PME-NA

ISBN: 978-1-7348057-0-3

DOI: 10.51272/pmena.42.2020

Revision

This PDF has been revised as follows:

- Minor corrections to the Table of Contents:
    - author names of two papers have been fixed;
    - corrections in the titles of two other papers.
- The paper “Understanding teachers’ professional development …” by Luc Trouche on p. 143 has been modified to its correct version.
- Corrected author information in paper “Disentangling the role of context and community …” on p. 2001
- Added missing transcript numbers on p. 2267

MATHEMATICS EDUCATION ACROSS CULTURES

MATEMÁTICA EDUCATIVA ENTRE CULTURAS

DIDACTIQUE DES MATHÉMATIQUES À TRAVERS LES CULTURES

Proceedings of the Forty-Second Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education, Mexico*

*Scheduled originally to take place in Mazatlán, México, 14-18 October, 2020;
postponed, due to the COVID pandemic, to 27 May-6 June, 2021

PME-NA History and Goals

PME came into existence at the Third International Congress on Mathematical Education (ICME-3) in Karlsrühe, Germany, in 1976. It is affiliated with the International Commission for Mathematical Instruction. PME-NA is the North American Chapter of PME. The first PME-NA conference was held in Evanston, Illinois in 1979.

Past PME and PME-NA conferences held in Mexico were:

- 1990 Oaxtepec: Joint Meeting PME 14 – PME-NA 12
- 1999 Cuernavaca: PME-NA 21
- 2006 Mérida: PME-NA 28
- 2008 Morelia: Joint Meeting PME 32 – PME-NA 30

Since their origins, PME and PME-NA have expanded and continue to expand beyond their psychologically-oriented foundations.

The major goals of the International Group and the North American Chapter are:

1. To promote international contacts and the exchange of scientific information in the psychology of mathematics education;
2. To promote and stimulate interdisciplinary research in the aforesaid area, with the cooperation of psychologists, mathematicians, and mathematics teachers; and
3. To further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof.

PME-NA Membership

Membership is open to people who are involved in active research consistent with PME-NA's aims or who are professionally interested in the results of such research. Membership is open on an annual basis and depends on payment of dues for the current year. Membership fees for PME- NA (but not PME International) are included in the conference fee each year. If you are unable to attend the conference but want to join or renew your membership, go to the PME-NA website at http://pmena.org. For information about membership in PME, go to http://www.igpme.org and visit the "Membership" page.

PME-NA Steering Committee

Elected Members

- **Chandra Orrill,** 2019-2020 Steering Committee Chair, (2017-2020), *University of Massachusetts Dartmouth,* chandra.orrill@umassd.edu
- **Julie Amador,** 2020-2021 Steering Committee Chair, (2019-2022), *University of Idaho,* jamador@uidaho.edu
- **Jennifer Holm,** Secretary, (2017–2021), *Wilfrid Laurier University,* jholm@wlu.ca
- **Theodore Chao** (2017-2020), *The Ohio State University,* chao.160@osu.edu
- **Jessica Hunt** (2018-2021), *North Carolina State University,* jhunt5@ncsu.edu
- **Ana Isabel Sacristán** (2018-2021), *Center for Research and Advanced Studies (Cinvestav),* asacrist@cinvestav.mx
- **José Martínez Hinestroza** (2019-2022), *Texas State University,* josemartinez@txstate.edu
- **Karl Kosko** (2019-2022), *Kent State University,* kkosko1@kent.edu
- **Alyson E. Lischka** (2019-2022), *Middle Tennessee State University,* alyson.lischka@mtsu.edu
- **Oyemolade (Molade) Osibodu** (2020-2023), *York University,* mosibodu@yorku.ca
- **María S. García González** (2020–2023), *Universidad Autónoma de Guerrero,* mgargonza@gmail.com
- **Joseph Antonides,** Graduate Student Representative, (2019-2020), *The Ohio State University*, antonides.4@osu.edu
- **Pavneet Kaur Bharaj,** Graduate Student Representative, (2019-2020), *Indiana University Bloomington*, pkbharaj@iu.edu
- **Geneviève Barabé ,** Graduate Student Representative , (2020–2021), *Université du Québec à Montréal,* gebarabe@gmail.com
- **Erika Janeth Frayre Larreta ,** Graduate Student Representative , (2020–2021), *Universidad Juárez del Estado de Durango,* janeth_fl31@hotmail.com

Appointed Members

- **Aaron Brakoniecki**, Webmaster 2017–2021), *Boston University*, brak@bu.edu
- **Ji-Yeong I**, Treasurer (2017–2021), *Iowa State University*, jiyeongi@iastate.edu
- **Chandra Orrill**, Past Steering Committee Chair (2020-2021), *University of Massachusetts Dartmouth*, chandra.orrill@umassd.edu

CONFERENCE CHAIRS

Past Conference Co-Chairs (2017–2020)

Samuel Otten
University of Missouri at Columbia
ottensa@missouri.edu

Amber G. Candela
University of Missouri at St Louis
candelaa@umsl.edu

Zandra de Araujo
University of Missouri at Columbia

PME-NA 42 Review Process & Reviewers

All submissions to the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education, included in these proceedings, were strictly peer-reviewed in a double-blind process by three (sometimes four) colleagues.

PME-NA 42 Strand Leaders

The Local Organizing Committee is extremely appreciative of the following people for serving as Strand Leaders. They managed the reviewing process for their strand and made recommendations to the Local Organizing Committee. The conference would not have been possible without their efforts.

Jeffrey Choppin, *University of Rochester*
José Carlos Cortés-Zavala, *Universidad Michoacana de San Nicolás de Hidalgo*
Laurie D. Edwards, *Saint Mary's College of California*
Ruby Ellis, *University of Missouri*
Martha Leticia García-Rodríguez, *Instituto Politécnico Nacional*
Silvia Elena Ibarra-Olmos, *Universidad de Sonora*
Santiago Inzunza, *Universidad Autónoma de Sinaloa*
Kim Johnson, *West Chester University*
Signe Kastberg, *Purdue University*
Stefanie Livers, *Missouri State University*
Charles Munter, *University of Missouri*
Samuel Otten, *University of Missouri at Columbia*
Cody L. Patterson, *Texas State University*
Priya Vinata Prasad, *The University of Texas at San Antonio*
Avenilde Romo-Vázquez, *CICATA-IPN*
Perla Marysol RuizArias, *Cinvestav*
Ana Isabel Sacristán, *Cinvestav*
Ivonne Twiggy Sandoval, *Universidad Pedagógica Nacional*
Marisol Santacruz-Rodríguez, *Universidad del Valle*
Armando Solares, *Cinvestav*
Sandy Spitzer, *Towson University*
Patrick Lane Sullivan, *Missouri State University*
Jennifer Wall, *Northwest Missouri State University*

PME-NA 42 Reviewers

Likewise, the Local Organizing Committee is also very appreciative of the following colleagues for peer-reviewing submissions to the conference:

Abassian, Aline
Abrahamson, Dor
Acevedo, Graciela Rubi
Acuña, Claudia Margarita
Adams, Anne E
Adeolu, Adewale
Aguas-Hidalgo, Maribel
Aguilar, Jair
Ahrens, Sally
Akkoc, Hatice
Akuom, Denish Ogweno
Alibali, Martha W
Altamirano Abad, José Antonio
Alvarado Sánchez, Jamil Fabiola
Alvidrez, Mariana
Amador, Julie
Anderson, Rick
Anderson, Robin Keturah
Andersson, Annica
Andresen, Mette
Antelo López, Irenisolina
Anthony, Monica
Antonides, Joseph
Aparicio Landa, Eddie

PME-NA 42 Strands

Strand	Description	Related Keywords
Algebra, Algebraic Thinking and Number Concepts	This strand includes papers that focus on the teaching and learning of early algebra, algebra, and number concepts.	- Algebra and Algebraic Thinking - Number Concepts and Operations - Rational Numbers
Curriculum, Assessment and Related Topics	This strand includes papers that focus on curriculum analysis, development, implementation, assessment and evaluation, or on technology as curricular or assessment tools.	- Curriculum - Curriculum Analysis - Curriculum Enactment - Standards (Broadly Defined) - Assessment and Evaluation - Technology - STEM / STEAM - Equity and Diversity - Social Justice - Special education - Teaching tools and resources
Equity and Justice	This strand includes papers that focus on marginalization, systems of oppression, or other similar issues related to mathematics education at any level or in any context.	- Equity and Diversity -Social Justice - Policy - Students with Special Needs - Gender and Sexuality - Inclusive education - Rural education - First nations/Indigenous cultures - Cross cultural studies - Marginalized communities
Geometry and Measurement	This strand includes papers that focus on the teaching and learning of geometry measurement and spatial reasoning	- Geometry and Geometrical and Spatial Thinking - Measurement
Instructional Leadership, Policy, and Institutions/Systems	This strand includes papers that focus on teacher leaders, coaches, or teacher educators as the subjects of research.	- Instructional Leadership - Teacher Educators - Systemic Change
Mathematical Knowledge for Teaching	This strand includes papers that focus on teachers' subject matter knowledge in relation to teaching.	- Teacher Knowledge - Number Concepts and Operations - Geometry and Geometrical and Spatial Thinking - Rational Numbers - Algebra and Algebraic Thinking - Technology

Mathematical Processes and Modeling	This strand includes papers that focus on topics such as, but not limited to, problem solving, reasoning and proof, modeling, etc.	- Problem Solving - Reasoning and Proof - Advanced Mathematical Thinking - Modeling - Representations and Visualization - Communication
Miscellaneous topics	This strand includes papers on diverse topics, such as Neuroscience, Ethno-mathematics, Interdisciplinary studies; and Mathematics for sustainability (interdisciplinary approaches and complex socio-scientific issues within mathematics education, related to the environment and climate change, economic growth and poverty, etc.)	- Neuroscience - Ethno-mathematics - Mathematics fos sustainability - Interdisciplinary studies - Modeling - Equity and Diversity - Social Justice - Socio-scientific issues
Precalculus, Calculus, or Higher Mathematics	This strand includes papers that focus on the teaching and learning of Precalculus, Calculus and/or Higher Mathematics	- Precalculus - Calculus - University Mathematics - Advanced Mathematical Thinking
Statistics and Probability	This strand includes papers that focus on the teaching and learning of probability, data analysis and statistics	- Probability - Data Analysis and Statistics
Student Learning and Related Factors	This strand includes papers that focus on students' experiences and the influence of various factors (e.g., beliefs, diversity) on mathematical learning.	- Cognition - Metacognition - Affect, Emotion, Beliefs, and Attitudes - Embodiment and gesture - Gender and Sexuality - Technology - Informal Education - Equity and Diversity - Social Justice - Students with special needs - Representations and Visualization
Teacher Education - Pre-service	This strand includes papers that focus on the development of prospective teachers and their knowledge.	- Assessment and Evaluation - Instructional activities and practices - Equity and Diversity - Affect, Emotion, Beliefs, and Attitudes - Teacher Knowledge - Technology

Teacher Education - In-service / Professional Development	This strand is for proposals that focus on in-service teacher learning and professional development.	- Instructional Vision - Affect, Emotion, Beliefs, and Attitudes - Equity and Diversity - Assessment and Evaluation - Teacher Knowledge - Technology - Distance education -MOOC
Teaching and Classroom Practice	This strand includes papers that focus on analyzing the nature of classroom instruction and activity (e.g., discourse, culturally relevant pedagogy)	- Classroom Discourse - Culturally Relevant Teaching - Instructional Activities and Practices - Inclusive education - Technology - Representations and Visualization
Technology	This strand includes papers that focus on the use and development of technology for, and in, teaching and learning.	- Technology - Computational Thinking - Programming and coding - Communication - Modeling - STEM / STEAM - Teacher Knowledge - Teaching and assessment tools and resources - Learning Tools - Distance education - MOOC - Representations and Visualization
Theory and Research Methods	This strand includes papers that focus on the development of theory and/or research methods.	- Research Methods - Design Experiments - Learning Trajectories (or Progressions) - Doctoral Education

PREFACE

When we set out to organize the 42nd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education (PME-NA 42) to take place in Mazatlán, Mexico, on 14-18 October, 2020, we never imagined, as no one did, that 2020 would freeze the world due to a pandemic. We therefore had to adapt to this world situation, postponing the conference to the summer of next year, and adapting it as a hybrid conference, both as in-person and virtual – with the virtual activities beginning around the 27 May, 2021 and the in-person conference planned for 2-6 June, 2021.

A history of PME/PME-NA conferences in Mexico

Mexico has hosted several past PME-NA conferences:

- 1990 Oaxtepec: Joint Meeting PME 14 – PME-NA 12
- 1999 Cuernavaca: PME-NA 21
- 2006 Mérida: PME-NA 28
- 2008 Morelia: Joint Meeting PME 32 – PME-NA 30

The PME-NA 42 conference was hoping to bring back, after twelve years, the conference to Mexico and have the honor to host our colleagues from Canada, the USA and other countries. Unfortunately, we will have to wait longer. But we hope to be able to welcome participants to Mazatlán in 2021, thirteen years after the last conference took place in Mexico. As of December, 2020, we have 527 registered participants for, at least, the virtual part of the conference.

Conference Theme

In accordance with the major goals of PME-NA (see PME-NA History and Goals section above) that include promoting international contacts, and stimulating interdisciplinary research, for the PME-NA 42 conference, we proposed as theme "*Entre Culturas* / Across Cultures". We consider that a way to promote the exchange and enrichment of mathematics education research is to look at its manifestations across different cultures, places and contexts. This is the focus of the PME-NA 42 conference, where we aimed to have an encounter of cultures, as well as forms of research in mathematics education. That is:

Across various cultures...

- of *languages, nationalities, communities, ethnicities,*
- of *genders*,
- of *indigenous people* and *migrants*;
- of different *abilities*;
- of different *generations*;
- of *teachers, researchers, policy-makers* and *parents;*
- of *school types*: urban vs. rural, multigrade, etc; and
- of *classroom cultures and modalities:* from traditional teaching to "new" classroom cultures: e.g., flipped classrooms, distance education, etc.;
- of *technologies and tools:* from pencil-and-paper, to the digital and connected;
- of *math and other disciplines* (multi-, inter- and trans-disciplinarity): e.g., STEAM, math and environmental sciences, etc.;

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

- of *research*: different strands of PME-NA research, including cognition, neuroscience, ethnography, and new types of research.

In other words, we wanted an academic exchange that would reflect the ample diversity of ways of teaching and learning of mathematics, and of the tools and communities involved in mathematics education; as well as explore how the differences in cultures imply a need to consider how research results can be taken into account in varying contexts. Through all of the above, we hoped to honor the major goals of PME-NA.

Conference program

A multi-cultural program

We received proposals from participants not only from North America, but from 20 countries (Australia, Brazil, Canada, Chile, China, Colombia, Ecuador, France, Germany, Italy, Mexico, Norway, Peru, Puerto, Rico, Spain, Sweden, Turkey, UK and USA). In fact, 82 proposals were submitted in Spanish and two in French. But a requirement of PME-NA is for all accepted proposals to have an English version for the proceedings; thus, in order to ensure the high quality of published papers, we hired an English language reviewer to make sure that the accepted proposals that had been submitted in Spanish would be up to standard in their English versions. It is thus that there are many bilingual versions included in these proceedings; in those cases, the title of the paper or poster is given in two languages, and the alternate language version (Spanish or French) is included after the English one.

Research reports and poster presentations

The papers included in these conference proceedings are categorized according to 14 strands (please see the PME-NA 42 Strands section above). Seeking to expand the interdisciplinary aspect of PME-NA, for the PME-NA 42 conference we added to the lists of keywords, topics such rural education; first nations/indigenous cultures; cross cultural studies; marginalized communities, and mathematics for sustainability.

We received 490 proposals for research reports and poster presentations (225 for Research Reports, 165 for Brief Research Reports and 100 for Poster Presentations). All submissions were strictly peer-reviewed through a double-blind process (see Review Process section above). In the end, we accepted 80 as Research Reports, 190 as Brief Reports and 147 as Poster Presentations. Most of the authors with accepted proposals, though not all, registered for the conference and sent final versions that are included in these proceedings.

Working groups and research colloquia

In addition to the usual Working Groups, this year the Steering Committee added Research Colloquia, to focus on a research topic of substantial interest within the PME-NA community that has been developed during multiple previous PME-NA (or PME) working groups. Research Colloquia involve longer planned presentations to share what has been done in previous meetings within the group.

We received 11 Working Group and 2 Research Colloquia proposals, and a Steering Committee subcommittee accepted 10 Working Groups and 2 Research Colloquia.

We were happy to see that many Working Groups and Research Colloquia themes were in accord to the “Across Cultures” conference theme.

Plenary and special lectures

In accordance to our conference theme "*Entre Culturas* / Across Cultures", we invited plenary and special speakers that would represent different cultural contexts, as well as forms of research in Mathematics Education. They come from different countries, not only in North America, but also from Europe. They represent different areas of research and disciplines within Mathematics Education; and we include researchers from different generations. We hope that these lectures will reflect parts of the ample diversity of ways of teaching and learning of mathematics, and of the tools and communities involved in mathematics education. In that way, we hoped also to honor the major goals of PME-NA.

Special tribute to Eugenio Filloy

When planning the program for PME-NA 42, we had envisioned, since 2019, including a special live-person homage to Eugenio Filloy, co-founder in 1975 of the Mathematics Education Department of the Center for Advanced Studies and Research (Cinvestav) and a driving force of the Mathematics Education discipline at an international level from the early 1970s (see the Special Tribute section below). Sadly, Eugenio Filloy passed away in March, 2020; but the more reason to include this special tribute in his memory.

A tribute to the PME-NA members who were affected by the COVID-19 pandemic

As we were wrapping the edition of these proceedings, we heard on the 15th December, of the passing of our dear colleague, graduate of Cinvestav and member of AMIUTEM, César Martínez-Hernández of the Universidad de Colima, from COVID-19. César has two contributions included in these proceedings. May he rest in peace; he will be sorely missed.

We don't know how many other members of the PME-NA community have lost their lives, family members or friends, or been deeply affected by this pandemic in other ways, but we hope it is not too many; to those who have, we send our sympathies to them or to their families, friends and colleagues.

Looking forward

With the prospect of the SARS-CoV-2 vaccines, we are a bit more optimistic that maybe we will be able to host the in-person part of the conference, and welcome you in June in Mazatlán, Mexico. In any case, we look forward to welcoming you, either in person or virtually, for PME-NA 42.

The co-chairs of PME-NA 42,

Ana Isabel Sacristán
Cinvestav

José Carlos Cortés-Zavala
AMIUTEM /
Universidad Michoacana de San Nicolás Hidalgo

December, 2020

Prólogo

Cuando nos propusimos organizar la 42a Reunión Anual del Capítulo Norteamericano del Grupo Internacional de Psicología de la Educación Matemática (PME-NA 42) para realizarse en Mazatlán, México, del 14 al 18 de octubre de 2020, nunca nos imaginamos, como nadie lo hizo, que 2020 congelaría al mundo debido a una pandemia. Por lo tanto, tuvimos que adaptarnos a esta situación mundial, posponiendo la conferencia para el verano del próximo año y adaptándola como una conferencia híbrida, tanto presencial como virtual – con las actividades virtuales comenzando alrededor del 27 de mayo, 2021, y la conferencia presencial planeada del 2 al 6 de junio, 2021.

Historia de las conferencias PME / PME-NA en México

México ha sido sede de varias conferencias PME-NA anteriores:

- 1990 Oaxtepec: Reunión conjunta PME 14 - PME-NA 12
- 1999 Cuernavaca: PME-NA 21
- 2006 Mérida: PME-NA 28
- 2008 Morelia: Reunión Conjunta PME 32 - PME-NA 30

La conferencia PME-NA 42 esperaba traer de regreso, después de doce años, la conferencia a México y tener el honor de recibir a nuestros colegas de Canadá, Estados Unidos y otros países. Desafortunadamente, tendremos que esperar más. Pero esperamos poder dar la bienvenida a los participantes a Mazatlán en 2021, trece años después de que se llevó a cabo la última conferencia en México. A la fecha, tenemos 527 participantes inscritos para, cuando menos, la parte virtual de la conferencia.

