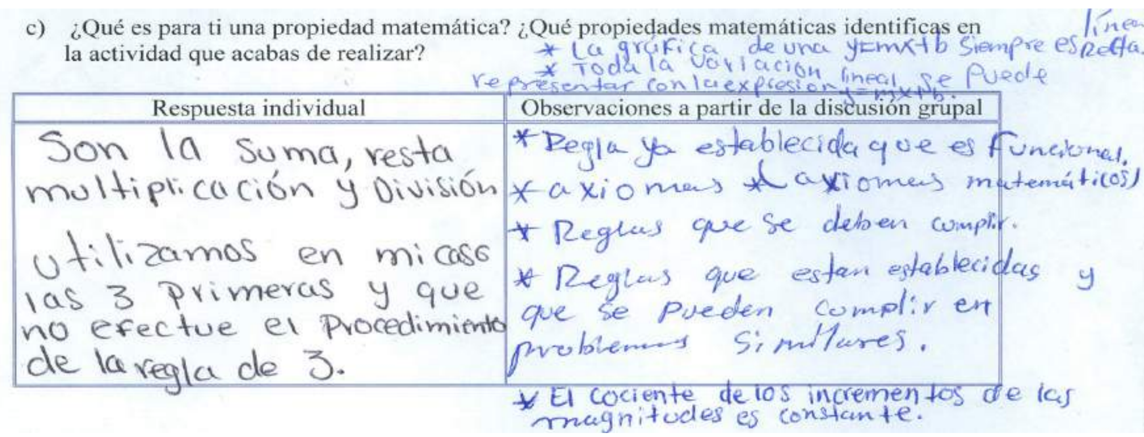
Identificación de objetos matemáticos primarios en sus prácticas matemáticas

Una parte esencial para el desarrollo de la competencia de identificación de objetos matemáticos primarios en las prácticas matemáticas propias o de los estudiantes es tener claridad sobre la diversidad de aspectos matemáticos involucrados al resolver una tarea matemática, es decir, comprender cada uno de los seis objetos matemáticos primarios. En este trabajo, por limitaciones de tiempo, se decidió delimitar la competencia de identificación de objetos primarios a los tres siguientes: procedimientos, conceptos y propiedades.

En la primera actividad didáctica, los futuros profesores realizaron las tareas matemáticas de la Parte I, orientadas a ampliar sus conocimientos matemáticos sobre variación lineal. Luego, en la parte II, donde los futuros profesores debían explicar qué es un concepto, una propiedad y un procedimiento, se encontró lo siguiente. Los futuros profesores no tuvieron problemas para explicar qué es para ellos un procedimiento y fue relativamente sencillo identificar en sus prácticas procedimientos como el cálculo de operaciones básicas (suma, resta, multiplicación y división). En la discusión grupal, la instructora realizó preguntas que guiaran a los futuros profesores al reconocimiento de otros tipos de procedimientos, por lo cual es importante resaltar que la interacción grupal fue fundamental para la identificación de una variedad más amplia de procedimientos, como la regla de tres, los despejes, y el cálculo la constante de proporcionalidad.

El objeto matemático *concepto* fue un poco más difícil de caracterizar por algunos profesores. Por ejemplo, E8 expresó que un concepto matemático "es el problema con el que se está trabajando para darle una solución", lo cual sugiere que para él un concepto es el problema por resolver. Además, E8 no logró emplear la noción expresada para identificar conceptos en sus prácticas matemáticas. Por otro lado, el futuro profesor E7, definió un concepto como: "el significado de una palabra" e identificó término, ecuación y magnitud como conceptos en el trabajo realizado en la parte I. Entre los conceptos identificados por los futuros profesores de manera individual se encuentran: pendiente, proporcionalidad, rectas, términos, constante de proporcionalidad, expresión algebraica y magnitud.

En contraste con lo anterior, para los futuros profesores resultó más complicado explicar qué es una *propiedad*. Por ejemplo, E5 expresó que una propiedad “es un axioma matemático” y E4 escribió que “es una regla ya establecida que es funcional siempre”. Ambos proporcionaron las expresiones algebraicas “$y = mx + b$” y “$K = \Delta y/\Delta x$” como ejemplos de propiedades intervinientes en la parte I de trabajo matemático, lo cual podría sugerir que para ellos las propiedades se expresan de manera algebraica. Otros futuros profesores no lograron proporcionar ejemplos de propiedades. Por otro lado, E8 no explicó que era una propiedad, pero mencionó a la suma y la resta como ejemplos. Es importante resaltar el enriquecimiento que se generó en las respuestas durante la discusión grupal de las respuestas (faceta epistémica del conocimiento didáctico-matemático). En la columna de la derecha (Figura 1), en color azul se puede observar que E8 retoma las ideas de sus compañeros y agrega algunos ejemplos de propiedades, como: “El cociente de los incrementos de las magnitudes es constante”. Esto pone de manifiesto la importancia de las interacciones durante los procesos de instrucción matemática.



c) ¿Qué es para ti una propiedad matemática? ¿Qué propiedades matemáticas identificas en la actividad que acabas de realizar?

* La gráfica de una y=mx+b siempre es recta. línea
* Toda la variación lineal se puede representar con la expresión y=mx+b.

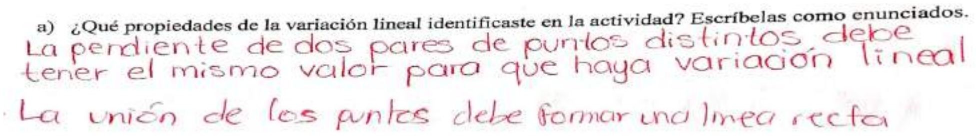
Respuesta individual	Observaciones a partir de la discusión grupal
Son la suma, resta multiplicación y División utilizamos en mi caso las 3 primeras y que no efectue el Procedimiento de la regla de 3.	* Regla ya establecida que es funcional. * axiomas * axiomas matemáticos * Reglas que se deben cumplir. * Reglas que estan establecidas y que se pueden cumplir en problemas similares.

* El cociente de los incrementos de las magnitudes es constante.

Figura 1. Enriquecimiento de la respuesta de E8 tras la discusión grupal

Explicar qué es un concepto y una propiedad fue una tarea difícil para los futuros profesores, como ya ha sido reportado por otros investigadores como Giacomone (2018), Giacomone, Godino, Wilhelmi y Blanco (2018), Burgos, Giacomone, Beltrán-Pellicer y Godino (2017), Burgos, Godino, Giacomone y Beltrán-Pellicer (2018b) y Burgos, Beltrán-Pellicer, Giacomone y Godino (2018a). El reconocimiento de estos objetos en las prácticas matemáticas es una competencia que necesita tiempo para ser desarrollada, en parte por la dificultad de comprender qué son estos objetos. Sin embargo, las tareas propuestas en la secuencia didáctica fueron elementos motivantes para iniciarlos en el desarrollo de su competencia.

Gradualmente, en las actividades posteriores, los futuros profesores lograron identificar de manera más consistente conceptos, procedimientos y propiedades en las prácticas matemáticas realizadas en torno al estudio del tema variación lineal, lo cual pone de manifiesto también el desarrollo de la faceta epistémica de su conocimiento didáctico-matemático. Por ejemplo, en la actividad 2, que trataba sobre la relación entre el peso y la estatura de una persona expresada en una tabla numérica, al crear una gráfica cartesiana los futuros profesores identificaron en sus prácticas matemáticas nuevos conceptos y nuevas propiedades de la variación lineal como las siguientes: “La pendiente de dos pares de puntos distintos debe tener el mismo valor para que haya variación lineal. La unión de los puntos debe formar una línea recta” (Figura 2).



a) ¿Qué propiedades de la variación lineal identificaste en la actividad? Escríbelas como enunciados.

La pendiente de dos pares de puntos distintos debe tener el mismo valor para que haya variación lineal

La unión de los puntos debe formar una linea recta

Figura 2. Respuestas de E5 y E1 durante el trabajo en equipo

Además, los futuros profesores mostraron cambios en el tipo de orientaciones que darían a los estudiantes. Inicialmente, sus orientaciones eran limitadas y se inclinaban a la manipulación de expresiones algebraicas. Después del trabajo matemático y las tareas de identificación de objetos matemáticos primarios en la actividad 2, analizaron de manera más detallada la respuesta hipotética de un estudiante de secundaria (parte III), quien elaboró una gráfica (Figura 3) con datos del peso y la estatura propuestos por el Instituto Mexicano del Seguro Social, y afirmó que se tenía una situación de variación lineal.

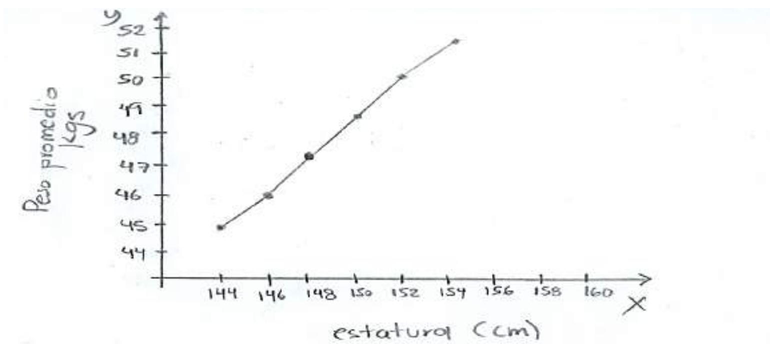


Figura 3. Gráfica trazada por un estudiante hipotético de secundaria

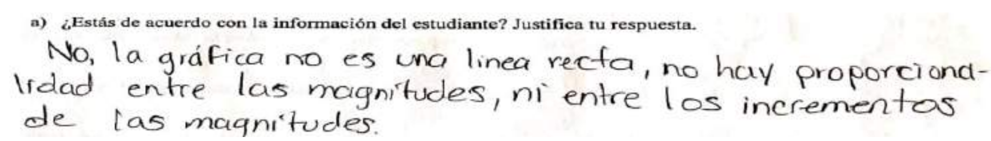
Se les preguntó a los futuros profesores: a) ¿Estás de acuerdo con la respuesta del estudiante?, b) ¿Qué argumentos le darías para reforzar tu punto de vista y retroalimentar al estudiante?, y c) ¿Cómo te ayudaría GeoGebra para retroalimentar al estudiante? Al valorar la respuesta del estudiante, los futuros profesores pusieron en juego los objetos matemáticos primarios identificados en sus prácticas (Figura 2). En la respuesta de E1 (Figura 4) se puede observar fue de su interés analizar la representación gráfica, pues afirma que “no hay proporcionalidad entre las magnitudes, ni entre los incrementos de las magnitudes”, lo cual fue trabajado en la parte I de la actividad. A partir de ese análisis concluye que la respuesta del estudiante no es correcta (hacer esta valoración corresponde a la faceta epistémica del conocimiento didáctico-matemático).

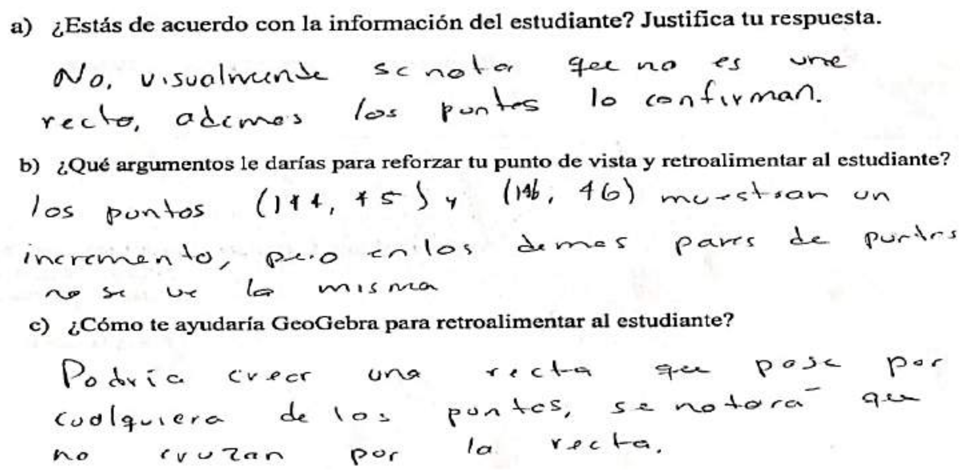


a) ¿Estás de acuerdo con la información del estudiante? Justifica tu respuesta.

No, la gráfica no es una linea recta, no hay proporciona-lidad entre las magnitudes, ni entre los incrementos de las magnitudes.

Figura 4. El futuro profesor E1 argumenta usando propiedades de la variación lineal

Otro ejemplo es el de E9 (Figura 4), quien primero expresa que “visualmente la gráfica no es una recta”. Luego, para retroalimentar al estudiante, propone elegir pares de puntos e identificar que no hay una variación constante. Además, expresa que GeoGebra ayudaría al estudiante mediante la creación de una recta que mostraría que no ésta no cruza por todos los puntos. Estas reflexiones de E9 sobre cómo orientaría a un estudiante, ponen de manifiesto el enriquecimiento de la faceta cognitiva de su conocimiento didáctico-matemático.



a) ¿Estás de acuerdo con la información del estudiante? Justifica tu respuesta.

No, visualmente se nota que no es una recta, además los puntos lo confirman.

b) ¿Qué argumentos le darías para reforzar tu punto de vista y retroalimentar al estudiante?

los puntos (144, 45) y (146, 46) muestran un incremento, pero en los demás pares de puntos no se ve la misma

c) ¿Cómo te ayudaría GeoGebra para retroalimentar al estudiante?

Podría crear una recta que pase por cualquiera de los puntos, se notará que no cruzan por la recta.

Figura 5. Respuesta de E9

En los ejemplos mostrados se puede identificar que los futuros profesores progresaron en sus conocimientos profesionales, tanto matemáticos como didáctico-matemáticos, pues muestran argumentaciones y orientaciones basadas en procedimientos diversos, y propiedades de la variación lineal en diferentes formas de lenguaje, que les permitieron valorar si las situaciones planteadas a ellos y a los estudiantes hipotéticos, corresponden o no a situaciones de variación lineal, en algunos casos utilizando GeoGebra. Es decir, la propuesta formativa permitió que los futuros profesores enriquecieran su conocimiento especializado del contenido de matemáticas, pues podían identificar en sus respuestas objetos primarios propios de la variación lineal, y después, con base a ellos, pudieron argumentar porqué algunas respuestas hipotéticas de los estudiantes estaban incorrectas y proponer estrategias de retroalimentación para el alumno en relación con el estudio de la variación lineal.

Conclusiones

Tras el análisis de las respuestas de los futuros profesores se concluye que la competencia de identificación de objetos matemáticos primarios fue una tarea desafiante para ellos, como se había documentado en trabajos como el de Burgos et al. 2017. Por otro lado, el análisis de sus respuestas sugiere que lograron realizar análisis más finos de sus prácticas matemáticas y de las prácticas matemáticas de los estudiantes hipotéticos, ya que fueron manifestando mayor diversidad de objetos matemáticos primarios en las tareas de reflexión (partes II y III de las actividades).

En la implementación de las actividades se dedicó tiempo a la discusión de ideas y a la comparación de las respuestas dadas, esto generó un momento muy rico de intercambio de opiniones y permitió que los futuros profesores reflexionaran y comentaran sobre otros objetos matemáticos que no habían identificado, pero que con la discusión grupal lograron identificar, lo que permitió enriquecer sus respuestas.

Un aspecto muy importante y que es necesario destacar es que se observó que en un inicio las reflexiones didáctico-matemáticas que generaban respecto a las tareas planteadas, solían ser reflexiones muy limitadas y carentes de argumentos. Posteriormente con el desarrollo de las actividades y con las tareas planteadas para iniciarlos al desarrollo de la competencia de identificación de objetos matemáticos primarios, generaban respuestas más detalladas, que incluían el uso de los objetos matemáticos primarios, esto ayudaba a que las estrategias que proponían para orientar a los estudiantes tuvieran mayor peso en la argumentación basada en el uso de propiedades y procedimientos, identificados previamente en la resolución de las situaciones problema planteados en el diseño de las actividades (trabajo de la parte matemática).

Esto resalta la importancia del desarrollo de esta competencia para su práctica docente, pues genera en los futuros profesores un análisis que toma en cuenta el tipo de objetos matemáticos primarios propios del estudio de algún tema en específico, es decir, funcionó como una herramienta que les permitió observar más que simple detalles, aspectos importantes que consideraron para la enseñanza de la variación lineal.

WHAT DOES IT MEAN TO BE ME? A PRESERVICE MATHEMATICS TEACHER'S IDENTITY DEVELOPMENT DURING AN EDUCATION ABROAD PROGRAM

Blair Izard
University of Northern Iowa
blair.izard@uni.edu

A review of the literature underpinning mathematics education illustrates that in order to achieve an equitable mathematics education, we must consider other methods of preparing mathematics teachers—methods that encourage identity development, specifically cultural awareness and open-mindedness as two key facets of this construct. This study describes and interprets a preservice mathematics teacher's identity development during a semester-long mathematics-focused education abroad program. Findings suggest that we can foster alternative visions of identity—ones that have a better understanding of culture and a greater sense of open-mindedness—through participation in such culturally-rich international programs.

Keywords: Cross-cultural Studies, Equity and Diversity, Teacher Beliefs, Teacher Education-Preservice

Purpose

A review of the literature underpinning mathematics education illustrates that in order to achieve an equitable mathematics education, one that is free of systemic forms of inequality, we must consider other methods of preparing mathematics teachers—methods that encourage identity development, specifically cultural awareness and open-mindedness as two key facets of this construct. For example, the National Council of Supervisors of Mathematics (NCSM) and TODOS: Mathematics for ALL (TODOS) have suggested that mathematics teachers must take a stance that "interrogates and challenges the roles power, privilege, and oppression play in the current unjust system of mathematics education—and in society as a whole" (2016, para.1). In addition, the National Council of Teachers of Mathematics (NCTM) has suggested that in order to promote a culture of access and equity within mathematics education, teachers should be "responsive to students' backgrounds, experiences, cultural perspectives, traditions, and knowledge" (2014, pg. 1). Furthermore, others have noted preservice or in-service mathematics teachers initially dismiss the idea of teaching social justice, believing that it does not belong in mathematics (de Freitas, 2008; Ahlquist, 2001; Weissglass, 2000). As De Freitas has said, "Those frequently heard comments—'I'm just a math guy,' 'I'm one of those people who likes math for the sake of the math only,' 'I'm not one for social justice'—share a particular vision of identity as being a fixed, unmovable, and irresolvable entity" (2008, p. 50), and unfortunately that is a mindset we often see in mathematics.

So, what kind of preparation program do preservice mathematics teachers need? Weissglass has said "any serious attempt to achieve equity in mathematics education must be rooted in an ongoing process of increasing our understanding of how individual prejudices, unaware biases, and systemic societal discrimination affect teaching and learning" (2000, p. 10). Gutstein has asserted that more work needs to be done to alter teachers' personal belief systems built on deficit thinking, specifically when working with diverse children (2000). De Freitas has suggested, "Alternative visions of identity are required" in order to change the fixed, closed mindsets of mathematics teachers and begin to develop a critical mathematics education (2008, p. 49). As Neumayer-Depiper has said, it is not enough to simply develop a set of effective mathematics teaching practices (2009). We must consider other methods of preparing mathematics teachers, methods that encourage identity development. Rather than having a fixed, closed mindset as De Freitas describes, we want preservice mathematics teachers to develop an identity that is more open-minded. We also want our preservice mathematics

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

teachers to have a developed sense of their own cultural identity and, as Weissglass says, an increased understanding of how their individual prejudices and unaware biases affect teaching and learning.

Participation in an education abroad program can address these needs and help foster mathematics teachers that are open-minded and have an established sense of their cultural identity. As such, the purpose of this study is to examine how education abroad influences the identities of preservice mathematics teachers in ways that they become more culturally aware and open-minded.

Theoretical Framework

Research has indicated that throughout an education abroad experience, students "challenge their beliefs about the world and its people, develop empathy for and trust in others, learn a significant amount about at least one other culture, and often to their surprise, learn quite a lot about their own culture" (Cushner, 2009, p. 160). Much of this learning comes from being immersed in another culture and having the experience of feeling like a cultural outsider. Merryfield (2000) found that those who left the US and experienced living in another culture "came to understand temporarily what it feels like to live outside of the mainstream…. They became conscious of what happens to identity when people know they don't belong" (p. 439). This reality of feeling like a cultural outsider is a feeling that many mainstream teachers in the US have never experienced, and it leads to a personal understanding of what it is like to be marginalized and stereotyped. This is an impactful experience that facilitates teachers "to become more ethnorelative in their understanding of others, more skilled at crossing cultures, and committed to bringing about change through their work" (Cushner, 2009, p. 165).

Beyond impacting students in these ways, education abroad also has the potential to impact identity on a deeper level. Teacher professional identity is a core aspect of the teaching profession (Sachs, 2005). "It provides a framework for teachers to construct their own ideas of 'how to be', 'how to act' and 'how to understand' their work and their place in society" (p. 15). The development of teacher professional identity is an ongoing process (Beijaard, Meijer & Verloop, 2004) that cannot be forced. Instead, "it is negotiated through experience and the sense that is made of that experience (Sachs, 2005, p. 15). Participation in an education abroad program can impact the identities of preservice mathematics teachers in ways that they become more open-minded and culturally aware, ultimately inspiring a more updated and progressive vision of teaching mathematics. However, little is known regarding the impact of education abroad programs on the identity development of preservice mathematics teachers—specifically their intercultural competencies and open-mindedness as two key facets of this construct. This research explores this timely area of inquiry.

Methods and Data Sources

This is a qualitative case-study of one preservice mathematics teacher's identity development throughout a semester-long education abroad program in England. This program was meant specifically for preservice mathematics teachers (elementary and secondary). Students work at a mathematics education research center, intern in schools, and take mathematics education classes at a university.

This study began the summer prior to their semester abroad and ended shortly after their return to the United States. Three main data collection methods were used: semi-structured interviews, in-country participant observation, and document review. Documents such as student journals, coursework, and the Intercultural Development Inventory (IDI) were used within this study.

The IDI (Hammer, Bennet & Wiseman, 2003) was administered to participants prior to their departure and again upon return to the United States. This assessment places participants on a continuum ranging from "ethnocentric" to "ethnorelative." Ethnocentrism is defined as "the experience of one's own culture as 'central to reality'", in which "the beliefs and behaviors that people receive in their primary socialization are unquestioned: they are experienced as 'just the way things are,'" (Bennett, 2004, p. 62). Ethnorelativism is "the experience of one's own beliefs and behaviors as just one organization of reality among many viable possibilities" (Bennett, 2004, p. 62). There are there categories related to ethnocentrism: Denial, Polarization, and Minimization, and two categories related to ethnorelativism: Acceptance and Adaptation. Teachers with an ethnorelative mindset would be more inclined to engage with students in ways that respect their cultures, backgrounds, and experiences, ultimately meeting NCTM's (2014) call for a responsive mathematics education.

The interviews and in-country observations provided insight into their experiences and day-to-day activities within the program and enabled me to explore and uncover in what ways participants' thinking about culture, mathematics teaching, and open-mindedness evolved throughout the program.

Results

The case presented in this study, whom I will refer to as Ben, showed growth in both cultural awareness and open-mindedness. Ben is a white male who turned 22 years old while participating in this program. Prior to departure, Ben fell in the "ethnocentric" category of the IDI, specifically within minimization (see figure 1). A person within minimization is typically color-blind, "focusing on commonalities and universal values, emphasizing similarities, and holding the belief that all people are fundamentally the same" (Cushner, 2009, p. 156).

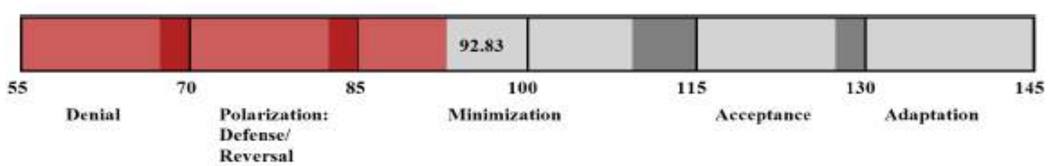

Figure 1: Ben's IDI score at the start of the program

This aligns with some of Ben's comments from the start of the program in which he expressed that he avoided seeing culture because it would prevent him from understanding the individual person at hand. Ben described that he preferred to pay attention to individual (not cultural) differences, saying, "Generalizing cultures, in my opinion, is a bad thing as it takes away the ability for the individual to be themselves."

Ben also had trouble describing his own culture. In our first interview, he described himself as "Caucasian," "Polish," and "Italian," but indicated these weren't identities that he felt connected to. Rather, he said "culturally, it would be more accurate to say my family is a family of helpers over any specific background" because his mom was an occupational therapist and his dad taught in an elementary school. He described that his family was privileged in the sense that they didn't need to identity with "race," or "culture," and that they could identify with something else entirely, like being "helpers."

To Ben, America was too multifaceted to generalize, and he had trouble articulating what it meant to be American. He discussed that there may be "things [people] in the US share, but a majority of those people have vast differences… The culture of the US is close to not being generalizable at all." He was also tentative to label himself as American:

> I guess I consider myself American in the sense that I was raised in America, but I feel like America is too broad of a thing for me to consider myself as…. So, I would say in a manner of speaking, I identify as American because I grew up in America. But I don't really identify with anything that I know could be a generalization of Americans, that I'm aware of.

Throughout the program, Ben wrote journals documenting his beliefs of what qualifies as good mathematics teaching. At the beginning of the program, Ben had little awareness of his own culture, his students' cultures, and how these identities would influence his classroom. When reflecting on what qualifies as good mathematics teaching, Ben spoke of his own views of the subject and what he deems important, saying, for example, that he values conceptual understanding of the subject and views procedures as "tedious," and "a mindless waste of time." However, he never mentioned his students or the experiences and perspectives they may bring to the classroom.

Once Ben arrived in England, he began to notice surface-level cultural differences like driving on the other side of the road, but throughout the program, he began to notice deeper cultural differences such as how the concept of time was viewed in England versus the United States along with contrasts in professional communication styles. He discussed the experience of feeling like an American, a concept he had never thought about previous to this education abroad experience, as he said, "once you open your mouth, people already have all these views of you." He also discussed how he was constantly asked to speak for all of America: "Right off the bat, people were asking me about Trump, school shootings, and violence in America. It was weird being the spokesperson for that." These experiences forced Ben to consider his culture, and he began to notice differences across cultures.

Throughout the program, Ben also began to recognize aspects of American culture. He discussed how America was founded on "sticking it to the man," and "standing up for itself at a time where they felt taken advantage of." He acknowledged that there is a spirit of rebellion in England, saying "there is plenty of public protesting" relating to Brexit, but that he sees this value as being more prevalent in American society. He wrote, "In England, being rebellious is not seen as something valuable," giving as examples, "Students wear uniforms to class, rather than getting to express themselves in different ways," and "They have a formal relationship with their teachers that revolves around the teacher being the head of the classroom." He also described how there was no desire to own a weapon in England, but that America was "founded on the ability to rise up against oppression and rebel," and that "We have a right to bear arms in America so that if we are oppressed, we can take appropriate measures to challenge what is there." He went on to say, "I would argue that the times have changed and we need to reconsider this value," but at the end of the day, the right to bear arms comes from "the spirit of rebellion, a crucial piece of our founding virtues." These types of reflections about cultural differences occurred throughout the entire program.

By the end of the program, Ben's IDI report demonstrated growth (see figure 2). While he still fell within the category of minimization, he was approaching acceptance, an orientation the reflects a recognition and appreciation of cultural differences.

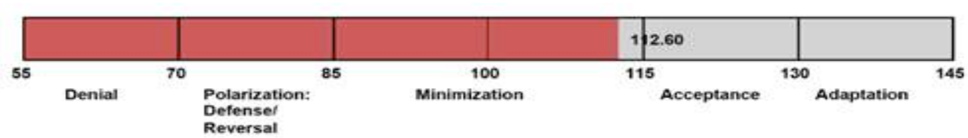

Figure 2: Ben's IDI score at conclusion of the program

Ben also expressed that he was now more interested in culture and that he "keeps cultural and identity in mind, rather than solely the individual." Additionally, he expressed a new understanding of himself and his students, saying:

> I can say my time in Europe has changed what I enjoy about math. I still believe in what I said previously, that the best piece for me is problem solving and the conceptual. I also think that's the most important piece of math. But I think that I've missed something crucial about math. Reflecting on different cultures and understanding of the world has helped me understand some of the disconnect between my students and I back when I was student

> teaching. The truth is, they valued getting a correct answer. They didn't care how. It was the beauty and relief of finishing a problem with a tool they had that pushed them forward. It wasn't their skill, but their ability to use a tool that connected them to the mathematics. Up until studying here and thinking deeply about cultural differences I failed to see some people fundamentally don't feel the way I do.

Throughout the program, Ben began to notice and appreciate cultural difference, ultimately saying:

> Looking at what my students' value, how my students view math, how my students view education, and applying it to my own understanding to grow and change my teaching style overtime is going to be fundamental to my practice…. I will be careful to not push my own view of the mathematics on the students, rather I will shape my strategies and methods to what they enjoy, value, and believe. Over time, after gaining my students trust, I will offer different options to pieces already in place…. Careful reflection on my students and their situations and their founding principles will lead me to become a better, more effective, efficient teacher that can reach out to students in many different ways rather than simply through the mathematics.

By the end of the program, Ben expressed a deeper understanding of his culture and a greater need to pay attention to his students' cultural identities. His descriptions of teaching mathematics had evolved to more closely align with NCTM's call for mathematics teachers that are "responsive to students' backgrounds, experiences, cultural perspectives, traditions, and knowledge" (NCTM, 2014, pg. 1).

Conclusions

Ben's journey throughout this program suggests that through participation in education abroad programming, preservice teachers can become more culturally aware and open-minded. At the start of the program, Ben had little understanding of his own cultural identity, and he avoided noticing cultural difference. His orientation towards cultural difference fell within the category of minimization, reflecting "a tendency to highlight commonalities across cultures that can mask important cultural differences in values, perceptions, and behaviors," (Ben's IDI profile, pg. 6). In addition, when Ben would reflect on his beliefs of what qualifies as good mathematics teaching, he never mentioned his students or the importance of including their perspectives, experiences, and backgrounds into his classroom. Proponents of culturally responsive teaching argue that "Explicit knowledge about cultural diversity is imperative" (Gay, 2002, p. 107) to meet the needs of the diverse student population. As such, Ben was far from achieving this.

However, by the end of the program, he was recognizing that culture influences the experiences, values, beliefs, and perspectives that people have, and he was aware that his students' culture, specifically their experiences and values, were different from his own. He indicated that he now believed his, and his students', cultural identities would influence their experiences in the classroom, and he discussed a desire to incorporate his students' perspectives and values into his teaching. He said that within his teaching, he would take "it slow and not make assumptions" about his students based on his prior experiences, and that he would instead consider his students' prior experiences.

Ben's orientation of minimization is a reflection of the orientations of many teachers across the country. For example, Mahon (2003) studied 155 teachers in the midwestern US, and found that 100% of them fell at minimization or below. This is problematic on many levels. When we avoid noticing culture, it's the dominant culture that is assumed to be "the" culture, and any other cultures may be ignored, or even worse, shut down or demonized. Furthermore, a minimization mindset would limit our ability to create an equitable mathematics education for all students. In order to address issues of racial, cultural, and socioeconomic inequity, we need to see race, culture, and socioeconomic status. Rather than ignoring culture, we want our teachers to acknowledge and include various cultural perspectives within the classroom.

Given Ben's evolution throughout this program, there appears to be potential for shifting the ways in which we prepare mathematics teachers. If we look to NCTM, NCSM, TODOS, and others, we can see calls for addressing issues of equity, access, and social justice in mathematics education. NCTM (2014) has articulated that teachers should be responsive to students' cultures, experiences, and backgrounds. NCSM and TODOS (2016) have suggested that mathematics teachers interrogate the roles of power, privilege, and oppression within mathematics education. At the beginning of this study, Ben was ignoring culture—not recognizing his own culture or the culture of others—making it nearly impossible to achieve the calls from NCTM, NCSM, and TODOS. This study highlights that we can foster alternative visions of identity—ones that have a better understanding of culture and a greater sense of open-mindedness—through participation in such culturally-rich international programs.

CLASSROOM EVENTS ON PROBLEM SOLVING WITH GEOGEBRA ANTICIPATED BY FUTURE MATHEMATICS TEACHERS

Alexánder Hernández	Josefa Perdomo-Díaz	Matías Camacho-Machín
Universidad de La Laguna	Universidad de La Laguna	Universidad de La Laguna
shernanh@ull.edu.es	jperdomd@ull.edu.es	mcamacho@ull.edu.es

This paper presents an analysis of the classroom events that a group of future teachers of Secondary Education mathematics identified from their own experience when using GeoGebra to solve problems. The data analyzed are from the written materials by twelve mathematics majors who were studying the Mathematics for Teaching course. The students, in pairs, solved three problems using GeoGebra. They were then asked to posit three events that could arise if their students were to use GeoGebra to solve problems. After analyzing the events presented, they were classified in terms of mathematical reasoning, mathematical creation and techno-mathematical ability.

Key words: Teacher training, problem solving, technology, classroom situations.

Introduction

Teacher training is a complex field of study that ranges from identifying the knowledge required to teach a discipline, to proposing strategies for developing that knowledge. The incorporation of technology into the process of teaching and learning mathematics poses new challenges in teacher training, particularly when defining training programs. What kinds of activities should be conducted during the training period of a mathematics teacher? What technological tools should be used? How should they be used? How does the use of technology influence their initial training?

On the one hand, the appearance of a certain type of technology has expanded the set of tools available to teachers to respond to events or contingencies that occur in the classroom. For example, Rowland and Zazkis (2013) analyze possible actions in response to a hypothetical answer from a student who is asked to provide a fraction between ½ and ¾. The student answers 2/3, stating that for the numerator she chose 2 because it is between 1 and 3, and for the denominator she chose 3 because it is between 2 and 4. One of the options, presented by the authors, for incorporating the student's idea into the classroom proposes representing, with the aid of technology, a geometric situation that can intuitively provide an answer. This would be done by representing the fractions as the slopes of lines that pass through the origin and through a coordinate point (n, d), where n is the numerator and d the denominator of each fraction.

On the other hand, the use of technological tools in the classroom gives rise to certain types of situations that would not appear in another context. Wasserman, Zazkis, Baldinger, Marmur, & Murray (2019) provide an example in which a group of students used a MAPLE command to confirm that a number is prime. When an operation was entered as the input argument (14:2), MAPLE indicated that it was not a prime. This would not have happened if the input had been a number (7). The authors note that this contingency could be exploited to interact with students and discuss the importance of differentiating number sets and conceptualizing multiplication with rational numbers. Hernández, Perdomo-Díaz and Camacho-Machín (2018) present an analogous situation, in this case by using GeoGebra. This program does not provide an answer when the Tangents tool is used, entering as input values two points, one outside the circle and the other on the circumference. This situation offers the opportunity to discuss, with students, questions such as: Why is nothing happening? What important properties related to lines tangent to a circle do these values not consider? That is, the contingency could be leveraged to have a discussion with students on the properties of lines tangent to a circle and how GeoGebra processes them when plotting these lines.

(2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

GeoGebra is one of the most widely used technological tools for teaching and learning mathematics. Its greatest potential lies in the fact that it is a dynamic geometry software (DGS) package that is dynamic enough to analyze questions, conjectures, discover mathematical properties and establish connections between known properties (Jacinto & Carreira, 2017; Sánchez-Muñoz, 2011; Santos-Trigo & Camacho-Machín, 2013). Given this context, teachers must be familiar with the program and have experience using it so as to take advantage of the opportunities that technology offers to gain mathematical knowledge (Camacho-Machín & Santos-Trigo, 2016). Teachers must also possess a certain ability and expertise to deal with the mathematical questions, doubts, and interpretations that arise every day in classrooms (Conner, Wilson, & Kim, 2011). When an event occurs in the classroom, the teacher must decide whether to ignore it, set the issue aside after considering it or try to incorporate it into the class, which in many cases has a certain improvisational component (Rowland & Zazkis, 2013). For Conner, Wilson and Blume (2011), making a good decision requires a certain type of knowledge and skill. It takes "a particular kind of expertise which includes a deep mathematical knowledge that allows them to recognize the opportunity, weigh its merits, and skillfully pursue or dismiss the opportunity" (p. 979).

An analysis of the problem-solving process with GeoGebra that an individual employ can be used to identify interesting situations to propose as activities for training teachers (Camacho-Machín, Perdomo-Díaz, & Hernández, 2019). But it is also interesting to see what situations future teachers imagine could occur when they ask their students to use GeoGebra to solve problems. Anticipating possible events or contingencies that could come up in class is one way to develop teaching skills (Carrillo, 2015). Consequently, analyzing contingencies and anticipating exercises can provide a connection between the training of future mathematics instructors and teaching in Secondary Education. This leads to the question that prompted this research: What kind of classroom situations do future secondary education mathematics teachers anticipate from their own experience using GeoGebra to solve problems?

The work presented here consists of an exploratory study that addresses this question. The research was conducted with a group of mathematics majors who were taking the "Mathematics for Teaching" course. One part of this course consisted of analyzing classroom situations proposed by Heid, Wilson, & Blume (2015), and another part of the course involved doing a Problem-Solving Workshop using GeoGebra. As part of the final activity in this workshop, the students were asked to identify situations that might arise in a secondary education math class in which GeoGebra is utilized to solve problems. The goal of this research is to analyze classroom situations involving the use of GeoGebra to solve problems anticipated by the participants.

Conceptual Framework

The reference for this research is a framework developed from real and hypothetical situations involving secondary education mathematics classes known as Mathematical Understanding for Secondary Teaching (MUST) (Heid, Wilson, & Blume, 2015). This framework considers that the mathematical understanding that an individual need to teach the discipline in high school can be described from three different, closely interrelated, perspectives: mathematical proficiency, mathematical activity and mathematical context. The first perspective focuses on "knowing" mathematics, the second on "being able to do" mathematics, and the third on the ability to "adjust" that knowledge and know-how to secondary education students (Kilpatrick et al., 2015). As these authors point out, this particular understanding of mathematics, typical of a teacher's endeavor, has a dynamic character, since it starts to take shape based on the understanding that a teacher would have as a student, before developing and transforming during the teacher's training and subsequent career.

When analyzing mathematical understanding for teaching from the perspective of mathematical proficiency, the focus is on mastering the content being taught and the ability to make connections between the concepts to be taught and other mathematical content. This perspective thus includes components such as conceptual understanding, proficiency with procedures, strategic competence and flexible reasoning (Kilpatrick, 2015). For Camacho-Machín and Santos-Trigo (2015), the development of these four components is essential for learning that is characterized by constant questioning and problem solving.

From the perspective of mathematical activity, mathematical understanding for teaching comprises the set of specific mathematical actions that an instructor performs while teaching. Zbiek and Heid (2018) advocate for a teaching practice in which the mathematical activity is made explicit, such that the discipline can be extended beyond the content of the subject, consisting of procedures and concepts. The MUST model defines this perspective from three interrelated components (Kilpatrick et al., 2015):

- Mathematical perception: Groups the actions of recognizing and identifying the mathematical characteristics specific to the different structures, the different notations or symbolic forms, as well as the ability to ascertain when a mathematical argument, whether expressed simply or rigorously, is valid, and the ability to connect mathematical ideas with each other (representing ideas in different structures and connecting various concepts) and with the real world (explaining physical problems through mathematics).
- Mathematical reasoning: Groups the observe, conjecture and justify or prove activities by using deductive logic, mathematical properties, regularities and patterns, generalizations of specific cases, restricting properties and extensions to other structures.
- Mathematical creation: Implies the ability to find new paths to express mathematical objects, generate new ones and transform their representation. This is related to choosing representations of objects that highlight their structure, restrictions or properties, when new objects are defined and when they are manipulated by changing their form, but not their representation.

Finally, the mathematical context perspective includes aspects of mathematical understanding that come into play exclusively in the teaching profession, such as recognizing the mathematical nature of students' questions and errors, or recognizing when an argument or solution provided by a student is incomplete or satisfies the conditions of a problem (Kilpatrick, et al., 2015). Among its components, the authors include: synthesizing mathematical ideas, interacting and understanding students' mathematical thinking, knowing and using the curriculum, evaluating students' mathematical knowledge, and reflecting on the mathematics employed in the classroom.

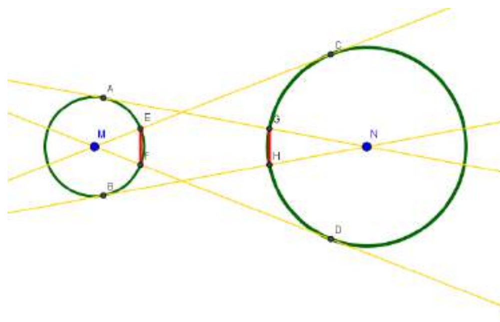
This research combines the mathematical context and mathematical activity perspectives. The former was taken into account in the design of the tasks proposed for the students; specifically, the last component was emphasized by reflecting on the mathematics employed in the classroom, asking students to anticipate *Situations* that could arise in a Secondary Education class where GeoGebra is used to solve problems. For MUST framework, a *Situation* is "a way of capturing classroom practice […] portrays an incident that occurred in the context of teaching secondary mathematics in which some mathematical point is at issue" (p. 4). In each *Situation* a *Prompt* and a set of *Mathematical Foci* can be distinguished. A *Prompt* is something that has occurred or may occur in the context of teaching mathematics, such as a student' question, or a mathematical fact that a student has identify. The *Prompts* proposed by participants were analyzed from the mathematical activity perspective, using their three components as the basis for classifying them.

Methodology

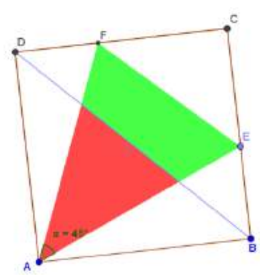
The participants in this research were the students in the "Mathematics for Teaching" course, which is offered as an elective for senior-year mathematics majors at the University of La Laguna (Spain). The main goal of this course is to develop the students' theoretical, practical and instrumental skills associated with the activity of teaching mathematics at the high school and university levels. This includes knowing and using heuristic strategies for solving math problems, as well as technological tools for teaching and learning mathematics.

The data were collected in the 2017-2018 school year over the course of four weeks, in which the students devoted half the class time to analyzing classroom situations designed under the MUST framework (Heid, Wilson & Blume, 2015), and the other half to participating in a GeoGebra Problem Solving Workshop. The workshop consisted of eight, two-hour sessions. In the first five, the students solved the following three problems:

Equal chords. Given two circles with centers M and N, lines are drawn from the center of each that are tangent to the other. The points where the tangents lines intersect the circumferences define two chords, EF and GH. Prove that the length of the chords is the same.



45º angle. Given a square ABCD, draw a 45º angle inside the square, with its vertex at A. This yields two rays that cut the sides opposite A at points E and F (see drawing). Study the relationship between the two parts when triangle AEF is divided by the diagonal BD.



Connect Islands. We want to connect three islands (A, B, and C) with a fiber optic network in a way that uses the least amount of cable. The distances between the islands are 79,322 m (A-B), 64,514 m (A-C) and 95,932 m (B-C). Where should the connection point be located to minimize the amount of cable needed?

In the last three sessions, students focused on identifying and analyzing *Situations*, in the sense of MUST framework, that could happen in a high school mathematics class in which GeoGebra is used to solve the above problems. The data analyzed in this paper are from the report that the students had to submit as a product of those last sessions. The instructions given to the students were:

- Write *Situations* resulting from the use of technology in solving workshop problems.
- In each *Situation* indicate at least three *Prompts*, using GeoGebra to show how they arise.
- Select a *Prompt* for each problem and identify a set of mathematical foci relevant to the prompt.

This activity was intended for students to establish connections between the problem solving activities with GeoGebra that they had carried out in the workshop and the analysis of classroom situations that they had done in the parallel sessions. In this way, the participants moved from a role as students to a role as teachers, taking their own experience using GeoGebra to solve problems as a reference point to reflect on possible situations that may occur in a mathematics classroom where this type of didactic resources.

The course was taken by 18 students, who worked in pairs. For this paper, only the reports from six of the student pairs were selected. The selection criterion was that the students must have handed in all the tasks from the workshop and the study correctly and on time.

The analysis process consisted of identifying what role GeoGebra played in each of the *Prompts* indicated by the participants, and what components of mathematical understanding for teaching that MUST proposes from the perspectives of mathematical activity underlies those prompts. From there, types of class situations were defined that future teachers anticipate from their own experience using GeoGebra to solve problems.

Data analysis

An analysis of the content of the reports prepared by the six students pairs allowed us to identify three types of *Prompts*:

Type 1: The focus is on giving a mathematical explanation to the operation of a GeoGebra tool. These *Prompts* have to do with the development of techno-mathematical ability (Jacinto and Carreira, 2017).

Type 2: *Prompts* that involve justifying or demonstrating a mathematical property that has been observed when making a dynamic construction with GeoGebra.

Type 3: *Prompts* where a conjecture is formulated and GeoGebra is used to build new elements that allow it to be proven or rejected.

The last two types of *Prompts* are closely related to mathematical reasoning and mathematical creation, which are components of mathematical understanding for teaching from the perspective of mathematical activity (Kilpatrick, et al., 2015).

Type 1: The *Prompts* in this category arise directly from the use of tools implemented in GeoGebra and from an understanding of the mathematics on which it is based. Four of the student pairs identified *Prompts* of this type (Table 1). Three of them (P1, P3 and P5) proposed an event related to the use of the Tangents tool that yields an answer they understand; however, it could lead to a classroom situation where a student asks about the steps GeoGebra performed to give that answer. Pair P8 identified an event in which students would question an answer provided by the DGS.

Table 1: Prompts related to the mathematical meaning of actions in GeoGebra

Problem	Topic	Summary of the Prompt	P1	P2	P3	P5	P7	P8
Equal chords	Tangent lines	Can a tangent line to a circle be drawn from an outside point without using the *Tangents* tool?	■	-	■	■	-	-
Equal chords	Tangent lines	Using the *Line* tool, a line tangent to a circle is constructed from an outside point. Why does it seem to satisfy the tangency property when it actually does not?	-	-	-	-	-	■

Type 2: This category includes *Prompts* that relate to the need to prove or demonstrate mathematical conjectures arising from the use of GeoGebra. These hypothetical events related to the action of seeking a justification, whether formal or not, describe a classroom situation in which a secondary education student discovers a property while solving a problem with GeoGebra and asks

the teacher about its veracity or gives an argument that requires formalization. This is the category into which most of the *Prompts* were classified, a total of 10 (Table 2), although all were proposed by three of the student pairs (P1, P3 and P5).

Table 2: Conjectures from Prompts related with mathematical reasoning

Problem	Topic	Summary of the conjecture	P1	P2	P3	P5	P7	P8
Equal chords	Tangent lines	A line tangent to a circle forms an angle of 90° with the radius that connects the center to the point of tangency.	-	-	■	-	-	-
Equal chords	Bisector	The two triangles that are formed by a chord, the two radii it connects and the bisector of these radii are congruent.	■	-	-	■	-	-
Equal chords	Bisector	The bisector of the two lines tangent to a circle from an outside point passes through the center of the circle.	■	-	■	-	-	-
Equal chords	Similarity	Two overlapping triangles (with a common angle) are similar, although they are not in the Thales position.	-	-	-	■	-	-
45° angle	Invariant	Given a family of triangles AEF, where angle A measures 45°, and inscribed in a square ABCD with side l, such that A is on a vertex and E is on side BC, then the height from A of any triangle in the family is constant and measures l.	-	-	■	■	-	-
45° angle	Diagonal of the square	Given a point P on the diagonal that joins two vertices of a square, draw two segments to the other two vertices. This yields four triangles. The heights of the triangles from P match pairwise.	■	-	-	■	-	-
Connect islands	The Fermat point	The Fermat point is the point of intersection of the three circles in which the equilateral triangles used to build it are inscribed.	-	-	-	■	-	-
Connect islands	The Fermat point	The Fermat point, along with three vertices of one of the equilateral triangles used to construct it, form a cyclic quadrilateral.	-	-	■	■	-	-
Connect islands	The Fermat point	The three segments that connect the Fermat point of a triangle with the vertices of the equilateral triangles used to construct it form angles of 120° with one another.	-	-	■	-	-	-
Connect islands	Rotations	Given two points A and B, the triangle formed by A, B and the point resulting from rotating B 60° with respect to A is equilateral.	-	-	■	-	-	-

Type 3: This last category includes the *Prompts* submitted by the student pairs who propose using GeoGebra as a resource to check a previous mathematical idea. Eight *Prompts* of this type were identified (Table 3), presented by four of the pairs (P1, P2, P7 and P8). Unlike the previous category, the formula to describe the *Prompt* starts from a situation in which the high school students have an idea, and then resort to technology to test it. This approach induces a change in the follow-up actions. An existing mathematical idea has to be transferred to a dynamic construction such that the mathematical property to be verified is represented and emphasized. This type of proposal would provide a starting point to develop mathematical creation.

Table 3: Properties from Prompts related to mathematical creation

Problem	Topic	Summary of the mathematical property	P1	P2	P3	P5	P7	P8

Equal chords	Tangent lines	Given two circles and the lines tangent to them from the centers of the other, the chords formed by the tangency points are equal, as are the lines formed by the points of intersection with the secant lines.	-	■	-	-	-	-
Equal chords	Bisector	The bisector of an angle divides any triangle limited by the rays into two congruent triangles.	-	-	-	-	■	-
45° angle	Invariant	The area of a family of polygons inscribed in a triangle is constant.	■	-	-	-	-	-
45° angle	Diagonal of the square	Given two similar triangles, there is a proportionality ratio between their areas.	-	■	-	-	-	-
45° angle	Invariant	Given a rectangle, draw a 45° angle at one of its vertices so as to make a triangle with the points of intersection on the non-contiguous sides. The diagonal of the rectangle divides the triangle into two surfaces with the same area.	-	-	-	-	■	■
Connect islands	The Fermat point	The Fermat point minimizes the sum of the distances to the vertices for any triangle.	■	-	-	-	■	-
Connect islands	The Fermat point	The three segments that join the Fermat point of a triangle with the vertices of the equilateral triangles used to construct it have the same length.	-	■	-	-	-	-
Connect islands	Significant points	In any triangle, the sum of the distances from the vertices to the circumcenter is the minimum possible. (Idem with barycenter, orthocenter, incenter)	-	-	-	-	-	■

This type of *Prompt* includes minor questions that extend or stray from the solution to the original problem. In general, delving into these questions could be useful to segue or connect to other mathematical results. A relevant exercise to prepare for future contingencies is knowing the various branches that originate from a problem and reflecting on potential connections to mathematics. From the point of view of Mathematical Context, the participants showed an ability to reflect on the mathematics of teaching practices, a necessary skill in the classroom (Heid, Wilson, & Blume, 2015).

Final discussion

The main objective of the reflection task proposed to the students in the "Mathematics for Teaching" course was to place them in the teacher's role after having solved a set of problems using GeoGebra. This activity was proposed as a way to anticipate potential contingencies that they would have to deal with in a classroom where GeoGebra is used to solve problems. The goal was to develop their mathematical understanding for teaching from the perspective of the Mathematical Context of Teaching, a component of which is reflecting on the mathematics of teaching practices (Heid, Wilson, & Blume, 2015).

All the student pairs proposed at least one event involving the use of technology for each of the problems. This shows that the participants, in this initial stage of their training as teachers, developed to a certain degree their ability to reflect on the mathematics of teaching practices (Kilpatrick, et al., 2015). However, there are some differences between the pairs. Just P1 has indicated *Prompts* of all three types; two couples indicated just type 1 and type 2 *Prompts* (P3, and P5); one pair gave types 1 and 3 *Prompts* (P8); the other two students pairs' report just include type 3 *Prompts* (P2, and P7). Since all three types of events are situations that can occur in a math class using Geogebra to solve problems, it would be desirable for future teachers to be able to identify, anticipate, and analyze them. The previous results show that this is not something that always happens, which points to the need for training that offers opportunities to reflect and deepen this type of analysis.

The group of proposals categorized as Type 1 included *Prompts* that have to do with classroom contingencies that could be used to interact with students and discuss mathematical meanings of technological facts (Wasserman, et al., 2019). The didactic steps to answer the questions that are proposed as a starting point of the *Prompts* would be the same in a university course as in a Secondary Education classroom.

As concerns the other two types of *Prompts* in our categorization (Types 2 and 3), we observed that the proposals included here were the most numerous. This could be related to the types of situations that each pair encountered while they were solving the problems themselves, during the first three tasks of the GeoGebra Problem-Solving Workshop, which would underscore the close relationship that exists between the different perspectives of Mathematical Understanding (Kilpatrick, et al., 2015).

The inclusion of technology as a tool for mathematical work in the classroom entails a change in the types of situations that a teacher must face in the classroom. This must be accompanied by a change in the types of training activities offered to future teachers of mathematics. The analysis conducted as part of this research shows how tasks involving reflection on one's own experience contribute to the development of mathematical understanding for teaching the discipline, particularly in Secondary Education.

LATINX PARAEDUCATORS LIVED MATHEMATICAL EXPERIENCES

David Slavit
Washington State University Vancouver
dslavit@wsu.edu

Gisela Ernst-Slavit
Washington State University Vancouver
gernst@wsu.edu

Mathematics teaching is an inherently social activity, highly dependent on the lived experiences of its members. Drawing on sociocultural perspectives, we explore the mathematical lives of Latinx paraeducators to better understand the ways in which their backgrounds might influence their attitudes toward mathematics and mathematics teaching. Eleven paraeducators participated in the study that used interviews, artifacts, and informal observations to document their lived experiences, particularly in regard to mathematics. The evidence suggests that aspects of their personal narratives, particularly family, home culture, and personal hobbies and interests, had important influences on many of the participants. Implications on the social aspects of mathematics teaching and the need for relevance are provided.

Keywords: Teacher Education – Preservice; Equity and Diversity; Teacher Beliefs; Culturally Relevant Pedagogy

Throughout this century, the percentage of teachers in the United States classified as white has held steady at about 80%, while the percentage of Latinx teachers remains below 10% (Taie & Goldring, 2019). Further, it is projected that by 2026 white students will make up less than half of the U.S. public school student population, with Latinx students nearing 30% (de Brey & colleagues, 2019). Why should this matter, particularly in regard to the teaching and learning of elementary mathematics?

One reason for considering the implications of these changing demographics is the role that teachers' backgrounds have on students and teaching (Glock & Kleen, 2019). For example, Copur-Gencturk, Cimpian, Lubienski, and Thacker (2020) found that teachers displayed the largest negative biases in regard to mathematical ability toward Black and Latinx girls. While explicit biases are more easily seen and measured, implicit biases are less visible but perhaps more harmful to those they marginalize (Greenwald & Banaji, 1995; Harber & colleagues, 2012). Implicit negative biases towards students, in regard to both academic and behavioral factors, tend to exist in teachers that come from differing backgrounds, cultures, and/or races (Glock & Kleen, 2019; Redding, 2019).

A second reason for considering the implications of the above changing demographics involves the role that dialogic interaction plays in mathematics teaching and learning (National Council of Teachers of Mathematics, 2000; National Governors Association, 2010). Mathematics teachers are participants in a dialogic process so, as in any such activity, draw on their personal backgrounds and resources when engaging students in active mathematics learning. It is important to understand the diverse perspectives that can be generated through lived experiences, and how this might impact the ways in which teachers view and approach mathematics instruction.

Frameworks

We view teaching as a social activity grounded in the perspectives and backgrounds of those involved (Vygotsky, 1978; Bruner, 1990). There are numerous perspectives on teaching that build on this idea and attend specifically to issues of equity, race, and power. This study draws from key precepts of *culturally responsive/sustaining pedagogy* (Ladson-Billings, 1995) and the *funds of knowledge* framework (Moll et al, 2005).

Culturally responsive/sustaining pedagogy is a strength-based perspective that celebrates students' home languages and cultures, but also emphasizes active learning and critical, reasoned challenges to the status quo (Ladson-Billings, 1995). While complex in nature, a central instructional premise of culturally responsive pedagogy is to find topics and contexts that are meaningful to a group of learners, and then create learning experiences that bridge these learners' cultural and linguistic heritages with more formal academic knowledge. Establishing meaningful connections to students is a key aspect of effective mathematics instruction, and teacher backgrounds play a significant role in this process (Boaler & Staples, 2008; Gholson & Martin, 2014; Téllez, Moschkovich, & Civil, 2011).

Funds of knowledge refers to an individual's historically accumulated set of abilities, strategies, or bodies of knowledge (Gonzalez et al. 2005; Vélez-Ibáñez and Greenberg 1992). These funds can be recognized by observing "the wider set of activities requiring specific strategic bodies of essential information that households need to maintain their well-being" (Vélez-Ibáñez & Greenberg, 1992, p. 314). In the context of this discussion, we employ the concept of funds of knowledge to encompass both academic and personal background knowledge, accumulated life experiences, skills used to navigate everyday social contexts, and world view(s) structured by broader historically situated sociocultural forces. Just as educators need to recognize the funds of knowledge that K-12 students bring to the school, teacher educator programs need to recognize, and tap into, the diverse social, linguistic, and cultural strengths and assets that teacher candidates bring to their programs.

Each of these theories is premised on building upon students' and families' linguistic and cultural resources and accumulated knowledge. This can support schools and teachers in sustaining students' linguistic and cultural identities and foster a more humanizing perspective of the learning process, including mathematics learning.

Methods

Context

The 11 participants in this study come from various linguistic, cultural, ethnic, and national backgrounds, including Panama, El Salvador, Guatemala, Cuba, Mexico, and the United States. Over half are fully bilingual English and Spanish. All earned a BA in Elementary Education, K-8 state teaching certification, and a K-12 ELL endorsement. In addition, eight pursued a K-12 bilingual endorsement (see Table 1 for more detail).

The participants completed their elementary education certification program while working 30 hours per week in one partnering district in the Pacific Northwest. Participants were selected due to experience and dedication as paraprofessionals working with English learners. Ten are female, over half are first generation college students, nine are Latinx (age range: 23-53), and three have foreign/domestic postsecondary degrees (e.g., dentistry, Spanish, journalism). Each participant also completed numerous requirements for acceptance into their elementary teacher education program at a Research 1 institution.

This preservice program was offered in two locations and served paraeducators located in seven school districts with large English language learning school populations (15%-95%). However, for this study, we focus on one program working in one school district that serves a diverse student population including Spanish speakers (40%), Russian and Ukranian speakers (33%), and smaller percentages of Vietnamese, Hmong, and Tagalog speakers, among others. The elementary and middle schools where the 11 paraeducators worked are located in urban and semi-urban settings. Most teacher education classes were offered face-to-face at the school district location. One course was conducted via videoconferencing and several courses were provided using a hybrid model (a combination of traditional face-to-face and online learning activities). In addition, through the Prior Learning Assessment process, many of the participants earned additional course credits by demonstrating work that matched specific competencies listed in the state standards for new teachers (Morrison & Lightner, 2017).

Table 1: Personal and professional backgrounds of participants

Participant	Languages Spoken	Ethnicity/Race	Origin	Years as a Paraeducator
Meredith	Spanish/English	Latinx	U.S.	1
Janice	Spanish/English	White	U.S.	2.5
Magdalena	Spanish/English	Latinx	Cuba	4
Inez	Spanish/English	Latinx	Panama	14
Javier	Spanish/English	Latinx	Mexico	2.5
Gabriela	Spanish/English	Latinx	Honduras	1.5
Maribel	Spanish/English	Latinx	U.S.	2
Evelyn	Spanish/English	Latinx	U.S.	1
Magda	Spanish/English	Latinx	U.S.	4
Sabrina	Spanish/English	White	U.S.	1
Irene	Spanish/English	Latinx	U.S.	8

Data collection and analysis

Mathematical autobiographies of all 11 participants represent the primary data set. The written stories of the participants' mathematical lives were part of the elementary mathematics methods course taken towards the end of their teacher education program. The evening course was conducted in an abbreviated five-week session while the participants were working in schools as paraprofessionals during the day. The stated purpose of the assignment was for the participants to "become conscious of your mathematical beliefs and the events that may have contributed to their creation." The four specific components of the mathematical autobiography were: 1) self-perceptions about your mathematical abilities and understandings, 2) feelings and attitudes toward mathematics, 3) important events in your mathematical life (in and out of school, with preference given to out-of-school experiences), and 4) where you are now in regard to both mathematics and mathematics teaching. The participants shared their autobiography in oral presentations throughout the semester.

Open, emic coding (Miles, Huberman, & Saldaña, 2015) was conducted on each of the participants' written stories in order to find salient features as identified by the participants. First-cycle codes provided broad categorizations of the kinds of stories being told. Specific codes included age (childhood/adolescence/adult), setting (school/home/community), and location (U.S., home country, other). Second-cycle codes began to delineate the salient features of the stories and included mathematical beliefs/attitudes, mathematical activities (e.g., budgeting), mathematical topics (e.g., numbers, measurement), role of language, and implications on teaching. This thematic analysis led to conclusions about the participants' feelings and attitudes toward mathematics, the role of mathematics in the participants' lives, and how these aspects of the participants' backgrounds were brought to bear on their perspectives on mathematics teaching and learning.

Results

Participants' lived experiences

The narratives of this group of mostly Latinx paraeducators emerged through oral and written reflections of personal language as they practiced culturally responsive teaching and engaged with their students' families and communities, all while enrolled in the elementary mathematics methods course. Recognition of the sociohistorical and political contexts of their own lives, along with the lives of their students, is an important aspect of enacting culturally responsive teaching (Ladson-Billings, 1995). Through their stories, these paraeducators demonstrate great courage and resilience. In many cases, their professional journeys include adapting to a new country or cultural context, learning a new language, facing immigration threats, and resisting pervasive local and national monolingual/monocultural ideologies. Their stories and reflections reveal the importance of listening to students' stories and building on their experiences and trajectories.

Therefore, we focus on the lived experiences of these emerging teachers from their childhood through their adult and professional life. We provide the above overview as background to the salient mathematical features of their lived experiences that constitute the focus of this particular study. The data below build on the above narrative, but provide a much deeper view of the role of mathematics in the life trajectories and eventual professional work of the participants.

Feelings and attitudes toward mathematics

The students exhibited a variety of feelings towards mathematics, including “love,” “love-hate,” “useful,” “neutral,” and “negative.” Many of these feelings stemmed from experiences as a child. For example, while speaking fondly of her times tending to farm animals and baking with her mother, Maribel also recalled several negative school mathematics experiences that framed her overall self-perception:

> I was usually one of those students that would take longer to find solutions to problems. One reason was because I would process what teachers were telling me in English and try to translate it into Spanish in order to understand it. Another reason is because I like to think about the process when trying to find solutions to a problem . . . I don’t remember ever being asked to find more than one solution to a problem by a teacher, or to find different ways to show my thinking. There was only one way, and if it was not how my teacher taught me it was wrong. I believe that this is when my fear of math, and answering questions in front of the class, started.

Many students also reflected on their adult experiences as helping to frame their views of mathematics. Magdalena described her mathematical experiences while making and selling cakes and *bocaditos* (snacks), and Gabriela spoke of her work in the dental field.

Overall, the participants relayed a variety of attitudes toward and self-perceptions of mathematics in their personal narratives. Many of these attitudes and self-perceptions were connected by the participants to particular events in their lived experiences, both as a child and adult. The next section provides more examples of these lived experiences and their importance in shaping their personal and professional lives.

Mathematics in the participants’ lives

The collection of mathematical autobiographies represents a rich set of examples of how personal, family, and cultural background impact the mathematical development of individuals. Javier related numerous examples of this from both his boyhood and adult life. Reflecting on his family heritage and youth, he stated:

> I come from a family of farmers who valued an education. I am the second of nine children and the second to go to college. My family always wanted us to get an education so that as we grew older, we would be able to know how to negotiate prices and know their value. My father sometimes bought and sold cattle and knew the importance of being able to calculate the weight of animals without weighting them and know their worth. As a result, he always encouraged me to study hard and do well in school so that in real life, I would be able to know what something was worth and others would not take advantage of me. When I was around 11 years old, my mom would often send me to buy a few grocery items and even medicine from the pharmacy. It was then that I started applying my math knowledge to buy

> and pay for items. I also started working selling jelly, popsicles, and ice-cream . . . I remember that Sundays were my best days because I would go to the football (soccer) games to sell popsicles and ice-cream. Most Sundays, I would sell around 300 pesos ($13) worth of popsicles and ice-cream. I usually made around 105 pesos ($4.5) from 8:00 am to 3:00 pm.

Javier related additional stories as an adult that involved woodworking, choosing phone plans, and making predictions. All were detailed and grounded in his personal story. Javier's stories reflect a use of mathematics that was grounded in his parents' desire for him to succeed, and in the life activities that dominated his early and adult life. Javier developed an applied view of mathematics throughout his life that, as an educator, translated into an instructional perspective in which mathematics is best learned through the use of applied contexts.

Maribel also had numerous reflections on the importance of her family, setting, and upbringing:

> I was born in a small farm town. Growing up every morning before school my brother and I would feed our farm animals, and make sure they had water for the day . . . Each animal needed a different amount of water in their tanks so the amount of buckets varied depending on the size of the tank, and the animal. Without knowing, I was figuring out volume, by figuring out how many smaller units would be needed to fill a larger unit. This is something that I remembered and used when I started learning about volume in school. I always thought of them as tanks being filled by little buckets.

Maribel's personal relationship with her mother also played a significant role and had an impact on her understanding of fractions:

> My mom would ask me to put ¼ cup of sugar into a mix, or ½ cup of flour into something before stirring. At the time fractions for me were just lines on a cup. As I continued to help my mother I started noticing how each measurement had a relation with the other. For example, if I filled the cup to ½ and then filled the other ½ I would have 1 cup. Or if I was to fill the cup with water to the ¼ line and then add ¼ more the water would add up to the ½ line. This led me to realize that I needed four ¼'s to fill 1 cup. I was around 2nd grade when I started making these relationships with fractions. When I got to 4th grade and started learning about fractions, the numbers looked familiar.

As in the case of Javier, Maribel's hands-on experiences with mathematics have translated into a desire to use both visual and hands-on representations when working with mathematics learners.

Evelyn described her parents as "from Mexico and have elementary and middle school level education. My father was always the one to work as my mother chose to stay home." Evelyn felt a power in mathematics at an early age:

> When it was time for me to start school, I entered Kindergarten with not being able to speak, write or understand English as only Spanish was spoken at home; however, I was able to count to 100 at the end of Kindergarten, and by first grade I was able to add and subtract.

Unfortunately, mathematics became an increasing challenge for Evelyn. In her view, this was because of a lack of support from both teachers and her own parents. These experiences brought on serious professional doubts:

> The things we were learning were beyond me. So since math was too hard for me, there was no way I could become a teacher.

Over time, Evelyn worked to overcome these doubts and recognized several positive mathematical traits in her current life. Her attitude towards mathematics instruction is promising:

> I am working on being more positive with math and am a little nervous about creating a lesson on it, but with supportive educators by my side, I think I will be okay!

Perspectives on mathematics teaching and learning

Despite the variety of personal stories and self-perceptions of mathematics, there was near consensus in regard to perspectives on teaching mathematics. All but one participant talked about allowing students to develop their own ways of thinking and solving problems and to develop understandings through the use of visual and hands-on representations. A variety of reasons were cited, including their own experiences, university mathematics and methods courses, and experiences working with students as paraeducators.

The above examples of Javier and Maribel provide details on two specific ways in which the participants' life stories had direct impact on both their views of mathematics and instructional perspective. Meredith used artistic representations to support the personal narrative of her lived mathematical experiences. As a young girl, she had difficulty engaging in the mathematics learning experiences that were devoid of context or lacked personal meaning. Her self-portrait during this time is quite telling:

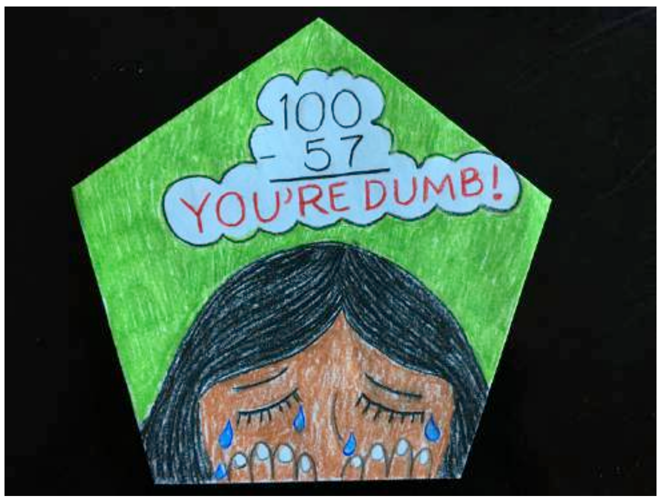

Figure 1: Image of Meredith as a young girl in a mathematics class.

Meredith learned to overcome these challenges, eventually making meaning of complex mathematical ideas in calculus. Her personal goal is to utilize students' home languages and cultures in the core of her mathematics teaching, and to work consistently on making mathematics relevant and personal to her students.

Conclusions

Our study is limited in that it considers only 11 participants who worked as paraeducators and achieved their elementary teacher certification in the same school district. We acknowledge this limitation, but argue that a similar study that would seek to decontextualize either the context or the participants' backgrounds would have other, and perhaps more alarming, methodological issues. The study also draws primarily from one data source when analyzing the participants' attitudes towards mathematics and mathematics instruction, though a secondary and much larger body of data was used to describe the broader socio-cultural backgrounds of the participants. Finally, while we document the participants' views of both mathematics and mathematics teaching, this paper does not address actual classroom practice. Future studies are ongoing to determine the degree to which the participants' views of mathematics instruction are being enacted in their own classrooms.

Our analysis of the stories of these paraprofessionals' lived experiences with mathematics provides a lens into key interactions with their families and other contexts that contributed to their mathematical and professional development as teachers of mathematics. While their views of mathematics differed markedly, nearly all shared the view of teaching mathematics that seeks to generate active learners through the use of contexts, language, and other representations meaningful to students, and that preferably utilize the lived experiences and backgrounds of their students. Each of these principles are consistent with both culturally relevant/sustaining pedagogy as well as funds of knowledge perspectives. Given the changing demographics and anticipated increase in the number of Latinx students over the next ten years, and the importance of caring educators who share students' backgrounds, interests, language, and culture, we hope that more Latinx teachers can enter the teaching profession and develop mathematical perspectives similar to those of the participants in this study.

"The main focus of the day was the "If the World Were a Village" activity/book. I thought it was a really good way to open one's perspective. As an American, I tend to be a bit focused on the US, so to see how much [or how little] of the world is actually represented in my perspective was enlightening."

"Living in the United States … I was surprised that only 5% [of the world population] were from North America"

Increasingly, mathematics is being positioned as a tool to support students' understandings of social (in)justice and their own unique social positioning in the world. To this end, this study analyzes the impact of curricular reform efforts in an elementary mathematics content course. The course focused on fractions and statistics, and the course content was taught through tasks designed to support prospective teachers in understanding and critiquing the world. The authors found that through the course, prospective teachers' content knowledge increased and their knowledge of the world's demographics and social inequities increased.

Keywords: Teacher Education Pre-service, Modelling, Social Justice

Objectives or purposes of the study

The National Council of Mathematics' (NCTM) Catalyzing Change (NCTM, 2018) states that "each and every student should learn the Essential Concepts in order to expand professional opportunities, **understand and critique the world**, and experience the joy, wonder, and beauty of mathematics." (emphasis added, p. 2). If we want students to "function as numerate, critical citizens who are able to use their knowledge in social and political realms, for the betterment of both themselves and society as a whole" (Ernest, 2000, p. 46), we need to teach these students how to understand and critique the world. Some school districts in the United States (for example Seattle Public Schools) are actively working on understanding and critiquing the world in their mathematics classes (Gewertz, 2020).

However, teaching mathematics in a way that enables students to understand and critique the world is challenging. Part of the challenge is due to the tension between focusing on the classical/dominant mathematics goals and on understanding and critiquing the world (Brantlinger, 2013; Gutstein, 2006; Yeh & Otis, 2019). Integrating real-world phenomena into the classroom requires questioning the status quo so as to not reinforce stereotypes (Esmonde, 2014) which may take time away from focusing on the dominant mathematics. This, in turn, may negatively impact student achievement on standardized assessments (Brantlinger, 2013; Chubbuck & Zembylas, 2008).

To address this tension, we selected real-world contexts that would allow both, learning mathematics as well as learning about the world we live in. We situated the mathematics learning in the context of shrinking the population of the world to either 100 people (Smith, 2011) or shrinking the US population down to the size of the class. Our research questions were:

Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

1. What mathematics do students learn when they engage in mathematics tasks based on shrinking populations to 100 or to class size?
2. What do students learn about the world when they engage in mathematics tasks based on shrinking populations to 100 or to class size?
3. How does working on such tasks affect the students' views of mathematics?

Perspective(s) or theoretical framework

In a teaching mathematics for social justice framework (TMfSJ), a primary goal is for students to become critical members of society who know how to use mathematics to make sense of and possibly change their world (Gutstein, 2003; Raygoza, 2016). TMfSJ tasks involve engaging students in thinking about both the mathematics concepts and social issues relevant to their lives and experiences (Frankenstein, 1983; Gutstein, 2006; Skovsmose, 1994). Therefore, another goal of incorporating social issues into mathematics is for students to both understand mathematics as well as understand and create a more just world (Frankenstein, 2009). To understand and critique the world students often begin by learning about how their own experiences relate to others' experiences in the world in order to understand privilege and injustice. Many prospective teachers (PTs) enter their coursework believing that mathematics is neutral or universal (Greer et al., 2007; Keitel & Vithal, 2008). Mathematics teacher educators need to address the fact that mathematics can never be neutral and no classroom is a neutral space (Frankenstein, 1983; Gutiérrez, 2013; Yeh & Otis, 2019). TMfSJ tasks can be a means of engaging teachers in building their sociopolitical consciousness about the political implications of mathematics, and how math can be leveraged to read and write the world (Gutstein & Peterson, 2005). Gutstein (2003), building on Paulo Freire's (1970) work, distinguishes between reading the world (supporting students in learning about inequities in the world and their own positioning within those inequities) and writing the world (supporting students in developing their own agency to address inequities).

Yet, most PTs have little experience with TMfSJ tasks during their K-12 schooling; therefore, it is important to integrate such tasks into their teacher education courses so they can explore how they may be able to enact TMfSJ tasks in their future K-12 classrooms. This is especially true for content courses so elementary PTs can experience such tasks from a learner's perspective and thus learn to read and write the world (Gutstein. 2006).

In some cases mathematics teacher educators (MTEs) have met resistance from PTs when integrating social justice issues into the mathematics curriculum (Aguirre, 2009; Ensign, 2005; Felton-Koestler et al., 2017; Rodríguez & Kitchen, 2004). However, MTEs have also found that they are able to broaden PTs' perspectives about mathematics and mathematics teaching to include the idea that mathematics could be a tool for social analysis that supports students in understanding the sociopolitical world better (Bartell, 2013; Ensign, 2005; Felton & Koestler, 2015; Felton-Koestler & Koestler, 2017; Leonard & Moore, 2014; Mistele & Spielman, 2009). This aligns with Gutstein's (2003) goal of supporting students in developing their sociopolitical consciousness, and possibly a stronger sense of agency and identity.

Finally, TMfSJ tasks can be designed towards teaching math about, with, and for social justice (Stinson & Wager, 2012). Stinson and Wager define teaching mathematics about social justice as focusing on reading the world. They define teaching mathematics with social justice as enacting equitable pedagogical practices. Finally, they define teaching mathematics for social justice as focusing on both reading and writing the world. Students benefit from all three forms of teaching mathematics about/with/for social justice. Benefits include a view of mathematics as useful and relevant and can potentially develop agency (Gutstein, 2006).

Methods or modes of inquiry:

The study took place in two mathematics content courses for prospective elementary school teachers in the United States, one in 2018 and one in 2019. Content courses are typically taken as prerequisites before students enter their teacher education program. The mathematical content of these courses focused on fractions and statistics.

The 2018 course had 26 PTs and the 2019 course had 7 PTs. The task described below was piloted in the 2018 course and spanned one homework assignment and one class day (2 hours). The task was then refined and implemented in the 2019 course across over two days of instruction (2 hours each). The first part of the task comprised (1) examining www.worldodometers.info and noting how many people are on earth and how some resources are distributed. (2) Shrinking the world population down to 100 people using the book **If the World Were a Village** (Smith, 2011), the movie https://www.youtube.com/watch?v=QrcOdLYBIw0, as well as the website https://www.100people.org/statistics_detailed_statistics.php?section=statistics to make observations about the distribution of the population and resources. (3) Creating of a poster focusing on one or two elements discussed in the book/movie. Students were given private think time, discussion time, and time to make the poster which was to include the following representations: a table, a hundred chart, a number line, and unifix cubes. Students were asked to connect these various representations to support their understanding of the relationships between fractions, decimals and percent. Sample posters can be seen in Figure 1. After the posters were displayed time was spent to discuss the mathematics (connecting decimals, fractions, and percent) as well as what we learned about the context.

In 2018 parts (1) and (2) were assigned as a homework assignment before the first class session, in 2019 they were done in class. In 2019 PTs were asked to estimate percentages for the village such as population, language, age, etc. For example, they were asked “If the world were a village of 100 people, how many would come from North America?” and “would speak English?” In both years part (3) was done in class and in both years, students responded to online survey questions after those three parts:

Online Survey Questions:

- What observations did you make when looking over this website http://www.worldometers.info/?
- What observations did you make when you watched the YouTube video "If the world were a village"?
- What observations did you make when you read the book "if the world were a village"?
- [2018] Please reflect on this homework assignment: What did you learn?
- [2019] What did you learn from today's lesson?
- [2019] What did you learn from today's lesson with respect to mathematics?
- [2019] What did you learn from today's lesson with respect to your understanding of the world?
- How can breaking the population down into 100 people help us better understand the information?
- What math do you think could be addressed with this book in a K-5 classroom?

At the end of the term PTs in each class were asked to respond to the prompt “I used to think math is … now I think math is …”

In 2019 a second day focused on PTs researching information about their hometown and creating a second poster for their hometown and then comparing across the two posters. Data collected included PTs responses to online surveys as well as detailed field notes of all class sessions and copies of all student work. Data analysis began by filling in the field notes with artefacts from class, and reading through survey responses to establish initial themes. Two researchers independently read survey responses and identified themes. The researchers then met to discuss and refine themes in order to create a final codebook of themes, and all data was coded with this codebook. Any disagreements were resolved through discussion. After all survey data was coded, similar themes were collapsed to make larger themes. Themes were collected across all questions rather than analyzing individual questions. These can be seen in Table 1.

Results

With regard to Research Question 1: What mathematics do students learn when they engage in mathematics tasks based on shrinking populations to 100 or to class size?

One major mathematical focus of the task was to make sense of the meaning of percent and connect percent, fractions and decimals. Several PTs commented that before this day they did not realize that percent refers to "per one hundred". Ellie, for example, stated, "I thought it [percent] was just a word," and Amanda wrote in her notes for the day, "Eva explained that percent actually means per hundred, which I never knew." Candy stated that she learned "that if the world was broken down into 100 people, each person would represent a percent. This allows us to conceptualize the population while understanding the real percentages (which can be translated into the actual population)." In addition, PTs connected decimals to fractions with base ten denominators. This is evidenced by Christa's response that "I learned how fractions, decimals and percentages relate to each other and that they all show representations of part of a whole." One way PTs made sense of percent and made connections was by using color purposefully. As shown in the posters below (Figure 1), PTs used colors to connect across representations. Sabine pointed out how the colors helped her: "It was very helpful for me to see with color and the number 100." Jamie reflected on her homework "OMG. As I was completing the homework I realized that a flat partitioned into 100-sized pieces is the same as a hundred chart!!!!! This was a very helpful connection for me."

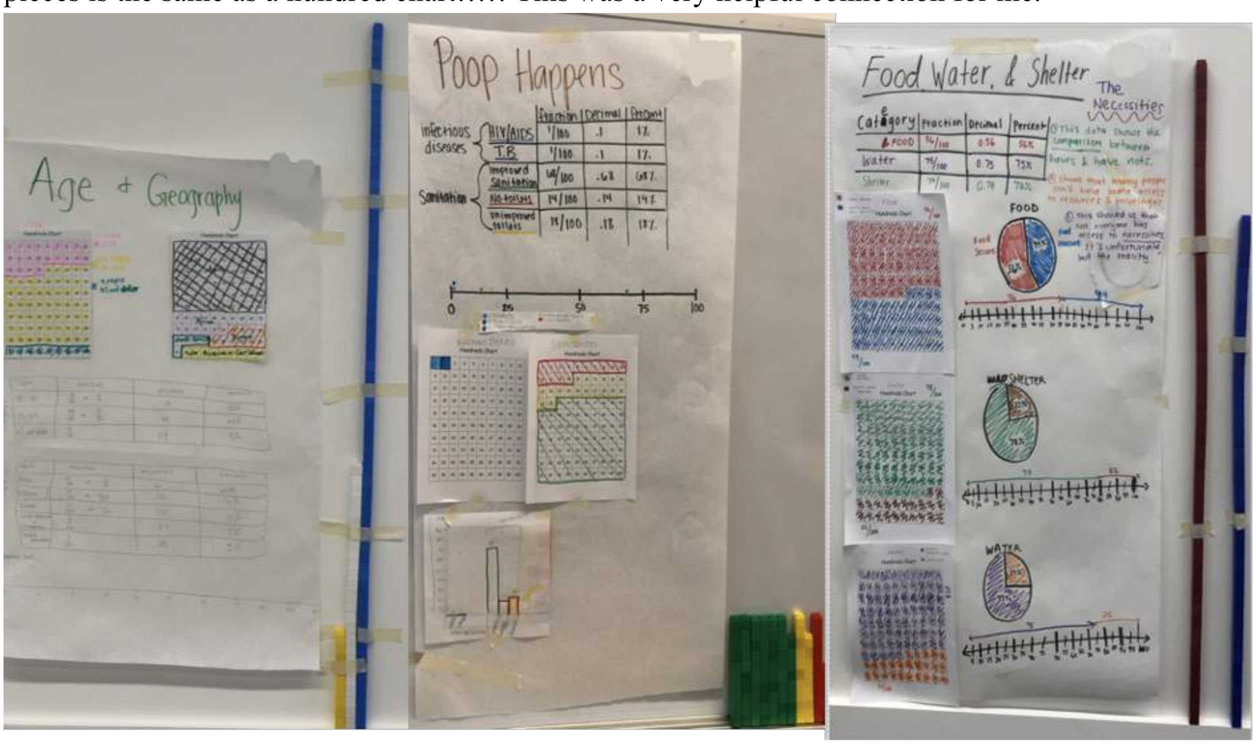

Figure 1: Three posters illustrating connections across representations

In addition to developing meaning for percent, fractions and decimals, scaling the size of the world's population helped the students make sense of the size of our world and the distribution of the world's population. For example, 76% of PTs reported that scaling down the population to 100 helped then understand the world better (see Table 1 for all survey themes). One way this supported their understanding of the world was the ease of visualizing a certain number of people out of 100 rather than billions of people. For example, Walter conveyed that "when numbers are so large the impact is usually lost. The number can be overwhelming and doesn't necessarily relate to us personally. Yet when we break it down to 100 we have a better visualization of what the population would look like. We can visualize 60 people out of 100 or 10 people out of 100. Compare that to billions of people... That is much more difficult to grasp." In this way, PTs were able to make sense of the world by considering a total population of 100 people, which provided a relatable scale.

With regard to Research Question 2: What do students learn about the world when they engage in mathematics tasks based on shrinking populations to 100 or to class size?

Another major focus of the task was to create a space for students to realize that the world is much more complex than they had originally thought, and that the US is not the center (or most of) the world. Seventy percent of the students stated this in the survey. For example, Aimee expressed feeling surprised "to see that a majority of the population came from Asia and not the United States," and Sophie also voiced, "I was surprised to learn about the abundance of other cultures. I think in America the media tends to be very self-centered and produce that as the norm, when in reality looking at the world we are a small fraction of diversity in the world." Additionally, Amanda reflected in her notes that "some of the results were surprising such as that 60% of the population is from Asia and only 5% is from North America."

Table 1: Themes, larger themes bolded, sub-themes not bolded

Theme	2018 N=26	2019 N=7	2018 and 2019 N=33
The world population is large and rising (at a scary rate)	18 (69%)	7 (100%)	25 (76%)
The use of smaller numbers (100 people in the village) was helpful to make the quantities easier to visualize/data easier to visualize	21 (81%)	4 (57%)	25 (76%)
Inequity is larger than I thought	**22 (84%)**	**6 (85%)**	**31 (85%)**
Inequity/inequality is larger than I thought	16 (62%)	3 (43%)	19 (58%)
Food insecurity is much higher than I thought	14 (54%)	5 (71%)	19 (58%)
Education levels are lower than I thought	8 (31%)	3 (43%)	11 (33%)
The world is more complicated/goes beyond the US	**17 (65%)**	**6 (85%)**	**13 (70%)**
World is complicated/diverse	13 (50%)	3 (43%)	16 (48%)
US is not the center of the world	5 (19%)	1 (14%)	6 (18%)
I am a small piece in the world/surprised by the small % of people from NA	2 (8%)	3 (43%)	5 (15%)
I am a small piece in the world/There are so many people in the world	1 (4%)	0 (0%)	1 (3%)
I am/was America centric/ gained perspective	2 (8%)	4 (57%)	6 (18%)
This activity was SHOCKING/jarring/terrifying	**6 (23%)**	**1 (14%)**	**7 (21%)**
Need for action/improving the world	**10 (38%)**	**3 (43%)**	**13 (40%)**
This activity made me realize the need for action	6 (23%)	3 (43%)	9 (27%)
found it helpful to quantify social issues/we can	6 (23%)	0 (0%)	6 (18%)

use number to improve the world			
This activity would be good for elementary students	**8 (31%)**	**1 (14%)**	**9 (27%)**

Thus, scaling the size of the world also helped PTs recognize their inaccurate perceptions of the distribution of people and languages in the world. In 2019 when PTs were asked to make predictions all 7 PTs overestimated how many people would come from North America. While the actual value is around 5, PTs' estimates ranged from 7 to 50 with the mean response being 18. All 7 PTs also overestimated the number of people who speak English. Their estimates ranged from 20 to 80 with a mean of 42 and a median of 40. The actual value is 5 (first language) and 20 (first and second language). Thus, all PTs seemed to overestimate the population of North America as well as the number of English speakers. This activity helped PTs adjust their understanding; Candy, for example stated in her class notes that "learning the proper answer resulted in new understanding of the world. This activity helped me realize that the US isn't the center of the world. Life is very different for people in other countries."