Tema de la conferencia

De acuerdo a los principales objetivos del PME-NA (ver la sección *PME-NA History and Goals,* arriba) que incluyen promover contactos internacionales y estimular la investigación interdisciplinaria, para la conferencia PME NA 42, propusimos como tema "Entre Culturas / *Across Cultures*". Consideramos que una forma de promover el intercambio y el enriquecimiento de la investigación en educación matemática es observar sus manifestaciones en diferentes culturas, lugares y contextos. Este es el tema central de la conferencia PME-NA 42, donde pretendíamos tener un encuentro de culturas, así como formas de investigación en educación matemática. Es decir:

A través de varias culturas ...

- de *idiomas, nacionalidades, comunidades, etnias*,
- de *géneros*,
- de *pueblos indígenas* y *migrantes*;
- de diferentes *habilidades*;
- de diferentes *generaciones*;
- de *profesores*, *investigadores*, *autoridades*, *políticos* y *padres* de familia;
- de *tipos de escuelas*: urbanas vs. rurales, multigrado, etc; y
- de las *culturas y modalidades del aula*: desde la enseñanza tradicional hasta las "nuevas" culturas en las aulas: por ejemplo, aulas invertidas, educación a distancia, etc.
- de *tecnologías* y otras herramientas: desde el lápiz y el papel, hasta lo digital y conectado;

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

- de *matemáticas y otras disciplinas* (multidisciplinaridad, interdisciplinariedad y transdisciplinariedad): por ejemplo, STEAM (CTIAM), matemáticas y ciencias ambientales, etc.;
- de *investigación*: diferentes líneas de investigación de PME-NA, que incluyen cognición, neurociencia, etnografía y nuevos tipos de investigación.

En otras palabras, queríamos un intercambio académico que reflejara la amplia diversidad de formas de enseñanza y aprendizaje de las matemáticas, y de las herramientas y comunidades involucradas en la educación matemática; así como explorar cómo las diferencias en las culturas lo que requiere considerar cómo los resultados de investigación pueden ser tomados en cuenta en diferentes contextos. A través de todo lo anterior, esperábamos honrar los principales objetivos de PME-NA.

Programa de la conferencia

Un programa multicultural

Recibimos propuestas, no solo de Norteamérica, sino de 20 países (Australia, Brasil, Canadá, Chile, China, Colombia, Ecuador, Francia, Alemania, Italia, México, Noruega, Perú, Puerto, Rico, España, Suecia, Turquía, Reino Unido y Estados Unidos). De hecho, 82 propuestas fueron enviadas en español y dos en francés. Pero un requisito del PME-NA es que todas las propuestas aceptadas tengan una versión en inglés para las memorias del evento; por tanto, con el fin de garantizar la alta calidad de los artículos publicados, contratamos a un revisor del inglés para asegurarnos de que las propuestas que habían sido evaluadas en español y que fueron aceptadas, cumplieran con el estándar en sus versiones en inglés. Así, estas memorias incluyen muchas versiones bilingües; en esos casos, el título del trabajo o cartel se presenta en dos idiomas, y la versión en idioma alterno (español o francés) se incluye después de la versión en inglés.

Informes de investigación y presentaciones de carteles

Los artículos incluidos en estas memorias de la conferencia, se clasifican de acuerdo a 14 áreas (consulte la sección *PME-NA 42 Strands*, más arriba). Buscando expandir el aspecto interdisciplinario del PME-NA, para la conferencia PME-NA 42 agregamos a las listas de palabras clave, temas como educación rural; primeras naciones / culturas indígenas; estudios transculturales; comunidades marginadas y matemáticas para la sostenibilidad.

Recibimos 490 propuestas para reportes de investigación y presentaciones de póster (225 para reportes de investigación, 165 para reportes breves de investigación y 100 para presentaciones de póster). Todas las propuestas fueron sometidas a un proceso estricto de arbitraje por pares doblemente ciego (consulte la sección *Review Process* más arriba). Al final, se aceptaron 80 reportes de investigación, 190 como reportes breves de investigación y 147 como presentaciones de póster. Casi todos los autores con propuestas aceptadas, aunque no todos, se inscribieron para la conferencia y enviaron versiones finales de sus escritos que se incluyen en esta memorias.

Grupos de trabajo y coloquios de investigación

Además de los Grupos de Trabajo habituales, este año el Comité Ejecutivo del PME-NA agregó la modalidad de Coloquios de Investigación (*Research Colloquia*), los cuales se centran en un tema de investigación de interés particular para la comunidad del PME-NA, y que ha sido desarrollado en grupos de trabajo durante múltiples reuniones del PME-NA (o PME). Dichos coloquios de investigación involucran presentaciones planeadas más largas que lo que se ha hecho en reuniones previas de los grupos.

Recibimos 11 propuestas para Grupos de Trabajo y 2 para Coloquios de Investigación; y un subcomité del Comité Directivo aceptó 10 Grupos de Trabajo y 2 Coloquios de Investigación.

Nos alegró ver que muchos temas de los Grupos de Trabajo y Coloquios de Investigación coinciden con el tema de la conferencia: “Entre culturas”.

Conferencias plenarias y especiales

De acuerdo con el tema de nuestra conferencia "Entre Culturas / *Across Cultures*", invitamos a conferencistas plenarios y especiales que representen diferentes contextos culturales, así como formas de investigación en Educación Matemática. Vienen de diferentes países, no solo de Norteamérica, sino también de Europa. Representan diferentes áreas de investigación y disciplinas dentro de la Educación Matemática; e incluimos investigadores de diferentes generaciones. Esperamos que estas conferencias reflejen partes de la amplia diversidad de formas de enseñanza y aprendizaje de las matemáticas, y de las herramientas y comunidades involucradas en la educación matemática. De esa manera, también esperábamos honrar los principales objetivos de PME-NA.

Homenaje especial a Eugenio Filloy

En la planeación del programa del PME-NA 42, teníamos previsto, desde 2019, un homenaje especial, y en vida, a Eugenio Filloy, cofundador en 1975 del Departamento de Matemática Educativa del Centro de Estudios Avanzados e Investigaciones (Cinvestav) y una fuerza impulsora de la disciplina de Educación Matemática a nivel internacional desde principios de la década de 1970 (ver la sección Homenaje Especial, más abajo). Lamentablemente, Eugenio Filloy falleció en marzo de 2020; pero esto es más razón para hacerle este homenaje especial, honrando sus contribuciones a la disciplina y su memoria.

Un homenaje a los miembros de PME-NA afectados por la pandemia COVID-19

Al cerrar la edición de estas memorias, el 15 de diciembre nos enteramos del fallecimiento, por COVID-19, de nuestro querido colega, egresado del Cinvestav y miembro de AMIUTEM, César Martínez Hernández de la Universidad de Colima. César tiene dos aportaciones incluidas en estas memorias. Descanse en paz; se le extrañará.

No sabemos cuántos otros miembros de la comunidad PME-NA han perdido su vida, de sus familiares o amigos, o han sido profundamente afectados por esta pandemia de otras formas, pero esperamos que no sean demasiados; a quienes lo han sido, les enviamos nuestro más sentido pésame, o a sus familiares, amigos y colegas.

De cara al futuro

Con la perspectiva de las vacunas contra el SARS-CoV-2**,** somos un poco más optimistas de que tal vez podamos ser anfitriones de la parte presencial de la conferencia y darles la bienvenida en junio en Mazatlán, México. En cualquier caso, esperamos darles la bienvenida, ya sea en persona o virtualmente, al PME-NA 42.

Los co-organizadores del PME-NA 42,

Ana Isabel Sacristán Rock
Cinvestav

José Carlos Cortés Zavala

Eugenio Filloy (1942-2020)

As we said in the Preface to these proceedings, when planning the PME-NA 42 conference in 2019, we had envisioned including a special live-person tribute to Eugenio Filloy, as the "father" of Mathematics Education in Mexico, with an extended influence in many countries in Ibero and Latin-America. Eugenio was one of the strongest supporters of PME-NA 42, and many contributions by his students and himself are included in these proceedings. Sadly, Eugenio passed away on the 23rd March, 2020. We do this tribute then, *in memoriam.*

Here is a brief sketch of his academic trajectory and his important contributions to the field of Mathematics Education:

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

- Eugenio studied Mathematics and Theoretical Physics at the National Autonomous University of Mexico, graduating in Mathematics in 1965.
- He did a Master's degree in Mathematics at Cinvestav, graduating in 1966, and was also visiting scholar at UCLA in that same year.
- He received his PhD in Mathematics from the University of Chicago in 1970
- In 1971, he joined the Mathematics Department at Cinvestav, and did some postdoctoral work at the University of Geneva, Switzerland in 1972.
- From 1973 to 1977, he was president of the Mexican Mathematical Society.
- In 1975, he co-founded the "Section of Educational Mathematics" (*Sección de Matemática Educativa*-SME), part of the Department of Educational Research at Cinvestav, with two other mathematicians from the Mathematics Department –Carlos Imaz and Juan José Rivaud— with whom he had been collaborating in designing and writing the Mathematics textbooks of the Mexican National Program of Free Textbooks for Primary Schools launched in the late 1960s by Mexico's Ministry of Education (SEP). Ramiro Ávila-Godoy (2013) explains that:

> This experience led Dr. Filloy to become aware of the importance and complexity of the problematic of the learning and teaching of Mathematics and of the need to deal with it at all educational levels […] and seek solutions. […]
>
> … in the name "Educational Mathematics" was implicit the intention to deal with the problematic of the teaching and learning of mathematics, from mathematics itself. At the time, this approach was innovative and led many countries in Latin America to talk of *Matemática Educativa*

- From the onset, i.e., from 1975, the newly founded section - SME (today the Department of Mathematics Education –DME, at Cinvestav), offered a Master of Science in "Educational Mathematics" (*Matemática Educativa*), "with a strong content in mathematics as well as on the history and foundations of mathematics" (Trigueros, Sacristán & Guerrero, 2008, p.220); and from 1982, a PhD program. Eugenio himself was supervisor, active until the day of his passing, of close to 100 students of those programs (directing more than 60 Master's thesis and over 30 PhD dissertations); many of his former students have contributions included in these proceedings.
- In 1983, Eugenio founded the ambitious and far-reaching National Program for Training and Professional Development of Mathematics Teachers *(Programa Nacional de Formación y Actualizacion de Profesores de Mathematicas* - PNFAPM) which, in collaboration with a network of many Mathematics departments in over 30 universities and higher institutions across Mexico, offered a Master of Science in *Matemática Educativa*; as well as an undergraduate program in the teaching of mathematics.

> The PNFAPM also established academic links with international institutions, and many members of the SME participated in doctoral and post-doctoral studies abroad. Simultaneously to the PNFAPM, national and international conferences and meetings were launched so that researchers and teachers could share and discuss their experiences." (Trigueros, Sacristán & Guerrero, 2008, p. 221)

In fact, Eugenio continuously promoted collaborations with researchers worldwide. For example:

- He actively participated in international events, such as CIAEM (chairing, in 1980, the XXXII CIAEM, in Oaxtepec, Mexico), PME, and ICMI, and was instrumental in having Mexico be part of PME-NA; Teresa Rojano explains: "It was Eugenio Filloy who, in the 1980s, proposed that Mexico be considered as a member of PME-NA, arguing that geographically, Mexico is part of North America. A year later, the [PME-NA] Steering Committee added a spot for Mexican member."

- Trigueros, Sacristán & Guerrero (2008, p. 221) describe the international collaborations and academic links promoted by Eugenio for the SME-Cinvestav:

> From its inception, the SME-Cinvestav group [led by Eugenio] began studying what was being done internationally, and developed academic links with foreign researchers and institutions. The first links were done with Brousseau and Glaeser, and later with the *Instituts de Recherche sur l'Enseignement des Mathématiques* (IREM) in Bordeaux and in the *Université Louis Pasteur* in Strasbourg, France, as well as the *École des Hautes Études en Sciences Sociales* in Paris. This established an influence of the French school of *Didactique.[…]* the SME-Cinvestav group also took into account theoretical frameworks from other countries such as the USA (e.g. the work of Bruner and Skinner) the Soviet Union (e.g. that of Kruteski), the UK, as well as the work of Piaget. Other academic links took place with the University of London, UK, Cambridge University, UK, and the University of Toronto, Canada. By the 21st century, many other international links had been established with the DME-Cinvestav. In addition to the aforementioned ones, others include those with the Universities of Granada and Valencia in Spain; the *Université Joseph Fourier* in Grenoble, France; the University of Quebec in Montreal (UQAM), Canada; the Universities of Georgia, and of Massachusetts-Dartmouth in the USA; and the Universities of Nottingham and of Bristol, UK.

- In 1979, Eugenio also did postdoctoral work at the University of Strasbourg, France, and was invited as visiting professor to the Autonomous University of Barcelona, Spain.
- In that way, researchers such as François Pluvinage (who coincidentally passed away on practically the same day as Eugenio), Kat Hart, Carolyn Kieran, Luis Puig, Celia Hoyles, Ros Sutherland, Richard Noss and James Kaput, among others, became regular collaborators of the Department of Mathematics Education of Cinvestav
- And the result of both the Master's (and later PhD) program at Cinvestav, as well as that of the PNFAPM, is several hundred of graduates trained through Cinvestav, not only from Mexico, but from all over Ibero and Latin America that have had an influence in their regions in the field of Mathematics Education; as well as the launching of many programs of professional development for mathematics teachers, and/or of research in Mathematics Education (or *Matemática Educativa*).

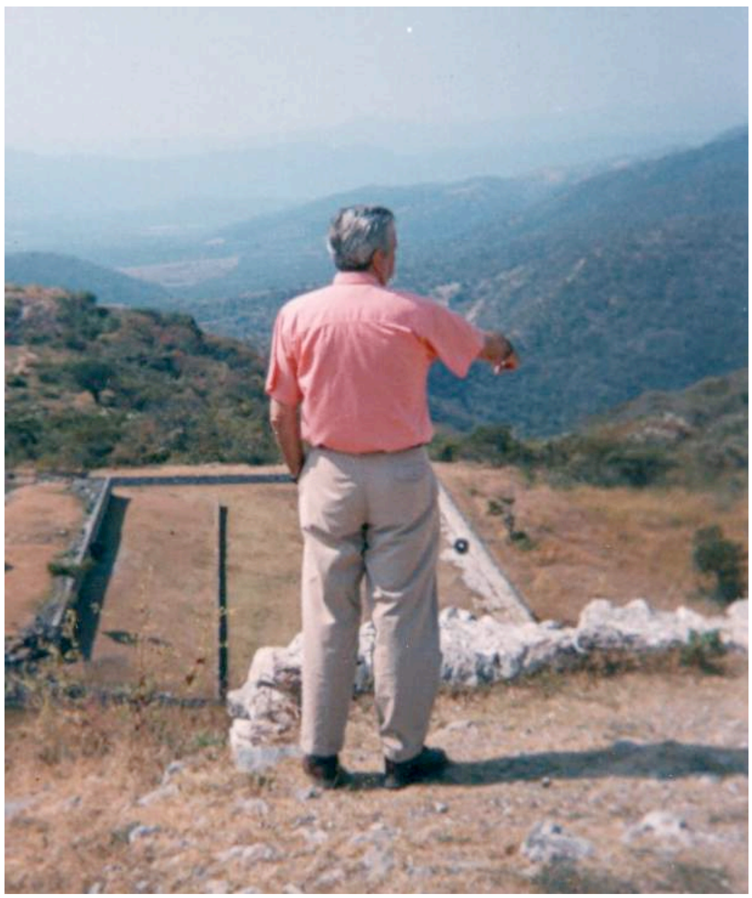
Eugenio not only strengthened the field of Mathematics Education through his professional development initiatives, but also through his research and the research approaches that he promoted (for further details, see Trigueros, Sacristán & Guerrero, 2008; and Solares, Puig & Rojano, 2020). For example,

- He promoted the analysis of the history and foundations of mathematics, as a research method in the field of mathematics education.
- He promoted the use and research of what used to be called "new technologies" (i.e., computers, audiovisual media, and other digital resources).
- In response to the need of carrying out controlled experimentation, he founded a school in which he could do that (the *Centro Escolar Hermanos Revueltas*).
- He recognized the limitations of general theoretical models and proposed the concept of Local Theoretical Models (see the book *Educational Algebra* by Filloy, Rojano & Puig, 2008).
- He produced close to 500 scientific publications in his areas of research: Didactics of Algebra and Geometry; History of Algebraic and Geometric ideas; Mathematical Systems of Signs; Curricular Design; Use of New Technologies;, and Local Theoretical Models.
- Eugenio was also a member of many Scientific and/or Editorial Committees, including of the journals *Educational Studies in Mathematics,* or *Recherche en Didactique des Mathématiques*.

- He received many distinctions, including being designed Professor Emeritus of Cinvestav (2002); being awarded an *Honoris Causa* Doctorate from the University of Sonora (2011); being granted the medal "*Mtro. Remigio Valdéz Gámez*" by the Mexican National Association of Mathematics Teachers (*Asociación Nacional de Profesores de Matemáticas A.C.)* for his transcendental trajectory in the field of Mathematics Education (2013); and receiving an honorific recognition from the Autonomous University of Guerrero for founding *Matemática Educativa* and having academic contributions that became international benchmarks (2016).

To all of that we add this tribute, in recognition of his profound legacy to the discipline of Mathematics Education.

Next we include some anecdote, memories and stories from some of his collaborators and former students:



"Eugenio will always be guiding us where to go forward." Luis Puig

Some happy memories of Prof Eugenio Filloy, by Celia Hoyles and Richard Noss

As far as we can remember, Celia first met Eugenio at an early PME conference – Grenoble 1981, or Antwerp 1982 we cannot be sure. Our relationship with Eugenio spanned many decades. It is full of so many wonderful memories, and we can only share their essence here.

Eugenio was remarkable in his deep commitment to mathematics and mathematics education, his devotion to Mexico and the promotion of mathematics education in the country. One only had to spend ten minutes in his company to recognise his charm, his sense of humour and perhaps most of all the twinkle in his eye. Not to mention his wonderful hospitality and his gourmet views on wine and food!

Celia and Richard with Eugenio in the 80s

In the mid-eighties, Eugenio and Celia set up the Anglo-Mexican Research Project, named “the Development of Mathematical Microworlds for Pupils and Teachers”. This was achieved with funding the British Council and Mexican Government and the work went forward in collaboration with *Programa Nacional de Formación y Actualizacion de Profesores de Mathematicas* or PNFAPM (Mexico´s National Program of Training and Professional Development for Mathematics Teachers) that Eugenio led. By the time Richard and later Teresa Rojano and Ros Sutherland joined the team in 1986, a steady stream of visits had been established in both directions along with research collaborations that lasted for many years.

A central feature of the project was to recruit PhD students whom we met in Mexico where they were subject to a selection process for working on an English PhD in Mathematics Education in London, with field work in Mexico.

This meant that there was, for us, an amazing ‘bonus’ to this project! We used to visit about once a year going to different parts of this amazing country with Eugenio as our guide and mentor. But that wasn’t all: Eugenio was not one to stay in a tent and eat in a roadside café! On the contrary, our visits were characterised by visits to wonderful restaurants, exotic hotels, and relaxed but fascinating seminars where we met several researchers who we now regard as friends and collaborators, Olimpia Figueras as just one example and notably one of Richard’s star PhD students on this program, Ana Isabel Sacristan who has become a leading figure in Mathematics Education in Mexico and internationally.

One incident stands out, one that is iconic in terms of Eugenio’s readiness to look at life – no matter how serious – with a twinkle in his eye. We were giving a talk in a seminar, somewhere in Mexico City. Celia was trying carefully to explain some key points of our research, and both of us were trying to communicate (shamefully, despite so many visits to Mexico, neither of us speaks Spanish well enough to give a talk)! Eugenio was kindly translating what we believed was an important and serious point, when the audience burst into laughter. Eugenio looked askance at us, a hint of a smile on his face. To this day we do not know what he said – or how closely – if at all – his 'translation' was to the real thing ☺

We miss Eugenio but at least have some consolation in the fact that our relationship with Mexico continues through collaborations with Ana and with Teresa that started with his initiative. We have again visited some of our favourite places to conduct workshops hosted this time by them. So we end with a photo of us with Ana taken at one of these workshops in the grounds of the lovely hotel Hosteria Las Quintas in Cuernavaca, which was introduced to us by Eugenio as the venue for one of his seminars and became one of our favourite places in the whole world ☺.

Richard and Celia with Ana Isabel Sacristan (left, who did her PhD in London as part of the collaboration set up by Eugenio Filloy) in the gardens of Hosteria Las Quintas

Celia and Richard in the gardens of Hosteria Las Quintas, Cuernavaca, Mexico

Memories of Eugenio, by Carolyn Kieran

Often, over the past several decades when I was invited to Mexico to give a talk to a group of teachers and young researchers, and Eugenio was requested to translate my oral presentation to the audience from English to Spanish, a strange thing happened: I would state a paragraph or so in English and then it would be Eugenio's turn to translate what I had just said. Inevitably, the translation took longer, but not only that, it often led to bouts of joyous laughter from the audience. Eugenio was an expert at injecting a note of humour into my otherwise straightforward and very serious presentations -- something that I was most grateful for and will always appreciate about Eugenio: his graciousness and keen sense of humour.

Memories of Eugenio, by Fernando Hitt

Eugenio was one of our Mexican "maîtres penseurs". He had a very broad vision of Mexico's problems in education and of our possibilities of contributing to the improvement of the teaching and learning of mathematics. When I was doing my doctoral studies abroad, he presented to the members of the Educational Mathematics Section a document on the evolution of the section and its members, which went down in history as the "Colorines document". In that document he made a projection of the future of the section. This document was used for several years as a guide to remind us of the objectives of the section.

At the beginning of the 80s Eugenio suggested that I reflect on a project related to the training of mathematics teachers to be presented to the office of Higher Education [of the Mexican Ministry of Education] shortly before a change of administration (in 1982). He proposed that we meet once a week at his house and that if the project wasn't approved, we would at least have a pleasant time discussing and having a couple of drinks... The result was that Jesús Reyes Heroles, who was appointed as Minister of Education, upon hearing of the project, mentioned that this was an excellent project and that many more of the same style should be implemented (for Spanish, Biology, Physics, etc.). This is how the *Programa Nacional de Formación y Actualizacion de Profesores de Mathematicas* or PNFAPM (Mexico´s National Program of Training and Professional Development for Mathematics Teachers) was born; the problem was that a short time later, Reyes Heroles died. Still, we were able to sustain the program for over 10 years.

Some memories of the PME conferences:

In a PME [of the late 80s or early 90s,] Eugenio went to a lecture on the use of new technologies. For the first time, Eugenio saw someone using a computer and beamer at a presentation. He explained that the image was a bit blurry and small. He told me that several minutes later a guy arrived, sat in the front near where the computer and the beamer were, got up, moved, did a couple of things and left a sharper and larger image. Eugenio told me that that moment was much more interesting on the usefulness of technology than the entire lecture.

At the PME in Asissi (Italy) in 1991, at the beginning of the conference, I saw him leave the hotel while I was in the cafeteria. I left about 5 minutes later and met him on the road. I told him that I thought he would be at the conference by now, and he replied that walking the Michael Jackson way took him longer ... ☺

Eugenio Filloy-Yagüe, a teacher who left me a legacy, by Miguel Díaz-Chávez

In my education, Professor Filloy was a very important person and the meetings were many; however I think the following are the ones I want to share.

My first meeting with Professor Filloy was in 1986 when I began my master's degree in *Matemática Educativa*, in the then section of the same name located in a beautiful house in Mexico City. In the first semester he was my teacher in a compulsory course on education and I think one of the first readings he left us was the book "Psychogenesis and history of science" by Jean Piaget and Rolando García. I read the sections he indicated and at the end I told him with great anguish that I did not understand and he very understandingly replied: someday you will understand. This course and his dissertations opened up the landscape of mathematics education for me.

A second memory that I have very much in mind was on my first trip to Europe in 1988 when I was surprised to find a book of his authorship in a bookstore in Madrid; this discovery showed me the importance of his work at an international level.

The last meeting I had with Professor Filloy was listening to him at an event in Mexico City about five years ago. At that time I was starting to do research on the free math textbook and I talked to him about the possibility of interviewing him about it, considering that he was one of the authors of those books in the 70's; as expected he agreed, but with his style he said: Yes, but hurry up. That interview never took place. To him, Professor Filloy, my infinite gratitude.

Some of my memories of Eugenio, by Ana Isabel Sacristán

When, in 1986, I began my Mathematics Education master's studies at Cinvestav, Eugenio Filloy was my teacher in the compulsory and introductory course in Education. I remember how intimidating his imposing presence was to me. For example, he was obsessive about punctuality and I was afraid of him for that: looking at his watch, he would tell me: "You were two minutes late"; or on one occasion: "You were 30 seconds late"!

On the other hand, in those days it was surprising to me how he valued more our reasoning than learning contents, and I remember how enlightening the study of the book "*Psychogenesis and history of science*" by Jean Piaget and Rolando García, was. Eugenio introduced me to an educational philosophy that was new to me then, but that I have followed since.

Some time after I finished my master's studies, one day in 1989, I ran into him by chance: At the outset he told me: "The English are here"; immediately, without my being able to utter a single word, or ask what he was referring to, he opened his agenda and ordered me to be there the next day to meet Celia Hoyles at a specific time. That was how short the meeting was, and I was not sure what it was about. But it was an interview for pursuing PhD studies at the University of London, England, with the support of the PNFAPM and the British Council. Thus it was that by a chance encounter, my future was sealed; and I will be eternally grateful to Eugenio, in addition to his teachings, for putting me on the path and supporting me on the way.

I am pleased to have been able to inform him, shortly before he passed away, that we would do this tribute at PME-NA 42. I think he was pleased.

Memories of Eugenio, by José Carlos Cortés

In 1991, I began my Master's degree in the Section of *Matemática Educativa* located at a house in Mexico City. Nearby was another building in which Dr. Filloy worked; at that time he was the head of the section. The first time I saw him, I was impressed by his strong tone of voice and his appearance. Since, in the first semester of my master's studies, I did not yet have a scholarship, one day Dr. Filloy approached me and asked me if I wanted to work at his school "Los Hermanos Revuelta" which I accepted with great pleasure and I will never forget that great experience. In the school "Los Hermanos Revuelta" directed by Maru, wife of Dr. Filloy, as teachers we were allowed to innovate; also, as masters and doctoral students, we were also allowed to carry out educational experiments (of course complying with all the protocols). Thus, Dr. Filloy was a pioneer in Mathematics Education research but he also put into practice through his school the new teaching trends in the field. Much later, Dr. Filloy participated with us at several AMIUTEM conferences of which we have very good memories. Best wishes to you, Eugenio, wherever you are.

Debating with Eugenio Filloy in Mexico City, by Armando Solares-Rojas (written in 2012)

I met Eugenio Filloy in the spring of 2000. The references I had of him made me place him as the founder of the Department of Educational Mathematics of Cinvestav, a member of the editorial committees of some of the most important research journals in the area, an international researcher famous for his contributions in the teaching of Algebra and as a very important figure in the educational reforms of the country. But there was still a lot to know about him...

The first work meeting we had was held at the offices of the *Sociedad Mexicana de Matemática Educativa* (Mexican Society of Educational Mathematics). I arrived promptly and we went to his meeting room. Three armchairs, a small table, several paintings, a collection of posters celebrating the 300th anniversary of the publication of Isaac Newton's Mathematical Principles of Natural Philosophy. We spoke very little, but in that short talk he invited me to a seminar on the philosophy of mathematics that was in progress, with Ignacio Garnica.

Together with Manuel Cruz, who was a fellow at the UNAM Institute of Mathematics and is now director of the Department of Mathematics at the University of Guanajuato, I plucked up the courage and spent long hours reading and discussing Gottlob Frege's text. With many ideas in mind, we launched into a seminar session in which we tried to answer questions such as: What are numbers?

What do expressions involving numbers refer to? Eugenio Filloy led the seminar to discuss theories about the meaning of mathematical texts and showed me the possibility of working, from mathematics, with epistemology, history and didactics. I entered the doctoral program in Educational Mathematics at Cinvestav in September of that same year.

As a formal student in the department, I continued to be part of the seminar whose sessions, intense and unforgettable, left me much more learning than I expected.

For example, the Wittgenstein readings. The long hours spent at the end of my bachelor's degree reading the Tractatus logico-philosophicus finally made sense! Today, language games continue to haunt my readings and, increasingly, they are incorporated into the texts that I write myself.

I also learned about Charles Sanders Peirce's semiotic theory and how Eugene used the triadic notion of the sign as a starting point to develop the Mathematical Systems of Signs, a theoretical notion that allowed him to describe the teaching and learning of algebra, thus articulating a new perspective on research that has given fruit to numerous studies and publications of which Dr. Rojano has already spoken extensively. I myself have had the fortune and honor to collaborate on some of them throughout the years of training and work with Eugenio and Tere: from presentations at the International Group for the Psychology of Mathematics Education (PME) Conferences, to the recent publication of the article "Problems of two unknown quantities and two levels of representation of the unknown" published in the *Journal for Research in Mathematics Education* in January of last year (2011).

From philosophy I went back to history. My previous readings on the history of calculus (Newton's De quadratura curvarum), of physics (Optiks, also Newton's) made sense also through my contact with Filloy!

Although I knew little about the history of the development of Algebra, like any mathematician in training, I knew the history of the short life of Galois, famous among young people for being bohemian, in love, anti-church, rebellious and… cool. But I knew nothing of the Indian astronomers and mathematicians Bhaskara and Brahmagupta, or of the Persian mathematician, astronomer and poet Omar Khayyám.

And that leads me to talk about a facet of Eugenio that characterizes him and that has had a profound influence on me and on many other people who have been close to him: his generosity. I think that the history and legacy of a man, of a teacher, can be described by the books he treasures, but even more by the books he offers and shares.

Entering the Filloy library is an invitation to navigate through the immense plurality of ideas that the history of mathematics grants us. There I came across different translations of Al-Kitāb al-mukhtaṣar fī ḥisāb al-jabr wa-l-muqābala (Concise Book of Calculation of Restoration and Opposition) and I was able to compare the versions and translations of Robert de Chester with that of Gerard of Cremona and with that of Frederic Rosen. Also the Arithmetic of Diophantus in several of its versions (See Eecke, P., J. Sesiano, Rashed, Tannery); the Liber Quadratorum 'The Book of Square Numbers' by Leonardo of Pisa ...

His generosity to his students goes beyond sharing his treasured library. An essential part of Filloy's didactic activity was supporting the student and teaching autonomy and self-sufficiency to write, participate in conferences, design and present research projects. I remember coming out of tutorial session and carrying a huge bundle made up of transcripts, videos, lessons, articles, books ... And hours of revisions and discussions on video-recorded interviews with laughter in front of the television; What did he say? What did he do? Where is it going? Sharing knowledge. Teaching. Learning.

I also received his generosity when becoming a teacher. Have you taught secondary school? Eugenio asked me. No… not yet, I replied. It was the middle of 2001 and by September of that year I was already preparing my math classes for second grade of middle school at Revueltas, the school with an alternative approach that Eugenio founded. How was I doing? Suffice to say that I came out sweating, hoarse, exhausted. Nothing to do with the classes that I had taught at the School of Sciences! More difficult? My friends asked me. Without a doubt!

That experience profoundly transformed my way of seeing the mathematics classroom, it was no longer just a matter of finding and designing good problems and putting them to the test in an interview situation, but of recognizing the complexity of the teacher's work, the diversity of tensions in those that build the mathematical activity of the classroom.

On the other hand, in Revueltas I saw how Eugenio, a researcher in educational mathematics, ran into students in the hallways who said: “high-five, Eugenio!" and they climbed on his back so that he would carry them "on horseback"; with administrators who were looking for him to say "teacher, the calculators and view-screens arrived"; and teachers who asked him for support for their classes "Eugenio, do we review what we are going to see in third grade next week?" Creating and sustaining a "living" research laboratory, as a school is, is one of the most demanding tasks I have seen, and in Eugenio it is also an example of the consistency between theoretical discourse and practice.

But Eugenio's generosity is not limited to books and mathematics… discussions, projects, articles, accompanied by a good meal and a good wine, taste even better!

What is the meaning and reference of the expression "good French wine"? Following Eugenio's teaching, we could say that his reference is located in the Montrachet vineyards, between the towns of Puligny and Chanssange, in the Côte-d'Or of the Burgundy region, in eastern France. Or perhaps in a bottle from a Château d'Yquem, produced in the Sauternes region of Bordeaux. The meaning in this case is even clearer, if you want to think about it like that. Sauternes is made with semillon, sauvignon blanc and muscadelle grapes that, affected by a fungus endemic to the region, are partially raisined, resulting in a higher concentration of sugar and wines with a distinctive aroma. The Château d'Yquem is also made in an artisanal way, processing grape by grape… by hand.

And just as he shared how much he knows about wines with me, I have had the opportunity to be close to him, to his family, to Maru, his wife. Close not only to his vision as a researcher but also to his vision of life, of what in Mexico and Latin America we understand of being a sybarite, that is, who enjoys life in all its vastness.

Today, from my own vision of closeness, I want to thank Eugenio for all that he has shared and still shares with me. A big hug and many congratulations, Eugenio.

Mexico City, November 2012.

Memories of one of Dr. Filloy’s last students, by María Leticia Rodríguez-González

Dr. Eugenio Filloy was a person with the ability to observe in order to know each and every one of us. He knew exactly what our strengths, weaknesses and especially feelings were. He was a man, with extraordinary universal knowledge, he always had a topic of conversation. He loved the narrative, weaving everyday life anecdotes into his stories, intermingling characters from Greek mythology and politics. Filloy was in love with life.

He loved it when we asked him things, although sometimes it was his students who were the most hesitant to ask him. The most interesting thing is that he wouldn’t give us the answer, instead he would provide a large number of books to research it. But the wonderful thing is that the material that he would share with us was unpublished in most cases.

However, it was sometimes very difficult to follow the logic of his speech; even though we were barely understanding the beginning, he was already coming to the end. Over time, I learned that all his ideas were mathematical and heuristic but above all scientific.

I dare to affirm that Eugenio Filloy was the scientist who gave legitimacy to mathematics education, breaking with the paradigm of finding problems in the way in which mathematics is taught and learned. He gave the arguments for the object of knowledge of Educational Mathematics to focus on mathematics itself, establishing a clear difference between Mathematics Education, Mathematics Didactics and Mathematics Psychology.

Eugenio Filloy, a visionary teacher that knew that the construction of scientific knowledge requires interaction between researchers, teachers and students through communication. Proof of this was his participation and in some cases founder of Conferences, Forums, Symposia, national and international such as the Mexican Mathematical Society, the National Program for Teacher Training (*Programa Nacional de Formación y Actualización de Profesores de Matemáticas*), the Central American and Caribbean Meeting on Teacher Training and Research in Educational Mathematics (*Reunión Centroamericana y del Caribe sobre la Formación de Profesores e Investigación en Matemática Educativa*), PME, PME-NA, CIAEM.

Thank you Dr. Filloy, even if you are no longer physically present, your presence will continue, starting with our Department of Educational Mathematics, which you founded together with Dr. Carlos Imaz. Your work is still present in your contribution to the research through the Local Theoretical Models.

Memories of Eugenio, by Ulises Xolocotzin

I will always be grateful that Dr Eugenio Filloy took the time to greet me and talk with me when we bumped into each other at our Department. In our talks, he either made me laugh, or made me think. He once said to me: "I entered the matter of mathematical thinking from the side of mathematics and I came out from the side of cognition. You are entering from the side of cognition, but who knows which side you will come out from!" He made me think and said goodbye to me smiling. I keep thinking and I hope he keeps smiling.

Eugenio Filloy (1942-2020)

Como dijimos en el prólogo de estas actas, cuando planeamos el programa del PME-NA 42, habíamos contemplado incluir un homenaje especial y presencial en vida a Eugenio Filloy, al que considero “el padre” de la matemática educativa en México, con una influencia que trasciende fronteras a otros países de Ibero y Latinoamérica. Eugenio fue de las personas que más apoyaron la realización del PME-NA 42 en México, y estas actas incluyen muchas contribuciones de sus estudiantes y suyas. Tristemente, Eugenio falleció el 23 de marzo de este año 2020. Hacemos este homenaje por tanto *in memoriam.*

Aquí bosquejamos su trayectoria académica y algunas de sus principales contribuciones al campo de la Matemática Educativa.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

- Eugenio obtuvo la Licenciatura en Matemáticas en la Facultad de Ciencias de la Universidad Nacional Autónoma de México, en 1965, habiendo también estudiado Física Teórica
- Obtuvo el grado de Maestro en Ciencias en Matemáticas, del Cinvestav, en 1966, y ese mismo año fue profesor visitante de la Universidad de California en Los Angeles.
- Obtuvo el grado de Doctor en Ciencias en Matemáticas de la Universidad de Chicago, en 1970.
- En 1971, ingresa como investigador adjunto del Departamento de Matemáticas del Cinvestav; pero también hace un trabajo posdoctoral en la Universidad de Ginebra, Suiza, en 1972.
- De 1973 a 1977, fue presidente de la Sociedad Matemática Mexicana
- En 1975, co-fundó la Sección de Matemática Educativa (SME), afiliada al Departamento de Investigaciones Educativas (DIE) del Cinvestav, junto con otros dos matemáticos del Departamento de Matemáticas –Carlos Imaz y Juan José Rivaud— con quienes colaboraba en el diseño y escritura de los libros de texto de Matemáticas para la escuela primaria, dentro del Programa Nacional de Libros de Texto Gratuitos, impulsado por la Secretaría de Educación Pública (SEP) a finales de los años 60s. Como explica Ramiro Ávila Godoy (2013):

> Esta experiencia del Dr. Filloy le permitió tomar plena conciencia de la importancia y complejidad de la problemática del aprendizaje y la enseñanza de las Matemáticas y de la necesidad de atenderla en todos los niveles educativos, en especial en el nivel básico; pero lo más trascendente no fue haberse percatado de la necesidad de atender dicho problema, sino el haber tomado la decisión de intervenir de manera directa en la búsqueda de solución al mismo. […]
>
> … en el nombre *Matemática Educativa* iba implícita la intención de enfrentar la problemática de la enseñanza y el aprendizaje de la matemática desde la matemática misma. En esa época, este enfoque resultó muy original, dando lugar a que en muchos países de Latinoamérica empezara a hablarse de Matemática Educativa como lo que en la actualidad es en la comunidad latinoamericana, *la disciplina dedicada al estudio de la problemática de la educación matemática*.

- Desde el inicio de la SME (hoy en día, el Departamento de Matemática Educativa –DME, del Cinvestav), i.e. desde 1975, se ofreció una Maestría en Ciencias con Especialidad en Matemática Educativa, “con un fuerte contenido tanto en matemáticas, como en la historia y fundamentos de las matemáticas” (Trigueros, Sacristán & Guerrero, 2008, p. 220); y a partir de 1982, un programa de Doctorado en Ciencias. Eugenio mismo (activo hasta el día de su fallecimiento) dirigió las tesis de casi 100 estudiantes de esos programas (más de 60 tesis de maestría y más de 30 de doctorado); muchos de sus ex alumnos tienen escritos en estas actas.
- En 1983, Eugenio fundó el ambicioso y trascendental Programa Nacional de Formación y Actualización de Profesores de Matemáticas (PNFAPM) que, en colaboración con una red de departamentos de Matemáticas de más de 30 universidades y tecnológicos regionales de México, ofreció una Maestría en Ciencias en Matemática Educativa; así como un programa de licenciatura en Enseñanza de las Matemáticas.