This task helped PTs to grasp the significance of our worlds' population and the current distribution of resources in our world. One of the major themes PTs mentioned across both years was that they learned that the world population is large and rising at an alarming rate (all survey themes are shown in Table 1). Seventy-six percent of all PTs mentioned this theme. Elsie for example stated "There are a lot more people living than I thought," and Sophie stated "The population to me was shocking. When I think about this small realm of people I interact with every day, it blows my mind to picture the world population, let alone this constant rapid increase."

Additionally, almost all PTs (84%) stated that they learned that the inequities are larger than they thought either in general (58%) or by mentioning a specific area such as food insecurity (58%) or education (55%). To give an example, Autumn mentioned general inequities: "I observed a lot of inequalities amongst all the topics explored." Additionally, Christa noticed that "food insecurity was a way larger number than I thought. It is almost half the world's population which is startling to me," and Sabine mentioned both food and education: "The number of people that always have food to eat is very low. I didn't expect it to be that low, it really surprised me. Also, that there are students that don't get an education. It is very sad that they don't get that opportunity."

For some PTs, their new understanding motivated a sense of urgency for action. Even though taking action was not yet an explicit goal of the course, 40% of the PTs mentioned the need to take action or need for improving the world. For example, Marcel stated "It is … important to realize that as Americans, everything is not as we assume it is. We just expect to turn on the faucet and have clean water poured out of it. We pay for tuition and we expect qualified professors. As Americans we must recognize our privilege and use it to help others as much as we can." Gertie said "I learned that there are a lot of things in the world that need our help and attention, and there is a lot of miss-distribution of wealth, food, and resources, and we need to be doing a better job of creating a more sustainable and equitable world.

With regard to Research Question 3: How does working on such tasks affect the students' views of mathematics?

At the end of the term PTs in each class were asked to respond to the prompt "I used to think math is … now I think math is …." Four themes emerged: (a) a shift from math as politically neutral to math as a place for the integration of social issues/social justice [8 PTs in 2018, 2 PTs in 2019], (b) a shift from rom math as boring/uninteresting, to math as interesting/useful [8 PTs in 2018, 4 PTs in 2019], (c) a shift form math as rules and procedures to math as sense-making [12 PTs in 2018, 3 PTs in 2019], and (d) shift from difficult to possible [7 PTs in 2018, 0 PTs in 2019]. Some PTs mentioned more than one theme [9 in 2018, 1 PT in 2019]. Ellie illustrated theme (a) in her response "I used to think math is the most politically neutral subject taught in school. Now I think math is a great place to bring up the issues that are going on in our world while developing a better understanding of the material because of the connections that students can make to their own lives."

Discussion and/or conclusions

Reflecting on the data analyzed for this study with respect to content it seems like PTs learned about the meaning of percent as well as the connection between fractions, decimals, and percent.

Reflecting on the data analyzed for this study with respect to the world, it seems the PTs learned about social justice (reading the world) but not quite yet for social justice (writing the world). PTs seemed to have a better understanding about various characteristics of the world as a whole, which is important for future elementary school teachers because these future teachers need to understand characteristics of the world themselves before they can enact TMfSJ tasks in their own future teaching. Additionally, being aware of their own unique social positions may support more reflective practice with elementary students who differ from them in social position.

The PTs also learned how to use math to make sense of the world. Moving forward, the authors intend to modify the tasks to move more towards learning for social justice. In 2019 the PTs compared what they learned about the world to what they learned about their own local city which allowed them to (a) learn about their local place and compare it to the world, and (b) refine their understanding of how they are situated in the world. Christa, for example, stated "My topic was shelter and that was an underestimate of one in 20 people are homeless [in local city]. … we obviously have issues in [local city]. But then comparing it to the real world numbers. It's still a very privileged place to live. So I think that's important to recognize." The act of comparing their new understandings of the world to the makeup of their local city appeared to make inequity more pressing for PTs. In the future, the authors will continue to develop ways to connect TMfSJ tasks to PTs local reality, e.g., local issues of homelessness, gentrification, in an effort to prompt PTs toward taking action and learning mathematics for social justice.

Reflecting on the data analyzed for this study with respect to the students' views of mathematics we reported on students' views at the end of the term, thus this tasks may only have played part of the reason for shifts, however, all students mentioned shifts in how they viewed math as either not neutral anymore, or more interesting, engaging, focused on sense making, and doable.

INVESTIGATING ELEMENTARY PRE-SERVICE TEACHERS' CONCEPTIONS OF MATHEMATICAL CREATIVITY

Anne N. Waswa
University of Georgia
anw04326@uga.edu

Kevin C. Moore
University of Georgia
kvcmoore@uga.edu

Research in mathematics education has overlooked creativity in mathematics, partially because of a lack of an accepted definition of mathematical creativity. The present study investigates elementary pre-service teachers' (PSTs') conceptions of creativity in teaching and learning mathematics. Data were collected using observations and semi-structured interviews with nine PSTs and analyzed using thematic analysis. PSTs' conceptions of mathematical creativity included using multiple approaches to solve problems, designing mathematical tasks from scratch, making learning challenging but not impossible, and exercising independence in learning. Implications of these results are applicable to teacher preparation programs, and they suggest a need for more research on the nature of experience(s) that shapes PSTs' conceptions of mathematical creativity and how to develop it.

Keywords: Instructional activities and practices, Affect, Emotion, Beliefs, and Attitudes.

Mathematics educators have argued that "mathematics is a creative, everyday human activity that cannot be built exclusively on rules and routines" (Schram, 1988, p. 8). Yet, according to Silver (1997), cited in Lithner (2008), "students hardly experience mathematics as the highly creative domain it is" (p. 7). If we intend to support students to discover and grow their mathematical talent, a change in broader classroom practices and curriculum materials is necessary, and in order to yield results from this change, creativity in mathematics should be part of educational experience (Mann, 2006). This educational experience should not be limited to students but should be made accessible to teachers who play a critical role in shaping the educational experience of students. Creative teachers are crucial to the development of mathematical creativity in each student through school mathematics education (Lev-Zamir & Leikin, 2011).

For us to nurture teaching with and for creativity by teachers, we must understand their conceptions of creativity (Lev-Zamir & Leikin, 2011). We address this need in the present study by investigating elementary pre-service teachers' (PSTs') conceptions of mathematical creativity. The purpose of the study was to understand how PSTs conceive creativity in the teaching and learning of mathematics. In the following sections, we review related literature and discuss a theoretical perspective that guided the study. We then describe the research methods, results and implications of the findings.

Literature Review

Research in mathematics education has overlooked creativity in mathematics (Haavold, 2018; Haylock, 1987; Leikin, 2009, 2011), partially because of a lack of an accepted definition of mathematical creativity (Mann, 2006). Among the researchers who have studied teachers' conception of creativity specific to mathematics, Bolden, Harries, and Newton's (2010) characterized elementary PSTs as holding a narrow conception of creativity in mathematics. The PSTs' conceptions were largely associated with the use of resources and technology and was bound up with the idea of teaching creatively instead of teaching for creativity. The National Advisory Committee on Creative and Cultural Education (NACCCE) (1999) defined teaching creatively as "teachers using imaginative approaches to make learning more interesting, exciting and effective" (p. 102), and they defined teaching for creativity as teaching that is aimed at developing students' creative thinking and behavior. The former emphasizes creativity in terms of teacher actions, while the latter emphasizes creativity in terms of student reasoning. Bolden et al. (2010) cited literature which indicated that teachers of younger children believe that mathematics is creative but a closer investigation into their beliefs showed that creativity was viewed less in terms of the mathematics itself and more in terms of the creative activities such as construction, art, songs and rhyme, which are availed by mathematics sessions. Complicating the matter, Beghetto's (2007) study with middle and secondary PSTs identified that these teachers can view unique student responses as a potential distraction to classroom teaching, while PSTs from other subjects viewed such responses as worth pursuing. The potential effect of dismissing unique responses by students was that it can hinder the development of creative thinking, even if the teacher is using techniques associated with teaching creatively.

With respect to research investigating PSTs and their awareness of mathematical creativity, Shriki (2010) described the experiences of PSTs in a methods course focused on middle-school geometry where they engaged in activities aimed at cultivating their awareness of mathematical creativity and the complexity of the nature of creativity. She examined creativity by focusing on the value of the process or the product with citations from other researchers. As a process, creativity refers to cognitive abilities, conceptual thinking that involve flexibility, fluency, and originality, and non-algorithmic thinking. As a product, creativity is defined in terms of the novelty or uniqueness of a solution to a problem. Shriki argued that the learning environment and the nature of the assignments were relevant in aiding and growing PSTs' awareness of mathematical creativity and its multifaceted nature. She specifically illustrated that the learning environment provided PSTs with the freedom to work and design their own problems without having to follow certain rules or algorithms, and without fear of having a right or wrong answer. This, in turn, led to PSTs' development of intrinsic motivation, interest and curiosity. PSTs were also encouraged to be reflective about their insights and determine possibilities of generalizing the ideas, which in the end enhanced their mathematical knowledge.

Theoretical Perspectives

Researchers have approached creativity from different perspectives, and there is no general accepted definition of creativity (Haylock, 1987; Mann 2006; Sriraman; 2005). However, most researchers (Haylock, 1987; Lev-Zamir & Leikin, 2011; Leikin, Subotnik, Pitta-Pantazi, Singer & Pelczer, 2013) have adopted Guilford's (1967) characterization of the nature of creative thinking. The common features include fluency, flexibility, and elaboration, all of which fall within the divergent production ability of creative thinking. Fluency pertains to "a matter of retrieval of information from one's memory store," flexibility is "a matter of transformations of information," and elaboration is "a matter of producing implications" (Guilford, 1967, p. 11). Originality is another component of general creativity which Lev-Zamir and Leikin, (2011) defined as characterized by a unique way of thinking and unique products of a mental or artistic activity" (p. 19). These characteristics are mutually related, but they are not required to be present at the same time in order to claim the occurrence of creativity (Lev-Zamir & Leikin, 2011).

At a finer level, some differences exist in researchers' approaches to creativity. Piirto (1999), cited in Lev-Zamir and Leikin, (2011), distinguished between general and specific creativity. He identified general creativity with the application of problem-solving skills used in one field to solve problems in another field, and he connected specific creativity to the logical deductive nature of a particular field. Our study focused on mathematical creativity, which is a specific type of creativity that focuses on mathematics.

To label a behavior as mathematically creative, Haylock (1987) argued that both mathematics and creativity must be clearly present. This implies that for any process or product to be labeled as mathematically creative, it should be valid to the mathematics that was involved in that specific context. Lev-Zamir and Leikin's (2011) later added that defining mathematical creativity in the context of teaching should allude to mathematics, teaching, learning and creativity. An understanding of mathematical creativity was therefore important in this study.

For the present study, we adopt a model for creativity designed by Lev-Zamir and Leikin (2011) to characterize teachers' conceptions of creativity in teaching mathematics. In the model, teacher conceptions are explained in terms of teachers' mathematical content conceptions, which are how teachers view creative mathematical content, and teachers' pedagogical conceptions, which are "their awareness of didactic and psychological aspects of creativity in teaching and learning mathematics" (p. 19). Of the four characteristics of general creativity mentioned previously, their model focuses on flexibility, originality and elaboration because these three are unique to creative teaching. With respect to fluency, the authors consider it a primary indicator of how a teacher is qualified in terms of knowledge and proficiency, rendering it trivial in this model.

In Lev-Zamir and Leikin's model, teacher conceptions of creativity in teaching mathematics are further subcategorized as teacher-directed and student-directed under each of the three components: flexibility, originality and elaboration. Teacher-directed conceptions of creativity are actions by teachers that make them creative and these can be of a mathematical or pedagogical kind. Student-directed conceptions of creativity entail "connecting creativity in teaching mathematics with opportunities provided for the development of students' creativity" (p. 28).

Methods

Context and Participants

The study took place at a university in the southern United States. We recruited nine female pre-service elementary teachers from the early childhood education program, and their participation was voluntary. At the time of study, they were taking a mathematics methods course from either of the two sections taught by two different professors. One of the authors acted as a teacher assistant in both sections. The course was accompanied by a field experience component and it was the first of two courses that students take in the program.

We chose to focus on PSTs at the elementary level because this a critical stage of a child's mathematical development and how teachers are prepared to support them in this development is important. Mathematical concepts are interconnected and having a strong foundation for basic concepts in mathematics is likely to enhance understanding and creativity in learning as students progress to higher levels. We chose this specific course because of the nature of questions that PSTs explored throughout the course. PSTs were expected to reflect more on what mathematics is and what it means to know and do mathematics. These reflections can influence PSTs' beliefs about mathematics, which they are likely to carry on into their teaching together with the experiences they get from the methods course, ultimately impacting how they teach by shaping the approach and attitude of students in mathematics.

The nine participants came from different backgrounds in terms of race which in turn implies different cultures. Three out of the nine participants were PSTs of color and six were white. Of the three PSTs of color, two were born outside the US and moved into the US in their early age. The other was born and raised in the US. It was important to mention this variation in participants as their experiences are likely to inform their conception of mathematical creativity. Moreover, Leikin et al. (2013) indicated that some variables concerned with mathematical creativity depend on culture while other variables are intercultural.

Data Collection

We conducted two observations, one in each of the course sections for a duration of approximately 1.25 hours each. "A major purpose of observation is to see firsthand what is going on rather than simply assume we know" (Patton, 2015, p. 331). Having been familiar with the site, this was a statement that guided our observation in order to avoid uninformed conclusions. Given one of the authors' role in the classroom as a teacher assistant, it was her intention to avoid as much interaction as possible in order to capture majority of the events of the lessons and we therefore assumed the role of an onlooker (Patton, 2015) for the most part of the observations.

We also conducted one individual semi-structured interview (Roulston, 2010) with the nine participants. The semi-structured nature of the interview allowed us to deviate from the order of interview questions, because our interviewees' responses informed the choice and order of questions. For example, we did not have to ask all questions that we had in our protocol when an interviewee responded by also answering a follow-up question(s). We also used probing questions to follow-up on our interviewee's responses and yield more detail and explanations about what our interviewees had said (Roulston, 2010). While probing, in most cases, we used our interviewees' own words to formulate questions. The interview focused on PSTs conceptions of what it means to teach mathematics creatively followed by their conceptions of what it means to learn mathematics creatively.

Data Analysis

To analyze data, we used thematic analysis (Braun & Clarke, 2006) which is a "method for identifying, analyzing, and reporting patterns (themes) within data" (p. 79) or a process that involves looking for patterns within the data and categorizing those patterns according to themes (Fereday & Muir-Cochrane, 2006) cited in Bowen (2009). Thematic analysis uses coding as a strategy (deMarrais & Lapan, 2003). The themes were mainly from the aforementioned framework of Lev-Zamir and Leikin (2011). We analyzed our participants' responses to interview questions and occurrences from the classroom observations in light of flexibility, originality and elaboration. From these categories, we further grouped our findings into the subgroups of teacher-directed and student-directed conceptions of mathematical creativity. Data in the flexibility group included statements about different types of transformation of information in teaching and learning mathematics and varied solution paths to problems that could result from the teacher and/or the student. Data in the originality group entailed PSTs' statements about novel ways of thinking while teaching and learning. Novelty in this case referred to uniqueness from the usual accepted norms and conventions of problem solving in the process of teaching and learning. Data in the elaboration group constituted PSTs' statements about advancing thinking to higher and related levels.

Results

The data presented in this report are from three (Nelly, Paula, and Laura – pseudonyms) out of the nine PSTs. We chose to focus on these three participants here because they provided concise but representative data of the nine participants. We categorized the findings in terms of teacher-directed conceptions of creativity and student-directed conceptions of creativity as explained in the theoretical perspective.

Teacher-Directed Conceptions of Mathematical Creativity

This form of creativity included PSTs' views and actions, both mathematical and pedagogical, that enhance their teaching of mathematics creatively. The different views of PSTs' teacher-directed conceptions of creativity included using multiple approaches to solve problems, designing mathematical tasks from scratch, and making learning challenging but not impossible. Table 1 represents a summary of these conceptions, their description, and their perceived enactment, or the actions that teachers envision to ordain the conceptions.

Table 1: PSTs' Conceptions of Mathematical Creativity in Teaching

Conception	Description	Perceived Enactment
Teacher-Directed Conceptions of Mathematical Creativity		
Use multiple approaches to solve problems	Finding the solution to a mathematical problem using varied solution paths.	Provide support for students, both pedagogical and mathematical to help them think of and use various perspectives when solving problems. This support can be in terms of using supporting and extending moves, and purposeful questioning.
Design mathematical tasks from scratch	Exercise teachers' independence and creativity in determining content and context that will be accessible to students.	Devise contextual problems, use manipulatives, hands-on activities, and games that are appropriate to the goals of the lesson to engage students in thinking about mathematical concepts creatively. Integrate other subjects e.g. English and Science in mathematics lessons.
Make learning challenging but not impossible	Providing challenging problems and situations that will build students' intellectual curiosity and challenge them to think deeply about the problem and its solution.	Teach concepts to enhance sense making by students by not dwelling on algorithms. Extend students' thinking through questioning. Use purposeful questioning to elicit ideas that will help students think for themselves with less input from the teacher. Encourage productive struggle.
Student-Directed Conceptions of Mathematical Creativity		
Exercise independence in learning	Students' ability to develop their own perspective into learning and reasoning independently.	Students solving problems in their own way without being directed on how to do everything. Students putting new perspectives in problem solving.

Use Multiple Approaches to Solve Problems. This conception involved a teacher believing mathematical creativity as teachers' ability to provide support for students, both pedagogical and mathematical, to help them consider multiple perspectives when solving problems. Example quotes from the participants are:

Paula: I think it is super important that kids have different tools coz I don't think people my age and adults were really given anything other than the standard algorithm to solve a problem.

Laura: I think the biggest thing is learning all these different kinds of strategies and knowing that you should encourage it for kids because I feel like usually teachers just want you to stick to a specific strategy.

Both Paula and Laura identified the relationship between a variety of strategies, knowing and flexibility. They emphasized the need to incorporate different approaches to solving problems and making them accessible to students by not restricting them to a specific approach. More generally, their idea fits under the flexibility component of mathematical creativity because shifting perspectives in problem-solving can be considered as a form of transformation of information, say for instance, multiple representations (e.g. visual, symbolic) of a solution.

Design Mathematical Tasks from Scratch. At the time of study, PSTs were working with elementary students once a week during which they designed activities and problems to be worked on by their students, an exercise that they deemed as involving mathematical creativity. Example quotes from the participants are:

Nelly: Making up problems and, like the literature assignment, I felt like that was really creative… We pretend to be elementary schoolers a lot. And so we had to put ourselves in their mindset…. But including games that kids have to problem solve, like problem solving, I think is more, like introduces more creativity into math."

> Laura: So I think we should make math more creative for them (students). So they can still be learning something while, doing a fun activity. Maybe being able to work in groups or making games out of the math,…

Nelly and Laura viewed mathematical creativity as generating tasks that encourage activity while learning. Specifically, they mentioned the need to incorporate games in activities. Creating such activities required them to position themselves like students in order to ensure accessibility of the materials that they would generate.

During classroom observations, PSTs were challenged to make in the moment decisions on how they would support their students' thinking in their placement. Their professors brought up hypothetical scenarios, for example, on student misconceptions and asked PSTs to think of how they would support and/or extend their students' thinking. During our interactions with the PSTs, they also identified the need to integrate science and English in their lesson, what Nelly explained as talk about math not in a math class as being mathematically creative. Generally, we categorized this conception under originality trait of mathematical creativity because the process included considering student's level of understanding and designing tasks that would be accessible to them in terms of context and content, hence requiring specificity and novelty in thinking about the nature of the activities.

Make Learning Challenging but not Impossible. PSTs explained that it is important to put less pressure on students but at the same time maintain their interest and engagement in learning. The following example quotes supported this finding:

> Nelly: creative learning should feel more fun and more challenging but not impossible… teachers should let them (students) figure out things for themselves, instead of just telling."
>
> Laura: But I can see like, why it's better to be more creative because you can put in a whole lot of different perspectives into it. And it doesn't have to be so straightforward.

Nelly emphasized the need for teachers to allow students to make sense of mathematical ideas on their own and Laura also supported this idea by emphasizing the idea of not being straight forward and having students develop their own perspectives into learning. We categorized this conception under the originality component because we portrayed making sense of mathematical concept with less scaffolding as requiring a higher personal cognitive input.

Student-Directed Conceptions of Creativity

PSTs' student-directed conceptions of creativity were closely aligned with their teacher-directed conceptions of creativity. They included students generating their own solutions to mathematical tasks, which we termed as exercising independence in learning.

Exercising Independence in Learning. PSTs viewed students' ability to generate their own and varied solutions and explain their thinking as an indication of mathematical creativity. Example quotes include:

> Nelly: students should be able to do it (math) their own way and not being told exactly how to do everything.
>
> Paula: I would say like being able to come up with like, explain it back to me verbally,…

Both Nelly and Paula address the need for students to own their learning with less input from the teacher and by describing their reasoning. They are allowed the freedom to bring their own perspective into learning and make sense in a manner that best suits their way of making sense. We situate this conception under originality because doing it in your own way and explaining it verbally foster uniqueness in individual thought processes.

Discussion and Conclusion

Findings of the present study indicate that PSTs conceive teaching mathematics creatively as supporting students to use various strategies to solve problems when teaching, developing appropriate mathematical tasks to enhance student activity and engagement while learning, and providing challenging but accessible learning opportunities for students. PSTs conceived learning mathematics creatively as students being independent in learning. These conceptions, teacher-directed and student-directed are intertwined in that, perceived enactments of teacher-directed conceptions of mathematical creativity enhance student-directed conceptions of creativity. For example, when teachers use purposeful questioning to elicit ideas that will help students to think independently and when they support students to use multiple problem solving approaches, teachers can enhance student independence in learning by challenging them to think and bring in self-generated and new perspectives. This observation is partly in line with Lev-Zamir and Leikin's (2011) assertion that defining mathematical creativity in the context of teaching should allude to mathematics, teaching, learning and creativity. Our reason for using partly in line with is because we observed that PSTs commented on, for example, using games and manipulatives to make the learning of mathematics fun, and as an avenue to teaching mathematics creatively. However, the math behind or within the "fun" was not given keen attention. PSTs tended to overlook creativity and mathematics, which was emphasized by Haylock (1987) and Lev-Zamir and Leikin (2011) and attended more to teaching and learning in their descriptions of their conceptions of mathematical creativity. Care should therefore be taken to differentiate between teaching creatively and teaching for creativity (NACCCE, 1999) to ensure that students do not just have fun in class while engaging in games but that they also understand the math behind or within the fun and develop their own creativity.

Connecting to research, results of this study are not unique to mathematical creativity, and thus tie closely to other findings and recommendations from researchers whose focus is not necessarily on mathematical creativity. To begin with, encouraging students to use different approaches to solving problems does not occur naturally if a teacher has not anticipated some of the strategies that students are likely to use. Anticipating student strategies is a key practice for successful orchestration of classroom discussions. Discussions stimulate interaction, an important catalyst to creativity, as the teacher responds to students using assessing and advancing questions, and notices important aspects of student thinking during instruction (Smith & Sherin, 2019). Second, teachers who are open to designing tasks from scratch are likely to demand of the same from their students, by not just providing students with problems to work on, but also challenging them to generate problems that address specific mathematical concepts. This practice demands high cognition and is at the level of doing mathematics (Smith & Stein, 1998). It discourages algorithmic thinking, requires students to comprehend mathematical concepts, processes, and relationships, and demands self-monitoring, only to mention but a few, according to Smith and Stein (1998). These conditions are equally important to cultivating mathematical creativity for both teachers and students. Third, providing students with challenging but not impossible questions has a potential to stimulate students' intellectual curiosity and hence develop their creativity. The points we raise in this discussion do not mean that we should not pay close attention to creativity in mathematics in the field of mathematics education, but rather consider investing in its research as it is a potential contributor to the growth and improvement of teaching and learning of mathematics.

We note that the findings of this study are not a complete representation of what conceptions of mathematical creativity are. Conceptions are informed not just by educational experiences, but by culture and beliefs and therefore this area of research is open to more studies, particularly with a focus on specific types of experiences that shape these conceptions. This will be important in shaping our teacher preparation programs to provide PSTs with those experiences necessary to support their understanding and development of mathematical creativity and that of their students.

We close with noting that a major observation from our literature review was that research in mathematics education has overlooked mathematical creativity due to lack of an accepted definition of mathematical creativity. We argue that we cannot overlook mathematical creativity simply because of lack of coherence in existing definitions of what mathematical creativity is, but we can instead focus on specific conceptions of it and develop its understanding because by doing this, we will not only be focusing on what it is, but also on what it could be, which is not always done in other fields of research with agreed definition of constructs. By doing that we won't limit our understanding on what it is but can explore the what it could be and find connections that will expand our horizon in understanding of the concepts, and possibly impact the field of mathematics education.

Exposure to technologies such as mixed-reality simulations (MRS) can influence the opinions of pre-service elementary teachers (PSET), as well as the way they see and perceive MRSs as a useful experience in their preparation. Particularly, in the implementation high-leverage practices. The study presented here was carried out in a course of mathematical methods for elementary. The research questions are: What are the PSETs perceptions of the use of MRS as part of their teaching preparation? What are the views of PSET on MRSs as a tool to improve their teaching skills? Results indicate that PSET perceive MRSs as a highly positive, relevant and meaningful tool that supports their learning, as well as a way to improve their high-leverage skills.

Key Words: Technology, Teachers belief, Pre-service teacher preparation.

Introduction

The perception, views, and opinions of pre-service elementary teachers (PSET) regarding their acquisition of teaching skills can be influenced by the integration of technology in their teacher preparation program. Perceptions change when these technologies are linked to practice and are recognized as having several benefits (Gordon, Brayshaw and Gray, 2015; Russell, Bebell, O'Dwyer & O'Connor, 2003). Specifically, we refer to the use of emerging technologies such as Mixed-Reality Simulations (MRS), which are tools intended –but not limited– to provide simulated experiences to pre-service teachers. Engaging with mixed-reality simulations take place in a controlled and safe environment, which has the potential to improve and strengthen teaching skills (Hixon & So, 2009).

This report presents the perceptions, opinions, and points of view of Pre-service Elementary Teachers regarding the utility, benefits, and challenges of using mixed-reality simulations, as part of the teacher training program. Pre-service elementary teachers were exposed to the use of MRSs in an elementary mathematics methods course. The use of MRSs with PSETs was intended to foster high-leverage practices (Ball & Forzani, 2011) such as productive mathematics talk moves (Chapin, O'Connor & Anderson, 2009; Moyer & Milewicz, 2002; Ginsburg, 1997). These productive teaching moves include eliciting, evaluating, and questioning elementary students as they share and explain their solutions to problem solving activities in mathematics. To this end, the following research questions are addressed: What are the perceptions and ideas of pre-service elementary teachers regarding the use of mixed-reality simulations as part of the teacher preparation program? What are the opinions of pre-service elementary teachers on mixed-reality simulations as a tool used to improve their teaching skills, particularly those related to productive mathematical talk move?

Theoretical Perspectives

Insights on The Use of Technology

In order for pre-service teachers have the theoretical understanding of the benefits of being exposed to the use of technologies such as mixed-reality simulations, their perceptions and opinions regarding the usefulness of this must be framed in what Venkatesh, Morris, Davis and Davis (2003) have called the theory of acceptance and perception of the use and exposure to technology. According to Venkatesh et al., the perception that PSETs have about the benefits and utility of the use of technologies can be influenced by their experiences with it in their preparation programs. Venkatesh et al. adopted Davis's (1989) definition of utility as the measure by which an individual believes or perceives that the use of a particular technology (e.g., Mixed-Reality Simulations) improves the work being done, in which case, for the PSETs and the purpose of this study, would be the learning process and the teaching skills fostered through high-leverages practices such as productive mathematics talk moves in problem solving where one seek to elicit and understand a student's thought.

Mixed-Reality Simulations and Teaching Strategies

Mixed-Reality simulations were implemented in the context of a course on mathematics methods for elementary school. High-leverage strategies were integrated into this course (Ball and Forzani, 2011). According to Ball and Forzani, these strategies, are pedagogical skills that directly impact the student's academic performance and that can be implemented at various school levels in a high number of subjects or context. Some of these pedagogical strategies include how to promote an active participation from students, provide positive feedback, how to reveal, understand, and interpret the students' thoughts and ideas through productive mathematical talk moves (Chapin, O'Connor & Anderson, 2009), among others. According to Chapin, O'Connor & Anderson, productive mathematical talk moves (PMTM) refer to all those actions that teachers must carry out during teaching (including moments of group discussion or during an exchange of ideas between a teacher and a student) to better understand the ideas and understandings of the students. Some PMTMs, for example, include asking a student to repeat another student's idea in their own words, or asking a student to go deeper in their explanations, or simply remaining silent to listen to what a student is saying. During mixed-reality simulation sessions, the pre-service teacher practiced how to implement the pedagogical strategies mentioned above. Similarly, Pre-service teachers were able to experience what they could potentially expect when interacting with real students.

What are Mixed-Reality Simulations?

New technologies in education are now implemented to improve the process of teaching and learning. However, little has been done to integrate and expose Pre-service elementary teachers to emerging technologies such as *Mursion*, which are simulation technologies that allow a pre-service teachers to have "repeated practices involving high-risk situations without necessarily risking the loss of valuable resources" (Dieker et al., 2014, p.22).

Mursion is a mixed-reality simulation software where students are avatars and a virtual classroom is simulated. The pre-service elementary teacher has the opportunity to experience situations related to teaching. During a simulation session, a pre-service elementary teacher sees students or avatars in a classroom through a computer–or device– screen. The pre-service elementary teacher initiates the interaction with these avatars in the same way as it would in a classroom. In MRSs, the avatars are controlled by an educational trained specialist. The pre-service teachers are actually in a semi-controlled, structured, and prepared interaction with a specialist. The specialist controls the avatar, and not a computer program as in virtual reality, which allows for greater flexibility to offer the various classroom situations, both expected and unexpected similar to those that occur in a real classroom with a sense of reality in which there is a "real presence", defined by Dieker et al. (2015) as the perception that something real is happening.

Methods

Approximately 166 pre-service elementary teachers have taken the mathematics methods course since fall 2018, of which 92% were women and 8% men. Participants were in their first or second year of the preparation program. All pre-service elementary teachers were required to conduct an interview with an elementary student and assess their understanding when solving a series of mathematics problems. To this end, pre-service elementary teachers were exposed to theories on problem solving. During the course, the PSETs were prepared by analyzing teaching videos, rehearsing play roles as student/teacher, and experiencing three MRS sessions. Each MRS session lasted between 7 and 12 minutes and were video recorded. Each session required the PSETs to implement a different problem. The problems were selected by the researchers following the theoretical framework of cognitive guided instruction problems (Carpenter, Fennema, Franke, Levi & Empson, 2014). MRSs sessions were scheduled three times during the semester to ensure that the theoretical and pedagogical concepts discussed in class were acquired. At the end of the semester, pre-service teachers were asked to complete a survey to measure their perceptions, views, and opinions about the use of mixed-reality simulations.

Instrument

The instrument was developed using items from Hudson, Voytecki and Zhang, (2018), Bousfield, (2017) and Rasimah, Ahmad and Zaman (2011), and adapted for the purposes of the research. The survey consisted of 27 questions with a scale ranging from 1 to 5, where one means completely agree, to a five strongly disagree (see appendix A). Additionally, 4 open-ended questions were included to capture the opinions of the PSETs on what was most positive or negative about the experience with MRSs, the challenges they had while rehearsing with MRSs, and their perceptions of the benefits of being able to be prepared with the use of mixed reality simulations.

Results and Discussion

The implementation of MRSs allows pre-service teachers to participate in virtual classroom environments that simulate real classrooms. In this sense, 94% of participants agree or totally agree that the MRSs simulated a very similar and real experience as classroom, and 97% expressed that they see the practices with the MRS as a very positive experience. For example, participants mentioned that MRSs "provides unexpected experiences that I had to deal with, and help me feel better prepared for the real-world "; "How the avatar speaks and acts, seems like a real children, especially with their responses"; "I liked being able to practice as if it were a real classroom"; "I was able to practice as if I was really in front of the classroom with real students."

The use of MRSs in a teacher preparation program is not intended to displace the actual experience, but rather to enhance the preparation experiences (Peterson-Ahmad, 2018), in a protected, semi-controlled and safe environment (Hatton, Birchfield and Megowan-Romanowicz, 2008). Participants in the study acknowledge the above, for which 97% agree or fully agree that the use of MRSs is an effective way to practice new skills in the classroom, particularly in mathematics, of which 94 and 97%, respectively, expressed feeling more confident and better prepared to teach mathematics effectively or to engage their students in topics that involve discussions of problem solving activities, as they mentioned: "What I liked about the MRSs is that I was able to practice math problems as if I was really teaching it to real students." In this same sense, 88% of the pre-service elementary teachers agree or totally agree that after having been exposed and practiced with MRSs, they feel better prepared to carry out an interview with an elementary student on mathematics topics, where they should evaluate and verify the ideas, thoughts, and understandings using PMTMs.

Pre-service elementary teachers recognized the benefits of been exposed to a cutting-edge technology that is used as an educational tool to improve, enhance, and facilitate the acquisition of educational practices such as high-leverage practices. Several participants mentioned that the experience with MRS “allowed [them] to get the necessary practice before finishing the program and teach real students." Finally, one of the most received opinions by the participants, was that they wish they had the opportunity to have more time to interact with MRSs.

Conclusions

The way in which teachers are prepared is significant, since it is during these times when they acquire the skills and knowledge necessary for their future work as teachers (Vagi, Pivovarova and Miedel Barnard, 2019). Then, its relevant to report the findings of this study, so that other teacher preparation programs know the benefits and potential of integrating emerging technologies such as Mixed-Reality Simulation in their courses and improve the teaching skills of their teachers, since the first day of the program. As shown in the previous section, the perceptions and opinions of the pre-service elementary teacher on the usefulness of MRS are very positive, which would facilitate their integration. Similarly, when the integration of MRSs is seen as positive, efforts and resources allocated to implement simulations would be justified. The use of MRSs in a teacher preparation program, particularly in a math method course, as it was done here, is an innovative way to improve the acquisition of teaching skills by pre-service elementary teachers. During this first phase of the study, it is shown that participants perceive MRS as a useful tool, that helped them improve their teaching skills — particularly with regard to eliciting and questioning students in a classroom or as a teacher-student interview. The well-structured, guided, and planned use of MRSs technologies (Venkatesh et al., 2003) helped the pre-service elementary teacher perceive MRS as a tool intended to improve their pedagogical teaching skills (Ball & Forzani, 2011), and not to replace the real experience, which is a common limitation during the first years in preparation programs.

The results presented here are only the first phase of a larger study that involves analyzing the transcripts of the pre-service elementary teacher after they have interviewed an elementary school student. The results of this study will be analyzed, contrasted and presented in another report in this same forum, meanwhile, more data will continue to be collected on the perceptions, points of view and opinions on the use of mixed-reality simulations in a teacher preparation program.

APPENDIX A

1. I like to experience with new technologies.
2. I enjoy rehearsing with Mixed-Reality Simulations.
3. I was unhappy when the Mixed-Reality Simulations sessions were over.
4. I would like to repeat the same experience using Mixed-Reality Simulations.
5. I feel that using Mixed-Reality Simulations enhanced my learning experience.
6. I feel better prepared to teach after my Mixed-Reality Simulation session.
7. Using the Mixed-Reality Simulation is an effective way to practice new classroom skills.
8. My Mixed-Reality Simulation session seemed like a real classroom experience.
9. The Mixed-Reality Simulation's students seemed like real elementary students.
10. After practicing my teaching methods using Mixed-Reality Simulations, I am more confident that I can effectively teach mathematics concepts.
11. After the MRS, I feel prepared to conduct a clinical interview to assess and elicit students thoughts and understanding using mathematics productive talk moves.
12. After my Mixed-Reality Simulation sessions, I have more confidence that I can engage students in a discourse about problem-solving activities.
13. I was able to effectively manage the interview during my Mixed-Reality Simulation sessions.

14. After the Mixed-Reality Simulation rehearsal, I feel prepared to orchestrate a group discussion in a classroom to assess understanding using mathematics productive talk moves.
15. After Rehearsing with the Mixed-Reality Simulations, I felt my Clinical interview with an elementary student was conducted effectively.
16. After the Mixed-Reality Simulation sessions, I have more confidence in my ability to manage undesired behaviors in group discussion.
17. After my Mixed-Reality Simulation sessions, I am better prepared to teach lessons involving problem solving.
18. I felt the Mixed-Reality Simulation's interviews were conducted effectively.
19. I felt like I was in a real classroom during the sessions.
20. The Mixed-Reality Simulation sessions prepared me to conduct the clinical interview.
21. The Mixed-Reality Simulation rehearsals helped me to create a plan for the clinical interview with an elementary student.
22. My experience with Mixed-Reality Simulations prepared me to teach.
23. I would like to use Mixed-Reality Simulation to develop my teaching skills in other courses.
24. Reflecting after each Mixed-Reality Simulation helped me to be better prepared for the next rehearsal.
25. Receiving peer feedback after each Mixed-Reality Simulation helped me to reflect on my strengths and weakness in assessing a students' understanding.
26. Receiving peer feedback after each Mixed-Reality Simulation helped me to reflect on my strengths and weakness in conducting a clinical interview.
27. Providing feedback to my peers after each Mixed-Reality Simulation helped me to reflect in my own teaching skills.

Open-Ended questions

1. What did you like the most about the Mixed-Reality Simulation?
2. What did you dislike the most about Mixed-Reality Simulation?
3. What do you consider was the most challenging aspect of interacting in with Mixed-Reality Simulations?
4. Do you believe using Mixed-Reality Simulation was beneficial for your Teacher-Preparation? If yes, why? if not, why?

USO DE SIMULACION DE REALIDAD-MIXTA COMO HERRAMIENTA EN LA FORMACIÓN DE MAESTROS: PERCEPCIONES Y OPINIONES

THE USE OF MIXED-REALITY SIMULATIONS AS A TOOL FOR PREPARATING PRE-SERVICE TEACHERS AND THEIR PERCEPTIONS AND OPINIONS

La exposición a tecnologías como simulaciones de realidad mixta (SRM) puede influenciar las opiniones de los maestros de primaria en formación (MPF), así como la manera en la estos ven y perciben las SRM como un instrumento útil en su preparación docente. Particularmente, en la implementación de estrategias pedagógicas de enseñanza de alto apoyo académico (EPEAA). El estudio aquí presentado se llevo a cabo en un curso de métodos matemáticos para primaria. Las preguntas de investigación son: ¿Cuáles son las percepciones de los MPF sobre el uso de las SRM como parte de su preparación docente? ¿Cuáles son las opiniones de los MPF sobre las MRS como herramienta para mejorar sus habilidades de enseñanza? Resultados señalan que los MPF perciben las SRM como una herramienta altamente positiva, relevante y significativa que respalda sus aprendizajes, así como una forma de mejorar sus habilidades de EPEAA.

Palabras clave: Tecnología, Creencias de los docentes, Preparación de Maestros en Formación.

Introducción

La percepción, puntos de vista, y opiniones de los maestros de primaria en formación (MPF) sobre cómo la tecnología puede ayudarlos a adquirir nuevos conocimientos y habilidades de enseñanza, pueden verse influenciadas si estas tecnologías se integran como parte de sus programas de preparación. Especialmente, si estas tecnologías están vinculadas a la práctica y se presentan como un instrumento con múltiples beneficios (Gordon, Brayshaw y Gray, 2015; Russell, Bebell, O'Dwyer y O'Connor, 2003). De forma específica, nos referimos al uso de tecnologías emergentes como las simulaciones de realidad mixta (Mixed-Reality Simulations en inglés). Los softwares de simulación de realidad mixta (SRM), son herramientas destinadas a proporcionar a los maestros de primaria en formación experiencias simuladas. Estas experiencias ocurren en un ambiente controlado y seguro, que busca mejorar y fortalecer las habilidades de enseñanza (Hixon & So, 2009).

El reporte que se presenta en esta propuesta muestra cuáles son las percepciones, opiniones y puntos de vista de los maestros de primaria en formación con respecto a la utilidad, beneficios y retos de utilizar simulaciones de realidad mixta, como parte del programa de formación docente. El uso de SRM con los maestros de primaria en formación tuvo la intención de fomentar estrategias pedagógicas de enseñanza de alto apoyo académico (Ball y Forzani, 2011) como los movimientos productivos de conversación matemática (Chapin, O'Connor y Anderson, 2009; Moyer y Milewicz, 2002; Ginsburg, 1997) para obtener, evaluar y cuestionar a los estudiantes mientras comparten y explican sus soluciones a actividades de resolución de problemas en matemáticas. Con este fin, se buscaron responder las siguientes preguntas de investigación: ¿Cuáles son las percepciones e ideas de los MPF sobre el uso de las simulaciones de realidad mixta como parte del programa de formación docente? ¿Cuáles son las opiniones de los MPF sobre las simulaciones de realidad mixta como una herramienta utilizada para mejorar sus habilidades de enseñanza, particularmente las relacionadas a los movimientos productivos de conversación matemática?

Marco Teórico

Perspectivas sobre el uso de la tecnología

Hoy en día, para que los MPF realmente tengan una comprensión teórica de los beneficios de ser expuestos al uso de tecnologías como las simulaciones de realidad mixta, sus percepciones y opiniones con respecto a la utilidad de esta se deben enmarcar en lo que Venkatesh, Morris, Davis y Davis (2003) han llamado la teoría de la aceptación y percepción del uso y la exposición a la tecnología. Según Venkatesh et al., la percepción que tienen los maestros en formación sobre los beneficios y la utilidad del uso de tecnologías pueden mejorarse significativamente cuando se abordan adecuadamente en los programas de preparación. Venkatesh et al. adoptó la definición de utilidad (Davis, 1989) como la medida por la cual un individuo cree o percibe que el uso de una tecnología en particular (p. ej., Simulaciones de Realidad Mixta) mejora el trabajo que se realiza, en cuyo caso — para los maestros de primaria en formación y el propósito de este estudio, sería el proceso de aprendizaje y las habilidades de enseñanza fomentadas a través de estrategias pedagógicas de enseñanza de alto apoyo académico como los movimientos productivos de conversación matemática (MPCM) en la resolución de problemas donde se busque entender y comprender el pensamiento del estudiante.

Estrategias de enseñanza y su relación con las Simulaciones de Realidad Mixta

Las SRM se implementaron en el contexto de un curso de métodos matemáticos para MPF. En este curso se integraron estrategias pedagógicas de enseñanza de alto apoyo académico (Ball y Forzani, 2011). Según Ball y Forzani, estas estrategias, mejor conocidas en inglés como *High-Leverage Practices*, son habilidades pedagógicas que impactan directamente el rendimiento académico del estudiante y que pueden ser implementadas en diversos niveles escolares en un alto número de materias o contenidos. Así mismo, son estrategias que se aprenden a través de la práctica docente y la retroalimentación oportuna y precisa. Algunas de estas estrategias pedagógicas incluyen el cómo tener una participación activa de los estudiantes, dar una retroalimentación positiva, como revelar, comprender e interpretar el pensamiento e ideas de los estudiantes a través de movimientos productivos de conversación matemática, entre otros. Los movimientos productivos de conversación matemática se refieren a todas aquellas acciones que debe llevar a cabo el maestro durante la enseñanza (incluyendo momentos de discusión grupal o durante un intercambio de ideas entre un maestro y un estudiante) para comprender mejor las ideas y entendimientos de los estudiantes acerca del tema que se está enseñando. Algunos MPCM, por ejemplo, incluyen pedir a un estudiante que repita la idea de otro compañero con sus propias palabras, o pedir a un estudiante que profundice en sus explicaciones, o simplemente guardar silencio para escuchar lo que está diciendo un estudiante.Durante las sesiones de SRM, los MPF practicaron como implementar las estrategias pedagógicas mencionadas anteriormente.

Simulaciones de Realidad Mixta

Hoy en día se implementan nuevas tecnologías en educación para mejorar el proceso de enseñanza y aprendizaje. Sin embargo, poco se ha hecho para integrar y exponer a los MPF a tecnologías emergentes como Mursion, que son tecnologías de simulaciones que permiten a los maestros en formación tener "prácticas repetidas que involucran situaciones de alto riesgo sin necesariamente arriesgar la pérdida de recursos valiosos" (Dieker et al., 2014, p.22). Mursion es un software de SRM en donde se simula que los estudiantes (comúnmente conocidos como avatar) están en un aula virtual. El MPF, consecuentemente, tiene la oportunidad de experimentar situaciones relacionadas con la enseñanza en un entorno simulado y seguro. Durante una sesión de simulación, los MPF ven a través de la pantalla de una computadora a los estudiantes o avatar en un salón de clases. El MPF inicia su interacción con estos avatars de la misma manera que lo haría en un salón de clases. De forma tal que lo que parece, a vista del MPF, una interacción con un avatar de computadora, es realmente una interacción semi-controlada, estructurada y preparada con un especialista. El hecho de que sea un especialista el que controla los avatar y no un programa de computación para realidad virtual, da la flexibilidad de poder ofrecer al MPF un infinito número de posibilidades de preparación, en situaciones tan inesperadas, como podría ocurrir en un salón de clases real. Algo importante, es que estos entornos proporcionan al MPF un sentido de la realidad en el que hay un "presente real", definido por Dieker et al. (2015) como la percepción de que algo real está sucediendo.

Métodos

Desde el otoño de 2018 hasta el otoño de 2019, 166 MPF que han tomado el curso de métodos matemáticos para primaria han participado en el estudio, de los cuales 92% han sido mujeres y 8% hombres. Todos los participantes se encontraban en su primer o segundo año del programa de preparación docente. Como parte de los requerimientos del curso, todos MPF debían realizar una entrevista con un estudiante de primaria y evaluar la comprensión de este al resolver una serie problemas de matemáticas. Así, durante el curso MPF fueron expuestos a las teorías de resolución de problemas, y de aprendizaje y enseñanza de métodos matemáticos para primaria, se analizaron videos, se hicieron prácticas y ensayos en clases y se les pidió que tuvieran 3 sesiones de simulación con realidad mixta. Las SRM duraron entre 7 y 12 minutos y fueron video grabadas, y en cada una se usó un problema diferente. Los problemas siguieron el marco teórico de problemas de instrucción cognitiva guiada o mejor conocido en inglés como "*Cognitive Guided Intruction*" de Carpenter, Fennema, Franke, Levi y Empson, (2014). Las sesiones de SRM se distribuyeron durante el semestre para garantizar que los MPF asimilaran los conceptos teóricos y pedagógicos discutidos en clase.

Instrumento

Se usó una encuesta adaptada de Hudson, Voytecki y Zhang, (2018), Bousfield, (2017) y Rasimah, Ahmad y Zaman, (2011). La encuesta comprende 27 preguntas en una escala de 1 a 5 que va desde completamente de acuerdo, a completamente en desacuerdo (ver apéndice A). Además, se incluyeron 4 preguntas abiertas para capturar las opiniones de los MPF sobre lo más positivo o negativo de la experiencia con SRM, los desafíos que tuvieron al ser preparados en su formación a través del SRM y las percepciones de los beneficios de la formación con SRM.

Resultados y Discusión

La implementación de simulaciones de realidad mixta permite a los MPF en formación participar en entornos de aula virtual que simulan aulas reales. En este sentido, el 94% de los maestros en formación están de acuerdo o totalmente de acuerdo en que las sesiones de SRM simulaban una experiencia muy parecida y real a la del aula, y 97% expresaron que ven las prácticas con los SRM como una experiencia muy positiva. Por ejemplo, algunos participantes dijeron:"[Las simulaciones con SRM] proporciona experiencias inesperadas que tuve que solucionar, y me ayudo a sentirme mejor preparado para el mundo real"; "Cómo hablan y actúan los avatar, parecen como niños reales, especialmente con sus respuestas"; “Me gustó poder practicar como si fuera un aula real”; "Pude practicar como si realmente estuviera delante de la salón de clase con estudiantes reales". El uso de SRM en un programa de preparación docente no pretende desplazar la experiencia real, sino más bien mejorar la experiencia de formación de los MPF (Peterson-Ahmad, 2018), en un entorno protegido, semi-controlado y seguro (Hatton, Birchfield y Megowan-Romanowicz, 2008). Los MPF en el estudio reconocen lo anterior, por lo que el 97% están de acuerdo o totalmente de acuerdo en que el uso de SRM es una forma efectiva de practicar nuevas habilidades en el aula, particularmente en matemáticas, de los cuales el 94 y el 97%, respectivamente, expresaron sentirse ahora con más confianza y mejor preparados para enseñar matemáticas de manera efectiva o para involucrar a sus estudiantes en temas que involucren discusiones sobre actividades de resolución de problemas. Por ejemplo, un MPF resaltó lo siguiente: "Lo que me gustó de la SRM es que pude practicar problemas de matemáticas como si realmente lo estuviera enseñando a estudiantes reales". Así, el 88% de los MPF están de acuerdo o totalmente de acuerdo con que después de haber estado expuestos y practicado con SRM, se sienten mejor preparados para llevar a cabo entrevista con un estudiante sobre temas matemáticos donde ellos deban evaluar y verificar las ideas, pensamientos, y comprensiones de sus estudiantes, utilizando MPCM. Otro MPF expreso su opinión en este sentido: “[Usar SRM] fue divertido y atractivo ... las simulaciones me ayudaron a fortalecer mi comprensión sobre los temas que se enseñan en clase, en particular mis habilidades para hablar e interactuar con los estudiantes en clases [es decir, los MPCM] ”.

Por último, los maestros de primaria en formación reconocieron los beneficios de haber estado expuestos a una tecnología de vanguardia que se utiliza como una herramienta educativa para mejorar, acrecentar, y facilitar la adquisición de prácticas educativas como las estrategias pedagógicas de enseñanza de alto apoyo académico, por lo que los MPF mencionan que desearían tener más tiempo para interactuar en con las simulaciones de realidad mixta.

Conclusiones

La forma en que los maestros son preparados es muy relevante, ya que es durante este tiempo cuando adquieren las habilidades y los conocimientos necesarios para su futuro trabajo como docentes (Vagi, Pivovarova y Miedel Barnard, 2019). Así, resulta relevante reportar los hallazgos de este estudio, para que otros programas de preparación de maestros conozcan los beneficios y el potencial de integrar tecnologías emergentes como las simulaciones de realidad mita en sus cursos y mejoren las habilidades de enseñanza de sus maestros de primaria en formación, desde el primer día del de clases. Como se muestra en la sección anterior, las percepciones y opiniones de los MPF sobre la utilidad de las SRM son muy positivas, lo que facilitaría su integración. De igual manera, al ser vista como positiva la integración de SRM, el tiempo, esfuerzo y recursos destinados a implementar las simulaciones estarían acertadamente justificadas. El uso de SRM en un programa de preparación docente, particularmente en un curso de método matemático, es una forma innovadora de mejorar la adquisición de habilidades de enseñanza de los MPF. El uso bien estructurado, guiado, y planificado de la tecnología (Venkatesh et al., 2003) — como se implementan las SRM en este estudio— ayudó a los MPF a percibir a las SRM como una herramienta destinada a mejorar sus habilidades pedagógicas de enseñanza de alto apoyo académico (Ball & Forzani, 2011), y no para sustituir la experiencia real, que es una limitación común durante los primeros años en el que los maestros reciben su formación.

Los resultados presentados aquí son sólo la primera fase de un estudio más amplio que involucra el análisis de las transcripciones de los maestros de primaria en formación una vez que han realizado la entrevista con estudiantes de primaria. Los resultados de este estudio serán analizados, contrastados y presentados en otro informe en este mismo foro, mientras tanto, se seguirán recopilando más datos sobre las percepciones, puntos de vista y opiniones de los MPF sobre el uso de simulaciones de realidad mixta como parte de la preparación de maestros.

PRE-SERVICE TEACHERS' OPERATIONALIZATION OF COGNITIVE DEMAND ACROSS CONTEXT

Monica Anthony — University of Maryland — mrd@umd.edu

Margaret Walton — University of Maryland — mwalton@umd.edu

William Viviani — University of Maryland — wviviani@umd.edu

This research uses a framing perspective to examine how pre-service teachers (PSTs) conceptualize cognitive demand when selecting tasks. Our results show that PSTs' operationalizations of cognitive demand are context dependent. Within their methods class, PSTs largely think of cognitive demand in terms of how it promotes understanding of mathematics. When PSTs interact with students, they tend to operationalize cognitive demand as a way to support perceived student disposition and ability, or as a way to determine problem difficulty.

Keywords: Cognition, Learning Theory, Teacher Education – Preservice, Teacher Knowledge

Introduction

Selecting tasks that promote reasoning and problem solving is an important part of mathematics teaching (CAEP Standards, 2020). Research shows that selecting such tasks can be difficult for pre-service teachers (PSTs), but interventions in university methods classes can improve PSTs' ability to choose mathematically rich tasks (Crespo, 2003; Crespo & Sinclair, 2008; Leavy & Hourigan, 2019). Attending to the cognitive demand of tasks is one way to focus PSTs' attention on the mathematical features of tasks (Stein et al., 1996; Stein, Smith, Henningsen & Silver, 2000). *Cognitive demand* (CD) refers "to the kinds of thinking needed to solve tasks" (Stein et al., 2000, p. 3). Low-level tasks rely on applying memorized facts or procedures, requiring little understanding of the underlying mathematical concepts. In contrast, high-level tasks provide for multiple entry points and solution paths, requiring students to engage in meaningful inquiry and problem solving. While tasks of each level of CD support different learning goals, high-level CD tasks are linked to the greatest gains in student learning (Stein et al., 2000). Therefore, it is important that teachers be able to select high CD tasks for instruction.

As teacher educators, we are interested in how PSTs think about task selection in relation to CD as they move from a methods class to their internships. We ask, *how do PSTs operationalize cognitive demand in task selection across contexts?* For the purposes of this study, we consider two contexts: (1) reflecting on CD as students in a methods course that emphasizes rigorous mathematical tasks, and (2) applying CD when teaching middle grades students. Our study adds to the literature of task selection because it considers how PSTs reason about the CD of tasks, which impacts their task selection.

Theoretical Framework

We use the lens of *framing* to explain PSTs' changes in conception of CD across contexts. Framing has been used in science education research to describe how teachers and students understand particular educational contexts, and how that understanding impacts their ideas about knowledge, along with their actions and interactions with others (e.g., Hammer, Elby, Scherr, & Redish, 2005; Elby & Hammer, 2010; Richards et al., 2020). From this perspective, people learn by activating resources, which are "fine-grained knowledge elements" (Elby & Hammer, 2010, p. 410) based on factors such as lived experiences, social interactions, and beliefs. When resources are repeatedly activated together, they form "locally coherent sets" (Elby & Hammer, 2010, p. 413) called frames. In the classroom, these frames give a teacher or a student a sense of "what is going on here"

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

(Hammer et al., 2005), which impacts how they interact with others and the content. A critical feature of this framework is that context determines the resources that people activate. Thus, framing allows for individuals to hold multiple beliefs or perceptions, while identifying which resources are foregrounded during a given activity.

Methods

This brief research report is a secondary analysis relying on a subset of data from a larger study that investigates middle grade mathematics and sciences PSTs' lesson planning behaviors throughout their early field experiences.

Middle grades mathematics methods course

The participants are 10 undergraduate PSTs in a middle grades mathematics and science dual certification program who completed a mediated field experience mathematics methods course, taught by the first author. The field experience component of the course took place at a local middle school, where PSTs selected and implemented tasks with small groups of students. The CD of mathematical tasks was explicitly and regularly addressed in the methods course.

Data sources

The data sources for this brief research report include PSTs' final course papers and the transcripts from two individual semi-structured interviews, conducted by the first author. The final course assignment (Fall 2018) asked PSTs to reflect on how the methods course supported their growth as a learner and doer of mathematics. The first interview was conducted the semester following the methods course (Spring 2019). PSTs were asked to reflect on their process for selecting tasks and preparing lesson plans for the after-school enrichment program. PSTs were probed for whether the CD of tasks played a role in their decision-making. The second interview was conducted a year after the methods course (Fall 2019). PSTs were asked about their teaching internship and to analyze tasks from the casebook authored by Stein, Smith, Henningsen, and Silver (2000).

Analysis

Our research builds on the work of Elby and colleagues (2020) who demonstrated how analysis of written reflections can provide teacher educators with insight on PSTs' framing of classroom activity in a more timely manner than the interaction-analysis techniques traditionally employed with a framing perspective. The authors describe this type of analysis as "framing lite." The data sources were initially coded by the first author for references to CD. Next, we independently looked for trends in PSTs' statements about CD both when they discussed selecting tasks in the abstract and when thinking about task selection in relation to their internships. We then discussed our observed trends and developed a codebook. Each transcript was randomly assigned to two authors who then completed independent coding. After independent coding, we met to examine discrepancies in codes. Once in agreement, we combined the codes into broader categories of the ways that PSTs' discussed CD. We found these categories clustered together based on context and we discussed what PST experiences (e.g. activities in the methods class or interactions with students) might be contributing to these clusters. These clusters became the general "lite" frames that describe PSTs' application of CD.

Findings

We found that PSTs operationalize CD as related to task selection differently depending on context. In situations devoid of K-12 students, like reflecting on their methods class, PSTs largely described CD in terms of math content and student understanding. In this instance, PSTs seemed to frame CD as a feature of mathematical tasks. In contrast, when reflecting on their experiences with real students, PSTs seemed to frame CD as a mediator of perceived student need. PSTs' discussion of CD in relation to task selection shifted toward cultivating student dispositions, attending to perceived student ability, and describing problem difficulty.

Cognitive demand as a feature of mathematical tasks

In their final papers, 7 of 10 PSTs wrote about CD as a significant element of the methods course. PSTs primarily wrote about CD in two ways, (1) a way to categorize tasks and (2) as a way to support students' mathematics learning. PSTs primarily focused on contrasting the features of low and high CD tasks. For example, when reflecting on how to select tasks based on cognitive demand, Briley wrote, "We determined that the former had lower cognitive demand because it only required the memorization of the formula for area, whereas the latter required the application of area and perimeter and an explanation or argument for their thinking." Briley's explanation of CD is congruent with the descriptions provided by Smith and Stein (1998).

When analyzing tasks during the second interview, half of the PSTs linked procedural thinking and application of well-rehearsed algorithms with lower levels of CD. Carson highlighted the difference between students applying a rote procedure and conceptual understanding. He said, "[if] there's a specific way to do it, I don't think that's cognitively high. But when you have to know the whole process and what that process means, then I think that's when it's a cognitively high demanding problem." Mary Jane agreed with Carson, stating that "the fact that you need to sit and think about it, and discuss with others about it shows that there's more cognitive demand that's needed". Both Mary Jane's and Carson's focus is on the mathematical understanding required to solve a high cognitive demand problem.

Cognitive demand as a mediator of perceived student need

When talking about their placements, PSTs still connected CD to task selection in terms of student understanding of mathematics, but it ceased to be their primary focus. Instead, PSTs largely attended to perceived (1) student dispositions, (2) student ability, and (3) task difficulty. For the purposes of this report, we will focus on (1) and (2).

Eight of the ten PSTs linked student disposition to the CD of tasks. According to PSTs, CD impacts students' interest in and willingness to complete the tasks. When reflecting on her field placement, Claire articulated the connection between motivation and tasks. She stated, "I think [cognitive demand] really surfaces, and I think it really ties well into motivation too. Because if you like, if you do get something too easy, like they lose motivation, like in my mentor's class and if you give them something too hard, then they just like, give up because they don't have it." Jessica talked about students' self-efficacy and confidence as considerations for selecting tasks. She stated that selecting high CD tasks "not only promotes a growth mindset, but also lets students know that you believe they can succeed at higher-level tasks."

PSTs addressed their perception of students' ability through task selection and providing instructional supports. Participants discussed the need to find tasks that were not too easy or too hard. In terms of CD, Elizabeth described a task that was the right-fit as "It was the high end where they were challenged, but it was still low enough that they could do it." Every PST made a comment about selecting tasks that were the "right fit" for students. PSTs also discussed providing scaffolds to make tasks more accessible for students. For example, some PSTs articulated the difference between language supports for English language learners and providing mathematical supports. When selecting the right-fit the level of tasks, PSTs also wanted to prevent unproductive struggle, as opposed to looking to create productive struggle. For instance, Grace says, "Or sometimes if it is too cognitively demanding and they're getting frustrated and too flustered I think sometimes it'd be like, helpful to take a break and be like, 'okay, so maybe like, what do you guys remember about this?'" In this case, Grace thought about possible actions if students' struggle became unproductive.

Discussion

The purpose of this study is to understand how PSTs operationalize the concept of CD as they move from university coursework to working with students. Our results show that PSTs apply their conceptions of CD in context dependent ways, which is consistent with a framing perspective (e.g., Elby & Hammer, 2010; Hammer, et al., 2005). Specifically, PSTs' variance in how they operationalize CD across contexts can be understood as the activation of different resources, and subsequently different frames, as they shift from learning formally about CD to applying CD when working with students. We describe PSTs' different frames as: (1) CD as a feature of mathematical tasks and (2) CD as a mediator of perceived student need.

The frame *CD as a feature of mathematical tasks* seems to be activated when PSTs discuss tasks abstractly. PSTs perceive "what is going here" as an assessment of their knowledge of the different levels of CD. Within this frame, activated resources could include PSTs' understanding of course readings and their experiences with selecting and completing tasks in the methods course. In contrast, the frame of *CD as a mediator of perceived student need* is activated in the context of their ongoing work with students. When this frame is activated, PSTs rely more heavily on their experiences with students, rather than the formal definition of CD. Frames are a helpful way of thinking about how PST knowledge builds across contexts, rather than attributing changes in PST behavior to a "washing out" of the teacher preparation program (Richards et al., 2020). We propose that PSTs retained the formal definitions of CD but in practice their framing focused on the perceived needs and dispositions of students.

As teacher educators, we posit that examining PSTs' framing of concepts, even rough frames, can be helpful in supporting PSTs to build new resources and shift their framing (Elby et al., 2020). For example, the framing *CD as a mediator of perceived student need* was supported by PSTs' beliefs that the CD of tasks should be matched to student disposition or perceived student ability. This framing could lead to PSTs choosing tasks of low CD or lowering the CD of tasks during implementation (Stein et al., 2000). PSTs also expressed concern for supporting linguistically and culturally diverse learners' access to high CD tasks. Thus, another implication of this frame is that PSTs' perceived support of students' needs may limit opportunities for students to engage with high CD tasks (de Araujo, 2017). Teacher educators could support PSTs' development of resources and shifts in framing by revisiting the formal definitions of CD and explicitly linking them to instructional practices beyond the initial selection of the task. For example, teacher educators should explicitly model for PSTs how to support students in meeting language objectives without lowering the CD of the mathematics. When linked to student learning and dispositions, these additional experiences may become resources in PSTs' framing of CD as it relates to students' needs.

REFLECTIVE CONVERSATION AS A MEANS TO DEVELOP KNOWLEDGE IN FUTURE MATHEMATICS TEACHERS

CONVERSACIÓN REFLEXIVA COMO MEDIO PARA EL DESARROLLO DE CONOCIMIENTO EN FUTUROS PROFESORES DE MATEMÁTICAS

Eddie Aparicio-Landa

smoguel@correo.uady.mx

This paper reports that the reflective conversation allows the development of professional knowledge in future mathematics teachers on the basis of questions about the nature and processes of construction of mathematical concepts, from both a mathematical and pedagogical point of view. The teacher of a didactics of mathematics course and ten future teachers participated in this study. The conversations held by them during three sixty-minute sessions were analyzed; the duration of these sessions was determined by the time it took to have the discussion of a question about even numbers and generalization. The type of knowledge developed consisted of recognizing the concept of even numbers as a process of mathematical generalization, andas an ability to be developed in elementary school students.

Keywords: Teacher Knowledge, Teacher Education.

This paper analyzes how reflective conversation helps to develop the knowledge for teaching the concept of mathematical generalization in future teachers. This interest is based on the fact that reflection and integration of content, and pedagogy are two central aspects of this development (Ponte & Chapman, 2016) equally, as is the collective (Arcavi, 2016; Chamoso, Cáceres & Azcárate, 2012; Horn & Little, 2010; Jaworski, 2006; Krainer & Llinares, 2010; Ponte, 2012; Preciado-Babb et al., 2015; Rasmussen, 2016; Rowland & Ruthven 2011; Santagata & Guarino, 2011).

It is now recognized that learning to teach requires the development of different types of knowledge in the teacher. In this sense, the problematization of the mathematical knowledge of the teacher has been the focus in several proposals in mathematics education in order to characterize and model it (e.g. Ball, Thames & Phelps, 2008; Carrillo-Yañez et al., 2018; Krauss, Neubrand, Blum, & Baumert, 2008; Kunter, et al., 2013; Pino-Fan, Godino, & Font, 2018; Shoenfeld, 2011; Llinares, 2012). In fact, a key question is “whether mathematical knowledge in teaching is located ‘in the head’ of the individual teacher or is somehow a social asset, meaningful only in the context of its application” (Rowland & Ruthven, 2011, p. 3).

On the other hand, little is known about the development of knowledge in future teachers (Thanheiser et al., 2014); in this regard it is stated that “it is important for programs to engage prospective teachers in learning opportunities that enable them to reconstruct their initial knowledge and understanding of mathematics teaching. This requires awareness and scrutiny of this prior knowledge. Reflection is a key process for achieving this” (Ponte & Chapman, 2016, p. 283). In this sense, we examine how knowledge of future teachers is developed in context of social interaction in the classroom, because it is a place that offers opportunities to teach, to learn from conversation and to reflect on their own knowledge and experiences (Horn & Little 2010; Kaminski, 2003; Toom, Husu, & Patrikainen, 2015).

One type of knowledge for teaching mathematics is generalization (Demonty, Vlassis, & Fagnant, 2018). Its importance can be seen mainly in two ways: as a way to teach for developing mathematical concepts (Davydov, 1990; Dörfler, 1991) and as an activity for the development of algebraic thinking

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

in the study of patterns (Radford, 2014; Warren, Trigueros, & Ursini, 2016; Zazkis & Liljedahl; 2002). Therefore, mathematical generalization was the subject of conversation and reflection.

Conceptual Framework

The ideas of conversational learning of Pask (1976) and Kolb and Kolb (2017) were used and integrated to study how professional knowledge associated with mathematical generalization is developed, as shown in Figure 1. For these authors, learning comes from conversations on a topic that leads to the construction of new meanings and transforms collective experiences into knowledge.

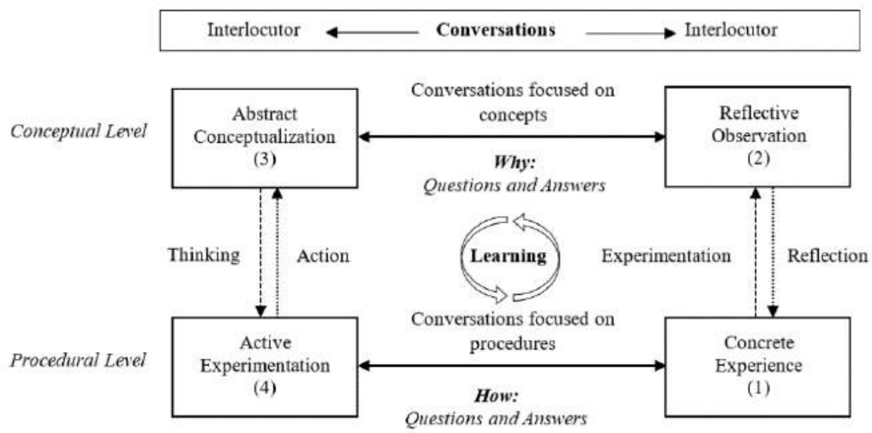

Figure 1: Reflective conversation and Learning based on Pask (1976) and Kolb and Kolb (2017)

We understand knowledge to be what is internalized in conversational interactions and it is relevant to those who share and participate in it (Gee, 2011). In this case, we refer to the specific knowledge of mathematics teachers with a clear orientation to the practical activity of teaching mathematics (Ponte, 2012).

Developing this knowledge from an RC implies the willingness to engage in a dialogue to negotiate meanings, accept questions and discuss the shared ideas of mathematics, its teaching and its learning (Earles, Parrott, & Knight, 2016). The knowledge of future teachers must be associated with their conversational context in such a way that the conversation establishes a space of participation to make explicit their ideas and knowledge related to a topic, making possible the emergence of meaningful relationships. Therefore, conversation allows the expression of thoughts in an open way, and by doing so, it gives way to a reflexive process that influences the meanings, thoughts, and actions of others; that is, it influences the development of knowledge.

Method

The development of knowledge of future teachers in the context of an RC was analyzed with a qualitative-interpretative methodology (Corbin & Strauss, 2008) considering interactions as the focus of the analysis (Kilpatrick, 1988). The analysis was carried out by organizing the data in (i) speaking shifts, and (ii) organizational sequence (Mazeland, 2006).

Seven women (W) and three men (M) from a training program for secondary and high school mathematics teachers at a public university in Mexico participated in this study. They were attending a didactic of mathematics course in their senior year. The participation of the teachers and the students was by invitation.

An open question was posed as a topic of discussion, since learning based on conversations can begin with questions associated to a topic (Pask, 1976) and the demands for solving a problem are a guiding factor for reflection (Dewey, 1938). The question was associated with the property of integer numbers and designed in such away that it could be answered by using the knowledge of arithmetic and of basic algebra and it allowed for the discussion of the idea of generalization, its teaching and its learning. The question was: *What can be said about the result of the multiplication of any two consecutive integer numbers?*

The analysis used the model shown in Figure 1 in the following way: First, the transition between the learning modes of the RC was analyzed based on the identification of the level of conversational interaction (procedural or conceptual levels). In the procedural level, it was considered that conversations are characterized by discussions focused on the construction or use of mathematical procedures, while the focus of the conceptual level is the use of conceptual ideas or theories that answer the posed question. Then, the experiences, reflections, thoughts and acts of the participants during their conversations were analyzed to characterize how it contributes to the development of their knowledge.

Results And Conclusions

Results show that the knowledge developed consisted in conceiving generalization as an important process to explore, explain and validate mathematical results and in recognizing its importance as a necessary mathematical ability to favor the teaching of arithmetic and basic algebra. Furthermore, the participants became aware that many mathematical concepts come from generalizations and raised the idea of the importance of using several representations (arithmetic, algebraic and geometric) to discover and test mathematical results, as happened in this case with the concept of even numbers:

M1: (…) I considered generalization as something of algebraic thinking, and the recognition of patterns and relationships between quantities proper of arithmetic. In this case, we can see a relationship between the quantities that increase from 2 to 4, then to 6, and 2 more units each time. It would be concluded that multiplying two consecutive numbers results in an even number, which is generalizing!

W4: I thought that there could be no generalization in arithmetic (...) but, after reflecting on what we understood as a generalization, as has been in this case: multiplying consecutive integer numbers results in an even number is a generalization; therefore, generalization can be made in arithmetic and algebra. In the sequence [2, 6, 12, 20, 30, …], number four is missing between 2 and 6, and the generalization that comes is that there are multiples of two. This is, an even number of the form $2k$.

RC fostered the development of knowledge to the extent that questions about the nature and construction of the concept of even numbers were made, from both a mathematical and a pedagogical point of view; it also promoted the free and open expression of ideas, answers and counter proposals associated with the initial question. This enhanced the transition between the four learning modes indicated in Figure 1. For example, participants moved from the concrete experience mode (CE) to the reflective observation (RO) mode by questioning and associating numerical relationships between algebraic structures. And they move from abstract conceptualization (AC) to the active experimentation (AE) mode by questioning meanings and looking for explanations and validations of their procedures. In this way, they managed to establish patterns and conceptualize an even number as a mathematical generalization (figure 2):

W2: How can I interpret the expression $2k$ in arithmetic and in algebra? I think that $2k$ can be seen as a whole area or it can represent an even number in arithmetic; in contrast, it may represent a quantity that is changing to double in algebra (...).

M1: Yes, let's say that by constructing a meaning for even numbers (…)

M2: (…) and considering it as the starting point for teaching even numbers.

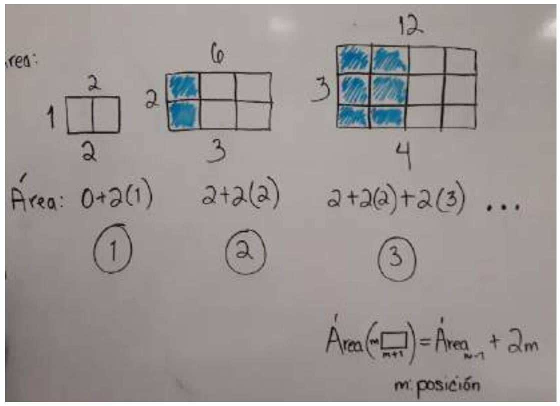

Figure 2: Consecutive multiplication, generalization and even number

We consider that the development of professional knowledge about mathematical generalization from an RC demands an exchange and articulation of ideas based on questioning the mathematical knowledge, its use and the argumentation of procedures and concepts used in the solution of problems, as well as the negotiation of meanings associated with them because this is what allowed the emergence of common understandings about the meaning of generalization and the cognitive demands for its teaching and learning.

These results are consistent with those reported by Demissie (2015), Jaworski (2006), Chamoso, Cáceres and Azcárate (2012) who found that participating in processes of collective inquiry promotes reflective thinking among peers. This study also confirms the results reported by Simoncini, Lasen and Rocco (2014) that a guided dialogue makes it possible for future teachers to obtain better perspectives of their teaching practices, including their thoughts and actions.

We plan to delve into how to incorporate RC in teacher training programs so that it can be a means to develop professional learning, promote reflections in relation to the professional practice, and encourage a shared vision of it (Preciado-Babb et al., 2015; Toom, Husu, & Patrikainen, 2015).

We examined the coaching practices of three mathematics teacher educators as they engaged in real-time coaching with secondary mathematics preservice teachers. Situated in a novel early field experience and under close supervision, preservice teachers instructed undergraduate students in an introductory mathematics course; teacher educators coached in real time during these teaching episodes. Forty-four preservice teachers participated in this study, resulting in a data corpus of 44 videos of their teaching. Findings indicate that direct coaching was used more than indirect coaching, and pacing was the most prevalent focus of direct coaching.

Keywords: Teacher Education – Preservice; Teacher Educators

Early development of preservice teachers' (PSTs') knowledge and practice for teaching mathematics typically occurs during a methods course and is often accompanied by school-based field experiences. One vexing challenge for the field is a disconnect between what PSTs see and experience in K-12 classrooms and what they learn about effective teaching in on-campus methods courses (Allsopp et al., 2006; Zeichner, 2010). Yet, teacher educators argue that teaching is best learned within, and from, practice (Ball & Cohen, 1999; Zeichner, 2010).

Over the last two years, we have engaged in a project designed to mitigate this challenge - a novel early field experience (EFE) for secondary mathematics PSTs called the University Teaching Experience (UTE; Bieda et al., 2020; Cirillo et al., 2020). In this model, PSTs, while enrolled in a concurrent mathematics methods course, engage in an EFE that takes place in a college-level introductory mathematics course, taught from a problems-based perspective, and under the close supervision of MTE(s). The PSTs work with small groups of students during problem-solving sessions and teach as pairs twice during the semester in a safe, collaborative, and highly mentored context. The MTE *coaches* the teaching PSTs in real-time, providing immediate feedback to the PSTs while in the act of teaching.

Coaching in the UTE resembles coaching that occurs during methods course rehearsals, where the mathematics teacher educator (MTE) can provide feedback in real time, pause the rehearsal for discussion, and/or model certain teaching moves for the PSTs to imitate (Arbaugh et al., 2019; Baldinger, Selling, & Virmani, 2016; Lampert et al., 2013). Although the field is beginning to understand coaching practices during rehearsals (e.g., Lambert et al., 2013), we know little about coaching practices in more authentic approximations of practice (Grossman et al., 2009) like the UTE. Our real-time coaching (RTC) also resembles a model used by Stahl et al. (2018), who investigated the effects of RTC with prospective English teachers through the use of "bud-in-the-ear" technology while PSTs engaged in micro-teaching with peers (although we did not use this technology). Stahl and colleagues found several positive benefits of RTC, including increased confidence in PSTs' knowledge, skills, and capabilities as a teacher, accelerated development of practical skills, and an increasingly discerning and critical position toward professional practice. Hence, RTC appears to be a productive method for MTEs to help PSTs improve their teaching practices and worthy of study. Akin to Lampert et al. (2014), our study was guided by this research question: What was the structure and substance of real-time coaching (RTC) as enacted in the UTE at three sites?

Methods

Data Collection: Participants, Context, and the UTE Teaching Episodes

To address our research question, we analyzed three MTEs' RTC practices at three different university sites. At one site, the UTE took place in Fall 2018; at the other two sites, the UTE took place in Spring 2019. A total of 44 PSTs participated in the UTEs across the three sites, resulting in 44 video recordings of their UTEs. These video recordings captured the interactions between the MTEs and PSTs as they taught in pairs, with each pair teaching twice in a semester.

Data Analysis

We began analysis by identifying RTC episodes in the UTE video recordings. Round one of open-coding (Miles, Huberman, & Saldaña, 2014) RTC episodes identified the *structure* of our RTC (see Table 1). Next, focusing only on the coaching episodes where direct coaching occurred, a list of *substance* codes was generated (see Table 2). The total number of coaching episodes for this study was 258; the number of direct coaching episodes was 227.

Table 1: Structure Codes

Structure Code	Description
Direct Coaching	MTE provides feedback directly to PST. Either MTE or PST may initiate this exchange.
Indirect Coaching	MTE enters the lesson as the teacher and directly addresses mathematics students for the purpose of modeling an instructional move for the PSTs.

Table 2: Direct Coaching Substance Codes

Substance Codes;	Description
Alerting PST to Notice Students	MTE interrupts or alerts the PST to notice a student who is confused or a student with their hand raised, whom the PST otherwise would not have noticed.
Asking for Volunteers	MTE advises PST on (a) how to ask for volunteers, or (b) who to ask to share an answer to the problem.
Asking PST to Expand on Mathematics	MTE requests that PST provides more information on mathematical concepts or examples.
Assisting with Classroom Technology	MTE assists PST with understanding how to use the technology they are attempting to use for their instruction.
Attending to Mathematical Precision	MTE attends to PST's written/oral language/notation, such as terminology, labeling, and mathematical symbols. This is an error in PST's communication, rather than a mathematical error.
Correcting a Mathematical Error	MTE requests that PST corrects a mathematical error. This is a mathematical error, rather than an error in communication.
Getting Math Students' Attention	MTE requests that PST refrains from giving instruction and first gains students' attention.

Getting Students to Write Notes	MTE requests that PST encourages math students to write notes.
Helping PST Understand Mathematics	MTE helps PST better understand a mathematical concept.
Helping PST Understand Student Thinking	MTE helps PST better understand a student's comment, answer, or question.
Making a Pedagogical Suggestion	MTE makes suggestions to PST regarding next steps for monitoring, whole class discussion, or other instructional moves.
Pacing	MTE coaches about speeding up or slowing down the lesson.
Providing Positive Feedback	MTE praises a PST's action.
Raising Voice	MTE asks the PST to speak louder.
Redirecting Instructional Move	PST uses a pedagogical move and the MTE redirects the PST to use a different pedagogical move.
Rephrasing PST's Language	MTE provides a rephrased question or statement for the PST to repeat to students.
Requesting Visual Display – Logistics	MTE requests that PST creates a visual display or makes the display clearer for students (emphasis on logistics; e.g., writing bigger).
Requesting Visual Display - Mathematics	MTE asks that PST adds further information to a visual display of mathematics.
Requesting Visual Representation or Verbal Communication	MTE requests that PST provides a visual representation of spoken mathematics, or to explain verbally an idea that is written.

Findings

The MTEs engaged in about seven times more direct coaching than indirect coaching (88% vs. 12% respectively), indicating that the MTEs made a large majority of their coaching comments directly to the PSTs as opposed to stepping in to teach the mathematics students and modeling teaching practices for PSTs. Examining the substance of direct coaching more closely (see Figure 1), *pacing* was the most prevalent focus of direct coaching, occurring in 24.23% of the direct coaching episodes. MTEs provided feedback to PSTs about both speeding up the lesson and slowing down the lesson. The second most prevalent type of direct coaching was *making a pedagogical suggestion*, occurring in 23.35% of the direct coaching episodes. *Making a pedagogical suggestion* covered a wide range of coaching moves. In general, these were instances where the MTE noticed something in the way mathematics students were interacting or reacting to instruction and had a suggestion for the PST that helped the PST navigate an issue. In contrast, *assisting with classroom technology* and *getting students to write notes* occurred in less than 2% of the direct teaching episodes.

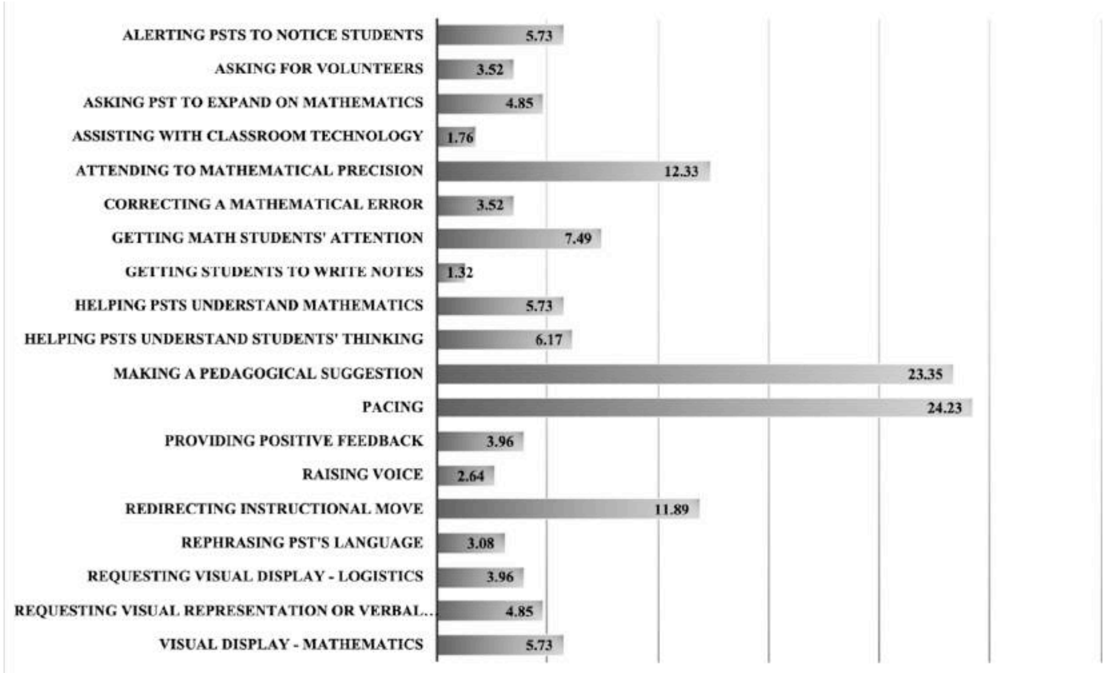

Figure 1: Percentage of Substance of Direct Coaching Episodes (Note: because some episodes were assigned multiple codes, percentages do not total 100%)

Discussion

The findings of this study extend those of Lampert et al. (2013) by providing additional ways that PSTs can be coached during instruction. Further, because PSTs in this study were teaching mathematics students (rather than their methods course peers), this study identified a new structure of coaching: *indirect coaching*. It is interesting to us that in the authentic context of PSTs teaching mathematics to students, the MTEs in this study coached about pacing more than any other focus. This stands in contrast to Lampert et al.'s finding that the MTEs in their study focused on managing time in only 4.3% of interactions between MTE and PST. Another difference between these two studies is in the area of the mathematics as a focus. In Lampert et al.'s study, the MTEs focused on *mathematics* in 11.94% of MTE/PST interactions, with mathematics being defined as "working on and understanding the mathematical content" (p. 233). In our study, while the MTEs focused on *helping PSTs understand mathematics* in 5.25% of coaching episodes, they also coached PSTs in the areas of *attending to mathematical precision* (11.38%), *visual display of mathematics* (5.28%), and *asking PST to expand on mathematics* (4.47%). Our findings show that RTC can occur while PSTs are teaching mathematics students in an authentic context, extending Stahl et al.'s (2019) work. We are left with questions about the impact of real-time coaching on PSTs' growth as mathematics teachers.

FRAMEWORKS FOR NOTICING IN MATHEMATICS EDUCATION RESEARCH

Dominique Banner
Boise State University
dominiquebanner@u.boisestate.edu

Eliciting student thinking and using what is learned of student understanding to inform instruction is critical to effective mathematics teaching. Professional noticing skills assist teachers in identifying, interpreting and responding appropriately to student thinking. Therefore, the development of professional noticing skills in teacher candidates has become a goal of some mathematics teacher education programs. For the purpose of determining whether instruction is assisting in the development of these skills, it is necessary to have a way to measure these skills. This paper is a brief review of how professional noticing has been operationalized in mathematics teacher education research. A search of the ERIC data bases resulted in 405 studies, 89 of which met the criteria for the review. The following results contain a representative subsample of the 89 studies due to space limitations.

Keywords: Teacher Educators, Teacher Education – Preservice, Teacher Education – Inservice/Professional Development, Research Methods

In recent years, there has been an increased focus on using evidence of student thinking to inform and support instruction. In fact, the 2014 National Council of Teachers of Mathematics (NCTM) publication "Principles to Action: Ensuring Mathematical Success for All," recommended "eliciting and using evidence of student thinking" as a mathematics teaching practices to support student learning (NCTM, 2014). As the focus of professional noticing, in general, is to recognize, interpret, and respond to student thinking, noticing aligns well with the aforementioned NCTM mathematics teaching practice. Therefore, the development of professional noticing skills in teachers support student thinking, learning and understanding.

Theoretical Framework

Within recent research, there are three commonly cited definitions of professional noticing. First, van Es and Sherin (2002) define noticing as consisting of "three components: identifying what is important in a teaching situation; making connections between specific events and broader principles of teaching and learning; and using what one knows about the context to reason about a situation". Second, Jacobs, Lamb and Philipp (2010) define noticing as consisting of "three interrelated skills: attending to children's strategies, interpreting children's understandings, and deciding how to respond on the basis of children's understandings". Finally, Mason (2002) describes the "discipline of noticing" as consisting of the following techniques: keeping and using a record; developing sensitivities; recognizing choices; preparing to notice at the right moment; and validating with others.

Professional noticing, or simply noticing, has been the focus of much research in the past two decades. Berliner (2001) found well developed noticing skills to be a feature of an expert teacher. Researchers have also stated, novice teachers do not naturally notice important events in a classroom (Jacobs et. al, 2010; van Es and Sherin, 2002; Star and Strickland, 2008). However, research had found noticing skills can be learned (Jacobs et. al, 2010; van Es and Sherin, 2002; Star and Strickland, 2008). There is also evidence to support the development of noticing skills has improved field experiences (Star and Strickland, 2008; Stockero, Rupnow, and Pascoe, 2017).