> El PNFAPM también estableció vínculos académicos con instituciones internacionales, y muchos miembros de la SME realizaron estudios de doctorado y posdoctorado en el extranjero. Simultáneamente al PNFAPM, se lanzaron conferencias y reuniones nacionales e internacionales para que investigadores y docentes pudieran compartir y discutir sus experiencias ”. (Trigueros, Sacristán y Guerrero, 2008, p. 221)

De hecho, Eugenio promovió continuamente las colaboraciones con investigadores de todo el mundo. Por ejemplo:

- Participó activamente en eventos internacionales, tales como los del CIAEM (presidiendo, en 1980, el XXXII CIAEM, en Oaxtepec, México), del PME e ICMI. Eugenio fue instrumental para que México formara parte del PME-NA; Teresa Rojano explica: "Fue Eugenio Filloy quien, en la década de 1980, propuso que se considerara a México como miembro del PME-NA, argumentando que geográficamente México es parte de América del Norte. Un año después, el Comité Directivo [del PME-NA] agregó un lugar para miembro mexicano."

- Trigueros, Sacristán y Guerrero (2008, p. 221) describen las colaboraciones internacionales y vínculos académicos promovidos por Eugenio para la SME del Cinvestav:

> Desde sus inicios, el grupo de la SME-Cinvestav [liderado por Eugenio] comenzó a estudiar lo que se estaba haciendo a nivel internacional y desarrolló vínculos académicos con investigadores e instituciones extranjeras. Los primeros vínculos se realizaron con Brousseau y Glaeser, y más tarde con los *Instituts de Recherche sur l'Enseignement des Mathématiques* (IREM) en Burdeos y en la *Université Louis Pasteur* en Estrasburgo, Francia, así como con la *École des Hautes Études en Sciences Sociales* en París. Esto estableció una influencia de la escuela francesa de *Didactique*. […] El grupo SME-Cinvestav también tuvo en cuenta los marcos teóricos de otros países como de los Estados Unidos (por ejemplo, el trabajo de Bruner y Skinner), de la Unión Soviética (por ejemplo, el de Kruteski), del Reino Unido, así como el trabajo de Piaget. Otros vínculos académicos tuvieron lugar con la Universidad de Londres, Reino Unido, la Universidad de Cambridge, Reino Unido y la Universidad de Toronto, Canadá. En el siglo XXI, se habían establecido muchos otros vínculos internacionales con DME-Cinvestav. Además de los mencionados, otras incluyen los de las Universidades de Granada y Valencia en España; la *Université Joseph Fourier* en Grenoble, Francia; la Universidad de Quebec en Montreal (UQAM), Canadá; las universidades de Georgia y Massachusetts-Dartmouth en los Estados Unidos; y las Universidades de Nottingham y de Bristol, Reino Unido.

- En 1979, Eugenio también lleva a cabo trabajo posdoctoral en la Universidad de Estrasburgo, Francia, y es profesor invitado en la Universidad Autónoma de Barcelona, España.
- De esa forma, investigadores como François Pluvinage (quien casualmente falleció prácticamente el mismo día que Eugenio), Kat Hart, Carolyn Kieran, Luis Puig, Celia Hoyles, Ros Sutherland, Richard Noss y James Kaput, entre otros, se hicieron habituales colaboradores del Departamento de Matemática Educativa del Cinvestav
- Y el resultado, tanto del programa de Maestría, y posteriormente del programa de Doctorado del Cinvestav, así como del PNFAPM, son varios cientos de graduados formados a través del Cinvestav, no solo de México, sino de toda Ibero y América Latina, los cuales han influido en sus regiones en el campo de la Educación Matemática; otra consecuencia es el lanzamiento de otros programas de capacitación para profesores de matemáticas y/o de investigación en Matemática Educativa.

Eugenio no solo fortaleció el campo de la Educación Matemática a través de sus iniciativas de desarrollo profesional, sino también a través de su investigación y los enfoques y métodos de investigación que impulsó (para más detalles, ver Trigueros, Sacristán & Guerrero, 2008; y Solares, Puig y Rojano, 2020). Por ejemplo,

- Impulsó el análisis de la historia y de los fundamentos de las matemáticas, como método de investigación en la disciplina de la matemática educativa.
- Promovió el uso y la investigación de lo que antes se solía llamar las "nuevas tecnologías" (es decir, computadoras, medios audiovisuales y otros recursos digitales).
- Ante la necesidad de realizar una experimentación controlada, fundó una escuela en la que podría hacerlo (el Centro Escolar Hermanos Revueltas).
- Reconoció las limitaciones de los modelos teóricos generales y propuso el concepto de Modelos Teóricos Locales (ver el libro *Educational Algebra* de Filloy, Rojano & Puig, 2008).

- Produjo cerca de 500 publicaciones científicas en sus líneas de investigación: Didáctica del álgebra y la geometría; Historia de las ideas algebraicas y geométricas; Desarrollo curricular; Uso de nuevas tecnologías en la enseñanza; Sistemas Matemáticos de Signos; y Modelos Teóricos Locales.
- Eugenio también fue miembro de muchos Comités Científicos y / o Editoriales, incluyendo de las revistas *Educational Studies in Mathematics* y *Recherche en Didactique des Mathématiques.*
- Recibió muchas distinciones, incluida la de ser nombrado Profesor Emérito del Cinvestav (2002); recibir un Doctorado *Honoris Causa* de la Universidad de Sonora (2011); ser otorgado la medalla "Mtro. Remigio Valdéz Gámez" de la Asociación Nacional de Profesores de Matemáticas AC (ANPM AC) por su meritoria y trascendente trayectoria en el ámbito de la educación matemática en México (2013); y un reconocimiento honorífico de la Universidad Autónoma de Guerrero por ser fundador en México y América Latina de la Matemática Educativa, aportaciones académicas de referente internacional (2016).

A eso le sumamos este homenaje, en reconocimiento a su profundo legado en el campo de la Matemática Educativa.

A continuación incluimos algunos, recuerdos e historias de algunos de sus colaboradores y ex alumnos:

"Eugenio siempre estará señalándonos hacia dónde seguir adelante." Luis Puig

Recuerdos felices del Prof Eugenio Filloy, por Celia Hoyles and Richard Noss

Celia y Richard con Eugenio en los años ochentas

Por lo que podemos recordar, Celia conoció a Eugenio en una de las primeras conferencias de PME: Grenoble 1981 o Amberes 1982, no podemos estar seguros. Nuestra relación con Eugenio duró muchas décadas. Está lleno de tantos recuerdos maravillosos, de lo que solo podemos compartir su esencia aquí.

Eugenio se destacó por su profundo compromiso con las matemáticas y la educación matemática, su devoción por México y el fomento de la educación matemática en el país. Uno solo tenía que pasar diez minutos en su compañía para reconocer su encanto, su sentido del humor y quizás sobre todo el brillo en sus ojos. ¡Sin mencionar su maravillosa hospitalidad y sus opiniones gourmet sobre el vino y la comida!

A mediados de los años ochenta, Eugenio y Celia pusieron en marcha el Proyecto de Investigación Anglo-Mexicano, denominado "El Desarrollo de Micromundos Matemáticos para Alumnos y Docentes". Esto se logró con la financiación del British Council y el Gobierno de México y el trabajo avanzó en colaboración con el Programa Nacional de Formación y Actualización de Profesores de Matemáticas o PNFAPM que lideró Eugenio. Cuando Richard y más tarde Teresa Rojano y Ros Sutherland se unieron al equipo en 1986, se había establecido un flujo constante de visitas en ambas direcciones junto con colaboraciones de investigación que duraron muchos años.

Una característica central del proyecto fue reclutar estudiantes de doctorado que conocimos en México, quienes fueron sujetos a un proceso de selección para realizar un doctorado en Educación Matemática en Londres, con trabajo de campo en México.

¡Esto significó para nosotros un gran "extra" de este proyecto! Solíamos visitar México una vez al año, yendo a diferentes partes de este increíble país con Eugenio como nuestro guía y mentor. Pero eso no fue todo: ¡Eugenio no era de los que se quedaban en una tienda de campaña y comían en un café al borde de la carretera! Por el contrario, nuestras visitas se caracterizaron por visitas a maravillosos restaurantes, hoteles exóticos y seminarios relajados pero fascinantes donde conocimos a varios investigadores a los que ahora consideramos amigos y colaboradores, como Olimpia

Figueras y en particular una de las estudiantes de doctorado estrella de Richard de este programa, Ana Isabel Sacristán quien se ha convertido en una figura destacada en Educación Matemática en México e internacionalmente.

Se destaca un incidente, uno que es icónico en términos de la disposición de Eugenio para mirar la vida, sin importar cuán seria sea, con un brillo en los ojos. Dábamos una charla en un seminario, en algún lugar de la Ciudad de México. Celia estaba tratando de explicar cuidadosamente algunos puntos clave de nuestra investigación, y ambos estábamos tratando de comunicarnos (vergonzosamente, a pesar de tantas visitas a México, ninguno de los dos hablamos español lo suficientemente bien como para dar una charla). Eugenio estaba traduciendo amablemente lo que creíamos que era un punto importante y serio, cuando el público se echó a reír. Eugenio nos miró de reojo, con un atisbo de sonrisa en su rostro. Hasta el día de hoy no sabemos lo que dijo, o qué tan cercana, si es que lo hizo, fue su "traducción" a lo que dijimos. ☺

Extrañamos mucho a Eugenio pero al menos nos da consuelo el hecho de que nuestra relación con México continúa a través de colaboraciones con Ana y con Teresa que comenzaron con su iniciativa. Hemos vuelto a visitar algunos de nuestros lugares favoritos para realizar talleres, en esta ocasión organizado por ellos. Así que terminamos con una foto de nosotros con Ana tomada en uno de estos talleres en el encantador hotel Hostería Las Quintas en Cuernavaca, que nos presentó Eugenio como sede de uno de sus seminarios y se convirtió en uno de nuestros lugares favoritos en todo el mundo. ☺

Richard y Celia con Ana Isabel Sacristán (izq., quien hizo sus estudios doctorales en Londres como parte de la colaboración iniciada por Eugenio Filloy) en los jardines de la Hostería Las Quintas

Celia y Richard en los jardines de la Hostería Las Quintas, Cuernavaca

Recuerdos de Eugenio, por Carolyn Kieran

A menudo, durante las últimas décadas, cuando me invitaban a México a dar una plática para profesores y jóvenes investigadores, y se le pedía a Eugenio que tradujera mi presentación al público del inglés al español, algo extraño sucedía: enunciaba más o menos un párrafo en inglés y luego era el turno de Eugenio de traducir lo que acababa de decir. Inevitablemente, la traducción tomaba más tiempo, pero no solo eso, a menudo provocaba ataques de risa en el público. Eugenio era un experto en darle un toque de humor a mis presentaciones que sin él eran sencillas y muy serias – algo por lo que siempre estaré muy agradecida y siempre apreciaré de Eugenio: su gentileza y gran sentido del humor.

Recuerdos de Eugenio, por Fernando Hitt

Eugenio era uno de nuestros "maîtres penseurs" mexicano. Tenía una visión muy amplia de los problemas de México en educación y de nuestra posibilidades de contribuir al mejoramiento de la enseñanza y del aprendizaje de las matemáticas. Cuando yo realizaba estudios de doctorado en el extranjero, presentó a los miembros de la Sección de Matemática Educativa un documento sobre la evolución de la sección y sus miembros, que pasó a la historia como el "documento de los colorines". En ese documento hacía una proyección de la sección hacia el futuro. Ese documento se utilizó durante varios años como guía para recordarnos sobre los objetivos de la sección.

Eugenio al inicio de los 80s me propuso reflexionar sobre un proyecto sobre la formación de profesores de matemáticas que se *debería* presentar a la Dirección General de Educación Superior Universitaria poco antes del cambio de sexenio (en 1982). Me propuso que nos reuniésemos un día cada semana en su casa y que si el proyecto no fuera aprobado, al menos pasaríamos un rato agradable discutiendo y tomando un par de copas... El resultado fue que Jesús Reyes Heroles al ser nombrado secretario de educación, al escuchar el proyecto por el Director General, mencionó que ese era un proyecto excelente y que se deberían implementar muchos más del mismo estilo (Español, Biología, Física, etc.). Fue así como nació el Programa Nacional de Formación y Actualización de Profesores de Matemáticas (PNFAPM), el problema fue que poco tiempo después murió Reyes Heroles. Aún así, pudimos sostener el programa por más de 10 años.

Algunas memorias de los PME:

En un PME de finales de los 80s o principios de los 90s, Eugenio fue a una conferencia sobre el uso de nuevas tecnologías. Por primera vez, Eugenio veía a alguien utilizando computadora y cañón en una presentación. Me explicó que se veía un poco borroso y la imagen pequeña. Me cuenta que varios minutos después llega un tipo, se sienta al frente cerca de donde estaba la computadora y el cañón, se levanta mueve realiza un par de cosas y deja una imagen nítida e imagen más amplia. Eugenio me dijo, ese momento fue mucho más interesante sobre la utilidad de la tecnología que toda la conferencia completa.

En el PME en Asissi (Italia) en 1991, al inicio del congreso lo ví salir del hotel estando yo en la cafetería. Salí unos 5 minutos después y me lo encontré en el camino. Le dije que pensaba que ya estaría en el congreso, y me contestó que caminando a la Michael Jackson le tomaba más tiempo... ☺

Eugenio Filloy Yagüe, un profesor que me dejó un legado, por Miguel Díaz Chávez

En mi formación, el profesor Filloy fue un personaje muy importante y los encuentros fueron muchos; sin embargo creo que los siguientes son los que quiero compartir.

Mi primer encuentro con el profesor Filloy fue en el año de 1986 cuando iniciaba mis estudios de maestría de matemática educativa, en la entonces sección del mismo nombre ubicada en el bello edificio de Dakota 379 en la colonia Nápoles. En ese primer semestre él fue mi profesor del curso básico de educación y creo que una de las primeras lecturas que nos dejó fue la del libro "*Psicogénesis e historia de la ciencia*" de Jean Piaget y Rolando García. Yo leí las secciones que nos indicó y al final le dije con mucha angustia que no entendía y él muy comprensivo me contestó: *Algún día lo entenderás*. Este curso y sus disertaciones me abrieron el panorama de la educación matemática.

Un segundo recuerdo que tengo muy presente fue en mi primer viaje a Europa en 1988 cuando me sorprendí de encontrar un libro de su autoría en una librería de Madrid, este descubrimiento me mostró la trascendencia de su trabajo a nivel internacional.

El último encuentro que tuve con él profesor Filloy fue escuchándolo en un evento en la ciudad de México hace aproximadamente cinco años. En ese tiempo yo iniciaba una investigación sobre el libro de texto gratuito de matemáticas y platiqué con él sobre la posibilidad de hacerle una entrevista al respecto, considerando que él fue uno de los autores de esos libros en los años 70's; como era de esperarse estuvo de acuerdo, pero con su estilo me dijo: *Sí, pero date prisa.* Nunca tuvo lugar esa entrevista. Para él, el profesor Filloy, mi gratitud infinita.

Algunos recuerdos de Eugenio, por Ana Isabel Sacristán

Cuando inicié, en 1986, mis estudios de Maestría en la Sección de Matemática Educativa del Cinvestav, tuve como profesor a Eugenio Filloy, en la materia que se llamaba "Básico de Educación". Recuerdo lo intimidante que me resultaba su presencia tan imponente. Por ejemplo, era obsesivo con la puntualidad y yo le tenía miedo por eso: mirando su reloj, me decía: "Llegaste dos minutos tarde"; o, en una ocasión: "Llegaste 30 segundos tarde"(!)

En contraparte, me resultó sorpresivo, en aquel entonces, cómo era más importante para él que razonáramos a que aprendiéramos contenidos, y recuerdo lo iluminante que fue el estudio del libro "*Psicogénesis e historia de la ciencia*" de Jean Piaget y Rolando García. Eugenio me introdujo a una filosofía educativa que desconocía entonces, pero que he seguido hasta ahora.

Tiempo después de haber terminado mis estudios de maestría, en 1989, me topé con él de casualidad un día: De entrada me dijo: "Los ingleses están aquí"; inmediatamente, sin que yo pudiera decir ni una sola palabra, ni preguntar a qué se refería, abrió su agenda y me ordenó estar al día siguiente para entrevistarme con Celia Hoyles a una hora específica. Así de corto fue el encuentro, y yo no sabía bien de qué se trataba. Pero era un entrevista para realizar estudios de doctorado en la Universidad de Londres, Inglaterra, con apoyo del PNFAPM y del *British Council*. De esa manera, por un encuentro que se dio de casualidad, mi futuro quedó sellado; y le estaré eternamente agradecida a Eugenio, además de sus enseñanzas, por ponerme y apoyarme en el camino.

Tengo la satisfacción de haberle podido informar, poco antes de que falleciera, que le haríamos este homenaje en el PME-NA 42. Creo que le dio gusto.

Memorias de Eugenio, por José Carlos Cortés

En 1991 inicié mis estudios de Maestría en la Sección de Matemática Educativa en el edificio ubicado en la calle Dakota en la Ciudad de México. En esa misma calle se encontraba también el edificio en el que trabajaba el Dr. Filloy, en ese entonces él era el jefe de la sección. La primera vez que lo vi me impresionó su tono fuerte de voz y su apariencia. Como en el primer semestre de mis estudios de Maestría no contaba aún con el apoyo de Conacyt, un día se me acercó el Dr. Filloy y me dijo que si quería trabajar en su escuela "Los Hermanos Revuelta" lo cual acepté con mucho gusto y nunca olvidare esa experiencia tan grande. En la escuela "Los Hermanos Revuelta" dirigida por Maru, esposa del Dr. Filloy, se nos permitía innovar a los profesores, también se nos permitía a los estudiantes de Maestría y Doctorado realizar experimentación educativa (claro cumpliendo todos los protocolos), es decir el Dr. Filloy fue pionero en la Investigación en Matemática Educativa pero a su vez ponía en práctica a través de su escuela las nuevas tendencias de enseñanza en Matemática Educativa. Mucho tiempo después el Dr. Filloy participó con nosotros en varios congresos de AMIUTEM y de lo cual tenemos muy Buenos recuerdos. Enhorabuena, Eugenio, en el lugar que te encuentres.

Discutiendo con Eugenio Filloy en Dakota 428, por Armando Solares Rojas (escrito en 2012)

Conocí a Eugenio Filloy en la primavera del año 2000. Las referencias que tenía de él me hacían ubicarlo como fundador del Departamento de Matemática Educativa del CINVESTAV, miembro de los comités editoriales de algunas de las revistas más importantes de investigación en el área, investigador internacionalmente famoso por sus contribuciones en didáctica del álgebra y como un personaje muy importante en las reformas educativas del país. Pero me faltaba mucho por conocer de él…

La primera reunión de trabajo que tuvimos se llevó a cabo en las oficinas de la Sociedad Mexicana de Matemática Educativa, en el número 428 de la calle de Dakota en la colonia Nápoles. Llegué puntalmente y pasamos a su oficina de reuniones. Tres sillones, una pequeña mesa, varias pinturas, una colección de posters celebrando los 300 años de la publicación de los Principios Matemáticos de la Filosofía Natural, de Isaac Newton. Hablamos poco, pero en esa corta charla me hizo una invitación a un seminario de filosofía de las matemáticas que estaba en curso, con Ignacio Garnica.

Junto con Manuel Cruz, quien era becario del Instituto de Matemáticas de la UNAM y es ahora director del Departamento de Matemáticas de la Universidad de Guanajuato, me armé de valor y dedicamos largas horas a la lectura y discusión del texto Sobre sentido y referencia de Gottlob Frege. Con muchas ideas en la cabeza nos lanzamos a las sesiones de un seminario en el que tratábamos de dar respuesta a preguntas como ¿qué son los números?, ¿a qué se refieren las expresiones que involucran números? Eugenio Filloy conducía el seminario para discutir teorías sobre el significado de los textos matemáticos y me mostró la posibilidad de trabajar, desde las matemáticas, con la epistemología, la historia y la didáctica. Ingresé al doctorado en Matemática Educativa en septiembre de ese mismo año.

Ya siendo formalmente alumno en el departamento seguí siendo parte del seminario cuyas sesiones, intensas e inolvidables, me dejaron muchos más aprendizajes de los que esperaba.

Por ejemplo, las lecturas de Wittgenstein. ¡Por fin cobraban sentido las largas horas dedicadas a finales de la licenciatura a la lectura del Tractatus logico-philosophicus! Hoy en día los juegos del lenguaje siguen rondando mis lecturas y, cada vez más, se incorporan en los textos que yo mismo escribo.

Conocí también la teoría semiótica Charles Sanders Peirce y cómo Eugenio utilizaba la noción triádica del signo como punto de partida para desarrollar los Sistemas Matemáticos de Signos, noción teórica que le permitiera describir fenómenos de la enseñanza y el aprendizaje del álgebra articulando así una nueva perspectiva de investigación propia que ha rendido frutos en numerosas investigaciones y publicaciones de la que ya ha hablado ampliamente la Dra. Rojano. Yo mismo he tenido la fortuna y el honor de colaborar en algunas de ellas a lo largo de los años de formación y trabajo con Eugenio y Tere: desde presentaciones en las Conferencias del International Group for the Psychology of Mathematics Education, hasta en la reciente publicación del artículo Problemas de dos cantidades desconocidas y dos niveles de representación de la incógnita publicado en el Journal for Research in Mathematics Education en enero del año pasado.

De la filosofía regresé a la historia. Mis lecturas previas sobre la historia del cálculo (el De quadratura curvarum, de Newton), de la física (la Optiks, también de Newton) tomaron sentido ¡también a través del contacto con Filloy!

Si bien sabía poco de la historia del desarrollo del álgebra, como todo matemático en formación, conocía la historia de la corta vida de Galois, famoso entre los jóvenes por bohemio, enamorado, anti-eclesiástico, rebelde y… genial. Pero nada sabía de los astrónomos y matemáticos indios Bhaskara y Brahmagupta, ni del matemático, astrónomo y poeta persa Omar Khayyám.

Y eso me lleva a hablar de una faceta de Eugenio que lo caracteriza y que ha tenido una influencia profunda en mí y en muchas otras personas que han estado cerca de él: su generosidad. Pienso que la historia y el legado de un hombre, de un maestro, puede describirse por los libros que atesora, pero aún más por los libros que ofrece y que comparte.

Entrar a la biblioteca de Filloy es una invitación a navegar por la inmensa pluralidad de ideas que la historia de matemáticas nos otorga. Ahí me encontré con distintas traducciones del Al-Kitāb al-mukhtaṣar fī ḥisāb al-jabr wa-l-muqābala (Libro conciso de calculo de restauración y oposición) y pude comparar las versiones y traducciones de Robert de Chester con la de Gerardo de Cremona y con la de Frederic Rosen. También la Aritmética de Diofanto en varias de sus versiones (Ver Eecke, P., J. Sesiano, Rashed, Tannery); el Liber Quadratorum 'El Libro de los Números cuadrados' de Leonardo de Pisa…

Su generosidad para con sus estudiantes va más allá de compartir su preciada biblioteca. Parte esencial de la actividad didáctica de Filloy es el apoyo al estudiante y la enseñanza de la autonomía y la autosuficiencia para escribir, participar en congresos, diseñar y presentar proyectos de investigación. Me recuerdo saliendo de asesoría y cargando un bulto enorme conformado por transcripciones, videos, lecciones, artículos, libros... Y horas de revisiones y discusiones sobre entrevistas video-grabadas con risas frente al televisor, ¿qué dijo?, ¿qué hizo?, ¿para dónde va? Compartir conocimiento. Enseñar. Aprender.

Recibí también su generosidad para formarme como maestro. ¿Has dado clases en secundaria?, me preguntó Eugenio. No… todavía, le contesté. Eran mediados del 2001 y para septiembre de ese año ya preparaba mis clases de matemáticas para segundo grado de secundaria en el Revueltas, la escuela con enfoque alternativo que Eugenio fundó. ¿Cómo me iba? Basta decir que salía sudando a chorros, afónico, exhausto. ¡Nada que ver con los cursos que me había tocado impartir en la Facultad de Ciencias! ¿Más difícil?, me preguntaban mis amigos. ¡Sin lugar a dudas!

Esa experiencia transformó profundamente mi manera de ver el salón de clases de matemáticas, ya no se trataba sólo de encontrar y diseñar buenos problemas y ponerlos a prueba en situación de entrevista, sino de reconocer la complejidad del trabajo del maestro, la diversidad de tensiones en las que se construye la actividad matemática del salón de clases.

Por otro lado, en Revueltas vi cómo Eugenio, investigador en matemática educativa, se topaba en los pasillos con alumnos que le decían "¡Chócalas, Eugenio!" y se subían a su espalda para que los llevara "de caballito"; con directivos que lo buscaban para decirle "maestro, llegaron las calculadoras y los view-screen"; y profesores que le pedían apoyo para sus clases "Eugenio, ¿revisamos lo que vamos a ver en tercero la siguiente semana?". Crear y sostener un laboratorio de investigación "vivo", como es una escuela, es una de las tareas más demandantes que he visto, y en Eugenio es también es una muestra de consistencia entre el discurso teórico y la práctica.

Pero la generosidad de Eugenio no se limita a compartir solamente sobre libros y matemáticas… las discusiones, los proyectos, los artículos, acompañados con una buena comida y un buen vino ¡saben aún mejor!

¿Cuáles son el sentido y la referencia de la expresión "buen vino francés"? Siguiendo las enseñanza de Eugenio, podríamos decir que su referencia se ubica en los viñedos de Montrachet, entre los pueblos de Puligny y Chanssange, en la Côte-d'Or de la región de Borgoña, en el este de Francia. O quizás en una botella de un Château d'Yquem, producido en la región de Sauternes, en Burdeos. El sentido en este caso es aún más claro, si quiere uno pensarlo así. El Sauternes se elabora con uvas sémillon, sauvignon blanc y muscadelle que afectadas por un hongo endémico de la región, quedan parcialmente pasificadas, de lo que resulta una mayor concentración de azúcar y vinos con un aroma distintivo. El Château d'Yquem se elabora, además, de manera artesanal, procesando uva por uva… a mano.

Y así como compartió lo mucho que sabe de vinos conmigo, he tenido oportunidad de estar en la cercanía de su persona, de su familia, de Maru, su esposa. Cerca no sólo de su visión de investigador sino también de su visión de vida, de lo que en México y América Latina entendemos por ser sibarita, o sea, quien disfruta de la vida en toda su vastedad.

Hoy, desde mi propia visión sobre la cercanía, quiero agradecer a Eugenio todo lo que ha compartido y comparte aún conmigo. Un gran abrazo y muchas felicitaciones, Eugenio.

Ciudad de México, noviembre de 2012.

Memorias de una de las ultimas estudiantes del Dr. Filloy, por María Leticia Rodríguez-González

El Dr. Eugenio Filloy era una persona con la habilidad de observar para conocer a cada uno de nosotros. Sabía exactamente cuáles eran nuestras fortalezas, debilidades y sobre todo sentimientos. Fue un hombre, con un extraordinario conocimiento universal, siempre tenía tema de conversación. Le encantaba la narrativa, anudando en sus historias relatos de la vida cotidiana, entremezclando personajes de la mitología griega y de la política. Filloy era un enamorado de la vida.

Le encantaba que le preguntáramos cualquier cosa, aunque algunas veces éramos nosotros sus alumnos quienes dudábamos en preguntarle. Lo más interesante, es que no nos daba la respuesta, sino qué nos proporcionaba un gran número de libros para investigarlo. Pero lo maravilloso, es que el acervo que nos compartía, eran materiales inéditos en la mayoría de los casos.

Sin embargo, a veces era muy difícil seguir la lógica de su discurso; pues aunque nosotros apenas estábamos entendiendo el principio, él ya estaba construyendo el final. Con el tiempo, aprendí que todas sus ideas tenían un sentido no sólo matemático y heurístico sino sobretodo científico.

Me atrevo a afirmar que Eugenio Filloy, fue el científico que le dio legitimidad a la matemática educativa, rompiendo con el paradigma de encontrar los problemas en la forma en que se enseñan y se aprenden las matemáticas. Él dio los argumentos para que el objeto de conocimiento de la matemática educativa se centre en las matemáticas mismas, estableciendo una clara diferencia entre Educación Matemática, Didáctica de las Matemáticas y Psicología de las Matemáticas.

Eugenio Filloy maestro visionario sabía que la construcción del conocimiento científico requiere de la interacción entre investigadores, maestros y alumnos a través de la comunicación, muestra de ello fue su participación y en algunos casos fundador de Congresos, Foros, Simposios, nacionales e internacionales como La Sociedad Matemática Mexicana, Programa Nacional de Formación de Profesores, Reunión Centroamericana y del Caribe sobre la formación de profesores e Investigación en Matemática Educativa, PME, PME-NA, CIAEM.

Gracias Dr. Filloy, aunque ya no estés físicamente, tu presencia seguirá vigente, empezando por nuestro Departamento de Matemática Educativa, el cual fundaste junto con el Dr. Carlos Imaz, Tu obra sigue presente con Tu contribución a la investigación a través de los Modelos Teóricos Locales.

Memorias de Eugenio, por Ulises Xolocotzin

Siempre agradeceré que el Dr Eugenio Filloy se diera el tiempo de saludarme y platicar conmigo cuando nos encontrábamos en nuestro Departamento. En nuestras platicas o me hacía reír, o me hacía pensar. Una vez me dijo: "Yo entré al asunto del pensamiento matemático desde el lado de las matemáticas y salí por el lado de la cognición. Tú estas entrando por el lado de la cognición, ¡Pero quién sabe por qué lado salgas!". Me puso a pensar y se despidió de mí sonriendo. Yo sigo pensando y espero que él siga sonriendo.

In this plenary presentation paper, we reflect on issues related to the role, potential and extent of integration of digital technologies in mathematics education, and attempt to give our perspectives on these issues from across cultures and over time stretching over the past four decades. Three experts, from three different countries, give their reflections on how mathematics teaching and learning has changed and developed since digital technologies were introduced in schools. Their individual narratives are then complemented by a discussion of the differences in adaptation to the constant changes in technology, changes that arise from diverse socioeconomic, political and cultural visions of the role of digital technologies and their influence and on how the potential of these technologies can actually be harnessed.

Keywords: Technology; Instructional activities and practices; Culturally relevant pedagogy; Computational thinking

Introduction, by Ana Isabel Sacristán and María Trigueros

For this plenary presentation, we invited three renowned experts on the integration of digital technologies in mathematics education: Celia Hoyles from the UK, Carolyn Kieran from Canada, and Teresa Rojano from Mexico. We asked each of them to reflect on what has happened with the roles and potentials of digital technologies in mathematics education since their adoption in school systems, in order to develop a perspective of this topic across cultures and countries.

This paper presents their contributions complemented by our own reflections. The next sections present the experts' contributions. First, Hoyles presents a reflection on how mathematics teaching and learning has changed and developed since digital technologies in general and programming, in particular, were introduced into school mathematics education, specifically in England. Then Kieran, through the lens of the Canadian experience, presents a discussion of how issues related to the emergence of new technologies and the restrictions involved in their use by teachers in their classrooms created conditions that privilege some approaches; she also presents an interesting discussion on how computational thinking relates to mathematical practice and thinking. In the next section, Rojano begins by discussing some results of an Anglo-Mexican project that highlighted some differences in the use of technologies for algebra, then describes some national projects developed in Mexico, and how economic and political circumstances had an impact on their possibilities of generalization and success.

We finish by including our own reflections, based on their visions, on how digital technologies have played an important role in mathematics education and on how different cultural and economical conditions have a strong influence on how the potential of these technologies can actually be harnessed.

Reflections on the Role of Digital Technologies in Mathematics Education: insights from the past and ongoing research, by Celia Hoyles

The invitation to make this contribution at PME-NA has provoked me to look back on about 30 years of research in the area of digital technologies and mathematics education, in general and in particular around programming. My passion is and has been to help learners open windows to mathematical knowledge by using digital technologies in innovative, future-oriented and intellectually rigorous ways (Hoyles, 2018). This passion I have shared with Richard Noss with whom I have worked on numerous research projects over the years. The research questions we have posed, the technologies designed, and the research methods employed have all reflected this desire to widen access to learning through digital technology and to tease out the conditions necessary for this to happen successfully. Mathematics is central to the school curriculum, yet all too often mathematics does not engage learners who do not discern the point of the mathematics they are forced to learn. This is important at the individual level, but at the same time, the technology-based 'information society' needs model-based reasoners who can exploit mathematical ways of thinking to make sense of their world. This has become ever more apparent at the time of writing this paper when the world is enduring a global pandemic where everybody is assailed by data and graphs of the numbers infected by Covid 19. These representations and the models that generate them need to be interpreted. Thus we need to take seriously the design challenge to engage our students in school in mathematical thinking and application which as far as is possible is actually needed for them to achieve the goals that they find compelling.

Background

My work has been grounded in constructionism originating from the vision of Seymour Papert (Papert, 1980a), which asserts that one way to achieve sense-making for learners was for them to take the role (to some extent at least) of *producers* rather than *consumers* of digital tools, so they are better able to explain the *effects* of the tools (see for some example Confrey et al., 2009, p. 19). Our approach originated with a Piagetian basis but evolved to embrace "a hybrid social constructivist/sociocultural approach… with a vision of human–machine interaction and design for mathematical activity" (Monaghan, Trouche and Borwein, 2016, p. 10). In my view, fundamental to constructionism are two notions: *epistemological pluralism*, that is accepting the validity of multiple ways of knowing and thinking (following Turkle and Papert, 1992) and *designing for interaction in microworlds*.

I make a small diversion to give the reader a glimpse of the challenge Seymour Papert set us many years ago on this first issue of *epistemological pluralism*. As a member of a plenary panel at a conference in Newcastle, Australia, to commemorate the work of Jon Borwein, I was tasked to address the new ways people think, move and feel mathematically, thanks to the opportunities offered by digital technologies: the abstract went on to state:

> …the emergence of new digital technologies and new theories have helped researchers recognise the breadth and depth of that change and simultaneously provide a framework for the design and implementation of computational tools for learning mathematics. The possibility of putting mathematical objects into motion, for example, fundamentally changes the nature of these objects, how they are perceived and reasoned about; moving these objects changes the bodily actions and gestures of both learners and teachers; making the objects transform, collide and overlap, changes the stories that can be told about them. Research on the use of digital technology has also provided an extraordinary 'window' on mathematical meaning making, to use the metaphor provided by Celia Hoyles and Richard Noss, in part because of the visibility of thought, motion and feeling enabled in expressive digital technology environments. (Drijvers et al., 2016).

The example I gave at the panel was stimulated by Papert's keynote at 10th conference of PME in London way back in 1986 that I simply mention here to provoke the reader. Papert talked about what is generally known as the "alternate segment theorem" (p. 3) and argued how simple it was *if only one thought of oneself in the motion* and then "it is easy to see the total turn of a circular arc is the same as the angle at the centre of the circle"(end of second paragraph, Papert 1986, p. 3).

And what about *microworlds*? In Hoyles (1993), I described the evolution of the *microworld* idea from its genesis in the artificial intelligence community, in which it was used to describe a relatively simple and constrained domain where computational systems could solve problems, to a more broadly conceived environment that served as a concrete embodiment of a knowledge domain or structure. The structure comprises tools that are *extensible* (so tools and objects can be combined to build new ones), but also *transparent* so their workings are visible, and rich in different representations. There is a duality here: a successful microworld is both an epistemological and an emotional universe, a place where powerful mathematical ideas can be explored; but explored "'in safety"', acting as an incubator both in the sense of fostering conceptual growth, and a place where it is safe to make mistakes and show ignorance. And, centrally these days, it is a place where ideas can be effortlessly shared, remixed and improved (for an earlier discussion of these twin aspects of engaging through building and sharing, see Noss and Hoyles, 2006).

Programming and Mathematics

Now let us fast-forward to 2014 where, at least in England, programming or coding is widespread and moreover part of a *compulsory* curriculum for all students from age 6 to 16 years. It is important to recall now that teaching of computer programming is not new, with educational programming languages such as Logo and BASIC widely used in both primary and secondary education settings during the 1980s and 90s. However, Manches and Plowman (2015) highlighted that recent discussion around how to teach programming in schools often omitted the earlier research conducted during this time: some of which are reported in Hoyles and Noss (1992). We need to learn from these earlier studies. Research on the efficacy of programming had in fact produced mixed results (Clements, 1999; Voogt et al., 2015). From the point of view of learning programming per se, some of the key challenges identified were difficulties with programming syntax, dealing with error messages along with the severely limited access to technology within the classroom (Resnick et al., 2009; Lewis, 2010). Since then there have been hugely significant developments in novice programming languages that have overcome many of these challenges (though maybe raised others), and technology access has become increasingly commonplace within schools with resources readily available for sharing through the Web.

When computing became mandatory in English schools in 2014[1], the time was ripe to revisit research on the impact of programming on mathematics learning taking account of the new context and critically learning from the past that had shown the importance of design of microworlds and critical need to take account of the teacher's role. Richard Noss and I then embarked on a new research project, the ScratchMaths (SM) project, which set out to explore the potential of programming for the 9–11 primary1 age group (upper Key Stage 2 (KS2)) in light of the curriculum changes and the renewed enthusiasm and motivation for the teaching of programming in schools. The project consists of a design phase following which the intervention comprising detailed computer tools and curriculum materials is implemented over 2 years with the same pupils. Some factors that contributed to Logo and other early programming initiatives not fulfilling their potential have been mentioned earlier, but a key factor being identified by Noss and Hoyles (1996) as the importance of

[1] During the late 1990s programming faded from the English curriculum and became subsumed and eventually replaced entirely by the subject of ICT (Information and Communications Technology), which focused more on the use of technology than on its creation (Brown et al., 2014).

fostering a *sense of teacher understanding and ownership* of any programming innovation. In addition, there have been significant technological developments since this early teaching of computer programming, with a number of block-based languages such as Scratch now freely available and widely used. These environments have helped to address some of the difficulties of mastering programming syntax, but there remains the challenge of ensuring that teachers first appreciate why they are introducing programming as part of mathematics – and then have opportunities to develop appropriate skills to teach programming.

The ScratchMaths (SM) designed a 2-year intervention aiming to develop the mathematical knowledge of pupils (aged 9-11 years) through programming. The SM approach was to select and design activities around core computational ideas that would then be used as vehicles to explore specific mathematical concepts and promote mathematical reasoning. This approach enables parts of computing to be taught within or as a supplement to mathematics lessons. For a summary of the SM design research phases, activities and outcomes see (see Benton, Hoyles, Kalas & Noss, 2017, for a detailed account of the design of the study). The SM content was divided into six modules, or in terms for this paper, microworlds, three per year. In the first year for 9-10 year-old students, computational concepts (see for example, Wing, 2006) were foregrounded with mathematical ideas more implicit in microworlds titled *Tiling Patterns, Beetle Geometry* and *Collaborating Sprites*. In the second year, the same students (now 10-11 years old) were introduced to mathematical concepts and mathematical reasoning explicitly through a programming approach along with a set of new computational concepts in microworlds titled Building with *Numbers, Exploring Mathematical Relationships,* and *Coordinates* and *Geometry*. SM was intended to comprise approximately 20 hours teaching time across each of these two school years.

Given the challenge of implementing a new curriculum, the SM teachers were provided detailed guidance for navigation through support materials, which were themselves carefully structured and progressive. Prior to teaching each year of the SM intervention, teachers were offered two full days of professional development, spaced a few months apart. During these sessions, the teachers were introduced to Scratch and the SM curriculum content. The SM design was framed by constructionist theory whereby pupils would engage with the mathematical ideas by building programs to explore so the PD followed this approach (see Noss & Hoyles, 2017, 2019). It was then intended that this constructionist approach would be operationalized in the classroom through what we called the '5Es pedagogical framework' with teachers given the opportunity to participate in activities that incorporated exemplars of the different pedagogical strategies. The five unordered constructs of the framework are summarised below:

Explore: Pupils should have opportunities to explore different ways of dealing with constraints and ambiguity as well as investigating their own and others' ideas and debugging different types of errors.