Structures (e.g. frameworks, scaffolds) can support teachers in the development of noticing skills. The purpose of this paper is to examine noticing frameworks used in mathematics education research to support and measure teacher noticing. The research questions which guided the analysis are: What

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

type of frameworks exist to measure professional noticing skills in mathematics teacher education research? How are these frameworks applied (e.g. for measurement, instruction, or both) in mathematics teacher education research?

Methods

I searched ERIC data bases using the search criterion of (notic* AND mathematics) OR ('professional vision' AND mathematics) yielding 405 results. Titles, keywords, and abstracts of the resulting articles were scanned and excluded using the following exclusion criteria (EC). EC 1: The focus of the article was not mathematics. EC 2: The article was not research concerning professional noticing. EC 3: The article was not published in a research journal. EC 4: The article was not regarding K-12 teacher education. EC 5: The article was not a research study. EC 6: The framework in the article was too specific (e.g. Fernandez et. al., 2011 framework for noticing a students' additive/multiplicative thinking in proportional reasoning). Although articles with a specific noticing purpose are important to developing noticing skills in specific instructional areas, these articles were excluded from this paper in the interest of space.

Results

After review, 89 articles were included for analysis. Thirty-two were excluded due to a focus other than mathematics, 224 of the remaining articles were not on professional noticing, 29 were excluded because the article was not published in a research journal, 6 were not K-12 education, 4 articles were not experimental studies, and 21 were excluded for having too specific a focus.

Many researchers use, or adapt, an existing framework to fit their research purposes, although some developed independent frameworks. Researchers used these frameworks in a variety of methods (e.g. to provide to candidates for instructions; to inform the creation of pre and post assessments; to create a coding scheme for qualitative data). Frameworks were used for either instruction, measurement, or both. If a researcher used a framework for both instruction and measurement, sometimes the same framework, occasionally different frameworks. Due to limited space, the following is an abbreviated representative sample of the 89 articles reviewed.

Frameworks

Leatham, Peterson, Stockero and Van Zoest (2015) describes the development of Mathematically Significant Pedagogical Opportunities to Build on Student Thinking (MOST) Framework. MOST is a linear framework developed through an iterative process in mathematics teacher education courses over a four-year period. The framework was developed to identify MOSTs in video captured lessons for analysis. Researchers found the framework to be applicable for instruction and measurement as well. The framework begins with Student Mathematical Thinking: can student mathematics be identified, if so, is there a mathematical point? The second part of the framework involves Mathematical Significance: is the mathematics appropriate, if so, is it central? The final part of the framework is Pedagogical Opportunity: opening, timing? (Leatham et. al., 2015; Stockero et. al., 2014; Stockero et. al., 2017). If the answer to each of the six questions is yes, the interaction is a MOST.

Star and Strickland (2008) developed the 5 Category Observation Framework to identify what teacher candidates noticed from watching a classroom lesson. Star and Strickland created a pre/post assessment consisting of questions related to items and actions in a video the teacher candidates watched. The pre/post assessment was designed to represent each of the five categories and question types evenly. The five categories of the framework include: classroom environment, classroom management, tasks, mathematical content, and communication. The researchers were able to show significant gains in all areas, with the exception of classroom management (which was higher on the pre assessment).

Santagata and colleagues (2007, 2010, 2016) developed and used the Lesson Analysis Framework (LAF). One version of the LAF consisted of three parts: goals/parts of the lesson, student learning, and teaching alternatives; another version of the LAF consisted of four parts: learning goals, analysis of student thinking, effects of teaching, and propose improvements in teaching (Santagata and Yeh, 2016). Researchers use the framework to guide teacher candidate analysis of video.

van Es (2011) introduced the Learning to Notice Framework. The framework consisted of two categories: what teachers notice and how teachers notice. Data in each of these categories are then assigned one of four levels: baseline, mixed, focused, and extended. Statements made concerning some overall aspect of the classroom aspects or interactions, and are evaluative in nature, represent baseline level statements. Mixed level statements are primarily focused on the teacher but begin to mention student thinking and start showing some interpretive qualities. Focused statements primarily concern specific instances of student thinking and began to predict student actions. Finally, the extended level statements began to make connections between teacher response and student thinking.

Sherin and van Es (2009) introduced the Professional Vision Coding Scheme based on their definition of professional vision. The coding scheme consisted of two components: selective attention and knowledge-based reasoning. Selective attention consisted of two dimensions of analysis: actor (student, teacher, other) and topic (management, climate, pedagogy, mathematical thinking). Knowledge-based Reasoning also has two dimensions of analysis: stance (describe, evaluate, interpret) and strategy (restate student ideas, investigate meaning of student idea, generalize and synthesize across student ideas).

Mitchell and Marin (2015) introduced the Structured Analysis Framework based on Mathematical Quality Instruction (MQI). A subset of MQI codes relevant to noticing were chosen to create the framework. Five areas of codes were chosen: lesson or segment structure; teacher mathematical error or imprecision, use of mathematics with students, cognitive demand of task, and student work with mathematics.

Applications of Noticing Frameworks

Noticing frameworks are applied within mathematics teacher education research in a variety of ways. Frameworks are applied in the areas of instruction, measurement, or both. In addition, researchers may use one existing framework for the purpose of instructions and another for measurement. The following are examples of each of these applications of noticing frameworks in mathematics teacher education research.

Instruction. Definitions of noticing (Mason, 2002; Jacobs et. al., 2010; van Es & Sherin, 2002) were the most common influence for instructional design. In fact, Fisher and colleagues (2019) provide an overview of their 3 meeting instructional model which shows alignment with the Jacobs and colleagues (2010) definition of noticing.

Measuring noticing. Jacobs and colleagues (2010) described three skills necessary for the "expertise" of professional noticing: attending to children's strategies, interpreting children's understanding, and responding on the basis of children's understanding. In their research, Jacobs and colleagues developed a coding structure for each of these skills: attending (1) evidence (0) lack of evidence; interpreting and responding (2) robust evidence (1) limited evidence (0) lack of evidence (Jacobs et. al., 2010). This coding structure was then used in their research to code writing prompts to compare the noticing skills of teachers at various levels in their careers (prospective teachers, initial participants, advancing participants and emerging teacher leaders). Many other researchers have adopted this method of measuring noticing skills in their own research (e.g. La Rochelle, Nickerson, and Lamb (2019); Fisher, Thomas, Schack and colleagues (2013, 2018, 2019)).

Another framework found often in mathematics teacher education research on noticing was the learning to notice framework (van Es, 2011). As previously described, the learning to notice framework consists of two categories, with four levels to each category. In the van Es, 2011 study, the researcher employed the framework to measure video club discussions, as a whole, and provide one level for each meeting. It was found the progression through the levels was not linear, especially in levels 2 and 3: meeting 3 was at level 2, meeting 4 was at level 3, meeting 5 was back at 2, meetings 6 and 7 were back at 3, and meeting 8 was back at 2 before jumping to level 4 in meetings 9 and 10. Amador and colleagues (2015, 2016, 2018) modified the learning to notice framework and used it extensively in their work.

Applying multiple frameworks. Amador, Carter and Hudson (2016) is an example applying multiple frameworks. Both Jacobs et. al. (2010) and van Es (2011) are applied in their noticing research. The learning to noticing framework was expanded to include a total of 9 levels: 2 sublevels for each level 1, 2, and 4; and 3 sublevels for level 3. In addition, researchers created a 9 level learning trajectory based on the Jacobs et. al. (2010) definition of noticing: 2 codes for attending, 5 codes for interpreting, and 2 codes for responding. This expansion of their coding scheme also shows influences of the Sherin and van Es (2009) professional vision framework.

Discussion

This paper reported on a small representative subset of the 89 results of a systematic review of the literature regarding operationalizing noticing. As can be seen from the results, the majority of the research on operationalizing professional noticing focuses on measuring noticing employing the Jacobs and colleagues (2010) definition or the van Es (2011) learning to notice framework. In addition, researchers are able to modify these frameworks to suit their research needs.

Of course, whenever a review of the literature is conducted, there are limitations. It is difficult to know, using the search criteria previously mentioned, whether all studies were identified. In addition, due to space limitations, it was not possible to include all studies. For example, in this review studies with specific foci were not included (e. g. curricular noticing).

The main purpose of the paper was to provide researchers and mathematics teacher educators with a summary of frameworks employed to inform instruction and the measurement of noticing. The goal was to assist in mathematics teacher researchers and educators who would like to begin research in professional noticing or developing an instructional unit on professional noticing with a list of common ways to operationalize noticing. Further research to summarize the theory which informed the development of these frameworks is still necessary.

PROSPECTIVE ELEMENTARY TEACHERS' USE OF CONTEXTUAL KNOWLEDGE WHEN SOLVING PROBLEMATIC WORD PROBLEMS

José N. Contreras
Ball State University
jncontrerasf@bsu.edu

This study investigates the extent to which pre-service elementary teachers (PETs) use their contextual knowledge to model and solve eight problems for which the result of the arithmetic operation is problematic, if one takes into consideration the reality of the context. A paper-and-pencil test was administered to 621 PETs enrolled in mathematics content courses. The test included eight experimental items and four buffer items. The findings for a sample of 97 PETs are not very encouraging. The total number of realistic responses varied from 5 to 80 (out of 97 possible for each problem). Overall, the percentage of realistic responses on the eight problematic items was only about 31%.

Arithmetic word problems play an important role in learning mathematics at the elementary school level. There are several practical and theoretical reasons of the inclusion of arithmetic word problems in the elementary curriculum. First, they provide contexts in which students can use their mathematical knowledge so they can develop their problem-solving abilities, an important goal of learning mathematics. Second, word problems provide practice so students can develop their abilities to use their knowledge in real-life situations. Third, word problems serve as motivators so students can see the relevance of the procedures and algorithms learned in school. Fourth, word problems have the potential to provide students with rich contexts and realistic activities in which to ground mathematical concepts and, thus, facilitate the learning of more complex concepts. Finally, word problems provide students with experiences to learn how to use mathematical tools to model aspects of reality, that is, to describe, analyze, and predict the behavior of systems in the real world (Burkhardt, 1994; De Corte, Greer, & Verschaffel, 1996; Verschaffel, Greer, & De Corte, 2000; Verschaffel & De Corte, 1997).

Some critiques (e.g., Gerofsky, 1996; Lave, 1992; Nesher, 1980) argue, however, that the mathematics curriculum fails to achieve these lofty goals because traditional instructional tasks tend to focus on a straightforward application of procedures and computations to solve artificial problems unrelated to the real world. As a result, students tend to approach word problems, more often than desirable, in a superficial and mindless way with little, if any, disposition, to modeling and realistic interpretation. Several pieces of research provide empirical evidence to these claims (Davis, 1989; De Corte & Verschaffel, 1989; Greer, 1993, 1997; Reusser, 1988; Reusser & Stebler, 1997; Schoenfeld, 1991; Silver, Shapiro, & Deutsch, 1993; Verschaffel, 1999; Verschaffel & De Corte, 1997; Verschaffel, De Corte, & Lasure, 1994).

Purpose of the Study

The purpose of the study was to examine prospective elementary teachers' (PETs) reactions and responses to problematic arithmetic word problems for which the solution is not the result of application of the most obvious arithmetic operation suggested by the two numbers given in the problem statement.

As suggested by the research literature, elementary school children tend to ignore the realistic constrains of the context embedded in the statement of the problem, a phenomenon that Schoenfeld (1991) coined "suspension of sense-making." Several critics and researchers argue that children' suspension of sense-making is the result of school practices (Davis, 1989; Greer, 1993; Nesher, 1980;

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Schoenfeld, 1991; Silver, Shapiro, & Deutsch, 1993). To develop children' disposition to realistic modeling, we must change curriculum and instructional tasks. Since the teacher has an important role in the construction or selection of learning tasks and opportunities, one may argue that researchers and curriculum developers need to understand teachers' reactions and responses to problematic problems.

Theoretical and Empirical Background

Mathematical modeling is the process of representing aspects of reality by mathematical means. In particular, the solution of some physical or real-world problems requires some form of mathematization. That is, the construction of a mathematical model. The complexity of the process of mathematization depends, of course, on the nature of the problem. There are several proposed models of representing reality by mathematical means (e.g., Silver, Shapiro, & Deutsch, 1993; Verschaffel, Greer, & De Corte, 2000), but Silver et al's model (Fig. 1) suffices for our purposes.

According to Silver, Shapiro, and Deutsch's model, a simplified version of the process of mathematical modeling consists of four different stages: understanding of the problem, construction of a model or selection of a mathematical procedure, the execution of the procedure, and the interpretation or evaluation of the outcomes of the procedure.

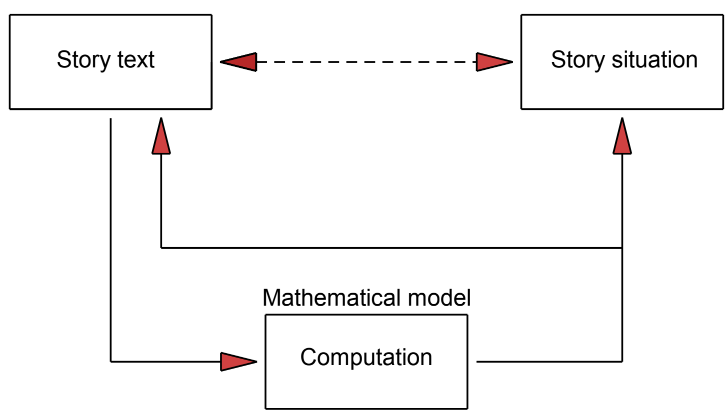

Figure 1: Silver et al.'s (1993) Referential-and-Semantic-Processing Model for Successful Solutions

The first stage of the process of mathematical modeling involves understanding the problem situation embedded in the story text. That is, we need to understand the given or known facts, the unknown information, the superfluous data, and missing information. The second phase involves the construction of a mathematical model or selection of a suitable procedure, operation, or algorithm whose outcome will lead us to the solution of the problem. To perform the second stage of the modeling process successfully, we must understand the mathematical structure of the problem. That is, we must understand the interconnections or relationships among the different types of information related to the solution of the word problem. The third stage of the problem involves mainly performing the computation, procedure, or algorithm either with paper and pencil or using a computational device. Finally, we should interpret and assess the outcome of the mathematical procedure in terms of the realistic context embedded in the story text of the word problem or in terms of the real-world story situation. It is during this step that we need to focus on the meaning of the result of the mathematical model so we can establish the connection between the outcome of the computation and the solution to the real-world story problem. It is during this stage that we need to assess whether our modeling assumptions are realistic or reasonable.

Silver, Shapiro, and Deutsch's model implies that there are three main potential sources of error when solving word problems: lack of understanding of the mathematical structure of the problem, which leads students to select an inappropriate procedure, executing the procedure incorrectly, and failing to interpret or assess the result of the procedure in terms of contextual or everyday-life knowledge. Silver, Shapiro, and Deutsch (1993) examined 195 middle grade students' solution processes and their interpretation of solutions to the following problem:

> The Clearview Little League is going to a Pirates game. There are 540 people, including players, coaches, and parents. They will travel by bus, and each bus holds 40 people. How many buses will they need to get to the game?

Their analysis revealed that 91% of the students selected an appropriate procedure (e.g., long division, repeated multiples, repeated additions, etc.), but only 61% of these students performed it flawlessly (about 56% of the total number of students). Overall, the researchers found that only 43% of the total number of students gave the correct answer (14) to the problem. However, some of these students provided inappropriate interpretations or justifications. For example, one student wrote "14 buses because there's leftover people and if you add a zero you will get 130 buses so you sort of had to estimate. Are we allowed to add zeros?" (p. 124-125). The researchers also reported that about 55% of the students did not get the correct answer because either they did not properly interpret the outcome of the computation or executed incorrectly the procedure. These computational mistakes could have been prevented if students had interpreted their solutions appropriately. Silver, Shapiro, and Deutsch proposed the model displayed in Figure 2 as a graphical representation of unsuccessful solutions that are due to a failure to connect the outcome of the procedure to the real-world context embedded in the story problem.

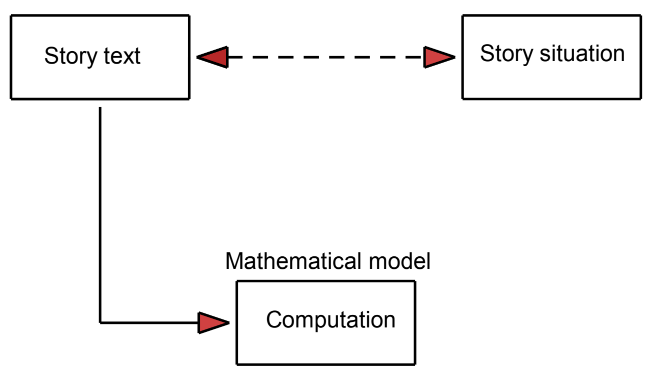

Figure 2: Silver et al.'s (1993) Referential-and-Semantic-Processing Model for Unsuccessful Solutions

Other pieces of research have amply documented elementary school children' improper modeling assumptions when solving problematic arithmetic word problems. Some further examples of the word problems that students have been asked to solve are the following:

1. What will be the temperature of water in a container if you pour 1 liter of water at 80° and 1 liter of water of 40° into it? (Nesher, 1980)
2. John's best time to run 100 m is 17 sec. How long will it take to run 1 km? (Greer, 1993)
3. Lida is making muffins that require 3/8 of a cup of flour each. If she has 10 cups of flour, how many muffins can Lida make? (Contreras & Martínez-Cruz, 2001)
4. In September 1995 the city's youth orchestra had its first concert. In what year will the orchestra have its fifth concert if it holds one concert every year? (Verschaffel, De Corte, & Vierstraete, 1999)

In their study with 75 fifth graders in Flanders, Verschaffel, De Corte, and Lasure (1994) reported that only seven (9%) students provided a realistic and correct response to the temperature problem. Similarly, in the same study, these researchers found that only two (3%) responses included realistic answers or reactions to the running problem. In another study, Contreras and Martínez-Cruz (2001) focused on prospective elementary teachers' solution processes and realistic reactions to the third problem. Their analysis revealed that only 19 (28%) of the participants' responses contained a realistic solution to the problem, but none of the participants made any comments about the problematic nature of the problem.

Verschaffel, De Corte, and Vierstraete (1999) addressed upper elementary school children' difficulties in modeling and solving nonstandard additive word problems involving ordinal numbers. The participants were administered a paper-and-pencil test consisting of 17 word problems, nine of which were experimental items and eight buffer items. The result of the straightforward arithmetic operation yields the correct answer for three of the nine experimental items. An example of such a problem is "In January 1995 a youth orchestra was set up in our city. In what year will the orchestra have its fifth anniversary? However, the solution of the remaining six experimental items is either 1 more or 1 less that the result of the straightforward arithmetic operation of the two given numbers. An example of such a problem is problem 4 stated above. Overall, the researchers found that the percentage of correct responses for each of the six problematic items was less that 25%. An error analysis revealed that 83% of the errors made on these problems were ± errors. In other words, most of the children' errors were due to their interpretation that the result of the addition or subtraction of the two given numbers yielded the correct answer.

Although research has convincingly documented elementary school children' strong tendency to model problematic problem unrealistically, the generalizability of the findings to more mature students, such as prospective elementary teachers, has not been sufficiently investigated. On one hand, since PETs have had even more experiences with traditional school problems, we may argue that there is no reason to expect that prospective elementary teachers would use their contextual knowledge and realistic considerations in their solution processes of problematic word problems. On the other hand, we may claim that PETs may have faced real-world problem situations outside school more often than young children and, having a more developed mathematical knowledge, have a stronger disposition to activate their contextual knowledge when confronted with problematic problems whose realistic solutions require taking into consideration contextual knowledge.

In their 1997 study, Verschaffel, De Corte, and Borghart examined future teachers' responses to seven problematic word problems. The problems were problematic in the sense that they cannot be appropriately modeled and solved by the straightforward application of the suggested arithmetic operation with the two numbers given in the problem statement. The researchers found that the future teachers had a strong tendency to ignore contextual knowledge and realistic considerations when modeling and solving the problematic word problems. In fact, the researchers reported that only 48% of all the responses to the problematic problems could be rated as realistic.

Even thought Verschaffel, De Corte, and Borghart's findings provide some insights into prospective teachers' use of realistic considerations when confronted with problematic word problems, more research is needed to provide a more complete picture about this research area, particularly across different cultures. In the present study, I focus on the extent to which the findings from previous research with pupils and future teachers are generalizable to prospective elementary teachers in the USA.

Methods and Sources of Evidence

The total sample of participants consists of 621 PETs enrolled in different sections of mathematics content courses for elementary teachers at two State Universities in the United States. The present paper reports the results of three groups (97 PETs) for which the analysis has been completed. The PETs had not been previously engaged in any intentional or systematic modeling activities or tasks.

A paper-and-pencil test consisting of eight experimental items and four buffer items was administered to the PETs during regular class instruction. The eight experimental items (Table 1) were problematic in the sense that the outcomes of the arithmetic operations performed with the given numbers in the problem story does not provide the answer to the problem, if one takes into consideration the real-world situation embedded in the contextual problem story. The buffer items, on the other hand, were standard routine problems whose solution is the straightforward result of the operation performed with the given numbers. The experimental items were adapted from Verschaffel and De Corte's (1997) study. An example of a buffer item is "Joel is building a collection of 175 different stamps. He has already collected 107 different stamps. How many more stamps does he need to complete the collection?"

Table 1: The Eight Experimental Items

1. 1175 supporters must be bused to the soccer stadium. Each bus can hold 40 supporters. How many buses are needed? (Carpenter, Lindquist, Matthews & Silver, 1983).
2. 228 tourists want to enjoy a panoramic view from the top of a high building that can be accessed by elevator only. The building has only one elevator with a maximum capacity of 16 persons. How many times must the elevator ascend to get all the tourists on the top of the building? Verschaffel, 1995)
3. At the end of the school year, 50 elementary school children try to obtain their athletics diploma. To receive the athletic diploma they have to succeed in two tests: running 400 m in less than 2 minutes and jumping 0.5 m high. All the children participated in both tests. Nine children failed the running test and 12 failed the jumping test. How many children did not receive their diplomas? (Verschaffel, 1995)
4. Carl and George are classmates. Carl has 9 friends that he wants to invite to his birthday party. On the other side, George has 12 friends that he wants to invite to his birthday party. Since Carl and George have the same birthday, they decide to give a party together. They invite all of their friends. All their friends come to the party. How many friends are there at the party? (Nelissen, 1987)
5. A man wants to have a rope long enough to stretch between two poles 12 m apart, but he has only pieces of rope 1.5 m long. How many of these pieces would he need to tie together to stretch between the poles? (Greer, 1993)
6. Steve has bought 12 planks of 2.5m each. How many 1 m planks can he saw out of these planks? (Kaalen, 1992)
7. Sven's best time to swim the 50 m breaststroke is 54 seconds. How long will it take him to swim the 200 m breaststroke? (Greer, 1993)
8. The flask is being filled from a tap at a constant rate. If the water is 4 cm deep after 10 seconds, how deep will it be after 30 seconds? (This problem was accompanied by a picture of a cone-shaped flask) (Greer, 1993)

After each problem, I have indicated its original source; however, in some cases the numbers were replaced by others.

Students' written responses to the problems were the source of data. Written directions asked students to show all their work to support each of their answers and to write down any questions or concerns they may have about each problem. I recognize that written responses have some intrinsic limitations when compared to verbal protocols. However, written protocols allow researchers to collect data from large samples. Moreover, some researchers (Hall, Kibler, Wenger, & Truxaw, 1989) have validated the use of written responses to infer cognitive processes.

Analysis and Results

Each response to problems 1 and 2 was coded as correct or incorrect. Each response to problems 3-8 was coded as correct, partially correct, or incorrect. Two raters judged every response. A response was judged as correct if it included a realistic numerical answer that estimated or indicated the range of possible solutions and took into account the contextual restraints of the real-world problem situation. A response was judged partially correct if it was incomplete or wrong but included a realistic comment suggesting that the student displayed awareness of the contextual restraints of the real-world problem situation. A response was judged incorrect when it did not suggest any awareness of the contextual restraints of the real-world problem situation. The inter-rater agreement was 99.7%. Table 2 summarizes the results of the analysis.

Table 2: The Number and Percentage of Correct, Partially Correct, and Correct Responses for the 8 Experimental Items

Problem	Number and percent of correct responses	Number and percent of partially correct responses	Number and percent of incorrect responses
1	76 (78.5%)	0 (0%)	21 (21.5%)
2	80 (82.5%)	0 (0%)	17 (17.5%)
3	3 (3%)	16 (16.5%)	78 (80.5%)
4	3 (3%	17 (17.5%)	77 (79.5%)
5	2 (2%)	4 (4%)	91 (94%)
6	24 (24.5%)	1 (1%)	72 (74%)
7	1 (1%)	4 (4%)	92 (95%)
8	0 (0%)	6 (6%)	91 (94%)
Total	189 (24.5%)	48 (6%)	539 (69.5%)
Subtotal	33 (5.5%)	48 (8%)	501 (86%)

As shown in Table 2, PETs' performance on most items was alarmingly poor: The percentage of incorrect responses ranged from a high 95% for item 7 to 17.5% for item 2. Overall, the percentage of realistic responses (correct responses and partially correct responses) on the eight problematic items was only about 30.5%. We should notice, however, that the number of realistic responses was considerable greater for the division problems involving remainders, problems 1 and 2. If we exclude these two problems from the analysis, then the percentage of realistic responses for the remaining six problems is only about 14%.

Discussion and Conclusion

The purpose of the present study was to collect systematically empirical data about the extent to which prospective elementary teachers in the USA activate their contextual knowledge when solving problems whose solution in not the direct result of an arithmetic operation. Using similar problems and methodology as previous studies (e.g., Verschaffel & De Corte, 1997; Verschaffel, De Corte, & Lasure, 1994), a test consisting of eight problematic items and four standard problems was administered to a sample of 621 PETs. The analysis has been completed for 97 PETs (three groups) and it is reported in the present article.

Although previous studies have convincingly demonstrated children' strong tendency to ignore the contextual realities embedded in the story of the problem situation, I was hoping that the findings with prospective elementary teachers would be much more encouraging. After all, prospective elementary teachers are part of a more mature and experienced population and it is reasonable to assume that they have an understanding of the contextual knowledge needed to realistically solve the problems. Therefore, the question of PETs' failure to activate this contextual knowledge needs to be further discussed and investigated. I offer several tentative hypotheses to explain PETs' lack of disposition to model contextual word problems realistically.

First, children and PETs' lack of activation of their contextual knowledge may be due to their constant exposure to traditional and stereotypical school word problems. If this is the case, then this tendency may remain constant or get stronger with additional years of immersion in the mathematical culture of traditional classrooms. Future research is needed to better understand the effects of traditional learning environments on students', including PETs, failure to activate their contextual knowledge to solve problematic problems.

A second possible explanation to understand PETs' tendency to ignore the contextual realities of the situation embedded in the problem story is that they lack enough real-world knowledge of the situational context of the problematic problems. Even though this seems unlikely, follow-up studies should provide empirical data to confirm or refute this hypothesis.

A third explanation may be that PETs approached the problematic problems in an automatic way thinking that they were standard mathematical problems without reflecting on the contextual realities of the problem. Further research is needed to better understand PETs' suspension of sense-making when solving these types of problems.

In conclusion, this study provides, at the very least, some empirical evidence that PETs in the USA lack an initial disposition or reaction to consider the contextual restraints of problems grounded in the real world. Further research is needed to better understand PETs' apparent suspension of sense-making when engaged in solving problems that require realistic interpretations.

USING STRIP DIAGRAMS TO SUPPORT PROSPECTIVE MIDDLE SCHOOL TEACHERS' EXPLANATIONS FOR FRACTION MULTIPLICATION

Eric Cordero-Siy
University of Wisconsin-Madison
epsiy@wisc.edu

In this report, I describe how prospective middle school teachers created strip diagrams to solve fraction multiplication problems. I analyzed classroom videos from a year-long content course in order to determine what how teachers drew the diagrams and found four critical features of the drawings. I explore how they used the features as they drew and explained their thinking.

Keywords: Teacher Education–Preservice, Rational Numbers, Representations and Visualization

In North America, representations are a critical component in school mathematics (La Secretaría de Educación Pública, 2011; Ontario Ministry of Education, 2005; National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). Researchers have also emphasized the importance of representations in mathematical thinking (Cuoco, 2001; Janvier, 1987). Both teachers and students use representations to help them solve and make sense of problems (e.g., Lobato et al., 2014), communicate their ideas (Roth & McGinn, 1998), and participate in mathematical activity especially if their language is not the privileged language in the classroom (Turner et al., 2013) However, there are some roadblocks presented in the research on teacher knowledge about representations. Researchers have produced little evidence that teacher preparation programs (both for practicing and prospective teachers) prepare them to successfully integrate representations in the classroom (Stylianou, 2010). In this study, I provide a case demonstrating prospective teachers can sensibly engage in mathematics with representations. In particular, I ask the following questions: *How do prospective teachers draw strip diagrams to solve fraction multiplication problems in class? How do they use the strip diagrams to solve fraction multiplication problems?*

Theoretical Framework

Researchers who have studied representation use in class (Izsák, 2003; Saxe, 2012) have generally agreed to distinguish what is being represented and what is "doing" the representing (cf. von Glasersfeld, 1987). In this study, I refer to representations as observable geometric inscriptions that can be referred or pointed to as the object of discussion (Goldin, 2002). It is this indexical and communicative nature of representations allowing students to explain their thinking and for others to engage in another's way of reasoning. When students create a display to represent their thinking, they also communicate with them. In other words, they tailor their display with an audience in mind (Saxe, 2012) and thus students select salient features to highlight and point when creating and talking with representations. Additionally, I frame representations as culturally and historically rooted. A representation's cultural and historical meaning stems from how communities interact with an inscription over time (Blumer, 1986). For example, a class can ascribe the meaning to the inscription "=" as "execute the arithmetic to the left" if they are continually asked to solve result-unknown problems over time.

Data and Analysis

I analyzed four weeks of instruction from a sequence of two mathematics content courses for prospective middle school teachers (PSMTs) enrolled in a teacher education program. The same instructor taught both courses. The objective of the course was to strengthen the students'

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

mathematical understanding of middle school topics. The 13 PSMTs enrolled in the course were predominantly white women. The students were expected to use a multiplicand-multiplier definition for multiplication, notated by equation N · M = P (Beckmann & Izsák, 2015). In this equation, N denotes the number of base units in one group (the multiplicand), M denotes the number of groups (the multiplier), and P denotes the total number of base units in M groups. The class also defined the fraction a/b as the quantity formed by a parts of size 1/b. They were also expected to explain with drawings rather than memorized algorithms or symbol pushing.

The main data corpus for this study was video and audio-recorded lessons from class. The primary analytical techniques I used were modified from Saxe et al., (2015) and focused on identifying forms and functions of the representations. In this report, I focus on how “coarse forms” were drawn. A coarse form is a set of inscriptions used sequentially. When listening to explanations during discussions, I segmented the drawings based on how the PSMT described the sequence of drawings as indicated by utterances such as “I did this…and then drew this…” (Fig. 1). I then found coarse forms that were similar across all the drawings.

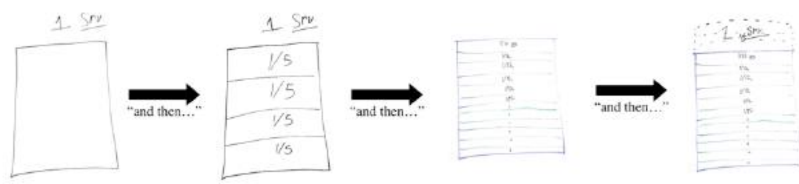

Figure 1: An example of distilling coarse forms

Results

I summarize the four main coarse forms I characterized in Table 1. I then describe how they were used for multiplication problems and illustrating it with student work.

Table 1: Coarse forms characterizing strip diagrams for fraction multiplication

Form	Partitioned Parts	Dual Function of a Strip
Schematic		Description	Equi-partitioned rectangle with each part partitioned further	A strip, rectangle
Function(s)	Create a particular number of parts	Represent two different quantities where the amount of one quantity is one
	Dual Function of a Part	**Phantom Parts**
Schematic		Description	One part of an equi-partitioned rectangle	Equi-partitioned rectangle then more parts are added
Function(s)	Part represents an amount of a quantity and another amount of another quantity	Determine the size of a part or partitioned part

Explicitly describing two quantities. As PSMTs drew strip diagrams, they described both the full strip and parts with respect to two quantities, the multiplier and multiplicand. Analytically, I found the Dual Function of a Strip and a Part present in all the strip diagrams. At the beginning of the sequence of lessons, the instructor formally introduced the multiplier-multiplicand definition of multiplication. Throughout the period, the instructor constituted the norm of identifying the group and units in the PSMTs diagrams.

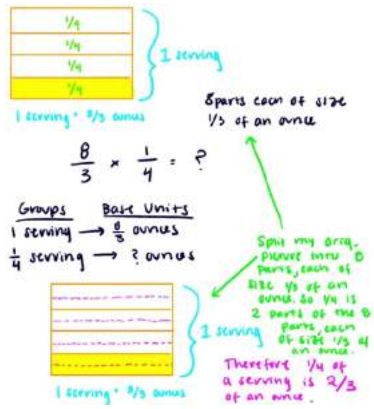

Figure 2: Hannah’s diagram for the Bat Milk Cheese problem

Hannah demonstrated working with two different quantities while solving the Halloween-themed problem, “You had 1/4 of a serving of bat milk cheese. One serving of bat milk cheese is 8/3 ounces. How many ounces of cheese do you have?” She began her drawing by showing one whole serving or one group and showing the size of the group. She wrote out the definition “8 parts each size 1/3 of an ounce.” She then realized she wanted to show eight parts in the strip and noticed she already had four parts. She partitioned each part into two smaller parts to show eight parts. She ended by saying there are two-thirds ounces in one-fourth of a part because there are two parts, each one-third of an ounce in the yellow part indicating one-fourth of a serving.

Determining the number of parts needed. The PSMTs wrestled with the appropriate number of parts required to solve the problems. They thought through the number of parts they created from the multiplicand when it was not divisible by the number of parts they needed.

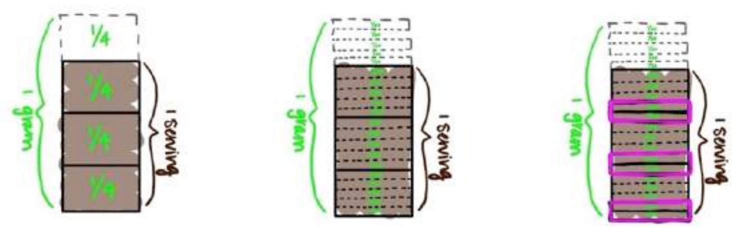

Figure 3: Elizabeth and Jack’s diagram for the Blank Multiplication problem

For instance, Elizabeth and Jack were thinking about the number of parts while working on a multiplication problem, “One serving of ___ is 3/4 ___. You had 2/5 of a serving. How many ___ of ____ did you have?” In this blank problem, the PSMTs were invited to provide their own quantities. During small group discussion, Elizabeth explained that they started with a strip representing one gram partitioned into four and shaded three parts representing three-fourths of a gram or one serving. She wanted to find two-fifths of three-fourths. She partitioned each fourth part five parts then Jack suggested she should “get” two partitioned parts from each parts to get two-fifths of the serving, she highlighted two of the three one-fourth serving partitions. Partitioning of the parts was prevalent in almost all the diagrams created.

Determining the size of a part. The last form, Phantom Parts, emerged towards the end of the sequence of lessons. PSMTs began with a strip representing one group and representing an amount of base units as indicated by the multiplicand. When the multiplier was less than one, the PSMTs they needed to add "Phantom" parts in order to determine the size of the parts. They drew out additional parts to describe the product with respect to the base unit, thus they had to draw a whole base unit to describe the size of the product in terms of base units.

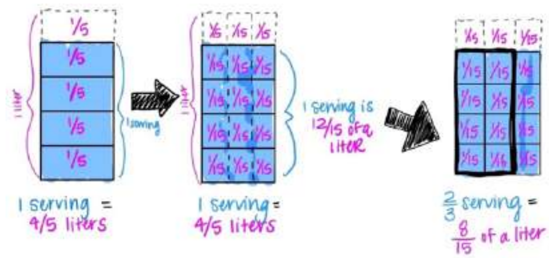

Figure 4: Elizabeth's diagram for the Goblin Goo problem

Consider Elizabeth working on the problem "You had 2/3 of a serving of goblin goo. One serving of goblin goo is 4/5 liters. How many liters of goblin goo do you have?" First, she drew a strip representing both one serving and four-fifths of a liter, similar to Hannah's use of the Dual Function of a Strip in the previous problem. She highlighted four parts to show four-fifths of a liter or one serving as seen in Figure 3. Upon partitioning each fifth into three, she labelled and described each partitioned part as one-fifteenth of a liter. She finally highlighted two-thirds of a serving by highlighting two columns of the partitioned serving to show two-thirds of a serving as eight-fifteenths. While she did not express any reason for changing her diagram from Phantom part to incorporating the Phantom part in the initial strip, the next day while talking to one of the graduate students about this problem, she said, "I think it helps understand how many parts there are of a liter. 'Coz that's why it was confusing to me was putting in in twelfths because that's not twelfths of a liter… You can do much less work if you just understand that there's a pretend liter… just go with liters the whole time. Don't change your wholes last minute."

Discussion and Conclusion

The results of this study provide a characterization of how representations evolve over time. In this case, the forms of strip diagrams evolved. The PSMTs' explanations for multiplication were rooted in two practices—using strip diagrams and a definition of multiplication. Strip diagrams evolved over time to address certain features of both the problem and diagram. By using a quantitative definition for multiplication, they were able to describe parts of the diagram (strips and partitions) with respect to two quantities. Some future steps for both researchers and teachers can be drawn from this report. When analyzing inscriptions, researchers must attend and be explicit about the grain size of the inscription. I have shown how describing coarse forms enabled me to describe continuities and discontinuities between points in time in order to characterize how representations change and potentially teaching opportunities for new forms and functions to emerge. However, although this was helpful for me analytically, such an analysis emerged from the data I had i.e., how these particular PSMTs talked.

PRE-SERVICE TEACHERS' PATTERNS OF QUESTIONING WHILE TUTORING STUDENTS WITH LEARNING DISABILITIES IN ALGEBRA 1

Anna F. DeJarnette
University of Cincinnati
anna.dejarnette@uc.edu

Casey Hord
University of Cincinnati
casey.hord@uc.edu

This study documented changes in the types of questions posed by pre-service teachers (PSTs) who participated in a semester-long professional development (PD) program focused on questioning in algebra. PSTs who participated in the PD—who were conducting 1-1 tutoring for students with learning disabilities during the same time—showed positive changes in the types of questions they posed. PSTs reduced their frequency of closed, leading questions to lead students through solution methods, and they increased their frequency of questions to probe students' thinking, to focus attention on important mathematical ideas, and to establish mathematical relationships.

Keywords: Algebra and Algebraic Thinking, Teacher Education – Preservice, Classroom Discourse, Special Education

The development of positive, productive classroom discourse practices is a challenging component of learning to teach mathematics. Posing questions is one way for teachers to scaffold students' mathematical learning, giving a teacher insight into students' thinking while promoting student autonomy and sense making (Anghileri, 2006). However, posing questions is a complex skill (Hufferd-Ackles et al., 2004; Imm & Stylianou, 2012; Kazemi & Stipek, 2001). For pre-service teachers (PSTs) to pose questions that probe students' thinking, help students focus on important mathematical ideas, and make necessary connections, they likely need consistent, ongoing professional development (PD) and opportunities for reflection. This is especially important for future special educators who may have less training in mathematics content and discipline-specific practices for teaching math.

The purpose of this study was to document changes in the types of questions posed by PSTs who participated in a semester-long PD program focused on questioning in algebra. We worked with four PSTs who were special education majors with a content emphasis in mathematics. We facilitated weekly training sessions, concurrently with which the PSTs tutored students with LD in 1-1 settings. We found that the PSTs became better throughout the PD at asking questions to probe students' thinking and make mathematical ideas explicit.

Research Perspectives

Teacher questioning is one aspect of classroom mathematical activity, and it is difficult to isolate teacher questioning from other aspects of teaching and learning. However, characterizations of the different types of questions that teachers pose—for example, leading (closed) questions, probing questions, or (open) questions to extend students' thinking—have been useful to document features of existing classroom practice (Boaler & Brodie, 2004; Hufferd-Ackles et al., 2004; Moyer & Milewicz, 2002) and to support teachers in improving their questioning practices (Aydogan et al., 2018; Di Teodoro et al., 2012; Piccolo et al., 2008). Boaler and Brodie (2004), for example, established a set of nine categories of teacher questions that shares features with other frameworks. The types of questions that mathematics teachers pose include categories like "leading students through a method," "exploring mathematical meanings," and "orienting and focusing."

Research has shown across multiple contexts that PSTs across grade levels especially struggle with questioning, primarily posing lower-order questions focused on the recall of facts or the steps of a procedure (Diaz et al., 2013; Kaya & Ceviz, 2017; Purdum-Cassidy et al., 2015). It can be difficult

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

for PSTs to anticipate how they might pursue extended sequences of questions to probe student thinking (Kilic, 2018; Weston et al., 2018). However, there is some evidence that sustained and supported reflection on the part of PSTs can support improvement in questioning practices, in particular when PSTs work in 1-1 settings with students, and when attention to questioning is integrated with the development of content knowledge and professional noticing (van den Kieboom et al., 2014; Weiland et al., 2014). Thus, it is reasonable to expect that PSTs can benefit from sustained PD in the area of questioning and consistent opportunities to practice questioning in controlled settings.

Data and Methods

Participants

Four PSTs participated in this project for three semesters during a teacher preparation program at a large university. Although the PSTs were special education majors, they had all selected math as their area of focus and were recruited from a mathematics methods course based on their achievement and engagement in the course. In the first year of the project, the PSTs met with the two authors on approximately a weekly basis, for a total of 15 sessions. Most of the time in our sessions was spent developing the PSTs' algebra content knowledge and questioning. Concurrently with our tutor training, PSTs tutored on a weekly basis. The students they tutored were all identified as having LD, and they were enrolled in the first year of a 2-year remedial algebra sequence at a large suburban high school.

Tutor PD

The math content of our PD sessions with the PSTs was primarily related to linear functions and solving systems of equations, because this was the content covered in the associated algebra course for most of the year. Our discussions of questioning proceeded along a trajectory:

- Distinctions between *funneling* sequences (i.e., a sequence of closed questions to lead students towards a solution) and *focusing* sequence (questions that build upon students' contributions and help to focus on key mathematical ideas) (Herbel-Eisenmann & Breyfogle, 2005; Wood, 1998).
- "Buying time" questions, intended for PSTs to slow the pace of conversation and have time to react to student thinking.
- The use of probing questions and how teachers have used probing questions to help students generate correct explanations (e.g., Franke et al., 2009).
- Distinctions between asking and telling, and considerations of when "telling" might be a more appropriate practice than asking closed questions (Baxter & Williams, 2010).

Data Collection and Analysis

In addition to the PD, PSTs provided 1-1 tutoring weekly for approximately 45 minutes per session. Each tutoring session was recorded using a document camera that captured the conversations as any written work produced on the table. We selected three sessions from each tutor to focus our analysis: one session each from the beginning and end of the first year, and one session from the second year of tutoring. For consistency in our sample of data, we selected sessions in which linear functions were the main topic of focus of students' work.

A research assistant transcribed the selected sessions, and we adapted Boaler and Brodie's (2004) categories of questions to code the PSTs' questions across the sessions (Table 1). First, both authors as well as the research assistant coded two transcripts and compared our initial coding. This allowed us to clarify coding criteria. At this stage we also shared our initial coding with an external advisor to get feedback on our coding criteria and improve the validity of our codes. After clarifying our definitions and distinctions between the question types, we each coded two more transcripts to test our reliability. Having achieved sufficient reliability, we divided the remaining transcripts to code. In this final phase, we each highlighted sections that seemed to be edge cases so that we could resolve such cases via discussion and consensus.

Table 1: Types of Teacher Questions, Adapted from Boaler and Brodie (2004)

Question Type	Description
Leading Through a Solution	Questions requiring short answers on the part of the student, generally focused on the steps of a solution.
Exploring Mathematical Meanings	Questions requiring students to establish connections between mathematical ideas.
Probing	Questions that ask students to explain why a particular solution was valid or reasonable.
Orienting and Focusing	Questions that ask students about important elements of a task, to help focus students' attention.
Connecting to Context	Questions about a real-world context, either the given context of a task or introducing a new context.

Results

Table 2 summarizes the PSTs' questions in semester 1 of year 1 in semester 2 of year 1. These two sessions occurred near the very beginning and, respectively, near the very end of our tutor training. (Results from year 2, during which PSTs continued tutoring but no longer received training, will be added prior to PMENA 2020.) Several outcomes are notable in Table 2. First, and most importantly, PSTs substantially reduced their use of "leading" questions with students from the beginning to the end of the tutor training program. Leading questions are those that roughly correspond to initiation (I) questions in an IRE sequence and are generally defined by the fact that they require very short (1-3 word) answers to move a student through a solution procedure.

Table 2: Changes in Tutors' Questions Over Time

	Year 1 Semester 1	Year 1 Semester 2
Leading Through a Solution	86%	68%
Exploring Mathematical Meanings	7%	8%
Probing	4%	15%
Orienting and Focusing	4%	6%
Connecting to Context	0%	2%

With the reduction in "leading" questions, PSTs asked many more questions to explore mathematical meanings, to probe students' thinking, and to focus students on important mathematical ideas. It is notable that, even by the end of the 15-week PD, over two-thirds of PSTs' questions were still leading questions. This is partly explained by the fact that leading questions—by their very definition—typically come in condensed sequences, for example with a tutor posing 3-4 such questions to lead a student through one task or part of a task. Other types of questions are less predictable in nature and create more opportunity for students to direct the discussion.

An Example of PST Questioning

We share one example, from a conversation between Linda (a PST) and a student, Mia, to illustrate the use of questions that went beyond leading questions. This example came from a year 1 semester 2 session. Linda and Mia were together looking at a "worked example," a task in which two linear functions had been graphed (incorrectly) to identify a point of intersection, and Mia needed to determine whether the solution was correct.

Linda: Okay, so did the student graph these correctly? (*leading through a solution*)
Mia: No.
Linda: What did they do wrong? (*probing*)
Mia: For the blue one they went up, well like they went up the y-axis correctly, but they went up-right instead of up-left when they graphed the -3.
Linda: Oh okay so, what did they do with the 3, like what did they do wrong with the 3? (*probing*)
Mia: They went to the right instead of to the left.
Linda: What does it mean when they go to the right? (*exploring mathematical meanings*)
Mia: It is a negative slope.
Linda: When they go to the right? (*leading through a solution*)
Mia: Oh wait no, it's a positive slope when you go to the right.
Linda: Oh okay, so they just forgot the negative.

One phenomenon that is illustrated in this conversation between Linda and Mia was the way in which different questioning types seemed to have a snowball effect. By posing two probing questions, Linda was able to draw enough information out of Mia that she could then use that information to establish more general connections. Just as "leading" questions tend to reproduce themselves, more open-ended questions also beget further open-ended discussion.

Discussion and Conclusion

Prior research has shown how challenging it can be for PSTs to develop productive questioning practices. This work has shown that pre-service special educators can learn to pose more questions that probe and extend the mathematical thinking of students with LD. Even so, leading questions may continue to serve a purpose in 1-1 tutoring sessions as a form of emotional scaffolding (Hord et al., 2018) to maintain students' engagement in their work. While there is not clearly an ideal ratio for the different types of questions tutors should pose during 1-1 work with students, it is promising to see tutors expand their range of questioning in ways that give students opportunities to engage in deep mathematical discussions.

This study uses hypothetical teaching scenarios as a methodology to explore pre-service teachers' reflective practices about social dynamics in elementary classrooms. Here we unpack tensions that emerged for pre-service teachers as they explored the role of the teacher in responding to a scenario involving third-grade students navigating ideas of mathematical equivalence. In particular, we contrast approaches focused on teacher control with approaches focused on student ownership, attending also to pre-service teachers' emphasis on the individual versus the group. Finally, we share design and methodological implications for the development and use of hypothetical teaching scenarios in teacher education.

Keywords: Teacher Education - Preservice, Elementary School Education, Classroom Discourse, Equity and Diversity

Background and Goals

This research explores how *hypothetical teaching scenarios* (or "case-based scenarios") as a methodology can foster pre-service teachers' reflective practices about social dynamics in classrooms. This paper sits at the intersection of literature on teachers' reflective practices (e.g., Zeichner & Liston, 1996) and case-based scenarios as a research tool for providing authentic windows into the teaching profession (e.g., Sykes & Bird, 1992). Here we explore how scenarios can elicit tensions among pre-service teachers (PSTs) about their views on teaching. One such tension, which has been highlighted in existing literature, centers on classroom approaches focused on teacher control versus student ownership (Stefanou et al., 2004). This tension is knowingly important as new teachers tend to teach in ways similar to how they were taught (Buchmann, 1989), yet mathematics reforms have encouraged a shift toward more student-driven mathematics engagement (National Council of Teachers of Mathematics, 2014). By identifying nuances in this tension through unpacking PSTs' responses to one scenario, we can learn more about how hypothetical teaching scenarios can foster reflective practices in this important area.

A body of work has documented the value of teachers developing *reflective practices* (Zeichner & Liston, 1996), or skills that enable teachers to observe and notice students' social interactions and ideas about content in a classroom. While these skills are important for responding to and building on students' thinking in the moment (Barnhart & van Es, 2015; Jacobs et al., 2010; Stockero, Rupnow, & Pascoe, 2017), learning to notice can be difficult (Jacobs, Lamb, & Philipp, 2010; van Es & Sherin, 2002), and teachers sometimes focus on their own behaviors at the expense of student thinking (Star & Strickland, 2008). While many approaches exist with related goals (e.g., Nichols, Tippins, & Wieseman, 1997; Rich & Hannafin, 2009), here we explore *hypothetical teaching scenarios* as a mechanism for supporting PSTs' development of reflective practices, particularly related to classroom social dynamics.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

In this work we use one hypothetical teaching scenario to examine PST perspectives on the role of the teacher in addressing issues related to social dynamics in the elementary classroom. Specifically, we explore the tension between traditional approaches in which the teacher maintains control and student-centered approaches in which students drive much of the decision-making and social work of learning (Stefanou, Perencevich, DiCintio, & Turner, 2004). The following two-part research question guides our work: How do PSTs respond to a hypothetical teaching scenario about social dynamics and mathematical equivalence in an elementary classroom? More specifically, what tensions emerge as elementary PSTs engage in reflective practices about mathematics teaching and learning through discussion of the scenario?

Methodology

Case Design

This study builds on the long history of using case-teaching in teacher education (Sykes & Bird, 1992) as a method for supporting teacher candidates in learning a variety of necessary teaching skills and practices for engaging in what Shulman (1992) called "the messy world of practice" (p. xiv). Here we continue the trend of using such cases to capture teaching dilemmas with no clear resolution (Carter, 1999) and to analyze these cases through open-ended qualitative coding of teacher candidates' discussions (Southerland & Gess-Newsome, 1999). In particular, we explore PST discussions that emerged in response to a particular scenario involving three third-grade students working to solve an equivalence problem ($8 + 5 + 4 = 4 + \_\_\_$). The teacher overhears their conversation (Figure 1), in which a hypothetical student ("Pat") tries to get his peers to attend to the location of the equal sign. After reading the scenario, PSTs were prompted to discuss the dynamic among the students: "How do you think the dynamic came about?" and "If you were the teacher, when would you intervene? How? What would you do?"

Rebecca:	I'm not sure what to do. I'm confused. Do I fill in the blank?
Pat:	This is so easy guys! The answer is just 13.
Rebecca:	I don't think it's easy. That was rude Pat.
Gabe:	Plus, I don't think you did it right Pat. I think the answer is 17. Cause 8 plus 5 plus 4 is 17.
Rebecca:	Yeah. That seems smart.
Pat:	You guys are so dumb. You have to pay attention to the equal sign...
Gabe:	Don't act like the boss of us. You always act bossy.
Rebecca:	I think it's 21. Cause I added it all up.
Pat:	If you guys would just listen I could teach you how to do it.
Gabe:	We can figure it out ourselves. Thanks anyway.

Figure 1: Student Dialogue in "Mathematical Equivalence" Teaching Scenario

The dialogue in Figure 1 was adapted from Heyd-Metzuyanim & Sfard (2012) and Langer-Osuna (2011), with a focus on issues of gender in math class interactions. Additionally, the mathematical content for this scenario (equivalence) connects with standards 1.OA.6 and 1.OA.7 in the *Common Core State Standards for Mathematics* (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010), as well as literature that highlights how noticing the location of the equal sign impacts strategy use and learning outcomes (Alibali, Crooks & McNeil, 2018; Gutiérrez et al., 2018). Further details about the design of this scenario, including the racialized and gendered aspects are discussed in Gutiérrez et al. (2019).

Data Collection and Analysis

Forty-eight elementary PSTs (Mean age = 23.9, *SD* = 4.1) who engaged with the "Mathematical Equivalence" scenario in a math content course for elementary teachers consented to participate. Thirty-three identified as female, two identified as male, and the rest did not report gender identification. The PSTs were randomly assigned to small groups (N=14; 2-4 per group), with 10 minutes to read and discuss the scenario. All discussions were audio recorded and transcribed, and analysis began with an initial process of open coding and data reduction (Saldaña, 2015). The complexity emerging in PSTs' responses related to the role of the teacher in the scenario then led us to identify tensions that emerged around how to address issues related to social dynamics, which we present here along with illustrative examples. Our goal here is to offer interpretations of the tensions we observed and capture the complexity of PSTs' perspectives (Stake, 1995), rather than attempt to systematically characterize all instances of PSTs' reflective practices in the data corpus. By offering rich examples, we aim to demonstrate how this particular hypothetical teaching scenario elicited and promoted critical reflection around crucial topics such as classroom power dynamics.

Findings

Here we examine tensions related to social dynamics that emerged as elementary PSTs discussed the scenario. While some PSTs groups directly grappled with the tensions identified, weighing the benefits and drawbacks of different approaches, other groups explored only one possible pathway. The presence of such wide-ranging approaches across conversations suggests affordances of bringing these approaches into conversation with each other, an implication we take up in our discussion section.

In their conversations, PSTs explored the tension between teacher-led and student-led approaches to addressing issues of power in the mathematics classroom. For example, Group 12 discussed when – and whether – the teacher should intervene in group dynamics. To begin, one PST commented, "I feel like really if I were listening when Rebecca's like that was rude Pat, I feel like I would have been like, Rebecca's right—that is rude, Pat! That's not really like a thing to do because then they're just gonna be wanting to be calling each other out." A second PST noted that "then Rebecca might feel that like you're on her side, like you're picking sides" and questioned, "Or do you kind of just like let them figure it out on their own?" After a brief discussion about lessons learned in another course, the first PST then noted that the latter approach aligns more closely with what the PSTs were taught: "I feel like there's—I mean—you're supposed to encourage them to talk it out." The second teacher concurred and added benefits, saying, "That's what I was thinking. Like let them learn more social skills and stuff."

In this discussion, the PSTs questioned whether they should jump in to let Pat know that his behavior was unacceptable, or whether they should let the students "talk it out" themselves. The PSTs also briefly attended to the goals a teacher might have related to avoiding choosing sides and helping students to learn social skills. This discussion exemplifies the tension between approaches that emphasize teacher control versus student ownership.

A PST in a different group encapsulated this struggle between wanting to take action and letting the students try to handle the situation on their own: "The initial reaction is to, as soon as you hear that negativity, step in. But, sometimes it's better to let that negativity keep going so that they work it out and then you approach at the end and say, 'Okay, how could we have done that better?'" (Group 11) After more discussion, the same PST then elaborated on one challenge of trying to refrain from intervening as a teacher: "It's also hard because in real time, you don't know what comes after each sentence. So you're like, do I stay and wait for this? Do I intervene now? Do I check out another group? I don't know." (Group 11) In both groups, the PSTs acknowledged benefits of letting students "work it out" or "talk it out" and "learn...social skills"; here, however, the PST identified a challenge related to that approach -- that the situation might get worse without teacher intervention ("you don't know what comes [next]") -- identifying one source of tension related to determining the teacher's response.

Within discussions about how to navigate student social dynamics, another issue emerged for PSTs – whether intervention should occur at the individual or group level. In Group 7, a PST started by suggesting that the teacher talk to Pat and "maybe say like, 'Just cause something's easy for you doesn't mean it's easy for everyone else….Can you help explain it to Rebecca?'" Then one of the other PSTs chimed in to suggest, "I think it'd be better to recognize [the] group. You know, I don't think anybody wants to be pulled aside individually." While many other PST groups did not explicitly debate these approaches, disparate ideas were offered ranging from "talk to Pat beforehand" to "go over group work rules [with] the whole class."

Here we see multiple dimensions of how the tension related to the teacher's role in addressing classroom power dynamics played out in PSTs' discussions. PSTs struggled through the issue of when (and if) to jump into conversations and whether intervention should occur at the individual or group level. In both instances they reflected on power dynamics while trying to work out the teacher's role in these interactions.

Discussion

Hypothetical teaching scenarios offer a productive avenue for eliciting tensions experienced by pre-service teachers. We argue that discussion of such scenarios serves multiple purposes: First, the scenarios serve as stimuli that allow PSTs to engage in and build their capacity for reflective practice in which they consider differing approaches to the teacher's role in responding to issues related to social dynamics. Second, hypothetical teaching scenarios can be used as research tools to understand PSTs' perspectives and struggles and to identify points of tension that are ripe for future investigation. Third, these scenarios can serve as teaching tools to elicit different PST viewpoints and then put contrasting perspectives in conversation with each other. While some PST groups in our data corpus explicitly discussed pros and cons of contrasting approaches in a given area, others primarily focused on one potential approach, suggesting benefits of facilitating discussion across groups, an approach we will take in future research. As teacher learning communities often avoid explicit disagreement and discussion of contrasting perspectives (Dobie & Anderson, 2015; Grossman, Wineburg, & Woolworth, 2001), we argue that hypothetical teaching scenarios can serve as a productive resource in teacher education for elevating issues with which PSTs grapple. Furthermore, engaging with such scenarios can help to create a culture of rich discussion around tensions of teaching and learning while also fostering PSTs' reflective practices in ways that can provide opportunities for future learning.

Acknowledgments

ERROR PATTERNS IN PROSPECTIVE K-8 TEACHERS' POSING OF MULTI-STEP ADDITION AND SUBTRACTION WORD PROBLEMS

Ali Foran
Texas A&M University
aliforan@tamu.edu

Rachael M. Welder
Texas A&M University
welder@tamu.edu

National and state standards in the US have emphasized the importance of solving and posing word problems in students' mathematics learning for decades. Therefore, it is essential for prospective teachers (PTs) to have the mathematical knowledge necessary to teach these skills to their future students. Unfortunately, little research has investigated how PTs develop problem-posing skills. This study investigated PTs' abilities to pose two-step addition and subtraction word problems in the context of a collegiate teacher education course. The researchers analyzed incorrect problems to identify error patterns among the mistakes made by PTs. By employing thematic qualitative text analysis, the researchers identified eight distinct common error categories. These results can be used to inform teacher education and to adapt tasks and instructional strategies for more effectively helping PTs develop their problem posing abilities.

Keywords: Teacher Education - Preservice, Mathematical Knowledge for Teaching, Instructional Activities and Practices, Number Concepts and Operations

Introduction

The Standards for Preparing Teachers of Mathematics put forth by the Association of Mathematics Teacher Educators (AMTE, 2017) call for beginning teachers of mathematics to "regard doing mathematics as a sense-making activity that promotes perseverance, problem posing, and problem solving. In short, they exemplify the mathematical thinking that will be expected of their students," (p. 9). The standards further indicate that effective mathematics education programs "develop positive dispositions toward mathematics, including persistence and a desire to engage in posing and solving problems," (p. 70). As such, helping prospective teachers (PTs) learn how to pose mathematics word problems should be a goal of teacher preparation programs. Towards this goal, the researchers investigated two research questions:

1. With what frequency are PTs able to write correct, two-step addition and subtraction word problems?
2. What patterns emerge in the errors that arise when PTs write two-step addition and subtraction word problems?

The researchers of this study evaluated addition and subtraction word problems posed by K-8 PTs enrolled in an undergraduate mathematics problem-solving course with the intent of identifying emergent trends of conceptual difficulties. The results of this study can inform mathematics teacher educators (MTEs) in developing targeted and meaningful activities to address PTs' difficulties and support their learning to pose multi-step word problems.

Literature Review

Even though problem posing has been discussed in mathematics education since the 1980s (Brown & Walter, 1983; Kilpatrick, 1987; NCTM, 1989), little has been done to investigate or ensure that teachers are prepared to pose problems to their students. Researchers have dug deeply into the role problem-posing can play in students' mathematical development (Akay & Boz, 2009; Alibali et al., 2009; Sharp & Welder, 2014; Bonotto, 2013; Silver & Cai, 1996; Ticha & Hospesova, 2013), and this work has found that problem-solving skills do not necessarily equate to problem-posing skills.

Furthermore, Alibali and colleagues found that having students write original multiplication word problems "revealed difficulty with the underlying meaning of multiplication" (p. 257). Similarly, Sharp and Welder (2014) found that asking seventh graders to write a division of fractions story problem exposed multiple "areas of limited conceptions that may not have been identified through traditional algorithm-driven assessments" (p. 546).

Since problem posing is an instructional activity that has been shown to benefit student learning by providing instructors insight into students' conceptions, teachers should be prepared to incorporate such activities in their future classrooms. However, to do so, they must first learn how to pose problems themselves. Therefore, it is important that PTs be given opportunities to develop problem-posing skills during their mathematics education preparation.

As MTEs, our attention then turns to how we can efficiently prepare PTs to pose a variety of word problems. The National Research Council tells us that "addition and subtraction are used to relate amounts before and after combining or taking away, to relate amounts in parts and totals, or to say precisely how two amounts compare" (2009, p. 32). Their work and the Common Core State Standards Initiative (NGA & CCSSO, 2010) have highlighted the multiple situations in which addition and subtraction occur by developing a framework for word problems that can be used to categorize them according to their structural differences. This framework produced 14 clearly distinguished categories, which give way to instructional strategies that MTEs can use for guiding PTs in developing problem-posing skills.

Methods

At a tier one research institution in the southern United States, the researchers collected data from PTs enrolled in an undergraduate mathematics problem-solving course that focuses on teaching mathematics through problem solving (Alwarsh, 2018; Bostic et al., 2016; Chapman, 2017; Fi & Denger, 2012). Instructors of this problem-solving course have incorporated a variety of instructional activities and strategies to support PTs in their learning to create original one- and multi-step addition and subtraction word problems that utilize a variety of problem structures. One such task asked PTs to pose four 2-step addition and subtraction problems to match four sets of specified structures (e.g., *change – add to – change unknown and part-part-whole – part unknown*). The data analyzed in this report includes problems posed by PTs in one instructor's course across two semesters. Thirty-seven PTs were enrolled in each semester of the class for a total of 74 PTs. All PTs were enrolled in programs leading to teacher certification in the areas of EC-6 (Generalist) or grades 4-8 mathematics and science, English, or history.

Throughout their coursework, PTs were introduced to the taxonomy of common addition and subtraction situations as identified by the Common Core State Standards (NGA & CCSSO, 2010) as a basis for discussing structural differences between addition and subtraction word problems. After categorizing and solving a variety of one-step word problems, the PTs posed one-step word problems to match each of the 14 possible problem structures. PTs received feedback on the one-step problems they wrote, which were mostly correct. Afterwards, class activities focused on categorizing and solving two-step addition and subtraction word problems. Lastly, PTs were given the aforementioned assignment in which they were instructed to pose four two-step word problems to match given pairs of addition and subtraction problem structures. This assignment resulted in 282 PT-posed, two-step word problems (n=282).

To analyze the 282 word problems, the researchers used thematic qualitative text analysis. First the problems were coded as being correct (n=124) or incorrect (n=158). Next, categories of error patterns identified in the 158 incorrect problems were created both deductively and inductively (Kuckartz, 2014), first at a macro and then micro levels. A temporary category was created based on the number of steps required to solve each incorrect problem, followed by whether the structures of the posed problem matched the assigned structures. As the researchers continued their analyses, they determined whether each new incorrect problem matched an existing category or if a new category was necessary. To test the validity of the devised coding scheme, the researchers re-coded all 282 word problems independently according to their correctness and the categories of error patterns that had emerged. After discussion, agreement was reached for 100% of the analyzed word problems. Lastly, the categories of error patterns were analyzed by the frequency at which they were exhibited by the PTs.

Results

As mentioned, 124 of the 282 word problems correctly provided a scenario that included two situations that matched both of the assigned structures and asked a question that required a two-step calculation utilizing the unknowns from each situation. Fifty-six of the remaining 158 problems correctly posed a valid two-step addition/subtraction question and were only deemed incorrect in this analysis because they simply did not meet the structural criteria of the prompts.

The remaining 102 PT-submitted problems were deemed as having one or more structural errors. The analysis of these errors led to the identification of eight distinct categories of error patterns, dependent upon the number of steps required to solve the problem, the appropriateness of the question(s) asked, and the use of the assigned structures. Due to space restrictions in this report, we will explicate only the most-frequent category of error pattern, problems that only required one step (n=68), and provide examples of the ways in which one-step errors occurred as found in PTs' work. Of the remaining 34 problems, 12 required more than two steps, three required zero steps (as the solutions had been provided within the context of the problems), four required algebra in their solutions, and 15 could not be solved with the given information.

One-step Problems (n=68)

The most common error resulted from PTs who were able to build up two addition/ subtraction structural situations but did not properly utilize the unknown information from the first scenario to form a question that required a two-step calculation (n=68). Sixty-three of these *one-step* problems posed a single question, but the question still failed to connect the two unknowns. These 63 *one-step – one question* problems were further categorized according to whether the PTs used the assigned structures or not. The remaining five *one-step* problems resulted in the posing of two separate questions. Examples of each type are provided below.

One-step – one question – two correct structures (n=31). Thirty-one of the 63 *one-step, one-question* problems built contextual scenarios that correctly matched both of the requested problem structures. However, due to a lack of connection between the two scenarios, the question posed only required one calculation to be solved. For example, one PT submitted the following problem, exhibiting this common error, in response to the second prompt (*change – add to – start unknown; compare – more – bigger unknown*):

> Sarah had some pieces of candy. Four more pieces were given to her, so she had ten pieces of candy total. Amanda had five more pieces of candy than the amount of candy Sarah was given. How many pieces of candy does Amanda have?

This PT provided a scenario that matched the two assigned structures but did not pose a question that would require the solver to utilize the unknown information from the first step as known information in the second step. Specifically, in this example, the unknown information in the first scenario is the number of pieces of candy Sarah starts with, but the second scenario connects the second unknown to the number of pieces Sarah was given. Since this information was provided ("*Four more pieces were given to her*"), the only required step to answer the question is adding four and five to get nine pieces of candy.

One-step – one question – incorrect structure(s) (n=32). The remaining 32 of the 63 *one-step, one-question problems* exhibited the same error as above but were further flawed in the sense that the scenarios posed did not fully match the requested structures. For example, for prompt 3 (*part-part-whole – addend unknown; compare – more – difference unknown*), one PT submitted the problem:

> Sarah has four red shirts and some green shirts. Sarah has two more red shirts than green shirts. How many green shirts does she have?

Again, in this problem, only one calculation is necessary to answer the question posed: four (red shirts) minus two (more red shirts than green shirts) equals two (green shirts), making it a *one-step* problem. However, this problem also exhibits structural issues. The first scenario (*part-part-whole – part unknown)* was not fully developed, as the whole amount was never provided (leaving two pieces of unknown information: the number of green shirts and the total number of shirts). Furthermore, the second scenario created a *compare – more – smaller unknown* situation (when the prompt specified *difference unknown*).

One-step – two questions (n=5). A small subgroup of these *one-step problems* (n=5) contained two independent scenarios and asked two separate questions in an effort to satisfy the two-step prompts. Four of these problems included the correct assigned structures, one did not. The PTs who wrote these problems knew that two steps were necessary to satisfy the given task but showed difficulty in connecting their unknowns into a single question. For example, one PT-submitted the following problem to the third prompt (*part-part-whole – addend unknown; compare – more – difference unknown*):

> Maria has 4 apples and some cherry pies. She has a total of 7 pies. Kara has more pies than Maria. They together have a total of 15 pies. How many cherry pies does Maria have, and how many pies does Kara have?

Discussion

The skill analyzed in this study was the ability of PTs to write addition and subtraction word problems that utilized one unknown in a second scenario to create a two-step problem. The level of difficulty of these problems for solving purposes is quite low, but the necessary skill to create such problems proved quite high with only 44% of the PTs able to correctly formulate a two-step word problem as requested. Alarmingly, a large proportion of the 56% of PTs who were unable to create two-step problems tended toward writing one-step problems with disconnected or incorrectly connected scenarios.

Teachers at every level need to be prepared to create original word problems and support their students in developing problem-posing skills. Our findings are especially concerning given that the participants in this study were being trained to teach mathematics in elementary classrooms yet displayed great difficulty in formulating elementary-level word problems. As we, the researchers, apply the findings to our mathematics problem-solving course, we are using the error pattern framework developed here to facilitate targeted discussions of common errors in the classroom. The findings of this study will inform our development of a task designed to confront common errors head on so that PTs will be more cognizant of effective and ineffective problem-posing strategies. Future research will study the effects of this task.

CONCEPTUAL AND PROCEDURAL LEARNING IN PRE-SERVICE MATHEMATICS TEACHERS DURING A CONVERSATION

APRENDIZAJE CONCEPTUAL Y PROCEDIMENTAL EN PROFESORES DE MATEMÁTICAS EN FORMACIÓN DURANTE UNA CONVERSACIÓN

Karla Gómez Osalde	Eddie Aparicio Landa	Landy Sosa Moguel
Universidad Autónoma de Yucatán	Universidad Autónoma de Yucatán	Universidad Autónoma de Yucatán
karla.gomez@correo.uady.mx	alanda@correo.uady.mx	smoguel@correo.uady.mx

This paper shows a study of the transition from procedural to conceptual learning from a conversational learning approach evidenced by students of pre-service teachers in mathematics in the context of the solution and discussion of a geometrical task. The study was conducted with a group of twelve future teachers and their instructor from a public university. Results found that students are able to move from procedural to conceptual learning when the procedures and understandings of the concepts involved in the task are confronted during the conversation, allowing them to move from the use of the formula of the area to the significance of geometric figures by establishing relationships between their dimensions.

Keywords: Instructional activities and practices, Teacher Education - Preservice, Teacher Knowledge.

In the social construction of knowledge, conversation has an important role in learning since it allows the negotiation of meanings and the emergence of common understandings (Baker, Jensen & Kolb, 2005; Scott, Mortimer & Aguiar, 2006), so learning is conceived as the result of conversations and experiences associated with a topic (Pask, 1976; Vygotsky, 1986; Kolb & Kolb, 2017).

This study is found in the previous approach because it is considered that the promotion of the transition between procedural and conceptual learning in pre-service mathematics teachers is possible through conversation. We are particularly interested in analyzing how to support the transition from procedural to conceptual learning when an instructor speaks with their students about the resolution of a geometrical task.

Authors such as Calcagni and Lago (2018) emphasize the relationship between learning and conversation in classroom interactions and their relationship with educational quality. They point out how the manners of speech in the classroom have implications for the quality of learning of students and propose breaking the typical sequence of conversations in the classroom starting with dialogical conversations. The field of professional development of mathematics teachers also delves into these ideas by exploring the type of learning opportunities that will help to achieve multifaceted and comprehensive conceptualizations in teachers and future teachers (Newton & Poon, 2015; Nagle et al., 2013), as well as the role of dialogue and reflection to generate learning that benefits the transformation of the teaching practice (Aparicio, Sosa, Cabañas & Gómez, 2020; Jaworski, 2006; Saylor & Johnson, 2014).

Procedural and conceptual learning in pre-service teachers in mathematics

Concept and procedure are considered to complement one another in mathematics because their interrelationships transform and expand knowledge (Star, 2005, 2007; Baroody, Feil & Johnson, 2007). Ramsden (1992) proposes that understanding the learning process requires understanding how procedural and conceptual learning lives in the classroom, that is, how a student organizes, proceeds and structures the learning experience and how the student manages to give meaning.

The proposal is to analyze the transition between "know how" (procedural learning) and "know what" (conceptual learning) in pre-service teachers based on the former ideas and the assumption that conversation can be a window for understanding. Understanding such a transition process would shed light on the type of professional learning opportunities that can be achieved by future teachers during conversations among them.

Procedural and Conceptual Learning from the Theory of Conversation

This study is supported by an integrated model between the learning proposal based on the theory of conversation of Pask (1976) and the experiential learning cycle of Kolb and Kolb (2017), as shown in Figure 1. It is recognized that conversational learning transits from a procedural level, characterized by questions and answers focused on how an actual experience is lived (1) and how it is extrapolated (4), to a conceptual level, characterized by questions and answers about the reflection of the experience (2) and its abstraction (3). An initial study reported in Aparicio et al. (2020) shows how conversation and reflection provide opportunities for the development of mathematical and pedagogical knowledge in future teachers when they move between the modes of learning in Figure 1, supported by questioning, exchange and articulation of their procedures and concepts.

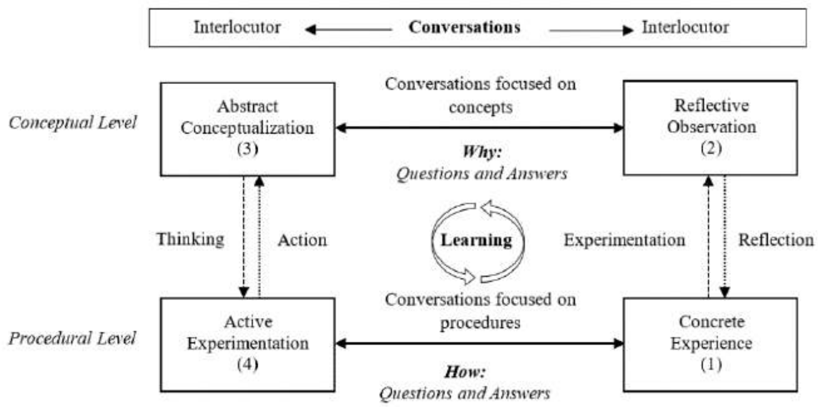

Figure 1: Conversational learning based on the models of Pask (1976) and Kolb and Kolb (2017) [Aparicio et al., 2020]

Method and Analysis

Twelve pre-service mathematics teachers participated in the study when they were taking a course in Didactics of Mathematics in their final year of university training. Two sessions of 90 minutes each were analyzed. During the sessions, the instructor and the students talked about the performance of a geometrical task (see figure 2) which was designed to promote reflection and discussion among the interlocutors about the forms used to solve the task and their arguments. The role of the instructor was to help the students to speak about the "how" and "why" of their procedures and concepts. The sessions were audio taped and transcribed for their analysis, the work done by the students with paper and pencil, and the group conversations conducted with the use of the blackboard were also documented.

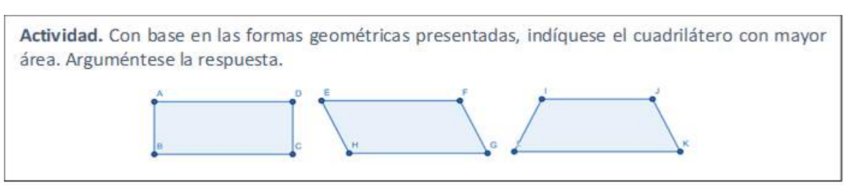

Figure 2: Instrument for data collection

The conversational analysis was carried out in two moments. The first moment examined how the discourse of the instructor and her underlying intent were externalized based on its form and content. The second moment related both aspects of the discourse with the procedural and conceptual learning of the students. The analysis focuses on the identification of references in the statements to techniques, methods, and procedures or to meanings, conceptualizations, and properties of the concepts.

Results

The transition from procedural to conceptual learning was evidenced; however, due to the limited space, this paper only reports the modes of learning through experimentation (1) and learning through reflection (2). Table 1 describes the transition.

Table 1: Relationship between the teaching discourse and conversational learning

		Discourse of the instructor	*Learning modes*
CE (1) Learning by experimentation	Mode	The way to proceed with the task is questioned.	*Procedural:* The spatial reconfiguration is proposed as a technique to solve the task.
	Content	Awareness of how the experience was lived and the selection of the procedure.	*Procedural:* The use of the formula of the area is proposed as part of the procedure
RO (2) Learning through reflection	Mode	a) The geometric content required to solve the task is questioned. b) The reason to use the formula of the area is questioned.	*Conceptual:* The geometrical transformation and the formula of the area are proposed as concepts that allow the task to be solved.
	Content	a) Awareness of how to posit the way in which to proceed with the use of the formula. b) Understandings of the area of the formula of a rectangle are confronted to explain their use in the task.	*Conceptual:* It is recognized that the use of the formula is not enough; it is necessary to signify the geometrical figures by means of the relation between their dimensions.

The transition from procedural to conceptual learning during the conversation of the task has the following sequence. Procedural learning begins with explanations on the technique of spatial reconfiguration which is used to obtain equivalent rectangular forms; subsequently, the formula of the area of a rectangle is used to guarantee the equivalence in the areas of the figures, provided that their base and height measurements are equivalent. This results in a conceptual learning by recognizing and proposing geometric concepts that are the basis for resolving the task; for example, the geometric transformation and the formula of the area. However, the conversation was led to the discussion of the relationships underlying the formula, discussing how to qualify the two-dimensional forms. Therefore, it was recognized that the first thing to do to give meaning to the task and use of the formula during the conversation is to signify the geometric figures by means of the relationship with their dimensions.

The first thing found with regard to the form and content of the conversation that favored such transition was the encouragement to explore ways of proceeding with the tasks. Secondly, opinions are sought on the geometric contents considered essential to its solution. This makes it possible to compare whether the presented concepts give an answer to the task, and finally discuss the understandings of the formula of the area and its contribution to the conceptualization of the area as a quality of flat figures.

Discussion and Conclusion

A contribution of this study is the approach towards a characterization of conversation in the transition between procedural and conceptual learning in pre-service teacher in mathematics. Conversation is characterized, first, by questioning and confronting procedures and concepts used in the resolution of the task. In the second instance, a discussion is held focused on the analysis of the geometric contents that should be moved to solve it, and finally, conversation is led to how to give meaning to the task. The latter opens up a process of negotiation of the proposed ideas and meanings; for example, questions such as: Why is the formula of the area expressed in that way and not in another way? How does it work and what information does it provide on the area concept and its measurement? Why and how is the geometric transformation important for the resolution of the task?

Results found that the characteristics of the conversation allow the participant to freely share their ideas, procedures and understandings of the task and its solution, as well as the contents of area, figure, and measurement, among others. The role of the instructor was as a guide to the reflections on the geometric contents. The conversation is much more reflective when the meanings are shared after being asked for explanations about the reasons why a procedure works and emphasizing the need to consider the meaning of what is done and why it is done.

This type of conversational analysis in the classrooms for training future teachers are necessary to understand with greater precision the limitations and potentialities of conversation in the integration of procedural and conceptual aspects of professional learning.

APRENDIZAJE CONCEPTUAL Y PROCEDIMENTAL EN PROFESORES DE MATEMÁTICAS EN FORMACIÓN DURANTE UNA CONVERSACIÓN

CONCEPTUAL AND PROCEDURAL LEARNING IN PRE-SERVICE MATHEMATICS TEACHERS DURING A CONVERSATION

Karla Gómez Osalde	Eddie Aparicio Landa	Landy Sosa Moguel
Universidad Autónoma de Yucatán	Universidad Autónoma de Yucatán	Universidad Autónoma de Yucatán
karla.gomez@correo.uady.mx	alanda@correo.uady.mx	smoguel@correo.uady.mx

Se presenta, desde una perspectiva del aprendizaje conversacional, un estudio sobre el tránsito de aprendizajes procedimentales a conceptuales que evidencian profesores de matemáticas en formación al resolver y conversar sobre una tarea geométrica. El estudio se realizó con un grupo de 12 futuros profesores y su instructora de una universidad pública. Se encontró que los estudiantes logran transitar de aprendizajes procedimentales a conceptuales cuando durante la conversación se confrontan procedimientos y entendimientos de los conceptos implicados en la tarea, permitiéndoles pasar del uso de la fórmula del área a la significación de figuras geométricas a partir de establecer relaciones entre sus dimensiones.

Palabras clave: Actividades y Prácticas De Enseñanza, Preparación de Maestros en Formación, Conocimiento del Profesor.

En la construcción social del conocimiento, la conversación tiene un papel importante en los aprendizajes toda vez que permite negociar significados y generar entendimientos comunes (Baker, Jensen y Kolb, 2005; Scott, Mortimer y Aguiar, 2006), de modo que el aprendizaje se concibe como resultado de conversaciones y experiencias relativas a un tópico (Pask, 1976; Vygotsky, 1986; Kolb & Kolb, 2017).

Este estudio se ubica en el enfoque anterior al considerarse que mediante una conversación es posible favorecer la transición entre aprendizajes procedimentales y conceptuales entre futuros profesores de matemáticas. En particular nos interesa analizar cómo apoyar el tránsito del aprendizaje procedimental al conceptual cuando una instructora conversa con sus estudiantes sobre la resolución de una tarea geométrica.

Autores como Calcagni y Lago (2018) destacan la relación entre aprendizaje y conversación en las interacciones del aula y su relación con la calidad educativa. Señalan cómo las formas de hablar en el aula tienen implicaciones en la calidad de aprendizaje de los estudiantes y plantean romper con la secuencia típica de las conversaciones en el aula a partir de conversaciones dialógicas. Estas ideas también se están explorando en el campo del desarrollo profesional del profesor de matemáticas, al indagar sobre el tipo de oportunidades de aprendizaje que ayude a alcanzar conceptualizaciones multifacéticas e integrales en profesores y futuros profesores (Newton & Poon, 2015; Nagle et al., 2013), así como el papel del diálogo y reflexión para generar aprendizajes que beneficien la transformación de la práctica docente (Aparicio, Sosa, Cabañas y Gómez, 2020; Jaworski, 2006; Saylor y Johnson, 2014).

Aprendizaje Procedimental y Conceptual en profesores de Matemáticas en formación

En matemáticas, el concepto y procedimiento son considerados complementarios ya que por medio de sus interrelaciones se logra transformar y ampliar el conocimiento (Star, 2005, 2007; Baroody, Feil & Johnson, 2007). Ramsden (1992) plantea que entender el proceso de aprendizaje requiere entender cómo viven en el aula el aprendizaje procedimental, es decir, cómo el alumno organiza, procede y estructura la experiencia de aprendizaje; y el aprendizaje conceptual, aquello que el alumno logra significar.

De estas ideas y la asunción de que la conversación puede ser una ventana al entendimiento, se propone analizar el tránsito entre el "saber cómo" (aprendizaje procedimental) y el "saber qué" (aprendizaje conceptual) en estudiantes para profesores. Entender tal proceso de transición permitiría esclarecer el tipo de oportunidades de aprendizaje profesional que se pueden lograr en futuros profesores al conversar de una u otra forma con ellos.

Aprendizaje Procedimental y Conceptual desde la Teoría de la Conversación

El estudio se sustenta en un modelo integrado entre la propuesta de aprendizaje basado en la conversación de Pask (1976) y el ciclo de aprendizaje experiencial de Kolb y Kolb (2017), como se muestra en la Figura 1. Se reconoce que el aprendizaje conversacional transita de un nivel procedimental caracterizado por preguntas y respuestas centradas en el cómo se vive una experiencia concreta (1) y cómo se extrapola (4), hacia un nivel conceptual caracterizado por preguntas y respuestas sobre la reflexión de la experiencia (2) y su abstracción (3). Un estudio inicial reportado en Aparicio et al. (2020) se muestra que la conversación y reflexión brindan oportunidades para el desarrollo de conocimiento matemático y pedagógico en futuros profesores si estos transitan entre los modos de aprendizaje de la figura 1, apoyados en el cuestionamiento, intercambio y articulación de sus procedimientos y conceptos.

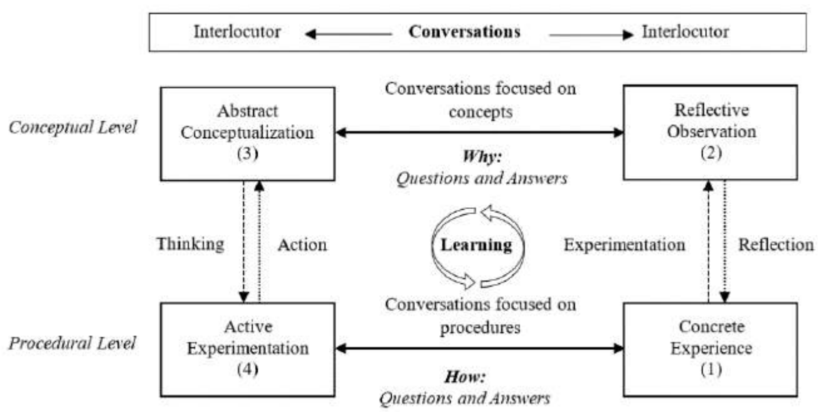

Figura 1: Aprendizaje conversacional basado en los modelos de Pask (1976) y Kolb y Kolb (2017) [Aparicio et al., 2020]

Método y Análisis

Participaron doce futuros profesores de matemáticas que al momento estaban llevando un curso de Didáctica de las Matemáticas en su último año de formación universitaria. Se analizaron dos sesiones de 90 minutos cada una, en las que instructora y estudiantes conversaron sobre la realización de una tarea geométrica (ver figura 2) cuyo diseño buscaba suscitar reflexión y debate entre los interlocutores sobre las formas de resolverla y argumentarla. El papel de la instructora fue apoyar que los estudiantes externaran el "cómo" y "por qué" de sus procedimientos y conceptos. Las sesiones fueron grabadas en audio y transcritas para su análisis, asimismo, se documentó lo realizado por los estudiantes en lápiz y papel y las conversaciones grupales promovidas con el uso de la pizarra.

Actividad. Con base en las formas geométricas presentadas, indíquese el cuadrilátero con mayor área. Arguméntese la respuesta.

Figura 2: Instrumento para la recolección de datos

El análisis conversacional se realizó en dos momentos. En el primero se examinó la manera en que se externalizó el discurso de la instructora, y su intencionalidad subyacente a partir de la forma y el contenido de este. En el segundo, se relacionó ambos aspectos del discurso con el aprendizaje procedimental y conceptual de los estudiantes. Se analizó si lo enunciado aludía a técnicas, métodos, procedimientos, o bien, a significados, conceptualizaciones, propiedades de los conceptos.

Resultados

Se evidenció la transición del aprendizaje procedimental al conceptual, sin embargo, por límite de espacio se reporta lo correspondiente al modo de aprender experimentando (1) y aprender reflexionando (2). En la Tabla 1 se describe la transición.

Tabla 1: Relación entre el discurso instruccional y los aprendizajes conversacionales

		Discurso de la Instructora	*Tipos de Aprendizaje*
CE (1) Aprender Experimentando	Forma	Se cuestiona la manera de proceder ante la tarea.	*Procedimental:* Se propone la reconfiguración espacial como técnica para resolver la tarea.
	Fondo	Se concientiza sobre cómo se vivió la experiencia y la selección del procedimiento.	*Procedimental:* Se plantea la aplicación de la fórmula de área como parte del procedimiento.
RO (2) Aprender Reflexionando	Forma	a) Se cuestiona el contenido geométrico que se requiere para resolver la tarea. b) Se cuestiona la razón del empleo de la fórmula de área.	*Conceptual:* Se plantea a la transformación geométrica y a la fórmula de área como conceptos que permiten dar respuesta a la tarea.
	Fondo	a) Se concientiza sobre cómo argumentan su forma de proceder con el uso de la fórmula. b) Se confrontan entendimientos de la fórmula de área de un rectángulo para explicar su empleo en la tarea.	*Conceptual:* Se reconoce que no es suficiente sólo aplicar la fórmula, sino que se requiere significar las figuras geométricas por medio de la relación entre sus dimensiones.

El tránsito del aprendizaje procedimental al conceptual durante la conversación de la tarea tiene la secuencia siguiente. En lo procedimental se inicia con explicaciones sobre la técnica de reconfiguración espacial con la cual se obtienen formas rectangulares equivalentes en área. Posteriormente se emplea la fórmula del cálculo de área de un rectángulo para asegurar la equivalencia en medidas de área entre ellas, siempre y cuando sus medidas de base y altura sean equivalentes. Lo anterior deriva en aprendizaje conceptual al reconocerse y proponerse conceptos geométricos que son base para dar respuesta a la tarea, por ejemplo, la transformación geométrica y fórmulas de cálculo de área; sin embargo, la conversación fue conducida hacia el debate de las relaciones que subyacen a la fórmula, discutiéndose la forma de cualificar las formas bidimensionales. Debido a ello, se reconoce que, para dar sentido a la tarea y empleo de la fórmula durante la conversación, primeramente, se requiere significar a las figuras geométricas por medio de la relación con sus dimensiones.

Sobre la forma y contenido de la conversación que favorecieron dicho tránsito se detectó que, en primer lugar, se propicia la exploración de las maneras de proceder en la tarea, en segundo lugar, se solicitan opiniones sobre los contenidos geométricos que se consideran esenciales para resolverla. Lo anterior permite confrontar si los conceptos expuestos dan respuesta a la tarea y finalmente, debatir los entendimientos de la fórmula de área y su aporte a la conceptualización del área como una cualidad de las figuras planas.

Discusión y Conclusión

El presente estudio aporta hacia una caracterización de la conversación en el tránsito del aprendizaje procedimental y conceptual de futuros profesores de matemáticas. La conversación se caracteriza, primeramente, por cuestionar y confrontar procedimientos y conceptos usados en la resolución de una tarea. En segunda instancia, se sostiene una discusión centrada en el análisis de los contenidos geométricos que se requieren mover para resolverla y finalmente, la conversación se dirige hacia cómo dotar de sentido a la tarea, en esto último, se abre un proceso de negociación de las ideas y significados propuestos para ello, por ejemplo, se cuestiona ¿Por qué la fórmula del cálculo de área es de esa manera y no de otra?, ¿Cómo funciona y qué información proporciona sobre el concepto área y su medida?, ¿Por qué y cómo la transformación geométrica es importante para la resolución de la tarea?

Se reconoce que las características de la conversación permiten a los participantes compartir libremente sus ideas, procedimientos y entendimientos de la tarea y su resolución, así como de los contenidos de área, figura, medidas, entre otros. La instructora asume un rol de guía para las reflexiones sobre los contenidos geométricos. La conversación es mucho más reflexiva cuando se confrontan significados a partir de solicitarse explicaciones sobre el porqué funciona un procedimiento y se enfatiza la necesidad de considerar el sentido de lo que se hace y porqué se hace.

Continuar este tipo de análisis conversacionales en las aulas de formación de futuros profesores, se considera necesario para entender con mayor precisión, las limitaciones y potencialidades de la conversación en la integración de lo procedimental y conceptual del aprendizaje profesional.

PROSPECTIVE TEACHERS' STRATEGIES FOR EVALUATING NON-STANDARD ANGULAR MEASUREMENT TOOLS

Hamilton L. Hardison
Texas State University
HHardison@txstate.edu

Hwa Young Lee
Texas State University
hylee@txstate.edu

Angle measure is pervasive within mathematics curricula from elementary school through higher education. Yet, there is evidence that students and teachers alike experience challenges in quantifying angularity. To promote critical thinking about tools for measuring angles in our geometry courses for prospective elementary and middle-grades teachers, we designed non-standard tools and asked prospective teachers whether these tools would be valid for measuring angles. We present these tasks and our analysis of prospective teachers' justifications regarding the validity of these non-standard tools.

Keywords: Instructional Activities and Practices, Geometry and Geometrical and Spatial Thinking, Quantifying Angularity, Measurement

Measurement is a critical domain of mathematics for students, as well as for prospective teachers (PTs) enrolled in teacher education programs (AMTE, 2017.) Within this domain, angle measure is pervasive within mathematics curricula from elementary school through higher education. Yet, we know from research and teaching that students, as well as prospective and practicing teachers, tend to experience challenges in quantifying angularity (Smith & Barrett, 2017). As mathematics teacher educators, we wanted to help PTs develop productive conceptions of angle measure, so we designed tasks for occasioning conversations about what it means to measure an angle to use in our geometry content courses. In particular, we asked PTs to determine whether several non-standard protractors were valid tools for measuring angles and to provide a justification for their decision. We focused on protractors because, (a) well-prepared beginning teachers are expected to "use measurement tools…[and] are skilled in describing how to select appropriate tools" (AMTE, 2017, p. 78), and (b) U.S. curricula and pedagogy have been critiqued for relying heavily on protractors without sufficiently emphasizing the underlying processes by which a protractor is used to measure angles (Moore, 2012). In this brief report, we present some of these tasks, summarize our analysis of PTs' ways of reasoning about them, and consider implications of these results.

Tasks and Methods

To promote critical thinking about tools for measuring angles in our geometry courses for PTs, we designed a set of five non-standard tools that might be used for measuring angles. Our intention was to design tasks with the potential for encouraging PTs to think about what marks on a protractor might mean and how a tool for measuring angles might be created in the first place, rather than simply taking conventional protractors and the marks upon them as givens. We refer to the tools we created as *funky protractors* (Hardison & Lee, 2020); these tools are the angular analogue of the "strange" and "broken" ruler tasks others have used to occasion reflection on measuring lengths (e.g., Smith, Males, Dietiker, Lee, & Mosier, 2013; Dietiker, Gonulates, & Smith, 2011). For each funky protractor we designed, we altered one or more features to differentiate a conventional protractor from a funky one (e.g., unequally spaced linear or angular intervals between markings, non-standard shape, etc.). We intentionally designed some funky protractors to be valid tools for measuring angles and some to be problematic for measuring angles (from our perspective). Each funky protractor featured points along the boundary numerically labeled in 10° increments as well as one larger point suggesting a position for placing the vertex of an angle to be measured. Here, we focus on two funky

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

protractors, which are both valid tools for measuring angles (Figure 1), and our analysis of prospective teachers' responses to these tasks. In this study we address the following research questions: (1) What decisions do prospective teachers make regarding the validity of potential angular measurement tools? (2) What strategies do PTs use to justify these decisions at the beginning and end of the course?

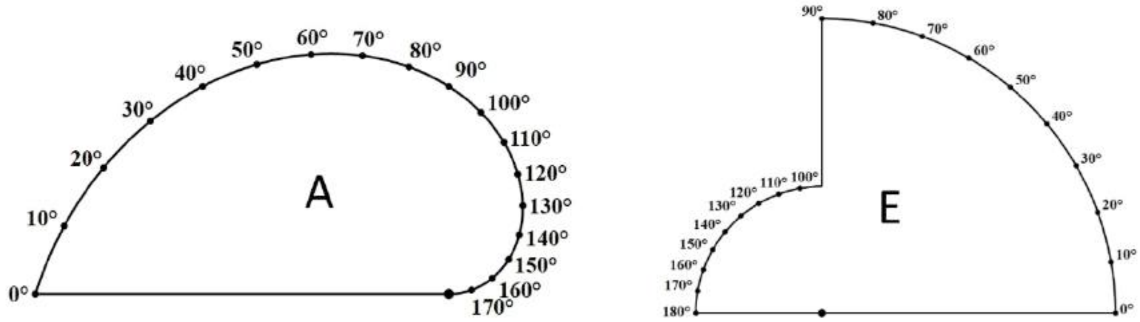

Figure 1: Two Valid Funky Protractors

Participants and Implementation

We implemented the funky protractors tasks with PTs enrolled in three sections of a geometry content course at a large public university; each section was taught by one of the authors. In the second week of the semester, 45 of the PTs evaluated the validity of four funky protractors, including Protractor A (Figure 1), as part of a written homework assignment following a lesson on angle measurement informed by the first author's prior research (Hardison, 2018) and principles of quantitative reasoning (Thompson, 2011). For further details regarding this lesson, see Hardison & Lee (2019). In addition to evaluating the validity of each funky protractor, we asked PTs to explain in writing why each funky protractor was, or was not, a valid tool for measuring angles. After collecting the written responses, we had a whole-class discussion in which PTs discussed their strategies for evaluating the validity of the funky protractors. Fourteen weeks later, 47 of the PTs evaluated the validity of Protractor E (Figure 1) and provided a written justification for their decision as part of their final written exam for the course. We analyzed responses from both the Week 2 homework assignment and final exam.

Analysis

We coded PTs' written responses for each protractor along two dimensions: validity and justification. We first coded whether PTs determined each protractor to be valid, invalid, or if they failed to make a determination of validity (noncommittal). Then the first author used open coding (Strauss & Corbin, 1998) to establish a set of justification codes for characterizing the rationales PTs wrote to support their decisions. When a stable set of codes was established via iterative analyses, all responses were coded independently by both authors and compared; discrepancies were discussed until consensus was reached. A single validity code was assigned to each response; responses could receive multiple justification codes. Descriptions of the justification codes are provided in the findings section below.

Findings

Regarding the validity of protractors, on the Week 2 homework assignment, only two of the 45 PTs (4%) identified Protractor A as a valid protractor; the remaining 43 PTs (96%) concluded Protractor A was invalid. In contrast, on the final exam 77% of PTs identified Protractor E as valid, and 21% of PTs deemed Protractor E invalid (see Table 1).

Table 1: Prevalence of Validity Codes for Protractors A and E

Protractor (Week)	# Valid (%)	# Invalid (%)	# Noncommittal (%)
A (Week 2; n=45)	2 (4%)	43 (96%)	0 (0%)
E (Week 16; n=47)	36 (77%)	10 (21%)	1 (2%)

To support their decisions regarding validity, PTs provided a variety of justifications, from which we abstracted six broad categorizations: *attending to measurable attributes, attending to particular angles, attending to shape features, attending to location, using a standard protractor,* and *other*. We assigned *attending to measurable attributes* to justifications indicating attention to extents of successive instantiations of an attribute; for example, justifications reliant upon checking whether the tool indicated a consistent unit received this code. Furthermore, we established subcodes denoting the quantity indicated: *angularity*, *distance between marks*, and *radial distance to marks*. A response received the *angularity* subcode if the PT attended to angular units (e.g., Figure 2, left) and the *distance between marks* subcode if the PT attended to the distance between marks on the boundary (e.g., Figure 2, right). The *radial distance to marks* subcode was assigned when justifications indicated a PT was considering whether marks along the boundary were equidistant from the suggested vertex position. Although this is equivalent to checking whether the boundary formed a circular arc, PTs were not necessarily aware of this. When the particular quantity could not be inferred, we assigned a fourth subcode: *ambiguous quantity*; for example, this subcode was assigned when justifications referred to "even spacing" without further elaboration or annotations. From our perspective, an appropriate justification involves attending to whether the protractor can be used for counting successive angular units of a specified size (i.e., subcode *angularity*).

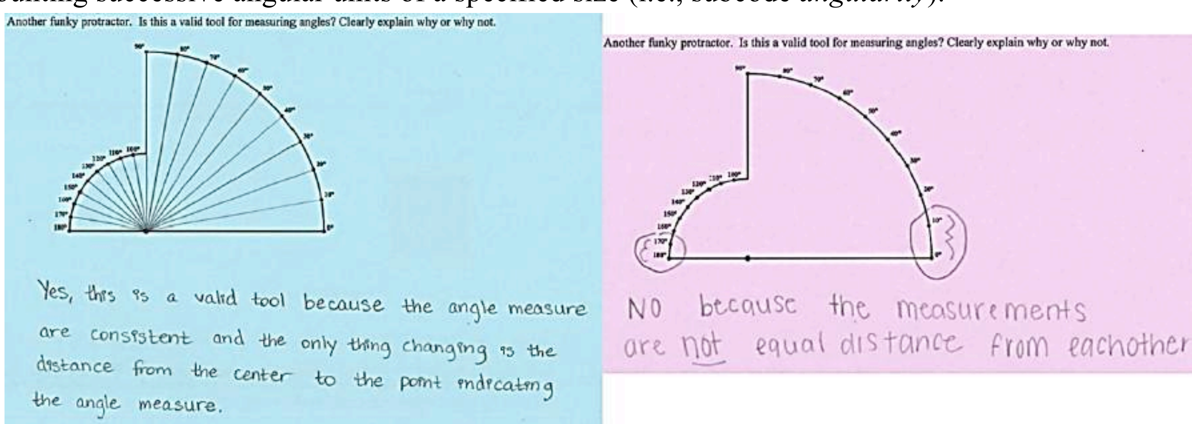

Figure 2: Justifications Coded as Attending to Measurable Attributes: Angularity (Left) and Distance Between Marks (Right)

We assigned *attending to particular angles* if a PT's justification was rooted in the measurements of one or more specified angles. For example, some PTs argued that Protractor E was valid because it was appropriate for measuring right and straight angles without indicating whether the protractor would be appropriate for measuring other, arbitrary angles. Justifications were coded as *attending to shape features* when PTs claimed that protractors were valid or invalid based on the shape of the protractor's boundary or the symmetry of the protractor. Justifications referencing position or location were coded as *attending to location*. For example, some PTs argued Protractor E was invalid because the suggested vertex position was not located on the midpoint of the protractor's straight side. *Using a standard protractor* was assigned to responses indicating that a PT physically superimposed a standard protractor atop a funky protractor to evaluate its validity. Finally, justifications that were unclear or did not fit into any of the aforementioned categories were coded as *other*. Codes for PTs' justifications for each protractor are summarized in Table 2; percentages do not sum to 100% because some responses received multiple justification codes.

Table 2: Prevalence of Justification Codes

Protractor (Week)	Measurable Attributes	Particular Angles	Shape Features	Location	Standard Protractor	Other
A (Week 2; n=45)	24 (53%)	6 (13%)	23 (51%)	4 (9%)	1 (2%)	6 (13%)
E (Week 16; n=47)	30 (64%)	9 (19%)	2 (4%)	4 (9%)	4 (9%)	11 (23%)

Table 3: Prevalence of Measurable Attribute Subcodes

Protractor (Week)	Angularity	Between Marks	Radial Distance	Ambiguous Attribute
A (Week 2; n=45)	1 (2%)	19 (42%)	1 (2%)	4 (9%)
E (Week 16; n=47)	11 (23%)	9 (19%)	0 (0%)	10 (21%)

As shown in Table 2, the majority of PTs (53%) attended to measurable attributes in their justifications for Protractor A. However, as indicated in Table 3, distance between marks along the boundary was the most prevalent attribute indicated in justifications for Protractor A; only one of 45 responses received the *attending to angularity* subcode for Protractor A. The majority of PTs (51%) also attended to shape features, which are irrelevant from our perspective, when evaluating the validity of Protractor A. In contrast, when evaluating Protractor E on the final exam only 4% of PTs attended to shape features. The percentage of justifications coded as attending to measurable attributes increased to 64% for Protractor E with 23% of all responses indicating attending to angularity; additionally, a lower percentage of responses (19%) indicated attending to distance between marks along Protractor E's boundary.

Concluding Remarks

In closing, we are encouraged by the increase in the percentages of PTs giving appropriate validity determinations and attending to angularity over the course of the study, as well as the decrease in the percentage of PTs attending to shape features; however, differences in the design of Protractors A and E merit cautious interpretation regarding these tasks' impact on PTs' content knowledge. More research is needed to understand how to better support PTs' in developing productive quantifications of angularity. From our perspective, the funky protractors activity and the accompanying classroom discussion afforded opportunities for PTs to think critically about the essential features of valid angular measurement tools. It also afforded opportunities for us as instructors to gain insights into PTs' thinking about measuring angles via the features to which they attended in their justifications.

PRE-SERVICE TEACHERS' DEVELOPING INSTRUCTIONAL STRATEGIES FOR ENGLISH LANGUAGE LEARNERS IN SECONDARY MATHEMATICS

Brittany Caldwell
University of California, Santa Cruz
bbettner@ucsc.edu

Salvador Huitzilopochtli
University of California, Santa Cruz
shuitzil@ucsc.edu

This study describes the knowledge and skills pre-service teachers (PSTs) identify as important for teaching secondary mathematics to ELLs before and after their credential program. Preliminary results show that most of the PST's (73%) initially described knowledge and skills globally with few specifics on implementation. During follow-up nearly half (45%) of the PSTs described more organized and specific ways to support learning for ELLs. Secondary analysis reveals various approaches to supporting ELLs, including 1) making mathematics accessible, 2) treating everyday language and experiences as resources, and 3) "engag[ing] students in mathematical practice" (Moschkovich, 2013, p. 49).

Keywords: Teacher Education-Preservice, Teaching Tools and Resources, Equity and Diversity

This study is part of a larger research project, Science and Mathematics Teacher Research Initiative (SMTRI), which seeks to explore novice secondary school teachers' beliefs, knowledge, and skills to provide effective mathematics instruction to culturally and linguistically diverse students. Participants in SMTRI are graduates of the Cal Teach program representing five UC campuses. This study is concerned with a subset of data from one campus. Previous research has documented that many teachers feel underprepared to teach mathematics to English language learners (ELLs) (de Araujo, Roberts, Willey, & Zahner, 2018). Therefore, this study identifies the ways pre-service teachers (PSTs) take up and develop ideas and practices for supporting ELLs in secondary mathematics classes. This study explores the research question: in a credential program that emphasizes the integration of content and language instruction, do PSTs ideas about knowledge and skills related to teaching ELLs change? If so, how?

Conceptual Framework

Research-based guidelines for equitable mathematics teaching practices for English Language Learners (Moschkovich, 2013) framed the analysis of the interviews. In particular, we considered the following guidelines because of their alignment with aspects of the SMTRI intervention: Engage students in the eight CCSS for mathematical practice, Keep tasks focused on high cognitive demand, conceptual understanding, and connecting multiple representations, Facilitate students' production of different kinds of reasoning, and Focus on language as a resource for reasoning, sense-making, and communicating with different audiences for different purposes (Moschkovich, 2013).

The study framed the development of teaching practices with a teacher development learning progression that describes a trajectory through four stages and considers the integration of English language development alongside content learning: 0 = *Not Present* (Rule-based or inflexible view of teaching practices), 1 = *Introducing* (global approach to teaching practices), 2 = *Implementing* (organized, planned approach to teaching practices, which includes probing, scaffolding, or connections to students' experience), and 3 = *Elaborating* (teaching practices are flexible and responsive to context) (Adapted from Stoddart, Pinal, Latzke, & Canaday, 2002).

Methods

Participants in this study include 11 PSTs from two cohorts in a single-subject master-credential program for mathematics from one of the five UC campuses. Each participant was interviewed at the beginning and end of their credential program. For this study, the authors solely focused on the sections and questions that were specifically related to ELLs.

Interviews were initially coded using a rubric adapted from the Math Classroom Observation Rubric (MCOR) (see Stoddart, Pinal, Latzke, & Canaday, 2002). The MCOR was developed to characterize mathematics teacher instruction in alignment with the Common Core State Standards. The MCOR characterizes four aspects of teacher practice and pedagogy: 1) mathematics sense-making through applied math/engineering practices, 2) mathematics discourse, 3) English language and literacy development, and 4) contextualized mathematics activity. For each of these categories, the interviews were coded on a scale of 0-3. Differences in scores on pre- and post-interviews were then evaluated to determine changes in participants' responses. Interviews were coded by both authors and scores were calibrated to reach 100% inter-rater agreement. Secondary analysis of the interviews included purposeful selection of four PSTs within three categories: 1) highest overall scores, 2) most improved scores, and 3) scores that decreased. The interviews from these four PSTs served as case studies for more in-depth analysis.

Results

Increased Implementation

During the initial interview, most of the PST's (73%) described knowledge and skills globally with little to no specifics on implementation. For instance, 7 out of 11 PSTs identified using "multiple representations" to support ELLs yet did not explain how or why they would use multiple representations. One PST said, "I think multiple means of representation and having multiple points of access of information at the same time." Another PST similarly explained,

> It's kind of the same supports that you use working with all types of students with IEPs is or just different learning types or abilities. It's the UDL lesson plan with the multiple modes of representation and engagement and expression. You're just trying as many different things as possible to try to activate learning and understanding within all your students. (Transcript, 2020)

During the follow-up, nearly half (45%) of the PSTs described more organized and specific ways to support mathematics learning for ELLs. Out of the eight participants who scored a "1" during their initial interview, two participants increased their scores by one point and two participants increased their scores by two. One participant scored a "2" on their initial interview and improved by one point. One participant's score decreased by one point.

Among participants who described more organized and specific plans for supporting ELLs, general ideas that were discussed initially became more organized and flexible. Illustrating this, one PST mentioned giving students time to practice language during mathematics instruction: "I think group work and discussing among peers is important as well because I think another important part of language development comes from talking and listening [...] so they all have to have that practice of using that academic language." In the follow-up interview, the same PST elaborated upon this idea of "practice" through their descriptions of having ELLs practice in a "safe way" and giving students opportunities to practice discourse in a "low-stakes environment" by using think-pair-shares and reflections. This PST then described, "in a math classroom you are trying to get the math across and not be so worried about that their response isn't in perfect English to you, but that they understand the mathematical concepts that are happening." Other PSTs discussed similar ideas across their pre- and post-interviews (e.g. multiple representations, getting to know the students, supporting practice with math and language, etc.) and the description of these descriptions often became more specific and organized during the follow-up.

Various Approaches to Supporting ELLs

Secondary analysis of PSTs with the most improvement and the highest overall score reveals various approaches to supporting ELLs. Approaches that emerged across the focal cases include 1) making mathematics accessible, 2) treating everyday language and experiences as resources, and 3) "engage students in mathematical practice" (Moschkovich, 2013, p. 49).

Making mathematics accessible. Across the three focal cases, each PST identified ways of making mathematics accessible. Case Study 1 (CS1) discussed getting to know where students came from including their "culture" and "home language" with the rationale that knowing this information supports "students [to] see themselves being involved in the curriculum and being involved in the classroom and that their language is validated and their culture is validated." Other ways CS1 discussed making mathematics accessible included using "discovery learning", supporting "students' understanding of a concept before introducing the term", using a familiar "context", and drawing on "peers" as resources to support learning. Similarly, Case Study 2 (CS2) discussed the idea of facilitating "practice" with mathematics and language. Initially CS2 described "practice" in terms of "talking and listening" and reasoned that students need "to practice their language skills." During the follow-up, CS2 discussed "practice" with more organization and flexibility. CS2 discussed the importance of practicing mathematics and language in a "low stakes environment" with peers and with the guidance of other instructional supports such as "think-pair-shares" and "personal reflection." CS2 stressed the idea that mathematics should be the focus, not correctness of vocabulary, as students are making meaning for concepts. Moreover, CS2 acknowledged that students need time "to process and think."

Treating everyday language and experiences as resources. An approach that consistently emerged across the focal cases included treating everyday language and students' experiences as resources for learning. Illustrating this, Case Study 3 (CS3) described drawing on various perspectives, bringing in context from students' "home lives that relate[s] to the subject matter," and being "flexible" with instruction. Further, CS3 discussed giving students various opportunities to draw on familiar context and their linguistic resources to develop conceptual understanding while supporting increased precision with ideas and terminology. CS3 mentioned, "If students are able to informally talk to each other about concepts and their initial ideas, then they can get more and more precise [...with] explaining, justifying their ideas." CS3 focused on ideas related to contextualizing mathematics activities in a way that reflects the lives and resources that ELLs bring with them to the classroom. Similarly, CS1 elaborated upon the idea that students should use be able to use their home language to support understanding when they described,

> Because mathematics requires students to explain one's thinking a lot of the times, if students bring to the class more proficiency in another language, then using that language to explain mathematical thinking and to process and to think is a really, really great way for them to build conceptual understanding. (Transcript, 2020)

In line with an elaborated view of instructional practices, the focal cases explicitly discussed connections to students' lives and activities and discussed language as a resource.

"Engage students in mathematical practice" (Moschkovich, 2013, p. 49). Two of the three focal cases identified teaching techniques that made explicit connections to supporting students' engagement in mathematical practices. Such techniques included attending to reasoning, eliciting justification and explanations, supporting negotiating, and supporting precision. CS3 described their approach to teaching as trying to uncover the "thinking behind it" as they talked about engaging with ELLs. Specifically, CS3 discussed giving assessments to ELLs where students could "come in and just talk to me and explain verbally or, you know, with a sketch." CS3 talked about creating a classroom culture where students "informally talk to each other about concepts and their initial ideas, then they can get more and more precise." These ideas reflected attending to the reasoning, not the correctness of vocabulary, while supporting students to gradually move towards precision of ideas and vocabulary. In a similar fashion, CS1 described modeling justifications and explanations and supporting students in this practice. As they explained, "you're constructing viable arguments that enforces a lot of communication and when you're communicating about your ideas and when you're defending your answers and you can explain something, that's when you really get a strong grasp on understanding the concept behind things." These two PST discussed instructional strategies that reflect an understanding of the mathematical practices as well as concrete ways of supporting engagement with the practices specific for ELLs.

Discussion

Specific approaches to mathematics instruction for ELLs emerged as a part of the secondary analysis of the focal cases. These approaches include: 1) making mathematics accessible, 2) treating everyday language and experiences as resources, and 3) "engage students in mathematical practice" (Moschkovich, 2013). These approaches align with other works looking at mathematics teaching and ELLs (e.g. Bunch, 2014; Moschkovich, 2013) that can be enacted by monolingual and multilingual teachers. Moschkovich (2013) highlights the importance of supporting mathematical reasoning, conceptual understanding, and discourse and broadening participation for ELLs in mathematics classes. Further, "to support mathematical reasoning, conceptual understanding, and discourse, classroom practices need to provide all students with opportunities to participate in mathematical activities that use multiple resources to do and learn mathematics" (Moschkovich, 2013, p. 46). The approaches that were discussed by the focal cases in this study reflect alignment with these. The consistency of these practices and explicit references to classes and professors throughout the interviews suggest that these PST are taking up and developing the ideas that were presented to them during their credential program. Since improvement was not consistent across PSTs, and one PST scored lower on the follow-up interview, this work also shows that other factors (beyond the scope of this study) may contribute to the ideas PST have about mathematics instruction with ELLs. This has implications for PST education that future teachers may need additional support, outside of the classes they are taking, to fully develop strategies for supporting ELLs in secondary mathematics. PSTs in secondary mathematics would benefit from additional efforts by Cal Teach and credential programs to examine the role of language when learning mathematics and reflect on beliefs about ELs (NASEM, 2018). This study is limited by small sample size and limits inherent to interview data.

PRE-SERVICE SECONDARY MATHEMATICS TEACHERS' EVOLUTION OF COMMUNALLY AGREED-ON CRITERIA FOR PROOF

Yi-Yin Ko

Developing communally agreed-on criteria for proof in a mathematics classroom has been found to empower pre-service secondary mathematics teachers' (PSMTs') learning of proof. To date, we do not know how creating class-based criteria for proof throughout a semester-long course with a focus on secondary school mathematics can promote PSMTs' understanding of proof. In this paper, we reported PSMTs' evolution of what constitutes proof by comparing their initial and revised class-based criteria for proof and investigating their videotaped lessons and video transcripts. Results indicated that PSMTs perceived mathematical values and norms of what counts as proof in their mathematics classroom community as the semester progressed.

Keywords: Teacher Knowledge, Reasoning and Proof, Pre-Service Teacher Education, Instructional Activities and Practices

Despite the importance of proof in school mathematics, pre-service secondary mathematics teachers' difficulties with proof are well-documented (e.g., Ko & Knuth, 2013; Yee, Boyle, Ko, Bleiler-Baxter, 2018). One of the primary challenges pre-secondary school mathematics teachers (PSMTs) face in understanding proof is that they might not perceive or accept mathematical values and norms with respect to learning proof in their classroom community (Dawkins & Weber, 2017). To address this challenge, an emphasis on teaching and learning proof as a social, negotiated, and sense-making process has been found to promote PSMTs' understanding of what constitutes proof and to enhance their ability to evaluate and construct proofs (e.g., Yee et al., 2018). To date, we have only found that Bleiler, Ko, Yee, and Boyle (2015) explicitly shared how undergraduate students in a transition-to-proof course developed, revised, and polished their communal criteria for proof throughout the entire semester. Given that mathematics teachers' knowledge for teaching proof has an impact on their instructional practices (e.g., Bieda, 2010; Stylianou, Blanton, & Knuth, 2009), there is a need to provide insight into how PSMTs' communal criteria for writing mathematical proofs is evolved throughout the semester-long course with an emphasis on secondary school mathematics. More specifically, this study investigated what PSMTs' initial communally agreed-on criteria for proof were and how they evolved throughout the semester.

Theoretical Framework

In the mathematics community, mathematicians actively engage in social practices to negotiate their agreement on the validity of acceptable proofs in the mathematics community (Harel & Sowder 2007). Along with this view, Stylianides's (2007) definition of proof incorporates a focus on the set of statements (i.e., definitions, theorems), the appropriate forms of argumentations, and representations accepted and understood within a particular mathematical community, which shows the general case will be always true without exception. However, research has not adequately investigated how engaging in this type of mathematics classroom community can facilitate evolution of PSMTs' understanding of proof in a course with a focus on secondary school mathematics. To address this research gap, attention must be paid to PSMTs' communally agreed-on criteria for proof in such courses throughout the entire semester.

Methodology

This study was conducted in an elective course focused on proof in secondary school mathematics at a Midwest University in the United States. The instructor (first author) selected, modified, or developed mathematical tasks in the domains of algebra, geometry, and number theory for the course. These three content domains are all vital to and pervasive in secondary school mathematics. In order for PSMTs to take ownership of their communally agreed-on criteria for proof and promote their self-regulation in learning proof throughout the semester, the instructor designed the course following the principle of the before-during-after (BDA) proof instructional sequence (see Ko, Yee, Bleiler, & Boyle, 2016 for detailed information about this three-part proof lesson plan and implementation). There were nine undergraduate students enrolled in the course, and only one PSMT, who transferred from another four-year college, had not taken any of the required proof-intensives courses for his major. The primary sources of data for this paper were the PSMTs' class-developed lists of writing good proofs, as well as the video recordings and their transcripts. The videotaped sections were transcribed by a research assistant and were validated for their accuracy by either the second or the third author.

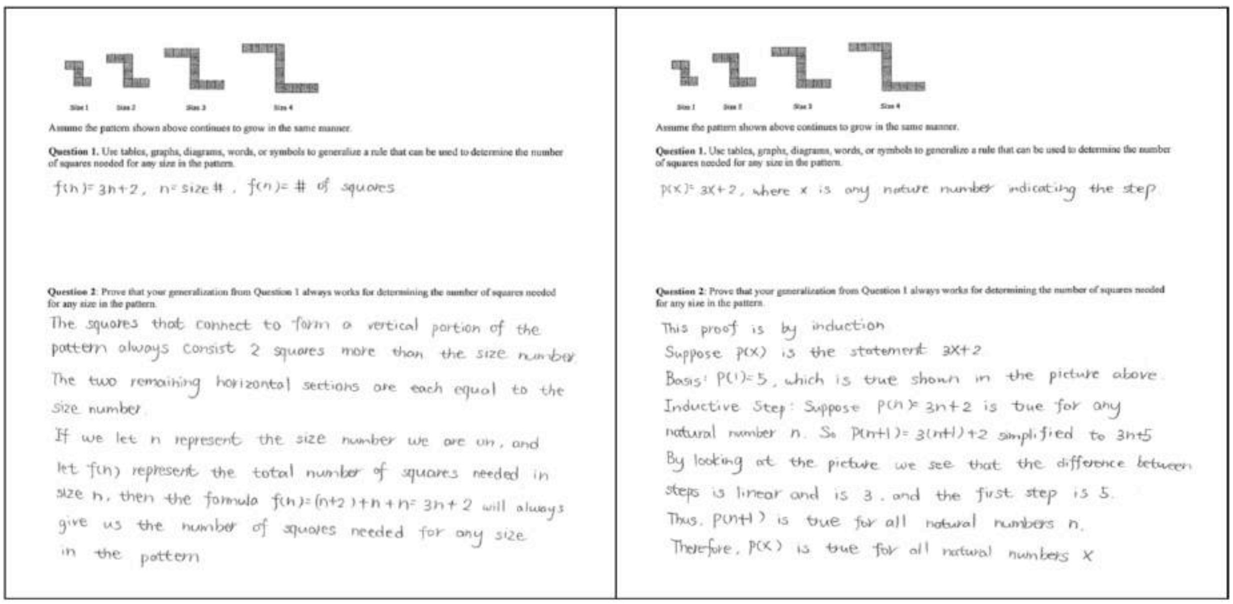

Figure 1: Two Sample Arguments for the Regina's Logo Problem

Results

Followed by the BDA instructional sequence, the PSMTs were asked to evaluate the validity of instructor-selected arguments (see the sample arguments of the Regina's Logo problem adopted from Seago, Mumme, and Branca, (2004) depicted in Figure 1). Also, the instructor served as the representative of the mathematics community to ensure the PSMTs' proposed characteristics for proof were acceptable. Then the whole class determined and ordered that generalization, logical order, correct terminology, clear and precise explanations, and identify given are the five most crucial characteristics of writing good proofs. The PSMTs then discussed their descriptions for each proof criterion as a whole class and came up with an initial list of writing proofs (see Figure 2).

Throughout the entire semester, the PSMTs had two opportunities to modify the initial list of writing good proofs. The first revision happened during the third week of the semester when the whole class did not come to a consensus on the validity of one instructor-chosen argument of the

Sticky Gum problem (Fendel, Resek, Alper, & Fraser, 1996) shown in Figure 3 according to their original proof writing rubrics. For example, Renee suggested that "we need to add something like correct and enough explanations for each step." For instance, Vivian said, "I was thinking maybe under [the] identifying the given [category]." Then the whole class agreed to change the description of the "Identify Given" category as "writing all given information that is pertinent to the proof." During the same time, some PSMTs also suggested that variables and symbols should be added to the "Correct Terminology" category (see Figure 2).

Proof Criterion and Its Order	Description of Each Proof Criterion		
	Initial List (Weeks 1-2)	First Revisited List (Weeks 3-7)	Final List (Weeks 8-15)
1. Generalization	Have to be true for every scenario. No examples.	Have to be true for every scenario. No examples.	Have to be true for every scenario. No examples.
2. Logical Order	Progresses in a sensible manner. Each step needs to build from the previous step(s) and build to the conclusion.	Progresses in a sensible manner. Each step needs to build from the previous step(s) and build to the conclusion.	
2. Logical Order/Clear and Precise Explanations			Progresses in a sensible manner. Each step needs to build from the previous step(s) and build to the conclusion. Correct and sufficient explanations for each step. No unnecessary information.
3. Correct Terminology	Have to use the correct theorems, notation, rules, etc.	Have to use the correct theorems, notation, rules, variables, symbols, etc.	Have to use the correct theorems, notation, rules, variables, symbols, etc.
4. Correct and Precise Explanations	Correct explanations for each step.	Correct and sufficient explanations for each step. No unnecessary information.	
4. Assumption of Knowledge			Only assumed knowledge previously discussed/defined in our course.
5. Identify Given	Writing all the things that we are given at the start.	Writing all given information that is pertinent to the proof.	Writing all given information that is pertinent to the proof.

Figure 2. Initial and Evolution of the Communal Criteria for Proof.

We know that we need to have k number of gumballs, where k represents the number of kids, so that each child has one. We also know that each child wants to have the same color. If we have c number of colors, then worst-case scenario would be that each time we use the machine, we receive a different color gumball. However, after c number of uses, we would have either multiple of at least one color or one of each. Therefore, if we only had one of each color, after the next repetition, we would have more than one in at one color. Following this pattern, we would need to keep using the machine as many times as there are colors multiplied by one less than the total number of kids. This would get us, in the worst-case scenario, one matching gumball for every child except the last one. In fact, if every turn of the machine produced a different color until all colors had been used and repeated this process continuously, we would, at this point, have enough of each color for every kid except one. We would, therefore, only need to use the machine one more time to find a match for the final child. From this information, we can extrapolate that c(k-1) represents the number of times we need to use the machine in order to have a full set of colors for all of the children except for one; adding one more turn would fulfill the request of the stingy children by giving us a full set of one color. Therefore, the expression c(k-1)+1 satisfies the conundrum for any number of children with any number of colors.

Figure 3: A Debated Argument for the Sticky Gum Problem.

As the semester progressed, PSMTs had another opportunity to revisit and modify the proof rubrics. When negotiating the validity of the sample arguments for the statements, "Suppose m, n, and p are positive integers. If m is a factor of n, and m is a factor of p, then m is a factor of $n + p$," some PSMTs pointed out that one of the biggest problems of the first revised proof criteria is clear and logical explanations. Given that not all the PSMTs in this class had completed the required proof-intensive courses for their major, they discussed how much information they should include in each argument to be considered as a proof based on their class rubrics. For example, Ethan explained that their group added the assumption of knowledge category because we "can't just assume that people know things that could have been learned in other classes or in other settings."

After the whole class discussion, all the PSMTs decided to keep the top four and the last characteristics of writing proofs and to combine the other two categories, "Logical Order" and "Clear and Precise Explanations," into one criterion. They also added the fourth criterion pointing out the importance of writing proofs that only used definitions, theorems, or principles that had learned, accepted, and discussed in this class (see Figure 1). The second revised list served as the final version of writing proofs, because all the PSMTs felt that this checklist was sufficient for them to construct and evaluate proofs for the rest of the semester.

Discussion

Throughout the semester the PSMTs did not make a major change on their initial list as seen in Figure 1, concurring with Bleiler et al.'s (2015) finding that instructor-selected sample arguments served as good foundations for students to consider the important characteristics of writing proofs. Another feature of the results is that the PSMTs' communal criteria for proof are consistent with mathematics professors' characteristics of a well-written proof, including logical correctness, clarity, and fluency (Moore, 2016). In addition, the PSMTs recognized that their written proofs should be readable and understood by audiences in their mathematics classroom community as the semester progressed. These two findings reveal that the PSMTs perceived mathematical values and norms of learning proof in their mathematics classroom community through constructing, evaluating, negotiating, and making sense of arguments, which more closely aligns with the practice of mathematicians (Harel & Sowder 2007). Even though PSMTs developed the initial list of writing good proofs and revisited it as the semester progressed, they still negotiated their evaluations for some of the instructor-selected arguments to be considered as proofs or not. Given that PSMTs' communal understanding of what counts as a proof is affected by their instructor of a proof course, comparing how PSMTs and their instructor use their class-developed criteria for proof to evaluate the same arguments can provide more insight into their individual interpretations of each proof criterion within their mathematics classroom community.

ANALYZING HOW REFLECTIVE DISCUSSIONS IN A CONTENT COURSE INFLUENCE PROSPECTIVE TEACHERS' BELIEFS

Alexa W.C. Lee-Hassan
Learning Sciences Research Institute, University of Illinois at Chicago
aleeha2@uic.edu

An important challenge in math teacher education is helping prospective teachers (PTs) develop mathematical beliefs that support effective mathematics teaching. A growing body of research has established the potential efficacy of strategies that incorporate reflection with collaborative mathematical problem-solving. However, previous studies tended to collect data only at an individual level and analyze change at an aggregate, whole-class level. This brief research report uses frame analysis of individual, written reflections and small-group and whole-class reflection conversations to provide insight into the reciprocal relationships between individual PT beliefs, small-group interactions, and the whole-class classroom culture in a math content course designed to support PTs in developing productive beliefs about mathematics.

Keywords: Teacher Beliefs, Teacher Education – Preservice, Classroom Discourse

Teachers' beliefs about mathematics teaching and learning can influence their instruction and either support or undermine student opportunities to learn (Conference Board of Mathematical Sciences, 2012; Wilhelm et al., 2017). As a result, mathematics teacher education programs have a long history of trying to develop more productive mathematical beliefs in prospective teachers (PTs) before they begin teaching (Schram et al., 1988). This work remains an ongoing challenge, however, because PT beliefs about mathematics are multi-faceted and based on years of emotionally-charged experiences (Ambrose, 2004; Holm, 2019) and are therefore often resistant to change (Grootenboer, 2008). Shilling-Traina and Stylianides (2013) suggested, therefore, that "it is important that beliefs be explicitly addressed not only in methods courses, but in mathematics courses as well" (p. 404). This report focuses on a content course that was designed to initiate the process of supporting PT belief change with an emphasis on collaborative, small-group problem solving—small groups were consistently identified as important aspects of successful belief interventions (Shilling-Traina & Stylianides, 2013; Szydlik et al., 2003). Based on open-ended reflections, PTs identified groupwork as central to their learning in the course, so it seems likely that group interactions influenced their experience of the class and therefore its effects on their beliefs. This report uses frame analysis to begin to explore the relationships between PTs' small-group interactions and their understanding of mathematics learning in a course designed to influence their beliefs about mathematics.

Literature

Many PTs enter their teaching programs with beliefs that are likely to hinder effective mathematics instruction (Grootenboer, 2008). They tend to hold procedural views of mathematics (Shilling-Traina & Stylianides, 2013) and to be skeptical of the possibility of solving novel problems (Szydlik et al., 2003), though there is significant variation within the PT population, and many PTs hold a mix of beliefs that may align with both more traditional and reform instruction (Ambrose, 2002). Ambrose (2004) identified a number of criteria that could potentially stimulate belief changes in PTs, including emotionally-resonant experiences, chances to reflect on their beliefs and experiences, and participating in a community that embraces such beliefs. Similarly, Szydlik and colleagues (2003) were able to support PT belief change by creating a classroom community that facilitated active problem solving and PT autonomy. The course that is the subject of this brief report followed similar design criteria.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

One challenge in researching change in PT beliefs, however, is that beliefs can be difficult to measure directly. Survey items may be misinterpreted by PTs (Szydlik et al., 2003), and when students are asked directly about their beliefs they may say what they think their instructor wants to hear without truly examining their beliefs or modifying their work with students (Grootenboer, 2008). Surveys and interviews also tend to focus analysis at the level of the individual and fail to address the importance of reciprocal relationships between classroom culture, individual beliefs, and group interactions in the classroom (Cobb, 2000). This brief research report uses frame analysis to begin to examine beliefs at the individual, small-group, and whole-class levels. Frames are the underlying, often implicit, structures of expectations that organize how people understand and react to events, and frame analysis investigates how groups come to a common understanding of a frame or frames that invite a particular type of action or change (Benford & Snow, 2000). Frame analysis can be particularly appropriate for attending to the roles that power and authority play in frame negotiations (Hand et al., 2012), which in the context of collaborative mathematics work often manifests as differences in status—perceived competence, levels of participation, and influence—between group members (Nasir et al., 2014). Frame analysis has been used to explore how particular frames became prevalent in a school community initiating instructional change (Coburn, 2006) and to examine collective belief change about mathematics learning in a collaborative group of teachers (Bannister, 2015). The analysis in this report will focus on identifying frame resonance (Benford & Snow, 2000; Coburn, 2006), which occurs when a frame that one individual offers is taken up and reinforced by others in a group. In particular, this report will investigate the following research question: What relationships can be seen between the frames that resonate in small-group and whole-class reflection conversations, and the frames that PTs use in their individual reflection responses across multiple time periods?

Methods

Context and Participants

The data analyzed in this paper were collected as part of a larger project analyzing PT beliefs about mathematical ability and learning—what Boaler (2016) labeled mathematical mindsets—in a required math content course for PTs in a large, urban, public university in the United States. Aligning with current recommendations to use active learning in content courses for PTs (Litster et al., 2020), the course used "group-worthy problems" to support students in developing their mathematical knowledge and productive beliefs about mathematics and mathematical learning (Nasir et al., 2014). The participants in the current study were drawn from two concurrently offered sections of the course—referred to as Class A and Class B. The author of this report was the instructor of Class B and planned collaboratively with the other instructor so that students in both sections had the same assignments and assessments. There were 65 PTs enrolled between the two sections, and 57 consented to have their classwork analyzed for research purposes.

Data Sources and Analyses

The data used in the current analyses were drawn from reflections that PTs completed in class during weeks 6, 12, and 15 of a semester course—T1, T2, and T3 respectively. The dates aligned with the two midterm exams and the last class session before the final exam for the course. The reflection prompts asked PTs to do the following:

1. Describe a significant or "Aha!" moment from class and explain why it was significant
2. Reflect on their work/participation in the class so far
3. Make or update a goal for themselves
4. Create a plan to move towards their goal
5. Reflect on how their learning in this class might apply to future teaching (only in T3)

PTs responded to the prompts individually and then discussed their memorable moments and goals in small groups. One PT from each group shared their response as part of a whole-class discussion. The small-group and whole-class discussions were audio-recorded. The written, individual reflections were entered into NVivo 12 and group reflections were imported into InqScribe. Individual and whole-class data were analyzed for all consenting participants from both sections, but the small-group analyses focus on the 29 participating students from Class B because a larger proportion of PTs in that class consented to the analysis of their audio data and because their groups for the group reflections were more consistent across timepoints.

The individual reflections were coded for whether they framed important mathematical learning as active, interactive, passive, or unclear. Responses were coded as using an "active" learning frame if the PT described learning through individual problem solving—either in a significant past experience or as part of their goal moving forward. Responses were coded as using a "passive" learning frame if they described learning from listening to an explanation, practicing rote memorization, or taking or reviewing notes. They were coded as using an "interactive" learning frame if the PT framed interaction with others as central to learning, describing a combination of listening, questioning, and problem solving or describing the actions of the group as a whole rather than their actions as an individual. Finally, responses were coded as "unclear" if there was not enough information to tell how the PT was framing learning. Each PT's response included multiple frames, so a given PT could be coded as using multiple types of frames in a given response. Responses were also coded to identify the most common categories of learning goal, which included some goals that were implicitly aligned with active, passive, or interactive frames for mathematical learning. For example, goals focused on participation in class tended to align with an active frame for learning, while goals focused on asking questions or going to office hours tended to imply a passive frame that assumed that the best solution to a challenge is for someone to provide an explanation. (In practice, interactions during office hours were supportive of active learning, but most of the PTs who made office hours attendance their goal did not actually attend them.) The audio-recorded small group reflections were analyzed to identify examples of frame resonance—interactions in which one PT presented a particular frame and other PTs or an instructor endorsed and reaffirmed the frame. These examples of resonant frames were then compared to the data from the individual reflections to look for patterns.

Findings and Implications

Preliminary analyses of these data found that the two classes and the small groups in Class B showed different frequencies and trajectories of particular frames in the individual responses, and many of those differences aligned with examples of frame resonance from the small-group and whole-class discussions from the preceding time periods, especially when those frames were endorsed by high-status individuals. For example, while both classes showed similar distributions of active frames over time, Class A showed a gradual increase in interactive frames, while Class B showed a gradual decrease. Class B's decrease could be traced to some groups having a particularly high frequency in T1 (100% of PTs in Group 3 used an interactive frame in T1) and to other groups (Groups 5 and 6) showing a marked decrease in interactive frames combined with an increase in passive frames. An initial review of those groups' discussions shows that a binary frame of correct versus incorrect strategies resonated particularly strongly in Groups 5 and 6—in contradiction with the course's goal of framing diversity of strategies as desirable, which appeared to resonate with the majority of PTs in both classes.

Another difference between classes was that Class A showed an increase in identifying participation as a focal goal, while in Class B that goal decreased to become almost nonexistent. The contrast may be related to the fact that in Class B's whole-class discussion one of the PTs shared participation as their goal and received minimal acknowledgement from the instructor (the author of this report), in contrast with more enthusiastic responses to other shared goals. While the lack of reinforcement was not intended as a value judgement, the instructor's position of authority within the classroom may have given it unanticipated weight. Frame resonance may have also played a counter-balancing role at the group level: in the two groups in which some PTs did create participation goals in T2 and T3 the conversations in T1 showed strong resonance for that goal. For example, in Group 3 two PTs shared that their goal was to participate more. A high-status PT affirmed the goal as "smart to do" and credited her own understanding of class material as "because I've participated and, like, gone up to the board." She then suggested that her groupmates share in the whole-group discussion to act on their goal.

Finally, both Class A and Class B had relatively low frequencies of goals that focused on grades and passing the class, and Class B's frequency decreased over time, but Group 2's frequency started at roughly twice the class average and stayed roughly constant over time. There are multiple examples in Group 2's discussions that show how strongly a focus on grades resonated with the group members, especially with the PT who seemed to have the highest social and mathematical status within the group. In the group's T1 conversation they encouraged one another to aim for As and Bs rather than just passing the class, which illustrated how the goal became associated with the supportive social relationships within the group. Their T3 conversation also highlighted the ways that larger school frames about the evaluative function of finals week and exams could overshadow the frames and experiences that our course tried to cultivate. In the words of the high-status PT: "So far I'm doing pretty well, but, you know, after this [final] that's probably not the case anymore…It's always the final that's going to break you down, so I'm going to let that go ahead and just be it. So, we're going to pray."

While these analyses are only preliminary, there are some potential implications. The examples all reinforce how important it is for instructors to pay attention to the implications of status during small-group and whole-class discussions, even when the topic is self-reflection rather than mathematical problem-solving (Cobb, 2000; Nasir et al., 2014). Group 2's T3 conversation illustrates why it is so important that PTs are exposed to multiple courses and experiences that support positive belief change over time rather than a single course. It also serves as a reminder that the pressure and structure of finals may make it so that studies that only take measures at the end of courses may underestimate the changes that PTs experience during the courses. Future studies could examine whether this regression is localized to the time around exams or persists after them. Researchers could also examine how the frames around goals and active/autonomous learning that are the focus of this study relate to other PT beliefs about mathematical ability (Boaler, 2016) and math instruction (Ambrose, 2004).

The research focuses on the analysis of confidence and doubt in mathematical statements. Based on the Grounded Theory, and on the analysis of a historical case, that of non-Euclidean geometries, and especially on the figure of Saccheri, the question in this document is answered. It is argued that confidence in the truth of Euclidean geometry had as an effect the attribution of qualities to said geometry and to the problems identified in that work. Also, expectations about the solution to those problems and logical, ontological and epistemological commitments were made explicit. It seems that handling these effects of confidence with biases and exaggerations can be negative for the development of mathematical work.

Keyword: Affect, Emotion, Beliefs, and Attitudes; Geometry and Geometrical and Spatial Thinking

Background, objective, and research question

This research focuses on the analysis of states such as the confidence or doubt that people experience around the veracity of mathematical statements (such as postulates, theorems, or results of school assignments, which will be denoted hereinafter as “H”). Rigo (2013) calls these states as “epistemic states of convincement” and represents them as “ESC”. Various studies have shown the presence of these states in all kinds of mathematical practice, both those carried out in school contexts and in professional mathematics (Fischbein, 1982; Harel and Sowder, 1998; Hersh, 1993; Segal, 2000).

In some cases, the security in certain H’s adequately guides the mathematical work, which leads to advances in learning. For example, Inglis, Mejia-Ramos and Simpson (2007) affirm that a considerable reduction in uncertainty allows us to determine when we already have enough tools to carry out a test; the reduction of doubt, works in this case as a force that encourages mathematical activity. In other cases, security can have detrimental effects on the advancement of mathematics learning. For example, in the context of mathematical proofs, Inglis, Mejia-Ramos and Simpson (2007) observed that when a student confidently associated an affirmation based on inductive warrants, he did not have the need later to construct a proof that supported this affirmation.

So, experts have warned that security in mathematical statements can sometimes positively influence the development of learning or disciplinary knowledge, but sometimes that influence can be negative. However, in mathematical education literature -and in that of other disciplinary areas- no systematic conceptual development has been found on the characteristics of this confidence in mathematical statements that account for co-related phenomena, nor, in particular, have they constructed theoretical explanations that allow identifying and understanding the conditions under which the ESC act favorably or unfavorably, at a didactic level. It is considered that it would be necessary to know these conditions in depth, to recreate or inhibit them in school contexts.

To meet these needs, this document suggests a first and provisional answer, based on theoretical explanations, to the question: Why does confidence in mathematical statementsnegatively influence the advancement of the discipline?

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Methodology and methods

The research question posed in the writing demands theoretical explanations associated with the phenomenon of convincement, which go beyond specific descriptions with little clarifying power. However, as already stated, no theories have been constructed that offer such explanations. For this reason, this document does not start from a theoretical framework (it simply does not exist) and its objective is to initiate the development of one. To develop this theory, the qualitative research perspective offered by the Grounded Theory was chosen (GT, Corbin & Strauss, 2015). An analytical tool of GT is “context analysis” (CA). In CA, it is considered that when people act or have some internal experience, they are responding to significant events. Those events are called “conditions”. From a fusion of conditions, and from the internal actions or experiences that they promote, results usually emerge. In CA these results are called “consequences”. Those consequences can stimulate more actions or change their course. The theory thus consists of a set of explanations on how certain actions or internal experiences can be given under a combination of certain conditions, and how certain consequences can arise from these conditions and actions or internal experiences.

This manuscript provides some explanations regarding the ESC phenomena that people experience when doing mathematical work. For this, following the GT, the CA will be used. But here the focus is only on the analysis of the consequences that these ESC have on mathematical work. For this analysis, historical data can be used, which is taken as empirical data (cf. Corbin & Strauss, 2015). This paper analyzes Saccheri's role in the development of non-Euclidean geometries - who is sadly famous for “being a victim of the preconceived notion of his time, that the only possible geometry was Euclidean” (Heath, 1956, p. 211) -, because it illustrates the phenomenon under study. In particular, parts of Saccheri's preface to his work *Euclid vindicated from every blemish* (Saccheri, 2014) are analyzed, because there he explains his ESC and suggest how these ESC negatively influenced his mathematical work. Following the CA, in the analysis the ESC are considered as internal experiences and the consequences of those ESC are identified. Subsequently, these consequences are denoted with concepts and, in the end, those concepts are used to explain how the ESC influenced (at the beginning) the mathematical work of Saccheri.

Report of results: certainty as an obstacle to the advancement of knowledge

Saccheri begins the preface to his work Euclid vindicated from every blemish with the following:

> Of all who have learned mathematics, none can fail to know how great is the excellence and worth of Euclid’s *Elements*. As erudite witnesses here I summon Archimedes, Apollonius, Theodosius, and others almost innumerable, writers on mathematics even to our times, who use Euclid’s *Elements* as foundation long established and wholly unshaken. (Saccheri, 2014, p. 62)

There, the mathematician begins by attributing to Euclid's *Elements* a positive quality (of "excellence") magnified (with the word "great"). Later, he supports the attribution of that quality in the ESC of "wholly unshaken" that various mathematical authorities attributed to the work over a long time. Saccheri (2014) thus continues:

> But this so great celebrity has not prevented many, ancients as well as moderns, and among them distinguished geometers, maintaining they had found certain blemishes in these most beauteous nor ever sufficiently praised *Elements*. Three such flecks they designate. (p. 62)

The attribution of magnified positive qualities to the Euclidean work, according to Saccheri, did not prevent mathematicians from identifying blemishes in it. However, the mathematician appealed to these magnified positive qualities, to interpret these imperfections as minimal negative qualities of the work (i.e. flecks). What consequences arose from this attribution of qualities to the Euclidean work and its imperfections? Saccheri continues:

> The first (fleck) pertains to the definition of parallels and with it the Axiom which in Clavius is the thirteenth of the First Book of the *Elements*, where Euclid says: If a straight line falling on two straight lines, lying in the same plane, make with them two internal angles toward the same parts less than two right angles, these two straight lines infinitely produced toward those parts will meet each other. No one doubts the truth of this Assertion; but solely they accuse Euclid as to it, because he has used for it the name Axiom, as if obviously from the right understanding of its terms alone came conviction. (Saccheri, 2014, p. 62)

There, Saccheri begins by announcing that an imperfection (described by him as "fleck") of the Euclidean work is related to the V Postulate. Then he states that postulate and connects it with an ESC: “No one doubts the truth of this Assertion”. So, for Saccheri, the Fifth Postulate's high degree of commitment to truth value was never questioned. For him, the imperfection was that this statement was given the status of axiom. That is, what he questioned was the strategy used to grant the truth value to the V Postulate. In sum, a first consequence of having attributed magnified positive qualities to the Euclidean work and of having interpreted its imperfections as minimal negative qualities was that, despite finding difficulties in one of its affirmations (the V Postulate), the truth of this affirmation was sustained with a high degree of commitment and only the strategy on which that truth value was based was questioned. Other consequences are disclosed below:

> For some, and these surely the keenest, endeavor to demonstrate the existence of parallel straight lines as so defined, whence they go up to the proof of the debated Assertion as stated in Euclid’s terms, upon which truly from that *Elements* (with some very few exceptions) all geometry rests. But others (not without gross sin against rigorous logic) assume such parallel straight lines, forsooth equidistant, as if given, that thence they may go up to what remains to be proved. (p. 62)

In criticizing the attempts of others to solve the problem of the V Postulate, Saccheri explains his commitment to the Euclidean definition of parallel lines, with the role of the V Postulate as “support of all geometry” or with “rigorous logic”. That Saccheri has made explicit those commitments around the Elements is consistent with the magnified positive qualities that he attributed to the work. Then he announces that he will divide his book into two parts:

> In the First Part will imitate the antique geometers, and … merely undertake without any *petitio principii* clearly to demonstrate the disputed Euclidean Axiom. (p. 65)

There, Saccheri (2014) indicates that the solution to the problem of the V Postulate would be "simple" and that "it would imitate the antique geometers". As a strategy to support the truth of the V Postulate, he intends to demonstrate it without incurring a *petitio principii*.

According to all the aforementioned, how can it be explained that Saccheri ‘reduced’ the problem of the V Postulate to **demonstrate** its veracity? As it was seen, in his preface he started from an ESC of “**wholly unshaken**” associated with the Euclidean work. One consequence of this ESC was to magnify the positive qualities of that work and minimize its imperfections or possible pitfalls. Consistent with these *attributions* and with the very charge of empirical truth that the V postulate had (in finite space), Saccheri maintained his truth and only questioned the strategy on which that truth value was based. In line with this, he raised *expectations* that the solution to the problem would be “simple” and it would suffice to "imitate" the antique geometers. This guided Saccheri's mathematical work, when he proposed as a solution to the problem to support the truth of the V in the strategy of “demonstrating"”(without *petitio principii*). Furthermore, that resolution respects Saccheri's *commitments*, such as following rigorous logic. This set of values, expectations, commitments of all kinds, beliefs, and intentions that are linked to the ESC here is called the *ESC interpretive framework* (IF).

To explain why Saccheri ‘minimized’ the problem of the V Postulate, we analyze how he handled that MI. In the first place, Saccheri accompanied this IF with a magnification of the positive qualities that he attributed to *the Elements* (with words like "great"), a minimization of its imperfections (with words like "fleck") and a simplification of the solution to those imperfections (with " I just commit"). This way of handling IF can be called *exaggeration*. Secondly, the solution to "demonstrate" that Saccheri proposed to solve the problem of the V Postulate, is totally consistent with the IF. It seems that the IF was considered as "rules that should be followed". Under those rules, other options for solving the problem would be discarded. For example, the option of questioning the Fifth Postulate as the only possibility would be ruled out, because it would go against the slogan of "imitating the antique geometers". Thus, the IF acted as a *bias* that guided Saccheri's strategy. According to what was said before, handling the IF with exaggerations and biases may explain why the mathematician trivialized the problem of the V Postulate. And why did Saccheri consider that IF as "rules that should be followed"? Saccheri asserts that the ESC of "wholly unshaken" in *the Elements* was long held by many mathematicians. Thus, questioning what emerged from that ESC would imply questioning centuries of tradition and great authorities, and it seems that neither Saccheri nor any mathematician of his time were willing to face that. Thus, *social consensus* may also explain why Saccheri appears to have "attenuated" the problem of the V Postulate.

Final remarks

We are now in a position to answer the research question, why does confidence in mathematical statements negatively influence the advancement of the discipline? Here it is argued that ESC have effects on mathematical work and decisions. Specifically, evidence has been provided here that ESC can give rise to the attribution of qualities to mathematical works and problems, to expectations on how to solve those problems, to logical, ontological and epistemological commitments, and in short, to an IF. From this IF, the person can guide his mathematical decisions and his disciplinary work, such as, for example, devising a strategy to solve a mathematical problem. It is necessary to clarify that the ESC are not, in essence, favorable or unfavorable for the advancement of mathematical knowledge. What the study shows is that, under certain conditions, they can be harmful. Some of these conditions have to do with how a person handles IF, particularly if it is accompanied by exaggerations, biases, and taking social consensus uncritically.

La investigación se centra en el análisis de la confianza o la duda en afirmaciones matemáticas. Con base en la Teoría Fundamentada, y en el análisis de un caso histórico, el de las geometrías no euclidianas, y en especial en la figura de Saccheri, se responde a la pregunta que precede a este documento. Se argumenta que la confianza en la verdad de la geometría euclidiana tuvo como efectos la atribución de cualidades a dicha geometría y a los problemas identificados en esa obra, expectativas sobre la solución a esos problemas y la explicitación de compromisos lógicos, ontológicos y epistemológicos. Parece que, manejar con sesgos y exageraciones esos efectos de la confianza, puede resultar negativo para el desarrollo de trabajo matemático.

Palabras clave: Afecto, emoción, creencias y actitudes; Geometría.

Antecedentes, objetivo y pregunta de investigación

La investigación se centra en el análisis de estados como la confianza o la duda que las personas experimentan alrededor de la veracidad de afirmaciones matemáticas (como postulados, teoremas o resultados de tareas escolares, las que en lo sucesivo se denotarán como 'H'). A esos estados Rigo (2013) los llama estados epistémicos de convencimiento en torno a H y los representa como "eec". Diversas investigaciones han dado cuenta de la presencia de esos estados en todo tipo de práctica matemática, tanto las que se llevan en contextos escolares como en las de la matemática profesional (Fischbein, 1982; Harel y Sowder, 1998; Hersh, 1993; Segal, 2000).

En algunos casos, la seguridad en ciertos H's orienta adecuadamente el trabajo matemático, de lo que se desprenden avances en los aprendizajes. Por ejemplo, Inglis, Mejia-Ramos y Simpson (2007) afirman que una considerable reducción de la incertidumbre permite determinar el momento en el que ya se tienen herramientas suficientes para realizar una prueba; la reducción de la duda, funciona en este caso como una fuerza que incita la actividad matemática. En otros casos, la seguridad puede tener efectos nocivos en el avance de los aprendizajes de las matemáticas. Por ejemplo, en contextos de prueba matemática, Inglis, Mejia-Ramos y Simpson (2007) observaron que cuando un alumno asoció confianza a una afirmación basada en garantías inductivas, no tuvo después necesidad de construir una prueba que soportara dicha afirmación.

Así que los expertos han advertido que la seguridad en afirmaciones matemáticas a veces puede influir positivamente en el desarrollo de los aprendizajes o de los conocimientos disciplinares, pero en ocasiones esa influencia puede ser negativa. Sin embargo, en la literatura de educación matemática -y en la de otras áreas disciplinares- no se ha encontrado un desarrollo conceptual sistemático sobre las características de esa seguridad en afirmaciones matemáticas que dé cuenta de sus orígenes y sus efectos ni, en particular, se han construido explicaciones teóricas que permitan identificar y comprender las condiciones bajo las cuales los eec actúan favorable o desfavorablemente, a nivel didáctico. Se considera que sería necesario conocer a fondo esas condiciones, con el objeto de recrearlas o de inhibirlas en los contextos escolares.

Con el fin de atender a esas necesidades, en este documento se sugiere una primera y provisional respuesta, con base en explicaciones teóricas, a la pregunta ¿Por qué la confianza en afirmaciones matemáticas puede llegar a influir negativamente en el avance de la disciplina?

Metodología y métodos

La pregunta de investigación planteada en el escrito demanda explicaciones teóricas asociadas con el fenómeno del convencimiento, que vayan más allá de descripciones puntuales con escaso poder clarificador. Sin embargo, como ya se dijo, no se han construido teorías que ofrezcan esas explicaciones. Es por esto que en el presente documento no se parte de un marco teórico (simplemente, no existe) y se plantea justo como objetivo iniciar el desarrollo de uno. Para desarrollar esa teoría, se eligió la perspectiva de investigación cualitativa que ofrece la Teoría Fundamentada (TF, Corbin & Strauss, 2015). Una herramienta analítica de la TF es el 'análisis de contexto' (AC). En el AC se considera que cuando las personas actúan o tienen alguna experiencia interna están dando respuesta a sucesos significativos para ellas. Esos eventos se llaman 'condiciones'. De una fusión de condiciones, y de las acciones o experiencias internas que propician, se suelen desprender resultados. En el AC a esos resultados se les llama 'consecuencias'. Esas consecuencias pueden estimular más acciones o cambiar su rumbo. La teoría consiste así en un conjunto de explicaciones sobre cómo ciertas acciones o experiencias internas se pueden dar bajo una combinación de ciertas condiciones, y de cómo a partir de esas condiciones y acciones o experiencias internas, se pueden suscitar ciertas consecuencias.

En este manuscrito se ofrecen algunas explicaciones relativas a los fenómenos de los eec que experimentan las personas cuando realizan trabajo matemático. Para eso, siguiendo la TF, se recurrirá al AC. Pero aquí se centra la atención únicamente en el análisis de las consecuencias que esos eec tienen sobre el trabajo matemático. Para ese análisis, se puede recurrir a datos históricos, que se toman como datos empíricos (cf. Corbin & Strauss, 2015). En este escrito se analiza el papel de Saccheri en el desarrollo de las geometrías no euclidianas -quien es tristemente célebre por "ser víctima de la noción preconcebida de su tiempo, de que la única geometría posible era la euclidiana" (Heath, 1956, p. 211)-, porque ilustra el fenómeno bajo estudio. En particular, se analizan partes del prefacio de Saccheri a su obra *Euclides reivindicado de todo defecto* (Saccheri, 2014), porque ahí él explicita sus eec y deja ver cómo esos eec influyeron negativamente en su trabajo matemático. Siguiendo el AC, en el análisis se consideran a los eec como las experiencias internas y se identifican las consecuencias de esos eec. Posteriormente, esas consecuencias se denotan con conceptos y, al final, se utilizan esos conceptos para explicar cómo los eec influyeron (al inicio) en el trabajo matemático de Saccheri.

Reporte de resultados: la certeza como obstáculo para el avance de conocimientos

Saccheri inicia el prefacio a su obra *Euclides reivindicado de todo defecto* con lo siguiente:

> De todos los que han aprendido matemáticas, ninguno ha dejado de saber cuán grande es la excelencia y el valor de *Los Elementos* de Euclides. Como testigos eruditos aquí, convoco a Arquímedes, Apolonio, Teodosio y otros, casi innumerables, profesionales de matemáticas, incluso de nuestros tiempos, que usan a *Los Elementos* de Euclides como fundamento totalmente incontrovertible establecido desde hace mucho tiempo. (Saccheri, 2014, p. 62)

Ahí, el matemático comienza por atribuir a *Los Elementos* de Euclides una cualidad positiva (de "excelencia") magnificada (con la palabra "grande"). Luego, él soporta la atribución de esa cualidad en el eec de "totalmente incontrovertible" que varias autoridades matemáticas atribuyeron a la obra a lo largo de mucho tiempo. Saccheri (2014) así continúa:

> Pero esta gran celebridad no ha impedido a muchos, tanto antiguos como modernos, y entre ellos distinguidos geómetras, sostener que habían encontrado ciertas imperfecciones en estos Elementos tan bellos y suficientemente elogiados. Ellos designan tres de esos lunares. (p. 62)

La atribución de cualidades positivas magnificadas a la obra euclidiana, según Saccheri, no impidió que los matemáticos identificaran imperfecciones en ella. Sin embargo, el matemático apeló a esas cualidades positivas magnificadas, para interpretar dichas imperfecciones como cualidades negativas mínimas de la obra (i.e. 'lunares'). ¿Qué consecuencias se desprendieron de esa atribución de cualidades a la obra euclidiana y a sus imperfecciones? Saccheri continúa:

> La primera ('mota') se refiere a la definición de paralelas y con ella el Axioma que en Clavius es el decimotercero del Primer Libro de *Los Elementos*, donde Euclides dice: "Si una línea recta que cae sobre otras dos líneas rectas, que yacen en el mismo plano, hace con ellas dos ángulos interiores sobre el mismo lado menores que dos ángulos rectos, estas dos líneas rectas producidas infinitamente hacia esas partes se encontrarán entre sí". Nadie duda de la verdad de esta afirmación; pero únicamente acusan a Euclides en cuanto a ella, porque él ha usado para esa afirmación el nombre de Axioma, como si obviamente solo por la correcta comprensión de sus términos se llegara a la convicción. (Saccheri, 2014, p. 62)

Ahí, Saccheri (2014) comienza por anunciar que una imperfección (calificada por él como "lunar") de la obra euclidiana se relaciona con el V Postulado. Luego, él enuncia ese postulado y conecta con un eec: "Nadie duda de la verdad de esta afirmación". De modo que, para Saccheri, nunca se puso en entredicho el alto grado de compromiso con el valor de verdad del V Postulado. Para él, la imperfección consistía en que a esa afirmación se le dio el estatus de axioma. Es decir, lo que cuestionó, fue la estrategia utilizada para otorgar el valor de verdad al V Postulado. En suma, una primera consecuencia de haber atribuido cualidades positivas magnificadas a la obra euclidiana y de haber interpretado sus imperfecciones como cualidades negativas mínimas fue que, a pesar de hallar dificultades en una de sus afirmaciones (el V Postulado), la verdad de dicha afirmación se sostuvo con un alto grado de compromiso y únicamente se cuestionó la estrategia en la que se basó ese valor de verdad. Otras consecuencias se desvelan a continuación:

> Algunos, y estos seguramente los más entusiastas, se esfuerzan por demostrar la existencia de líneas rectas paralelas, como se definen en *Los Elementos*, de donde salen a la prueba de la afirmación debatida, como se indica en Euclides, y sobre la cual verdaderamente descansan esos *Elementos* (con algunas muy pocas excepciones) y toda la geometría. Pero otros (no sin un gran pecado contra una lógica rigurosa) asumen tales líneas rectas paralelas, como equidistantes, como si de allí pudieran llegar a lo que queda por demostrar. (p. 62)

Al criticar los intentos de otros para resolver el problema del V Postulado, Saccheri explicita su compromiso con la definición euclidiana de rectas paralelas, con el papel del V Postulado como "soporte de toda la geometría" o con la "lógica rigurosa". La explicitación de esos compromisos en torno a los *Elementos* es congruente con las cualidades positivas magnificadas que Saccheri atribuyó a la obra. Luego, él anuncia que dividirá su libro en dos partes:

> En la primera parte imitaré a los geómetras antiguos, y… simplemente me comprometo sin ningún *petitio principii* a demostrar claramente el disputado Axioma Euclidiano. (p. 65)

Ahí, Saccheri (2014) indica que la solución al problema del V Postulado sería "simple" y que "imitaría a los geómetras antiguos". Como estrategia para sustentar la verdad del V Postulado, él se propone demostrarlo sin incurrir en una petición de principio.

De acuerdo a todo lo antes dicho ¿Cómo se puede explicar que Saccheri 'redujera' la problemática del V Postulado a **demostrar** su veracidad? Como se vio, en su prefacio él partió de un eec de **incontrovertible** asociado a la obra euclidiana. Una consecuencia de ese eec fue *magnificar las cualidades* positivas de esa obra y *minimizar sus imperfecciones* o los posibles escollos. De forma congruente con esas atribuciones y, hay que decirlo, con la propia carga de veracidad empírica que tenía el V postulado, Saccheri sostuvo su verdad y solo cuestionó la estrategia en la que se basaba ese valor de verdad. En línea con esto, él se planteó *expectativas* de que la solución al problema sería "simple" y bastaría con "imitar" a los geómetras antiguos. Lo anterior orientó el trabajo matemático de Saccheri, cuando planteó como solución al problema desprender la verdad del V por medio de la estrategia de "demostrar" (sin petición de principio). Además, esa resolución respeta *compromisos* adquiridos por Saccheri, como seguir la lógica rigurosa. A ese conjunto de valores, expectativas, compromisos de todo tipo, planes, creencias e intenciones que se coligan con los eec aquí se llama *marco interpretativo de los eec (MI)*.

Para explicar por qué Saccheri 'minimizó' la problemática del V Postulado, a continuación se analiza cómo él manejó ese MI. En primer lugar, Saccheri acompañó dicho MI de una magnificación de las cualidades positivas que él atribuyo a *Los Elementos* (con palabras como "grande"), de una minimización de sus imperfecciones (con palabras como "lunar") y de una simplificación de la solución a esas imperfecciones (con "simplemente me comprometo"). A esa forma de manejar el MI se le puede llamar *exageración.* En segundo lugar, la solución de "demostrar" que Saccheri se planteó para resolver el problema del V Postulado, es totalmente congruente con el MI. Pareciera que el MI se consideró como "reglas que deberían seguirse". Bajo esas reglas, otras opciones para resolver el problema quedarían descartadas. Quedaría descartada, por ejemplo, la opción de cuestionar al V Postulado como la única posibilidad, porque iría en contra de la consigna de "imitar a los geómetras antiguos". Así, el MI actuó como un *sesgo* que orientó la estrategia de Saccheri. De acuerdo a lo antes dicho, manejar el MI con exageraciones y sesgos puede explicar por qué el matemático trivializó el problema del V Postulado. ¿Y por qué Saccheri consideró a ese MI como "reglas que deberían seguirse"? Saccheri afirma que el eec de incontrovertible en *los Elementos* lo sostuvieron prolongadamente muchos matemáticos. Así, cuestionar aquello que se desprendía de ese eec implicaría cuestionar siglos de tradición y a grandes autoridades, y parece que ni Saccheri ni ningún matemático de su época estaban dispuestos a enfrentar eso. De modo que, el *consenso social* también puede explicar por qué Saccheri parece haber 'atenuado' el problema del V Postulado.

Consideraciones finales

Se está ahora en condiciones de responder a la pregunta de investigación ¿por qué la confianza en afirmaciones matemáticas puede influir negativamente en el avance de la disciplina? Aquí se argumenta que los eec tienen efectos sobre las decisiones y los trabajos matemáticos. Específicamente, aquí se han aportado evidencias de que los eec pueden dar lugar a la atribución de cualidades a obras y problemas matemáticos, a expectativas sobre cómo resolver esos problemas, a compromisos lógicos, ontológicos y epistemológicos, y en suma, a un MI. A partir de ese MI, la persona puede orientar sus decisiones matemáticas y su trabajo disciplinar como, por ejemplo, plantear una estrategia para resolver un problema matemático. Es necesario aclarar que los eec no son, en esencia, favorables o desfavorables para el avance del conocimiento matemático. Lo que muestra el estudio es que, bajo ciertas condiciones, pueden resultar perjudiciales. Algunas de esas condiciones tienen que ver con cómo una persona maneja el MI, en particular si lo acompaña con exageraciones, sesgos y tomando el consenso social de manera acrítica.

A group of preservice mathematics teachers participated in a course on history and technology in mathematics which includes a study of the historical development of mathematical concepts. This study examined the effect of the course on their critique of teaching materials using history. Results show that the participants developed more insightful critiques of teaching materials that integrated history poorly into the development of mathematical concepts.

Keywords: Teacher Education - preservice, Teacher Beliefs, Middle School Education

Introduction

Using the history of mathematics as a way of learning mathematics itself is a well-established part of many mathematics curricula and teacher preparation programs. There are many arguments supporting the place of history of mathematics from enhancing learners' cultural sophistication to helping learner's understanding of concepts. The purpose of this study is to examine changes in pre-service teachers' analysis of mathematics lessons purporting to integrate history into teaching mathematics after they engage in a semester-long course focussed on deploying history as a driver of development of mathematical concepts.

Literature review and relationship to research

The use of history as a lever for teaching mathematics in middle and high school is often relegated to the realm of footnotes and passing mentions of historical facts in textbooks adding historical context to some content (Smestad. Jankvist & Clark, 2014) or use of biography, sometimes in the form of student projects on individual figures, to add historical and/or cultural context to the study of mathematics (see e.g. Tzanakis et al., 2002). Jankvist (2009) referred to this kind of approach as using history as "a motivating factor for students in their learning and study of mathematics" (p. 237) but argued that history can also be used to "support the actual learning of mathematics" (p. 238). Indeed, Siu and Tzanakis (2004) argued for thinking in terms of "integrating history of mathematics" rather than "using history of mathematics."

In the realm of teacher preparation programs Furinghetti's (2007) analysis of the literature identified the following approaches to history of mathematics in teacher preparation programs: (i) "delivering a course in the history of mathematics with the aim of giving a historical background to teachers' mathematics knowledge" (p. 132); (ii) "packages of historical materials focused on mathematical concepts difficult to teach were used to deepen teachers' pedagogical reflection on these concepts" (p. 132); and (iii) attention to the link between history and mathematics teachers' beliefs and attitudes about mathematics. The first of these aligns closely with the use of history noted by Smestad et al. (2014) and Tzanakis et al. (2002). Furinghetti herself adopts a different approach in her program: to use the history of mathematics "as a mediator of knowledge for teaching. The aim was to make the participants reflect on the meaning of mathematical objects through experiencing historical moments of their construction." (p. 133)

The goal of the course in which this study takes place, aligning with Furinghetti, was to provide students with examples of the historical necessity for the development of select concepts on mathematics so that participants would gain a deeper understanding of those topics. The goal of this study is to examine the effect of participating in that course on pre-service mathematics teachers' critique of teaching materials deploying the history of mathematics.

Methods and Methodologies

Setting and Participants

Participants (n = 20) in the study were prospective middle school teachers in a course on history and technology in mathematics which includes a study of the historical development of mathematical concepts. The central assignment for the course was for students to produce a classroom-ready lesson that infuses mathematics history and technology into instruction.

Data Collections Methods

In order to assess the trajectory of the participants' growth in infusing history into lessons in a meaningful way, they were asked to analyze/critique sample teaching materials that were designed to be poor examples of using history of mathematics for concept development.

The first lesson (Open University, 1988) involved students exploring the Fibonacci sequence. They are told at the end that "the sequence discovered by Leonardo of Pisa in 1202 in connection with the breeding of rabbits!" This was intended as a poor example of infusing history into mathematics lessons in a meaningful way in that there are simply a few historical notes added to the lesson and the history is not integral to the development of the concept.

In the second lesson (Penn Museum, n.d.) students are shown pictures of several famous domes and given the vocabulary apex, oculus, diameter, radius, circumference, and area. Students are then given the formulae for calculating diameter, radius, circumference, and area and, given one or two of those values asked to find the others. This was also intended as a poor example of infusing history into mathematics lessons in a meaningful way in the sense of there being a very low cognitive demand with students simply required to plug numbers into formulae with no emphasis on how concepts were developed historically.

Students were asked to respond to the following prompt: "Comment on the quality of these teaching materials in terms of their capacity to engage middle grades students in the history of mathematics. Identify several strengths and several weaknesses of each resource." In addition, participants submitted a brief biography of their experiences with the use of history in teaching mathematics from their own school and college classes.

During the semester participants worked through a series of activities in which the historical necessity of a mathematics concept is demonstrated i.e. exemplar lessons in which history is integrated into mathematics content. These included John Graunt's development of data analysis and the introduction of Rene Descartes coordinate system. In addition, the students worked on developing their own teaching materials that integrate history in mathematics teaching.

At the end of the semester the participants were asked to reread their original critique/analysis of the "bad" lesson plans and respond to the following prompt: "Describe your reaction to your earlier writing. Specifically: How has that reaction been informed by your experiences of the course? Be specific about how the experiences in the course have either reinforced your opinions about the sample lessons or changed your opinion about the sample lessons."

Data Analysis

The participants' original critiques were analysed using the constant comparative method (Glaser & Strauss, 1967) to establish trends in the data and to develop a code book. The code book was then applied to the critiques at the end of the semester with a focus on any changes asserted and the reasons for those changes. In addition, data analysis focused on whether students spoke about a motivation approach or a concept development approach to using history.

Results

Initial analyses/critiques

Of the 20 participants 19 said they would use the domes worksheet (with three saying they would need to add to the worksheet). In contrast, 13 out of 20 said they would use the Fibonacci worksheet with 7 of the 13 saying they would need to add to/modify the worksheet.

The codes associated with the positive aspects noted by the participants were: Integrating history & mathematics (INT), relating to "Real Life" (RL), engaging visual learners (VIS), and crossing disciplines beyond history & mathematics (CD)

Domes worksheet The historical context of the Domes was assessed positively by 13 of the 20 participants for relating the mathematics to "Real Life" (RL). For example, Participant 5 (P5) said "My favorite part of the math domes worksheet is its link to the past through real life examples." P7's view was that the lesson was positive "making the historical knowledge relevant to the student by describing Domes that exist with these measurements all across the world."

The Domes lesson was assessed by 7 participants as being a positive example of integrating mathematics and history (INT) e.g. "I feel like I am walking in a mathematics museum, each page helps me have the connection between the mathematics history" (P6) and "I thought it succeeded in giving a balanced math-history knowledge to the student" (P7).

Other notable positives in the participants critiques were the use of visuals (VIS), mentioned by 6 participants and crossing disciplines (CD) beyond history and mathematics mentioned by 3 participants. It is noteworthy that the positive aspects reported by the participants were always consonant with Jankvist's (2009) category of using history as motivation.

Fibonacci worksheet The Fibonacci worksheet was assessed less positively by the participants. Only one participant assessed the Fibonacci lesson positively for relating to "real life." (RL): "Also, the lesson outline offered great background on Fibonacci, allowing the students to see a real-life relationship and reason for creating such an idea" (P10).

There was an interesting dichotomy in responses coded with INT+/- (Integrating history & mathematics). Several students remarked that the history portion of this lesson was a little "tacked on." For example, "There was only a small short paragraph on the mathematician who created the "Golden Sequence" . . . which in my opinion added no value to the material." (P14) and "The worksheet focused a lot on the mathematics part and less on the history." (P15). However, several participants viewed the lesson positively on the INT code. For example, "It also makes a good connection between the history of the math and the math itself" (P20) and "It allows students to understand how the history relates to the topic that they are learning." (P11)

Use of history to develop mathematical concepts The critiques were also coded, owing to the focus of the activities in the course, for attention to using history to develop mathematical concepts, either providing evidence from the lessons or noting its absence (DEV+/-).

In coding the participants' initial critiques the code DEV was used 6 times. 5 of those were positive assessments of the Fibonacci lesson as using history as a tool for developing concepts. Examples of the positive assessments were "It gave relevance to why the Fibonacci sequence was created by mentioning it was done in connection to rabbits" (P10) and "Understanding . . . where a math equation or concept comes from can be great for student learning. History gives a better understanding when students wonder how a concept was discovered." (P15)

In summary, the participants were positively disposed towards the "bad" lessons. They mostly said they would use the lessons albeit with some modifications. In addition, they tended to note connections to real life as the main positive factor for using history in teaching mathematics.

End of semester analyses/critiques

At the end of the semester the participants were asked to read their critiques of the lesson plans from the beginning of the semester and to react to what they wrote at that time. Analysis of the responses focussed on whether they had changed their mind about the quality of the lessons and what values the participants espoused regarding the use of history in mathematics teaching.

Overall, the participants were better able to recognise the deficiencies of the sample lessons after the course although they mostly continued to say that they would use the materials in their own classrooms. Changes to the participants' thinking were mostly centred on the idea that the use of history, particularly in the Fibonacci lesson, was an add-on and did not contribute to the development of mathematical concepts (DEV). In contrast to the initial critiques where 5 of the 6 uses of the DEV code were positive attributions to the Fibonacci lesson, all 8 uses of the DEV code in the final critiques were negative. For example, one participant noted "the history of the Fibonacci Sequence . . .was added on at the very end . . . This is more of a short "fact," rather than integrated math." (P8) and another noted that "it adds very little to the lesson and would be easy for a teacher to skip over." (P4).

The participants continued to consider relating to "real life" (RL) as an important aspect of mathematics lessons involving the history of mathematics. For example, Participant 5 argued that "students should be able to find domes in their community and complete the new math concept with things in the world around them." Thinking about the class in general as well as the sample lessons one participant remarked "This class helped show me how important it is for math to have real world applications and connect with history." (P2)

One final theme that emerged in the post analysis was the idea of history "humanising" mathematics i.e. making the idea that actual people were involved in the making of mathematics clear. Participant 4 noted that "teaching math history also helps students to see that normal people like them can make big discoveries that change the world" (P4) and Participant 8 noted that "I learned so much about mathematicians. I think this is important to have in our class because students can learn where the math they are learning comes from." (P8). The participants' interest in this was presented more in the sense of motivation for learning rather than for the development of mathematical concepts.

In summary, the participants, while continuing to see positive aspects of the lessons were much more sensitive to the deficiencies of the lessons in terms of the use of history for the development of mathematical concepts.

Conclusion

The use of history in teaching mathematics is commonplace in the preservice teacher mathematics programs. Preservice teachers' prior experiences, and often their experiences in programs, with history tend towards a focus on biography and the use of history as a provider of context and motivation. This study shows the potential for preservice mathematics teachers to begin to view the use of history as a lever in the development of mathematical concepts. This is an important idea for use of history in pre-service mathematics preparation programs. Through participation in a course with exemplars of such mathematical development, the preservice teachers made more insightful critiques of teaching materials that were deficient in this aspect. They continued to consider connections to real life and to mathematicians as an important positive aspect of mathematics lessons using history for its potential to motivate students.