Explain: Pupils should have opportunities to explain their own ideas as well as answer and discuss reflective questions from the teacher and peers.

Envisage: Pupils should predict outcomes of their own and others' programs with specific goals *prior* to testing out on the computer.

Exchange: Pupils should have opportunities to share and build on others' ideas as well as justify their own solutions.

bridgE: Pupils should be helped to make links between contexts beyond the Scratch programming environment by explicit re-contextualization and reconstruction within the language of mathematics, by for example unplugged activities.

The SM intervention was subject to cycles of iterative design research following which it was scaled out across England. The project was also evaluated through a randomised control trial conducted by another university (Boylan et al., 2018[2]). For the trial, 111 English primary schools (6300 pupils) were recruited and randomly assigned to control and treatment groups with the final quantitative outcome measures based on scores in first a test of computational thinking (designed by the evaluation team) to be applied in the first year of the evaluation, and second, scores on national standardised mathematics tests taken by all students at the end of primary school.

For completeness, I summarise the findings of the external evaluation of SM, which reported:

- a positive and significant impact on Y5 Computational Thinking skills, which was
  - particularly evident among disadvantaged pupils that is those who had or currently have free school meals
  - with no difference between girls and boys
- no evidence of impact on the national Key Stage 2 Maths test

Clearly what is interesting in these outcomes for researchers is to seek to explain the reasons for these outcomes. To be honest we are not sure and welcome research replications and adaptations that are underway, which throw light on these issues. I note for example the nationwide large scale study in Spain (INTEF, n.d.), which reported the following: "…the results show that it is possible to include programming activities in 5th grade in the area of mathematics, so that students not only learn to program and engage in computational thinking, but also improve the development of their mathematical competence greater than their colleagues who have worked in this same area using other types of activities and resources not related to programming."

Here I simply mention what I see as important contextual influences in England that might well have shaped the outcomes. First, why the significant positive effect of the SM intervention on CT scores as measured by the test used at the end of the first year of the trial. We cannot be certain, but simply point to the fact that the SM package is a systematic, progressive research-based curriculum that offers detailed support to teachers. The independent evaluators also remarked that SM was popular among the teachers who sustained their participation. Our surveys told us that fidelity to SM in terms of engagement in professional development, provision of SM curriculum time and coverage was very high in Year 5.

However, there was a dramatic drop in this fidelity in Year 6, along with huge variation in pedagogy. This was, we conjecture, a result of the negative impact of the high-stakes testing in mathematics in England at the end of Year 6. There is massive pressure on teachers who therefore might feel unable to engage with a new curriculum. In addition, our data indicated that many SM Y6 classes were taught by *teachers with little or no experience of SM,* either from teaching SM in Y5, or from engaging in the SM professional development (for more detail see Noss et al., in press). This was a matter of fidelity but also of the considerable teacher churn in schools – the average for the staying in the profession is 4-5 years. However, I would go so far to say that where professional learning was taken seriously by schools, as in the first year of the innovation, implementation tended to be successful. And, conversely without this it is very unlikely that an innovation like SM would operate in the classroom as planned.

Celia Hoyles' final remarks

I end by calling for more intensive and systematic classroom research and evaluation to explore the classroom implementation of SM or other computing initiatives, not least as computing is now embedded in school practice, and learners and teachers are more confident and competent in

[2] The evaluation report can be found at https://educationendowmentfoundation.org.uk/projects-and-evaluation/projects/scratch-maths/

programming. Such research would also need to reconsider methods of evaluation of research outcomes in terms of teacher and pupil learning.

Digital Technologies in Canadian Mathematics Education, by Carolyn Kieran

My contribution to the cross-cultural digital-technologies panel focuses on three aspects: i) how the digital-technology culture has evolved in the Canadian school system since the 1980s when the Logo movement began, ii) brief comments on the characteristics of computational thinking and how they relate to mathematical practice and mathematical thinking, and iii) Canadian research that illustrates the use of digital technologies for fostering mathematical thinking.

Evolution of the digital-technology culture in Canadian schools since the 1980s

When the Logo movement began in the 1980s, a corps of enthusiastic Canadian mathematics educators and teachers adopted MIT professor Seymour Papert's vision of having children use computers as tools to think with. The Logo programming language was at the heart of this movement. The mathematical connections associated with the Logo movement spilled off the pages of Papert's (1980a) book, *Mindstorms: Children, computers, and powerful ideas*. Mathematics education researchers across Canada, as well as in other countries, developed projects involving primary, secondary, and tertiary level students, which were aimed at exploring mathematical ideas in turtle geometry by programming with Logo.

However, the Logo movement in the public schools was hampered by a lack of funds – in other words, the absence of political will on the part of government to invest massively in any such endeavours – that would have allowed for obtaining the appropriate hardware and software. The promising results that were being highlighted in research reports and in presentations at various Logo conferences throughout the 1980s and early 1990s would unfortunately not lead to more widespread implementation in Canadian schools. By the end of the 1990s, many had let go of their interest in Logo. Handheld calculators with graphing capability, as well as Computer Algebra System (CAS) calculators, proved to be easier (and more economically feasible) to integrate into mathematics classes than the more expensive computers necessary for Logo.

Some time passed. Then by the end of the first decade of the new millennium, the situation with respect to digital technologies had begun to change in many ways. In 2006, Jeannette Wing, herself a computer scientist, wrote a brief paper titled *Computational thinking* where she argued that computer science was more than just programming; it also involved ways of thinking (Wing, 2006). The effect of this paper was probably more influential than Wing had expected or even dreamed. In contrast to what had not happened during the Logo movement, the idea of computational thinking began to have an effect on K-12 education. As in other countries, Canadian policy makers and curriculum leaders decided that our students needed to develop their technology skills within the school system.

Education in Canada is not a federal matter; there is no national curriculum. Every province is responsible for setting its own school programs. So far, five provinces have begun to develop new technology programs. The pioneers in this movement have been British Columbia, New Brunswick, Nova Scotia, Quebec, and most recently (in 2020) Ontario. But, in the main, these new programs are stand-alone technology programs – primarily for grades 6-8, with an emphasis on a range of technological tools, processes, and applications, especially coding. In contrast, Ontario opted to integrate coding within its Grades 1-8 mathematics curriculum.

With the exception of Ontario, one wonders if this new interest in computational activity will make its way into mathematics classes? Any optimism one could have might be tempered by the results of a recent survey of teachers of 5- to 14-year-olds in 23 countries around the world, carried out by Rich and colleagues (2019): While the teachers noted that their students loved the new coding activities, they also stated that they were more confident in their ability to teach students coding/computing as a stand-alone subject than they were with integrating it into other subjects. This finding suggests that, along with current curricular changes, an equally important component that cannot be neglected is the need for an ongoing form of professional development to allow teachers of mathematics to keep up with constant changes in digital technologies and to feel confident in their ability to integrate these technologies into the exploration and development of students' mathematical thinking.

Computational thinking, mathematical practice, and mathematical thinking

Papert (1980a) emphasized that when children use computers as tools to think with, they are also "talking mathematics" (p. 6) to these computers. It is upon his shoulders that the present computational thinking movement stands. So it seems appropriate to ask at this point how computational thinking has been characterized in this recent movement. Wing (2006), for example, states that she has drawn on ideas fundamental to computer science and asserts that "computational thinking is using heuristic reasoning to discover a solution" (pp. 33-34). And in a later paper, Wing (2014) writes: "The most important and high-level thought process in computational thinking is the abstraction process" (p. 1). Relevant to the questions addressed to this panel, she adds that computational thinking can be defined as "the thought processes involved in formulating a problem and expressing (with a linguistic representation) its solution in such a way that a computer – human or machine – can effectively carry it out" (p. 1). Interestingly, Andy diSessa (2018) – one of the two authors of *Turtle Geometry* back in 1981 – has taken issue with this point and has argued that non-computer scientists rarely map out exactly how a problem can be solved before actually doing the solving. But is he right?

In opposition to diSessa, and more in line with Wing, Al Cuoco (2018) in a paper on mathematical practice offers three examples. The first of these (see Fig. 1) relates to Wing's emphasis on the process of abstraction and her point about formulating a problem and expressing its solution in a way that a computing being or machine can carry it out.

- I take a guess, say 1200 miles.
- Check it:
  (∗) $\frac{1200}{60} = 20$
  (∗) $\frac{1200}{50} = 24$
  (∗) $20 + 24 \neq 36$
- That wasn't right, but that's okay— just keep track of your steps.
- Take another guess, say 1000, and check it, making the check more efficient:
$$\frac{1000}{60} + \frac{1000}{50} \stackrel{?}{=} 36$$
- Keep it up, until you get a "guess checker"
$$\frac{\text{guess}}{60} + \frac{\text{guess}}{50} \stackrel{?}{=} 36$$
- The equation is
$$\frac{x}{60} + \frac{x}{50} = 36$$

Figure 1. Arriving at an equation from abstracting the regularity in numerical guesses (Cuoco, 2018, p. 3)

This example involves what Cuoco refers to as "the dreaded algebra word problem," where he insists that we think of the *answer to the algebra problem as an equation* rather than a number – in a method that involves abstracting from numerals. The problem is as follows: *"Mary drives from Boston to Chicago, travels at an average rate of 60 MPH on the way down and 50 MPH on the way back. The total driving time takes 36 hours, how far is Boston from Chicago?"*

The method that Cuoco suggests builds upon students' ability to solve similar problems in middle school (note: they have already learned the relationship between speed, time, and distance) and is as follows: *Take a guess* – but the aim is not intended to get closer to the answer with each succeeding guess; rather it is to arrive at an equation, not a number. The idea is to carry out enough guesses so as to see the regularity of the calculations that allow for checking the guesses – in Cuoco's words: Develop "a generic 'guess checker' that is the desired equation". The processes of mathematical practice that are employed here, and which are ones that Cuoco declares he uses all the time in his own mathematical work, are:

1. Abstract regularity from repeated calculations, and
2. Use precise language (and algebraic symbolism) to give a generic and general description – the equation – for how you check your guesses. (Cuoco, 2018, p. 4)

The conclusion to be drawn from this example is that these two processes of mathematical practice fit well with the programming and thinking-like-a-programmer characteristics of computational thinking (Wing, 2006, 2014), and that students who are currently engaged in using digital technologies (e.g., laptops, robots) to code with visual (e.g., *Scratch*) or text-based languages are participating in mathematical practices. Nevertheless, other research (e.g., Bråting & Kilhamn, 2020) suggests that, while the representations used in programming languages may be similar to mathematical notations, the meanings of several concepts in the two domains differ. But that is a whole other story! In any case, digital technologies afford multiple varieties of mathematical activity that can offer experiences that involve coding but also those that do not.

Some Canadian research on the use of digital technologies to foster mathematical thinking

I take *mathematical thinking* to include the various processes that have been drawn upon by Wing and others to characterize aspects of computational thinking – but also more than this, for example, its conceptual aspects. While computational thinking is focused toward coding, mathematical thinking occurs within a host of activities that are not coding oriented, but which can clearly be engaged in within specifically-designed digital environments. However, the tricky thing about terms such as *computational thinking* and *mathematical thinking* is their overlap when referring to anything mathematical. Moreover, as Cuoco (2018, p. 2) has pointed out: "In real mathematical practice, it is rare that a piece of work employs only one aspect of mathematical thinking" – and, similarly, only one aspect of computational thinking. Despite the obvious intersection between the two terms, I find it helpful when discussing the use of digital technologies in mathematical activity to distinguish between *coding-related activity* and *non-coding-related activity.* In line with this distinction, I offer some examples that give a flavour of Canadian research that has focused on these two types of activity, both of which have successfully combined selected aspects of computational thinking and of mathematical thinking.

Digital Technologies in Coding-Related Mathematical Activity

***Scratch* coding on laptops.** My first example is drawn from the funded, multi-study research project of George Gadanidis and colleagues from across Canada, titled *Computational Thinking in Mathematics Education* – a project aimed at researching the use of computational thinking (via, e.g., digital tangibles such as circuits, programmable robots, and coding with *Scratch* on laptops) in mathematics education, from pre-school to undergraduate mathematics, and in mathematics teacher education (see ctmath.ca/about). In one of the publications from this project (Gadanidis et al., 2017), the initial activity engaged in by the Grade 1 students of a school in Ontario was the use of the block-based, visual programming language, *Scratch* (available at http://scratch.mit.edu), for exploring squares by drawing a set of squares rotated around a point (see Fig. 2; see also Gadanidis, 2015). One of the fundamental principles underpinning these study projects is connecting the digital technology work in classrooms to the math curriculum that teachers need to teach.

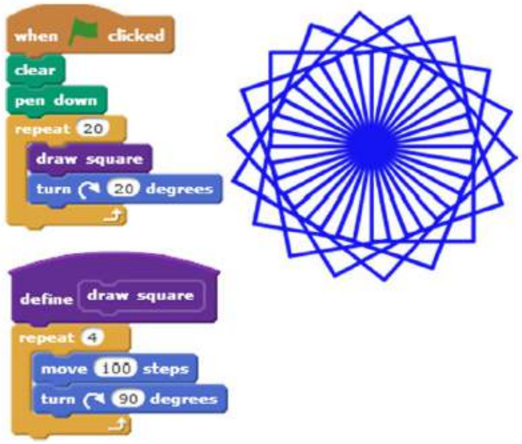

Figure 2: *Scratch* coding in Grade 1 (from Gadanidis et al., 2017, p. 81)

Figure 3. Programming a robot using loops (from Francis & Davis, 2018, p. 82)

Coding robots. Francis and Davis (2018) studied 9- and 10-year-olds' understanding of number, and the transition from additive to multiplicative thinking, in the context of learning to build and program Lego Mindstorms EV3 robots. The sequence of tasks focused on students' becoming aware of the architecture of robots, programming the robots to trace a triangle, square, pentagon, or hexagon; and building a robot that could find and douse a 'fire' in any of four rooms of a miniature model building. In one of the scenarios that Francis and Davis report on, a student learns how the number of sides and angles of a polygon connects to the number of repeats in a loop, which illustrates a developing shift from thinking additively in terms of a sequence of like actions to thinking multiplicatively in terms of a repetition of a single action (see Fig. 3). The authors argue that coding-related activity with digital technologies can co-amplify mathematics learning, as long as computer programming is seen as "something for" and is integrated into the existing curriculum with well-designed tasks, not as "something more" in a separate curriculum.

Digital Technologies in Non-Coding-Related Mathematical Activity

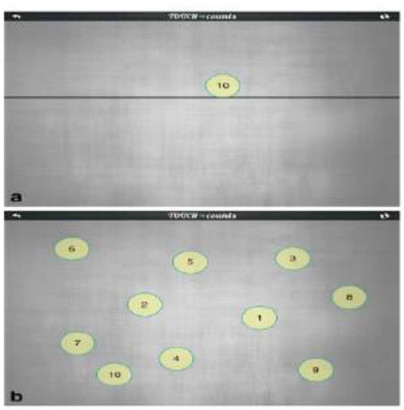

Figure 4. *TouchCounts* App: upper -- 10th tap; lower -- result of 10 single taps (Rodney, 2019, p. 169)

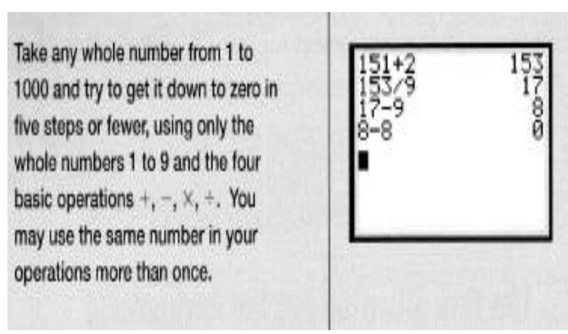

Figure 5. "Five Steps to Zero," with a starting number of 151 (adapted from Williams & Stephens, 1992)

***TouchCounts* – an iPad touchscreen App.** The *TouchCounts* application software, developed by Sinclair and Jackiw (2014), served as a window for the researcher Rodney (2019) to study how a 5-and-a-half-year-old, Auden, thought about number. Although Auden was able to say the number names initially, he seemed unaware that the written numeral '10' would appear right after '9' and that '10' also represented the number of taps made on the iPad screen (see Fig. 4). Auden's unsuccessful initial activity with the App revealed that his memorized number chanting needed the further support that *TouchCounts* could afford in order to reach a fuller understanding of counting and to begin to identify the relational aspect of numbers.

Calculators with multi-line screens. Calculators remain a staple in many mathematics classes. This resource, one with a multi-line screen, served as the digital tool underpinning a study that focused on the mathematical practice of seeking, using, and expressing structure in numbers and numerical operations (Kieran, 2018). The study (co-conducted with José Guzman†) involved classes of 12-year-old Mexican students on tasks adapted from the "Five Steps to Zero" problem (Williams & Stephens, 1992; see Fig. 5). Successfully tackling the designed tasks, and subject to the rules of the game, involved developing techniques for reformulating numbers (prime or composite) into other numbers in the same neighbourhood (not more than 9 away from the given number) that have divisors not larger than 9 so as to reach zero in five or fewer steps. Some of the most powerful structural explorations that occurred during the week of activity on the tasks involved the search for multiples of 9. For example, students became aware that "738 and 729 are two adjacent multiples of 9 and, when they are both divided by 9, the quotients are consecutive," and "in the 9-number interval from 735 to 743 inclusive, there is exactly one number divisible by 9." In trying to explain the often-surprising results produced by their digital tools, the students developed several mathematical insights that were new to them.

Carolyn Kieran's concluding remarks

My concluding remarks pick up on the interest shown by students in the use of digital technologies – be they coding-related or not. For example, Gadanidis et al. (2017) emphasize "learning experiences that offer the pleasure of mathematical surprise and insight" (p. 80). Similarly, Sinclair, Healy, and Noss (2015) speak of the "sense of delight" offered by digital technologies, but also of the need for a certain degree of "intellectual travel" (p. 2). In this latter regard, an early Logo study by Idit Harel (1990) is exemplary. Her 4th graders took up the challenge of designing and programming fractional representations that they thought would be helpful for younger children. This project led to significant gains in their understanding of both fractions and programming. As Harel points out: "the children's involvement in a rich, meaningful, and complex task, designing and programming a 'real' product for 'real' people, enhanced their understanding of Logo and their knowledge of how to use it" (p. 30). Clearly, embedding computational thinking into disciplinary contexts can be most productive and yields a strong lesson for policy-makers who advocate for stand-alone, coding programs in school.

The Use of DT in Mathematics Education: Experiences from Anglo-Mexican Collaborative Research And Implementation Programs in Mexico, by Teresa Rojano

Potential of the use of DT in the teaching and learning of algebra

There is abundant literature on research pertaining to the use of digital technologies for teaching and learning algebra, in which it can be observed a distinction between two types of tools, those developed expressly for this mathematical domain, such as *Computer Intensive Algebra*, *Cabri-Géomètre, Geometer Sketchpad*, *SimCalc*, and those that have been adapted for educational use, such as *Computer Algebra Systems* (CAS) and *Spreadsheets* (Sutherland & Rojano, 2014). Studies carried out with both types of programs have shown their strengths and limitations (Olive et al., 2010), and have highlighted the relevance of task or activity design in order to use them to create significant teaching environments (Donevska-Todorova et al, in press). A common denominator among many of these digital technologies, which is also one of its main potential strengths, is the connection between different representations, which allows for avenues to be created, where students can approach notions and learn novel and powerful algebraic methods, in an intuitive way (Zbeik & Heid, 2011).

Spreadsheets fall under the latter case, as the interconnection between the representation of numerical tables, the graphic representation and the use of algebra-like formulas, allows for the possibility of shifting between numerical and quasi-algebraic treatments, both for concepts like variable, unknown and function, and for word problem solving methods. Here I will specifically refer to my direct experience recreating intrinsic concepts and processes of algebraic thought, in this environment.