PRESERVICE TEACHERS' PERCEPTIONS OF A LESSON STUDY CONNECTING MULTICULTURAL LITERATURE WITH CULTURALLY RESPONSIVE MATHEMATICS TEACHING

Alesia Mickle Moldavan
Fordham University
amoldavan@fordham.edu

This study examines preservice teachers' perceptions about a microteaching lesson study (MLS) that integrated multicultural literature to elicit culturally responsive mathematics teaching (CRMT) during a mathematics methods course. Participation in the MLS' iterative cycle of plan-teach-revise encouraged preservice teachers to develop their pedagogical knowledge, make cultural connections from texts to mathematical concepts, and engage in productive reflection. The MLS also provided preservice teachers with a supportive peer learning community that fostered collaborative learning to improve professional practice around CRMT. Suggestions are shared for how similar practice-based experiences can be used to enhance teacher education with focused practice addressing mathematical thinking, language, culture, and social justice.

Keywords: Teacher Education-Preservice, Instructional Activities and Practices, Teacher Knowledge, Culturally Relevant Pedagogy

Mathematics teachers committed to humanizing pedagogy recognize schools as cultural spaces that draw on students' identities and experiences to leverage mathematical competencies (Yeh & Otis, 2019). When students explore mathematics from global perspectives (e.g., non-Western, indigenous) and applications, they can engage in enriched, meaningful learning that promotes empathy for diverse cultures and fosters problem-solving that transcends borders. One way for students to develop cultural awareness is through reading multicultural literature, which can serve as a mirror to reflect on one's own culture and a window to gain perspective into other's values, beliefs, and traditions. While multicultural literature naturally fits in literacy studies, it can also be used to study mathematics in culturally relevant contexts (Chappell & Thompson, 2000; Leonard, Moore, & Brooks, 2014). Those who wish to bridge multicultural literature into the mathematics classroom must recognize mathematics as a cultural construct and have the opportunity to plan, teach, and reflect on lessons with such texts (Iliev & D'Angelo, 2014; Sletter, 1997). This study reports on preservice teachers in a mathematics methods course who participated in a microteaching lesson study that integrated multicultural literature to make social justice and cultural connections to elementary school mathematics content. The following research question served as motivation for this study: What are preservice teachers' perceptions about a microteaching lesson study using multicultural literature to elicit culturally responsive mathematics teaching during a mathematics methods course?

Theoretical Framework

Reform efforts in teacher education recommend preservice teachers have opportunities to teach mathematics through practice-based experiences that develop pedagogical knowledge and encourage reflective practice (AMTE, 2017). A microteaching lesson study is an example of a practice-based experience that utilizes a simulated teaching environment to reduce teaching complexities, develop pedagogical content knowledge, and elicit reflection from peer and self-assessment. Preservice teachers engaged in a microteaching lesson study benefit from collaborative participation in the iterative cycle of plan-teach-revise in a modified format (see Figure 1) that promotes connections between theory and practice in mathematics education (Fernández, 2005). This study builds on the

research of microteaching lesson studies and examines how preservice teachers can develop consciousness of culturally responsive mathematics teaching (CRMT) with multicultural literature.

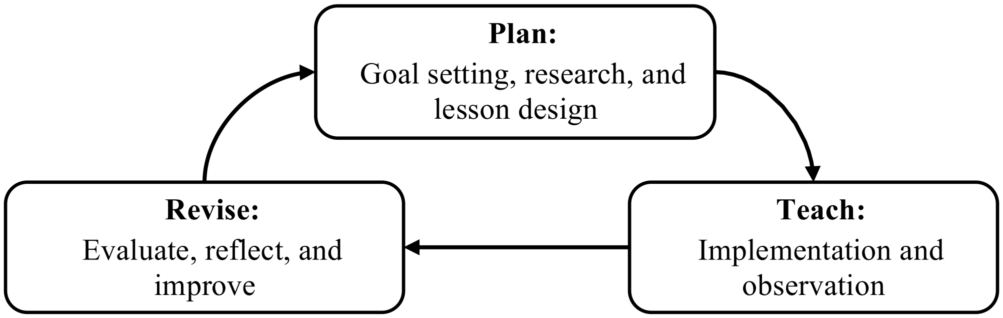

Figure 1: Lesson Study Model of the Iterative Cycle of Plan-Teach-Revise

CRMT can be used to privilege students' cultural and linguistic funds of knowledge, foster meaningful connections to students' prior experiences, and value students' strengths and performance styles to make learning relevant and effective (Gay, 2009). This research used the framework for CRMT coupled with Aguirre and Zavala's (2013) CRMT Lesson Analysis Tool to examine explicit characteristics of CRMT: mathematical thinking, language, culture, and social justice. Framing the inquiry in terms of CRMT aided with organizing the synthesis and examining where efforts were made by preservice teachers to use multicultural literature to elicit CRMT in a simulated teaching environment.

Research Methods

A qualitative case study design was used with multiple data sources. Participants included 16 preservice teachers (14 females and 2 males) enrolled in an elementary mathematics methods course at an urban university in the northeastern United States. In the course, the preservice teachers were introduced to CRMT as the notion of contextualizing mathematics teaching and learning to students' lives (Gay, 2002; Ladson-Billings, 1995a, 1995b). After the preservice teachers familiarized themselves with CRMT with the aid of course readings and a discussion-based review of a sample lesson that was critiqued using Aguirre and Zavala's (2013) CRMT Lesson Analysis Tool, the preservice teachers were assigned a microteaching lesson study that required them to plan, teach, and revise an elementary mathematics lesson with reference to a multicultural text of their choosing.

To help guide the text selection and the design of the activity, the preservice teachers reflected on the ways the text and the lesson: (a) portrayed cultural authenticity, (b) depicted cultural diversity as an asset, and (c) promoted culturally relevant mathematical connections (Harding, Hbaci, Loyd, & Hamilton, 2017). Next, the lessons were critiqued for components of mathematical thinking, language, culture, and social justice as noted in the CRMT Lesson Analysis Tool. Each group was asked to submit their analysis and make any necessary modifications to strengthen the lesson prior to beginning the next phase of the practice-based experience.

After submitting their lessons and planning reflections, the preservice teachers were videotaped teaching their lessons twice to their peers. In round one, two group members taught the lesson while their other two group members and peers observed. Next, the group members reflected on their instruction and revised their lesson. In round two, the group members switched roles, reflected on their instruction, and submitted their final revised lesson. Peers gave constructive feedback throughout the rounds and assessed how the overall experience influenced their perspective of CRMT and their future use of multicultural literature in elementary mathematics instruction. The lessons, videos, reflections, and peer feedback were coded for themes of CRMT using in vivo and descriptive coding techniques (Saldaña, 2016).

Results

Findings revealed that the preservice teachers' perceptions of participating in the microteaching lesson study's iterative cycle of plan-teach-revise encouraged them to develop their pedagogical knowledge, make cultural connections from texts to mathematical concepts, and engage in productive reflection. Overall, the preservice teachers expressed positive experiences engaging in the microteaching lesson study and shared that this particular focus on lesson design with multicultural literature helped them to engage and be reflective in CRMT. They also shared how the practice-based experience provided them with a supportive peer learning community that fostered collaborative learning to improve their professional practice around ways to make social justice and cultural connections to mathematical concepts.

Through strategic lesson design with multicultural literature, the preservice teachers were successfully able to engage their peers in mathematical thinking of various concepts (e.g., measurement, counting, addition, geometry) through the elicitation of meaningful mathematics discussions related to cultural connections. Several preservice teachers used the stories found in the texts to set a context for learning a mathematical concept. For example, one group selected a text about a girl named Sadako and her paper cranes. The story provided a context for students to explore adding paper cranes using various addition strategies (e.g., counting all/on, making tens, friendly numbers, compensation, adding up in chunks). Another group referenced a book about quilt making and created a lesson about how the arrangement of patches on a quilt could generate different dimensions (e.g., 1 x 24, 2 x 12, 3 x 8, 4 x 6). The lesson addressed various mathematical concepts (e.g., rectangular arrays, factors, area, perimeter) and provided opportunities for participants to create their own quilt patch that honors their cultural heritage to add to the classroom quilt. Through the lessons, the preservice teachers were able to elicit ways for participants to self-identify with the mathematics and see themselves as doers of mathematics. A preservice teacher summarizes this nicely in her statement: "In this experience, I was given the opportunity to think outside the box when it came to thinking of different ideas that would interest my students where they would have some ownership over the activity and feel included."

The practice of using multicultural literature to facilitate cultural connections also influenced the preservice teachers' awareness of and confidence in using cultural practices to address issues of social justice and exercise mathematics as an analytical tool to critique societal norms. For example, a preservice teacher shared, "I plan to use multicultural literature in my classroom to help students identify cultural assets and challenge/remove potential barriers." Additionally, several preservice teachers reflected on how they plan to use such texts to advocate for exploring new mathematical concepts (e.g., numerical representations, computations) that may not be present in the dominant mathematics studied. This is evident in a preservice teacher's reflection that said: "I have newfound confidence to incorporate other texts than what may appear in the curriculum to provide alternative perspectives and purposefully incorporate students' native languages in the teaching of mathematical concepts."

The preservice teachers also reflected on their own professional growth to enhance their pedagogical practice given the collaborative nature of the microteaching lesson study. Several preservice teachers noted the amount of effort that goes into planning meaningful lessons. For example, a preservice teacher said: "I now realize that a lot of planning and preparation is required to really give students the best possible mathematics lessons. I now have new tools to help me prepare the best lessons I can for my students." Other preservice teachers reflected on their newfound realization about culture in the classroom. For instance, a preservice teacher said: "Not only did this experience teach me how to create a lesson plan and be aware of the academic needs of my students (or peers), but it also taught me how to be aware of their backgrounds and how culture plays a huge role in all subjects." Similarly, another preservice teacher commented on how her appreciation has grown for using literature to shed light on how people engage with mathematics outside of the mainstream, Westernized perspective. She stated: "By incorporating multicultural literature, mathematics can become relatable and mathematics can create bridges that connect cultures and people. I now realize how much it can elevate a lesson." A comparable statement made by another preservice teacher noted: "Previously, I had not considered how to integrate multicultural content into mathematics instruction. Yet, incorporating multicultural mathematics literature into instruction can foster greater acknowledgement and appreciation of students' cultural identities, which facilitates better learning environments in our classrooms and schools."

Discussion

The significance of this work is to build on the research of microteaching lesson studies and examine how preservice teachers' perceptions engaging in such a practice-based experience provides insight into how preservice teachers develop pedagogical knowledge and benefit from reflective practice. This study was unique in that the microteaching lesson study connected multicultural literacy with CRMT. Participation in this experience benefited the preservice teachers in that they were able to collaborate with one another and use constructive peer feedback to guide improvements in the planning, implementation, and reflection of their lessons. The preservice teachers were tasked with creating a learning environment that empowered students to see and engage with mathematics across cultures. Multicultural literature can serve as a conversation starter to introduce new mathematical ideas and widen students' horizons. The findings from this work signify that efforts must be made in teacher preparation to implement innovative practices (e.g., microteaching lesson studies, multicultural literature) that elicit CRMT to improve the quality of mathematics instruction for all students.

CONCEPTUAL SYSTEMS WHEN IMPLEMENTING MODEL-ELICITING ACTIVITIES

SISTEMAS CONCEPTUALES AL IMPLEMENTAR ACTIVIDADES PROVOCADORAS DE MODELOS

In this article we analyze the results of a study focused on promoting the development of conceptual systems of teachers, associated with the teaching and learning of the exponential function when implementing Model-Eliciting Activities [MEA] in the classroom. For the theoretical framework we used the models and modeling perspective [MMP]. The methodology was qualitative, and a multilevel approach (researcher, teacher, and students) was used. The results show how the conceptual system of a teacher was modified, extended, and refined. First, the teacher focused on the instructional dimension, then he expanded, and refined to include the mathematical and historical content dimensions.

Keywords: Preparation of teachers in training, Mathematical Knowledge for Teaching, Modeling, Pre-calculation.

There is a need to carry out research related to the professional development of mathematics teachers (Doerr, 2004; Kieran, 2007; Jung, 2013; Sevinc & Lesh, 2018). According to Clark and Lesh (2003), Doerr and Lesh (2003), Sevinc and Lesh (2018) the MMP allows the description of the teachers' conceptual system related to the teaching and learning of mathematics and how this system evolves. The research question discussed in this article is: How does the teachers' conceptual system –related to the process of teaching and learning of the exponential function– evolve as they design, implement and evaluate MEAs?

Theoretical Framework

The Models and Modeling Perspective mentions that learning is a process of developing conceptual systems, which continually change, modify, extend, and refine during the student's interactions with their environment (teachers and peers) and when solving problems (Lesh, 2010). The theoretical framework used in this document is the MMP (Doerr, 2016; Lesh, 2010; Lesh & Doerr, 2003), which suggests the use of multi-level methodologies to support the development of teacher training programs. The MMP makes it possible to provide a context for students to develop models when carrying out the MEAs; at the same time, teachers are immersed in environments where the development of models is encouraged by interpreting, explaining, and predicting student behavior when modelling MEAs (Sevinc & Lesh, 2018). The interaction among students, teachers, and researchers is considered important to promote the development of knowledge, and to understand the evolution of teachers' knowledge based on the interpretation they make about how individuals reveal, test, refine, and review their knowledge and skills (Clark & Lesh, 2003). In other words, the teacher influences the construction of knowledge by students and vice versa. Something similar occurs with researchers; they influence teachers and, at the same time, are affected by them.

Doerr and Lesh (2003) propose to design didactic sequences (model development sequences) to support the development of conceptual systems. Sequences include Model Eliciting Activities [MEA], Model Exploration Activities [MXA], and Model Adaptation Activities [MAA] to promote the student to manipulate, share, modify, and reuse models to build, describe, explain, manipulate, predict or control mathematically significant systems (Lesh, Cramer, Doerr, Post, & Zawojewski, 2003). Helping teachers understand the MMP and how to use it to promote mathematics learning is an interesting and complex task.

Clark and Lesh (2003) point out that knowing the nature of teacher understanding involves understanding at least three dimensions such as: "psychological connections, instructional connections, and historical connections" (p. 159). That is, how ideas develop in the minds of children and adults, how the development of ideas can be supported by the use of available curriculum materials, and the circumstances under which students develop an idea in a historical way. Therefore, the description of the teacher's conceptual system can be done through the use of dimensions such as: the teacher's mathematical knowledge dimension [DM], the instructional dimension [DI] and the historical dimension of the students' development of knowledge [DH] (Clark & Lesh, 2003). These dimensions are used to describe the teacher's conceptual system about teaching and learning of the exponential function and its evolution, or modification, extension and refinement during the process of designing, implementing, and evaluating a didactic sequence based on the MMP.

Methodology

The methodology was qualitative. The "teacher training under the models and modeling perspective" scheme was developed over 18 months, under a multilevel perspective (researcher, teacher and students) (Doerr & Lesh, 2003). The participants in this study were two teachers, but the process will only be exemplified with one of them. The data sources were: activities designed by the teacher, students' documents, audios of the interactions –student-student, teacher-student, researcher-teacher– and the students' interpretations of the created models when carrying out activities. Three stages are described, each characterized by: design, implementation and evaluation of a didactic sequence (MEA-MXA-MAA). The evolution of the teachers' conceptual system related to the teaching and learning of the exponential function is interpreted through the dimensions observed by Clark and Lesh (2003): a) DI, b) DM, and c) DH.

Results and Discussion

First stage (MEA Design-Implementation-Evaluation Cycle)

i) MEA design (researcher-teacher). The researcher encouraged the teacher to reflect on the following dimensions. a) DM: analysis of the concept of exponential function; b) DI: revision of textbooks, bibliography of the MMP, and use of technology. The teacher built an MEA in the population growth context. The underlying knowledge was the exponential function. Previously, the teacher participated as an observer in the implementation of an MEA.

ii) First implementation (teacher-students). Five students participated, which were grouped into two teams. a) DM: One of the teams included tabular, graphic, and verbal representations in their models. The other team included only tabular and verbal representations. The teacher and the students, during the group discussion, wrote the algebraic function $P(t) = P_i(1 + r)^t$ associated with the situation. b) DI: The design and implementation of the MEA enabled students to use calculators and spreadsheets to solve the problem situation. c) DH: The teacher focused on the students' interest generated by the activity and on the final representations they presented. He did not observe the process of building the model.

iii) Evaluation of the first implementation (researcher-teacher). The interaction between the teacher and the researcher allowed the interpretation and analysis of how the concept of exponential function was constructed, modified, extended and refined (DM) by the students, when carrying out the MEA (DH). Based on the review of audios, the letters of the students, and the six design principles of the MEAs, the teacher analyzed the activity (Vargas-Alejo & Montero-Moguel, 2019). The support that the researcher provided to the teacher was essential to modify the MEA before the next implementation, as well as the role of the teacher in the classroom (DI).

Second stage (Design-Implementation-Evaluation Cycle of MEA-MXA)

i) Design of MEA and MXA (researcher-teacher). The teacher's conceptual system evolved in the three dimensions. a) DM: The teacher proposed that students should perform an MXA to deepen the mathematical concepts of variation, covariation, base, exponent, ordered to the origin, growth rate, graph translation, increasing and decreasing function that emerged when carrying out the MEA. b) DI: The researcher proposed to include NetLogo –multi-agent programmable modeling environment– in the MXA. The teacher, supported by an expert researcher, modified one of the activities of the software library; he also included a GeoGebra applet in the sequence. c) DH: The modifications made by the teacher were based on the analysis of how the students created, modified, and expanded their conceptual system in the first implementation.

ii) Second implementation (teacher-students). Ten students were grouped into four teams a) DM: the four teams included tabular, graphical, algebraic and verbal representations in the models. The teacher validated all the representations, but observed that some teams did not differentiate constant growth from exponential growth, therefore, during the group discussion, he intervened through questions to clarify the difference. b) DI: The activity with NetLogo and the GeoGebra applet allowed the students to dive deeper into the concepts associated with the exponential function. c) DH: The teacher extended his interpretation and explained, in a more detailed way, the process of model construction by the students.

iii) Interaction of the researcher and the teacher after the second implementation (Researcher-Teacher). The teacher described how the students went through different cycles when they carried out the MEA. Then, he pointed out how in each cycle the students expanded and refined their knowledge of the linear function and, later, the exponential function. Finally, he mentioned how the MXA made it possible to go deeper into the mathematical concepts immersed in the models, even when it was necessary to institutionalize them (DM and DH). Based on the review of "the MEA quality assessment guide" (Lesh, 2010, p. 32) the teacher analyzed the audios and letters of the students. He characterized the models constructed by the students, with or without technology (DI) and distinguished between models that require direction, models that require extension or refinement, situated models, and comparable and reusable models.

Third stage (Design-Implementation-Evaluation Cycle of MEA-MXA-MAA)

i) Design of MAA (researcher-teacher). a) DM: The teacher, supported by the researcher, designed the MAA in the context of energy saving and investments where the concepts of linear function and exponential function are underlying. He gave meaning to the design of a model development sequence composed of MEA, MXA and MAA, to promote the development of the exponential function concept. b) DI: He designed the sequence based on Lesh et al. (2003). c) DH: The teacher enabled the transition through different modeling cycles, and encouraged students to review, deepen and expand their mathematical knowledge related to the exponential function.

ii) Third implementation (teacher-students). Ten students participated and were divided into four teams a) DM: All students construct models that include: the linear function to describe the savings situation, the exponential function to analyze investments, and a diversity of verbal, tabular, graphical and algebraic representations. b) DI: The models created to solve the problem situation included in the MAA were based on the knowledge developed using NetLogo and GeoGebra (MXA). c) DH: The teacher explained how the knowledge about the exponential function learned by the students when carrying out the MEA allowed them to carry out the MAA. The models were characterized as shareable and reusable.

iii) Interaction of the researcher and the teacher after the third implementation (researcher-teacher). The teacher described the different modeling cycles developed by the students when solving the model development sequence and analyzed how they evolved during the realization of the MEA, MXA and MAA (DH). He used the levels of covariation (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002) and "the MEA quality assessment guide" (Lesh, 2010, p. 32) to generate a classification of the models built, in terms of the use of linear and exponential relationships (DM); the understanding of the exponential function and differentiation of the linear function; as well as the use given to the functions to interpret and predict the situation.

Conclusions

How does the teachers' conceptual system –related to the process of teaching and learning of the exponential function– evolve as they design, implement and evaluate MEAs? The evolution of the conceptual system was as follows: the emphasis was placed first on DI, then on DM, and finally, the three dimensions, DI, DM and DH, became relevant. In the first stage, the teacher focused on the description of representations created with and without the support of technology. He described whether or not the students proposed the exponential function in its algebraic form. He emphasized the final product and not the process of construction of the exponential function concept, which he did in the second stage. In the third stage, the teacher was able to describe how the students developed mathematical ideas, modified them, adapted them and refined them throughout the process of carrying out the sequence. This allowed him to realize that in the process of learning the exponential function, students can first use the linear function by assuming a constant variation and then build knowledge about the exponential function.

The MXA allowed the students to go deeper into concepts. This was observed when they carried out the MAA, as students were able to use the concepts of exponential and linear function to solve a different activity, in a different context. They learned to differentiate and use both functions to describe the MAA. The multilevel interaction between students, teacher and researcher, during each phase of the different stages was fundamental for the evolution of the conceptual system of the teacher related to the process of teaching and learning of the exponential function. Although it is true that there is no linearity in the development of conceptual systems, this study identified that the design, implementation and analysis of each activity contributed to the modification, expansion and refinement of the teacher's conceptual system.

SISTEMAS CONCEPTUALES AL IMPLEMENTAR ACTIVIDADES PROVOCADORAS DE MODELOS

CONCEPTUAL SYSTEMS WHEN IMPLEMENTING MODEL-ELICITING ACTIVITIES

En este artículo se analizan resultados de una investigación centrada en promover el desarrollo de sistemas conceptuales de los profesores, asociados a la enseñanza y aprendizaje de la función exponencial al implementar Actividades Provocadoras de Modelos (MEAs por sus siglas en inglés: Model-Eliciting Activities) en el aula. El marco teórico fue la perspectiva de modelos y modelación [PMM]. La metodología fue cualitativa, se usó un enfoque multinivel (investigador, profesor y estudiantes). A partir de los resultados, se observó cómo el sistema conceptual se modificó, amplió y refinó. Primero se centró en la dimensión instruccional, enseguida se amplió y refinó para incluir la dimensión de contenido matemático y dimensión histórica.

Palabras Clave: Preparación de maestros en formación, Conocimiento Matemático para la Enseñanza, Modelación, Pre-cálculo.

Existe necesidad por realizar investigaciones relacionadas con el desarrollo profesional de los docentes de matemáticas (Doerr, 2004; Kieran, 2007; Jung, 2013; Sevinc & Lesh, 2018). De acuerdo con Clark y Lesh (2003), Doerr y Lesh (2003), Sevinc y Lesh (2018) la PMM permite describir el sistema conceptual de los profesores sobre la enseñanza y aprendizaje de las matemáticas y cómo este sistema evoluciona. La pregunta de investigación que se discute en este artículo es: ¿Cómo evoluciona el sistema conceptual de los docentes sobre la enseñanza y aprendizaje de la función exponencial al diseñar, implementar y evaluar MEAs?

Marco Teórico

En la PMM se menciona que aprender matemáticas es un proceso de desarrollo de sistemas conceptuales, que cambian de manera continua, se modifican, extienden o amplían y refinan a partir de las interacciones del estudiante con su entorno (los profesores y compañeros) y al resolver problemas (Lesh, 2010). El marco teórico utilizado en este documento es la PMM (Doerr, 2016; Lesh, 2010; Lesh & Doerr, 2003), la cual sugiere el uso de metodologías multinivel para apoyar el desarrollo de programas de formación docente. Este enfoque posibilita proveer un contexto para que los estudiantes desarrollen modelos al resolver MEAs; de manera simultánea, los profesores se ven inmersos en ambientes donde se propicia el desarrollo de modelos al interpretar, explicar y predecir el comportamiento de los estudiantes al modelar las MEAs (Sevinc & Lesh, 2018). Se considera importante la interacción entre estudiantes, profesores e investigadores para propiciar el desarrollo de conocimiento, además permite entender la evolución del conocimiento de los profesores a partir de la interpretación que hacen acerca de cómo los individuos revelan, prueban, refinan y revisan sus conocimientos y habilidades (Clark & Lesh, 2003). Es decir, el profesor influye en la construcción de conocimiento por los estudiantes y viceversa. Lo mismo ocurre con los investigadores, quienes influyen en los docentes y se ven afectados por los mismos.

Doerr y Lesh (2003) proponen la estructuración de secuencias didácticas para apoyar el desarrollo de sistemas conceptuales. Las secuencias incluyen Actividades Provocadoras de Modelos [MEA], Actividades de Exploración de Modelos [MXA] y Actividades de Adaptación de Modelos [MAA] para promover que el alumno manipule, comparta, modifique y reutilice modelos, para construir, describir, explicar, manipular, predecir o controlar sistemas matemáticamente significativos (Lesh, Cramer, Doerr, Post, & Zawojewski, 2003). Apoyar que los profesores comprendan la PMM y la utilicen para propiciar el aprendizaje de las matemáticas es una tarea interesante y compleja.

Clark y Lesh (2003) señalan que conocer la naturaleza de la comprensión del profesor implica entender al menos ciertas dimensiones, como: “conexiones psicológicas, instruccionales e históricas” (p. 159); es decir, cómo se desarrollan las ideas en la mente de los niños y adultos, cómo puede apoyarse el desarrollo de ideas mediante el uso de materiales curriculares disponibles, y las circunstancias bajo las cuales se desarrolló una idea en los estudiantes, de manera histórica. Por lo tanto, la descripción del sistema conceptual de los docentes se puede hacer mediante el uso de dimensiones tales como: dimensión de conocimiento matemático del docente [DM], dimensión instruccional [DI] y dimensión histórica, sobre el desarrollo de conocimiento por los estudiantes [DH] (Clark & Lesh, 2003). Con estas dimensiones, se describe en este documento el sistema conceptual de un profesor sobre la enseñanza y aprendizaje de la función exponencial y su evolución o bien modificación, ampliación y refinamiento durante el proceso de diseño, implementación y evaluación de una secuencia didáctica fundamentada en la PMM.

Metodología

La metodología fue cualitativa. El esquema de formación de docentes bajo la PMM se desarrolló a lo largo de 18 meses, bajo una perspectiva multinivel (investigador, profesor y alumnos) (Doerr & Lesh, 2003). Los participantes en este estudio fueron dos docentes, pero sólo se ejemplificará el proceso con uno de ellos. Las fuentes de datos fueron: actividades diseñadas por los docentes, documentos de los estudiantes, audios de las interacciones estudiantes-estudiantes, docente-estudiantes e investigador-docente y los reportes de las interpretaciones a los modelos construidos por los estudiantes al realizar actividades. Se describen tres etapas, cada una caracterizada por: diseño, implementación y evaluación de una secuencia didáctica (MEA-MXA-MAA). La evolución del sistema conceptual de los docentes sobre la enseñanza y aprendizaje de la función exponencial se describe a través de las dimensiones observadas por Clark y Lesh (2003): a) DI, b) DM y c) DH.

Resultados y Análisis de Resultados

Primera etapa (Ciclo Diseño-Implementación-Evaluación de MEA)

i) Diseño de MEA (investigador- profesor). El investigador propició reflexión del docente en las dimensiones: a) DM: análisis del concepto de función exponencial; b) DI: revisión de libros de texto, de bibliografía de la PMM y uso de tecnología en la MEA. El docente construyó una MEA en el contexto de crecimiento poblacional. El conocimiento subyacente fue la función exponencial. Previamente, participó como observador en la implementación de una MEA.

ii) Primera implementación (profesor- alumnos). Participaron cinco alumnos, agrupados en dos equipos. a) DM: Uno de los equipos incluyó en sus modelos representaciones tabular, gráfica y verbal y el otro equipo, sólo tabular y verbal. El docente y los alumnos, durante la discusión grupal, construyeron la función algebraica $P(t) = P_i(1 + r)^t$asociada a la situación. Se basaron en los modelos desarrollados en la clase. b) DI: El diseño e implementación de la MEA, contempló que los alumnos pudieran utilizar calculadoras y hojas de cálculo de Excel para que resolvieran la situación problema. c) DH: El profesor centró su atención en el interés de los alumnos generado al realizar la actividad y en las representaciones finales presentadas por los alumnos. No observó cómo fue el proceso de construcción del modelo.

iii) Evaluación de la primera implementación (investigador- profesor). La interacción entre el docente y el investigador permitió interpretar y analizar la forma como el concepto función exponencial fue construido, modificado, ampliado y refinado (DM) por los estudiantes, al realizar la actividad (DH). Con base en los seis principios de diseño de las MEAs, la revisión de audios y las cartas de los estudiantes, el docente analizó la actividad, publicada por Vargas-Alejo & Montero-Moguel (2019). El apoyo del investigador fue fundamental para modificar la MEA antes de una siguiente implementación, así como las estrategias instruccionales (DI).

Segunda etapa (Ciclo Diseño-Implementación-Evaluación de MEA-MXA)

i) Diseño de MEA y MXA (investigador- profesor). El sistema conceptual del docente evolucionó en las tres dimensiones. a) DM: El docente propuso que los alumnos deberían realizar una MXA para profundizar en los conceptos matemáticos –variación, covariación, base, exponente, ordenada al origen, tasa de crecimiento, traslación de gráficas, función creciente y decreciente– que emergieron al realizar la MEA. b) DI: El investigador propuso incluir NetLogo –el entorno de modelación programable multi-agente– en la MXA. El docente apoyado por un investigador experto modificó una de las actividades de la biblioteca del software; incluyó, además, en su secuencia un applet con GeoGebra. c) DH: Las modificaciones que realizó el docente se fundamentaron en el análisis de cómo los estudiantes habían construido, modificado y ampliado su sistema conceptual en la primera implementación.

ii) Segunda implementación (Profesor- Alumnos). Diez estudiantes fueron agrupados en cuatro equipos. a) DM: los cuatro equipos incluyeron representaciones tabulares, gráficas, algebraicas y verbales en los modelos. El docente validó todas las representaciones, pero observó que algunos equipos no diferenciaban el crecimiento constante de un crecimiento exponencial, por lo tanto, durante la discusión grupal, intervino mediante preguntas para que se aclarara la diferencia. b) DI: La actividad con NetLogo y el applet de GeoGebra permitieron que los estudiantes pudieran profundizar en los conceptos asociados a la función exponencial. c) DH: El profesor extendió su interpretación y explicó, de una manera más detallada, el proceso de construcción de modelos por los estudiantes.

iii) Interacción del investigador y el docente después de la segunda implementación (Investigador- Profesor). El docente describió cómo los alumnos transitaron por diferentes ciclos cuando realizaron la MEA, señaló cómo en cada ciclo los alumnos ampliaron y refinaron su conocimiento sobre la función lineal y, posteriormente, la función exponencial. Finalmente, mencionó cómo la MXA posibilitó la profundización en los conceptos matemáticos inmersos en los modelos, aún cuando se requirió institucionalizarlos (DM y DH). Con base en la revisión de “la guía de evaluación de calidad de MEA” (Lesh, 2010, p. 32) el docente analizó los audios y las cartas de los estudiantes. Caracterizó los modelos construidos por los estudiantes, con o sin tecnología (DI) para distinguir entre los modelos que requieren dirección, modelos que requieren extensión o refinamiento, modelos situados, y modelos compartibles y reutilizables.

Tercera etapa (Ciclo Diseño-Implementación-Evaluación de MEA-MXA-MAA)

i) Diseño de MAA (investigador- profesor). a) DM: El docente, apoyado por el investigador, diseñó la MAA en el contexto de ahorro de energía e inversiones donde subyacen los conceptos de función lineal y función exponencial. Dio significado al diseño de una secuencia de desarrollo de modelos compuesta por MEA, MXA y MAA, para propiciar el desarrollo del concepto de función exponencial. b) DI: Él diseñó la secuencia con base en Lesh et al. (2003). c) DH: El docente posibilitó la transición por diferentes ciclos de modelación, y fomentó que los alumnos revisaran, profundizaran y ampliaran su conocimiento matemático relacionado con la función exponencial.

ii) Tercera implementación (Profesor- Alumnos). Participaron diez alumnos agrupados en cuatro equipos a) DM: Todos los alumnos construyeron modelos que incluyeron: la función lineal para describir la situación del ahorro, la función exponencial para analizar las inversiones, y una diversidad de representaciones verbal, tabular, gráfica y algebraica . b) DI: Los modelos creados para resolver la situación problema incluida en la MAA, se basaron en el conocimiento desarrollado al usar NetLogo y GeoGebra (MXA). c) DH: El profesor explicó cómo el conocimiento sobre la función exponencial, aprendido por los estudiantes al realizar la MEA, les permitió realizar la MAA. Los modelos fueron caracterizados como compartibles y reutilizables.

iii) Interacción del investigador y el docente después de la tercera implementación (Investigador- Profesor). El docente describió los diferentes ciclos de modelación desarrollados por los alumnos al resolver la secuencia de desarrollo de modelos y analizó cómo ellos evolucionaron durante la realización de la MEA, MXA y MAA (DH). Utilizó los niveles de covariación (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002) y “la guía de evaluación de calidad de MEA” (Lesh, 2010, p. 32) para generar una clasificación de los modelos construidos, en términos del uso de relaciones lineales y exponenciales (DM); de la comprensión de la función exponencial y diferenciación de la función lineal; así como del uso que se les dio a las funciones para interpretar y predecir la situación (MAA).

Conclusiones

¿Cómo evoluciona el sistema conceptual sobre el proceso de enseñanza y aprendizaje de la función exponencial de los docentes al diseñar, implementar y evaluar MEAs? El mayor énfasis se puso primero en la DI, enseguida en la DM, y finalmente, las tres dimensiones, DI, DM y DH, tomaron relevancia.

En la primera etapa el docente se concentró en describir las representaciones construidas con o sin el apoyo de la tecnología. Describió si los alumnos propusieron o no la función exponencial en su forma algebraica en su modelo. Puso énfasis en el producto final y no en el proceso de construcción del concepto de función exponencial, lo cual hizo en la segunda etapa. En la tercera etapa, el docente logró describir cómo los estudiantes desarrollaron ideas matemáticas, las modificaron, adaptaron y refinaron durante todo el proceso de realización de la secuencia. Ello le permitió concluir que, en el proceso de aprendizaje de la función exponencial, los estudiantes podrían usar primero la función lineal al suponer una variación constante y, posteriormente, construir la función exponencial.

La MXA permitió que los estudiantes lograran profundizar en conceptos matemáticos relacionados con la función exponencial. Esto se vio reflejado al realizar la MAA, ya que los estudiantes pudieron usar los conceptos sobre función exponencial y lineal para realizar una actividad distinta, en diferente contexto. Aprendieron a diferenciar y utilizar ambas funciones para describir la MAA. La interacción multinivel entre los estudiantes, profesor e investigador, durante cada una de las fases de las distintas etapas fue fundamental para que evolucionara el sistema conceptual del docente relacionado con el proceso de enseñanza y aprendizaje de la función exponencial. Si bien es cierto que no existe linealidad en el desarrollo de sistemas conceptuales, en este estudio se identificó que el diseño, implementación y análisis de cada actividad contribuyó para que el sistema conceptual del docente se modificara, ampliara y refinara.

EXPLICIT TEACHING OF QUESTIONING IN MATH METHODS COURSE: PRESERVICE TEACHERS' ATTEMPTS TO ASK PROBING QUESTIONS

Susie Morrissey

popogor@iit.edu

After an explicit unit of core activities on questioning, preservice teachers (PTs) completed an assignment to select a problem-solving task, anticipate student solutions, and plan probing questions. After analyzing PTs' work, we discovered that, although most PTs planned probing questions, many also planned questions focused on information or procedures. Next steps include exposing PTs to probing questions focused on meanings, context, or representations.

Keywords: Instructional activities and practices, Teacher Education- Preservice

According to National Council of Teachers of Mathematics (NCTM, 2014), effective teaching of mathematics requires asking "purposeful questions to assess and advance students' reasoning and sense making about important mathematical ideas and relationships" (p. 35). Although teacher questioning has long been viewed as a critical component of mathematics teaching, rigorous and challenging mathematics standards (Common Core State Standards for Mathematics [CCSSM], 2010) and NCTM's (2014) release of effective mathematics teaching practices brought attention back to teacher questioning in the U.S. Especially, given that teachers in the U.S. ask fewer probing questions that support the deep levels of student understanding than teachers in other high-achieving countries (Stigler & Hiebert, 2009a,b), it is critically important to put emphasis on the practice of asking purposeful questions in teacher preparation programs. The main reasons for asking purposeful questions are to surface the student's understanding and reasoning, to probe student thinking, and to gather more information related to the student's understanding of their problem-solving strategies, key mathematical ideas, and meaning inherent in representations (Huinker & Bill, 2017). In an attempt to foster preservice teachers' (PTs) ability to use such purposeful probing questions, we contemplated that an explicit teaching of questioning was needed, and we planned and implemented a series of core activities in a methods course for teaching mathematics in the elementary and middle grades. After PTs were explicitly taught questioning through the series of core activities, they completed an assignment in which they selected a problem-solving task, generated different anticipated student solutions to the task, and planned probing thinking questions for each of their anticipated student solutions. We analyzed PTs' planned questions in the assignment, in order to determine how our explicit teaching of questioning through a series of core activities helped them cultivate good questioning skills, and to identify next steps that we would either begin to address or continue to implement in our methods courses. The guiding question for this study is: What types of questions do elementary PTs propose in order to probe the thinking of their students?

Theoretical Framework

Teacher questioning in mathematics has been investigated in many studies with a focus on inservice teachers (e.g., Boaler & Brodie, 2004; Franke et al., 2009; Kawanaka & Stigler, 1999; Martino & Maher, 1999; Myhill & Dunkin, 2005; Shahrill, 2013; Sahin & Kulm, 2008; Wimer, et al., 2001); however, fewer studies have focused on PTs' questioning (e.g., Akkoç, 2015; Cakmak, 2009; Hähkiöniemi, 2017; Hollebrands & Lee, 2016; Moyer & Milewicz, 2002; Weiland, et al., 2014). Akkoc, Hollebrands and Lee, and Hähkiöniemi investigated PTs' questioning in relation to technology, in computerized environments, or with the use of dynamic software. Moyer and

Milewicz observed PTs' assessment interviews with students, and found that they often asked questions with single answers in rapid succession, rather than probing for student thinking. Weiland et al.'s case study observed two PTs' assessment interviews in their field study; found an increase in their competent follow-up questions; and suggest that PTs can develop their questioning skills through rich field experiences. Cakmak reported that PTs often view the role of questioning as simply a way to motivate students or get their attention.

Many of the studies have produced classifications for probing questions in mathematics. Sahin and Kulm classified teacher probing questions as ask students to (1) explain/elaborate their thinking, (2) use prior knowledge/apply, (3) justify/prove. Kawanaka and Stigler classified questions as requesting (1) analysis/synthesis/conjecture/evaluation, (2) how to proceed in solving a problem, (3) the methods that were used to solve a problem, (4) the reasons why something is true/why something works/why something is done, and (5) other information. Boaler and Brodie's classification was: (1) exploring mathematical meanings and/or relationships, (2) probing, getting students to explain their thinking, and (3) extending thinking. Moyer and Milewicz categorized PTs' questioning strategies as questioning of (1) only incorrect responses, (2) non-specific questioning that did not acknowledge an individual child's responses, and (3) competent questioning that attended to a child's responses and probed for more information. Hähkiöniemi (2017) divided PTs probing questions into categories as probing method, reasoning, cause, meaning, argument, extension, and unfocused probing.

In this study, we aim to explore the nature of elementary PTs' probing questions as a result of explicit teaching of questioning skills through a series of core activities, and in relation to implementing problem-solving tasks. Rather than using an existing classification, we explored the question types that emerged from our PTs, which would complement the previous studies, help us better understand the ways our elementary PTs attempt to ask probing questions, and aid us in redesigning our explicit teaching of questioning module based on the emerging types.

Methods

The sample consisted of 115 PTs in five sections of an elementary/middle math methods course for a mix of elementary and special education majors. In an attempt to foster PTs' ability to use purposeful probing questions, we designed and implemented an explicit questioning module involving a series of core activities, as recommended by Morrissey, et al. (2019).

First, PTs studied the four types of questions as gathering information, probing thinking, making the math visible, encouraging reflection and justification (NCTM, 2014), and the idea of assessing and advancing questions (Huinker & Bill, 2017) through descriptions, examples, and discussion. Then, they watched and analyzed classroom teaching episodes that demonstrate the teacher's use of purposeful questions, and examined excerpts from lesson transcripts for the types of questions posed by the teachers. They categorized teacher's questions by four types and also identified whether each question was assessing or advancing. Next, they examined lesson plans that include planned purposeful questions during implementation of problem-solving tasks. These lesson plans included teacher's planned questions for a variety of anticipated student solutions to a mathematical problem involving various degrees of mathematical sophistication and understanding. Last, they studied four different student works to a given problem-solving task, and created three (two assessing and one advancing type) purposeful probing questions for each of the four student work samples. Finally, they completed an assignment in which they selected a problem-solving task, generated a number of different anticipated student solutions to the task, and planned probing thinking questions for each of their anticipated student solutions. The assignment prompted PTs to ask questions about the anticipated student work in order to help students deepen their understanding, to probe into their reasoning, and/or to have them evaluate and judge their own work. We analyzed PTs' planned questions in order to explore PTs' competency in asking probing questions, as a result of explicit teaching of questioning through a series of core activities. We used an open coding strategy (Strauss & Corbin, 1990) to categorize PTs' probing questions. One researcher analyzed the questions, and proposed initial categories with descriptions. Two other researchers reviewed a subgroup of the data, and agreed with the categories, and suggested revisions for the descriptions. Then, the three researchers, in collaboration, revised the descriptions to make them more subtle and accurate. After finalizing the categories and descriptions, one researcher coded the data; another researcher reviewed the codes and indicated their disagreements with the coding. The discrepancies were discussed, and the codes were revised, repeatedly, until 100% agreement was achieved.

Six categories of questions emerged: (1) focusing on information and/or procedures, which ask students to identify numbers, shapes, key words, and/or procedures to use to solve a problem; (2) focusing on context, which ask students to identify information given in a problem, think in the context of the problem, or connect their solution back to problem context; (3) focusing on meanings, which ask students to explain why something was done, interpret the meaning of given information, explain their reasoning, or interpret the meaning of the answer in terms of the context; (4) focusing on representations, which ask students to use different ways to represent a problem situation, such as draw a picture, write an equation, use manipulatives, etc., ask students about their current representation, or ask students to justify their representations; (5) general questions with no focus, which ask students to explain how they approached solving a problem with no reference to the context of a problem, or ask students general questions about the concepts involved in a problem - overall, this type of question can be used with any other problem students are asked to solve; and (6) other, in which the PT will show, explain, talk through, remind, give an alternative problem –in general, questions are not directed at students. The emerging categories showed that PTs were able to ask probing questions that focus on context, meanings, or representations. Yet, some question types that focus solely on information and procedures, and do not probe into student thinking also emerged, along with general questions and other comments/questions unrelated to students' current work and understanding.

Results and Discussion

All but eight PTs proposed more than one type of question. The assignment required PTs to only ask questions that probe into student reasoning in their current solution, and that help them deepen their understanding. However, 88% of the PTs asked at least one question related to information and procedures, which do not consider the underlying conceptual understanding of the student, and do not probe into student thinking as required. It is worrisome that the majority of the PTs believed that questions related to information and procedures are probing thinking questions. For example, "Why did you solve for the smaller numbers instead of doing it as a large number?" is a question that is not linked to underlying meanings, problem context, or meanings inherent to representations. Frequently, the questions in this category focused on numbers, procedures, or notations, as in "Why did you use an equal sign instead of any other sign?" and "Could you use any other number and get the same result?"

Most (72%) of the PTs asked questions that focus on the meanings. This is an important component of questioning, as requiring students to explain the meaning of their solutions serves to reveal underlying gaps in students' conceptual understanding. Sample questions coded in this category are when PTs asked questions about the meanings of the numbers or operations involved in the solution, such as "What does 159 represent [in your solution]?" "Why do we add 1 to Fred's equation?" "Why did you use multiplication?" and "What does the graph tell you?"

About 35% of the PTs asked questions that focus on the representations, which also require students to explain their reasoning as they justify their representations. These types of questions provide the strong base of conceptual understanding that is necessary for building procedural fluency (NCTM, 2014). Sample questions coded in this category are: "How did you show in your picture that Johnny gave away to Tina?" "How could you represent this with pictures?" "What if they added two more bow colors, how would your drawing and equation change?" and "How could you show your circles using a number sentence?"

Although making connections between the solution and the problem context is also an important part of mathematics proficiency, as recommended in the CCSSM, only 14% of the PTs planned questions asking students to relate their solution to the problem context. For example: "What does your equation have to do with the lights Garrett wants to buy?" and "What relationship does doubling the savings have to do with the price of the shirts [in the problem]?"

Thirty-four percent of the PTs planned general questions with no relationship to the context of the problem, which did not assist students in evaluating their solutions and moving forward in solving a problem. For example, "How did you get your answer?" or "What strategy did you use to solve this problem?" were coded as general questions, because they are not specific to the student's current understanding, and can be asked for any type of student work. When PTs ask how students got their answers, students in most cases would simply go through the steps of their solutions. Another most frequent general question was, "Have you thought of another way this could be done?" which is not related to a student's work and understanding. Other general questions asked about general facts without connection to a student's work or problem, such as "How many minutes are there in an hour?" "What is the formula for area?" etc.

In a few cases, PTs either planned to show, explain, or talk through the problem and solution, instead of asking probing questions, or planned to tell students to check their work. Further analyses of question types in the future will consider variability across content and grade level.

Implications

The high percentage of PTs who planned to ask probing questions indicated that explicit teaching of questioning through core activities helped cultivate PTs questioning skills. Nevertheless, the low percentage of PTs who proposed questions relating student solutions to problem context will be addressed in future methods courses, as authors focus specifically on planning questions that move students forward and are related to meaning, representations, and context of solutions rather than general or procedural questions. The emerged categories of probing questions, as focusing on meanings, context, or representations, will be used as a guide for potential types of probing questions that can be asked specifically to probe into students' conceptual understanding. PTs will be asked to analyze teaching episodes and lesson plans in relation to these three probing question categories and create assessing questions focusing on meanings, context, and representations. The other two categories, general questions or focus on information/procedures, will be used as non-examples of probing thinking questions. PTs will also be asked to analyze teaching episodes and lesson transcripts to look for these two categories. The five categories of PTs' questions, and three categories of PTs' probing questions, complement the existing question classifications in the reviewed literature. In particular, the emerged categories provided subcategories for a combination of Boaler and Brodie's and Moyer and Milewicz's classifications.

This brief report describes the initial results of The Fractions as Measures for Prospective Elementary School Teachers (PTs) Study. Research shows that PTs' conceptions of fractions on a part-whole understanding may be problematic when teaching children about improper fractions. We created an instructional lesson sequence for PTs focused on using unitizing, iterating, and partitioning to think of fractions as measures in multiple situations. Initial results from this ongoing study indicate that PTs' manipulations of unpartitioned rod manipulatives supported both their construction of more powerful fractions schemes and their ability to verbally justify their reasoning.

Keywords: Teacher Education-Preservice, Instructional Activities and Practices, Rational Numbers

The Standards for Preparing Teachers of Mathematics state that beginning elementary school teachers should have a strong foundation in fractions, including the idea that "fractions have multiple interpretations, including part-whole relationships, measures, quotients, ratios, and operators" (AMTE, 2017). Although the conception of a fraction as a *measure* (Kieren, 1980; Lamon, 2007) is emphasized early in the Common Core State Standards for Mathematics (NGA/CCSSO, 2010), many students and prospective teachers (PTs) remain focused on *part-whole* meanings of fractions (DeWolf & Vosniadou, 2015; Newton, 2008; Norton & Wilkins, 2010; Olanoff, Lo, & Tobias, 2014). In this paper, we present an instructional sequence in an online mathematics methods course for supporting PTs' construction of conceptions of fractions as measures. Our aim of this study is to describe how PTs reason with fractions in this online environment, with the goal of informing design modifications to support measurement conceptions.

Theoretical Framework

We adopt a constructivist epistemology in thinking about PTs' fractions meanings as the product of their organizing mental structures (*schemes*) to fit their experiences (von Glasersfeld, 1995). The construct of *scheme* refers to the way researchers model how individuals operate mentally in service of a goal. A scheme consists of three parts – recognition of a situation, operations (mental actions), and an expected outcome. Individuals' schemes become established as they become refined and generalized through their use, via processes of assimilation and accommodation (Piaget, 1970). When a scheme is interiorized, the situation, operations, and anticipated result are experienced altogether as a unified and connected structure (a concept) that can itself be operated upon (Hackenberg, 2010; Piaget, 1970).

We focus on four specific schemes pertaining to fractions – the part-whole scheme (PWS), the measurement scheme for unit fraction (MSUF), the measurement scheme for proper fractions (MSPF), and the generalized measurement scheme for fractions (GMSF) (Steffe & Olive, 2010; Wilkins & Norton, 2018). The PWS involves *partitioning* a whole into discrete pieces that can be disembedded (removed from the whole without modifying the whole) and double-counted to form a numerosity of part(s) within a numerosity of a whole. The distinction between the PWS and the measurement fractions schemes is the individual's ability to iterate fractional units (which is absent from PWS). The MSUF builds upon the PWS as the individual conceives of the *size* of a disembedded unit fraction and its relation to the size of the unpartitioned whole (i.e., that *equipartitioning* an amount of 1 into *n* parts and *iterating* that amount *n* times results in the size of 1). The MSPF extends this notion to the size of a composite (but proper) fraction. An individual with a GMSF understands the size of an (im)proper fraction (*m/n*) as the result of coordinating mental operations to include partitioning the size of ‘1’, disembedding a unit fractional size (1/*n*), and iterating the disembedded fractional unit *m* times.

In order for an individual’s fraction scheme to become interiorized as a fraction concept, his or her fraction scheme must be *reversible*. For instance, an individual with a reversible GMSF could reverse his or her ways of operating to determine the size of ‘1’ from a given improper fraction size. Reversing the MSPF involves forming the size of ‘1’ from a given (composite) proper fraction size, and reversing the MSUF involves forming the size of ‘1’ from a given unit fraction size. Reversing the PWS involves forming the numerosity of the whole from a given proper fraction (e.g., reasoning that if three parts represents the fraction 3/7, then the whole must be 7 parts). Wilkins and Norton (2018) explain PWS requires partitioning and disembedding, whereas MSUF also requires iterating. By engaging in both partitioning and iterating, individuals are constructing actions with inverse relationships between each, which also promote reversibility (e.g., partitioning undoes iterating and vice versa when these actions are composed).

Methods

Participants, Context, and Instructional Sequence

We began with a pilot of six PTs enrolled in a face-to-face mathematics methods course to investigate PTs’ understandings of linear fraction tasks (Boyce & Moss, 2017). We provided the PTs with unpartitioned rods to help them carry out iterating and partitioning operations for different tasks with fractions. PTs video recorded themselves discussing how to solve particular tasks and showed how they used the rods to help them make sense of each task.

The positive results from the pilot study encouraged us to create an instructional lesson sequence for unitizing, iterating, and partitioning in the linear representation of fractions and expand data collection to an online, asynchronous, undergraduate mathematics methods course for elementary school teachers (*n*=80). This methods course is delivered 100% online for 15 weeks. PTs are typically enrolled in their junior year and one year from a student teaching experience. They complete readings, watch lectures and supplemental videos of whole class instruction, participate in a group discussion, and take a quiz each week. The course content is teaching and learning rational numbers and proportional reasoning.

We designed and implemented the instructional lesson sequence for PTs. The lessons begin with reading the first two chapters of *Fractions into Practice*: *Grades 3-5* (Chval, Lannin, & Jones, 2013). Chapter 1 provides examples of children’s work with analyses of children’s understanding of partitioning, fair shares, and the meaning of fractions. Chapter 2 provides an overview of developing children’s understanding of the meaning of the unit in a fraction. PTs engage in an activity in which they use various pattern blocks to think about partitioning into equal parts. Then, we introduce fractions as measures and the roles of unitizing, iterating, and partitioning in forming sizes consistent with standard and discretized representations (i.e., linear). PTs also engage in thinking about why it is essential for students to identify the unit and recognize its connection with a fractional part. This is accessible to PTs who have not yet constructed fractions as measures. We then foster reflection on iterating and partitioning by asking PTs to complete a series of activities using rods that increase in sophistication and difficulty in terms of thinking of fractions as measures (Baroody, Baroody, & Coslick, 1998, p. 9-16). These tasks encourage use of partitioning, iterating, and unitizing with fractions in order to arrive at an accurate answer. The tasks from the culminating activity, which, use similar wording and form of items from Norton and Wilkins (2010), are listed below:

- If the red rod is 1/5, what rod represents 1/2?
- If the light-green rod is 1/4, what rod represents 1/2?
- If the purple rod is 2/3, what rod represents 1/2?
- If the purple rod is 2/3, what rod represents 7/6?
- If the light-green rod is 1/2, what rod represents 9/6?

We conjectured that PTs might describe reasoning with a MSUF scheme to solve tasks 1 and 2, a MSPF scheme to solve task 3, and a GMSF scheme to solve task 5. We randomly assigned PTs in discussion forums to one of the five aforementioned tasks and asked them to make a video showing their solution(s). PTs posted the video to a discussion forum and discussed the different ways of making sense of their group's assigned task.

Data Collection and Analysis

The design research approach (Cobb, Confrey, diSessa, Lehrere, & Schauble, 2003; Collins, Joseph, & Bielzaczyc, 2004; Kelly, 2003) was used to investigate how PTs reasoned in an online setting and employed to study and understand the means of supporting and organizing student learning of fraction tasks presented in the online course. The framework of design research allowed us to engineer the learning environment, systematically study what takes place, and make adjustments to the curriculum (Cobb et al. 2003; Collins et al., 2004; Kelly, 2003).

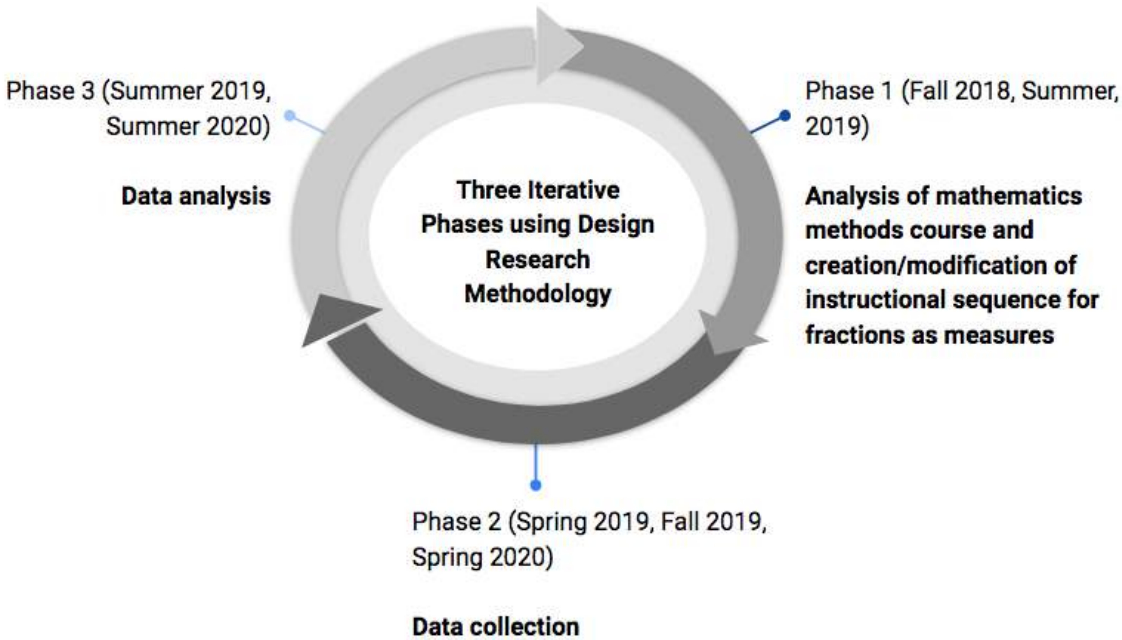

Figure 1: Iterative Phases of Data Collection and Analysis

The data consisted of videos of PTs verbally reflecting on how they solved fraction tasks using rods and PTs' online discussions contrasting their reasoning and their peers' reasoning on these tasks. First, a graduate assistant blinded and renamed the video files and blinded the online discussions so that the five raters could not identify PTs' names. Two researchers identified repeating themes in PTs' videos, while acknowledging unique instances (Corbin & Strauss, 2014). Themes were organized according to "the unit and the whole", "reasoning with arithmetic operations, "alternative methods", and "orientation of the video". The two researchers created a list of twenty questions based on the themes and six researchers quantitatively coded (1: evidenced, 0: not evidenced) in pairs. Following the coding, pairs compared codes to determine inter-rater reliability. Using what we learned from the data analysis, we refined the pedagogy of the online course as well as the content. Figure 1 outlines the phases of our data collection and analysis.

Results

The videos showed that the unpartitioned rods helped PTs verbalize their constructed unit and show how their partitioning and iterating relates to particular fraction reasoning. As PTs began working with concrete manipulative rods, we found that they were able to develop physical actions that were both reversible and composible (e.g. iterating and partitioning). By acting on length models in this way, PTs had to iterate and partition. Before this, many PTs commented that they had used linear representations, but usually in the form of a number line. Thus, conceptualizing fractions with bars using rods was new to them.

Conclusion and Significance to the Field

Results from the study showed that tasks similar to those in the sequence tested provide opportunities for PTs to progress from PWS toward measurement fraction scheme development. By anticipating their own strategies and solutions with (im)proper fractions, PTs will better be able to consider their own students' reasoning strategies more systematically and critically determine (in)effective instructional moves when teaching fractions. By providing PTs means to visualize the unit and engage in reversible actions, and verbally reflect on their thinking (with their video explanations) we posit they might interiorize measurement schemes and be able to anticipate solutions more fluently. Findings from this study could inform (1) (in)effective instructional sequences and progressions that PTs experience when constructing fractions as measures, and (2) affordances and constraints of online asynchronous learning environments for the development of these instructional sequences.

We are currently in Phase 2 of Data Collection and are including new data in the form of drawings, paired with the videos in online and face-to-face mathematics methods courses. We are refining the list of questions based on the themes used to analyze the videos so that other instructors that collect similar data can use the protocol to determine fraction schemes.

PREPARING TO ELICIT STUDENT THINKING: SUPPORTING PST QUESTIONING IN AN UNIVERSITY TEACHING EXPERIENCE

Sheila Orr
Michigan State University
smorr11@msu.edu

Kristen Bieda
Michigan State University
kbieda@msu.edu

This study examines how preservice teachers (PSTs) plan for and enact questions that elicit student thinking during an early field experience. We analyzed teaching videos and their corresponding lesson plans from 17 PSTs over 34 lessons in a field experience in a freshman-level university mathematics class. Our findings show PSTs tended to use three types of questioning sequences when teaching, with the quality of questioning in those sequences linked to the quality of planned questions. Findings described here discuss the implications for supporting PSTs' lesson planning during early field experiences.

Keywords: Teacher Education – Preservice; Teacher Educators; Classroom Discourse

Being able to elicit and respond to student thinking is a core practice of ambitious teaching (Gotwals & Birmingham, 2016). In order to elicit student thinking, teachers need to: (1) select a task that affords opportunities for eliciting, (2) anticipate student thinking, (3) know the learning goal and assess students' proximity to the goal, and (4) plan questions to deepen student understanding (Boerst et al., 2011; Orr et al., 2020; Shaughnessy et al., 2019; Sleep & Boerst, 2012; TeachingWorks Resource Library, 2020). Each of these components of eliciting student thinking is complex. The complexity of this practice makes it difficult for novice teachers, whether being utilized through simulations or in face to face interactions with students (Shaughnessy & Boerst, 2018). One-way math teacher educators (MTEs) help preservice teachers (PSTs) prepare for this complex practice is through lesson planning. In this brief research report, we share findings from a project that explored the following questions: *During the UTE, to what extent did PSTs enact questions as planned? How did the quality of planned questions correspond to the quality of questions as enacted?*

Methods

This project analyzed data collected for a larger project studying the effects of the *University Teaching Experience* (UTE) model for secondary mathematics PST learning across three different teacher preparation programs[1]. In the UTE, PSTs teach an entry-level undergraduate mathematics course while taking their first methods course (Bieda et al., 2019). PSTs plan, enact, and reflect on a series of lessons while being supported by MTEs. The MTEs support the PSTs through providing feedback on lesson plans, in-the-moment coaching and leading post-lesson debriefs. In addition to the support of their MTEs, the PSTs are also supported by a mentor teacher who is the course instructor for the mathematics course. Throughout the course of the UTE semester, PSTs teach at least two lessons and observe other PSTs teach while working with mathematics students in groups. In this brief report, we will only present findings from data collected at our university site.

Data Collection

During the implementation of the UTE in fall 2018, there were 17 PSTs. The PSTs planned and taught lessons in pairs, resulting in seven pairs and one group of three. The PSTs taught two lessons over the course of the semester in a college algebra course. The first lesson was roughly half the class period (~40 minutes). The second lesson was the entire class period (~ 80 minutes). Lesson enactments were captured using Swivl robot video-recording (www.swivl.com) and audio from the class sessions was later transcribed. PSTs completed lesson plans for each session following a modified version of the Think Through a Lesson Protocol (TTLP) (Smith et al., 2008) and shared with MTEs for feedback through Google Docs.

Data Analysis

In order to understand the relationship between the quality of questions enacted as compared to the quality of questions planned, all the questions in the lesson plans and the transcribed enacted lessons were coded based on the Instructional Quality Assessment Academic Rigor (AR) for Teachers' Questions rubric (Boston, 2012). This tool was selected because reliability and validity has been established (Boston & Wolf, 2006). For any question written in the plan or asked of students during the lesson, it was assigned one of 6 question types: probing, exploring mathematical meaning and relationships, generating discussion, procedural or factual, other mathematical, and nonmathematical (Boston, 2012). Examples of each type from our data are represented in Table 1.

Question Type	Example
Probing	Why does this work?
Exploring mathematical meaning and relationships	Why do you think that would work, to switch P and M, given what we've been doing with the other inverses?
Generating Discussion	Looking at these examples here, take a second, look at them, and think, which of these relations or graphs are functions?
Procedural or Factual	Is it invertible?
Other Mathematical	Any questions on how we did those few steps?
Nonmathematical	Why would technology affect the prison rate?

Table 1: Examples of Question Types

For the enacted lessons, we narrowed the data to examine only situations where PSTs engaged in sequences (sustained questioning) involving AR questions, thus excluding any questions that were primarily procedural or factual, other mathematical, and non-mathematical. We segmented lesson transcripts into questioning sequences by determining when the PST asked the initial question to elicit student thinking around a specific question. Then, we identified a sequence end when the PSTs moved to another topic. We analyzed these sequences and generated three categories to describe the patterns of questioning in these sequences. Afterwards, we compared the enacted sequences to the portion of the lesson plan with corresponding content. We looked for patterns in how the questioning sequences evolved depending upon whether PSTs had asked questions that were planned or unplanned. In the section below, we share our findings about the patterns that surfaced related to describing relationships between planned and enacted questions.

Findings

We discovered that PSTs utilize three distinct questioning sequences when they asked questions involving Academic Rigor (AR). In the first type, PSTs maintained AR throughout the sequence. In this type, PSTs began with an AR question, the students responded, and the PSTs continued to ask AR questions throughout the sequence. The second type of questioning sequences involved PSTs reducing the AR. In this type, the PSTs started with an AR question, the students did not respond, and the PSTs lowered the AR of the questions for the remainder of the sequence. The third type –the "hook" method – emerged when PSTs began with a non-AR question, which "hooked" the students to respond, and then the PSTs raised the AR of the questions for the remainder of the sequence.

Given our research focus, we wanted to explore the relationship between questions as planned and the emergence of these different types of questioning sequences. When looking at the total amount of enacted questions, as sorted by questioning sequence, we found the most common questioning sequence was the "hook" method followed by the scenario where the AR is maintained. In further analysis of mapping enacted questions on to the lesson plan, we found PSTs enactment involved more planned questions for sequences where the AR is maintained when compared to the other two questioning sequences (see Figure 1).

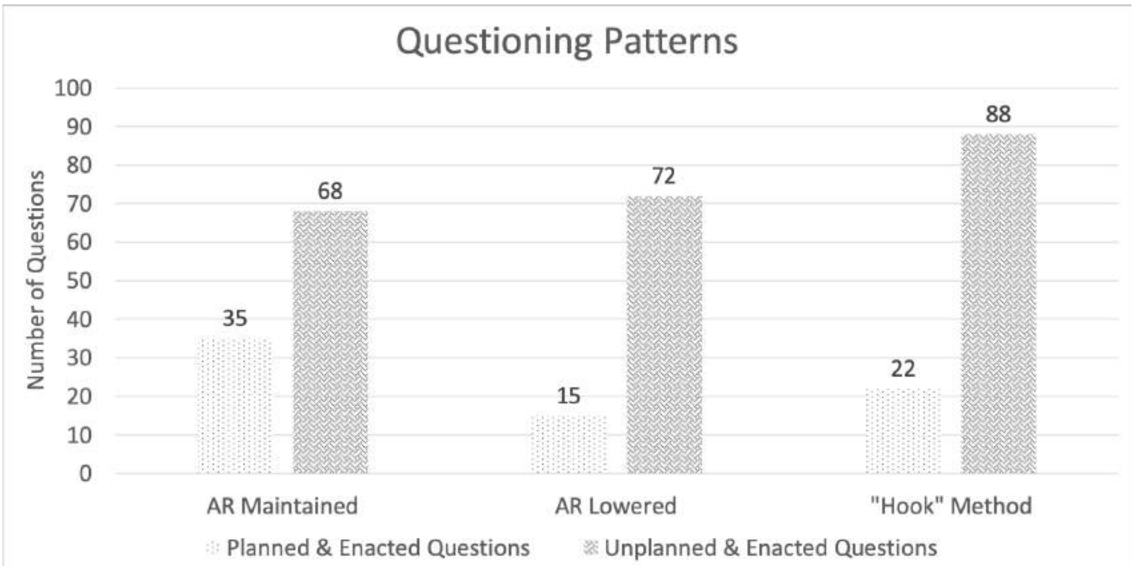

Figure 1: Planned vs Unplanned Questions in Enactment

Note in Figure 1 that situations where PSTs lowered the academic rigor involved the fewest number of planned questions. To investigate whether planning high-quality questions correlated with a greater number of AR questions in enactment, we also investigated the quality of enacted questions during parts of the lesson where AR questions had been planned (but not enacted). We hypothesized that planning AR questions would ultimately support higher-quality questioning sequences during the parts of the lesson the questions were being employed, even though the planned questions were not asked. Our findings are represented in Figure 2.

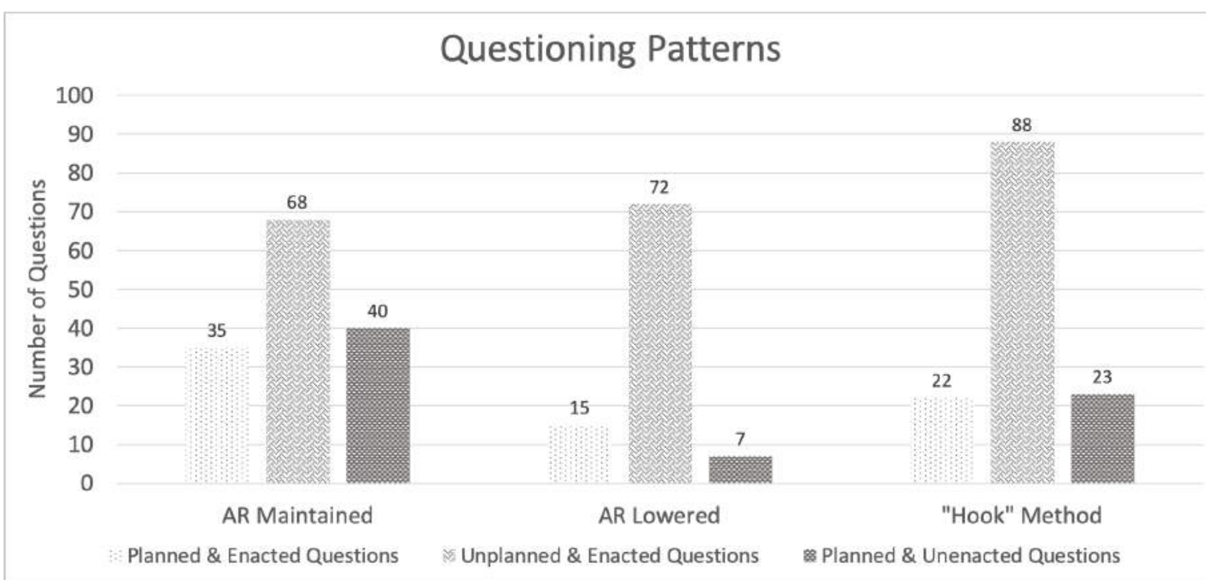

Figure 2: Planned & Unenacted Questions vs Enacted Questions

Through this investigation we found, in situations where AR is maintained, PSTs not only asked the most planned questions, but they also had the most planned and unenacted questions for these sequences. We also found the reverse was true. In situations where the AR was lowered, PSTs not only asked the least amount of planned questions, but they also had the least amount of planned and unenacted questions (fewer questions overall) suggesting that less attention to those situations in planning affected the quality of their eliciting of student thinking during enactment

Discussion and Conclusion

Through engaging in the UTE experience, PSTs are given opportunities to plan for and elicit student thinking through questioning while being supported by MTEs. These findings suggest that even with support, PSTs find themselves in classroom situations they had not anticipated and are unsure of how to respond. The situations tend to arise when students have gaps in prior knowledge or engage in the task in an unanticipated way. This is to be expected, as PSTs classroom inexperience often means that they face difficulties with anticipating students' responses (Arbaugh et al., 2019; Taylan, 2018). Improving the quality of PSTs' questioning must involve not only helping them to anticipate student responses, which typically improves with more classroom experience, but also how to draw on high AR questioning when the situation does not unfold as planned. MTEs can provide this support through encouraging PSTs to consider follow up questions, as well as, how the questions align with the learning goals. Giving additional attention to the alignment between the questions and learning goals may result in (the inevitable) unplanned questioning sequences that more likely maintain AR.

PROSPECTIVE TEACHERS' INTERPRETATIONS OF MATHEMATICAL REASONING

Hyejin Park

Calls for teaching school mathematics with a focus on mathematical reasoning (MR) are included in curricular documents across the world, but little is known how prospective teachers (PSTs) understand MR. In this paper, we report on a study in which we engaged 24 PSTs preparing to teach grades 1-8 in analyzing a series of student-generated arguments for evidence of student reasoning with a focus on student-provided justifications. We examined PSTs' interpretations of MR prior to and after instruction. Our results showed that PSTs interpreted MR broadly in terms of student thinking, validating thinking, problem-solving, connecting ideas, or sense-making. Some PSTs also interpreted MR as evidence of student understanding or described MR in terms of strategies teachers use to support students' reasoning skills. We discuss changes in PSTs' interpretations of MR after instruction.

Keywords: Teacher Beliefs, Reasoning and Proof, Teacher Education - Preservice

Framing of the Study

Developing students' mathematical reasoning (MR) skills is the desired goal of school mathematics education (Australian Curriculum, Assessment and Reporting Authority, 2015; Department for Education, 2014; National Council of Teachers of Mathematics [NCTM], 2000, 2009; National Governors Association Center for Best Practices, & Council of Chief State School Officers, 2010). However, little is known about how teachers, including prospective teachers' (PSTs'), interpret MR. To date, only a handful of studies documented how practicing and PSTs make sense of and understand MR (Clarke et al., 2012; Herbert et al., 2015). Herbert et al. (2015) shared that Australian and Canadian elementary practicing teachers have broad and ambiguous perceptions of MR. As such, they interpreted MR as thinking, communicating thinking, problem-solving, validating thinking, forming conjectures, using logical arguments to validate conjectures or connecting aspects of mathematics.

In this paper, we describe instructional intervention designed to heighten elementary PSTs' attention to students' reasoning in the context of generating mathematical arguments. Our study draws on the variation theory of learning (Lo, 2012), which highlights the importance of providing learners with multiple experiences with a given phenomenon, to generate a wide range of opportunities that help learners attend to and make sense of different features of that phenomenon. In our work with PSTs, we draw on the variation theory to purposefully bring PSTs' attention to elementary students' MR, particularly different ways in which students might reason to justify while generating mathematical arguments. Our goal was to answer the following research questions: (1) How do PSTs interpret MR in the context of elementary school mathematics classrooms? And, (2) How does engaging PSTs in analyzing elementary students' arguments for evidence of MR impacts PSTs' views on MR?

Method

Participants and Study Context

Participants were 24 PSTs enrolled in a semester-long mathematics content course for elementary and middle grades education majors, Algebra and Geometry for Teachers. The course was designed to support PSTs' conceptual understanding of mathematical ideas essential to elementary and middle

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

school mathematics curriculum. Instructional emphasis was placed on understanding, interpreting, and assessing students' MR about fundamental mathematics concepts in the K-8 school mathematics.

Drawing on descriptions of elementary students' reasoning provided by the NRICH team at the University of Cambridge (see https://nrich.maths.org/11336) and the variation theory of learning, we designed the Student Reasoning Assessment Tool (SRAT) (see Table 1) to bring PSTs' attention to different justifying actions in the context of student-generated arguments and to help PSTs develop reasoning assessment skills. Along with the SRAT, we also created a set of class activities that we used to engage PSTs in analyzing MR evident in elementary students' written arguments.

Table 1: Student Reasoning Assessment Tool (SRAT)

Levels	Descriptions of elementary students' reasoning levels
L0	Student tells what he or she did
L1	Student attempts to provide some reasoning (not necessarily relevant, complete, or valid) for what he or she did
L2	Student provides a chain of reasoning, which is incomplete, insufficient, or invalid, to support the assertion
L3	Student provides a chain of acceptable valid reasoning in support of the assertion; the argument is at best partial
L4	Student provides an exhaustive acceptable chain of valid reasoning in support of the assertion; the argument can be accepted as proof

Prior to class intervention, we asked PSTs to share in writing their own interpretations of MR. They were also given a set of student-generated arguments and asked to analyze these arguments for evidence of student reasoning with attention to student-provided justifications. During the intervention, using the SRAT, individually and in small groups, PSTs examined a wide collection of sample arguments for evidence of student reasoning. They were also asked to anticipate how elementary students could reason and communicate their mathematical reasoning in different problem contexts. After the intervention, we asked PSTs to revisit their initial descriptions of MR.

Data and Data Analysis

We analyzed PSTs' written responses to two journals, which each PST completed at the beginning and end of the semester and in which they reflected on the meaning of MR. The journal prompts were intentionally open-ended to avoid leading PSTs in any specific direction that could suggest interpretations of MR. The prompts were as follows:

- Journal 1: Think about yourself as a mathematics teacher. When you hear the term mathematical reasoning, what does it mean to you? In the best possible way, describe your understanding of this term. Explain how mathematical reasoning might look.
- Journal 2: Building on your learning in this class, define mathematical reasoning. Did your understanding of mathematical reasoning change when comparing to how you interpreted it at the beginning of the semester? If yes, explain why. If no, explain why not.

We first coded the data with analytic codes derived from the existing literature on teachers' perceptions of MR (e.g., Davis & Osler, 2013; Herbert et al., 2015). We then conducted the inductive analysis to identify any additional themes within our PSTs' responses. We continued comparing and contrasting the identified themes until we established final definitions of codes, which then were applied to our data. Finally, we tabulated code frequencies to identify any patterns in our PSTs' interpretations of MR.

Results

PSTs' Interpretations of MR

Our PSTs interpreted MR in multiple ways, and that overall, they used two lenses while discussing the term MR. Most frequently, PSTs interpreted MR from the perspective of a learner (see Table 2). Some PSTs also viewed MR from the perspective of a teacher. PSTs with the learner perspective saw MR as the process that describes how students think, validate (justify), make sense, solve problems, or connect mathematical ideas. PSTs with the teacher's perspective viewed MR as data (products) that give teachers evidence of students' understanding of mathematical concepts, or as strategies with which teachers engage students in MR in the mathematics classroom.

Table 2: PSTs' Views of MR

View	Interpretation of MR	The number of PSTs* with the view (n, %)	
		Semester beginning	Semester end
Student-Centered	Thinking	6 (25%)	10 (42%)
	Validating thinking	18 (75%)	22 (92%)
	Sense-making	13 (54%)	17 (71%)
	Problem-solving	8 (33%)	9 (38%)
	Connecting mathematical ideas	9 (38%)	14 (58%)
Teacher-Centered	Evidence of students' understanding	2 (8%)	7 (29%)
	Teacher support for students' reasoning	3 (13%)	3 (13%)

Note. The total number of participants, n = 24. The categories are not mutually exclusive. Most PSTs shared multiple views.

Student-centered Views of MR

With a focus on an individual student, PSTs most frequently viewed MR as validating thinking. They emphasized justifying actions as representative of MR. PSTs also discussed modes of representations (e.g., verbal, written, or pictorial forms) that students might use to validate or explain their reasoning. They focused on the role that reasoning plays in supporting the growth of one's mathematical understanding by describing that while students reason about mathematics, they learn and develop a deeper understanding of mathematical concepts or problem-solving strategies. PSTs also viewed MR as specific aspects of the problem-solving process, the entire process of problem-solving, or decision-making in problem-solving situations. Some PSTs described MR as one's thinking about mathematics, mathematical problems, or specific problem-solving strategies.

Teacher-centered Views of MR

PSTs interpreted MR as evidence of student learning and articulated that teachers use students' reasoning as a resource for making instructional decisions. PSTs also described that by paying attention to students' reasoning, teachers identify the needs of students with diverse mathematical abilities or levels of understanding.

Changes in PSTs' Interpretations after Class Intervention

We observed two changes in PSTs' interpretations of MR while comparing their views from the beginning to the end of the semester. (1) Change in the breadth of interpretations (17 PSTs, 70%). After the class intervention, many of the PSTs augmented their initial interpretations and included additional perspectives on the meaning of MR, which they did not initially consider. On average, after the intervention, most PSTs gained awareness of one to three additional interpretations of MR. (2) Change in the depth of interpretations (14 PSTs, 58%). PSTs' views of MR after the class intervention remained largely consistent with their initial views. However, their interpretations of MR were more nuanced and included more precise descriptions of reasoning actions. While describing justifying prior to the class intervention, for example, many of the PSTs interpreted justifying broadly as explaining why. After the class intervention, PSTs discussed justifying with attention to specific attributes of justifications such as logic, generality, or modes of representations that a student might use to justify a mathematical statement.

Conclusion and Discussion

In our work with PSTs, we positioned them to analyze students' MR as future mathematics teachers (see presented earlier journal prompts). Our data revealed two perspectives that PSTs used as their lenses while describing MR: student-centered and teacher-centered. With a focus on each of these perspectives, PSTs interpreted MR in a broad sense. Within their student-centered interpretations, PSTs described MR as thinking, validating thinking, sense-making, problem-solving, or connecting mathematical ideas. Within their teacher-centered interpretations, PSTs interpreted MR as evidence of student learning that helps teachers make instructional decisions or as a pedagogical practice that teachers use to engage students in reasoning and encourage their mathematical thinking. PSTs' broad interpretations of MR might not be surprising since reasoning, problem-solving, sense-making, mathematical thinking are all intertwined and often viewed as interconnected practices that support one another (NCTM, 2009; Kilpatrick et al., 2001).

Our results also revealed that classroom activities that exposed PSTs to a large sample of students' work with a focus on student reasoning about justifications increased PSTs' awareness of specific justifying actions. While sharing their views of MR, PSTs have begun to provide more nuanced and precise descriptions of reasoning actions related to justifying. Supporting PSTs in building a comprehensive vision of MR should include efforts of helping them make a shift from a broad understanding of MR as thinking, sense-making, problem-solving, or connecting mathematical ideas to seeing these aspects of reasoning in terms of more specific and tangible reasoning actions. Loong and colleagues (2013) argued that teachers who do not have a strong understanding of specific reasoning actions might likely be ineffective in promoting MR in their classrooms.

This study examines a professional development (PD) program, set in a summer mathematics program for middle grades students with a research-based curriculum, where preservice and inservice teachers collaborated in interpreting and responding to student thinking. We investigated the resources that participants contributed to this collaboration, and the opportunities the non-traditional PD setting afforded for the sharing of these resources. Our embedded case study consisted of two classes, where participants taught and then engaged in video-recorded debriefing sessions each day. Their discussions focused on what they noticed in class and how they responded in the moment or anticipated responding in future lessons. We find that participants' observations from class catalyzed the sharing of resources, both from the program and from outside experiences, that contributed to the analysis of student thinking.

Keywords: Teacher Knowledge; Instructional Activities and Practices

Professional development (PD) focused on practice offers prospective and practicing teachers opportunities to learn and examine the real work of teaching (Ball & Forzani, 2009; Grossman et al., 2009a). Representations of practice (Grossman et al., 2009) captured in video episodes, student work, transcripts, and narratives are often used by researchers as effective tools to help unpack and decompose practice (e.g. Sherin & van Es, 2005; Kazemi & Franke, 2004; Silver et al., 2007; Oslund, 2016). Lacking in these studies, however, are opportunities to interact or be present within the dynamics of the context. Experiences such as lesson study (Lewis, Perry, & Hurd, 2009) provide direct access to the classroom with demonstration lessons that serve as representations of practice, followed by debrief opportunities for the decomposition of practice.

Little (2003) posits that improvement of teaching and learning is strengthened when teachers collaboratively engage in analysis of teaching practice. When representations of practice (Grossman et al., 2009a) are contextualized in a common work environment, they become resources for teacher learning. Researchers have noted differences in what expert, beginning, and novice teachers perceive and understand of classroom events (Berliner, 2001). This skill of professional noticing is an important component of decomposing core practices of teaching (Jacobs, Lamb, & Philipp, 2010). Our work examines a PD where preservice and inservice teachers taught together in an informal summer mathematics program and engaged in discussion sessions about the student thinking and teaching practices they noticed. We hypothesize that a "neutral" setting provides a productive space for negotiation of norms and practices across distinct cultures in which these groups are immersed: the preparation programs of preservice teachers, and inservice teachers' schools. Additionally, the program uses a research-based curriculum in which students construct understandings of pre-algebra concepts while using representations to explore problems and communicate their reasoning. We hypothesize that this curriculum creates opportunities for the analysis of students' mathematical thinking.

In this study we focus on two research questions:

1. What resources do preservice and inservice teachers contribute when discussing how to respond to students' mathematical thinking in a non-traditional setting?
2. What opportunities for the analysis of student thinking and the decomposition of teaching practice does a non-traditional collaborative teaching setting afford?

(2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Methodology and Theoretical Framework

Our study is an embedded case study (Yin, 2009) that took place in an informal summer mathematics program for students in grades 3-8 in the United States. In the two-week program, students took courses that explored pre-algebra concepts. Each class was taught by a "master teacher" (MT), an inservice teacher with multiple years of experience in the program, and assisted by inservice teachers seeking professional development (PDT), undergraduate preservice teachers (PST), and undergraduate "fellows" (F). The focus of our study is on the "teachers" at this summer program. The cases consisted of two classes collectively taught by two master teachers, three inservice PD teachers, six preservice teachers, and two undergraduate fellows.

During the program, inservice teachers and undergraduates taught together each morning, then convened after class in small groups, with each group consisting of the teacher and assistants for one class. In the meetings, participants responded individually to written reflection prompts, then engaged in videotaped group discussions about what they had observed in the day's class. We transcribed these discussions and divided the transcripts into conversational "episodes," with each episode focused on a unified theme or observation. We coded an episode as a *rich episode* if it included sustained discussion of students' observed mathematical thinking.

To address the first research question, we analyzed these episodes and identified how participants interpreted or suggested responding to student thinking. We also identified resources that various participants contributed to the discussion in each episode. In conceptualizing *resources* we use *mathematical knowledge for teaching* (MKT, see for example Ball, Thames, & Phelps, 2008) as an organizing framework. MKT consists of mathematical and pedagogical knowledge used in the work of teaching, comprised of components such as *specialized content knowledge*, *knowledge of content and students*, and *knowledge of content and curriculum*. Rather than attempt to sort resources into discrete MKT domains, we use these domains to orient our awareness of intellectual resources (Little, 2003) that participants use to make sense of student thinking, weigh possible responses, and understand the curricular context in which this thinking takes place. We take a grounded approach (Strauss & Corbin, 1997) in our analysis of resources, identifying and categorizing instances in which participants share knowledge and experience.

To address the second research question, we coded for instances in which participants made reference to features of the non-traditional context of the collaboration, either comparing this context with other mathematics teaching settings, or describing affordances or challenges of the context itself (such as opportunities for students to develop ideas prior to the presentation of formal procedures, or the fact that the program is not bound by the school calendar). We analyzed these instances for evidence that the non-traditional teaching context afforded opportunities for participants to make explicit their beliefs and dispositions about mathematics teaching (whether in their current non-traditional setting or in other more conventional settings) or their reasoning in interpreting or choosing how to respond to student thinking.

Results

In this section we describe some preliminary results of our analysis of the resources that teacher participants in the program offered in their discussions, and of the opportunities that the shared teaching context afforded for the collaborative analysis of student thinking.

Types of Resources Offered by Teacher Participants

In addressing the first research question, we offer three examples of categories of resources that have emerged from our data.

Awareness of alternative algorithms: a resource offered by PSTs. In Episode 3X_ 505, a group consisting of one MT, two PDTs, two PSTs, and two Fs discussed a fellow's observation of a student who lacked access to an activity on the Pythagorean theorem because he did not know how to multiply numbers by hand. The group discussed different resources that might help the student. A PDT mentioned two students who had shared their own algorithms for multiplication to the whole class. Two PSTs indicated that they had learned about alternative algorithms, and the pedagogical value of these, in a content course for elementary teachers. Even though neither PST described any algorithms for multiplication other than those described from class, their awareness of the existence and value of multiple algorithms helped to frame the discussion of students' knowledge and use of non-standard algorithms in an asset-oriented way.

Knowledge of models and metaphors for operations: a resource offered by PDTs. In Episode 1Y_506, one MT, two PDTs, and one F brainstormed strategies for helping students understand integer subtraction; the fellow had observed some difficulty with the idea of subtracting an integer by adding its opposite. The participants launched into a discussion of possible ways to make the connection between subtraction and addition concrete for students:

PDT.155: You can think like banking terms I owe you an orange.

F.145: I think they kind of understood that a little bit when that was brought up …

MT.152: Yeah, and what if someone owes you, like we talked about bigger numbers, let's say that you have $25.00 … your brother had borrowed 20 of your dollars … Well, what if he paid you back – well, that's not subtracting …

PDT.180: Because we're subtracting –

MT.152: Do you see what I'm wanting? I want to subtract a negative to make it – I mean it is going back … Well, subtracting 20 – oh, I don't know. Okay, so I don't know. Anyway, think about that.