Spreadsheets and algebraic thinking. Outcomes from the *Anglo-Mexican Spreadsheets Algebra Project* (Sutherland & Rojano, 1993) carried out during the 90s, showed that students of different ages and school levels can work with algebraic ideas, taking a numerical approach, and using formulas whose syntax is similar to that of algebra. One of the studies was undertaken with two groups of students 10 to 11 years of age, one group in Mexico and the other in the UK, who worked with spreadsheet activities focused on the notions of function and inverse function, as well as on equivalent algebraic expressions and the solution of algebra word problems (Rojano & Sutherland, 1994). Figures 6 and 7 show examples of the type of worksheets used in the study.

The results of the pre-questionnaire applied to the students from both groups, before the experimental work, showed that the majority of the pupils did not think spontaneously in terms of a general object. Initially their mode of thought was on specific cases (for instance, on a particular line of a variation table) and the activities with spreadsheets helped them to move from focusing on particular cases to considering a general relation (see the worksheet in Figure 6). What is more, the sequence of activities on functional relations, the sequence on solving word problems helped the students to accept the idea of working with unknowns, to represent relations among data and the unknown of a problem, and to vary the numerical value of the unknown until they found the solution to the problem (see the worksheet in Figure 7). The experience with such activities enabled them to go from intuitive strategies for solving problems (such as trial and error, for example) to strategies in which they systematized their trials (trial and refinement) to finally encapsulate the relations between unknown and data in spreadsheet general formulas (Rojano & Sutherland, 1994; Sutherland & Rojano, 1993).

Function and Inverse Function

A) Copy the rule of the function that appears in the figure. Find the value of the function, when x = *30* ____________.

B) In B4, change the value of x to 100. Find the value of the function, for x = *115* ____________.

C) Make the x values vary in steps of 2. Copy down the function rule, when x is between *1* and *200*. Find the value of the function, when x = *150* ____________.

D) Try to vary the x values in steps of *0.5*.

	A	B	C
1			
2		x	Function of x
3			
4		1	6
5		2	7
6		3	8
7		4	9
8		5	10
9		6	11
10		7	12
11		8	13
12		9	14
13		10	15
14		11	16
15		12	17

Figure 6. Example of one of the worksheets provided for the teaching of function and inverse function.

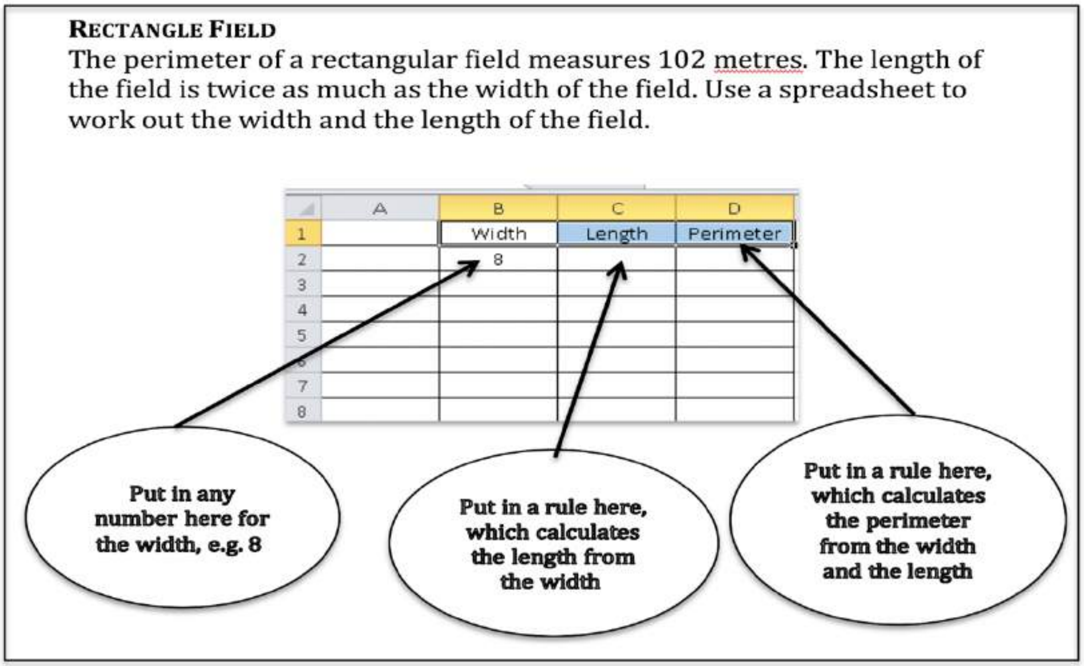

Figure 7. Rectangular field problem (Rojano & Sutherland, 1993).

In general, it is worth noting that despite the different experience in school mathematics that British and Mexican students could have had, given the differences in the mathematics teaching approaches in Mexico and the UK, there were no significant differences in the performance of the Mexican and British students, neither in the results of the pre-questionnaire nor during the work with the spreadsheets. The latter may be attributed to the connection that the students could have made between their own notions and intuitive strategies and the algebraic notions of function and unknowns, thanks to the combination of a numerical approach and the use of spreadsheet formulas, characteristic of the didactic design of the activities. In a second phase, the Anglo-Mexican project focused on working with 14 to 15 year-old students from both countries, students with a history of school failure in mathematics and who had already been introduced to the study of symbolic algebra. The results of the pre-questionnaire revealed that participating students were able to solve the problems using intuitive strategies and in some cases those strategies led them to the right solution. During the experimental work of this phase, activities with spreadsheets were used that were very similar to those of the study involving 10-11 year olds, in the end achieving the same effect –a connection between intuitive and non-formal approaches of the students, and notions and methods on the path toward algebraic thinking (Rojano & Sutherland, 1994).

Although spreadsheets were not developed for educational purposes, both the study undertaken with pre-algebraic students (10 -11 year-olds) and the study involving algebra resistant secondary school pupils show that use of that program accompanied by worksheets with an appropriate didactic design has great potential as a digital learning environment for exploring algebraic ideas and concepts.

The surprising work that participating students carried out in those studies did not prevent us from identifying the limitations of the environment that we used, which relate to what Zbiek et al. (2007) call 'mathematical fidelity'. In my interpretation, the distance between the syntax of Spreadsheet formulas and algebraic syntax may be a hallmark of weak mathematical fidelity; in the former case, formulas allow for representation and manipulation of generalizations, but they cannot be transformed with internal rules from that system of signs; while in the latter case, on the one hand, the analytical expressions of functions can be analyzed and transformed, under the rules of algebraic syntax so as to delve into the variation phenomena that they represent and, on the other, in advanced mathematics courses, those analytical representations can be treated as entities of more abstract mathematical structures. This continuity through the different educational levels is absent in the Spreadsheet environment. For its part, the spreadsheet method for solving word problems is mathematically and didactically pertinent to some families of problems, but it is far from the Cartesian method of solving problems, which is a general method and consists of getting the situation described in the text of the problem 'put into an equation'. In summary, finding the didactic connection between the versions of notions and methods used in the digital technologies and the 'paper and pencil' versions used in school mathematics is still a significant challenge for teachers, trainers and curriculum designers.

In addition to understanding its potential and limitations, one should recognized that, together with the first dynamic geometry programs, the adaptation of Spreadsheets in mathematics education can be considered as part of the background to open source software Geogebra, which indisputable widespread use has more recently led to a large number of reports of practical experiences and research that use this package and that, among many other things, highlight the didactic feature of being able to create connections between algebra and Euclidean, Cartesian and Analytical geometries.

Research experiences: Windows of mathematics school culture

From our first forays into collaborative research on technology and algebraic thinking in the late 1980s, Rosamund Sutherland and I found differences between the educational systems of Mexico and the United Kingdom, some of which appeared specifically in the presentation of the topics of algebra in the curriculum, as well as in the diverse various educational material to be used in class. Both the differences and the commonalities permeated the design of the tasks used in the studies we undertook. However, observation and analysis of the ways in which each of the two groups solved the same task served as a window that allowed us to glimpse the distinctive features of the students' mathematical practices, where multiple representations of the same situation or phenomenon play a central role.

Spreadsheets as a mathematical modeling tool. More recent versions of spreadsheets offer a suitable environment for mathematical modeling tasks using (hot-linked) graphical, symbolic and numeric representations of phenomena of the physical world. The activities in this environment correspond to a parameterized version of the behavior of the modeled phenomena, and knowledge of advanced mathematics is not necessary in order to explore and build the models. In the Mexican-British project, *The role of spreadsheets within the school-based mathematical practices*[3], research was carried out with two groups (one in Mexico and another in the UK) of pupils of 16-18 years of age, in which it was observed how the differences of school culture experienced by each of the groups influences both their mathematics practices and their mathematics modeling activities using spreadsheets (Molyneux, Rojano, et al., 1999).

In the pilot phase, important differences were observed in the preferences of students for certain external representations of situations and phenomena. For example, when answering questions about the long-term behavior of the phenomenon, UK students showed a clear preference for graphic representation, while students in Mexico were inclined to use algebraic representation. However, even though work with Spreadsheets, in the experimental phase, did not significantly change those preferences, in the end the students recognized the value of having a varied repertoire of representations. In fact, one of the relevant results of this research was that participants developed the

[3] The Anglo-Mexican Project was developed as a collaboration between the Institute of Education of the University of London and the Department of Mathematics Education of the Centre for Research and Advanced Studies (Cinvestav) in Mexico, funded by the Spencer Foundation of Chicago, Ill, Grant No. B-1493.

ability to move smoothly from one representation to another and to realize the advantages afforded by some of them in answering certain types of questions posed about the behavior of the modeled phenomena (Rojano & García Campos, 2017).

Notwithstanding the fact that the main purpose of our research was not to study or compare school culture contexts, when analyzing the data collected in the two countries differences emerged that could not be explained, other than on account of what was emphasized or valued in the mathematics classroom, that is, it could be said that the differences originated in the school mathematics culture.

Research and Practice. The use of DT in the Mexican Educational System

In Mexico, as in many other countries, it has not been easy to bridge the results of research on the role of DT in the teaching of mathematics and incorporating their use in the educational system. We have gone through government programs ranging from the use of TV (in the 1960s) to broadcast live or pre-recorded classes, to the *Teaching Mathematics with Technology* (EMAT), *Enciclomedia* and the *New Model for the Telesecondary System.* The EMAT project was conceived specifically for the subject of mathematics in middle school, based on results from research in mathematics education. An international team of researchers designed a constructivist pedagogical model and student-centered activities, with an exploratory approach that encourages bottom-up practices, rather than traditional top-down practices. The tools used were Spreadsheets, Cabri-Géomètre, the TI-92 Algebraic Calculator and Logo, and a gradual implementation was planned starting in 1997, that would expand the use of different tools in different states of the country. Despite the fact that said implementation was not carried out as planned, some teachers who participated in the initial stages have continued to work for several years with EMAT activities, managing to integrate use of the tool repertoire into their own long projects (Trouche et al., 2013).

The experience from the EMAT project was used in the design and implementation of the New Model for Telesecundaria (Lower secondary system of rural areas without access to regular schools), which main feature is the articulation of printed, video and digital interactive resources, which are still in use. It is worth mentioning that the results of a study carried out by the Ministry of Education revealed that since the New Telesecundaria Model was launched, this system, compared to that of regular secondary schools, showed more sustained progress in terms of improved student scores on the yearly national mathematics and language exams (SEP, 2016).

Other national programs were suspended shortly after they were started, however, together with EMAT, Enciclomedia and the New Model for the Telesecundaria, the infrastructure and diverse experiences left by the programs throughout the country have been used by some teachers who have adapted the activities and the use of different tools to the curricular changes derived from the educational reforms. Whereas other teachers have limited the use of technology to displaying Powerpoint material, video material and YouTube, as it has been recently documented by Salinas, Sacristán and Trouche (2018). Thus, the use of DT to fundamentally transform mathematical practices at school and outside of school continues to be a great challenge in this country.

Reflections on the integration of digital technologies for mathematics education, by Ana Isabel Sacristán and María Trigueros

Taking into account the previous authors' reflections on the way digital technology culture has evolved in different countries' curricular approaches, teachers' professional development and students' participation and learning, we present some additional thoughts and discuss also observed contrasts and what happens in societies with different socioeconomic and cultural backgrounds. We also consider to what extent the potentialities of digital technologies have been harnessed to enhance mathematics learning and to engage students.

The previous authors have given us a panorama of the digital technologies that have been used in mathematics education. To summarize these, we refer to the USA's NCTM Position Statement which states that, in addition to content-neutral technologies such as tools for communication and collaboration and Web-based digital media, mathematics' content-specific technologies that can support students in exploring and identifying mathematical concepts and relationships, "include computer algebra systems; dynamic geometry environments; interactive applets; handheld computation, data collection, and analysis devices; and computer-based applications" (NCTM, 2015). To that we can add other expressive technologies such as computer programming environments, as well as eBooks.

On the potentials and historical evolution of digital technologies for mathematical learning

As Hoyles discussed above, it is clear that today's technology-based society needs to develop students' abilities not only in the use of technology, but as reasoners to exploit their use. The question is how digital technologies can be integrated and exploited in schools for achieving that and enhancing mathematical learning.

As many researchers in mathematics education, the panellists and ourselves believe (and a wide corpus of research has demonstrated) that digital technologies have the potential to change education, the teaching and learning of mathematics (e.g., by opening windows to mathematical knowledge, as Hoyles suggested), the curriculum, and also rethink mathematics as a field. Also, as Hoyles also mentions, using digital technologies in innovative ways could potentially widen access to learning.

Both Hoyles and Kieran cite Seymour Papert's vision of having students use computers as tools to think with and of how mathematical understandings can be changed by the use of digital technologies. Papert's (1980a, 1971/1980b) vision was for students using and programming computers for *doing* mathematics, rather than learning *about* mathematics; it is interesting that more recently, Chevallard (2015) also called for students to do mathematics, rather than visit them as if looking at a monument.

As explained by Hoyles above, programming allows users to interact with and visualize mathematics in new ways; it also can be used together with other technological tools so that it is possible to construct relations among concepts that so far have been considered as different, avoiding compartmentalization of knowledge.

In any case, an important potential of technology is for *empowering* students, be it through computer programming or through providing mediums for them to express themselves as well as mathematical ideas, and to build their own products (which is why Papert, 1991, called this *constructionism*) – in Hoyles' words, where students are producers, rather than consumers, of technology. And as Hoyles also emphasizes, Papert's vision had two central ideas: epistemological pluralism and microworlds. Hoyles discusses epistemological pluralism above, but we could add that when one has multiple means and representations to engage, interact with, and express mathematical ideas, those ideas become less abstract (Wilensky, 1991) and can more easily be appropriated. As discussed by Hoyles, computer programming, in particular, helps students to interact with mathematical objects in different ways, enabling students to visualize and reflect on the factors involved in different types of interactions.

The other important idea is that of microworlds, which Hoyles above described as a place where powerful mathematical ideas can be explored 'in safety'.

In the advent of the digital age, the Logo programming environment provided an ideal medium and microworld for students to engage in this epistemological pluralism and develop mathematical thinking, through computer programming and computational thinking. As touched upon by Hoyles and Kieran, following the publication of Papert's 1980's book *Mindstorms,* Logo had a widespread influence on the use of digital technologies in (mathematics) education. It was thus that Logo was implemented in countries around the world during the 1980s (including Mexico); and it was a crucial turning point in countries such as the UK and Canada, as well as the USA.

And yet, for a couple of decades starting in the 1990s, there was a generalized abandonment of Logo and Papert's vision, which happened in most countries. Kieran mentions a lack of funds for Logo projects losing ground in Canada, but the general reasons for that abandonment around the world are much more complex, and involve a confrontation with what Sacristán (2017) calls the 'inertia of school cultures'. Agalianos, Noss & Whitty (2001; see also Agalianos, Whitty & Noss, 2006) explain this complexity by pointing to how technologies and their use in the classroom are socially contextualized and often appropriated in ways unanticipated by their developers – something that is still true today:

> To work with Logo in the way its developers had envisaged meant that teachers should make a fundamental shift in their relationship with pupils….This, however, was a lesson not learnt for many teachers who felt uncomfortable […] Logo (...) automatically constituted a disruption of the classroom's traditional social organisation. [...]
> Logo's introduction into mainstream US and UK schools in 1980 marked the beginning of **a struggle to integrate new forms of teaching and learning into old educational structures**. (p. 486-487, our emphasis).

On his part, Ruthven (2008; see also Ruthven, 2014) points to the conjunction of several influential factors that are needed for successfully uptaking an innovation in school mathematics, and discusses how difficulties related to each of those factors acted against the continuation of the use of Logo in schools (and, we argue, in general, of more innovative visions, including Papert's). Those factors are:

- *Disciplinary congruence* with an influential contemporary trend in scholarly mathematics.
- *External currency* in wider mathematical practice beyond the school.
- *Adoptive facility* in terms of ease of incorporation into existing classroom practice.
- *Educational advantage* through perceived benefits of use considerably outweighing costs and concerns. (Ruthven, 2008)

In terms of adoptive facility, in the 1990s other developments, such as graphing calculators, CAS, Excel, dynamic geometry, etc. became popular and, as Kieran points out, seemed to offer teachers a more direct, less costly and perhaps easier to adopt, use of technology for mathematics teaching (and learning?). Many producers of such technologies also pushed newer software and hardware as solutions for the introduction of digital technologies in classrooms, but there is a difference between having a technology and using it for meaningful learning: we argue that, very often, schools became consumers of commercial developments, due to political and administrative decisions, failing to integrate those technologies in ways that would improve learning.

In any case, due to those complex reasons, in the 1990s and early 21st century the use of programming, and its relation to the development of mathematical thinking, was abandoned. During that period, in some countries, such as Mexico, there were efforts to return to something closer to Papert's vision through the development of the EMAT national project presented by Rojano, above. That project highlighted the importance of design and showed a way to use popular software, such as Excel, as in the example given by Rojano, in a way that could help in making the transition from arithmetic to algebra smoother for students. However, the EMAT project, though successfully tested, succumbed to political changes (Trouche et al., 2013), as we discuss further below; although, as Rojano points out, some teachers have continued using the EMAT technologies and materials in their classrooms until today, to promote their students' learning.

It is only in the last decade that interest and the recognition of the importance of computer programming, and computational thinking, has resurfaced in developed countries (but, as discussed below, not so much in other countries). Computational thinking, popularized by Wing (2006), and 'coding' have now become educational trends. How programming and computational thinking relate to mathematical thinking had already been discussed by Papert (1980a) and others in the 1980s and 90s. But Kieran above gives a profound discussion of their relationship. She agrees that computational thinking and mathematical thinking overlap, and engaging in programming and computational thinking implies participating in some mathematical practices. She argues, however, that mathematical thinking is more than what is achieved through coding and computational thinking but that other specifically-designed digital environments can also be helpful in promoting it.

Digital technologies in mathematics curricula across cultures

In any case, because of the attention that coding and programming have received in the past decade, many developed countries around the world have integrated these into school curricula.

In the UK, Hoyles mentions above how programming has come to the forefront since 2014; and Kieran describes experiences in Canada where programming has also been included in the curriculum. The question is how this integration affects the mathematics curriculum. Hoyles describes how she and her colleagues in the UK developed ScratchMaths in a research attempt to integrate the computer science curriculum with mathematics. It is interesting that ScratchMaths has been adopted in other countries outside the UK, such as Australia (Holmes et al, 2018), to use coding to teach mathematics.

In Canada, Kieran describes how programming activities have been introduced early in school but are used together with other technological tools to foster opportunities to construct relations among mathematical concepts.

However, in other countries, programming and computational thinking have not been included in the curriculum, nor sometimes even considered. In fact, there is thus a huge gap in the recognition of the possibilities that the use of digital tools offer to mathematics students and teachers and how the use of technology has evolved in countries and cultures around the world. The political strategies vary in different parts of the world to foster the inclusion of technologies in the mathematics classroom and rethink the curriculum.

In the USA, according to the NCTM: "All schools and mathematics programs should provide students and teachers with access to instructional technology—including classroom hardware, handheld and lab-based devices with mathematical software and applications, and Web-based resources—together with adequate training to ensure its effective use" (NCTM, 2015). This statement indicates a public recognition of the necessity of integrating a wide range of digital tools for teaching mathematics at schools, as well as the importance of teacher training for an effective and strategic use of those resources in the classroom. However, it is striking that in that statement, there is no mention of programming and computational thinking, which, in other countries have been considered more prominently as central for the development of mathematical thinking.

In Mexico, as discussed by Rojano, although at the turn of the century the potential of digital technologies in the teaching of mathematics was recognized when different public administrations, between 1998 to 2006, launched national projects directed at middle and elementary school children – EMAT, the New Telesecundaria Model, and Enciclomedia (Trigueros et al., 2006) –, this is no longer the case. Unfortunately, when the government changed, those projects disappeared. Since then, only the use of calculators and office applications have been recommended, but not included, in the following curricular changes. (Only some teachers, who found them useful to promote students' mathematical learning continue to use the EMAT or Enciclomedia tools in their teaching).

Thus, in many countries, and perhaps for different reasons, schools and curricula have remained attached to the use of software and/or calculators that are aids to the set curriculum and are considered useful in mathematical problem solving and in helping students understand specific concepts. In other words, they are added on to existing curricula and used to do the same as before but with the technology add-on, instead of for innovative ways of interacting with mathematics.

How the learning potential of digital technologies is considered varies from country to country, but also in different regions inside countries (as in the case of Canada, discussed by Kieran). In some places, digital technologies are embedded in school culture and specifically in mathematics classrooms, while in others, this is not the case. Julie et al. (2010) had already presented perspectives from different parts of the world illustrating the diversity of access and implementation of digital technologies. Some of these differences persist, perhaps due to diverse policies but also because of socioeconomic differences and factors (also, in terms of how technology is used and perceived in schools, gender may also be an issue). More problematic is the fact that many parts of the developing world still have issues of lack of access to technologies, rely on very old hardware, if any is available at all (see, for example, Sacristán et al., in press), and teachers have insufficient or no training in their use and pedagogical integration.

Thus, economic and social problems result in a widening gap, not only between different countries, but also inside these countries since development, technological opportunities and even the possibility to have access to technology are not the same. As technology continues to quickly develop, the gap between students who have opportunities to use technologies for mathematical thinking and learning, and those who don't, widens, and inequalities among different populations increase.

This gap in opportunities along the whole schooling process, has an important impact in terms of equity and on students' future. Jobs will need more and more mathematical and computing abilities so students who have not had the opportunity to develop them in depth will find it difficult to find jobs, thus the social context in different countries is increasingly divided.

On integrating new technologies and adapting to their changes

When integrating digital technologies for learning in schools, there is a recognition of the importance to provide, in Hoyles' words above, "a framework for the design and implementation of computational tools for learning mathematics." The issue of design is paramount. In summarizing Papert's constructionism, Hoyles mentioned the two central ideas of epistemological pluralism and microworlds. The design of the learning and exploratory universes that microworlds are, need include epistemological pluralism and take into account different components, as described by Hoyles and Noss (1987): the student component, the pedagogical component, the contextual component and the technical component. EMAT was a project that designed a model that took into account all of those aspects (Sacristán and Rojano, 2009). But careful design is only as good as what can be taken up by the educational system. As in the case of why Logo and Papert's vision declined in the 1990s, there is also the issue of the difference between an intended design and how it is implemented. In projects like EMAT or ScratchMaths, a very careful research-based design involving many researchers in mathematics education, as well as some teachers, was carried out aiming at maximizing the (mathematical) learning possibilities. These designs included, not only mathematical tasks, but also pedagogical models, associated teacher training models and possibilities for scaling up in order to expand to cover all, or a majority of, schools at a national level. However, when implemented, many of the initial intentions are lost. In the EMAT project, teacher training was never achieved as designed, and the scaling up was suspended due to government changes. In ScratchMaths there was also the problem of fidelity that Hoyles referred to above (see also Hoyles and Noss, 2019): how faithfully teachers (and schools) adopt, or are able to do so, the intended design. This necessarily leads to results that are generally less than expected.

Also, technology designers look for ways to offer educational systems, software with more capability in terms of interactivity and in terms of what they believe is needed in schools. Research on the use of technologies is constantly adapting to better understand how teachers and students use new resources in order to incorporate change in teachers' training programs and to look at how and if implementation in the classroom works in terms of students' mathematical learning.

Results often do not meet designers' expectations and real use of technology at school do not match with them either. On the one hand teacher adaptation to new technologies takes time and on the other hand when teachers find out that some tools work well in terms of their student' learning they are unwilling to try something new which may or may not work. These problems, together with the lack of access to tools and the fact that teacher training programs do not reach all teachers and the need to convince many teachers who don't want to take risks of finishing curriculum on time or don't see how technology matches with official curricula, need to be taken into account if the use of digital technology is considered important for the learning of mathematics.

When analyzing the efforts in the past couple of decades of educational systems around the world to integrate digital technologies in schools (not necessarily for mathematics), the words of Healy (2006), although she was referring to the case of Brazil, are valid in the cases of many countries: the attempts may tend to emphasize the computer as a catalyst for pedagogical change, but "they fail to acknowledge the epistemological and cognitive dimensions associated with such change or the complexity associated with the appropriation of tools into mathematical and teaching practices" (Healy, 2006, p. 213).

Moreover, technologies change fast. Keeping up with those changes is difficult for teachers, particularly if they have to catch up by themselves and only highly motivated teachers who have had good opportunities to evidence positive changes in their students are willing to do the needed efforts to develop teaching plans for their students to work with technology. There are also institutional constraints that limit teachers' possibilities to fully use the potential of digital technologies. Sacristán (2017) discussed in depth some of the challenges for teachers (and schools) to meaningfully integrate digital technologies into teaching practices for mathematical learning. Hoyles above also mentions the pressure of preparing students for national examinations, but there are others, such as the time needed to cover specific curricular topics, or the way a topic is presented in the textbook. All these factors need to be taken into account when designing teachers training courses.

Projects that involve collaboration between university researchers and teachers have proved to play an important role in the possible success of implementation in schools and in the promotion of students' learning, as was the case of the example given by Hoyles as well as the EMAT project mentioned by Rojano. Collaboration offers teachers opportunities to discuss strategies to use technology to transform their practice and to develop technological skills to make decisions to guide students' mathematical thinking. This type of approach, together with other teacher training initiatives, are indispensable for teachers to overcome their difficulties.

Unfortunately, teacher training opportunities are unequally supported in different cultures. While in some places programs are offered continuously to teachers, in others teachers are left to develop their own strategies to introduce technology in their classrooms; thus teachers are in many occasions discouraged and leave technologies aside.

Another phenomenon that has been observed is that in most places research projects to introduce technology to the classroom create lots of activity in terms of groups of researchers and teachers working together to creatively devise ways of using new technologies to teach mathematics. However, when those projects end, this activity stops. Regrettably, the lack of continuity and the gap between research and school policies, is true everywhere: Even in developed countries, as is the case with many European projects, when the funding finishes, interesting innovations abruptly end, and researchers move on to different proposals. This cycle repeats over and over, leaving aside the possibility to develop long term proposals which could make an imprint in the educational system.

Only a handful of creative and motivated teachers continue using the materials developed for research projects or previous government initiatives, adapting them to their teaching, and developing strategies to use those proposed technologies with their students.

Teachers and school systems have difficulty adapting to the perpetual changes in projects, as well as in the technologies available. It is therefore important to develop long-term professional development strategies and programs so that teachers can develop knowledge to be able to cope with and adapt to the technological changes in a productive way.

Concluding remarks

Digital technologies have played an increasingly important role in changing the mathematics classroom. Research has come a long way in terms of how to harness the possibilities that technologies can offer in terms of developing students' mathematical learning, although schools today are very different than when digital technologies first became available for education. But we should not forget that in this information age where information and communication technologies dominate, there are also other content-specific digital technologies, such as expressive and computer programming environments, that are important to develop mathematical thinking and practices. In particular, the tools that are generally used (including, more recently, communication ones during the COVID pandemic), haven't fully led to a meaningful integration of digital technologies *in* and *for* mathematics education. Thus, despite the exponential growth and influence of digital technologies in society, innovative visions (such as Papert's) haven't fully come to fruition.

Many projects, developed around the world, have shown that students enjoy using digital technologies in the mathematics classroom and there is evidence of the potential of these technologies to promote students' learning. But, although we have clear evidence that they can be used to foster students' mathematical competencies and learning, the expected results of their use in the classroom are still far from those desired. There are some important areas, such as evaluation and assessment (including self-assessment), and activities outside school, for which the potential of technologies has not been harnessed to support students' learning.

An important area that needs attention is the need to foster teacher training programs to overcome an existing tendency of teachers to improvise in the classroom, and for developing creative ways to use technology, including for assessment and self-assessment.

Also, inequalities in different school systems around the world, as discussed above, can be bridged through the development of long term projects that foster equality in the access of technologies, rich teacher training programs and activities for students to promote their learning autonomy. As it is now, differences among educational systems are widening but also differences in terms of opportunities within specific systems are far from what would be expected in terms of mathematical learning for all. When social and economic conditions are considered at this particular moment in time when the COVID pandemia has strongly affected all countries, life has become dependent on the use of technology in many aspects; but the difference between children that have access to technology and those who don't (or only have access to state-produced educational TV programs, as is the case in Mexico) is expected to increase the education gap.

It is time to consider more thoroughly how to harness the technologies that are already widely available to students in most countries: in particular, mobiles and smartphones. These accessible technologies have spread quickly around the world and are used by many students, but their rich educational potential has not received enough attention from researchers and from policy makers. These technologies are powerful and it is shown that more people have access to these than to computers. These tools need to be taken into account to develop interesting ways for their users to develop mathematical thinking inside and outside the classroom, with diverse uses and applications. New developments need creative ways of thinking and of using the growing potential of digital technologies in order to provide opportunities for all students to have access to computational and mathematical thinking, thus providing them with a potentially better future in the technology-based society. But this also implies transforming school cultures – not an easy task, as the story of Logo and other innovations shows.

Nevertheless, it is necessary to focus on how to use the technology potential to help reduce access inequalities, by looking for creative ways to help children around the world develop their mathematical thinking potential, and contributing to the creation of a better world for all. At the same time, we should also continue to devote time and effort to consider what has been dubbed "Papert's 10%" (from his call in his keynote speech at the ICMI 17 Study in Vietnam 2006): how mathematics and mathematical practices can change due to the availability and access to digital technologies.

EDUCATIONAL NEUROSCIENCE: PAST, PRESENT, AND FUTURE PROSPECTS

Stephen R. Campbell
Simon Fraser University
sencael@sfu.ca

This talk provides the speaker's perspective on how the fledgling new area of educational neuroscience has emerged from a disenchantment with brain-based education, through various multidisciplinary, interdisciplinary, and transdisciplinary initiates and collaborations involving educationists and neuroscientists. Specific examples and results pertaining to research in mathematics education will be presented. Beyond the current state-of-the-art, the speaker will conclude with some speculations on what might be anticipated as this area of research continues to unfold into the near and far futures.

Keywords: Educational Neuroscience; Embodied Cognition; Electroencephalography; Electrooculography

Good day. I'm pleased to be here to address an area of research that has occupied me for some time, one that has come to be known, somewhat ambiguously, as educational neuroscience. First, a few introductory comments. I have always been interested in the nature of consciousness, and how it is that we are able to experience the world in the way that we do. Oddly enough, back in the 1970's my industry experience in seismic imaging utilizing the most advanced computing technologies of the time, including one of the first CRAY I computers, led me to the study of philosophy and mathematics. How so? I had come to view seismic imaging as the social development of a new sense of perception. I blame Teilhard de Chardin for that.

During the 1980's I had the great pleasure to encounter a number of books that had a great influence on my subsequent interests and career development, ranging from Haugeland's edited volume *Mind Design* (1981), the epic volumes of Rumelhart, McClelland and the PDP Group on *Parallel Distributed Processing*, to Gardner's *The Mind's New Science* (1987) and Churchland's *Neurophilosophy* (1989). These books motivated a shift in focus away from imaging the Earth's interior to the knowledge engineering of intelligent software systems using neural nets and automated reasoning, and on to graduate studies in neurophilosophy.

I managed to escape the siren call of the oil and gas industry in the early 1990's and venture west from Calgary to Vancouver to study computing and education at Simon Fraser University, eventually settling into doctoral studies in mathematics education with Professor Rina Zazkis. During those days I was, as were many others at that time, drawn to Varela, Thompson, and Rosch's *The Embodied Mind* (1991). Subsequently, after half a decade at the University of California, Irvine, I returned to SFU and obtained funding to establish an educational neuroscience laboratory, the ENGRAMMETRON.

A good way to begin exploring the manner in which the area of educational neuroscience began is to chart its origins and development through its affiliated Special Interest Group of the American Educational Research Association called Brain, Neurosciences, and Education. That SIG, in its original incarnation in 1988, was referred to as the Psychophysiology and Education SIG. When Bill Clinton designated the 1990s as the "decade of the brain," the SIG was renamed the Brain and Education SIG, promoting "Brain-based Education." Despite growing popularity of brain-based education amongst educational practitioners, scholars and researchers became increasingly critical towards the point of dismissiveness, citing a number of "neuromyths" that were usually based on partial truths.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Subsequently, in reaction against the growing uncritical educational use of brain-based metaphors, such as right and left brain learners, and appeals to multiple intelligences and VAK (visual, auditory, and kinaesthetic) learning styles (Geake, 2008), the Brain and Education SIG committed to being more rigorously grounded in neuroscience by including that term in 2003. The stated purpose of this newly-branded SIG "… to promote an understanding of neuroscience research within the educational community [with a] hope to achieve that goal by promoting neuroscience research having implications for educational practice and providing a forum for the issues and controversies connecting these two fields." Keynote speakers for the SIG shifted accordingly from champions of brain-based education to neuroscientists themselves with interests in educational problems, such as Bruce McCandliss and others.

This AERA SIG initiative wasn't as novel as it sounded, as an earlier funding initiative back in the 1980s between the *National Science Foundation*, the *Sloan Foundation*, and the *National Institute of Education* enabled scholars and researchers from neuroscience, cognitive science, and education to seek middle ground in what Rita Peterson aptly described as "the middle ground between those three points on a triangle." One term being bandied about for that disciplinary nexus was "pedagogical neuroscience" (McCulloch, 1989).

One of the main pioneers, perhaps *the* main pioneer, in bringing cognitive science, neuroscience, and education together and exploring that middle ground in a true disciplinary sense was the recently departed Kurt Fisher of *Harvard Graduate School of Education*. Professor Fisher founded the Mind, Brain, and Education program at the HGSE, and then went on to establish the *International Mind, Brain, and Education Society*, as well as serving as the founding editor of that society's flagship journal *Mind, Brain, and Education*.

This triangle of disciplines, and the vast areas of research and practice falling within it that they delineate, has come to be known as the new academic field of neuroeducation (Tokuhama-Espinosa, 2008). Within the broad purview of neuroeducation have emerged multidisciplinary, interdisciplinary, and transdisciplinary initiatives. The one that interests and concerns me most is referred to as educational neuroscience. This area of research can be considered in a variety of ways, distinguished perhaps most notably as to where one places the emphasis, educational *neuroscience* or *educational* neuroscience. Whereas contributions to the former come predominantly from cognitive neuroscientists, my focus has been on the latter.

Whereas neuroeducation is more broadly conceived, linking as much or more to educational practice, I see educational neuroscience as an area of *educational* research, and one that naturally draws on the neurosciences, especially cognitive neuroscience and psychophysiology. That is to say, I see *educational* neuroscience as an area of educational research that draws on, as in being informed by, theories, methods, and results from the neurosciences, but unlike educational *neuroscience*, arguably an applied cognitive neuroscience, is *not restricted* to them. This difference is important, as the focal point of *educational* neuroscience is the subjective experience of learners, not *just* their associated mechanisms.

In multidisciplinary initiatives where neuroscientists and educators collaborate, there is typically a strict separation between their respective philosophical frameworks and research methodologies, whereas interdisciplinary initiatives typically motivate collaborators to adopt more of a mixed methods approach. Educational neuroscience as a bona fide transdisciplinary activity, by definition, must entail the forging of new philosophical frameworks and research methodologies for bridging education and neuroscience, and especially, mind and brain (Campbell, 2011). Bruer famously referred to this as a bridge too far (1997).

Bridging mind and brain, and body more inclusively, is exactly the aim of Varela, Thompson and Rosch's *Embodied Mind* (1991), and Varela's initiatives in the area of *neurophenomenology*, to bridge what he referred to as the gap between the biological mind and the experiential mind via "reciprocal constraints" (1996, p. 343). In my view, this amounts to the hypothesis that any changes in subjective experience must in principle manifest objectively in some manner as changes in brain, body, and behavior, and vice versa (Campbell, 2011, p. 10). I have taken this hypothesis as both a foundational assumption and a necessary condition in striving toward a transdisciplinary view of educational neuroscience.

My approach to educational neuroscience in this transcendental sense has been to focus primarily on qualitative educational research rather than quantitative educational research, *per se*. That is because I am interested more in questions pertaining to ontology than epistemology. That is to say, I am more interested in the lived experience of learners of mathematics than I am, for instance, in how widespread their experience might be in the general population of learners.

That is not to say, however, that I do not draw on quantitative research from cognitive neuroscience, because I do, and it is central to my methodology that I do. As an exemplary case in point, consider the so-called "aha!" moment. Jung-Beeman and his colleagues in cognitive neuroscience (2004) have identified what they refer to as an "insight effect" in the right anterior superior temporal cortex detectable as a burst of electrochemical energy from neuronal activity in the gamma range (>30Hz) via electroencephalography (EEG), which they cross-validated using functional Magnetic Resonance Imaging (fMRI).

Knowing that such an "insight effect" had been identified enabled me to design an experiment using an instrument developed by Dehaene and his colleagues (2006) to explore "aha!" moments using an integrated methodology drawing upon audiovisual, eye-tracking, and EEG along with a palate of psychophysiological metrics including heartbeats and respiration. Figure 1 illustrates the setup in my laboratory (following excerpts from Campbell, in press).

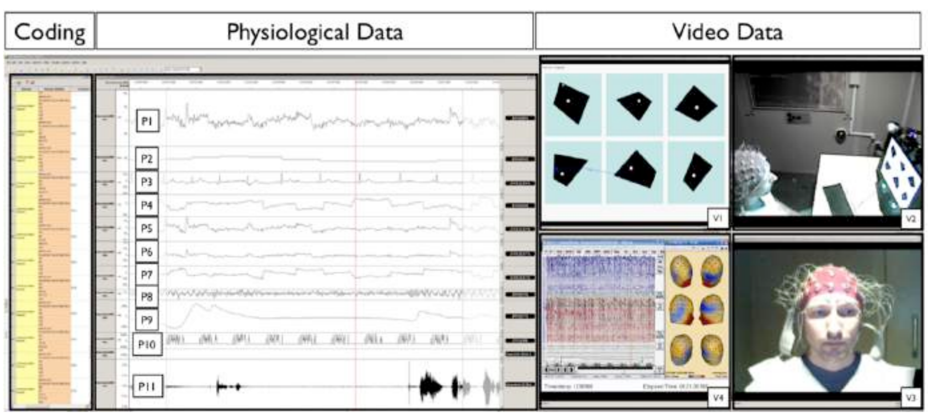

Figure 1: Integration of physiological and behavioral observations

The leftmost column is for coding for the observation. The physiological data includes P1, the central EEG channel; P2 is the heart rate in beats per minute; P3 are heart beats from which P2 was derived; P4 and P7 capture horizontal eye-movements, whereas P5 and P6 capture the vertical eye-movements (using electrooculography, EOG); P8 measures muscle movements (using electromyography, EMG) from the back of the neck; P9 is respiration; P10 the time code; and P11 is the voice channel. Video data: V1 screen captures the eye-tracking as the participant views a slide from Dehaene, et al's instrument; V2 and V3 video recordings of the participant; and V4 the full EEG data set.

Figure 2 below illustrates how EOG data can be used to identify gaze areas (d0 through d6) and movement intervals (1-10) and their associated times in the physiological data to integrate with the eye-tracking data (corresponding to and illustrated in Figure 5 below).