PDT.810: And he already owes you money. It would be like you're subtracting from his deficit, right?

The PDTs' contributions, rooted in pedagogical knowledge of common metaphors for the concept of integer subtraction (Quigley, 2011), added to the group's opportunities to develop a coherent explanation for why subtracting an integer is equivalent to adding its opposite.

Knowledge of the program curriculum: a resource offered by MTs. In Episode 1Y_203, one MT, one PDT, and one F discussed students' efforts to determine distances between numbers on the number line prior to the introduction of any formal procedure for integer subtraction. All three participants (MT, PDT, and F) commented that one student had shown evidence of beginning to realize that the distance from a negative integer to a positive integer could be found by adding the absolute values of the two numbers, but that she did not apply this principle consistently. The MT commented, "She doesn't have the rules down yet, which we're not even to yet … so, it's pretty cool that she's already getting it." The MT's comment referenced her curricular knowledge that formal procedures for subtracting integers and solving distance problems would come later in the summer course. This allowed her to frame the student's developing fluency as a stage of mathematical discovery rather than as a deficit.

Affordances of the Non-Traditional Teaching Context

Our analysis suggests that the shared context affords at least two distinct types of opportunities for in-depth analysis of students' mathematical thinking and of teaching practice.

The first type of opportunity emerges from the curricular context for the shared representation of practice. The program curriculum provides students with opportunities to use visual and tactile representations to explore problems, and postpones the introduction of formal procedures. As a result, teacher participants sometimes have opportunities to describe students' conceptual thinking about pre-algebra ideas without the backdrop of a normative procedure against which student performance might be compared. We see this in the example of Episode 1Y_203, in which the absence of a formal procedure for finding distances on the number line afforded an opportunity for teacher participants to notice students' improvised methods for calculating distance, such as counting unit intervals on the number line and adding absolute values in the case in which the two endpoints are on opposite sides of the origin.

The second type of opportunity emerges from the contrast between the participants' shared teaching context and other contexts in which these participants had been mathematics teachers or learners. We find that the contrast among these teaching settings can provide the stimulus for a participant to make explicit their beliefs about mathematics teaching and learning. For example, in Episode 3X_505, in which teacher participants discussed a student who had difficulty with multiplication, several undergraduate students (PST and F) expressed surprise that such a student had been placed in an upper-level course in the summer program. They noted that the MT of their morning class (not present in the discussion) helped the student access the activity by providing a multiplication chart, but also stated that if they encountered such a student in a traditional setting, they would want to divert the student to remedial instruction. This afforded the MT an opportunity to provide a counterpoint for this deficit framing of the student, asserting that the activity's aim was to lead students to discover the Pythagorean theorem, not to assess multiplication, and that such an accommodation did not significantly undercut the mathematics.

Discussion and Next Steps

Our initial findings suggest that instances of non-standard student thinking serve to activate the unique knowledge resources of preservice and inservice teachers and offer opportunities for negotiations of teaching beliefs and norms across teaching cultures. Because the non-traditional structure and curriculum of the shared teaching context creates disequilibrium with the course-based preparation of PSTs and the more traditional teaching experiences of inservice teachers, participants from both constituencies are encouraged to make explicit their own initial conceptions of students' thinking, mathematical dispositions, and attitudes (Figure 1).

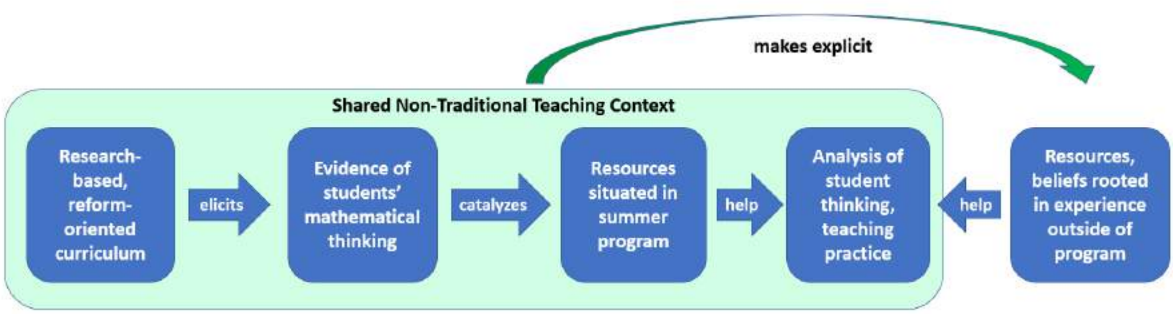

Figure 1: Model for the role of a shared non-traditional teaching context in PD.

Next steps for our study include a more thorough synthesis of the types of knowledge resources that participants contribute to the collaborative analysis of student thinking, along with an analysis of the degree to which these resources are differentiated by participant type (MT, PDT, PST, F). We also plan to develop a more robust coding scheme for assessing the role of the non-traditional setting in activating (or muting) the external resources, such as preservice teacher experiences and knowledge of traditional curricula, that participants bring into the program.

PROSPECTIVE ELEMENTARY TEACHERS' CONTENT KNOWLEDGE OF DECIMAL MAGNITUDE AND PLACE VALUE

Rachel Starks
Boston University
RNStarks@bu.edu

Ziv Feldman
Boston University
ZFeld@bu.edu

Research suggests that robust mathematical knowledge for teaching is essential for high quality instruction and learning, and yet studies also reveal that prospective teachers (PTs) may not have had sufficient opportunities to develop this knowledge. Decimal understanding is one particular area of difficulty for elementary students and PTs alike, but few studies have focused on characterizing PTs' decimal understanding. In this study we examine 28 PTs' ability to create and explain models for comparing decimals, following instruction on this topic. We find that participants are able to effectively use models to identify and reason about the larger of two decimals, but that they struggle to articulate underlying mathematical ideas such as the role of place value in decimal magnitude or connections among decimal models.

Keywords: Teacher Education – Preservice, Mathematical Knowledge for Teaching, Rational Numbers

Research suggests that teachers of mathematics must have substantial knowledge of the content that they will teach and of appropriate ways to do so; these together are known as mathematical knowledge for teaching (MKT; Ball, Thames, & Phelps, 2008). Unfortunately, some studies also suggest that prospective elementary teachers' (PTs') MKT is still developing; areas for growth span topics such as fractions (e.g., Van Steenbrugge et al., 2014), geometry (e.g., Aslan-Tutak & Adams, 2015), decimals (e.g., Stacey et al., 2001; Widjaja et al., 2008) and more (Hill, 2010). Although decimal concepts have been shown to be difficult for learners, fewer studies focus on PTs' knowledge of decimals (Kastberg & Morton, 2014) than fractions (Olanoff et al., 2014) or whole numbers and operations (Thanheiser et al., 2014). This study attempts to contribute to and update the small body of literature on PTs' knowledge of decimal magnitude and place value. Based on PTs' responses to two open-ended tasks, we describe the models and strategies they use to make sense of and compare two decimal quantities. Further, we analyze PTs' written explanations of their models and strategies, and the underlying mathematical ideas that they identify as important.

Background & Theory

Here, we introduce some recommendations for supporting PTs' MKT and studies which give images of it, then highlight a gap in this literature. We describe how the MKT framework bounds our study by defining what is visible in the data, and discuss *conceptual understanding* and how this strand of mathematical proficiency figures in our analysis.

Decimals in Elementary Mathematics and Teacher Preparation

Elementary mathematics standards span many topics, including *number concepts*. Number concepts pertain to the structure of the base ten system and its extension to decimal quantities. Number concepts are important because of the ways in which they undergird foundational elementary mathematics such as counting and operations (Association of Mathematics Teacher Educators, 2017; Conference Board of the Mathematical Sciences (CBMS), 2012). Knowledge of decimals, specifically, is also expected of students. In grades 4 and 5 alone, the Common Core State Standards call for students to order, compare, and model decimals (National Governors Association Center for Best Practices, Council of Chief State School Officers, 2010).

Because of their presence in elementary school mathematics, policy documents call for coursework for PTs to also focus on number concepts, including decimals (CBMS, 2012). This call is amplified by empirical research suggesting that children and PTs alike struggle with decimal understanding (e.g., Muir & Livy, 2012, Steinle & Stacey, 1998). Stacey and colleagues (2001) found that some overgeneralizations common among children are much rarer among PTs, but that other misconceptions persist from childhood through to adult populations. Despite knowledge that sense-making around decimals is challenging for PTs, few studies have characterized their understanding. In Kastberg and Morton's (2014) literature review, they identified just three studies since 1998 which attended specifically to PTs' decimal understanding. Broader inclusion criteria uncover a few additional studies with relevant findings, but PTs' decimal understanding and learning processes remain under-researched. The literature does not effectively characterize PTs' understanding of the magnitudes of decimal quantities or explore their reasoning related to comparing decimals.

It is concerning that research on PTs' decimal MKT is so scarce. Without robust images of PT knowledge, mathematics teacher educators may be without the information needed to support PTs' growth. PTs must have deep understanding of decimal concepts and procedures, since this topic is prevalent in upper elementary curriculum, and since their MKT is known to contribute significantly to quality teaching and learning (Hill et al., 2005, 2008). We turn our focus to a brief elaboration on the construct of MKT generally, and a look at how it informs this study.

Mathematical Knowledge for Teaching

MKT includes *subject matter knowledge* and *pedagogical content knowledge* (Ball, Thames, & Phelps, 2008). The former is knowledge which a teacher must have about the mathematics itself, including knowledge which is common among adults, as well as specialized knowledge, needed primarily or exclusively by teachers. Pedagogical content knowledge focuses on the teaching of mathematics. Our participants had the opportunity to demonstrate understanding of the relative sizes of two decimals, and knowledge of how tools for modeling decimals relate to concepts about decimal place value. These are examples of subject matter knowledge; PTs in this study did not have the opportunity to display pedagogical content knowledge.

Conceptual Understanding as Part of Mathematical Proficiency

Given the importance of teachers having robust MKT, policy documents recommend that prospective elementary teachers engage in substantial coursework focusing specifically on elementary mathematics (CBMS, 2012). Studying these concepts at an appropriately deep level for adults who are future educators involves a higher level of connection-making between mathematical ideas than would be expected of elementary students, in part because robust MKT includes knowledge of the *connectedness* of mathematical ideas within and across grade levels. Furthermore, this connection-making is important because it is characteristic of *conceptual understanding*, one of the five "Strands of Mathematical Proficiency" outlined by the National Research Council (2001). Mathematical proficiency requires learners to have *well-connected* knowledge of concepts within a larger body of mathematical knowledge. This conceptual knowledge is, by nature, "rich in relationships" (Hiebert & Lefevre, 1986, p. 3). In our study, we attend to the mathematical connections that participants in our data set do or do not make.

Research Questions

In this study, we pose two main research questions. Following instruction on elementary decimal concepts, (1) what models and other strategies do PTs use to compare two decimal quantities, and to what extent do they use these models appropriately and successfully? (2) What is the nature and quality of PTs' understanding of decimal place value and magnitude, as evidenced by their writing about comparing two decimal quantities?

Methods

Data for this study was collected in the context of the Elementary Mathematics Project (EMP), an NSF-funded project which designs and conducts research surrounding curriculum for use in content courses for prospective elementary teachers. One of EMP's seven instructional units is *Number Concepts*, which focuses on the consistencies of place value structure from large to small (decimal) numbers, as well as on modeling numbers. Regarding decimals, PTs using this curriculum have the opportunity to learn about decimal place value; area, linear, and other models; comparing decimals by place value or by looking at same-sized pieces; and more.

Participants in this pilot study are 28 PTs from two different institutions. Site A was a public community college in the Northwest of the United States. The course instructor at Site A has a doctorate in math education, but her appointment is in the mathematics department; she taught 17 of the 28 participants. Site B was a private four-year college in the Midwest. The instructor has a master's degree in math education but is also housed in a mathematics department. Socio-demographic data was not collected from participants, however, the student body of undergraduate teacher education programs tends to be primarily female, and roughly 19-22 years of age. All participants used the EMP Number Concepts unit, then completed an eight-item, open-ended post-test, designed by the EMP team. We analyzed this item:

> As a future teacher, you may encounter a student who is having difficulty determining which of two decimal values is greater. For example, 0.4 and 0.32.
>
> a) Provide a model that would help a student to think about the sizes of 0.4 and 0.32.
>
> b) Explain how your model would help a student compare these two quantities and which important mathematical ideas it addresses.

We analyzed responses by first open coding all elements of PTs' drawings, writing, and symbols. We did this by examining whether the participant explicitly and correctly identified the larger value, what model they provided and how it was labeled, and what they wrote about. This resulted in 32 codes which together captured PTs' choices of model and the content of their explanations. 100% consensus was achieved between two coders, after discussion.

Preliminary Results

Promising findings from our preliminary analysis include the fact that the majority of PTs explicitly identified the correct quantity as larger (n=20, 71%) and were able to provide one or more models that was accurate and useful for comparing (n=25, 89%). Seven responses were unclear as to whether 0.4 or 0.32 was larger, but only one was explicitly incorrect. Ten PTs provided decimal squares only as a model for comparison, nine provided number lines only, and six gave both. (It is unsurprising that these models were most common, in that these were two of the most prominent models in the EMP curriculum.) Two of the three PTs remaining used place value charts. This reveals that, generally, PTs are able to compare decimals, and to create and interpret models to aid in comparison, following instruction.

Data from this study also uncovered three primary challenges and areas for growth for PTs. First, we found that it seems to be more difficult to use a number line than decimal squares for the purposes of understanding decimal magnitude and relative magnitude. Most decimal squares were proportional and well-labelled, showing the size of each of the two decimal values, relative to a whole, and to each other. PTs' number lines were also generally proportional (80% of 15 number lines) and showed how hundredths could be created by partitioning tenths into tenths (67%). However, many number lines were truncated (67%), often beginning at 0.3, which limited their ability to communicate the magnitude of each of the individual decimal quantities. Furthermore, two of the 15 number lines were partitioned into elevenths instead of tenths, and two were drawn or interpreted "backwards" (smaller numbers to the right); comparable challenges did not emerge for decimal squares. Finally, explicit interpretation of the number lines was rare, just 27% described how their number line should be read and understood, while 63% of PTs who drew decimal squares explained how to interpret their model.

Second, we found that PTs' explanations did not always attend to relevant connections or reasoning, specifically surrounding the representation of 0.4 as 0.40. Of the 28 responses, 11 PTs stated or showed that 0.4 is equivalent to 0.40, or that it is appropriate to "add a zero" to the end of a decimal number. However, only five of these 11 PTs explained why this is true or useful. Though several PTs highlighted this equivalence or stated this "trick" for re-representing the quantity, less than half of those who did so attempted to justify the equivalence, or explain why a learner might find it easier to think of four tenths as forty hundredths. This leaves us uncertain as to the depth of understanding achieved by some of these PTs.

Finally, we found that references to the importance of place value were conspicuously rare. Although PTs had been asked to "Explain how your model would help a student compare these two quantities and which important mathematical ideas it addresses," less than half of the participants mentioned place value as one of these important mathematical ideas. This was highly surprising to us, as we conceive of place value as *the most* important mathematical idea undergirding these models and comparisons.

Discussion

Above, we highlighted the importance of well-connected *conceptual understanding* for both students and teachers. Our findings suggest that, while PTs have notable strengths for completing decimal tasks and using relevant tools to do so, they are less likely to articulate underlying mathematical connections. For example, few PTs in our study connected their models to decimal place value concepts, or their strategies for comparison to reasoning and justification for those strategies. This calls into question whether they have sufficient conceptual understanding to contribute to robust MKT.

A clear vision of PTs' skills and knowledge related to decimal concepts and procedures is useful and necessary for mathematics teacher educators, as they are charged with developing curriculum for use in teacher preparation coursework. We suggest that characterizations such as we have provided here may support these teacher educators in understanding PTs' strengths and needs, a first step in making changes to improve teacher preparation courses.

Next steps for this study include continuing analysis of a larger set of tests from the corpus of EMP data. The 28 tests in this study were selected as a pilot sample, but represent only about 10% of the PT participants who took the EMP unit test during this phase of data collection. We also hope to analyze corresponding pre-tests, to better understand the growth which may have happened as a result of engagement with instruction around decimal concepts. In addition to going broader, we also hope to go deeper by re-examining the types of claims that PTs made about place value in particular and exploring possible connections between these claims and PTs' chosen models. This will empower us to create more robust characterizations of PTs' knowledge of decimal place value concepts and examine the ways in which models may facilitate or demonstrate knowledge development.

In this multiple-case study, we track the diverging paths of two teacher candidates enrolled in an undergraduate elementary mathematics methods course as they developed their understanding of equitable teaching practices that were central to their course learning objectives. The cases were purposefully selected based upon our previous finding that, by the end of the course, Mary and Rose were extreme opposites in terms of their implementation of equitable mathematics teaching practices they attributed to the course. Teacher preparation programs are designed to help beginning teachers develop the skills to teach content equitably to diverse learners. Thus, methods instructors must consider the ways that teacher candidates use their knowledge and skills in their teaching.

Keywords: Instructional activities/practices, equity and diversity, teacher education, pre-service teachers, mathematics education

Amid the complex debates about the nature and purposes of teacher preparation, a critical question pervades: How do we prepare mathematics teachers to enact equitable teaching practices? The authors seek to understand their elementary mathematics methods teacher candidates' understanding and implementation of equitable mathematics teaching practices that are centered in their elementary mathematics methods course by looking deeply at two cases over the course of the semester. One teacher candidate, Mary (pseudonym), implemented equitable mathematics teaching practices that she attributed to learning in the course (via her end of course survey) with 100% fidelity for extended periods of time in her final project video. Another teacher candidate, Rose (pseudonym), implemented a few of the practices. The differences observed in Mary and Rose's final course project videos led us to wonder how two students in the same course and section could finish with such dramatic differences in their level of understanding and implementation of equitable teaching practices.

Related Literature and Framework

This study is rooted in socio-cultural theories that argue that: knowledge is developed and transmitted through social contexts, culture plays a fundamental role in cognition, and knowledge is dependent upon human interactions with each other and the world around us (Crotty, 1998).

Individuals bring their culture to the learning environment, and their culture and knowledge are constructed and reconstructed in the moment-to-moment interactions in the learning environment. With this perspective, classroom contexts provide a space where culture is produced and possibly changed (Nasir & Hand, 2006).

Although our definition of equity and equitable mathematics teaching continues to evolve, in principle it focuses on deliberate efforts to interrupt systems of oppression, harm, racism, and violence as they show up in schools, classrooms, and teaching practices particularly in ways that ensure students have access to learning ambitious mathematics content and learn mathematics in empowering environments that support their development of a positive mathematics identity.

Course Description and Design[1]

The mathematics methods course which catalyzed this study is designed to equip teacher candidates with the instructional skills to develop classroom cultures that enable students from diverse backgrounds to fully participate and learn using a practice-based model[2]. Course resources, targeted reading assignments, and focused class sessions exposed teacher candidates (TCs) to issues of status, equity issues that arise in mathematics classrooms, and effective teaching practices that help mitigate them for diverse learners, including Native American, Latinx and, Black boys.

To understand equity issues affecting Native American, Latinx and, Black boys in mathematics classrooms, our teacher candidates reviewed frameworks and publications by the Smithsonian National Museum (2019) and the National Indian Education Association (2019) to explore local Native American communities, artifacts, and curricular resources; they learned about emergent bilingual Latinx (EBL) supports including allowing students to use their first language, incorporating sentence starters and sentence frames within anchor documents, and attending to the language demands of mathematics lessons (Aguirre et al., 2012; Ahn et al., 2011; Bresser, 2003; Khisty, 2002; Torres-Velasquez & Lobo, 2005, & the Board of Regents of the University of Wisconsin System's WIDA English Development Standards, 2020); and they incorporated supports for mathematics learning and identity development for Black boys (Berry, 2004; Jett et al., 2015).

Methods

This multiple case, follow up study is designed to expand our knowledge of factors that might have influenced Mary and Rose's alignment to and/or divergence from the equitable mathematics teaching practices centrally featured in our elementary mathematics methods course (Seawright & Gerring, 2008). The following research questions guided our study:

1. In what ways do Mary and Rose's elementary mathematics coursework demonstrate their alignment with or divergence from the equitable mathematics teaching practices that were explicitly taught in their elementary mathematics methods course?
2. How does the work produced by Mary and Rose compare to each other, as students enrolled in the same course section who were both placed in internship classrooms with culturally and linguistically diverse students?
3. What might explain this alignment and/or divergence?

Study Participants

This study took place at a large, predominantly white, research-intensive, 4-year university. The two cases were a subset from teacher candidates enrolled in one of three elementary mathematics methods courses during the fall semester of their senior year ($n=55$). Our prior study incorporated a funneling sampling sequence (Erikson, 1986) where nine cases (two of which were Mary and Rose, who are both white and female) were selected for further examination of equitable teaching practices. In that study, Mary had the highest degree of implementation fidelity over an extended period of time, and Rose had the lowest. Thus, we selected these two divergent cases for our current study.

[1] Some of the work and ideas represented in this course, including the title and structure of the major projects are drawn from Math Methods Planning Group at the University of Michigan (under the direction of Dr. Deborah Ball (https://deborahloewenbergball.com).

[2] This course was developed by Dr. Imani Goffney as a part of her NSF grant, Mathematical Knowledge for Equitable Teaching, Award No. 1725551.

Data Sources and Equitable Mathematics Practices

Written materials submitted by Mary and Rose for 3 course projects, assigned at the beginning, middle, and end of the course, provided opportunities to demonstrate their understanding of equitable mathematics teaching practices in their internships and are the primary data sources for this study. The first project was the Student Thinking Project (STP). TCs prepared 2- 3 grade appropriate mathematics tasks and a series of probing questions to elicit student thinking with 2 students selected from their internship. TCs analyzed their own video recordings to explain student selection, and useful strategies in raising and equalizing their students' status. The second project was the Circulating and End of Class Check Project (EOCC). TCs video recorded themselves circulating while students worked independently. They practiced observing, responding to questions, and probing and intervening when appropriate. The final project was Leading a Whole Class Discussion Project (WCD). For this project, TCs video-recorded themselves teaching a mathematics lesson that incorporated a whole class discussion and an end of class check. For their analysis, they identified a 3-5-minute video segment highlighting one equitable mathematics practice covered in the course. They explained their practice selection and identified areas for improvement.

Analytical Techniques

Our qualitative data analysis (Saldaña, 2015) began with deductive coding of Mary and Rose's written projects to identify evidence of equitable teaching practices that were the central focus of the course. Two members of the research team independently coded each of the participants' written submissions for all three projects. Codes were labeled and mapped to the course. Then, the five members of the research team met to review initial codes for each case to ensure inter-rater reliability and to confer on preliminary findings. Next, we drafted analytical memos for each participant. In the second phase of analysis, we independently examined our coded data to identify evidence of each participant's alignment with, or divergence from, the equitable mathematics teaching practices that were the focus of the course. We also examined the relationship between the participants' degree of alignment with course goals across the term. Coded phrases, such as "repositioning a low status student," were secondarily assigned one of two codes: "aligned," as in this teaching practice or description was similar to the equitable teaching practices featured in the course, or "divergent," not aligned with the equitable teaching practices featured in the course. Secondary codes were examined by two members of the research team to ensure at least 80% inter-rater reliability. Once at least 80% inter-rater reliability was confirmed, secondary codes were integrated with our analytical memos to develop the participants' case narratives. Our findings are described in the following section.

Findings and Summary

Mary and Rose began the course with differing levels of understanding of equitable mathematics teaching. Both Rose and Mary's STPs incorporated asset-based language to describe their students and both cases discussed their desire to learn more about their students' thinking through this project. However, 95% of Mary's STP was aligned with the equitable teaching practices taught in the course, while only 61% of Rose's STP was aligned, indicating that she grappled with implementing equitable teaching practices. The most compelling data was the EOCC data. Mary's EOCC and WCD data was 100% aligned with equitable teaching course goals. Rose's EOCC data showed a decrease in alignment with course goals (50%) and a movement toward procedural mathematics instruction. Rose's divergent trend increased on her WCD. She described supporting her students' "math smarts" by acknowledging their correct solutions. Differences in their understanding and implementation of equitable teaching were evident from the first project (STP) to the EOCC.

Tables 1-3: Percentage of Alignment with Course Goals by Participant and Course Project

	Table 1: Student Thinking Project
Rose: 61% aligned	*I think that in order to equalize status issues in the classroom, it is important that students work in a variety of groups. It is important that students are in groups with students as the same abilities as them, but it also equally as important that they work with a variety of students. This way, students are learning from their peers and they are all seen as equals. If students are always in the same group they may realize they are grouped by ability. However, if every once in a while students are working and sharing with a variety of people in the classroom, they will also benefit from others that are on a different level.*
Mary 95% aligned	*To neutralize the status of the groups, I would ask the children to stay within their table groups when discussing answers so one child doesn't always go up to the same person for discussions. Additionally, I would ask students to help their peers by teaching them a skill, not doing it for them. I would want to emphasize group success and the idea that unless everyone is successful, then no one in the group is fully successful. I would set roles within the group so that the children could each have a task to perform.*
	Table 2: Circulating & EOCC Project
Rose: 50% aligned	Exit ticket: Does the problem 6789+987 require regrouping? How do you know? *I hope to learn if students know when it is appropriate to regroup, and if they can explain what regrouping is.*
Mary: 100% aligned	Exit ticket: Miss Smith is preparing materials for the table groups. She puts 4 worksheets in each table group bin. There are 5 table groups. Write an equation or draw a picture to illustrate this problem. *By giving this prompt, I hope to develop a deeper understanding of the students' skills at drawing arrays. The children have been working on this skill for 2 days. However, through completing this project, I noticed that the children still have some confusion about arrays and while they may get the problems correct, they might not always be confident about their answers. This leads me to believe that there could be some confusion about the concept, and I would like to learn more about where this confusion comes from so that I can re-teach the confusing parts.*
	Table 3: Leading a Whole Class Discussion
Rose: 6% aligned	*I chose the first aspect, purposefully using questions to elicit, probe, and connect students' mathematical ideas. I did this during the lesson when I was doing the first problem with my class. After they decided what the single digit number was, and they decided what number was in the ones place, they knew they had to multiply. The numbers were 5 times 2, and with the traditional algorithm this requires regrouping. However, I asked the students "If I wrote the number 10 down instead of regrouping, what method would I be doing?" Students responded by saying that that method is partial products. In this lesson, I also addressed students' math smarts by reaffirming them when they solved problems correctly*
Mary: 100% aligned	*The reason why I chose this skill is because it is important for students to be able to participate in whole class discussions. First, it minimizes status issues because if all students are able to participate in a respectful class discussion, each child's affective filter will naturally be lowered to (hopefully) a level where they are able to participate in the class activity since there will be an environment of respect in the classroom. I chose to practice this skill on this particular day because money is something that almost every child has seen before, but many children don't understand the value of it. So, everyone will be able to contribute to the conversation and it will be engaging because it is a topic that they are probably curious about.*

Discussion and Conclusion

How can two teacher candidates who receive the same content in the same class, with the same instructor, have dramatically different outcomes? One explanation may be mentoring. In her final course project, Mary describes classroom norms like using a positive behavior intervention system, and she reflects on failing to implement two talk moves due to minimal modeling from her mentor. However, Rose does not reflect on existing classroom norms or practices. Therefore, we wonder whether her mentor modeled equitable mathematics instruction and whether Rose may have been constrained by structures in her internship. Another possible explanation is that Rose's personal experiences or beliefs may have prevented her from implementing equitable teaching strategies. We know that our experiences shape our beliefs, biases, and identities. It is possible that Rose's personal beliefs and identities did not align with our course teachings. We know that changes in beliefs occur if equity is deliberately and explicitly implemented throughout teacher preparation. These cases suggest that teacher preparation programs should develop interventions to help TCs demonstrate proficiency for teaching mathematics in equitable ways. Finally, this tells us that novice teachers, even graduates from the same program, will have a wide range of understanding and skills relating to equitable mathematics teaching, so it is essential for school districts to provide induction support.

EXPLORING SHIFTS IN A STUDENT'S GRAPHICAL SHAPE THINKING

Madhavi Vishnubhotla

teop@udel.edu

In this report, we present results from semi-structured clinical interviews with a preservice secondary teacher which were conducted prior to and after a teaching experiment intended to support the student in developing emergent graphical thinking. We illustrate how the student engaged in static shape thinking in the pre-clinical interview to describe relationships represented graphically. In the post-clinical interview, the student used both static and emergent reasoning to describe relationships. Hence, we provide an empirical example of a student developing more sophisticated graphing meanings while underscoring the importance of probing students' shape-based thinking.

Keywords: Algebra and Algebraic Thinking, Preservice Teacher Education

Researchers have shown that graphs represent information and relationships in ways that are difficult to express in other forms (e.g., Arcavi, 2003) and provide insights into students' thinking and learning (e.g., Moore et al., 2014). However, students and teachers experience persistent difficulties creating and interpreting graphs (e.g., Clement, 1989; Leinhardt et al., 1990). For instance, students often treat graphs as literal representations of a situation (e.g., interpreting a time-speed graph of a biker as the bikers' traveled path). The research examining students' graphing meanings indicates common instructional approaches do not provide students sustained opportunities to develop meaningful ways of representing relationships between covarying quantities. These failings may stem from the fact that covariational reasoning is generally absent in U.S. school curricula (Thompson & Carlson, 2017). Hence, in this paper we leverage Moore and Thompson's (2015) construct of graphical shape thinking to explore the research question: Can (and if so how can) a student whose meanings for interpreting graphs are constrained to shape-based thinking reorganize her meanings to include emergent thinking?

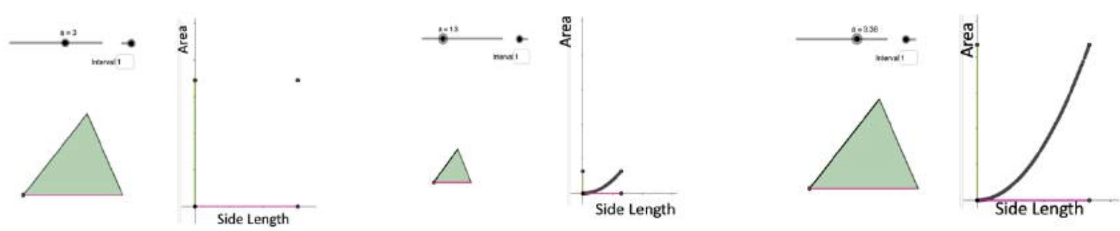
Methods, Participants, and Analysis

This report is situated in a larger teacher experiment (Steffe & Thompson, 2000) that sought to examine two preservice teachers (hereafter students) developing meanings for quadratic and exponential relationships via their covariational reasoning. Here we focus on one student, Josie (pseudonym). Josie was enrolled in a secondary mathematics teacher education program at a large university in the northeast U.S. and had completed a calculus sequence. We present data collected during the clinical interviews prior to and after the teaching experiment to provide insights into Josie's mathematics at the outset of the study and to explore shifts in her meanings at the end of the study. Two members of the research team were present at each interview and each session was video and audio recorded. In order to analyze the data, we used generative and convergent approach (Clement, 2000) in combination with conceptual analysis (Thompson, 2008). With the goal of characterizing Josie's meanings, we used an iterative approach to construct viable models of her meanings and ways of reasoning. During retrospective analysis, we re-watched all interview and teaching sessions to identify instances that provided insights into Josie's static and emergent shape thinking, which we used to develop initial models of Josie's mathematics. We compared these models to researcher notes taken during on-going analysis. When evidence contradicted our initial models, we made new conjectures, including the possibility of shifts in Josie's meanings, and refined our models with the new conjectures in mind. This process resulted in viable characterizations of Josie's mathematics.

Theoretical Perspective: Graphical Shape Thinking

Extending previous characterizations of students' quantitative and covariational reasoning (see Thompson & Carlson, 2017), Moore and colleagues (Moore & Thompson, 2015; Moore, 2016) described two types of *graphical shape thinking* students leverage when constructing or interpreting graphs. Moore and Thompson (2015) characterized static graphical shape thinking as entailing "actions based on perceptual cues and the perceptual shape of a graph" (p. 784). Static shape thinking may include *associations* between the shape of the graph, function name, and analytic rules. For example, a student may associate a parabolic graph (or "U-shape") with the term "quadratic" and a rule of the form "$y = \mathrm{a}x^2 + \mathrm{b}x + \mathrm{c}$". While such associations likely have been productive for a student as she addressed tasks in school mathematics (e.g., shifting 'parent' functions), these associations may not support students when addressing a novel task (e.g., determining a relationship from a data set) or representation (e.g., the polar coordinate system).

Whereas, static shape thinking involves treating a graph as an object, Moore and Thompson (2015) described emergent thinking as a student conceptualizing "a graph *simultaneously* as what is made (a trace) and how it is made (covariation)" (p.784). A student thinking emergently conceives a graph as an in-progress trace representing two covarying quantities magnitudes or values. For example, consider the *Growing Triangle Task* which shows a scalene growing triangle (https://bit.ly/2BjdEKZ). Students are asked to represent the relationship between the triangle's base (in pink) and area (in green). To reason emergently, the student must first construct a coordinate system that represents each quantity on an axis and understand a point in this coordinate system as simultaneously representing both quantities' magnitudes (Figure 4a). The student can then imagine how this point will move in the coordinate system as the triangle's area and side length vary; reasoning emergently entails understanding the graph of the relationship as being produced by the trace of this point as the quantities covary (Figure 1b/c).



(a) (b) (c)

Figure 4. The Growing Triangle Task

Results

In both clinical interviews, we provided Josie two graphs representing quadratic and exponential relationships and asked her to identify the relationship represented by each graph (Figure 5a/b). We hoped to gain insight into Josie's meanings for graphs and her ways of identifying relationships. We also provided tables (e.g., Figure 2c) of values representing quadratic and exponential relationships to explore the connections between Josie's meanings for these relationships in different representations. We note during the teaching episodes, we engaged the students in tasks designed to support their reasoning covariationally and emergently (e.g., the *Ferris Wheel Task* as described by Carlson & Moore, 2012; Moore, 2014). While Josie's activities addressing these tasks was critical to her reorganizing her graphing meanings, we focus on data from the pre- and post-clinical interviews to highlight shifts in her graphical shape thinking for brevity's sake.

Pre-Clinical Interview

When asked to identify the relationship represented by the graph in Figure 5a, Josie claimed:

> It looks like half a parabola, I would say x^2… but I would have to see the other half, definitely to clarify. But it looks like it is going to come back up (*motions as if making a curve to the left of the graph with her hands*)...yeah...It [the graph] doesn't look like, it's, it's… to me if it [the graph] is exponential, they start close to kind of here (*showing the intersection of the axes*), they are closer to zero and shoot up ....so, to me it's [the graph in Figure 2a] half a parabola.

For the graph in Figure 5b, Josie explained, "this one looks like an exponential growth… it started from something very close to zero and then increases very fast. Yeah, that's what I am thinking, it's an exponential growth." We infer Josie leveraged static shape thinking as she determined the relationship represented by each graph. Specifically, she focused on the shape of the graph (e.g. "half a parabola", "started… close to zero and then increases very fast") which she associated with a functional class and analytic rules (e.g. x^2, "exponential growth").

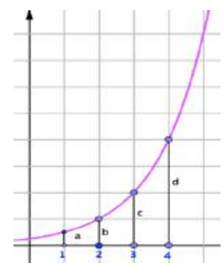
5	75



(a) (b) (c) (d)

Figure 5: A graph representing (a) quadratic and (b) exponential relationship, (c) Table of values representing quadratic relationship, (d) a recreation of Josie's explanation

Although Josie's meanings grounded in static shape thinking supported her in correctly describing that Figure 2a and b represented a quadratic and exponential relationship, respectively, her meanings did not entail a way to describe the same types of relationships represented in a table. For example, after determining several consecutive slopes to determine the relationship in Figure 5c was non-linear, Josie noted "All the y's are multiples of three and it is rapidly increasing, maybe it could be an exponential growth." We infer that Josie's meanings for determining a relationship from a table only supported her in determining if a relationship was linear or non-linear; one possible explanation for this is that her meanings for non-linear relationships (e.g., quadratic, exponential) entailed mostly shape-based associations.

Post-Clinical Interview

After having multiple opportunities to construct and graphically represent covariational relationships in the teaching experiment, we engaged Josie in the post-clinical interview 6 weeks after the last teaching episode. Addressing the same problems in Figure 2, she initially engaged in static shape thinking as she relied on visual properties of the curve. However, in this case Josie was able to unpack her thinking via her covariational and emergent reasoning to make claims about the relationships represented by each graph and table. For example, for Figure 5a, Josie first responded, "[the graph] looks quadratic… it is increasing and something like that is either exponential or quadratic or cubic." She further described, "it looks like half a parabola" and making hand motions as if drawing a parabolic curve to the left of the vertical axis explained, "then it would be a parabola and it would be a quadratic." However, Josie then claimed, "let's see if the amounts of amounts of change are the same" and determined two points, (1,2) and (3,8), on the curve, and calculated the differences in the y-coordinates as 6. She said, "if I knew the next one point, I could check if the amounts of amounts of change are same and it would be quadratic" and concluded, "but it looks like a quadratic and I am going to say quadratic." Hence, Josie's meanings now entailed that a graph represents quadratic change if the amounts of change of amounts of change are constant, a defining characteristic of quadratic change.

As a second example of Josie unpacking her static shape thinking, consider her response when determining the relationship represented by the graph in Figure 5b. She first claimed the relationship as exponential because the graph "is starting off slow and then shoots up." After this, she imagined points on the horizontal axis and motioned as if drawing vertical distances from these points to the graph (see Figure 5d for a recreation of her hand motions) and described, "for equal changes in the x's", and motioning her fingers on imaginary segments as seen in Figure 5d "like from 1 to 2 we are not increasing... maybe a half, but 2 to 3 we are increasing maybe by a one, 3 to 4 we are increasing by a two maybe, that is a little more and so on and so forth, and then it increases by more. So, definitely I am going to say it is exponential." In each case, rather than being constrained by making shape-based associations, Josie's meanings for interpreting graphs (and tables, like Figure 5c) now included being able to unpack a graph in terms of the relationship between covarying quantities (e.g., constant second differences for quadratic, increasing by amounts that themselves increase by a factor of two for exponential).

Discussion

In this report, we characterize a student's static and emergent shape thinking before and after a teaching experiment designed to support her in developing meanings for graphs as emergent traces. Addressing our research question, the student was able to reorganize her shape-based meanings for interpreting graphs to meanings that entailed interpreting graphs according to the underlying covariational relationships they represented. We conjecture the numerous opportunities Josie had to reason about and represent relationships between covarying quantities in the teaching experiment supported her in moving beyond static shape thinking.

Second, and addressing the "and if so how" part of the research question, we note how Josie's meanings for interpreting graphs included elements that appeared static in the post-interview. For instance, she continued to use shape-based associations, which is not surprising as these associations can still be useful in determining the relationship represented by a graph. However, as she justified her choice, Josie was able to unpack the graph in terms of the relationship represented by the covarying quantities, which is indicative of her emergent shape thinking. Hence, Josie's activity highlights how a student may still use shape-based meanings while being able to unpack these meanings in terms of the underlying relationship. This underscores the importance of researchers carefully attending to students' graphing meanings. A student engaging in shape-based activity does not mean they are constrained to such reasoning; it is important to examine if the student can unpack their thinking further.

EXPLORING PRESERVICE TEACHERS' PEDAGOGICAL CONTENT KNOWLEDGE OF TEACHING FRACTIONS

Maryam Zolfaghari

Teachers' pedagogical content knowledge (PCK) influences their instruction and, by consequence, their children's opportunities to learn better. Within the domain of fractions, items assessing PCK are nested within larger assessments, with little explicit focus on the PCK domain. We report on the development and initial validity argument for a PCK for Fractions assessment that assesses preservice teachers' (PSTs') knowledge of students' fractional reasoning. Results suggest the assessment can differentiate between PSTs of different levels in their teacher education program, and that items appear to assess the intended construct. Implications for future study, and for how PCK may develop among PSTs is discussed.

Keywords: Teacher Knowledge; Number Concepts and Operations

Teachers' professional knowledge influences their instruction and, as a result, their students' mathematical learning (Hill et al., 2008a; Hill et al., 2008b). Within mathematics education, such professional knowledge is described by Ball et al. (2008) as Mathematical Knowledge for Teaching (MKT), with a pragmatic distinction between content knowledge (CK) and pedagogical content knowledge (PCK). Although both domains are considered essential, there are relatively few measures of teachers' PCK (Copur-Gencturk et al., 2019; Hill et al., 2008a). Copur-Gencturk et al. (2019) note that many items designed to assess PCK may be better described as CK items both at a theoretical and statistical level. We conjecture that one potential reason for such misalignment of PCK items is due to the nature of the overarching assessments themselves. Rather, by designing an MKT assessment that measures both CK and PCK, there is a risk of unintentionally overemphasizing elements of CK and underrepresenting elements of PCK (Copur-Gencturk et al., 2019).

In the current paper, we report on efforts to design and pilot an assessment of preservice teachers' (PSTs) PCK for teaching fractions in grades 3-5. Current measures of PCK for fractions tend to situate such items as part of an overarching MKT assessment (Depaepe et al., 2015; Kazemi & Rafiepour, 2018). Such assessments tend to distinguish CK and PCK items and may align certain items with key elements of PCK. However, many designed PCK items are open responses, which are time-consuming to code. Our own efforts focus on designing closed-response items to allow for less time-consuming coding for practitioners who may use the assessment. Additionally, we chose to initially focus on one element of PCK, knowledge of students' conceptions, and reasonings about fractions. Our intentional narrowed focus allows for a more concerted effort to examine the nature of this subconstruct, as well as aspects of item design that may inform development of measures for additional aspects of PCK. Thus, the purpose of this study is to construct an initial validity argument for a measure of PSTs' PCK for elementary children's reasoning about fractions.

Theoretical Framework

Developing professional knowledge is an essential component of teacher education programs (AMTE, 2017). Such knowledge is distinct from content knowledge and general pedagogical knowledge and it is called pedagogical content knowledge (PCK) (Shulman, 1986). PCK represents essential knowledge for teaching to facilitate student learning of the subject matter. Ball, Hill, and colleagues extended Shulman's work to articulate a framework for Mathematical Knowledge for

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Teaching (MKT) (Hill et al., 2008b). Extending Ball et al.'s (2008) framework, different scholars have examined teachers CK and PCK on various grounds. Herbst and Kosko (2014) developed an instrument to assess high school teachers' mathematical knowledge for teaching geometry (MKT-G). Khakasa & Berger (2016) applied six domains of MKT to categorize secondary school teachers' mathematical knowledge based on their interpretations of open-ended tasks. They found both the amount of experience and quality of experiences affect teachers' MKT (Herbst & Kosko, 2014; Khakasa & Berger, 2016).

Of particular interest in the present study are those analyses of teachers' MKT for fractions. Depaepe and colleagues (2015) compared CK and PCK on rational numbers among secondary and elementary preservice teachers. They found that CK items are generally easier for PSTs to answer correctly than PCK items. Additionally, PSTs' CK scores were considered low, despite taking a course related to teaching rational numbers. Although secondary PSTs significantly outperformed elementary PSTs on CK for rational numbers, there was no observable difference in how both groups scored on PCK for rational numbers. This is an interesting finding, considering that PSTs' CK and PCK scores are positively correlated (Depaepe et al., 2015; Kazemi & Raflepour, 2018). A common assumption in the literature on teacher knowledge is that strong CK is required to have strong PCK (Izsák et al., 2019; Shulman, 1986). However, in comparing professional development approaches for elementary PSTs, Trobst et al. (2018) found that focusing on enhancing CK of PSTs was less effective than focusing specifically on PCK. Collectively, these findings suggest that teachers' PCK for fractions is related to CK for fractions, but growth in PCK stems from a focus on contexts related to the teaching and learning of fractions.

Method

Sample & Measure

Participants included 58 preservice teachers enrolled in a teacher education program in a Midwestern U.S. university. Participants included 47 early childhood education majors (grades Preschool to 3rd, with optional 4^{th} & 5^{th} grade endorsement) and 11 middle childhood education majors (grades 4-9). Each licensure program includes two mathematics methods course and participants were solicited from each course across both programs (31 juniors; 27 seniors).

An initial version of the PCK assessment included 20 questions, which were subjected to cognitive interviews with two experienced elementary math coaches (Karabenick et al., 2007). In the cognitive interviews, we asked two expert teachers to interpret each item and explain their rationale for their responses. Following cognitive interviews, we analyzed responses related to each item. Some items were interpreted as intended and remained unchanged, while others were revised or removed based on participants' responses. The revised PCK assessment included 15 questions; 9 multiple-choice, 5 multiple-response. Figure 1 illustrates an example question including four items (where an item is counted as a singular response, a question may group one or more items). The question was inspired by literature describing children's fraction learning progressions (Battista, 2012; Hackenberg et al., 2016). Each image represents a specific task of teaching that illustrates a scenario in the form of student work (assessing the reasoning of students' shading 2/3 of 12). Items in the assessment followed a similar structure of assessing children's reasoning based on descriptions from the research literature.

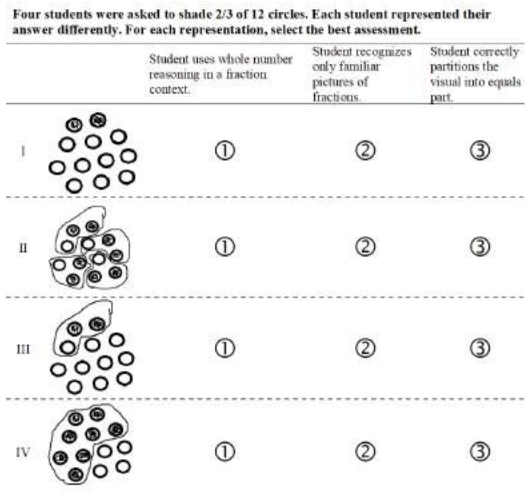

Figure 1: The Example of Item for Measuring PCK-Fractions

Analysis and Results

Analysis of data followed recommendations from the *Standards for Educational and Psychological Testing* (AERA et al., 2014), which states that survey/assessment development should integrate various sources of evidence across multiple studies to construct a validity argument. We collected validity evidence for response processes and test content. Validity evidence of *response processes* focuses on whether participants' responses to our items aligns with the intended theoretical design of the item. In this paper, we conducted a classical item analysis to examine the internal reliability of both the assessment and the items. We also used cognitive interview data to inform decisions on whether certain items should be retained or removed when conducting the item analysis. Evidence for *test content* focuses on how an assessment represents the content and whether scores can be interpreted as intended (AERA et al., 2014). Since our PCK assessment seeks to measure the effect of teacher education initiatives or interventions, we used an independent t-test to compare PCK scores of juniors and seniors as one example of such evidence (considering progress in a teacher education program as the intervention).

The initial item analysis of 30 items resulted in a Cronbach's alpha coefficient of .284. Although the customary threshold for Cronbach's alpha for piloted assessments is typically at or near .70 (Nunnally & Bernstein, 1994), many pilots of successfully validated PCK assessments have tended to report initial Cronbach's alpha coefficients above .60, but somewhat below .70 (e.g., Depaepe et al., 2015; Herbst & Kosko, 2012). Nevertheless, the initial model's reported alpha coefficient was below accepted norms. For each item, we examined point-biserial correlations as an indicator for potential removal. Point-biserial coefficients correlate an item's score (0 or 1) with the total score of the assessment, providing an index of potential fit for the assessment (Crocker & Algina, 2006). It is customary to identify items with point-biserial coefficients below the accepted norm of .30, and consider any interview data, aspects of face validity, etc. before determining whether an item should be removed. Items are removed one-at-a-time and the Cronbach's alpha and point-biserial coefficients are recalculated again.

Our final item analysis model yielded a Cronbach's alpha coefficient of .640. While the majority of remaining items had point-biserial coefficients at or near .30, we chose to retain a subset of items that had lower coefficients (~.20). We retained these items for several key reasons. First, initial pilots of assessments often include smaller samples and may not represent the variance in responses of participants from a larger, more representative sample. As our assessment included PSTs from a single university and no inservice teachers, we believe our sample is unlikely to be representative. Second, although point-biserial and Cronbach's alpha coefficients are useful psychometric indicators, they are but one part of the validity argument for developed measures (Wolf & Smith, 2007). Cognitive interview data for these particular items indicated that they were both interpreted in the manner they were intended and that both responding math coaches considered such content as normative (i.e., these were demonstrated student actions they had seen or seen something similar). Thus, the resulting PCK assessment includes 17 items nested in 7 questions (M=9.48, SD=3.04; *Range* = 4 to 15). Item difficulty ranged from .28 (28% of items answered correctly) to .93 (93% answered correctly), suggesting a wide range in difficulty.

Next, we used an independent samples t-test to compare PCK scores of juniors and seniors in our sample. Results were statistically significant ($t = 2.23$, $df = 56$, $p = .03$), suggesting that PSTs in the sample who were enrolled in their second mathematics methods course had higher scores (M=10.34) than their counterparts enrolled in the first mathematics methods course (M=8.62). This result was still statistically significant for early childhood majors when middle childhood majors were removed from the sample ($t = 1.97$, $df = 45$, $p = .05$), with a similar difference in scores between juniors (M=8.31) and seniors (M=10.00). These results suggest that the PCK assessment distinguishes between PSTs who are earlier and later in their teacher education program.

Discussion

Prior scholars' efforts to construct items assessing PCK are typically open-response and part of MKT measures covering both CK and PCK domains (Depaepe et al., 2015; Kazemi & Rafiepour, 2018; Trobst et al., 2018). Contrasting prior approaches, we sought to develop items exclusively focused on the PCK domain, with particular attention to the knowledge of students' conceptions and reasoning about fractions. The purpose of this study was to construct an initial validity argument for an assessment of PSTs' PCK. Thus, we reported results of a pilot on our assessment that included items on knowledge of students' conceptions and reasonings about fractions, with validity evidence supporting test content and response processes. Results from psychometric analysis, as well as evidence from previously conducted cognitive interviews, supports the claim that our assessment measures teachers' PCK for fractions. Findings from the independent t-test support the claim that our assessment can measure growth due to teacher education initiatives. Although preliminary, the evidence presented in this paper provides a useful baseline for an initial validity argument. Future study is needed to both verify these preliminary findings and to examine other features of validity for such assessments.

This qualitative research had the purpose of identifying the crossroads between the school cultures of secondary school and teacher training institutions in their training practicum. With the teacher's specialized Theory of Knowledge, geometry activities were analyzed. We conclude that geometry in secondary school is linked to shape and measure, while teachers in training struggle to access deductive reasoning. However, the crossroad between geometric reasoning and secondary school is weak, because the mathematical knowledge of the content is not robust.

Keywords: School culture, geometry teaching, cognition, teacher training

Crossroads Between Mathematical Cultures

Basic education schools and teacher training institutions have their own mathematical cultures. In the case of geometry, is the formation of knowledge about its teaching achieved at the crossroad of mathematical cultures?

The phenomenon of crossroads had already been addressed by Engeström, Engeström and Kärkäinen (1995), in order to explain institutional cognition and the construction of symbolic ceilings in cultural communities. For the analysis of the empirical data recovered from the observation of the practicum of future secondary school mathematics teachers, this research uses the Mathematics Teacher's Specialized Knowledge (MTSK) (Carrillo et al., 2018), as it addresses an analytical model of the teacher's knowledge in an integral way for all its dimensions. Furthermore, it is a methodological tool that helps analyze the practices and knowledge of future mathematics teachers, and identifies the construction at the crossroad.

Conclusion: crossroads as a condition of teacher training

The professional practice of the future teacher goes beyond the classroom, as it is a favorable context for the exploration of specialized knowledge. In addition, it allows for the prominence of the figure of the student as a knowing subject to decrease, which gives way for the process of learning itself to rise as the protagonist of a teaching activity.

The analysis of the initial training context in which this research was developed allowed us to observe important aspects about the future teacher's knowledge linked directly to the transmission process of mathematical knowledge. This allowed us to recognize knowledge within the practice of the future teacher, which was reflected in practical aspects such as the design of tasks. However, the crossroad between such reasoning and secondary school is not consistent, because the mathematical knowledge of the content is weak.

Esta investigación de corte cualitativo tuvo el propósito de identificar el cruce de fronteras entre las culturas escolares de la escuela secundaria y de la institución formadora de docentes, en el prácticum de la formación. Con la Teoría del Conocimiento especializado del profesor, se analizaron actividades de geometría. Se concluye que la geometría en la secundaria está ligada a la figura y la medida, en tanto que los estudiantes para maestro luchan por acceder al razonamiento deductivo. Pero el cruce de frontera del razonamiento geométrico a la escuela secundaria es débil, porque el conocimiento matemático del contenido no es robusto.

Palabras clave: Culturas escolares, enseñanza de la geometría, cognición, formación docente

Los cruces de fronteras entre culturas matemáticas

La escuela de educación básica y la institución formadora de docentes tienen sus propias culturas matemáticas. En el caso de la geometría ¿La conformación de conocimientos sobre su enseñanza se logra en el cruce de fronteras de las culturas de las matemáticas?

El fenómeno de cruce de fronteras ya había sido abordado por Engeström, Engeström Y Kärkäinen (1995), para explicar la cognición institucional y la construcción de techos simbólicos en comunidades culturales. Para el análisis del referente empírico recuperado de la observación del prácticum de futuros maestros de matemáticas de secundaria, esta investigación apunta al Conocimiento Especializado del Profesor de Matemáticas (MTSK) (Carrillo *et al*., 2018), pues aborda un modelo analítico del conocimiento del profesor de manera integral en todas sus dimensiones, y es una herramienta metodológica para analizar las prácticas y el conocimiento del futuro profesor de matemáticas, e identificar la construcción en el cruce de fronteras.

Conclusión: el cruce de fronteras como condición de la formación docente

La práctica profesional del futuro profesor es una actividad que va más allá del aula, es un buen contexto para la exploración del conocimiento especializado, además de perseguir la idea de mostrar menos protagonismo a la figura del estudiante como sujeto cognoscente y más al propio proceso de aprendizaje como protagonista de una actividad docente.

El análisis del contexto de formación inicial en la que se desarrolló esta investigación nos permitió observar aspectos importantes acerca de los conocimientos del futuro profesor ligados directamente a los procesos de transmisión de conocimiento matemático; nos permitió reconocer conocimientos dentro de la práctica del futuro docente, que se reflejaron en aspectos prácticos como el diseño de tareas. Pero el cruce de frontera de dicho razonamiento a la escuela secundaria no es consistente, porque el conocimiento matemático del contenido es débil.

DEVELOPING PROSPECTIVE TEACHERS' REPRESENTATIONAL FLUENCY OF WHOLE NUMBER MULTIPLICATION USING ARRAY REPRESENTATIONS

Keywords: Number Concepts and Operations, Representational Fluency, Teacher Knowledge

Representational fluency, the ability to make "connections among mathematical representations to deepen understanding of mathematics concepts and procedures" is an important aspect of building problem-solving skills (NCTM, 2014, p.10). From our experience teaching mathematics content courses for prospective elementary teachers (PTs), we have found that PTs often struggle to make connections between different models of multiplication, which is supported by prior research (Lo, et al., 2008). To attend to this issue, we designed a series of multiplication tasks (see, Olanoff et al. 2018). In this poster we present findings from our second round of implementation with the goal of deepening PTs' specialized content knowledge of multiplication by fostering representational fluency and connecting representations to sense-making procedures.

Our sequence of tasks started with presenting PTs with an 29 x 23 array grid, followed by subsequent tasks. Our goals for these tasks were for PTs to 1) Utilize the array model to understand that a product can be found by decomposing the array into different regions and combining those regions, 2) Use the strategies of summing and combining in this model to develop the partial products algorithm, 3) Understand the connection between the standard US multiplication algorithm as related to the array model, and (4) Recognize the distributive property as a driving force behind the partial products algorithm. Our analysis showed that we were successful at achieving some of our goals, but that the tasks would require modifications in order to meet others. For example, we found that PTs were successful with breaking the array into different amounts and summing them, but many used chunking that was inefficient, as they did not actually make multiplication easier. In subsequent tasks the PTs were also found to focus on the total number of squares (as 667) in a base-10 representation of the array rather than the connection to the original 29 x 23 grid. In addition, the majority of PTs were unable to create symbolic notations that matched with the way they used the base-10 blocks, indicating that in spite of success with prior tasks they struggled to make the connection between the array model and the standard or partial products algorithms.

Overall, through reflecting on our implementation we learned that we needed to re-consider ways to help PTs focus more explicitly on the two numbers being multiplied in an array, rather than only the total number of units. Additionally, we needed to identify ways to better support them in relating symbolic representations of multiplication to array models, *specifically* to understand how the distributive property manifests itself in the symbolic algorithms (both US standard and partial products) and in the array representations. In our poster, we will share our task sequence, show sample PT strategies and examples that indicated a success in representational fluency and places where PTs struggled.

THE POWER OF CARING AND FUNDS OF KNOWLEDGE IN TEACHER LEARNING

Jessica Davidson
Montclair State University
davidsonj5@montclair.edu

Eileen Fernández, PhD
Montclair State University
fernandeze@montclair.edu

Keywords: Culturally Relevant Pedagogy, Teacher Knowledge, Teacher Education - Preservice

This study honors the premise that teaching mathematics meaningfully for diverse learners includes developing *dispositions* and *practices* that draw on children's "cultural, linguistic, and community-based knowledge" (Turner, Drake, McDuffie, Aguirre, Bartell, & Foote, 2012; p. 68). We propose that supporting practicing and prospective K-6 mathematics teachers (PMTs) as *learners* who utilize their *own* "cultural, linguistic, and community-based knowledge" can authenticate the potential of such opportunities in PMTs' future work with students. In our poster, we describe such a learning experience for Maya (a practicing, pre-school teacher) and Zoe (a poster author, preservice mathematics teacher, and project researcher), two PMTs in a graduate mathematics education course who were tasked with 3D designing and printing a manipulative that would be used with a child in a problem-solving interview.

We utilize *funds of knowledge* to capture the value of "historically accumulated and culturally developed bodies of knowledge and skills" that are deemed essential for human functioning and well-being (Moll, Amanti, Neff, & Gonzalez, 1992; p. 132). Noddings (2010) illuminates how a *relational sense of caring* that is "receptive" to "what the cared-for is feeling" (p. 2) can create an authentic space for sharing funds of knowledge during learning, which occurred when Zoe embraced Maya's experiences growing up in the Dominican Republic (DR).

This case is part of a larger teacher education study to help understand PMTs' knowledge development as they Make manipulatives (blinded). Data includes videos from design sessions and written assignments, *and* the tools, because a manipulative's design reflects the intentions and understandings of the Maker(s) (Pratt & Noss, 2010). Purposeful sampling (Patton, 2002) for an exploratory case study (Yin, 2009) helped us analyze how funds of knowledge connected to the design and use of Maya and Zoe's tool, called *No Más Caídas* (*No More Spills*).

Maya and Zoe hoped No Más Caídas would make counting playful—a trait they viewed as fading from K-6 activities. As Maya articulated anxieties over the intricacies of the design process, Zoe invited her to share her experiences learning mathematics as a child in the DR. At first, Maya was reluctant, deeming her lived experiences as irrelevant, but as the PMTs engaged in and out of class, a *confianza* (mutual trust) (González, Moll, & Amanti, 2005) developed that informed the design of their tool and their learning. For example, they opted for marbles as their counting objects, to connect to the everyday objects children use to count in the DR (like beans and rocks). Also, Maya invited her pre-school age daughter for the final interview with their tool, integrating the funds-of-knowledge focus on family (Moll, et al., 1992). To her delight, Maya discovered her daughter's mathematical capabilities with the tool exceeded her expectations, writing *"trabajando con números más grande a los que ella estaba acostumbrada, más su alegría y dedicación al usar nuestra herramienta favorecio nuestra entrevista."*

Providing PMTs funds-of-knowledge learning opportunities can offer a transitioning vehicle between the teacher education setting and the PMTs' own classrooms. In our poster, we share these and additional funds of knowledge from Maya and Zoe's experiences, relaying their power in the PMTs' learning, and promoting PME-NA's goal to support the "ample diversity of ways of teaching and learning mathematics" (PME-NA, 2020).

Keywords: Instructional Activities and Practices, Equity and Diversity

Educational policy and national reform movements in mathematics education emphasize the importance of drawing on students' resources, fostering students' identities, and attending to power dynamics during instruction (Nasir & de Royston, 2013; NCTM, 2008). This poster shares initial findings from a cross-institutional study of 223 prospective teachers (PTs) enrolled in elementary mathematics methods courses with a focus on how to see students' strengths.

The research question was: *What affordances and challenges arose for PTs as they reflected upon and attempted implementation of pedagogical strategies focused on seeing students' strengths?* Across seven institutions, mathematics teacher educators (MTEs) chose Skinner and colleagues' (2019) *Learning to See Students' Mathematical Strengths* as a common text for their courses because it highlights strengths-based teaching and offers five strategies PTs could enact in their varied PreK-6 field experiences. The text's strategies are (1) trusting students with complex tasks, (2) randomly grouping students, (3) having conversations about smartness in math, (4) noticing power and privilege, and (5) using critical friends to challenge and support you. The strategies were used as a framework to examine specific ways PTs consider and build upon students' mathematical strengths.

Data sources included PTs' written responses to (a) pre-reading questions, (b) post-reading reflection prompts, and (c) reflective questions at the end of the semester. Post-reading prompts included questions that asked PTs to identify which strategy seemed easiest to implement in practice and which might be most difficult. While PTs were not required to implement any of the strategies in their field experiences, at semester end they were asked to specify if they had attempted any strategies and why, and to identify which strategy they might focus on next and why. Data was examined by the MTEs across student, across prompt, and across course, and then cross-intuitionally for prominent themes in PTs' responses.

Initial findings across institutions indicate that trusting students with challenging tasks was perceived as the second-most difficult strategy for PTs to implement yet was also the most attempted strategy during field experiences. Noticing power and privilege had the lowest occurrence of all the strategies, and examination of corresponding qualitative data revealed that PTs may not feel ready or equipped to do this work. Of note is that only one of the 223 PTs responded that they would not consider using any of these strategies in their future practice. The poster explores how PTs discussed each of these strategies, and potential pathways to leverage the affordances of a common text across institutions to support PTs' seeing strengths.

Study Overview and Methods

The UTE model affords secondary mathematics PSTs with the chance to combine their first methods course with an early field experience in a first-year undergraduate mathematics course, learning about teaching strategies while attempting to implement them in the classroom (Author et al., 2019). During the UTE, PSTs plan, execute, and receive feedback as they teach a series of lessons in the undergraduate mathematics course while being supported by mentor teacher educators. PSTs participated in pre- and post-UTE interviews that followed Munter's (2014) protocol for assessing PST's vision for high-quality mathematics instruction (VHQMI). These interviews allow for insights into the experience of these PSTs and reveal evolutions in their shifting beliefs about the role of the teacher in the classroom, the use of mathematical tasks, the nature of classroom discourse, and the level of student engagement. All interviews were transcribed and then analyzed using Munter's (2014) rubric as a guide.

Results

While findings across all four VHQMI categories have been noteworthy, of particular interest to this study has been PST responses that fall into Munter's 'student engagement' category. Codes in this category refer to "non-content-specific characterizations of student behavior", making this category a way to capture PST thoughts that describe a generic vision for the classroom that lack sufficient specificity regarding the role of the teacher, the nature of classroom discourse, or the use of mathematical tasks. Tracking the presence or absence of these generic responses has been helpful in revealing the places where PST visions gain specificity, shifting from the ambiguous to the explicit, from broad sweeping claims to detailed articulations of classroom practice. For example, consider the comparison of a PST's pre-interview answer: "If [the students] are engaged in instruction, I think is a big indicator if they are actually grasping the concept" to the same PST's post-interview answer: "I would pay attention to the types of questions [the teachers] are asking students and how that's eliciting responses." This shift in thinking may suggest an early field experience can promote high-leverage teacher questions as a concrete, specific means of enacting a previously generic vision for student engagement. This study tracks these movements from the generic to the specific, looking for insights into the development of PST thought that might inform our understanding of teacher preparation.

Teacher candidates (TCs) can learn how to teach complex skills when teacher education programs (namely methods courses and field experiences) provide clear and purposeful experiences (Grossman et al., 2009). The following poster describes one such innovation, a complementary field experience called SEE Math (Support and Enrichment Experiences in Math) that is paired with a mathematics methods course. SEE Math aims to support TCs as they learn to teach mathematics through problem solving while promoting equity over multiple iterations with a single child.

The SEE Math program is an extension of the TEACH Math module called "Learning Case Study Module" (Drake et al., 2015; Turner et al., 2012). In the TEACH Math module, TCs conduct a series of interviews with a child about their funds of knowledge and mathematical knowledge through a series of Cognitively Guided Instruction (Carpenter et al., 1999; Carpenter et al., 2015) tasks. The Learning Case Study module is one way in which TC can learn how to elicit children's thinking and make small adjustments to existing curricula in ways that are relevant to children and their lives.

During our eight-week program of SEE Math, TCs are also paired with an elementary-aged student in a case-study setting. TCs learn to craft and implement tasks that promote problem-solving in the context of a case study of a child's thinking while they collect and analyze student data to inform future instructional moves. For example, the TCs conduct a Getting to Know You Interview (as is outlined in the TEACH Math module) and create a Venn Diagram about the connections and individual interests of the TC and the child. The bulk of the SEE Math activities support TCs to leverage existing curricula (such as the book by Kazemi & Hintz, 2014) to adapt tasks and create new tasks in ways that is relevant to their child based on the first interview.

There are multiple culminating outcomes of the program. For the children, SEE Math culminates in a final experience where children and TCs engineer a tower or a catapult out of normal materials found in a home. For the TCs, their experience with SEE Math Program culminates in a mock parent-teacher conference that they conduct with their elementary mathematics teacher at the conclusion of the semester. Examples of student work in the poster will show how SEE Math builds on the TEACH Math module and offers TCs an opportunity to focus on the nuances of children's strengths rather than traditional measure of achievement and skill. In addition to the theoretical foundations of SEE Math, we also intend to include examples of work from the TCs' case studies and experiences from TCs, students, and parents who participated in the program.

PRE-SERVICE ELEMENTARY EDUCATION TEACHERS' SOLUTIONS FOR WORD PROBLEMS: USING STRIP DIAGRAM VS. ALGEBRAIC APPROACH

Melike Kara
Towson University
mkara@towson.edu

Kimberly Corum
Towson University
kcorum@towson.edu

Creating, connecting, and translating multiple representation are "important cognitive processes that lead students to develop robust mathematical understandings" (Huntley, Marcus, Kahan, & Miller, 2007, p. 117). These cognitive processes are also considered to be crucial elements of preservice teachers' (PSTs') pedagogical content knowledge (Dreher, Kuntze, & Lerman, 2016).

In order to investigate PSTs' cognitive processes regarding multiple representations, we collected data from 73 PSTs, who enrolled in a mathematics content course for elementary education majors in Spring 2019. We analyzed PSTs' solutions to an assessment task following seven weeks of instruction related to the use of strip diagrams, double number lines, and algebraic equations to solve problems involving ratio and proportional relationships and word problems (Beckmann, 2014). The PSTs were asked to determine the total number of cookies Bonnie baked when given information about the cookie types (e.g., 1/3 of the cookies were chocolate chip, 1/6 were peanut butter, 1/6 were oatmeal raisin, and 24 were cinnamon) in two ways: using a strip diagram and writing and solving an algebraic equation. We used an error analysis technique (Radatz, 1979) to sort and interpret the responses based on fluency with strip diagram and algebraic solutions. The PSTs who exhibited complete reasoning were able to use both representations and the PSTs who exhibited incomplete reasoning were unable to use at least one of the representations. The preliminary analysis of solutions revealed the following themes in the PSTs' strategies (Table 1).

Table 1: PSTs' Strategies for Solving the Cookie Problem

	Complete Reasoning	Incomplete Reasoning
Strip Diagram	Partitioned a single bar based and labeled parts based on cookie type and fractional amount or quantity	-Drew multiple bars to represent each fractional amount -Did not consider fractional amounts as parts of the same unit -Misinterpreted the unit of fraction
Algebraic Solution	Defined variable as total amount of cookies wrote expressions based on type of cookie in terms of the fraction of the whole	Assumed sum of given amounts equaled the number stated in the problem Considered fractional amounts as numbers rather than representing parts of the unit

Students' identification of the unit of a fraction is related to unitizing mental process (Lamon, 2012). The findings of our analysis indicate that PSTs' unitizing mental processes is a determining factor in their use of representations to solve word problems. No matter which representation the PSTs used, the way they considered the unit or sub-unit amount was the foundational step in their solutions. These results suggest that further studies investigating PSTs' understanding of unitizing related processes within representations can help us prepare instruction that aligns with their understanding path for the mathematical concepts.

DESIGNING PEDAGOGIES OF PRACTICE FOR A CRITICAL PRACTICE-BASED TEACHER EDUCATION

Joshua H. Karr
West Virginia University
jkarr1@mail.wvu.edu

Keywords: Teacher Education – Preservice, Teacher Educators.

The current moment of practice-based teacher education (PBTE) has set out to develop a shared language in the field (Grossman & McDonald, 2008), disrupt the assumption that learning to teach does not require sustained learning (Ball & Cohen, 1999), establish teacher education as an "agent of professional countersocialization" (Ball & Cohen, 1999, p. 6), restructure teacher education's organizational dichotomy between theory and practice (Grossman, Hammerness, & McDonald, 2009), and to do so by learning in, from, and through practice (Ball & Cohen, 1999).

Since the initial call for a turn toward PBTE (Ball & Cohen, 1999), much of the scholarly attention has been on the development of and research on various pedagogies of practice (Grossman et al., 2009) – the vehicles by which practice-based actually becomes practice-based. Reflective of and responding to Grossman, Compton, and colleagues' (2009) finding of the lack of approximations of practice within teacher education, contemporary PBTE researchers and teacher educators intensely focus on the design, facilitation, and outcome of approximations.

Despite this focus, little attention has been paid to the nature of the simplification (Grossman & McDonald, 2008) within approximations of practice. Critiques of the current moment of PBTE have included these simplifications and their ties to a technocratic view of teaching and teacher preparation (Zeichner, 2012). While it may be necessary for these pedagogies to expose TCs to context less complex and authentic than a classroom, what have we lost in the process? Have we compromised preparing teacher candidates to respond to students in adaptive (Hatano & Inagaki, 1986) and culturally responsive ways (Gay, 2002)? Have we marginalized the "social, cultural, political, and situated dimensions of teachers' practices" (Philip et al., 2018, p. 9) and inadvertently worked against education's ultimate goals of equity and justice?

In order to turn the gaze of PBTE toward goals of equity and justice, PBTE must (re)evaluate the structures we have built, with pedagogies of practice being a main focus. Some PBTE scholars (Dutro & Cartun, 2016; Kavanagh, 2017; Kavanagh & Danielson, 2020) have begun to explore the ways in which core practices can become social justice oriented, possible theoretical considerations for such endeavors, and the design and facilitation of pedagogies of practice to serve social justice purposes. Despite these efforts, must is left to accomplish in developing critical practice-based teacher education pedagogies.

In order to further establish a framework of critical PBTE, this poster presentation will provide an initial proposal in the design of various pedagogies of practice through the representation, decomposition, and approximation of discretionary spaces (Ball, 2018). Through discretionary spaces, teacher educators and teacher candidates will investigate moments where teachers have the "discretion either to reproduce unjust and inequitable social patterns or to interrupt those patterns through their embodied activity in the classroom" (Kavanagh & Danielson, 2020, p. 71). These spaces are inherently tied to systems of oppression and inquiry such as race, class, gender, and language. Calling upon these spaces centers the design and investigation of pedagogies at the intersection of the relationship between practice and improvisation and the social, historical, and cultural complexities of teaching.

While orchestrating a whole-class discussion, a teacher draws upon a variety of "moves" (Boerst et al., 2011) to maintain the structure and goals of the discussion. In this paper, we focus on the orienting move of asking students to restate what a peer has said as a means to have an idea made public and mark it as a worthwhile part of the discussion (Chapin et al., 2013. We follow Ghousseini and colleagues (2015) by conceptualizing such moves as *enactment tools*, which "translate abstract conceptual tasks into more concrete steps and objectives" (p. 462), and considering the context, steps, and goals surrounding the move. To facilitate and document the development of adaptive expertise (Hatano & Inagaki, 1986), researchers have centered the use of enactment tools in coached rehearsals (e.g., Ghousseini et al., 2015), leaving more to know about how tool use transitions into more complex settings, such as student teaching. In this work, we address the following research questions: In what ways has a teacher candidate's (TC's) use of the restating tool evolved over time? In what ways has the purpose and goals associated with the restating tool changed?

We focus on one TC ("Diana") who regularly and explicitly "took up" this move in a secondary mathematics methods course and in her student teaching. She used the restating tool in coached rehearsals (e.g., Campbell et al., 2020), scripting tasks (e.g., Baldinger et al., 2018; Campbell et al., 2019), classroom videos from student teaching, and reflected on her use of the tool in interviews. To focus on Diana's evolving use of the restating tool, instances of the tool's use were identified in the data and paired with rationale and contextualization Diana provided for using the tool. Instances underwent open coding and analytic memo writing (Miles et al., 2014), which focused on: (1) the sequence of how the dialogue unfolded, (2) consistencies and changes in the restating tool, and (3) the purposes and goals associated with the tool's use.

Initial findings illustrate Diana's adaptive use of the enactment tool, as well as the purposes associated with its use. Over the course of a year and across contexts, Diana adapted the tool and her enacted sequence based on contextual, mathematical, and social purposes. These purposes included highlighting an important mathematical idea, orienting students to an idea, and positioning students productively in the classroom. Contextual and situational factors across contexts and time also contributed to nuances in the tool's use and purposes in enactment.

We found that TCs can develop adaptive expertise through opportunities to be responsive to students' social and mathematical needs. Such development can be documented by attending to changes in enactment tools—specifically how changes in the sequence and associated goals relate to contextual factors. These findings have implications for the contextualization and authenticity of the design of approximations of practice (Grossman et al., 2009) in teacher education and in research on TC development.

EVALUATION OF A SOFTWARE SOLUTION FOR REFRESHING PRE-SERVICE TEACHERS' MATHEMATICS CONTENT knowledge

Anjali Khirwadkar
Brock University
akhirwadkar@brocku.ca

Steven Khan
Brock University
skkhan@ualberta.ca

Joyce Mgombelo
Brock University
jmgombelo@brocku.ca

Keywords: Mathematical Knowledge for Teaching, Teacher Education – Preservice, Teacher Knowledge

Mathematics has a privileged place in the school curricula. One of the primary concerns of teacher education institutions is to prepare future teachers to take a leadership role in school mathematics education. Wahyu, Mahmudi, and Murdanu (2018) argued that pre-service teachers should have sufficient knowledge of both mathematics and pedagogy to be successful in their teaching career. However, Bowie, Venkat, and Askew (2019) indicated a need for student teachers to revisit primary school mathematics that provides a deep understanding of key mathematical concepts in order to be better prepared for future teaching careers. This poster draws from our 2-year Consecutive B.Ed. program in which students are required to complete an online elevatemymath (EMM) before their mathematics methods course. The EMM was designed as self-paced modules where pre-service teachers first complete a pretest, followed by modules and the post-test. This software solution was implemented in response to elementary pre-service teachers' perceptions about their level of mathematical preparedness and challenge of split attention in attempting to (re)learn elementary mathematics content alongside learning the specific mathematical (pedagogical) knowledge and classroom practices for effective teaching.

We were interested in the perceived value of the online refresher course in pre-service elementary teachers' perceptions of their mathematical preparedness and competence for their methods course in the program. We asked: How do pre-service teachers perceive the value of a software solution for refreshing their mathematics content knowledge? In what ways the software solution was helpful in engaging pre-service teachers in the methods course? and, to what extent was the software solution beneficial for the pre-service teachers in preparing them to teach elementary mathematics? Data was collected using an online questionnaire focusing on the perceived value of the EMM refresher course, pre-service teachers' perception of preparedness for engagement in the methods course, and their perception of preparedness to teach mathematics in the first year. The questions were a mix of quantitative and qualitative open text responses.

Data were analyzed based on emergent themes related to perceived value and perception of preparedness and the percentages of responses. The numerical and free-response (qualitative) data (anonymous) from online surveys (n = 204) over a 2-year period shows a variation in pre-service teachers' perceived value of EMM refresher course and perception of preparedness to teach elementary mathematics. Findings indicate that there was a considerable increase in the depth of knowledge and degree of connectedness of elementary school mathematical concepts after the refresher course. More than 50% of the pre-service teachers felt that the refresher course contributed to positive growth and better prepared them with planning and assessing a mathematics class. Some of the pre-service teachers did express that having a refresher course helped them to some extent during their first teaching practice and the refresher course was a good value for money. For example, one pre-service teacher expressed that "the refresher course helped in revising some concepts, recognizing some areas that needs improvement. Knowing my strengths helped me in moving forward."

PROFESSIONAL TEACHER NOTICING AS EMBODIED ACTIVITY

Karl W. Kosko
Kent State University
kkosko1@kent.edu

Jennifer Heisler
Kent State University
jheisle4@kent.edu

Enrico Gandolfi
Kent State University
egandolf1@kent.edu

Keywords: Embodiment and Gesture; Teacher Knowledge; Technology.

There is growing evidence to suggest that construction of knowledge is an embodied activity (Alibali & Nathan, 2012; Barsalou, 1999; Gallese & Lakoff, 2005). We conjecture that embodied cognition is a useful theoretical lens for explaining teachers' professional noticing. Evidence from eye-tracking studies suggest that experienced secondary teachers process visual events in a recorded classroom more quickly, while preservice teachers (PSTs) scan the room more frequently and with fewer fixations on particular students or events (van den Bogert et al., 2014). More recently, Kosko et al. (2019) observed that differences in where PSTs attended when watching a 360 video of an elementary math lesson coincided with differences in written descriptions of their noticing. 360 video records in a spherical direction, and PSTs can move their head to determine where in the classroom they attend. Given such evidence, we sought to examine further examine the relationship between where PSTs attend in watching 360 video and what they describe in written noticings. To this end, the purpose of this study is to report preliminary evidence supporting a theory of professional noticing as embodied activity.

Participants in this study included four elementary preservice teachers (PSTs) at the beginning of their teacher education coursework (sophomores). Using Oculus Go headsets to record their viewing session, participants watched a 360 video of third-grade students informally explored the Commutative Property. After viewing the video, PSTs wrote what they noticed to be significant moments for the teaching or learning of mathematics. We used Systemic Functional Linguistics (SFL) to examine PSTs' written noticings. SFL examines how grammar functions to convey meaning (Eggins, 2004). In this analysis, we examined how transitive processes conveyed experiential meaning of referents in the grammar. We then examined how this experiential meaning was related to recordings of where PSTs attended in the video. One PST wrote "The teacher **was moving** all around the classroom and he [teacher] **was asking** students to work together…" The first bolded words signify material processes, which corresponded to the PST moving their head to attend to the teacher walking around the classroom at various points. The second bolded words signify a verbal process. Interestingly, the PST did not always visually track the teacher when he was asking questions. Contrasting this example, a second PST, who consistently used material processes but no verbal processes in their written noticings, always looked at the teacher when the teacher was talking. Analysis of these patterns is ongoing, but initial findings suggest PSTs' attending manifests in both auditory and visual means, which are represented in how meaning is conveyed in their written noticings.

As mathematics teacher educators (MTEs), we design methods courses to "provide candidates with tools and frameworks to support a more asset- and resource-based instructional approach focused on students' strengths in learning" (AMTE, 2019, p. 35). Through an asset-based orientation, MTEs can foster preservice teachers (PSTs) ability to view every student as a doer of mathematics, thereby recognizing that *all* students have mathematical strengths (Bannister et al., 2018; Featherstone et al, 2011; Jilk, 2016). PSTs who develop more robust orientations about what it means to do mathematics and by whom, are more likely to question and disrupt any socially-learned deficit orientations they may have about diverse learners (see Celedón-Pattichis et al., 2018). Countering and replacing these orientations among PSTs with cultural and mathematical *asset-based orientations* will require MTEs to better understand how PSTs understand and notice mathematical strengths.

Complex Instruction (CI, Cohen & Lotan, 1997) is an asset-based pedagogical framework, grounded in the recognition that each and every student brings varied and different mathematical strengths and statuses to the classroom. The framework recognizes that during group work, peer's assign competences to one another, impacting who contributes to the groups' thinking and who learns mathematics. Often, the mathematical strengths of a "low-status" student may be ignored or dismissed. CI defines techniques for teachers to disrupt these socially-influenced biases. To enact these techniques, however, PSTs must believe and be able to recognize mathematical strengths in every student.

Our work seeks to answer the following research question, *What distinctions in the quality of mathematical strengths do PSTs notice during a group-worthy task?* To do so, we draw upon the research on teacher noticing aligned with Sherin's (2001) notion of professional vision as the ability to notice and interpret significant features of classroom interactions. Four cohorts of PSTs enrolled in our different teacher preparation programs during their junior or senior methods course engaged in three key activities to learn to consider students' mathematical strengths: (1) read and respond to a CI paper; (2) name strengths in peers after completing a group-worthy task together; and (3) implement the same task with a group of 4–6 middle school students to identify mathematical strengths for every student. Data from PSTs' class artifacts, group recordings, reflection papers across the two sites were analyzed using both holistic and descriptive coding (Saldaña, 2016).

Results indicated that PSTs welcomed the invitation to learn about students' mathematical strengths and were able to identify them in most middle schoolers. Yet, PSTs' noticed qualitatively different types of mathematical and behavioral strengths. In this poster, we present the distinct types of strength-noticing patterns among the PSTs, and their movement towards asset-orientations. Results will be useful for MTEs and further analyses of PSTs' dispositions.

MATHEMATICS IS EVERYWHERE: INTERSECTION OF PST PERCEPTIONS AND NON-MATHEMATICS-EDUCATION FACULTY PERCEPTIONS AND OBSERVABLE ACTIONS

Mary Elizabeth Riley Lloyd
College of Charleston
lloydb@cofc.edu

Keywords: Standards; teacher educators; teacher education- preservice; interdisciplinary studies

Mathematics traditionally has been taught as a discrete set of content areas related to numbers and operations, algebra, geometry, measurement, and data analysis and probability. And, while the National Council of Teachers of Mathematics [NCTM] (2000) has stressed the need for students to make connections between these mathematical content areas, to other disciplines, and to the real world, these connections have been weak. These weak connections are consequential. When students of mathematics do not make these connections, they are limited in their development of mathematical thinking. They may be able to attain procedural fluency, but they are unable to continuously develop conceptual understanding, necessary for the understanding of more abstract mathematical concepts. Without such connections, they do not develop the strategic competence and adaptive reasoning necessary to problem solve successfully. Too, these weak connections perpetuate long-standing cultural beliefs that mathematics is irrelevant to other content areas and/or to the real world.

Within teacher-preparation programs, instruction is frequently given in a discrete fashion in which pre-service teachers [PSTs] receive mathematics instruction from one professor in one class, social-studies instruction from one professor in another class, and so on. This lack of integration among disciplinary methods reinforces the lack of connection that is encouraged in the NCTM and Common Core [CC] process standards for children to become fully proficient in their mathematical thinking. While structurally this discrete division of content appears overt, my suspicion was that most of the non-mathematics-education professors were integrating mathematical practices in their instruction. This assumption guided the study and was confirmed in the triangulated analysis of a three-part, data-collection process of (1) 180 PSTs' alignment of the CC Standards of Mathematical Practices [MSPs] with instructional examples from their non-mathematics education courses (Spring '14 to Spring '18); (2) 19 non-mathematics-teacher educators' survey data on how they use the MSPs in their instruction; and (3) 11 full-class, video-taped observations of two social-studies, two science, two English-and-language-arts, one creative-arts, and one physical-education/health teacher educators who were surveyed (Spring 2018). While PSTs and their non-mathematics education professors initially held exclusive views of their definitions of mathematics and mathematical thinking, project results reveal that even in non-mathematics-focused courses, most of the MSPs are being reinforced.

Overall, the objective of this project is to provide evidence that mathematical thinking occurs everywhere, despite beliefs about its discrete nature. Educators, no matter their disciplinary expertise, can strengthen students' mathematical thinking in meaningful ways. Through a more united front in helping students develop their mathematical thinking, we can strengthen the connections students make between mathematical content areas, other disciplines, and the real world. Only in making these connections will students be able to attain all five strands of mathematical proficiency: conceptual understanding, procedural fluency, strategic competence, adaptive reasoning, and productive dispositions (NRC, 2001).

CREATIVE MATHEMATICAL REASONING AND CONTENT AS AN EVALUATIVE FRAMEWORK FOR PRESERVICE TEACHER EXPERIENCES

Tami S. Martin
Illinois State University
tsmartin@ilstu.edu

Craig J. Cullen
Illinois State University
cjculle@ilstu.edu

Our research focused on developing a profound understanding of fundamental mathematics (PUFM; Ma, 1999) for Preservice Secondary Mathematics Teachers (PSTs). We considered content and reasoning ability. Our research questions were: (a) To what extent does working on a quadratic exploration task engage preservice secondary mathematics students in components of creative mathematical reasoning (CMR; Lithner, 2008)? (b) Which mathematics concepts do preservice secondary mathematics students draw upon while engaged in the task?

Theoretical Perspectives

We used Lithner's (2008) classification of CMR and imitative reasoning (IR) to describe student reasoning. CMR includes a *novel* reasoning sequence, makes use of *plausible* strategies, and has a *mathematical foundation*. Lithner described IR as the "opposite" (p. 256) of CMR.

Methods

In a mathematics content course for third- and fourth-year PSTs focused on the roles of technology in the teaching and learning of mathematics (Cullen, Hertel, & Nickels, 2020), we asked students to explore the effects on the path of the vertex as each parameter in the quadratic standard form, $y = ax^2 + bx + c$, was varied. We video recorded class sessions, coded for CMR and IR (Lithner, 2008), and identification of secondary mathematics curricular concepts.

Results

Throughout the exploration we identified students engaged in CMR with concepts from secondary mathematics. For example, Jared reasoned about the concept of slope and linearity while reasoning about the path traced by the vertex as b was varied. Jared's reasoning was *novel* because he asked himself why the path was linear. Jared's strategy—to purposefully adjust parameter sliders, one at a time—was *plausible* because it allowed him to draw conclusions about the effects of those parameters. Jared's conclusion that the slope depended on b was based on a *mathematical foundation* of what is meant by dependent. Thus, we concluded that Jared's reasoning was an example of CMR that involved consideration of secondary-level mathematical content (e.g., linearity, quadratics, rate of change, loci of points) at a profound level.

Discussion and Conclusions

As we reflect on our PSTs' engagement with the Exploring Quadratics task (Cullen, Hertel, & Nickels, 2020), we learned that the task kept PSTs engaged in CMR (Lithner, 2008) throughout the multi-day exploration. Likewise, the content areas which they drew upon were pertinent to their developing subject matter knowledge (Shulman, 1986) and, because concepts were debated in a way that focused on meaning, rather than from an algorithmic approach, the activity seemed to be supporting the development of PSTs' PUFM (Ma, 1999). As a result, we suggest that analyzing tasks for PST populations looking for CMR as well as in-depth engagement with mathematical content linked to future teaching assignments may serve as a framework for identifying appropriate tasks.

TEXTBOOK USE OF CHILDREN'S THINKING TO SUPPORT PROSPECTIVE ELEMENTARY TEACHERS' GEOMETRIC UNDERSTANDING

Brooke Max
Purdue University
bmax@purdue.edu

Rachael Welder
Texas A&M University
rachael@rachaelwelder.com

Keywords: Post-Secondary Education, Geometry and Geometrical and Spatial Thinking, Teacher Education - Preservice

Researchers have suggested that one way to motivate and support prospective elementary teachers' (PTs) mathematical understanding is through the use of authentic examples of children's mathematical thinking (e.g., *Circles of Caring*, Philipp, 2008). Philipp notes that some PTs may care more about children as whole beings than they care about mathematics. Therefore, integrating how the content directly relates to the teaching and learning of children can offer a way to leverage the care PTs have for children to motivate PTs to care about the mathematics.

Ball and her colleagues (2008) have identified the ability to analyze children's mathematical thinking as a valuable component of Specialized Content Knowledge (SCK), or knowledge unique to teachers of mathematics. However, Max and Amstutz (2019) found that activities related to the content domains of Geometry and Measurement & Data (Conference Board of Mathematical Sciences, 2012) provided fewer opportunities for PTs to develop their SCK.

Therefore, the goal of this study is to investigate the intersection of the Geometry and Measurement & Data content domains with examples of children's mathematical thinking in textbooks currently used in content courses for PTs. For this investigation we focused our analysis on the top three textbooks that US mathematics teacher educators recently reported using (Max & Newton, 2017): Beckmann (2018), Sowder et al. (2017), and Billstein et al. (2020). This poster will report findings and provide examples of children's thinking being utilized in the study of two-dimensional geometric concepts (e.g., shapes, polygons, angles) and measurement (e.g., length, angle size, area). Initial textbook analysis involved identifying instances relating content to the teaching and learning of children and noting the ways in which these instances were being used to support PTs' development of SCK. For example, some samples illustrated children's work in which they had applied a non-traditional method and asked PTs to analyze the validity of the child's thinking.

All three textbooks included practice exercises at the end of some sections that attached names to sample thinking, at times referencing the names as students or by grade level. However, Beckmann (2018) and Sowder et al. (2017) actively used examples of children's thinking throughout their lessons to support PTs' development of content knowledge, specifically SCK. Additional references to children were found in mentions of elementary concepts, content standards, and research conducted with children, prompting consideration of whether these types of connections to the teaching and learning of children might also serve as motivation for PTs.

Future analysis will continue to investigate the ways textbooks used in content courses for PTs reference children and their mathematical thinking as well as the potential impact of these instances on motivating PTs' development of SCK. By revealing and highlighting the integration of connections to the teaching and learning of children in content courses designed for PTs, we hope to support mathematics teacher educators in creating classroom cultures that can leverage the care PTs have for children to motivate PTs to deepen their mathematical understanding in ways that will support the learning of their future students.

USING MULTIPLE STRATEGIES TASKS TO EXPLORE PRE-SERVICE TEACHERS' PERSISTENCE

Amanda Jo Meiners
Northwest Missouri State University
ameiners@nwmissouri.edu

Kyong Mi Choi
University of Virginia
kc9dx@virginia.edu

Dae Hong

dae-hong@uiowa.edu

Keywords: Teacher Education-Preservice, Teacher Educators, Teacher Education-Inservice/Professional Development

This study explored influential factors that affect pre-service teachers' (PSTs) persistence in mathematics learning during professional development (PD). As a part of a larger study, this study was guided by concepts of persistence and mindset - "the core beliefs students have about learning and the change that learners may or may not be conscious of." (Dweck, 2006; p.6) Persistence is an action when students continue to engage in a mathematical task despite facing challenges (Boaler & Staples, 2008). Studies on persistence have focused on students' traits (Cobb, Gresalfi, & Hodge, 2009; Grant & Sonnentag, 2010; Rayneri, Gerber, and Wiley, 2006), while factors that affect students' development of such traits have not been studied.

In mindset interventions, MS has been used as a problem-solving approach, but few have studied how MS fosters a growth mindset (Lynch & Star, 2014). Lynch and Star developed instructions to encourage MS in the student-teacher dialogue. Multiple Strategies (MS) intervention encourages students to use more than one method to solve a math task (Silver, Ghousseini, Gosen, Charalambous, & Strawhun, 2005). This includes teachers' ability to assess which solutions that students came up with should be discussed to encourage students for further inquiry (Stein, Engle, Smith, & Hughes, 2008). However, if teachers are not careful, the instructional can become a "show-and-tell" (Ball, Lubienski, & Mewborn, 2001), and subsequently hinder students' persistence. This led to the research questions of the study: *How do PSTs choose to persist when problem-solving with challenging tasks? How MS-based PD impacts PSTs' persistence in challenging mathematics tasks?*

The study participants are a convenient sample of pre-service K-12 teachers who attended the PD, delivering the MS intervention, an opportunity offered by the College of Education at a large mid-western university. Surveys were used to measure PSTs' to measure mindset (Levy, Stroessner, & Dweck, 1998), and persistence (Duckworth, Peterson, Matthews & Kelly, 2007). Among the PD attendees, PSTs attended at least four sessions out of five total PD sessions. 12 PSTs met this requirement Further qualitative analysis was done among the 12 and six PSTs agreed to participate in follow-up PD interviews.

Analyses of PSTs' cases helped understand PSTs persistence views on the task can be affected by knowing the instructional practice of MS was available through working with peers in a collaborative learning environment. PSTs also appreciated the opportunity to work on challenging tasks with a reminder of the availability of MS during the PD. It was challenging to understand the relationship between PSTs' persistence levels and their views on success or failure, as all demonstrated a high persistence level. Further studies with PSTs with varied persistence will reveal this relationship.

ADVANCING UNDERSTANDING OF EQUITY WITH CASE STUDY DILEMMAS: LESSONS FROM PRESERVICE TEACHERS

Alesia Mickle Moldavan
Fordham University
amoldavan@fordham.edu

Monica Gonzalez
East Carolina University
gonzalezmo18@ecu.edu

Keywords: Teacher Education-Preservice, Instructional Activities and Practices

Recent reform in teacher education looks to understand and support equity initiatives in mathematics education (AMTE, 2017; NCTM, 2000, 2014). These efforts encourage preservice teachers (PTs) to engage in authentic classroom situations that explore equity-based practices by connecting theory and practice (Chao, Murray, & Gutiérrez, 2014; Ching, 2014). PTs can use case studies to reflect on their own teaching experiences and position themselves in scenarios in which they may not be familiar (Redman & Redman, 2007). This study reports on PTs in mathematics methods courses participating in a series of case study dilemmas designed by the researchers to elicit conversations of equity in mathematics education. We examined the following research question: How do PTs engage with case study dilemmas in mathematics methods courses to advance their understanding of equity in teaching mathematics?

We conducted a qualitative case study design that used multiple data sources and referenced Gutiérrez's (2007) equity framework that describes equity as a complex notion in terms of access, achievement, identity, and power. Participants included 43 PTs enrolled in three mathematics methods courses across two universities in the United States. Both courses were structured to introduce equity on the first day of class and address equity-based teaching practices throughout the semester with course readings, activities, and discussions. In planning for the methods courses, we created two case study dilemmas to facilitate equity discussions focused on identifying and challenging assumptions, biases, and stereotypes as well as exploring equity through a lens of fairness. The first dilemma prompted the PTs to examine equity in terms of access and identity by exploring a teacher's response to receiving a new student in her classroom that did not look like her or the rest of her students. The second dilemma, focused on access and achievement, analyzed a teacher's intent to have equitable expectations in the context of a zero-tolerance homework policy. Pre- and post-surveys were collected from the PTs to gain insight into their changed perspectives on equity. The surveys and transcripts of the recorded discussions were coded using in vivo and descriptive coding techniques (Saldaña, 2016).

Participation in the case study dilemmas encouraged the PTs to reflect on their understanding of equity and develop their pedagogical knowledge of equity-based teaching practices. The first dilemma prompted the PTs to examine a teacher's assumptions toward a student. The PTs identified how the assumptions invited marginality and reaffirmed mathematics identity. They also discussed how the assumptions impacted the student's opportunity to learn ambitious mathematics and strategized ways teachers can be proactive in learning students' needs and cultural backgrounds. In the second dilemma, PTs debated what it means to have equitable expectations and how teachers can leverage multiple mathematical competencies using a variety of resources and assessments. Overall, the PTs commented on how they benefited from using the case study dilemmas to make them more aware of their biases and better understand what equity looks like in the mathematics classroom. Recommendations will be shared for using similar instructional activities to equip PTs with the knowledge and skills needed to embed equity-based practices in their professional practice.

Conceptual Perspective and Research Questions

Mason and Spence (1999) state that "awareness of knowing and of not knowing is crucial to successful mathematical thinking" (p. 147). Synthesizing few studies on the topic of not knowing, one may conclude that not knowing is a step to understanding, carrying an important value in learning because from it knowing can follow. In our previous study, we found that students have difficulty externalizing not knowing while solving reasoning tasks (Author, 2019). Taking it further, in this study we are examining the following *research questions*: does the complexity of task relate to students' externalization of not knowing? to what extent students' not knowing is associated with successful problem solving?

Methodology

This study employed quantitative methodology. Pre-service secondary mathematics teachers (N=116) enrolled in a math methods course were selected for the study. The problem solving protocol was used to collect student written work while solving connected algebraic reasoning tasks. The protocol consisted of two instructions: a) solve the given task, and b) describe what you are not-knowing while solving the task. The tasks were designed based on the same concept of weighted average in numerical (task 1), semi-abstract (task 2), and abstract (task 3) contexts. Students' demographics data was also collected including grade point averages in discipline-specific coursework (M-GPA) as well as in pedagogy-related coursework (P-GPA). Each task was graded using the following levels: 1) no solution provided, 2) incorrect solution, 3) partially correct solution, and 4) correct solution. Along with this, students' externalization of not knowing while solving each task was rated using the following levels: 1) ignorance, 2) deflection, 3) non-relational not knowing, and 4) relational not knowing. The data was analyzed using descriptive statistics.

Results

In response to the research question 1, we found that complexity of the task relates to the level of students' externalization of not knowing. More specifically, if the task is too easy (task 1), the correlation between correctness of task and externalization of not knowing is negative $r=-.01$ ($p>.05$). As complexity of the task rises from numerical to semi-abstract level (task 2), the correlation becomes practically significant ($r=.16, p<.10$). However, as the task becomes more complex (task 3) the correlation coefficient decreases in value and significance ($r=.03, p>.05$). Another observation revealed significant correlation between students' externalization of not knowing for tasks 2 and 3 ($r=.53, p<.01$). In response to the research question 2, the study findings showed significant correlation between students' overall successful problem solving on all three tasks and not knowing expressed while solving the tasks ($r=.37, p<.01$). Moreover, students' discipline specific M-GPA was significantly related to their overall problem solving performance ($r=.35, p<.01$) whereas the pedagogy-related P-GPA was significantly associated with students' externalization of not knowing ($r=.28, p<.01$).

The study results might serve as a stepping-stone to further research not knowing, as it may directly link to more effective and efficient student learning.

Spatial reasoning has been identified as a key element not only for learning mathematics, but also other fields related to science, engineering and technology (Gold, et al. 2018; Julià & Antolì, 20016, 2018). Research in this venue has identified some issues, including gender disparities in spatial reasoning abilities and their impact on the gender gap in STEM achievement (Lauer et al., 2019). These differences, however, can be reduced with targeted training (De Castell et al., 2019; Laurer et al., 2019). Such training can start at early years through robotics tasks (Francis et al., 2016; Francis et al., 2017). Teacher education program can be informed by such research results, increasing their focus on spatial reasoning and robotics.

Since 2014, the University of Calgary required all student teachers to complete the course STEM Education which has an emphasis on innovation and transdisciplinary (Preciado et al., 2016). The course involves robotics through exploration and design using Lego EV3 and WeDo kits. We conducted a preliminary study analyzing 20 student teachers' narratives, corresponding to a component of the course, with the purpose of identifying the elements of spatial reasoning involved in the task through the lens of the students.

The literature on spatial reasoning encompasses diverse perspectives including definitions of spatial reasoning (Davis et al., 2015; Ramful, et al. 2016; Zwartjes et al, 2019), spatial skills and spatial habits of mind (Kim & Bednarz, 2013), as well as the framework provided by Francis et al. (2017), developed from utterances of 19 experts in different fields on spatial thinking. We considered this variety of perspectives on spatial reasoning to conduct a deductive thematic analysis (Braun & Clarke, 2006) on the narratives from students' Mars Challenge robotic task (Francis et al., 2019) which requires students to work as a team to build and program a robot that moves different objects to designated areas.

Findings and discussion

From the students' narration on the Mar Challenge regarding the robotics tasks, seven significant aspects of spatial reasoning were identified: Visualization, 2D-3D reasoning, construction process, pattern recognitions, transformation (rotation), scaling, and the design process involved imagining. From this analysis, we can conclude that the task has potential to develop spatial reasoning skills for student teachers, with a potential impact on their future students. Such approach has also the potential to both reduce the gender disparities regarding spatial reasoning through the engagement in robotics tasks and address the need for more people to consider STEM career paths.

The narratives evidenced some impact of the course on student teachers' spatial reasoning in the Mars Robotics task. However, the sample size does not allow a generalization of the results to other students in the program. Therefore, there is a need for the development of a research design that addresses these limitations to explore the impact of the course on students' spatial abilities and describe their learning processes.

METHODOLOGY FOR THE DESIGN OF DIDACTIC SEQUENCES FOR SECONDARY MATHEMATICS IN A TECHNOLOGICAL CONTEXT

METODOLOGÍA PARA EL DISEÑO DE SECUENCIAS DIDÁCTICAS PARA MATEMÁTICA DE SECUNDARIA EN UN CONTEXTO TECNOLÓGICO

In this paper a didactic proposal is presented which consists of a methodology aimed at secondary level mathematics teachers, the aim of this proposal is to provide the teacher with a tool to design teaching sequences in order to take them to the classroom; These designs have the particularity of incorporating digital technology for the development of the sequence and its implementation. The methodology was developed based on the articulation of: the didactic structure of Díaz-Barriga, the teaching method ACODESA of Hitt and the curricular developments of Taba. The methodology has been tested with a group of 11 teachers in a course-workshop of 40 hours, the results obtained were three didactic sequences elaborated by three teams of teachers in a technological context (using Geogebra), where it is perceived that it is possible to design using this methodological proposal, however, teachers presented some difficulties during the process of articulation with technology.

Keywords: Teaching activities and practices, Secondary education, Technology, Teacher training

Introduction

The curriculum of basic education in Mexico points out the importance of teachers being involved in the design of activities or didactic sequences, as part of their practice; however, this task can be complicated for teachers, since their working conditions and prevailing teaching practices have limited their practice to the reproduction of textbook activities, away from the design and planning of teaching.

Careful analysis shows that curricula and study guides do not provide sufficient guidance in order for teachers to design teaching activities. This explains the low production of didactic sequences designed by teachers. Taking into account the absence of specific methodological recommendations for the design of didactic mathematical sequences, the following question arose: how do you structure and evaluate a methodological proposal for the design of didactic sequences of the subject of mathematics from a problem situation with the support of Geogebra software aimed at secondary school teachers? The following specific objectives were derived from this:

1. Establish a didactic structure for the design of sequences.
2. Characterize the type of problem situations, which will be the starting point for each sequence.
3. Determine the role that Geogebra will play in the design of didactic sequences.
4. Develop the methodology and experiment with it by designing didactic sequences.
5. Structure a course-workshop for mathematics teachers to evaluate the methodology.

Theoretical References

1. Elements to structure a didactic sequence

Within our work, the didactic structure of Díaz-Barriga (2013) is used, since it is an appropriate way to organize activities. Also, it rescues some interesting points that should be incorporated in the design. However, the aspects considered by Díaz-Barriga have been modified within this methodological proposal due to the fact that they were adapted to the needs of the mathematical discipline.

2. Teaching method ACODESA

ACODESA was used for the purpose of organizing classroom management and mathematical knowledge. This teaching method proposed by Hitt and Cortés (2009) is divided into 5 stages that take into consideration individual work, teamwork, classroom debate, self-reflection and institutionalization. This method proposes a specific way of carrying out the teaching process and the learning process, highlighting the role that the student should play within the classroom and that the teacher should play through the use of problem situations, where the pupil's task is specified in each of its stages, paying special attention to the representations that are generated during the development of mathematical activity.

3. Methodology to plan a learning unit

Taba (1962) proposes a set of four stages to elaborate what she calls a "teaching-learning unit", of which we have only taken and adapted the stage of generalization, which is considered a crucial stage in the mathematical discipline. This stage is not reflected in other proposals, but here it has been considered important in order to involve the student in activities that allow him to generalize the mathematical concepts discussed in a sequence.

Articulation of the theoretical references used

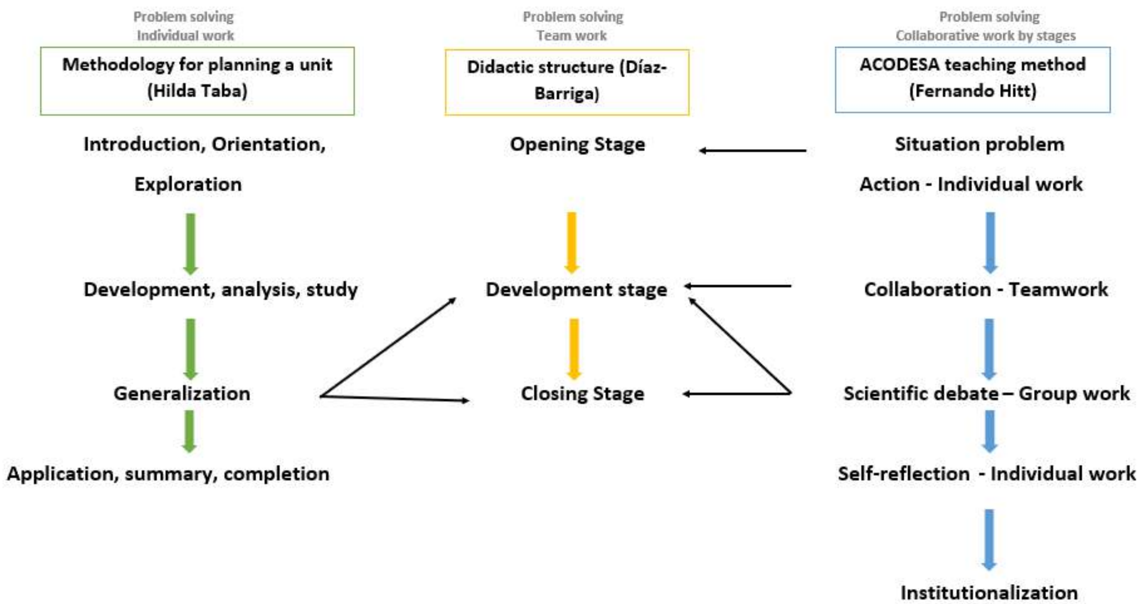

Figure 1: Diagram of the theoretical articulation. Source: own elaboration

Methodological actions

The methodology is qualitative and consists of the following actions.

Phases	Methodological actions
1.- Actions related to specific objective 1	Research of the contributions towards the design of didactic sequences. Characterization of the didactic structure in which the sequence will be broken down, based on the analysis of several didactic structures.

2.- Actions related to specific objective 2	Characterization and elaboration of the problem situations, based on the revision of books, articles and scientific journals related to mathematics.
3. Actions related to specific objective 3	Establishment of the use of Geogebra for the didactic sequence, starting from the review of contributions where technology is used as an educational resource.
4. Actions related to specific objective 4	Elaboration of the design methodology for didactic sequences, based on the articulation of the theoretical references used. Design of didactic sequences based on the methodology developed. Analysis of the didactic sequences designed, taking as reference the characteristics presented by the methodology and analyzing its correspondence with it.
5. Actions related to specific objective 5	Elaboration of the didactic-mathematical reflections, with the purpose of identifying the characteristics that describe the design methodology. Structuring of a course-workshop aimed at mathematics teachers to test the methodology and designs of didactic sequences elaborated. Evaluation of the design methodology, based on the analysis of the products produced in the workshop implemented.
6. Actions related to the general objective	Evaluation of the design methodology based on the general analysis of the workshop.

Table 1: Methodological actions. Source: own elaboration

Characteristics of the methodological proposal

Once the theoretical references were articulated, a methodological proposal was defined with the following characteristics: it is based on a problem situation that does not allude to the mathematics that will be used, contextualized to show the application, meaning and utility of mathematics.

The methodology specifies the objective of each of the elements of the didactic structure (opening, development and closing); the activities and questions in the opening stage are oriented towards the understanding of the problem situation. The development stage involves the mathematical procedures necessary for the resolution of the problem situation. Where it is considered relevant, a stage of generalization is started, with the purpose of extending the applications of mathematical concepts at the development stage. Finally, at the closing stage, the mathematical concepts that have emerged during the resolution of the situation and during the generalization are institutionalized and formalized.

The use of technology is incorporated into the methodology with the aim of linking various contents and putting into play the mathematical thought of the student. Geogebra software is considered to be a powerful tool to reach the proposed goal, since this technology offers the possibility to enrich the discussion on concepts, to diversify problems or exercises and to explore various solution strategies. It also allows the student to explore and visualize the meaning of the relationships between mathematical objects.

The methodology includes specific recommendations for incorporating the use of digital technology, specifically Geogebra, for each stage of the teaching structure. In the opening stage Geogebra is used to build simulations of the problem situation, allowing the exploration of this situation qualitatively. At the stage of development and generalization Geogebra is used to model the problem situation without the context in which it was posed and also to model the generalizations arising during the process of resolution of the situation.

In the closing stage the software is used as a tool to justify the mathematical results arising during the development of the sequence or to propose different solutions strategies to those employed.

The following is an outline of the characteristics described in this proposal:

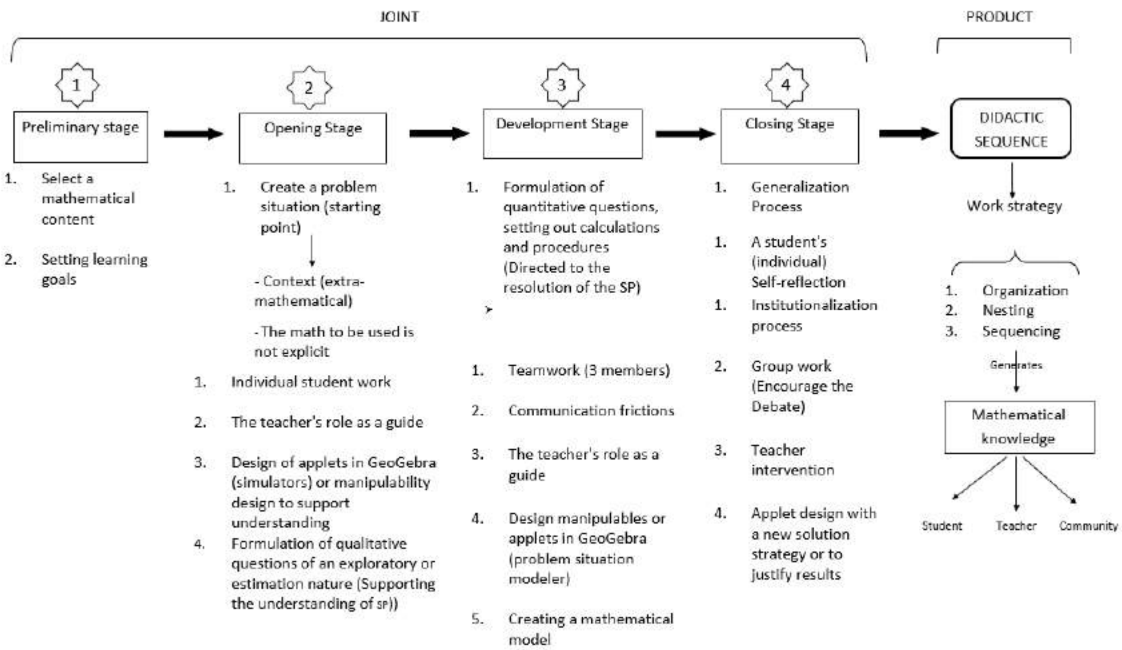

Figure 2: Outline of the methodological proposal developed. Source: own elaboration

Design of didactic sequences using the methodological proposal

Based on the elaborated methodological proposal, three designs of didactic sequences were made, with the intention of testing the methodology and applying them in a course-workshop for teachers. These designs were analyzed a priori to identify if the sequence was able to respond to the characteristics that were established in the methodological proposal elaborated. Once the design of the didactic sequences was completed, the program of a course-workshop for teachers was developed in which the designed sequences were analyzed as a starting point.

Implementation of a course-workshop

In order to involve teachers in the design of didactic sequences, a course-workshop was developed in which 11 mathematics teachers participated, with a duration of 40 hours. The purpose of the workshop was to analyze whether it was possible to design didactic sequences, which would present the characteristics that integrate this methodology. To carry out this workshop-course, three designs of didactic sequences were used, one of them is shown above this section and didactic-mathematical reflections were prepared with the intention that the teacher will identify and become familiar with the elements of the methodological proposal, through reflection on the work carried out in the resolution of the sequences. A bank of problem situations was prepared as well, with the aim of facilitating the task of the participants in the transformation of the situations for the purposes of the present study.

The following activities were carried out: (a) Addressing and analyzing didactic sequences previously designed with the proposed methodology; b) analyzing the proposed methodology based on the didactic sequences discussed and c) designing didactic sequences based on the proposed methodology.

Analysis

The analyses are described below. The tools to collect information were: paper productions of teachers, audio recordings of a work team, field diary (observations during sequence design), video recording of the presentations of the sequences designed and an evaluation format for participants.

Analysis of didactic sequences designed by teachers

The focus was on the products developed by the teachers, to evaluate how they take into account the characteristics of the proposed methodology in the designs built, as well as identifying the purposes they pursue in each of the activities, this with the aim of analyzing the correspondence between the design perspective that the teacher has and the ideas proposed by the instructors in the course-workshop.

A general analysis was made of the way in which the elements of the product are contrasted with the methodology, the coherence between the activities developed with the purposes of the didactic structure, the way in which they suggest organizing work in the classroom and the role of the student and teacher, the use teachers assign to technology in the sequence designed and the level of mathematics used in the product developed by the teacher.

The following is an analysis of a didactic sequence designed by a team of teachers.

Didactic sequence	**Product analysis**
Opening Stage	
Didactic Sequence: The Track **Opening** Figure 1 shows a plane with the official measurements in meters that must have an athletic track for 400-meter flat races. The track has 8 numbered lanes from 1 to 8, we will call here runner 1 the athlete who runs down lane 1, runner 2 to which he runs down lane 2 and so on.  **Individual work** 1. Will all players run the same distance if everyone starts from the finish line and their finish line is also the finish line? Explain your answer. 2. Applet1 shows that it would happen at the first corner of the track if all players exit the finish line at the same time and assuming they all run at the same speed.  3. Write with your words what you observe. 4. Explain why runner 1 is the first to travel the curve if everyone advances at the same speed. **Teamwork** 5. Why do runners, at the start of a race, stand in a staggered row?	The teacher selected a problem situation from the problem bank, however, they adapt the problem situation according to the content they want to promote. An ideal situation would be that the teacher would first be aware of a content and from there conceive a problem situation (Hitt and Quiroz, 2009; Soto, Hitt and Quiroz, 2019). Within the problem situation, the text is devoted to providing information about the image included in such a situation. However, no context is defined that would lead to the formulation of a problem. Motivation is one of the most important points in teaching mathematics (Gravemeijer and Doorman, 1999). By not properly elaborating the problem situation, teachers do not analyze in greater depth what the present mathematics will be. They set out very general questions, rather than asking questions that need to be more in depth, leading to a specific mathematical theme. They requested technical and mathematical support from the instructors in order to carry out their construction, since they had the idea of how the construction should be, but they did not know how to make it in Geogebra. It was not clear to the teachers that the

	construction of applet requires mathematical relationships in the software to be able to capture the intended idea in the activity (Rabardel, 1995). The applet succeeds in playing the role of simulator of the problem situation. The teacher needs to have a greater interaction with the use of software to develop their potential in mathematical tasks. The teacher would have to go through a process of "instrumental genesis" as authors (Rabardel, 1995; Guin and Trouche, 1999) have pointed out.
Stage of development	
Development **Teamwork**  5. Describe the trajectory each runner performs. 6. How would you get the distance a player runs in corners? 7. Calculate the distance that player 1 travels when taking a full turn. 8. Expose to the group as they gained the distance traveled by Player 1. **Individual work** 9. As the width of each lane has an official measurement of 1.22 m, that will be the distance that will separate Corridors 1 and 2. Calculates the distance corridor 2 will travel, if part of the finish line and its finish line is also the finish line. 10. If the start line of Corridor 1 is the finish line, where should the start line of Corridor 2 be located for Corridors 1 and 2 to travel the same distance to reach the finish line? 11. Indicates where each of the other runners (runners 3, 4, 5, 6, 7 and 8) should be located at the start of the race so that everyone travels the same distance when reaching the finish line. 12. I put your findings before the group	The development stage rescues the purposes set out in the proposed methodology. The teachers managed to identify when to introduce the different working modalities with respect to the student's learning purpose. The types of questions show an attempt to involve other mathematical content such as proportionality, but teachers rule out introducing this content and focus on the perimeter. They include teamwork as support to carry out complicated tasks of the didactic sequence, group dialogue to communicate the different representations of the strategies of each team, as well as self-reflection to reinforce what was learned individually from practice (Hitt, Saboya and Cortés, 2017). It does not describe the role that the teacher will have when carrying out these different working modalities in the classroom (Hitt, Saboya and Cortés, 2017). The design does not present an applet within the development stage, because the teachers presented difficulties in making it within the software due to their lack of knowledge about its use and how to represent the image of the track (Rabardel, 1995; Guin and Trouche, 1999; Soto, Hitt and Quiroz 2019).

Closing Stage	
Closing **Individual work** 1. You will be given the drawing of a circumference and its midpoint on a white sheet. Follow the instructions to discover a procedure for calculating the length of a circumference from them. -Plots the diameter of the circumference. -Cut at least four pieces of thread whose length is the measurement of the diameter. -With those pieces of thread surround the circumference, How many pieces of thread did you need to surround the circumference? 2. From what is done expresses a procedure to find the length of the circumference. 3. Look carefully at Applet 2 and answer the following: is the procedure you developed equivalent to the one shown on the Applet? 	The use of manipulatives is promoted, which motivates the student to carry out the activity and allows for the activation of his imagination and his mathematical reasoning (according to the teaching method ACODESA). Generalization is promoted by establishing a formula for calculating the perimeter of the circle. The applet serves to show the results of the activity carried out with the manipulatives. The institutionalization process was a complicated task for teachers since the closure is limited to discovering geometric formulas rather than emphasizing the formalization of the mathematical concepts used (Hitt and Cortés, 2009). This gives us the indication that the teachers do not manage to abstract the mathematics that is broken down in the didactic sequence in order to formalize it.

Table 2: Analysis of the sequence prepared by the team 1. Source: own elaboration.

Analysis of the course-workshop taught

Once the course-workshop was completed, the teachers' perceptions of the methodological elements, the correspondence between the product and the proposed methodology and the didactic sequences elaborated by the teachers were analyzed. From this analysis, he obtained a general idea of the aspects in which it was necessary to devote more time and why, and what the advantages and disadvantages were of having taught the workshop course to teachers in such conditions.

Results and conclusions

The teachers were able to adapt to the proposed methodology based on the experience they gained in dealing with and analyzing the didactic sequences by contrasting them with the methodology; the didactic-mathematical reflections on previously designed sequences allowed them to identify the characteristics of the methodology used for the design.

The workshop course has shown that teachers can apply this methodology to design their own sequences when working in collaboration with other teachers. However, they faced difficulties in institutionalizing the mathematics involved in the sequence and in constructing the applets they proposed in Geogebra.

The problem situations proved to be a challenge for the teacher, it is recommended in a second edition of the course, to open a wider space dedicated to the formulation of problem situations by the participants of the course, on the mathematical topics of their greatest interest.

The methodology was structured by articulating theoretical elements. This was evaluated through the implementation of a course-workshop in which participants managed to design didactic sequences.

The theoretical elements taken from Díaz-Barriga and Taba served as the basis for the design of the didactic structure, however, it was necessary to adapt them according to the specifications that the discipline calls for.

METODOLOGÍA PARA EL DISEÑO DE SECUENCIAS DIDÁCTICAS PARA MATEMÁTICA DE SECUNDARIA EN UN CONTEXTO TECNÓLOGICO

METHODOLOGY FOR THE DESIGN OF DIDACTIC SEQUENCES FOR SECONDARY MATHEMATICS IN A TECHNOLOGICAL CONTEXT

Jamil Fabiola Alvarado Sánchez
Universidad de Sonora
jamilalvarados@gmail.com

José Luis Soto Munguía
Universidad de Sonora
jlsoto@mat.uson.mx

En este trabajo se presenta una propuesta didáctica la cual consiste en una metodología dirigida a docentes de matemáticas de nivel secundaria, el objetivo de dicha propuesta es brindarle al docente una herramienta para elaborar diseños de secuencias didácticas con el fin de llevarlos al aula de clase; estos diseños tienen la particularidad de incorporar tecnología digital para la elaboración de la secuencia y para la implementación de esta. La metodología fue elaborada con base en la articulación de: la estructura didáctica de Díaz- Barriga, el método de enseñanza ACODESA de Hitt y los desarrollos curriculares de Taba. La metodología se ha puesto a prueba con un grupo de 11 docentes en un curso-taller de 40 horas, los resultados obtenidos fueron tres secuencias didácticas elaboradas por tres equipos de docentes en un contexto tecnológico (usando GeoGebra), donde se percibe que es posible realizar diseños aplicando esta propuesta metodológica, sin embargo, los docentes presentaron algunas dificultades durante el proceso de articulación con la tecnología.

Palabras clave: Actividades y prácticas de enseñanza, Educación Secundaria, Tecnología, Capacitación docente

Introducción

El currículo de educación básica en México señala la importancia de que el docente se involucre en el diseño de actividades o secuencias didácticas, como parte de su práctica, sin embargo, esta tarea puede resultar complicada para el docente, puesto que sus condiciones laborales y las practicas docentes predominantes han limitado su práctica a la reproducción de actividades de los libros de texto, alejándolos del diseño y la planeación de la enseñanza.

Un análisis cuidadoso nos muestra que los planes y programas de estudio no proporcionan las orientaciones suficientes para que el docente pueda diseñar actividades de enseñanza. Se explica así la escasa producción de secuencias didácticas diseñadas por los docentes. Tomando en cuenta la ausencia de recomendaciones metodológicas específicas para el diseño de secuencias didácticas matemáticas nuestro objetivo es estructurar y valorar una propuesta metodológica que permita a los docentes de matemáticas diseñar secuencias didácticas con apoyo del software GeoGebra, teniendo como objetivos específicos, los siguientes:

1. Establecer una estructura didáctica para el diseño de las secuencias.
2. Caracterizar el tipo de situaciones problema que serán el punto de partida para cada secuencia.
3. Determinar el papel que jugará GeoGebra dentro del diseño de secuencias didácticas.
4. Elaborar la metodología y experimentarla diseñando secuencias didácticas.
5. Estructurar un curso-taller dirigido a docentes de matemáticas para valorar la metodología.

Referentes teóricos

1. Elementos para estructurar una secuencia didáctica

Dentro de este trabajo se utiliza la estructura didáctica de (Díaz-Barriga, 2013), dado que es una forma apropiada para organizar las actividades y además rescata algunos puntos interesantes por incorporar en el diseño. Sin embargo, los aspectos que considera Díaz-Barriga se han modificado dentro de esta propuesta metodológica por el hecho de que se adaptaron a las necesidades de la disciplina matemática.

2. Método de enseñanza ACODESA

ACODESA se utilizó con el propósito de organizar la gestión dentro del aula y el conocimiento matemático. Este método de enseñanza propuesto por (Hitt y Cortés, 2009) se divide en 5 etapas que toman en consideración el trabajo individual, trabajo en equipo, debate en el aula, la auto-reflexión y la institucionalización. Este método propone una manera específica de cómo llevar a cabo el proceso de enseñanza y el de aprendizaje, resaltando el papel que el alumno debe jugar dentro del aula y el que debe realizar el docente mediante el uso de situaciones problema, donde la tarea del alumno es especifica en cada una de sus etapas, poniendo especial atención a las representaciones que se generan durante el desarrollo de la actividad matemática.

3. Metodología para planificar una unidad de aprendizaje

Taba (1962) propone un conjunto de cuatro etapas para elaborar lo que ella llama una "unidad de enseñanza-aprendizaje", solamente hemos tomado y adaptado, la etapa de *generalización*, la cual se considera una etapa crucial en la disciplina matemática. Esta etapa no se ve reflejada en otras propuestas, pero aquí se ha considerado importante para involucrar al alumno en actividades que le permitan generalizar los conceptos matemáticos discutidos en una secuencia.

Articulación de los referentes teóricos utilizados

Acciones metodológicas

La metodología es de carácter cualitativo y está constituida por las siguientes acciones.

Fases	Acciones metodológicas
1.- Acciones relacionadas con el objetivo específico 1	Investigación de las aportaciones hacia el diseño de secuencias didácticas. Caracterización de la estructura didáctica en la que se desglosará la secuencia, a partir del análisis de varias estructuras didácticas.
2.- Acciones relacionadas con el objetivo específico 2	Caracterización y elaboración de las situaciones problema, a partir de la revisión de libros, artículos y revistas científicas relacionadas con la matemática.
3. Acciones relacionadas con el objetivo específico 3	Establecimiento del uso de GeoGebra para la secuencia didáctica, a partir de la revisión de aportaciones donde se utilice como recurso educativo la tecnología.
4. Acciones relacionadas con el objetivo específico 4	Elaboración de la metodología de diseño para secuencias didácticas, tomando como base la articulación de los referentes teóricos utilizados. Diseño de secuencias didácticas basándose en la metodología elaborada. Análisis de las secuencias didácticas diseñadas, tomando como referencia las características que presenta la metodología y analizando su correspondencia con esta.
5. Acciones relacionadas con el objetivo específico 5	Elaboración de las reflexiones didáctico – matemáticas, con el propósito de que el docente identifique las características que describe la metodología de diseño.

	Estructuración de un curso-taller dirigido a profesores de matemáticas para probar la metodología y diseños de secuencias didácticas elaborados. Valoración de la metodología de diseño, a partir del análisis de los productos elaborados en el curso-taller implementado.
6. Acciones relacionadas con el objetivo general	Valoración de la metodología de diseño a partir del análisis general del curso-taller.

Tabla 1: Acciones metodológicas. Fuente: elaboración propia

Características de la propuesta metodológica elaborada

Una vez realizada la articulación de los referentes teóricos, se ha dado forma a una propuesta metodológica que presenta las siguientes características: se parte de una situación problema que no hace alusión a la matemática que será utilizada, contextualizada en la medida de lo posible para mostrar la aplicación, significado y utilidad de la matemática.

La metodología especifica el objetivo de cada uno de los elementos de la estructura didáctica (apertura, desarrollo y cierre); las actividades y preguntas en la apertura están orientadas hacia la comprensión de la situación problema, en el desarrollo se ponen en juego los procedimientos matemáticos necesarios para la resolución de la situación problema; cuando se considera pertinente se abre una etapa de generalización cuyo propósito es la ampliación de las aplicaciones de los conceptos matemáticos en la etapa de desarrollo y por último en el cierre se institucionalizan y formalizan los conceptos matemáticos que han emergido durante la resolución de la situación y durante la generalización.

Se incorpora el uso de tecnología dentro de la metodología con el objetivo de vincular varios contenidos y poner en juego el pensamiento matemático del alumno. Se considera que el software GeoGebra es una herramienta potente para llegar al objetivo propuesto, ya que esta tecnología brinda la posibilidad de enriquecer la discusión sobre los conceptos, de diversificar los problemas o ejercicios y de explorar varias estrategias de solución. Permite además que el alumno explore y visualice el significado de las relaciones entre los objetos matemáticos.

La metodología incluye recomendaciones específicas para incorporar el uso de tecnología digital, específicamente GeoGebra, para cada una de las etapas de la estructura didáctica. En la etapa de apertura GeoGebra se utiliza para construir simulaciones de la situación problema, que permitan explorar esta situación de manera cualitativa, en la etapa de desarrollo y generalización GeoGebra se usa para modelar la situación problema desprovista del contexto en el que se planteó y para modelar también las generalizaciones surgidas durante el proceso de resolución de la situación. En la etapa de cierre el software se usa como herramienta para justificar los resultados matemáticos surgidos durante el desarrollo de la secuencia o bien para plantear estrategias de solución diferentes a las empleadas.

Diseño de secuencias didácticas aplicando la propuesta metodológica

Con base en la propuesta metodológica elaborada se realizaron tres diseños de secuencias didácticas, con la intención de poner a prueba la metodología y aplicarlas en un curso-taller para docentes. Estos diseños fueron analizados a priori para identificar si la secuencia lograba responder a las características que se establecieron en la propuesta metodológica elaborada. Una vez concluido el diseño de las secuencias didácticas se elaboró el programa de un curso-taller para docentes en el cual las secuencias diseñadas se analizaron como punto de partida.

Implementación de un curso-taller

Con el propósito de involucrar a los docentes en el diseño de secuencias didácticas, se elaboró un curso-taller en el cual participaron 11 docentes de matemáticas, con una duración de 40 horas. La finalidad del curso-taller fue analizar si era posible elaborar diseños de secuencias didácticas, los cuales presentaran las características que integran esta metodología. Para llevar a cabo este curso-taller, se utilizaron tres diseños de secuencias didácticas, una de ellas se muestra arriba de este apartado y se elaboraron reflexiones didáctico – matemáticas con la intención de que el docente identificará y se familiarizará con los elementos de la propuesta metodológica, a través de la reflexión del trabajo realizado en la resolución de las secuencias.; así como también se elaboró un banco de situaciones problema, con el propósito de facilitar la tarea a los participantes en la transformación de las situaciones para los fines del presente estudio.

Las actividades realizadas fueron las siguientes: a) Abordar y analizar secuencias didácticas previamente diseñadas con la metodología propuesta, b) analizar la metodología propuesta tomando como referencia las secuencias didácticas discutidas y c) diseñar secuencias didácticas a partir de la metodología propuesta.

Análisis

A continuación, se describen los análisis que se realizaron. Las herramientas para recolectar la información fueron: producciones en papel de los docentes, grabaciones de audio a un equipo de trabajo, diario de campo (observaciones durante el diseño de secuencias), grabación de video a las exposiciones de las secuencias diseñadas y un formato de evaluación para los participantes.

Análisis de las secuencias didácticas diseñadas por los docentes

Se tomaron como foco de atención los productos elaborados por los docentes, para evaluar la forma en que toman en cuenta las características de la metodología propuesta en los diseños construidos, así como también se identificaron los propósitos que persiguen en cada una de las actividades, esto con la finalidad de analizar la correspondencia entre la perspectiva de diseño que tiene el docente y las ideas propuestas por los instructores en el curso-taller.

Se analizó de manera general la forma en que se contrastan los elementos del producto con la metodología, la coherencia entre las actividades elaboradas con los propósitos de la estructura didáctica, la forma en que sugieren organizar el trabajo en el aula y el papel que presenta el alumno y docente, el uso que le asignan los docentes a la tecnología en la secuencia diseñada y el nivel de matemática que se utiliza en el producto elaborado por el docente.

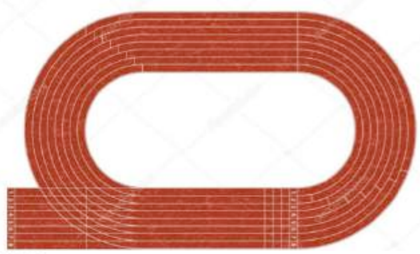
A continuación, se muestra el análisis de una secuencia didáctica diseñada por un equipo de docentes.

<table>
<tr><th>Secuencia didáctica</th><th>Análisis del producto</th></tr>
<tr><th colspan="2">Etapa de Apertura</th></tr>
<tr><td>

Secuencia Didáctica: La pista

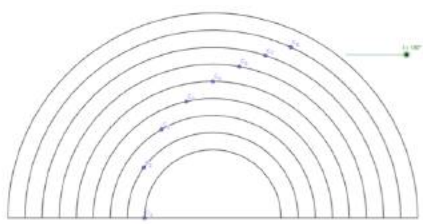
Apertura

En la figura 1 se muestra un plano con las medidas oficiales en metros que debe tener una pista de atletismo para carreras de 400 metros planos. La pista tiene 8 carriles numerados del 1 al 8, llamaremos aquí corredor 1 al atleta que corre por el carril 1, corredor 2 al que corre por el carril 2 y así sucesivamente.



Trabajo individual

1. ¿Correrán todos los jugadores la misma distancia si todos parten de la línea de meta y su línea de llegada es también la línea de meta? Explica tu respuesta.
2. El applet1 muestra que sucedería en la primera curva de la pista si todos los jugadores salen de la línea de meta al mismo tiempo y suponiendo que todos corren a la misma velocidad.



3. Escribe con tus palabras lo que observas.
4. Explica por qué el corredor 1 es el primero en recorrer la curva si todos avanzan a la misma velocidad.

Trabajo en equipos

5. ¿Por qué los corredores, al inicio de una carrera, se ubican en una fila escalonada?

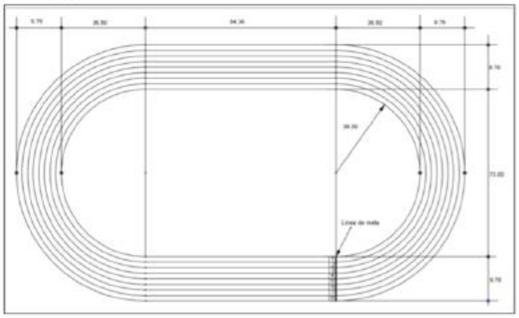
</td><td>

El docente seleccionó una situación problema del banco de situaciones problema, sin embargo, adaptan la situación problema acorde al contenido que desean promover. Una situación ideal sería que primero el docente fuera consciente de un contenido y a partir de ahí concebir una situación problema (Hitt y Quiroz, 2009; Soto, Hitt y Quiroz, 2019). Dentro de la situación problema, el texto se dedica a dar información acerca de la imagen incluida en tal situación. Sin embargo, no se define un contexto que dé pie a la formulación de un problema. La motivación es uno de los puntos más importantes en la enseñanza de las matemáticas (Gravemeijer y Doorman, 1999). Al no elaborar apropiadamente la situación problema, los docentes no analizan con mayor profundidad cuál será la matemática presente. Establecen preguntas muy generales, en lugar de plantear cuestionamientos que necesiten de mayor profundidad, que vayan conduciendo hacia una temática matemática específica. Solicitaron apoyo técnico y matemático de los instructores para realizar la construcción, dado que ellos tenían la idea de cómo podría ser la construcción, pero desconocían como elaborarla en GeoGebra.

Los docentes no tenían claro que la construcción de un applet requiere establecer relaciones matemáticas en el software para poder plasmar la idea pretendida en la actividad (Rabardel, 1995). El applet logra cumplir con el papel de simulador de la situación problema.

El docente necesita tener una mayor interacción con el uso de softwares para desarrollar su potencial en las tareas matemáticas. Precisamente el docente tendría que pasar por un proceso de "*génesis instrumental"* como lo han señalado autores como (Rabardel, 1995; Guin y Trouche, 1999).

</td></tr>
</table>

<table>
<tr><th colspan="2">Etapa de Desarrollo</th></tr>
<tr><td>
Desarrollo
Trabajo en equipos


5. Describan la trayectoria que realiza cada corredor.
6. ¿Cómo obtendrían la distancia que corre un jugador en las curvas?
7. Calculen la distancia que recorre el jugador 1 al dar una vuelta completa.
8. Expongan ante el grupo como obtuvieron la distancia recorrida por el jugador 1.
Trabajo individual
9. Como el ancho de cada carril tiene una medida oficial de 1.22 m, ésa será la distancia que separará a los Corredores 1 y 2. Calcula la distancia que recorrerá el Corredor 2, si parte de la línea de meta y su línea de llegada es también la línea de meta.
10. Si la línea de salida del Corredor 1 es la línea de meta, ¿dónde deberá ubicarse la línea de salida del Corredor 2 para que los Corredores 1 y 2 recorran la misma distancia para llegar a la meta?
11. Indica dónde deberán ubicarse, al inicio de la carrera, cada uno de los otros corredores (corredores 3, 4, 5, 6, 7 y 8) para que todos recorran la misma distancia al llegar a la meta.
12. Expón ante el grupo tus conclusiones
</td><td>
La etapa de desarrollo rescata los propósitos que se establecen en la metodología propuesta. Los docentes lograron identificar en qué momento introducir las diferentes modalidades de trabajo con respecto al propósito de aprendizaje del alumno.
Los tipos de preguntas muestran un intento de involucrar otros contenidos matemáticos como la proporcionalidad, pero los docentes descartan introducir este contenido y se enfocan en el perímetro.
Incluyen el trabajo en equipo como apoyo para llevar a cabo tareas complicadas de la secuencia didáctica, y al mismo tiempo el diálogo grupal para comunicar las diferentes representaciones de las estrategias de cada equipo, así como la autorreflexión para reforzar lo aprendido de manera individual a partir de la práctica (Hitt, Saboya y Cortés, 2017).
No se describe el papel que el docente tendrá al momento de llevar a cabo en el aula estas diferentes modalidades de trabajo (Hitt, Saboya y Cortés, 2017).
El diseño no presenta un applet dentro de la etapa de desarrollo, dado que los docentes presentaron dificultades para poder realizarlo dentro del software por falta de conocimiento acerca de su uso y de cómo representar la imagen de la pista (Rabardel, 1995; Guin y Trouche, 1999; Soto, Hitt y Quiroz 2019).
</td></tr>
<tr><th colspan="2">Etapa de Cierre</th></tr>
<tr><td>
Cierre
Trabajo individual
1. Se te entregará el dibujo de una circunferencia y su punto medio en una hoja blanca.
Sigue las instrucciones para que a partir de ellas descubras un procedimiento para calcular la longitud de una circunferencia.
-Traza el diámetro de la circunferencia.
-Corta al menos cuatro trozos de hilo cuya longitud sea la medida del diámetro.
-Con esos trozos de hilo rodea la circunferencia,
¿Cuántos trozos de hilo necesitaste para rodear completamente la circunferencia?
2. A partir de lo realizado expresa un procedimiento para encontrar la longitud de la circunferencia.
3. Observa cuidadosamente el Applet 2 y responde lo siguiente: ¿el procedimiento que desarrollaste es equivalente al mostrado en el Applet?
</td><td>
Se promueve el uso de manipulatives, lo cual motiva al alumno a realizar la actividad y permite activar su imaginación y su razonamiento matemático (de acuerdo con el método de enseñanza ACODESA).
Se promueve la generalización a partir del establecimiento de una fórmula que permita calcular el perímetro del círculo. El applet sirve para mostrar los resultados de la actividad realizada con los manipulatives.
El proceso de institucionalización fue una tarea complicada para los docentes dado que el cierre se limita a descubrir fórmulas geométricas en lugar de enfatizar la formalización de los conceptos matemáticos utilizados (Hitt y Cortés, 2009). Esto nos indica que los docentes no logran abstraer la
</td></tr>

	matemática que se desglosa en la secuencia didáctica para formalizarla.

Tabla 2: análisis de la secuencia elaborada por el equipo 1. Fuente: elaboración propia.

Análisis del curso-taller impartido

Una vez culminado el curso-taller, se analizaron las percepciones de los profesores sobre los elementos metodológicos, la correspondencia entre el producto y la metodología propuesta y las secuencias didácticas elaboradas por los profesores. A partir de este análisis obtuvo una idea general sobre cuáles fueron los aspectos en los cuales se requirió dedicarle más tiempo y por qué, y cuáles fueron las ventajas y desventajas de haber impartido en tales condiciones el curso-taller a los docentes.

Resultados y conclusiones

Los docentes lograron adaptarse a la metodología propuesta a partir de la experiencia que obtuvieron al abordar y analizar las secuencias didácticas contrastándolas con la metodología; las reflexiones didáctico-matemáticas sobre las secuencias previamente diseñadas les permitieron identificar las características de la metodología empleada para el diseño.

El curso-taller ha puesto en evidencia que los docentes pueden aplicar esta metodología para diseñar sus propias secuencias cuando trabajan en colaboración con otros docentes, aunque han enfrentado dificultades principalmente a la hora de institucionalizar la matemática involucrada en la secuencia y al construir en GeoGebra los applets propuestos por ellos mismos.

Las situaciones problema resultaron ser un reto para el docente, se recomienda en una segunda edición del curso, se abra un espacio más amplio dedicado a la formulación de situaciones problema por parte de los asistentes al curso, sobre los temas matemáticos de su mayor interés.

La metodología se logró estructurar articulando elementos teóricos, esta fue valorada a través de la implementación de un curso – taller en el que los participantes lograron diseñar secuencias didácticas.

Los elementos teóricos tomados de Díaz-Barriga y Taba sirvieron como base para el diseño de la estructura didáctica, sin embargo, fue necesario adaptarlos de acuerdo con las especificaciones que la disciplina necesita.

We share results of a study on the analytic stances of coaches' and teachers' as they annotated key moments from classroom video of the teacher's lessons. In the analysis, emphasis was on the analytic stances of the coaches and how their annotations related to trends in teachers' annotations. Findings indicate differences in how coaches and teachers noticed across the coaching cycles, suggesting the annotations were influenced by the interactions between the coaches and teachers and the teachers' perceptions of coaching process. As a result of our analysis, we characterized one coach as having a high ratio of questions to suggestions, another as having annotations coded as interpretation, another as having more evaluations and suggestions, and the fourth as having asked more questions. Some teachers mirrored the analytic stance of their coach over time and other teachers shifted their analytic stance in ways that suggest they were responsive to their coach's analytic stance.

Keywords: Middle School Education, Teacher Education, Technology, Annotation, Video

Noticing is a crucial practice for teachers attempting to engage in responsive or ambitious teaching. Noticing is defined as attending to students' thinking, interpreting that thinking, making decisions in response to what they have noticed, and making connections to broader principles of teaching and learning (Jacobs, Lamb, & Philipp, 2010; van Es & Sherin, 2008). Researchers have noticed differences in how novice and expert teachers notice students' mathematical thinking; experts are more likely to notice relevant aspects of student thinking, while novices initially focus on superficial aspects of instruction (van Es & Sherin, 2008; Walkoe, 2015). However, novices improve their noticing as a result of interventions or training (e.g. Huang & Li, 2012; van Es & Sherin, 2008).

Researchers have documented the impact of a number of interventions on teachers' ability to notice student thinking, but coaching as an intervention to influence teacher noticing has not been adequately explored. Coaching is an emerging form of professional development; researchers highlight the impact of coaching on teacher learning and students' mathematical understanding (Gibbons & Cobb, 2017; Kraft, Blazar, & Hogan, 2018). Multiple models for coaching have been used in mathematics education, including instructional coaching (Knight, 2006), student-centered coaching (Sweeney, 2010) and content-focused coaching (West & Staub, 2003). Content-focused coaching emphasizes mathematics content learning goals as an outcome of coaching cycles. In a content-focused coaching model, teachers and coaches meet to plan lesson that is then collaboratively taught. Following the lesson, the coach and teacher meet to debrief the lesson, with attention to the mathematical learning goals of the lesson. Recently, we adapted the content-focused coaching model for an online context (see Author, 2019). We included an asynchronous annotation component in which the coach and teacher recorded written reflections tied to specific moments in the video of the teacher implementing the lesson. Engaging educators in annotating is not new in mathematics education, but annotating video through a coaching cycle is new.

Non-coaching professional development contexts show how interventions influence annotations. Stockero, Rupnow, and Pascoe (2017) engaged secondary prospective teachers in field experience

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

interventions focused on noticing and analyzing video to mark moments that were mathematically important. Similarly, as part of a video club, Walkoe (2015) had teachers tag video where they noticed interesting student algebraic thinking. Findings showed evidence that the annotation process, as part of a larger professional development project, impacted teachers' noticing of students' algebraic thinking. Based on these findings, and our prior experience with annotations (Author, 2019), we engaged coaches and teachers in the process of annotating as part of online content-focused coaching cycles. We focused primarily on the analytic stances of the coaches' annotations, with a secondary focus on the teachers' noticing to illustrate the relationship between the frequency of particular analytic stances for coach-teacher pairs. Van Es and Sherin (2010) define analytic stance as an aspect of noticing to describe *how* noticing occurs. The analytic stance is the way one approaches and analyzes practice through noticing and the process through which they communicate noticing. We answered the following research questions: 1) What analytic stances do coaches assume as they annotate? 2) How do teachers' analytic stances relate to coaches' analytic stances across coaching cycles?

Method

Using a cohort model, we engaged nine coaches and twenty-eight teachers teachers in an intensive two-year professional development model that focused on supporting teachers to engage in ambitious, responsive instruction. For this study, we focus on four coaches and five teachers in the first cohort because they completed four coaching cycles. The four coaches all had experience with a variation of face-to-face content-focused coaching articulated by West and Staub (2003). We explored the analytic stances of the four coaches; we looked for variation in the coaches' stances and the ways that variation had an impact on the nature and evolution of how the teachers reflected on their lessons. We also explored the analytic stances of the teachers in the annotation process to better understand the associative relationships between the annotations of the coaches and teachers.

Participants

Each coach (Alvarez, Lowrey, Bishop, Riess) was highly knowledgeable about mathematics education and mathematics teacher education, with extensive experiences leading professional development opportunities for mathematics teachers. Three of the coaches had more than a decade of mathematics coaching experience. Each coach was partnered with a middle grades mathematics teacher for up to four coaching cycles. Alvarez, Lowrey, and Riess all coached one teacher and Bishop coached two teachers.

Data Collection

Teachers in the project took part in a professional learning model that included three components: a course based on the *5 Practices for Orchestrating Mathematics Discussion*, (Smith & Stein, 2011); demonstration lessons that we termed *teaching labs* (similar to studio model or lesson study, e.g. Fernandez & Yoshida, 2004; Higgins, 2013; TDG, 2010); and online content-focused coaching cycles. During the annotation process, the coach and teacher were each asked to annotate the lesson video of the teacher's own implementation of the collaboratity planed lesson, with the teacher always annotating before the coach. The following prompt was provided to teachers:

> Add your comments, questions, and thoughts to the video segment in Swivl at any points in the video that might be interesting to discuss further. For example, were there any moments that surprised you? (i.e., misconceptions that emerged, strategies that you did not anticipate, struggles/challenges, or any "Ah-ha" moments) Were there particular instances that showed evidence of student thinking? Is there something that you see as you watch the lesson that relates to the goal you set for this coaching cycle?

The coaches were not given specific instructions for how to annotate the videos. The goal for this study was to understand what the teacher and coach noticed from the video, particularly because the video was the coaches' first view of the lesson, as they were not present in person during the lesson. To enter the comments, the coach or teacher paused the video and typed their comments, which were then synced to the video with time-stamps. This allowed the teacher or coach to watch the video and comment on specific moments. The purpose of the coaches' annotations were to spur dialogue for the lesson debrief meeting, so we note that some comments were intended as conversation catalysts and were influenced by what the coach wanted to discuss with the teacher. The unit of analysis for this study was the annotations from the coaches (n=328) and teachers (n=213) as they took part in coaching cycles across a two-year span. The coaches annotations accounted for 60.6% of the total annotations (n=541).

Data Analysis

We considered each annotation a separate data unit for analysis. Given the focus on understanding noticing, we created a codebook with four main categories: subject (who), specificity (general or specific; coded as specific if there is some connection in the annotation) analytic stance (how noticing was communicated), and content (see Figure 1). For the purposes of this paper, we focus on analytic stance. We based our articulation of analytic stance largely on the work of Sherin and van Es (2008) and van Es (2011). Their list of stances included tag, describe, evaluate, interpret, suggest, and question. Based on the literature, we considered the codes of *tag* and *describe* to reflect less advanced noticing and *evaluate* and *interpret* to reflect more advanced noticing because of the attempt to assign a value judgment (evaluate) or provide some meaning (interpret). The code of interpret was assigned when the annotation included an inference to make meaning (e.g. Sherin & van Es, 2009). We consider *suggest* and *question* to be less advanced forms of noticing than evaluate and interpret because the content of suggestions and questions do not necessarily center on something that happened or could be noticed. The code for *tag* was only used in the absence of any other code for analytic stance.

To analyze the annotation data, three researchers met initially and coded a subset of the annotations, representing approximately 10% of the total data set. In this process, the codebook was refined to its current status (Figure 1). Following the finalization of the codebook, the three researchers analyzed another 10% of the data together to ensure consistency with coding. After several rounds of coding to ensure reliability, pair coding commenced with two researchers independently coding all annotations from a given coach-teacher coaching cycle. We calculated Kappa for each coaching pair and the two researchers met to reconcile differences in codes, resulting in final codes for each coach-teacher pair for each coaching cycle. Kappa ranged from 0.63 to 0.70, indicating good to excellent reliability (Landis & Koch, 1977). Following the assignment of codes, we conducted frequency counts related to all codes for the coaches and teachers across coaching cycles. We then conducted frequency counts for the coaches as a group.

Subject			
Teacher		Students(s)	
Teacher		A Student	Group of Students (2+)	Whole Class
Specificity			
General	Specific	General	Specific
Focus on General Teaching Strategies, Pedagogy, Content of a Lesson, Context of a Problem	Focus on a connection between the teacher and another person(s) or aspect (e.g. pedagogical strategies, interactions with others, or students' thinking)	Focus on general actions, aspects, ideas, topics, lesson structure or contextual features (e.g. physical environment, home environment, disposition, behavior, etc.)	Focus on connection between a student and another person(s) or aspect (e.g. his/her mathematical thinking, his/her interactions with others, or specific teaching strategies)

Analytic Stance (How)					
Tag	Describe	Evaluate	Interpret	Suggest	Question
Identify a moment; absence of other codes	Recount or explain event or interaction	Statement with value judgement	Attach or attempt to make meaning; make sense	Offer a suggestion	Pose a question directly to another person watching video

Figure 1. Codebook for Subject, Specificity, Analytic Stance, and Content of annotations.

Results

The analytic stance varied across the coaches. Collectively, the coaches' annotations were coded as evaluation 23.8% of the time, interpretation 21.3% of the time, suggestion 30.2% of the time, and question 42.4% of the time. Table 1 reports the percentages for each analytic stance code for each coach. The codes were not exclusive, as each annotation was coded with as many analytic stance codes as applied.

Table 1. Analytic stance of coaches

	Evaluate	Interpret	Suggest	Question
Alvarez	14.9%	7.5%	10.5%	49.3%
Lowrey	17.6%	48.3%	22.0%	40.7%
Bishop	39.0%	12.7%	46.6%	27.1%
Riess	11.5%	11.5%	32.7%	71.2%

Analysis across coaches reveals differences in the frequency with which we applied the codes of evaluation, interpretation, suggestions, and questions. Alvarez, Lowrey, and Riess were coded as evaluative in approximately 15% of the annotations. In contrast, Bishop was coded as evaluative in 39% of the annotations. Coaches also varied the extent to which they were coded as interpretative. Lowrey was coded as interpretative in 48.3% of the annotations compared to 7.5%, 12.7% and 11.5% for Alvarez, Bishop, and Riess, respectively. There were also differences in the application of the suggestion code, with Alvarez' annotations coded least frequently and Bishop most frequently. Riess's annotations were coded as questions far more than the other coaches. Given the variation in analytic stance across the coaches, we provide profiles of each of the four coaches to illustrate the differences in how coaches annotated, based on what they noticed. We then consider coaches' analytic stances in relation to trends in the analytic stances of the teachers they coached.

Alvarez: High Questioner to Suggestion Ratio

Alvarez had the highest question to suggestion ratio of any of the coaches. By the third and fourth coaching cycles, Alvarez posed questions in nearly 70% of the annotations she wrote. As an example, in one annotation, she wrote:

> How did you decide who to call on? This question gets at the idea of always paying attention to the instructional strategies laid out in the 5 Practices. So even at a "micro share out level", how do you decide who to call on and why? (I think about this a lot in my own practice and there are a variety of answers! The key is to make those decisions as often as possible to support students' thinking and understanding!)

In this example, Alvarez included both a question and a suggestion in the same annotation. She used questioning to prompt the teacher to consider certain aspects of practice and then suggested that the teacher be purposeful when deciding who to call on during discussions.

Over the coaching cycles, the annotations of the teacher Alvarez worked with were increasingly coded as interpretation, although the interpretation code was still infrequently applied. During the first and second coaching cycle, the teacher did not make any interpretations; however, during the third and fourth coaching cycle, 13% of the teacher's annotations included an interpretation. In the third coaching cycle, the teacher wrote, "Students were saying that the dependent variable is being multiplied every time, but they meant that the previous y-value is multiplied by the growth factor to get the next value." In this example, the teacher interpreted by providing an explanation about what students were saying to make meaning from the experience. The data from the annotations matched data from our analysis of the pre- and post-lesson debrief meeting transcripts for conversations between the coach and teacher, in which Alvarez was more likely to elicit information from the teacher than other coaches (Authors, 2019).

Lowrey: High Interpretive

Lowrey's annotations were coded as interpretation 48.3% of the time, a much higher frequency than other coaches. Lowrey also posed questions to the teacher in many of her annotations (40.7%). During the first coaching cycle, Lowrey annotations were coded as interpretation 60.4% of the time. As an example of an interpretation, Lowrey wrote, "How is the independent think time then moving into group talk working for your students? It seems natural for the students to work in this way and I was wondering your take on how it supports student learning." The example was coded as interpretive because Lowrey referenced students having think time and then made meaning of the situation, noting that the process seemed "natural" for the students. In the interpretation, Lowrey described how she made sense of the teaching move with respect to the students. In addition to frequent interpretations, Lowrey asked questions, with the prevalence of questions increasing across the coaching cycles. She included questions such as, "Moving to the back of the room puts the focus on the problem rather than on you. Was this an intentional move? Is it a typical move for you?"

The increased frequency of Lowrey asking questions across the coaching cycles coincided with a decrease in the frequency of annotations of the teacher with whom Lowrey worked. During the first coaching cycle, the teacher wrote 44 annotations. During the second coaching cycle, the teacher wrote three annotations. During this same coaching cycle, Lowrey there was an increase in the number of annotations coded as questions. This increase in asking questions, such as, "Do these partners see the connections between their ideas? Are they working independently or as a partner group?" was evident in the third coaching cycle as well, when the teacher wrote only four annotations. The questions Lowrey wrote often asked about specific aspects of the lesson that may not have been obvious from the lesson video. The increase in Lowrey posing questions suggests Lowrey may have been responding to the teacher's lack of annotations. This raises further questions about the purpose behind Lowrey's increase in questioning and the intentionality of Lowrey's decisions in response to the teacher. Perhaps Lowrey posed questions to the teacher to encourage the teacher to increase the frequency of annotations. Lowrey and the teacher were not able to complete a fourth coaching cycle because of a lack of participation from the teacher.

Bishop: High Evaluation and Suggestion

Bishop's annotations were more frequently coded as evaluations and suggestions. Bishop's annotations were coded as evaluation 39% of the time. As an example, she made statements such as, "I like how you gave these students advance warning that they would be sharing with the whole class. This helps them prepare and feel more comfortable doing so." In this example, Bishop evaluated the teacher's decision to tell students they would be presenting to the whole class. She initiated the annotation with a statement of what she liked and followed up by including text about why that teaching move was important. In addition to including evaluative comments in the annotations, Bishop provided suggestions to the teachers much more often than the other coaches, with 46.6% of the annotations coded as suggestion. The following is a suggestion Bishop provided:

> I noticed that earlier in the video, you read the problem to the class. I was wondering if you might consider using a literacy strategy to introduce the problem to the class. There is a lot of information to deal with in this problem. So, I was wondering if a literacy strategy designed to focus students on all the important information might result in more students (during the individual think time) incorporating the tax into their thinking.

In this example, Bishop made the suggestion to use a literacy strategy to support students. In contrast to Alvarez and Lowrey, Bishop's rate of asking questions was much lower. She asked questions in approximately one-quarter of the annotations.

The annotations of the two teachers with whom Bishop worked both had high numbers of annotations coded as evaluation, with 23.8% of their combined annotations containing some type of evaluation across the four coaching cycles, as compared with approximately 10% of the annotations of the other teachers. At the end of the four coaching cycles, the annotations of both teachers were coded as evaluation at a similar frequency as Bishop, suggesting that the teachers may have followed Bishop's lead to view the lesson videos with an evaluative perspective. Additionally, both teachers and Bishop evaluated the students as well as the teacher. As an example of one teacher providing and evaluation of herself, Parsons wrote, "That was a very thorough explanation!" Bishop regularly included evaluations of the teacher, such as, "Another great move! 'What do you like about ___ answer?' A great assessing question." In this example, Bishop evaluated the assessment question that Parsons included. Evaluations focused on students included text such as, "I loved how they got right into the discussion." Across the four coaching cycles, evaluative comments were frequent for both Bishop and the teachers with whom she worked, which may suggest similarities in how the coach and teachers perceived the annotation process. Analysis of Bishop's coaching debrief meetings show consistent patterns; there was a high percent of conversation dedicated to evaluative comments and direct suggestions for teachers.

Riess: High Questioner

Riess's annotations were coded as questions at a much higher rate than any of the other coaches, more than 70%. Questions included "Do we know if they really understand what the words independent and dependent mean? How could you check for understanding here?" The frequent use of questions was evident across all of the coaching cycles. During the second coaching cycle, Riess included a question in every single annotation she wrote (n=10). The other coaching cycles included frequent questions as well. In addition to posing questions, Riess provided a suggestion to teachers in

32.7% of the annotations. This rate of providing suggestions was not all that different from other coaches, but was the second most common analytic stance associated with Riess's annotations. The frequent use of questioning distinguished Riess from the other coaches.

Interestingly, the two most notable trends across the coaching cycle for the teacher with whom Riess worked related to suggestions and questions. Across the coaching cycles, the teacher reduced the number of suggestions she provided for herself through the annotations and increased the frequency of questions she asked to Riess. Initially, the teacher included comments to suggest to herself what she should have done pedagogically, as compared to what actually transpired. In the first and second coaching cycle, she included suggestions 30.0% and 50.0% of the time. Suggestions included, "Missed connection about 13 and Baker's Dozen; could have asked more questions." In this example, the teacher provided an evaluation and then suggested to herself that she should have made a connection for students and then asked for questions. By the fourth coaching cycle, the teacher did not include any suggestions to herself in the annotations. Instead, in the third and fourth coaching cycles, the frequency of posing questions increased. Questions were written directly to the coach, as a way to ask for input from the coach, most commonly about instructional moves. As an example, the teacher wrote, "When should I have gotten the students more involved? For them to ask clarifying questions or have them restate task expectations?" The teacher sought direct input from the coach on student participation. This type of interaction points to the function of the annotations as a way to initiate conversation prior to the debrief meetings that followed the annotation process. We conjecture that the teacher may have started to write questions to the coach that she wanted answered during the debrief meeting, when the two of them would discuss the lesson.

Discussion and Implications

Annotations were an intermediary for communication that occurred after the teacher's lesson implementation and before the debrief meeting between the coach and teacher as part of online content-focused coaching cycles. Substantive differences existed in how coaches annotated aspects of instruction and learning, meaning how they approached and analyzed practice. Additionally, results show an associative relationship between the analytic stances of coaches and teachers. The analytic stances of the coaches and teachers illustrate aspects of the coach-teacher relationship. The following elaborates on the trends in noticing, with conjectures grounded in research literature to explain the results.

First, the findings of this study highlight the perceived relationship between the coach and teacher, from the teacher perspective. Data from Alvarez and her teacher show stark differences in the analytic stance, with the coach having a high question to suggestion ratio and an absence of the teacher posing direct questions to the coach in any coaching cycle. We conjecture that the teacher had perceived roles for the participants in the coaching process (i.e. coach and teacher) and may have assumed it was the coach's responsibility to pose questions to the teacher, not vice versa. As another example of a perceived relationship, we found evidence in other coaching interactions to suggest that teachers began to annotate in ways similar to coach, in a process similar to enculturation. The situated perspective of the teacher (e.g. Lave & Wenger, 1991), in relationship to the coaching cycles, appears to have influenced the analytic stance of the annotations.

Second, we conjecture that over the coaching cycles, the shift in some teachers' annotations may have been the result of thinking about how the annotation process coordinated with the coaching debrief meetings. Over time, the teacher working with Riess began to ask more questions, directly posed to the coach. It is possible that these questions were intended to be reminding prompts to support the synchronous debrief meeting that would follow the annotation process; over time, we believe the teachers may have recognized the relationship between the constituent parts of the content-focused coaching cycle (i.e. planning meeting, lesson implementation, annotations, debrief meeting) in a way that supported increased integration (i.e. annotations were discussed during the debrief meeting). Further analysis of the coaching debriefing meetings, in coordination with the annotations will allow us to draw substantive claims about this interaction.

Third, we conjecture that coaches used the annotations to be responsive to the teachers beyond the video lesson and debrief process. In the case of Lowrey, the teacher began to show signs of decreased participation in the online professional development project. In turn, Lowrey increased the number of questions she posed directly to the teacher, as a way to elicit reactions from the teacher. It is possible that Lowrey's questions were intended to encourage increased the teacher's participation in the coaching cycles. Interviewing the coaches about their rationales for their annotations will help us understand their annotations.

The focus on analytic stance for both coaches and teachers is important to understand *how* individuals notice within the context of online coaching cycles. Researchers have emphasized the importance of noticing to enact ambitious instruction (Jacobs et al., 2010; van Es & Sherin, 2008). Many researchers have focused on the noticing of particular participant groups, such as prospective teachers (e.g. Roth McDuffie et al., 2014; Schack et al., 2013) or practicing teachers (e.g. van Es & Sherin, 2008), but few have focused on the noticing of individuals with different experience levels as they interact with the same representations of practice. Researchers have shown notable differences in expert and novice noticing (e.g. Huang & Li, 2012); we contend that our study provides data on the interactions of different participants in a way that highlights the importance of coaching to support teachers. Researches have shown that coaching impacts teacher practice (e.g. Gibbons & Cobb, 2017; Kraft et al., 2018; Sailors & Price, 2015), but knowing exactly how coaches approach noticing provides a clearer understanding of how to support both coaches and teachers. As evidenced in the data, the four coaches analytically approached their noticing in very different ways. These findings raise questions about the intentionality with which particular coaches are assigned to work with particular teachers. Perhaps some teachers would respond better to the practices of some coaches over others. Knowing these various trends in coaches' analytic stances and knowing how the teachers interacted with the coaches provides increased understanding for professional developers as they consider coach-teacher pairs and how to support coaches. We encourage others to be aware of the differences in coaches' noticing and recognize the associative relationship that may develop between a particular coach and teacher based on how the two analytically notice.

ARTICULATING EFFECTIVE MIDDLE GRADES INSTRUCTIONAL PRACTICES IN A TEACHER-RESEARCHER ALLIANCE

Joe Champion

One of the most intransigent problems in mathematics education is the culturally-influenced divide between classroom practice and educational research. This paper describes our explicit attempt to bridge that divide by translating research on instructional practices linked to improving students' mathematics achievement into a brief guide outlining constructs, features, strategies, routines, and tools for use in a teacher-researcher alliance. We outline the design and development process, share the guide itself, and summarize data addressing the utility of the guide for a research and professional development project in which 100 U.S. Grades 6-8 teachers are collaborating to improve middle grades modeling and problem solving achievement.

Keywords: instructional activities and practices, teacher education - inservice / professional development, middle school education

The persistent, culturally-situated divide between educational research and teaching practice in school mathematics is well documented (Cai *et al*., 2017). In addition to vastly different contexts and goals, one reason for the teacher-researcher divide arises from communication - researchers and teachers rarely interact as colleagues, researchers typically disseminate findings in ways that foreground abstractions of teaching and learning, and teachers often seek out specific, situated tools for their everyday practice (Labaree, 2003). One area of common ground centers around shared goals among teachers and researchers to generate information about "what works" in particular contexts in hopes they may inform educators in other contexts (Krainer, 2014). An emerging model for nurturing that common ground is to establish a *Teacher-Researcher Alliance for Investigating Learning* [TRAIL] (Koichu & Pinto, 2018). While the TRAIL format addresses many of the challenges of teacher-researcher collaboration, there are few examples in the literature, and none addressing research aimed at investigating instructional methods for improving student mathematics achievement. Recently, we have engaged in an intentional effort to build a U.S. teacher-researcher alliance centered around investigating and articulating effective instructional routines to promote modeling and problem solving achievement among Grades 6-8 students. One of the first efforts within our alliance has been to create a 2-page instructional practices guide that communicates findings from research in ways that support teachers' translation into practice.

The framework we have developed is organized around the constructs of *Explicit Attention to Concepts* (EAC) and *Student Opportunities to Struggle* (SOS) (Hiebert & Grouws, 2007). Hiebert and Grouws (2007) identified EAC and SOS as broad clusters of instructional methods which researchers have linked to increases in student achievement. In this paper, we describe efforts to form a teacher-researcher alliance to further articulate features, strategies, and routines for EAC and SOS instructional practices, with the specific aim of supporting teachers' implementation of these constructs in their classrooms. We emphasize our methods for translating research findings into actionable practices, especially our engagement with 100 teachers as partners in investigations the effectiveness of the associated instructional routines for improving student achievement.

Perspective(s) or Theoretical Framework

The driving motivation for this research project is an optimistic belief in the capacity of teachers and researchers to collaborate for improving student achievement. Broadly, large-scale analyses suggest teacher factors account for about 30% of the variation in student's mathematics performance, second only to student factors - which account for about 50% of variation - and exceeding all other remaining identified factors combined (Hattie, 2003). In addition, literature suggests mathematics teachers can (and do) serve as co-producers of relevant professional knowledge with researchers, while directly improving outcomes for their students and affecting positive changes in their local contexts (Kieran, Krainer, & Shaughnessy, 2012). Locally, our prior work with hundreds of teachers through a university-based professional development center has led our team of researchers to view mathematics teachers as having rich, varied expertise, with pragmatic insights from adapting and enacting curriculum in their schools. For this project, we leaned into that perspective by seeking a way to situate our research within a broader effort to bridge cultures through a mutually-valuable partnership centered around shared goals for improving student achievement.

Teacher-Researcher Alliance

Historically, relationships between university researchers and teachers have been asymmetrical; teachers are positioned as in need of the knowledge that researchers provide, with little acknowledgement of the value the experiential knowledge of teachers (Gore & Gitlin, 2004). Ironically, the knowledge produced by researchers often does not have the practical and contextual information that teachers find useful for their practice (Gore & Gitlin, 2004; Krainer, 2014). To bridge the cultures of teaching and research, we must recognize different ways of knowing and view relations as symmetries rather than hierarchies (Krainer, 2014). Central to this perspective is a view of teaching as an ongoing process of experimentation in which teachers naturally engage in regular testing of often informal hypotheses about student's abilities, the effects of instructional activities, and learning outcomes (Cobb, 2000). Researchers can play a role in that experimentation, helping to coordinate activities, gather evidence for drawing inferences, and plan for implementation of teacher-led interventions.

In particular, we conceptualize this project through the five features in the Teacher-Researcher Alliance for Investigating Learning (TRAIL) theoretical framework for scalable partnerships between educational researchers and teachers (adapted from Koichu & Pinto, 2018):

- **Professional Growth** - through participation, teachers enhance their educational research competencies, researchers build their knowledge and abilities to engage in classrooms.
- **Authenticity** - teachers engage in substantive research around questions drawn from real problems of practice, researchers match methodology to existing school systems.
- **Shared Agency** - mechanisms are established so teachers and researchers can each advance individual needs and goals, with room for personal expression and creativity.
- **Choice** - the partnership includes a network of projects, run simultaneously, so that teachers can select from a menu of options for participation.
- **Creating and Using Knowledge** - opportunities for determining "what works" flows from both teaching and research; practical knowledge is co-created.

EAC & SOS Instructional Practices

Nearly all mathematics professional development programs are designed to improve student learning by attempting to affect teachers' knowledge, beliefs, and instructional practices. However, student achievement is a distal goal for programs primarily focused on teachers, and there is limited research demonstrating even modest effects of professional development programs on student achievement (Gersten *et al.*, 2014; Kennedy, 2016). To design professional development with the greatest potential to positively impact instruction and student achievement, our project has focused on instructional strategies identified in research literature as most likely to improve student learning. Hiebert & Grouws' (2007) synthesis of research on instructional strategies with evidence for improving students' mathematical learning has been our primary touchstone.

Hiebert and Grouws identified two constructs underlying instructional practices supporting conceptual understanding (defined as "the mental connections among mathematical facts, procedures, and ideas", p. 382) with research evidence indicating positive effects across study design, teaching formats, and contexts (p. 387):

- **Explicit attention to concepts** (EAC) - Teachers and students explicitly discuss mathematical concepts and make connections among concepts, facts, and procedures through activities such as questioning, discussing, comparing, and relating.
- **Student opportunity to struggle** (SOS) - Students engage in productive struggle with important mathematical ideas through sense-making around comprehensible problems that require them to"figure something out that is not immediately apparent".

EAC can be seen as a more externally mediated approach in which the teacher ensures concepts and connections are made public and clear to students. In contrast, SOS is focused on experiences that engage students in developing understandings through their own sense-making activity. Recently, Stein, Correnti, Moore, Russell, and Kelly (2017) found group means on achievement measures were significantly higher for students of teachers who self-reported a preference for, as well as demonstrated through video-recorded instruction, instructional practices centered around EAC and SOS. Students whose teachers aligned with EAC alone performed significantly better than students of teachers aligned with SOS alone, who in turn performed better than students of teachers aligned with neither element. Additionally, several studies have shown that SOS positively impacts student achievement, particularly when it precedes EAC practices (Kapur, 2014; Loehr, Fyfe, & Rittle-Johnson, 2014; Schwartz, Chase, Oppezzo, & Chin, 2011).

Methods

The goal of this project was to establish a teacher-researcher alliance (with TRAIL features) in order to articulate instructional practices for the purposes of an extended research project in the context of professional development. To put the research in context, we next provide (a) a brief overview of the project, (b) a description of the project team members who developed the framework, (c) a summary of our process for developing a framework related to the EAC and SOS constructs, and (d) a brief description of the associated data collection and analysis.

Project Overview

The heart of this project is a group of 100 Grades 6-8 teachers across 45 schools and 23 districts working in an area spanning approximately 200 miles of a U.S. state with low population density and a strong tradition of local control in education. Funded by a multi-year federal research grant to investigate methods for improving middle grades mathematics achievement, the researchers recruited the teachers by obtaining approvals from their respective district administrators to invite Grades 6-8 mathematics teachers to participate in a 3-year research-professional development partnership. The professional development (PD) involves (a) three module meetings (15 hours total) for collaborative development of the EAC and SOS framework with opportunities for classroom implementation between each session, followed by (b) three week-long summer institutes (one each summer) for planning teacher-led classroom studies of EAC and SOS instructional routines, and (c) embedded classroom support provided by an experienced, dedicated instructional support team (the PD Team).

The PD Team plays a pivotal role in our teacher-researcher alliance by bringing together personnel to bridge the research-practice divide through developing and implementing PD to support teachers' implementation of EAC and SOS instructional practices in their classrooms. The PD team includes a math professor, a math education professor, three full-time mathematics instruction specialists (similar to coaches), a postdoctoral researcher, and a graduate student. The team has extensive expertise and knowledge in mathematics education and professional development. Four of the PD Team members have taught mathematics at the secondary level in the local area for between seven and 16 years, three PD Team members have worked as math coach/specialists for between five and eight years, and four PD Team members have masters or doctoral degrees in mathematics education.

Development of an EAC-SOS Guide

In collaboration with the researchers and teachers, the PD Team led the development of a 2-page **EAC-SOS Guide**. The PD Team met weekly for three months to expand and interpret the conceptual and research foundations of EAC and SOS instructional practices, with a primary purpose of communicating research findings in ways deemed relevant and useful among teacher participants. Using Hiebert & Grouws' (2007) and Stein et al. (2017) as initial resources, the PD Team unpacked the research concepts and associated studies in the context of situated instructional practices. The central challenge of the development work was to communicate instructional routines under investigation by the researchers in ways that maintain fidelity to the research supporting EAC and SOS as effective for promoting students' mathematics achievement while clarifying distinguishing features and levels of specificity that are necessary for teachers to translate the research to their day-to-day instruction. Eventually, the EAC-SOS Guide came to include separate pages for EAC and SOS as **constructs** of instructional practices with robust research evidence supporting positive effects on development of mathematics students' conceptual understanding. For each construct (identified by a distinguishing color and icon), the guide lists three **features** of mathematics instruction characterized by the respective constructs, as well as four **strategies** teachers can engage in during classroom instruction and two **routines** per strategy selected by the researchers to be further investigated through clinical cross-over trials in the teachers' classrooms (see Figure 1 for the design template). Based on teachers' feedback on early drafts, each strategy was supplemented by a short list of instructional tools which may be well-suited to implementation of the associated routines.

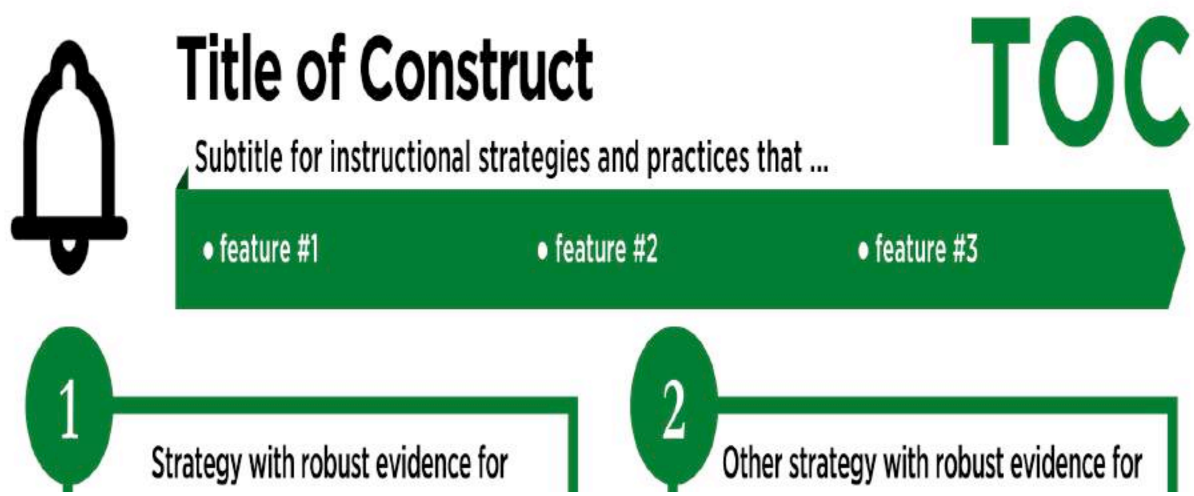

Figure 1. Design Template for the EAC-SOS Guide, with features, strategies, routines, and tools.

Data Sources

We used the PD modules to evaluate and refine the articulation of instructional practices in the EAC-SOS Guide. Participating teachers completed a Teaching Context Survey (adapted from Stein *et al*., 2017), addressing their beliefs and current practices surrounding EAC & SOS instruction, as well as curricular formats, school characteristics, instructional content, and related factors needed to estimate effects of instructional interventions on student achievement across teachers' individual contexts. During the first PD module, teachers previewed the Guide, recommended changes to better support implementation, and rated their level of familiarity and experience with the 8 strategies listed in the guides. Teachers each also selected one of the 8 strategies they would like to try first in their classrooms, and completed a "Stop Light" reflection at the next professional development meeting to communicate the challenges they encountered (red light), ways in which the PD Team can support implementation (yellow light), and positive outcomes they saw in their classroom practice (green light). In the Results section below, we present the final EAC-SOS Guide and summarize the teachers' strategy selections.

Results

The EAC-SOS Guide (see Figure 2, or http://bit.ly/eac-sos-guide) is the primary result of our collaboration among teachers and researchers to articulate instructional constructs, features, strategies, routines, and tools supporting research into the improvement of student mathematics achievement. Following the first PD Module, 94 teachers selected a routine to try in their classroom. More teachers selected an SOS routine (59%) instead of an EAC routine (41%). Teachers' rationales for their choice of an SOS or EAC routine are summarized in Table 1.

Table 1. Counts of rationale provided for teachers' selected routines, by construct.

	Supporting Student Thinking	Fit with Curriculum	Improving Teaching Skills	Fit with Content	Other (Collaboration, General Interest)	*Total*
EAC	15	10	2	9	3	*39*
SOS	24	8	16	6	1	*55*
Total	*39*	*18*	*18*	*15*	*4*	*94*

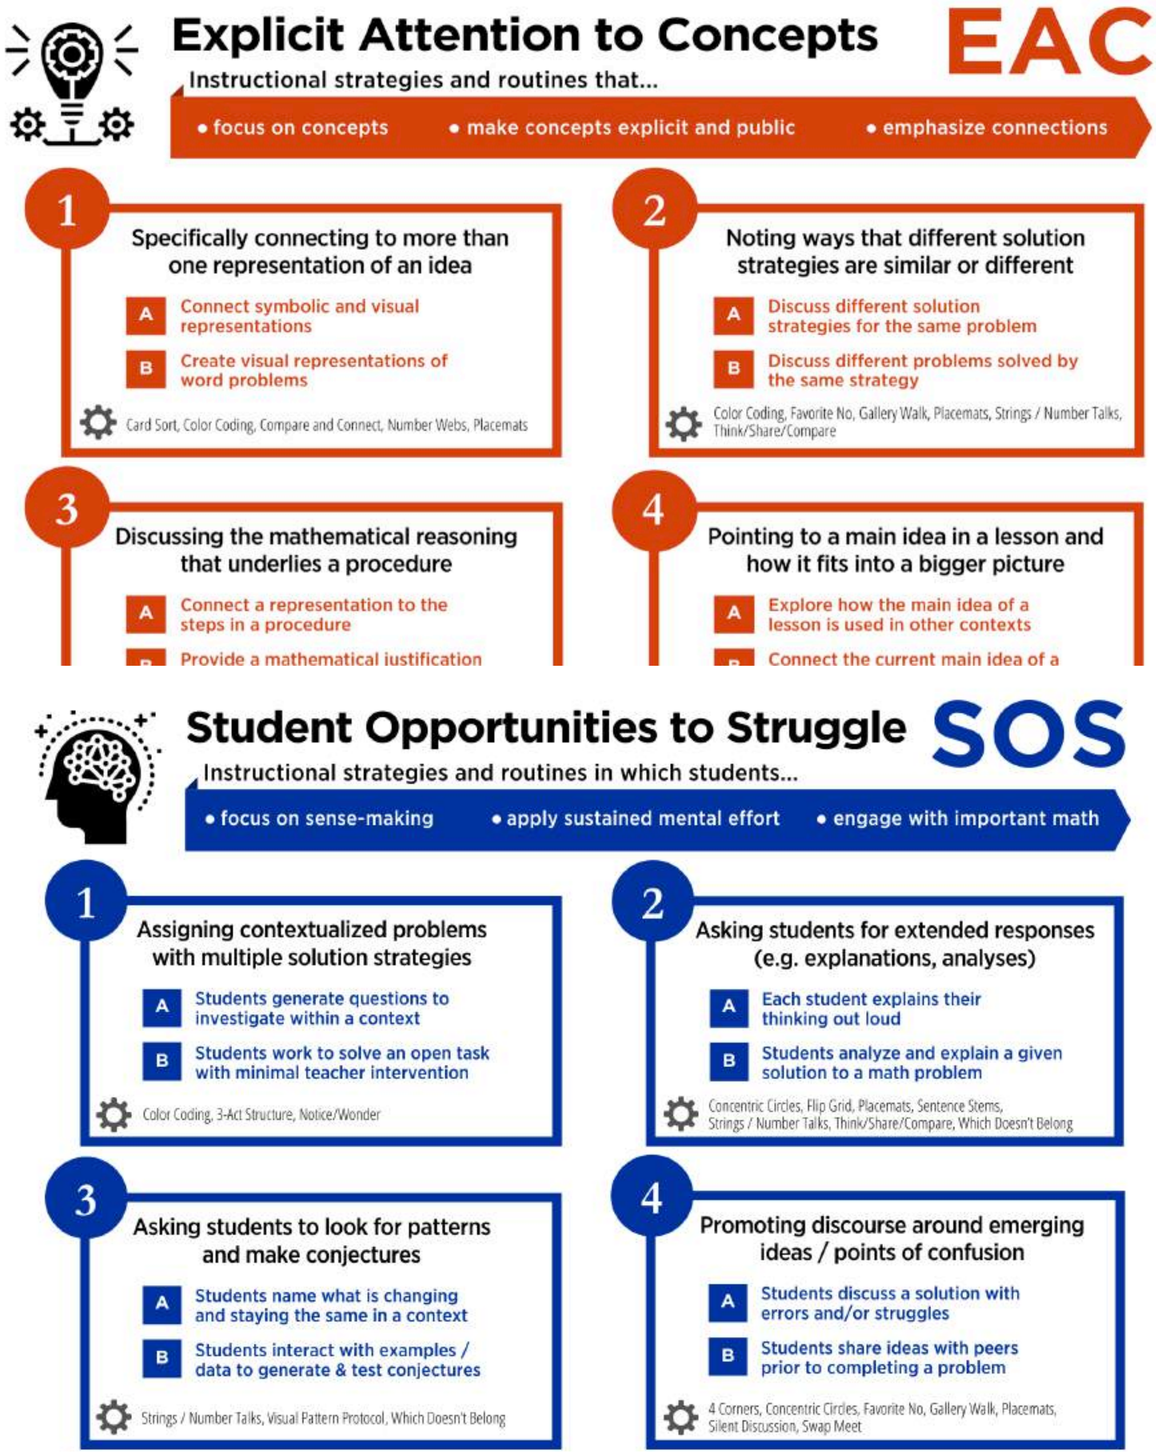

Figure 2. EAC-SOC Guide to Instructional Practices for Improving Math Achievement

Table 2 shows the routines selected by teachers for initial testing, together with exemplar statements related to why that particular routine was selected. (The examples were selected based on a combination of frequency of occurrence of 'why' reasoning across multiple responses in conjunction with those that seem well tied to the routine itself.).

Table 2. Routines selected by participating teachers, with example rationales they provided.

Routine	Frequency	Example Whys?
EAC1A: Connect symbolic and visual representations	7.4% (7)	...Many of my students are procedural, but they actually don't understand the nature of the problem and what it's saying.
EAC1B: Create visual representations of word problems	10.5% (10)	My students have been taught a lot of procedures and do not always understand what it looks like...
EAC2A: Discuss different solution strategies for the same problem	10.5% (10)	Students will use various methods to solve systems of equations and I would like to have them compare and contrast the different strategies.
EAC2B: Discuss different problems solved by the same strategy	0.0% (0)	*No exemplars*
EAC3A: Connect a representation to the steps in a procedure	4.3%(4)	I'm hoping that an explicit connection to steps in a procedure to a context will help with understanding systems of equations.
EAC3B: Provide a mathematical justification for the steps in a procedure	3.2% (3)	...it is important for my students to be able to explain how they work through a problem and also collaborate with peers...
EAC4A: Explore how the main idea of a lesson is used in other contexts	3.2% (3)	Because this will relate to what I am currently teaching students. Relate percents to fractions
EAC4B: Connect the current main idea of a lesson to a prior math concept	5.3% (5)	I will be starting out percent lessons next week...I want to focus on making connections to what they did with ratios & proportions.
SOS1A: Students generate questions to investigate within a context	2.1% (2)	I always ask them questions but they rarely ask each other questions. I feel like we all need to improve in this.
SOS1B: Students work to solve an open task with minimal teacher intervention	8.5% (8)	I want to see the productive struggle with my students and see how the handle it.
SOS2A: Each student explain their thinking out loud	10.5% (10)	I think understanding becomes more clear and cemented in our brains when we can express them in words.
SOS2B: Students analyze and explain a given solution to a math problem	2.1% (2)	Teaching Intervention math my students often just want to say the answer instead of explain how they arrived at that answer.
SOS3A: Students name what is changing and staying the same in a context	5.3% (5)	I want to incorporate more "non-teacher directed" entry point activities and I feel that this is a place to start...
SOS3B: Students interact with examples or data to generate and test conjectures	4.3%(4)	...I want my students to interact with data to understand how adding/subtracting numbers from the data will affect the mean and median.
SOS4A: Students discuss a solution with errors and/or struggles	14.9% (14)	I want students to get more comfortable with analyzing others answers and share ideas
SOS4B: Students share ideas with peers prior to completing a problem	8.5% (8)	...Students can bounce and gain ideas that they may not have thought of or get reinforcement on an idea they had.

Discussion

The primary outcome of this research is the EAC-SOS Guide. The time and resources supporting the design and development of the document - especially the associated efforts to situate the development within a teacher-researcher alliance - indicate great potential value in the document to support efforts to address the culturally-entrenched challenges of merging research and practice in the context of professional development aimed at improving mathematics achievements in the middle grades. In addition to the direct input teachers had in the development of the Guide itself, teachers' initial selections of routines to try in their classrooms also provides positive indications that both EAC and SOS constructs are appealing to practicing teachers interested in better understanding and leveraging their students' thinking, implementing their curriculum, improving their repertoire of teaching methods, adapting their instruction to the mathematical content, and collaborating with peers.

In addition to practical uses for the EAC-SOS Guide in professional development and research settings, we encourage colleagues to consider transferring our conceptual framework, especially the TRAIL model for collaboration between teachers and researchers and emphasis on articulating research findings in practical terms, to future projects. We view the results reported in this paper as provisional, and intend to further refine and articulate the constructs, features, strategies, routines, and tools by creating a modern website using similar development methods (e.g., selection preferences, challenges, affordances, supports, evidence for positive effects). In addition, we look forward to conducting classroom research with our teacher partners, and are hopeful the associated research findings will clarify the contexts under which the instructional routines are especially promising for classroom implementation. We welcome collaborators interested in extending that work.

We studied two iterations of an online course provided to rural mathematics teachers. The online courses, which involved primarily synchronous activity, emphasized high-leverage discourse practices. We applied a community of inquiry framework, which emphasizes deep intellectual work, and its three tenets: cognitive presence, social presence, and teaching presence. We adapted the framework by creating a category on content-related interactions and by using mediating processes from our conjecture maps (e.g., Sandoval, 2014) to characterize cognitive presence. The adapted framework allowed us to notice substantive differences between the course iterations, especially in relation to teaching presence and cognitive presence. The implications of the study are that the framework helps us gauge the efficacy of synchronous online interactions and to better gauge goals for future iterations of the course.

Online platforms and learning environments are emerging as important contexts for teachers' professional development (Johnson et al., 2018; Keengwe & Kang, 2012; Means et al., 2009), and thus as sites of research. The online context provides access to professional development to teachers who may be geographically distant from conventional professional development providers, such as institutions of higher education, and from critical masses of colleagues. Because this trend is likely to grow, it is important to conceptualize ways to research online professional development, specifically within mathematics education. Many online learning projects have asynchronous environments. We argue that online *synchronous* learning environments also have the potential to provide impactful professional learning experiences for teachers, as they incorporate features of face-to-face environments. However, there has been inadequate research on the efficacy of features within synchronous online environments. In this study, we explore one component of a three-part online professional development model for middle grades mathematics teachers in rural contexts. We apply a *community of inquiry* framework (Garrison, Anderson, & Archer, 2000) because of its assumptions about engaging participants in demanding intellectual work, and connect the framework to the design literature, specifically *design conjectures* (Sandoval, 2014). The mediating process component of design conjectures provides a way to characterize and analyze the cognitive presence in a community of inquiry, which has been an outstanding methodological problem in studying online contexts (Akyol & Garrison, 2011).

The purpose of this study is to examine the quality of the learning environment we created in a synchronous online course. The community of inquiry framework allowed us to examine the characteristics of the teaching, cognitive, and social presences. Prior research has shown that confirmed that online environments can establish social presence (e.g. Whiteside, Dikkers, & Swan, 2017). However, it has been less clear how content-related features of online courses are evident, particularly interactivity related to subject matter, cognitive presence, and aspects of teaching presence. In this study, we use the community of inquiry framework to explore these features within and across two cohorts of teacher participants who took the same online course.

Online Professional Development Course

We designed a three-part online professional development model with the goal of providing rural mathematics teachers access to high quality professional development. We originally designed and implemented the three components in face-to-face formats, which we then iteratively transformed into fully online versions for the purposes of this project. Our project utilized a series of synchronous online experiences, which departs from the typical asynchronous nature of much of the current online professional development, educational coursework, and virtual teacher communities. The three parts of the model included online course modules, demonstration lessons, and online coaching.

The online course modules emphasized discourse practices that orient teachers toward high-leverage discourse practices to facilitate mathematically productive classroom discussions (Smith & Stein, 2011). These discourse practices are catalyzed by five practices emphasized in the course, entitled *Orchestrating Mathematical Discussions* (OMD), anticipating, monitoring, selecting, sequencing, and connecting. The modules also emphasize key aspects of lesson planning, such as goal-setting, in addition to having teachers solve and discuss high-cognitive demand tasks. The specific goals of the modules were to: develop awareness of specific teacher and student discourse moves that facilitate productive mathematical discussions; to understand the role of high cognitive demand tasks in eliciting a variety of approaches worthy of group discussions; and to further develop participants' mathematical knowledge, particularly the rich connections around big mathematical ideas (Ball, 1991; Ma, 1999). The modules involved a combination of synchronous and asynchronous work to minimize the amount of time teachers met together virtually (Robinson, Kilgore, & Warren, 2017). This minimized logistical challenges and maintained a high degree of teacher effort and attention due to the shortened synchronous time. Hrastinski (2008) found that synchronous and asynchronous components complement each other.

We conducted the OMD course in Zoom, a video conferencing platform, which allowed for synchronous whole class and small group interactions. In addition, we simultaneously used Google Docs and Google Draw, which allowed participants to collectively develop and share artifacts, including approaches to mathematical problems. The instructor presented challenging tasks to the participants, who then worked in virtual breakout rooms to create a document that they shared with the other groups. They talked to each other, worked simultaneously on the shared document, and used the chat window to communicate in the virtual space. The course instructor listened to and participated in these group discussions to facilitate the group work.

Framework

We draw primarily from the community of inquiry framework (Garrison et al., 2000), that identifies three components of online learning environments: cognitive presence, teaching presence, and social presence. Garrison and Cleveland-Innes (2005) define a community of inquiry in terms of deep learning that extends beyond simple interactions, stating that a community of inquiry is a place where "ideas can be explored and critiqued; and where the process of critical inquiry can be scaffolded and modeled" (p. 134). Below, we describe each of three components of online learning environments: teaching presence, cognitive presence, and social presence.

Teaching Presence

Teaching presence entails three aspects of teaching: interactive instruction, design, and direct instruction. We highlight the interactive aspects of teaching, following Garrison and Cleveland-Innes (2005), who state that "if students are to reach a high level of critical thinking and knowledge construction, the interaction or discourse must be structured and cohesive" (p. 134). Structuring interaction in productive ways includes explicitly articulating the designed features of the learning environment and directing students via explanation, scaffolding, or evaluative feedback. Anderson, Rourke, Garrison, and Archer (2001) describe these three roles of the instructor as designer, facilitator, and subject matter expert. In our perspective, the most critical role of the instructor is to *facilitate* productive interactions with and between the participants, as this is most likely to elicit and advance thinking related to the goals of the course. This is different from the social interactions described below, which are not necessarily related to course goals but are productive for building community. Articulating the design of the learning environment creates expectations and opportunities for participants; however, as learners engage with design, the instructor must insert themselves into the online interactions (via feedback, explanation, and scaffolding) in order to support students understand expectations and develop their thinking.

Cognitive Presence

Garrison, Anderson, and Archer (2001) describe *cognitive presence* as "the extent to which learners are able to construct and confirm meaning through sustained reflection and discourse" (p. 11). Cognitive presence is synonymous with critical engagement with content; consequently, developing analytic tools to characterize cognitive presence must include the intellectual practices deemed essential to the learning goals. In past research, cognitive presence has been the least analytically developed dimension of community of inquiry (Akyol & Garrison, 2011), in part because processes and content that determine cognitive presence are specific to a given discipline and domain.

In order to characterize cognitive presence, we turned to the design literature to identify the essential processes related to our learning goals. We utilized *conjecture maps* to operationalize cognitive presence analytically. According to Sandoval (2014), "*conjecture mapping* is a means of specifying theoretically salient features of a learning environment design and mapping out how they are predicted to work together to produce desired outcomes" (p. 19) and is intended to reify the conjectures regarding the learning environment and how they interact to promote learning. There are four main elements to a conjecture map. The first element involves *high-level conjectures* about how the learning context supports learning. Researchers then operationalize these conjectures in the *embodiment* of the learning design, the second element, by articulating tasks, participant structures, and so forth that provide opportunities for learners to engage with content. In the third element, researchers conjecture how the design of the learning environment (embodiment) generates *mediating processes* that produce desired *outcomes.* Mediating processes occur *within* the learning environment and potentially lead to the outcomes that may occur *outside of* the learning environment, such as enacting high-leverage discourse practices in mathematics classrooms. To analyze cognitive presence, we turn to the third element, the mediating processes, as they were the intended targets of the designed learning environment.

Designers of a learning environment articulate mediating processes to reflect the desired practices, and associated cognitive work, that should result from the design of the learning environment. Thus, observations of mediating processes focus on the interactions between learners and the learning environment. To articulate the mediating processes, the project team reflected on the goals of the project, the goals of the course, and specific aspects of the learning environment, to generate four mediating processes, described in the methods section.

Social Presence

Garrison et al. (2000) describe *social presence* as the ability for participants to project themselves and to establish personal and purposeful relationships. Rourke, Anderson, Garrison, and Archer (2001) state that the three main components of social presence are affective responses, interactive responses, and cohesive responses. As described in our analysis below, we separated out content-related interaction from the other two categories and primarily used affective and cohesive responses to define social presence.

Research Focus

We used the community of inquiry framework to focus on how the synchronous online environment affected the teaching presence and the opportunities for the teacher participants to engage with the content directly and with each other around the content. We studied two cohorts of teachers who participated in the same online course; this allowed us to compare the two course enactments to better characterize teaching and cognitive presence within and across cohorts. As noted above, the ability of designers to facilitate social presence is sufficiently documented, and we, too, found that the teacher participants engaged in friendly banter around their lives and jobs. We conjecture that this social presence facilitated interaction around content, but we do not explicitly explore that conjecture in this paper. Our research questions were:

1. What aspects of teaching presence were evident in the two online courses, especially in terms of interactive teaching and direct instruction?
2. How did this teaching presence differ across the two cohorts, and how were these differences related to teacher participation?
3. To what extent did the participants in the two cohorts engage in mediating processes (evidence of cognitive presence)?
4. To what extent did the participants in the two cohorts engage with each other around the content (level of content-related interactions)?

Methods

Data Collection

We video recorded the OMD sessions, six for each cohort, twelve in total, using screen capture technology. For each session, we video recorded the host computer as well as each of the breakout rooms, creating three to five video files for each session. We used Panopto so that we could record the Zoom window and simultaneously the Google Docs the groups were creating. We transcribed all of the breakout rooms and the subsequent whole class discussions, omitting the introductory whole class segments in which the instructor outlined the task goals and expectations. This reduced the frequency of the design aspect of teaching, which was not emphasized for this study. Overall, there were 24 episodes for Cohort 1 and 45 for Cohort 2. These differences reflect data collection issues we encountered in Cohort 1 and less participation from Cohort 1 in the OMD course relative to Cohort 2.

Data Analysis

We coded the transcripts turn-by-turn, assigning as many codes as were relevant to a given turn across the three presences. After a few rounds of consensus coding, we independently coded transcripts, with pairwise kappas between 0.45 and 0.54, considered moderate agreement (Landis & Koch, 1977). Below, we provide more details related to the codes we applied for each of the presences.

Cognitive presence. The coding team for cognitive presence included members of the project team who were most familiar with the course design, including two instructors and one designer, in addition to the two lead researchers. To analyze cognitive presence, we coded all turns for the presence of the following four mediating processes we had previously developed in the conjecture mapping process (Sandoval, 2014):

- Explaining how features of a lesson/task design influence opportunity to engage in mathematical thinking;

- Explaining mathematics in the task in ways that make connections;
- Explaining anticipated or observed strategies or misconceptions for a given task; and
- Explaining how teaching moves impact access to mathematical thinking, participant frameworks, student authority, or formative assessment.

Teaching presence. We coded for the three forms of teaching presence, though we minimized the emphasis on the design aspect of teaching. For interactive teaching, we adapted the facilitating discourse category from Anderson et al. (2001). Our codes included: *identifies areas of agreement/ disagreement*; s*eeks to reach consensus*; *encourages (acknowledges, reinforces)*; e*licits contributions; presses or probes*; and r*edirects discussion*. For direct teaching, we adapted the direct instruction category and our codes included: *explains content*; *focuses or funnels*; *summarizes or provides feedback*; and *responds to technical concerns*. The coding team consisted of one of the two lead researchers and four doctoral students.

Social presence. Adapting the work of Rourke et al. (2001), we used the three main categories of affective responses, content-related interaction, and cohesive responses, each of which had sub-categories that we modified to take into account that we were working in a synchronous video-based environment. For example, in the content-related interaction category, we revised *continuing a thread* to *building from or extending another participant's response* and we revised *quoting from other messages* to *repeating or paraphrasing another participant's response*. The coding team was the same as for teaching presence.

Second phase of analysis. In the second phase of our analysis, we reorganized and reduced the codes. We pulled out the two codes for content-related interaction - *building from or extending another participant's response* and *refers to or paraphrases another participant's response* – because we felt these codes involved interaction around content and were not purely social in nature. That left the affective and cohesive categories to represent social presence. We collapsed all codes in the cognitive presence category into one count, and did the same for social presence and for each of the three aspects of teaching presence – design, interactive teaching, and direct teaching. We also added a category for *technical*, which involved all turns related to resolving technical issues in the Zoom and Google environments. We then collected all the totals of the reorganized and collapsed categories across each cohort.

Results

We present the results initially by looking at cross-cohort comparisons, which allowed us to look at patterns within cohorts and then patterns within cohorts. The comparisons look at different distributions and rates within and across categories for both instructors and teacher participants. The purpose of presenting the cross-cohort comparisons is not to evaluate the instructors or teacher participants, but to highlight the ways the community of inquiry framework provides insights into the dynamics and efficacy of the online courses. We noticed three distinct trends. First, we noticed a much more prominent teacher presence in the Cohort 1 course. Second, we noticed that participants in Cohort 2 had much higher rates of cognitive and social presence, as well higher rates of turns involving technical issues. Third, we noticed that the teacher participant turns were more evenly distributed in Cohort 2 than Cohort 1. We discuss each of this in detail below.

Teaching Presence

The Cohort 1 instructors had six times as many turns coded as interaction (building from or referring to other participants' contributions) and roughly three times as many turns coded as interactive and direct teaching, with similar rates of design codes (see Table 1). There are some possible reasons why these differences occurred. One reason is that the instructor with the most prominent presence in the Cohort 1 implementation had a different teaching style than the instructor with the most prominent presence in Cohort 2. This is borne out in the analysis of the coaching cycles that were another component of the professional development project, in which the primary instructor in Cohort 1 had considerably higher rates of direct assistance (explanations, suggestions) than the other coaches. A second reason is that the number of participants in Cohort 2 was 50% higher per session (roughly three more participants per session in Cohort 2), perhaps allowing the instructor to offload some of the work onto the participants. For example, the *interactive presence* and *interactive teaching* categories for Cohort 1 indicate that the instructor was much more active in engaging participants with their contributions, and referring to and paraphrasing those contributions to make them objects of discussion. Perhaps this was because the participants did not engage each other with their ideas to the satisfaction of the instructor and she felt compelled to intervene. At any rate, these substantive differences likely had an impact on the learning opportunities for the participants.

Table 1: Teaching Presence across Cohorts

Instructors	Interactive Response	Interactive Teaching	Design	Direct Teaching
Cohort 1	41	82	38	99
Cohort 2	7	28	28	30

Participant Rates across Categories

The teacher-participants in Cohort 2 contributed nearly twice as many turns in three categories: cognitive presence; social presence; and technical concerns, with roughly equal numbers of turns coded as content-related interaction. This may have been in part because there were on average 50% more participants in each session relative to Cohort 1, but this does not account for all of the difference nor does it account for the fact that the content-related interaction was roughly equal. In the two sessions in which there were the most participants in Cohort 1 (8 of the 11), roughly 80% of the overall turns coded as interactive response and social presence occurred, and over 50% of the cognitive presence. This suggests that for this group, having more participants was associated with higher levels of interaction, both content-related and socially-related. Importantly, Cohort 2 participants engaged in the mediating processes at much higher rates, which we hope eventually to tie to the project outcomes and other data sources in the project.

Table 2: Participant Rates across Cohorts

Teacher Participants	Cognitive Presence	Content-related interaction	Social Presence	Technical Concerns
Cohort 1	101	104	185	77
Cohort 2	189	108	406	194

Distribution of Turns across Participants

We noted that contributions from teacher participants were more equitably distributed in Cohort 2 than Cohort 1 with respect to cognitive presence. The top four contributors in Cohort 1 accounted for 61% of the cognitive presence codes, while the top four contributors in Cohort 2 accounted for 48% of the cognitive presence codes. Although this may be related to the fact that there were more 50% participants per session on average for Cohort 2, one of the participants in Cohort 1 who attended all of the sessions had very few turns coded as cognitive presence. This participant similarly had low levels of interaction with her coach in the coaching cycles, which suggests that she was having difficulties engaging with key processes emphasized in the project. Nevertheless, the distribution indicates that learning opportunities, and evidence of potential learning, were not ideally distributed in Cohort 1.

Two Cases of Participants

We turn to two cases of teachers, one from Cohort 1 and one from Cohort 2 to provide nuance to our findings. The participant from Cohort 1, Dixon, had the second highest number of codes applied from his cohort (70), with the highest number of cognitive presence and social presence codes. Much of the turns coded as social presence were related to expressing vulnerabilities related to his teaching, while much of the turns coded as cognitive demand explained the impact of teachers' actions, often including detailed examples from his class. The participant from Cohort 2, Fleming, had a below average number of contributions for that cohort (67), with above average for turns coded as cognitive presence (24) and content-related interactions (16), and below average for turns coded as social presence (20). Fleming's contributions were mostly related to content, though she occasionally joined in the social banter. Most of her cognitive presence turns involved describing mathematical strategies. These two cases demonstrate differences in the content and nature of participation. Dixon was introspective with respect to his teaching, describing situations he faced, often in a self-deprecating manner; however, he did not often describe or analyze mathematical strategies. Fleming, by contrast, talked more frequently about mathematical strategies, her own and those she anticipated seeing in students, and relatively less frequently engaged in social banter or talked about her teaching.

Discussion

A goal for this study was to explore how a synchronous online environment could engage mathematics teachers in demanding intellectual processes that could help them grow professionally. We employed a community of inquiry framework to research the social and intellectual vibrancy of the environment and the ability of instructors to productively structure interactions around the goals of the course. The framework allowed us to see substantive differences between instructors and between participation rates of two cohorts enrolled in the same online course. It also allowed us to conjecture about the relationship between the instructors' actions and the ways the teacher participants interacted with each other and with the content.

The results provide insights into how the online courses achieved content-related purposes related to interaction (recognizing and building from the contributions of others) and cognitive presence (engaging in the mediating processes). Participants in both cohorts engaged in forms of social and cognitive presence, albeit in ways that differed substantively. Notably, the instructors in Cohort 1 were far more active in structuring and modeling content-related interaction, in explaining content, and in providing feedback to participants. Conversely, the participants in Cohort 2 contributed in considerably higher rates with respect to cognitive and social presence. We conjecture that these differences occurred because Cohort 2 had on average 50% higher attendance rates and because the most active instructor in Cohort 1 had a style oriented toward direct instruction, which was consistent with results related to her coaching style (Authors, date). We will attend to these patterns closely as we finalize our analysis for the same two cohorts in the second online course. We also note that the two cases of teacher-participants discussed above demonstrate how participants in the same learning environment engage differently with the content and with the social features of the environment. These results highlight the ability to research dynamics between instructors and participants in a synchronous online environment and to consider how differences in individuals contribute to those dynamics.

Implications

We focus on three implications. First, we feel this study is a step toward formulating a version of the community of inquiry framework suited for synchronous online professional development in mathematics education. Three key adaptations we made to the framework reflect issues highlighted in the mathematics education literature: productive content-related interactions, characteristics of cognitive presence that reflect learning processes for mathematic teachers, and a stronger focus on non-design aspects of teaching. The category of content-related interactions is comprised of high-leverage practices with respect to developing collective knowledge within a community. Related to the second adaptation, using mediating processes to characterize cognitive presence provided us meaningful ways to connect our conjectures about our learning environment and the practices we hoped they would facilitate. A third adaptation involved focusing on interactive teaching and direct instruction as the two teaching components of greatest interest to research a synchronous online environment. These two aspects of teaching account for the ways instructors intervene to structure interactions and to focus those interactions on content in synchronous moments. The online learning environment afforded us a comprehensive picture of these actions, as all teacher-participant interactions took place in an environment that was video-recoded. From this study, we can reach a tentative conclusion that online synchronous platforms can be sites of teacher learning and research.

Along with the rapid development of technology, videorecording teachers' lessons for professional development or educational research have become commonplace. Although the benefits of the use of videorecording has been well documented, few studies have attended to teachers' affective experiences in relation to videorecording. In this study, we examined teachers' emotions to being videorecorded and watching their videos. We found that all teachers experienced negative emotions related to videorecording at the initial stage of the PD but these negative experiences faded over five coaching cycles. Despite the negative emotions all teachers found the use of video tremendously beneficial to their own professional development.

The Role of Video in Professional Development

The value of videorecording in teacher education and professional development has been widely acknowledged (Gaudin & Chaliès, 2015; Marsh & Mitchell, 2014). Having access to video of one's own instruction allows teachers to re-watch the teaching episodes and analyze the aspects of their teaching that go beyond just recall (Roller, 2016). By providing teachers with a clear picture of what their teaching looks like, videos provide essential information about their practices that allows teachers to craft a professional vision oriented towards developing necessary skills critical for appropriately noticing and attending to students' academic needs (Sherin 2004; Sherin et al. 2011). Having continuous experience with watching videos enhances teachers' abilities to observe, identify, and interpret classroom actions (Coffey, 2014; Krammer et al., 2006; Sherin & van Es, 2009; Star & Strickland, 2008). Gaudin and Chaliès (2015) pointed out that, "viewing a classroom video engages [the] teacher in a complex activity that elicits cognitive, emotional, and motivational processes" (p. 46).

Chan et al., (2018) suggests that videos engage teachers in retrospection about their own practices, while minimizing the "cognitive and emotional involvement they experience while teaching" (Chan et al., 2018, p.193). However, others (e.g., Kleinknecht & Schneider, 2013) suggest that teachers' do engage emotionally and motivationally when watching videos, but this engagement is higher while watching the videos of unknown teachers. Although having opportunities to watch and reflect on instruction is generally useful for teachers' professional development, there is added value in engaging in this practice around one's own teaching (Zhang et al., 2011). Gradual exposure to similar experiences helps teachers get accustomed to recognizing elements in their existing practices that need improvement (Borko et al., 2008). However, despite the benefit of reflecting on your own instructional video, researchers found that the teachers usually feel uncomfortable with being filmed or being watched by others (Borko et al., 2008; Lasagabaster & Sierra, 2011; Sherin & Han, 2004). Hence, public viewing of teachers' videos requires building a safe and friendly community of support. As pointed out by Borko et al. (2008, p. 422), "to be willing to take such a risk, teachers must feel a part of a safe and supportive professional environment. They also should feel confident that showing their videos will provide learning opportunities for themselves and their colleagues, and that the atmosphere will be one of productive discourse." Although watching videos can elicit a range of negative emotions, they provide evidence of the complexity of classroom practice and make student thinking visible (Barnhart & van Es, 2015; Santagata & Yeh, 2013), thereby motivating teachers to continue with effective practices and innovative to address issue they observe that deter positive student outcomes (Siry & Martin, 2014; Sun & van Es, 2015).

Teaching is emotional work (Hargreaves, 2000; Nias, 1996, Sutton & Wheatley, 2003). Studies of teachers' emotions has increased in recent years because of their influence on teachers' motivation and subsequently their behaviours (Mesquita et al., 1997). Teachers' negative emotions (e.g., anger and frustration) (Emmer, 1994) have been found to negatively influence teachers' focus and attention, thereby reducing their intrinsic motivation to teach (Ryan & Deci, 2000; Trigwell, 2002). On the other hand, emotions, like joy and satisfaction, assist in generating effective ideas and strategies (Sutton & Wheatley, 2003). As such, emotions are deeply connected to teachers' cognitive and psychological processes which influences their instructional outcomes. In this regard, exploring teachers' emotional experiences related to videorecording – including being videotaped and watching the videos – will provide insight into the range of emotions teachers' experience in relation to videorecording and the reasons underlying these emotions. A significant number of studies have documented the positive influences of video on teachers' professional growth, however, these findings of this study will provide insight into the extent to which elementary teachers may experience negative emotions related to videorecording; the extent to which elementary teachers experience positive emotions related to videorecording; what triggers these emotions; and, whether or not, they may influence what and how a teacher instructs. We focus specifically on answering the following research questions:

1. How do elementary teachers describe their emotions in relation to videorecording their instruction and watching their videos? How do they describe these emotions?
2. What reasons do teachers describe for their emotions related to videorecording their mathematics instruction?

Method

Participants

The participants included seven elementary (grades K-6) teachers working across three different schools within the same district. Table 1 shows demographic data on the teachers.

Table 1. Demographic data on participants

Teacher	Position	Gender	Grade Level	#of years of teaching
Bill	Special education teacher	Male	3rd	5
Sandra	Special education teacher	Female	Kindergarten	6
Laura	Elementary grades teacher	Female	4th	9
Anthony	6^{th} grade math teacher	Male	6th	15
Wilma	Elementary grade teacher	Female	2nd	10
Katie	Kindergarten teacher	Female	1st	19
Jessica	Elementary grade teacher	Female	2nd	5

Holistic Individualized Coaching (HIC)

This study was situated in a larger study that unfolded over a year. Participants were involved in a year-long professional development (PD) program, that involved a coaching model called Holistic Individualized Coaching (HIC) (Author, 2019). Holistic Individualized Coaching (HIC) is a coaching model designed to attend to the multi-dimensional aspects of teaching with the goal of advancing teachers’ instructional practices and overall professional well-being. For an academic year, the participants engaged in five cycles (5) of coaching that focused on enhancing their mathematical knowledge for teaching (MKT), shaping productive mathematics-specific beliefs, developing emotional regulation strategies, and promoting efficacy calibration. It involves five steps: (i) a pre-coaching discussion of a lesson to be coached, (ii) development of a content-specific mini teacher profile, (iii) third, pre-lesson support, (iv) in-class coaching where the instruction is videotaped, and (v) the post-coaching conversation which focused on data from the videotaped lesson. The teacher and coach watched the videorecorded lesson before the post-coaching calls. Pre-coaching and post-coaching conversations were audio-recorded.

Data Sources

Audio-recordings of post-coaching conversations. The post-coaching conversations provided data about participants’ mathematical knowledge for teaching, emotions, efficacy, and their teacher role during the lesson. Regarding emotions we specifically asked teachers to describe their emotions related to the video-recording. We also probed to determine the underlying reasons for the emotion. For this study we specifically focused on data related to the teachers’ emotions about videorecording. Each of seven teachers engaged in five coaching cycles that had one post coaching conversation where they talked about emotions related to videorecording. In total, there were 35 possible instances where teachers described their emotions and the reasons underlying these emotions.

Analyses and Findings

(1) What emotions do elementary teachers describe in relation to having their instruction videorecorded and watching their instructional videos? How do they describe these emotions?

To answer this research question, we focused on the emotion they stated, in relation to being videotaped and watching their own instructional videos and used thematical analysis (Braun & Clarke, 2006) to determine their emotion categories. To value the participants experiences, we used their own words. In instances where the word or term used was not a documented emotion, we determined by the category of emotion by analyzing the context in which it was stated. Of the 35 possible experiences (5 coaching cycles x 7 teachers), teachers reported emotions on 30 experiences. For five instances the teachers did not state an emotion related to videorecording. Figure 1 shows the words and phrases teachers used to describe their emotions related to videorecording – including being videotaped and watching their instructional videos.

Teacher	Coaching Sessions				
	Post-coaching 1	Post-coaching 2	Post-coaching 3	Post-coaching 4	Post-coaching 5
Kate	Pretty good/Ok/not anxious Neutral	Not too anxious Negative	Feel good/Curious Positive	Usually don't care Neutral	No emotional reaction/Pretty comfortable Neutral
Wilma	Unbothered Neutral	More comfortable Positive	N/A	Fine Neutral	Struggled/Relief Mixed-C
Bill	Uncomfortable Negative	n/a	A little bit of anxiety Negative	Pretty calm/Never excited Neutral	Easier to watch Negative
Laura	Positive outlook Positive	Nervous Negative	Avoided watching/Pleased Mixed -C	Not anxious anymore Neutral	Frustration Negative
Antwon	Felt good/Anxious Mixed -C	N/A	Anxious/useful Mixed-C	Reflective Neutral	Appreciative Positive
Sandra	Nervous/Uncomfortable /Better Mixed-C	Enjoyment/better Positive	N/a	Dislike/Fine Mixed-C	Comfortable Neutral
Jessica	Anxiety/Relief Mixed-C	Intimidating/self-conscious/Comfort/ More calm/less nervous/less anxious Mixed -C	N/a	Excited/Anxious/Comfort Mixed-C	Comfort Positive

Figure 1. Teachers' descriptions of their emotions related to videorecording

Very few of the emotions stated aligned with the discrete emotions described in the literature, such as enjoyment and anxiety (Barrett, Gendron & Huang, 2014; Frenzel, 2004). In particular, there was one instance of enjoyment (which was mixed); no instances of anger or excitement; and, no instances of pride, shame, or guilt. Teachers tended to describe their emotions in non-typical ways, such as (a) in reference to a previously felt emotion, "easier to watch" or "feeling better" and (b) using a negative emotion in a positive way, for example "not bothered" or "not anxious anymore". We also observed that teachers talked about their experiences with multiple emotions. For example, when talking about the video-recording experience, Jessica described three emotions, "excited-anxious-comfort". We labeled teachers' experience of multiple emotions as mixed emotions. Figure 2 shows the categorizations of the emotions.

Teacher	Emotions			
				Mixed
	Positive	Negative	Neutral	Complex
Katie	Feel good/Curious	Not too anxious	Pretty good/Ok/not anxious Usually don't care Pretty comfortable	
Wilma	More comfortable		Unbothered Fine	Struggled/Relief
Bill		Uncomfortable A little bit of anxiety Easier to watch	Pretty calm/Never excited	
Laura	Positive outlook	Nervous Frustration	Not anxious anymore	Avoided watching/Pleased
Antwon	Appreciative		Reflective	Felt good/Anxious Anxious/useful
Sandra	Enjoyment/better		Comfortable	Nervous/ Uncomfortable/Better Dislike/Fine
Jessica	Comfort			Intimidating/self-conscious/Comfort/ More calm/less nervous/less anxious Excited/Anxious/Comfort Anxiety/Relief
Total	6	6	9	9

Figure 2. Teachers' emotions about videorecording organized by category

We observed that when teachers experienced mixed emotions, they were a combination of both negative, positive and neutral emotions; for example, “anxiety-comfort-intimidating” [Jessica, coaching cycle 2]. This was in contrast to prior work on teachers’ emotional experiences related to teaching (e.g. Authors, under review) where teachers also experienced what we referred to as mixed-positive, a combination of multiple positive emotions; and, mixed-negative, a combination of multiple negative emotions. Jessica’s videorecording experience during the second round of coaching provides an example of the mixed-complex emotional experience. She stated,

> …when it started, it was, you know, just videorecording myself, it was a little intimidating. And then having people watch it. You weren't-- you weren't sure, because it's like, OK. What are they going to think?... I believe in what you say, that you're not in here to judge what's kind of going on. You're in here to help with-- or, you know…. Because, I mean, I'm not saying I'm not a little self-conscious when somebody is in here watching and listening, but I-- it's helped me work through that, because I don't want to be. When somebody comes in my room, I don't want to have to change my way of teaching or be nervous or things like that. So, it's helped me in that aspect, also. [So I’m] a little bit more calm, less nervous, less anxious.

In the excerpt Jessica described her initial feelings of intimidation about the videorecording, concerned about whether she would meet expectations. She talked about feeling a bit self-conscious about being watched but she felt comfortable knowing that the coach was in the classroom to provide support, not to judge. She had been actively working on regulating her emotions so she was relatively calmer and less nervous about being videotaped.

Along with neutral emotions, mixed-complex were the most predominantly felt emotions related to videorecording stated by teachers in nine instances each. Teachers also experienced positive and negative emotions with similar frequency – six instances each. Teachers appeared to become more neutral or positive about videorecording over time or repeated exposure, although they didn’t end the year having positive emotions. This may be due to the reasons underlying the emotion – why they were feeling these emotions. We describe these reasons next.

(2) What reasons do teachers describe for their emotions related to videorecording their mathematics instruction?

To answer the second research question, we identified teachers’ responses related to their emotions about videorecording and the reasons underlying these emotions. We coded each of these reasons to reflect what elicited the emotion. We then looked across the codes and organized them in themes that captured the core aspects of teachers’ videorecording experiences including: (i) teacher self-related, (ii) student-related, (iii) teaching-related, (iv) coach-related, and (v) videorecording related. Table 2 shows types of emotions (row) in relation to reasons (column).

Table 2. Reasons Underlying Emotions

Emotions	Reasons				
	Teacher (Self)-related	**Student-related**	**Teaching-related**	**Coach-related**	**Videorecording-related**
Positive	Knowing teacher self Appreciation of the entire process	Opportunity to enhance learning opportunities for students	Opportunity for reflecting on and improving instructional practices Objective	Conversation around the video is helpful	Video captures crucial moments in teaching not accessible in memory

			evaluation of teaching		
Negative	Discomfort with watching self on video (hearing voice and seeing self)	Makes students’ thinking visible	Unsatisfied with lesson Discomfort with watching instruction process	Pressure to perform for coach Ensure they meet coach’s expectations	Video reveals the unknown about students’ thinking, behavior and teaching
Neutral	Objective evaluation of teaching	Provides window into students’ thinking	Opportunity for reflecting on and improving instructional practices	Will not be judged by coach Comfort with conversation around the video	Comfort with video in the classroom over time Video does not record personal thoughts
Mixed-Complex	Reasons including a combination of those described from each of the above categories				

Positive. Reasons for positive emotions were aligned with a mastery goal orientation perspective (Elliot, 2005) where teachers saw the videorecording experience as a way to learn more and improve their instruction in ways that would benefit students’ learning (Maher et al, 2014). Sandra and Anthony’s statements capture the teachers’ experiences well.

> Teachers don't get this. You do have to watch yourself when you were student teaching, but then you had no experience so you couldn't really use it very well. Whereas now I've been teaching only seven years, but it's nice to see myself and what I'm doing. I really enjoyed that part of it and it's great. There's nothing I don't like about it. Because you've [the coach] provided me with ideas and you also tell me some things I can work on or things that you like. Just the feedback is great. I really liked it. [Sandra, Coaching Cycle #2]

> I don't want to mess up the concept, as far as presenting it to the students. Number one, I don't want myself as a professional to look bad. And then, number two, I don't want the students to get the wrong information, or for me to tell students something that's inaccurate. And so the video documents that. If I said something that was inaccurate or if I taught the students something that was wrong, it's documented. [Anthony, Coaching Cycle #5]

Teachers appreciated the videorecording as it allowed them to see who they were as teachers and how that was enacted in the classroom. They allowed the teachers to see critical moments in their teaching that were not accessible through memory and with enough detail that would be useful. Watching the videos also allowed for meaningful conversation around their teaching that was data-driven. One central reason was that being able to watch their teaching themselves, teachers did not have to rely on the feedback of others, or interpretations from their own memory, but allowed for a more objective self-evaluation of their teaching.

Negative. Teachers experienced a range of negative emotions related to videorecording including, “uncomfortable”, “a bit of anxiety”, “nervousness”, “frustration”, and “more comfortable”, in relation to being videotaped, the anticipation of watching the video, and watching the video. Most teachers experienced discomfort in seeing and hearing themselves on video and felt anxious thinking about what would possibly be revealed on the video that they did not observe during instruction. Sandra, for instance, reported her sense of discomfort to seeing herself teaching on the video:

> Yeah, and then hearing your voice, maybe no one likes to hear their voices. I'm so high-pitched, I'm like really, no wonder they don't listen to me. I don't have that voice, down and deep [Sandra, Coaching Cycle #1]

Wilma, Anthony, and Jessica also discussed the presence of the camera seemed to set both teachers and students in performance mode – making them more conscious of their actions and perhaps diminishing authenticity. Willa discussed her feeling to "perform" in front of camera:

> Instead of probably conducting my class in a way that maybe I typically would, it's like I got to speed this through to the end because by gosh, this is what she's [the coach] here to see... It's still--I'm getting more comfortable with having the camera there, but I still feel like I'm performing versus just teaching somewhat. [Wilma, Coaching Cycle #2]

Neutral. Several teachers reported neutral emotions such as "calm", "not bothered", "not anxious", and "comfortable", as they did not feel they were being judged about their teaching (e.g., Katie). In recognizing that his calibration between his thoughts about the lesson and the actual lesson was misaligned, Bill had feelings of calm about the videotaping process.

> I was pretty calm today. Yeah, I think when I think the lesson goes terribly, I watch the video and go, oh, it wasn't as bad as I thought. And when I think the lesson goes really well, I watch the video, and I was like, oh, it wasn't as good as I thought either. It's always somewhere in the middle of what I actually perceived it to be. [Bill, Coaching cycle #4]
>
> I mean, does anybody really like the way they look on video? I don't know...Yeah. So I didn't even think about that. Yeah, I don't really mind being recorded because I don't think that anybody will ever see that in the way that they would judge me. Like only teachers or people involved in education would ever look at that-- which makes it way more comfortable [Katie, Coaching Cycle #5]

Mixed-Complex. Mixed-complex emotions include a combination of positive, negative, and/or neutral emotions in relation to the videorecording experience. As shown in the quote below. Sandra felt initially nervous about watching herself on video but seeing her instruction made her feel great because it turned out well. She also expressed some generalized discomfort about watching herself on video. Sandra's range of emotions reflects the complexity of calibration and evaluation processes before and during watching videos.

> So I was nervous, and then so I was able to watch it by myself, which was great. but yeah, I was really nervous at first. And being that you never see me teach, you don't want to look like you don't know what you're doing. It turned out good. I personally like the whole process, because when you have a regular evaluation in the classroom-- well, you have lesson plans, and you turn it in, but you never really talk about it. you never know what day they are going to show up anyways. I guess I just felt like I was more prepared doing this this way, and it made me really think it through. Really doing it, like when you said, what activities will you have? What are you expecting from them? And then watching, which is just very uncomfortable, for anybody watching it, and seeing yourself in the video. [Sandra, Coaching Cycle #1]

Emotions about Watching Video vs. being Videotaped. One interesting point to note is that five of the seven teachers distinguished their emotions about watching videos and being videotaped. They expressed 23 instances within three major types of emotions about being videotaped: positive emotions (6 instances, e.g. "I think it's [videorecording] one of the best things going on" Anthony C4); neutral emotions (12 instances, e.g. "I was okay being videotaped…comfortable, Sandra C5); and negative emotions (5 instances, e.g., I feel like during my lesson especially when you guys are there, when it's being videotaped, I'm paying extremely close attention to things that, you know, every little detail that is going on, Jessica C4). Reasons underlying these negative emotions include the first time of being videorecorded, perceiving videorecordings as performances, and the anxiety of meeting instructional expectation. These concerns and negative emotions were not reported in emotions related to watching videos.

Discussion

One key finding was that the emotions teachers described about videorecordings do not align with the kinds of discrete emotions described in the literature. Instead of using the emotion words such as “anger”, which is one of the most reported emotions in prior studies (e.g. Sutton & Wheatley, 2003), or “anxiety”, teachers used words and phrases like “avoided watching” or “intimidating” to explain the negative emotion they felt about videorecording. Moreover, teachers’ descriptions of their emotions about videorecording did not mirror the emotions related to teaching described in the literature. For example, the teachers used words such as “better, feel good, felt better” more in expressing their positive emotions around videorecording, while the most commonly used words for positive emotions found in the literature in relation to teaching are “enjoyment” and “pride” (Frenzel, 2014).

While there was greater consistency across teachers in moving towards neutral and positive after cycle 3, some of our teachers did not get “used to” the videorecording over 5 cycles even though they appreciated the benefits of it. Although they became more comfortable or positive over time, most of the teachers did not feel positive emotions by coaching cycle 5. For example, Bill expressed that he found watching the recordings of his instruction “easier to watch” meaning he still did not feel comfortable about watching the videorecordings. Borko and colleagues suggest that gradual exposure to similar experiences helps teachers to get accustomed with recognition of the elements in their existing practices that need improvement (Borko et al., 2008). This suggests some teachers need more experience with the videorecording so their respective emotions are neutral or positive.

One important take-away for us as professional developers and researchers is that although teachers experienced negative emotions, they still found the experience valuable and they wanted to continue the program because of the perceived benefits. This implies that teachers have professional capacity to prioritize their learning and growth, even if it comes with negative emotions. Researchers and professional developers should pay close attention to teachers’ emotions when videorecording is utilized, so that teachers’ negative emotions are addressed in a way to maximize their learning. Another point to consider is the relative nature of emotions when multiple PD sessions are used over time. As shown in our data, teachers often reported their emotions in the current video recording in comparison to their earlier video-recordings. Thus, professional developers need to listen and attend to teachers’ emotions carefully from the onset of their collaborative work to create a rapport, engendering trust and showing genuine interest in supporting teachers in their work. In so doing, we can more effectively utilize available tools and resources, like videorecording, to foster teachers’ continued engagement in professional development.

RECONCILING LOCAL CONTEXTS AND EXTERNAL CONCEPTUAL RESOURCES IN MATHEMATICS TEACHERS' COLLABORATIVE SENSEMAKING

Mathematics teachers develop understandings about instruction across multiple settings, such as classrooms, workshops, and professional learning communities. When teacher teams collaborate, their prior teaching and learning experiences meaningfully inform their sensemaking. However, current research does not explicitly link teacher conversations and these multiple settings for learning. In this study, we seek to understand secondary mathematics teachers' collaborative learning in schools as part of broader teacher learning ecologies. Using discourse analysis and a comparative case study design, we examine how two teacher teams' conversations recruit external conceptual resources to support the development of their collective pedagogical judgment. In particular, these external resources offered the teams rich representations of practice and productive framings of teaching problems.

Keywords: Teacher Education - Inservice / Professional Development, Communication, Teaching Tools and Resources, Learning Theory.

In a recent review of research on teacher collaborative discourse, Lefstein and colleagues (2019) noted that researchers in this nascent field rarely attend to broader contexts of teacher conversations; "rather, they primarily focus on the immediate context of the setting or intervention" (p. 6). This stands in sharp contrast to calls to develop theory and methods to study teacher learning as distributed across contexts (e.g., Kazemi & Hubbard, 2008). For example, consider Borko's (2004) AERA presidential address:

> For teachers, learning occurs in many different aspects of practice, including their classrooms, their school communities, and professional development courses or workshops. It can occur in a brief hallway conversation with a colleague, or after school when counseling a troubled child. To understand teacher learning, we must study it within these multiple contexts, taking into account both the individual teacher-learners and the social systems in which they are participants. (p. 4)

Borko's call resonates with the PME-NA Conference's theme of "manifestations across different cultures, places and contexts," pointing to the need to develop tools to look across contexts for making sense of learning. It also aligns with our own experience as teacher educators (Buenrostro & Ehrenfeld, 2019; Marshall & Horn, under review) and our overall goal to develop better ways to design, facilitate, and analyze teacher collaboration toward improved mathematics instruction.

For the past four years, we have been supporting teacher learning through conversations with mathematics teacher teams in their schools. In these conversations, we noticed that teachers often build their ideas on what we refer to as external conceptual resources. We define external conceptual resources as frameworks, tools, and concepts that transcend different teacher learning environments, which are external to the local school context and echo voices external to the local team. Examples of such resources include teaching practices from workshops, curricula from previous schools, or teaching strategies introduced at a conference.

We have multiple motivations for looking at mathematics teacher learning across contexts. First, calls to study teacher learning across multiple contexts (e.g., Borko, 2004; Kazemi & Hubbard, 2008; Lefstein et al., 2019) coincide with recent moves in the learning sciences away from seeing learning as tied to specific places to learning that is distributed across environments — multiple settings for individuals' sensemaking that are sometimes referred to as learning ecologies (Barron & Bell, 2016). When they are invoked, external conceptual resources often echo voices from these other contexts; by attending to them in our analysis, we offer a method to study teacher conversations as they are embedded in broader learning ecologies. Second, we think there is practical value in analyzing the particular role of external conceptual resources in mathematics teachers' collaborative sensemaking; understanding how teachers recruit these resources in their sensemaking can illuminate productive ways to design things like professional development, curricular tools, and analytic frameworks for teaching with the goal of supporting their productive use in schools and classrooms. Thus, our main goal in this study is to better understand how external conceptual resources contribute to mathematics teacher collaborative sensemaking.

Theoretical Framework: A Situative View on Teaching and Teacher-Learning

We take a situative perspective on mathematics teachers' learning which supports investigations into activity systems and contexts that shape meanings (Borko, 2004; Greeno, 1998; Horn & Kane, 2015). Teachers constantly make sense of pedagogies and educational reforms in the context of their classrooms and amidst wider socio-historical forces (Coburn, 2001; Horn & Little, 2010). For example, Marshall & Horn (under review) found teachers' uptake of learning from professional development (PD) workshops is largely influenced by the goals and demands in their local teaching situations. As mathematics teacher educators, we aim to design environments that present teachers with opportunities to learn (OTLs) which, in turn, will support their instruction.

To study mathematics teachers' OTLs in conversations about instruction, we follow Horn & Kane (2015) who emphasize how rich conceptual resources support rich OTLs. In previous analyses of conceptual resources in teacher conversations, researchers attend to teachers' representations of practice and productive frames for problems of practice as being consequential in how teachers make sense of and improve instruction (Bannister, 2018; Brasel et al., 2016; Hall & Horn, 2012; Horn & Kane, 2015; Vedder-Weiss et al., 2018). Representational infrastructures are "technologies, ways of talking, and materials that support how people engage with conceptual practices in their activity" (Hall & Jurow, 2015, p. 174). Representations of practice are a part of these infrastructures that make different aspects of teaching more or less visible (Little, 2003), and they are critical for considering alternative ways of working in the future (Hall & Horn, 2012). Framing is a discursive process by which meanings are generated by participants to imply what are relevant and legitimate ways of understanding and discussing a situation (Goffman, 1974). Vedder-Weiss and colleagues (2018) argue that productive, collaborative framing of problems of practice links teaching, learning, and subject-matter, creates opportunities to rethink practices, and positions teachers as having the power, authority and responsibility to cope with the problem. Bannister (2018) underscores that looking at collaborative problem frames is a useful analytic tool both in identifying problems (diagnostic frames) of practice and in suggesting solutions (prognostic frames). In this study we contribute to the research of conceptual resources in mathematics teacher conversations by investigating how, through teachers' references, external conceptual resources have the potential to support both rich representations and productive framing of practice, which in turn can provide the collaborative team with rich learning opportunities.

In our analysis of teacher learning, we draw on Horn's (2020) conception of teacher learning as the development of pedagogical judgment to inform our research question: How do external conceptual resources contribute to teachers' pedagogical judgment? In our work, pedagogical judgment consists of three interrelated but analytically distinct components: (1) pedagogical action: choices teachers make, intentional or not; (2) pedagogical reasoning: different interpretations and rationales supporting actions; and (3) pedagogical responsibility: teachers' sense of ethical or situational obligations. In this analysis, we look for evidence of teachers' efforts towards the alignment of these three components during their development of pedagogical judgement.

Data and Methods

Research Context and Data

To investigate the role of external resources in mathematics teachers' collaborative sensemaking, we use data from a larger research-practice partnership between our research team and a professional development organization (PDO) for secondary mathematics teachers, where we designed a system for video-based feedback on teachers' instruction. We facilitated and filmed 33 cycles of classroom observations followed by a lesson-debrief conversations with teacher teams in their schools, organized around videos of teachers' classrooms. The primary goal was to use the classroom video to elicit, engage, and develop secondary math teachers' pedagogical judgment.

Data Analysis

Phase 1: Conceptualizing teacher conversations as part of a larger teacher learning ecology and selecting cases. During our analysis of the lesson-debrief conversations, we noticed that teachers often built their ideas on the external conceptual resources we defined earlier. Our primary units of analysis were episodes of pedagogical reasoning (EPRs), which are segments of conversation participants reason about an issue of instruction (Horn, 2007). We created an inventory of EPRs in which we noted what, when, where, and by whom such resources were referenced. In building this inventory of EPRs, we started to better understand how the debrief conversations are discursively connected to other settings in the larger teacher learning ecologies (see Figure 1). For this paper, we chose to analyze cases around two conceptual resources from contexts often mentioned in teacher conversations: experiences in previous schools and workshops. We selected these two cases from Noether High School and Rees Middle School (see Table 1, all names of schools and teachers are pseudonyms) because they provide exceptionally illuminating examples of ways teachers reason with and about external conceptual resources in their respective local contexts.

Table 1: School Context Summary

School	Student Demographics	Debrief Participants
Noether High School	60% Latinx, 15% African/African American, 15% Asian/Asian American, 10% White, 5% Filipinx	Teachers: Brad (filmed), Marisa and Greg. Researchers: Lani and Nadav
Rees Middle School	80% Latinx, 5% Asian, 5% White, 5% Filipinx, 5% African/African American	Teachers: Ezio (filmed) and Veronica. Researchers: Patty, Lani and Nadav

Phase 2: Analyzing the intersection of local contexts and external conceptual resources. Using interaction analysis methods (Jordan & Henderson, 1995), we looked closely at videos of each of the two debrief episodes. To pursue our overarching research question, we asked a number of sub questions that allowed us to understand the meanings the teachers were negotiating and (re)constructing; these questions included: How are the resources referenced in teachers' conversations? How are they taken up (possibly with transformations) by other participants (Goodwin, 2018)? How do they support reasoning about teachers' goals and responsibilities (Horn,

2020)? How do they offer (or not) adequate representations of practice (Hall & Horn, 2012; Little, 2003) and productive problem framings (Bannister, 2018; Vedder-Weiss et al., 2018)?

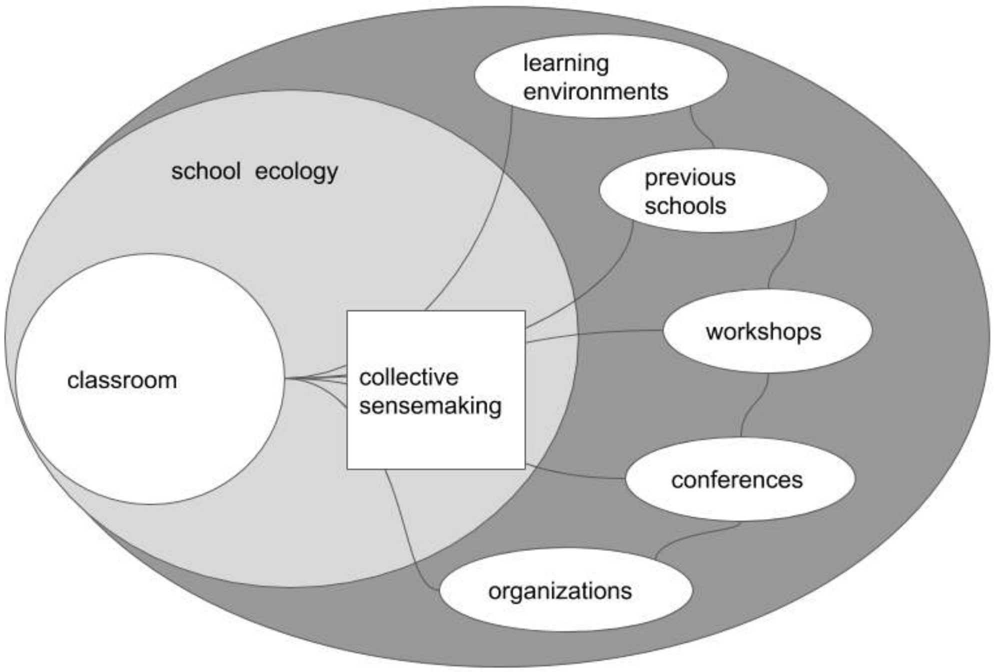

Figure 1: A Schematic Representation of Collective Sensemaking as Part of Teacher Learning Ecologies

Findings: Honing Pedagogical Judgment by Reconciling Local Contexts and External Conceptual Resources

In the focal debrief conversations, external conceptual resources supported the development of teachers' pedagogical judgment by affording richer representational infrastructure and more productive problem frames, which in turn increased alignment among teachers' pedagogical action, reasoning, and responsibility. We illustrate this process in the following cases, where teachers collectively reconciled local problems of practice by mobilizing external resources for their sensemaking. Table 2 summarizes the two cases.

Table 2: Case Studies Summary

External Conceptual Resource	Recruited From...	Local Context	Afforded...
College Preparatory Math (CPM) curriculum	Marisa's previous school	Noether debrief conversation May 2018	representation of teaching as establishing learning environment. framing of the problem of students' mathematical agency around processes of building classroom culture.

Random Grouping and Purposeful Grouping as instructional practices	Park City Mathematics Institute (PCMI) workshop and Kagan training	Rees debrief conversation December 2017	representation of teaching as entailing judgments between contrasting structures. framing the problem of labeling students by underscoring local school context and teacher agency.

EPR 1: Representation and Framing of the Problem of Leveraging Students Agency

The first case is of a debrief conversation at Noether High School. After filming Brad's Algebra 1 classroom, we returned to debrief the lesson with him and his school-based team consisting of Brad, Marisa, and Greg. We introduced clips from this lesson to discuss Brad's topic of interest which was the way he provides feedback to students. The first clip featured Brad giving a group of students a strong cue about how to proceed with the problem. Following Brad's comment "I wonder if there's a better question that I could have asked" the research team and teachers in the debrief then suggested alternative interactions that would promote more independent student thinking. For example, Greg suggested "why do you think that?" and Marisa suggested "how did you figure that out?" as alternative responses. Important to our analysis is that at this point, the conversation was focused on illustrations of teacher-student interactions, and that the team was motivated by a shared responsibility to leverage students' mathematical agency.

Problem-based curriculum as an external resource. After some comments about the content of the task, Marisa referenced her experience of teaching a problem-based curriculum, College Preparatory Math (CPM), in her previous school:

> I'm looking forward to hmm possibly next year having a problem-based curric- well, I don't know if we're going to teach geometry- what we're going to teach, but if we do teach geometry, if we could possibly use the CPM curriculum because one of the reasons I like that particular curriculum is because it's in groups from day one. Every day students are working in groups. That's the culture of the classroom that's built up. So, they're creating the meaning from doing the problems and developing the mathematics by the problem solving that they're doing and the teacher's kind of just there facilitating and you're walking around the whole time asking the questions and guiding if they need it, but it's all coming from the students all the time.

Marisa describes her experience in a classroom where students have mathematical agency and see themselves and their peers as resources of mathematical knowledge. She attributes it to the problem-based curriculum, but more specifically to the structures (such as working every day in groups) that contribute to a collaborative classroom culture. Marisa then contrasted this experience with their current classrooms' situation, where they are "going kind of back and forth" between direct instruction and groupwork. She perceived that students in their current classrooms get frustrated when teachers don't hand over answers, as in her narration of students saying—"well, just tell me, just tell me what it is." The episode ended with others acknowledging that the problem involves the disruption of traditional classroom norms, and that even with a problem-based curriculum, students are always "going to struggle the first time" (Greg).

Representation and framing. In the Noether team's debrief, the teachers discussed the focal teacher, Brad's, groupwork facilitation and ways to leverage students' agency and communication. The representation of teaching made visible in this episode began with a focus on teacher-student interactions. Then, Marisa shared her previous experience of teaching the CPM curriculum. Drawing on the external conceptual resource of CPM, Marisa supplemented this representation of teaching with aspects of designing a learning environment and reframed the problem of practice from the particularities of the teaching interactions (micro) to the construction of a certain classroom culture (macro). We see the new frame as productive in that it moved the conversation away from the problem frame of leveraging students' agency as transient and technical and yet still positioned the teachers as having the power to address it.

Pedagogical judgment. Implicit in this reframing is Marisa's reasoning that to leverage students' mathematical agency, teachers' differing responses is not enough; teachers need to engage in a more macro pedagogical action, in this case setting collaborative classroom norms from the first day. This frame offered the team images of new actions that support students' mathematical agency. We argue that Marisa's experience in her previous school with the CPM curriculum was a meaningful external resource for learning in this conversation; CPM was not used as a resource to reason about CPM. Teachers in conversation were not trying to teach CPM as a new curriculum; rather, they reasoned with CPM about groupwork facilitation, towards a better alignment of the team's pedagogical actions with their pedagogical responsibilities.

EPR 2: Representation and Framing of the Problem of Labeling Students

The second case comes from a debrief conversation at Rees Middle School. We filmed Ezio's classroom and returned after a few days to debrief the lesson with him and his colleague Veronica. We introduced clips from this lesson to discuss Ezio's topic of interest which was group dynamics. Ezio's lesson objective was to help students distinguish between linear and nonlinear equations, and he structured his 90 minutes lesson around two group tasks. Students were randomly assigned to groups of three. After listening to some student conversations in the debrief, Ezio became concerned that not all students were contributing to their group conversations, and we discussed whether providing more structure might have helped students work more productively together. For example, Ezio mentioned a structure where the student holding the marker can't talk, and Veronica wondered if group roles would have been helpful.

Random and purposeful grouping as external resources. At this point, a member of the research team (Patty) prompted the teachers to elaborate on their understanding of group dynamics. Ezio responded by initially distancing himself from the practice of random grouping used at PCMI: "at least in PCMI, I really did not agree with the random grouping." Veronica pressed him on this, saying, "But you are doing random grouping." He confirmed that he was:

Ezio:	Yeah. I let the computer pick it out. I've been trying it out. We got Kagan training
Patty:	mm-hmm
Ezio:	a couple years ago and at least what they said made sense, where it's purposeful—
Veronica:	Purposeful grouping.
Ezio:	Yeah, like a high low—
Patty:	Yep.
Ezio:	There was a structure to everything. and uh—
Patty:	so you're wondering if—
Ezio:	I was wondering, I didn't agree with PCMI but I wanted to try it out to see.
Patty:	Okay

Ezio repeated twice how he first did not agree with random grouping at PCMI. He contrasted random grouping with purposeful grouping, which was introduced to him a few years before and made sense to him. However, Ezio then narrated how random grouping became a resource for him to experiment with. He continued by connecting his experience to the local school context and to an institutional practice he saw as inequitable (tracking):

Ezio:	I know where my bias is but—
Patty:	Yeah.

Ezio: Let's try it out. and I do— one thing I do fear... (1.5-second pause) so like what's bothering me in this school, we do— ok unofficially, unofficially we track kids.
Patty: Yeah.
Veronica: Officially.
Ezio: No, unofficially.
Patty: Yeah, well, we talked about this, right? last time.
Ezio: so I've had kids tell me, "Oh, we're in the dumb class." They know; they already have that label.
Lani: Is this one of the groups of kids that is in the "dumb class"?
Ezio: No, no.
Veronica: No.
Lani: Okay.
Veronica: ...like in a Kagan, when you purposefully group, the kids automatically know.
Lani: Yeah.
Patty: Yeah, which they do.
Veronica: Whereas if you randomly group, they don't know.
Lani: Right.
Ezio: Right, so I don't want to subconsciously be telling kids, "Oh, I think you're awesome."
Patty: Yeah, yeah.
Ezio: That's the one thing I did like about the random grouping.

Ezio contrasted random and purposeful grouping twice: First, when introduced to them; while he did not agree with random grouping, purposeful grouping made sense to him. Second, when evaluating their contribution to his sense of pedagogical responsibility; even though purposeful grouping made sense to him, it functioned to reproduce what was "bothering in this school." In contrast, even though he did not agree with random grouping for its lack of structure, the one thing that he did like about it was that it disrupted the institutional process of labeling kids.

Representation and framing. An aspect of teaching that becomes visible in Ezio's representation of teaching is that teachers are constantly exposed to many different, sometimes even contrasting instructional practices that they need to compare, contrast, and reason about. This representation, supported by the reference of the two external conceptual resources of random and purposeful grouping, afforded a framing of the problem of labeling kids that (1) underscores the local school context as Ezio experiencing it; and (2) positions the teachers as having "the power, authority and responsibility to cope with the problem" (Vedder-Weiss et al., 2018).

Pedagogical judgment. Ezio used the story of his engagement with random grouping, first at PCMI and then in the ongoing work of teaching, to reason about his pedagogical actions, and to stress their connection to his sense of responsibility to disrupt what he saw as unethical tracking in Rees Middle School. Specifically, random grouping could ensure that students did not perceive themselves to be "lower" or "higher" than others with regard to mathematical placement or ability. Puncturing the conversation at multiple points, random and purposeful grouping served as resources to support Ezio and Veronica's reasoning about their instruction. Ezio described himself as a reluctant user of random grouping while carefully articulating the reasons to use the practice. By doing that, Ezio made visible pedagogical judgments as an ongoing aspect of his practice, and the team consolidated connections between their actions and their shared sense of responsibility.

Discussion

We presented cases of mathematics teachers collectively reconciling local contexts and external resources. Teachers are exposed to many different, sometimes even contrasting, conceptions of good teaching (Britzman, 2012) in their larger learning ecologies, and external resources often aid in their sensemaking with and about these conceptions. By attending to these external resources, we underscore a unique role of collaborative sensemaking opportunities in the overall teacher learning ecologies. Specifically, we build on previous situated research of teacher conversations to offer a discursive mechanism by which external conceptual resources contribute to teachers' pedagogical judgment: by affording richer representational infrastructure and more productive problem frames, teachers were able to bring their pedagogical responsibility, actions, and reasoning into closer alignment.

As a field, we came to acknowledge the importance of what the PME-NA Conference theme describes as "manifestations across different cultures, places and contexts." We see this work on external conceptual resources as a step towards developing better ways to design, facilitate and analyze mathematics teacher learning across contexts.

EXAMINING HOW TEACHERS ENACT THE SUGGESTIONS OF A COACH: CRITIQUE OF A METHODOLOGY

In this methodology paper, we present a methodology for characterizing how teachers use coaches' suggestions. We identified suggestions from planning conversations and explored the extent to which the teachers implemented the suggestions in enacted lessons. The planning conversations took place within online content-focused coaching cycles. A primary challenge confronting content-focused coaches when working one-on-one with teachers is finding a productive balance between giving suggestions and inquiring into teachers' practices through reflective questioning. This paper articulates a process for identifying suggestions made by a coach during a planning conversation and an analytic process for examining how a teacher takes up the suggestion during lesson implementation. We discuss the methodological challenges we encountered and tradeoffs in our decisions related to low- and high-inference claims.

Keywords: Inservice Teacher Education/Professional Development, Research Methods, Coaching

Coaching as a form of professional development is a promising practice (Campbell & Griffin, 2017; Ellington, Whitenack, & Edwards, 2017). Within mathematics education, content-focused coaching (e.g. West & Cameron, 2013) is a common model. Content-focused coaching involves iterative cycles in which a coach works one-on-one with a teacher, with a focus on students' mathematical learning goals. Each coaching cycle contains three sequential components: a pre-conference discussion to plan a lesson; a collaboratively taught lesson; and a post-conference discussion to debrief the lesson (Bengo, 2016; West & Staub, 2003).

Research on coaching has highlighted two competing stances for how coaches talk with teachers: *reflective* or *directive* (Deussen, Coskie, Robinson, & Autio, 2007; Ippolito, 2010; Sailors & Price, 2015). Coaches using a *reflective* stance emphasize collaborative inquiry in which the coach elicits ideas from the teacher; these ideas become the basis of the coach-teacher discussion (Ippolito, 2010). Coaching moves associated with a reflective stance include probing questions and low-inference, non-evaluative observations as means to catalyze teacher thinking (Costa & Garmston, 2016). In contrast, a *directive* coaching stance involves the use of suggestions and evaluative feedback (Ippolito, 2010). The challenge in content-focused coaching is to find the right balance between when to provide a teacher with direct assistance in the form of a suggestion and when to employ an inquiry stance (West & Staub, 2003). It is crucial for researchers within mathematics education to explore these stances and their impact on teacher learning and uptake of new practices.

Despite the importance of mathematics coaches strategically choosing appropriate actions when working with teachers, little is known about how mathematics coaches using a content-focused coaching model interact with teachers (Gibbons & Cobb, 2016). Furthermore, little research exists on how direct assistance from a coach during a coaching cycle supports a teacher to implement a lesson. As a first step in addressing this gap, this paper outlines a methodology for analyzing how teachers take up a coach's suggestions when planning and enacting lessons. Specifically, this study is guided by the question: How do we characterize the extent to which a teacher uses the suggestions of a coach during the implementation of a lesson? This methodology would help mathematics educators better understand the impact of a coach's suggestions on the pedagogical actions of a teacher and serve as a first step towards the larger inquiry of how the discursive actions of a coach impact teachers' practices.

Methodological Processes Applied to Coaching Conversations

To identify the suggestions made by the coach during the collaborative planning conversations, we used results from a broader analysis of the coaching conversations. These results came from a broader study that analyzed planning and debriefing conversations within content-focused coaching cycles from four coaches paired with eight teachers over a period of two years. In that broader analysis, we focused on the discursive moves of mathematics coaches during coaching cycles. We developed a codebook to analyze the transcripts of planning and debriefing discussions between coaches and teachers; this codebook characterized the discursive moves of the coaches and teachers as well as the content of the conversations. The section of the codebook that focused on the discursive moves of the coach was comprised of five broad categories; including suggestions (see Figure 1). We defined a *suggestion* as a statement from the coach recommending an action for the teacher.

Coaching Stance	Discursive Move	Description	Example
Reflective	Invitation	Statement or question that invites the teacher to reflect or respond	“What might be some strategies we could use to increase student participation?”
	Description	Statements that share a direct observation and do not contain inference, interpretation, judgement or opinion	“I noticed that during the turn-and-talk, Alex did not say anything to his partner.”
Directive	Suggestion	Statement that recommends an action	“I think we should use a turn-and-talk prior to the whole class discussion.”
	Explanation	Statements that provide an interpretation or rationale of an event, interaction, or mathematical idea	“Turn-and-talk is a powerful strategy to use prior to a whole class discussion because it increases student participation.”
	Evaluation	Statements that offer praise or critique	“I think it was a great idea to use a turn-and-talk.”

Figure 1: Excerpt from the larger codebook focusing on coaching discursive moves

We parsed the transcripts of the planning and debriefing conversations into stanzas, which included a coach’s statement and the participant’s response, as well as text needed for context (Saldaña, 2013). This broader data set included the analysis of n = 1719 stanzas from 41 transcripts of coaching conversations. We coded stanzas in pairwise teams after a lengthy calibration process that involved five researchers. We met via video conferencing software, Zoom, to reconcile disagreements. Kappas ranged from 0.39 to 0.65, considered moderate to strong reliability (Landis & Koch, 1977).

The following is an excerpt from a coach’s comments that was coded as a *suggestion*:

> One of the really nice moves you can do if the group shares a thought about something, and it’s somewhat ambiguous, is you can turn to the class and say, “Can someone else use their own words to explain what Dave is saying?”

In this comment, the coach recommended the teacher prompt students to paraphrase a peer’s explanation as a means to increase student participation in classroom discussions.

Piloted Version of Data Analysis Process for Coaches’ Suggestions

The purpose of this paper is to detail a methodological process for identifying suggestions made by coaches and characterizing how those suggestions were taken up by the teachers during lesson implementation. We wanted to understand how teachers incorporated the suggestions coaches provided during planning meetings into their teaching. We describe our current analytic attempts to highlight the methodological affordances and challenges of the work and to gain insight from others in the mathematics education community. Knowing the extent to which teachers follow coaches' suggestions in their teaching is important information for coaches as they plan to support teachers.

Coding Suggestions from the Coaching Transcripts

We collected all stanzas previously identified as involving a coach's suggestion. If a stanza contained multiple distinct suggestions (i.e. more than one action was recommended by the coach), each suggestion was placed into a different row in the spreadsheet where we tracked the suggestions, with the goal of distilling a coach's suggestions to the smallest granular size. This process converted the unit of analysis from a stanza to an individual suggestion. For example, a coach made the following statement to the teacher during a planning conversation:

> Whereas, if you really want them to be able to understand the formula, you're going to be asking different questions about, where did this come from? What do we know about volume? What does volume mean? Those kinds of more probing questions as they're working or as they're thinking about it, and as you're launching. Then, what I'm also thinking about is your ticket out the door idea. This idea of, do you want to do some checking in with students in terms of their understanding about volume related to the cylinder and the cone, either before they leave you Monday, or possibly Tuesday, so that you get a sense of, beyond just your questioning and asking each individual group, would you want to have—would it be helpful to have some kind of—some documentation to look back at in terms of students' understanding? I'm just thinking of a little, mini half-sheet, or something, if it would be, again, helpful to figure out where kids are in their thinking.

We coded this statement as two distinct suggestions. First, the coach suggested that the teacher ask different questions about the concept of volume. Then, the coach provided suggestions about the ticket out of the door. These two suggestions were listed separately.

Next, two coders individually coded each of the coach's suggestions for the content of the suggestion using the codebook (see Figure 2).

Content								
Lesson Goals	Instructional Practice	Math Content	Coaching					
Contextualizing	School/Classroom Context	Math Content or Curriculum	Students(s)					
Lesson Content	Introduction/Launch	Task Description & Sequencing	Questions/Questioning	Summary	Assessment	Adaptions	Discourse	
Lesson Features	Instructional Needs	Misconceptions/ Challenges	Anticipating	Selecting/Sequencing	Connecting	Participation Structure	Next Steps	Student Strategy
Technology	Technical Logistics/Challenges	Referencing Swivl/Annotations/Video	Use of Technology					

Figure 2: Content codebook, with categories in purple and codes in yellow.

Each coder created a concise statement capturing (a) the *general nature of the suggestion* and (b) the *specific action in the suggestion* recommended by the coach (see Figure 3). The coders then met to reconcile and reach consensus for their content codes and created statements. For example, during a planning conversation, a coach said:

> Kids are always surprised that getting one of each happens so much more often than getting two of the same. Your experimental data is definitely going to show that. What if you asked them, "If you toss a coin twice, what are the things that could happen?" You ask them that at the beginning, just to get an idea of where they are.

We applied the content codes of *question*/*questioning*, *assessment*, and *introduction*/*launch* because the coach recommended the teacher ask a question during the launch phase of the lesson to assess student thinking prior to beginning a task (see Figure 3). The general nature of the suggestion was written as: "Ask students questions during launch to assess their understanding." The specific action suggested by the coach was captured by the coders through the statement, "Ask the question 'If you toss a coin twice, what are the things that could happen?' during the launch to assess student understanding."

Stanza Excerpt	Content Codes	General Nature of the Suggestion	Specific Action in the Suggestion
Kids are always surprised that getting one of each happens so much more often than getting two of the same. Your experimental data is definitely going to show that. What if you asked them if you toss a coin twice, what are the things that could happen? You ask them that at the beginning, just to get an idea of where they are.	Assessment, Question/ Questioning, Introduction/ Launch	Ask students questions during launch to assess their understanding	Ask the question "If you toss a coin twice, what are the things that could happen?" during the launch to assess student understanding.

Figure 3: Excerpt from the coding spreadsheet

If there was not a specific action within the suggestion, the *specific action in the suggestion* column was left blank. Additionally, if the suggestion was deemed to not be observable within the lesson video, we coded the suggestion as *not observable*. For example, if the coach suggested an action for the teacher in future lessons beyond the current coaching cycle, the suggestion would be *not observable* during the lesson video.

Coding Enactments of Suggestions

The coders independently watched the video of the implemented lesson to identify how the teacher followed the general and specific suggestions from the coach. For each suggestion marked in the spreadsheet generated from analyzing the coaching transcripts, the coders worked on two levels. First, they considered if the general nature of the suggestion was *present* or *not present* in the lesson. Second, they considered the extent to which the specific action of the suggestion was taken up by the teacher. To code the specific action, they chose between the following codes that represented a continuum of uptake: *not present*, *partially adhere*, *mostly adhere*, or *fully adhere* (see Table 1).

Table 1: Coding Scheme for a Teacher's Enactment of a Specific Suggestion

Code	Description	Example (connected to Figure 2)
Not present	The teacher did not enact any part of the coach's suggestion during the lesson.	The teacher did not ask any questions during the lesson launch.
Partially present	The teacher enacted only a single part of the coach's suggestion during the lesson.	The teacher asked a question during the lesson launch but the question does not relate to assessing understanding.

Mostly adhere	The teacher enacted multiple, but not all, parts of the coach's suggestion during the lesson.	The teacher asked a question during the lesson launch to assess understanding but used a question worded differently the question suggested by the coach.
Fully adhere	The teacher enacted all parts of the coach's suggestion during the lesson.	The teacher asked the exact question suggested by the coach during the lesson launch.

In cases where the teacher did not have the opportunity to enact a suggestion from the coach, the instance was coded as *no opportunity*. For example, if the coach suggested the use of a specific teacher talk move during a whole-class summary discussion of a task (e.g. Smith & Stein, 2011) but the class period ended before the teacher was able to begin the summary discussion, we coded that as the teacher not having the opportunity to enact the coach's suggestion. The code *no opportunity* is different than *not observable* in that *no opportunity* was based on a suggestion that could be observable but was beyond the scope or inclusion of the implemented lesson due to constraints such as time or classroom happenings in the moment of the lesson. Figure 4 contains a flowchart summarizing this analysis process.

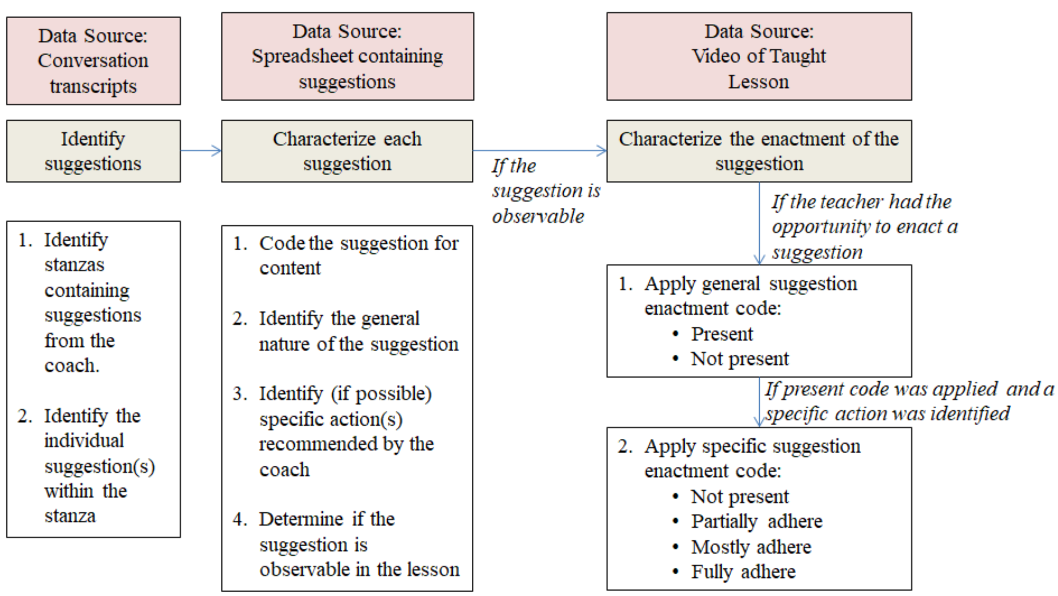

Figure 4: Flowchart of analysis process

Methodological Affordances and Challenges

In this section we describe the methodological affordances of our analysis process as well as the challenges we encountered when: a) identifying suggestions given by the coach within conversation transcripts; b) categorizing a coach's suggestions based on how the suggestion invited action from the teacher; and c) characterizing the extent to which teachers took up a suggestion when teaching a lesson. We discuss these affordances and challenges within each step of our analysis process to highlight methodological issues when characterizing direct assistance from coaches and the impact of that direct assistance on teachers' instructional practices.

Identifying Suggestions

The first challenge we encountered was establishing a reliable coding process for determining when coaches made suggestions. The coaches used a range of discursive moves when recommending an action to a teacher (Gillespie, Amador, & Choppin, 2019), making the identification of suggestions problematic. For example, a coach said:
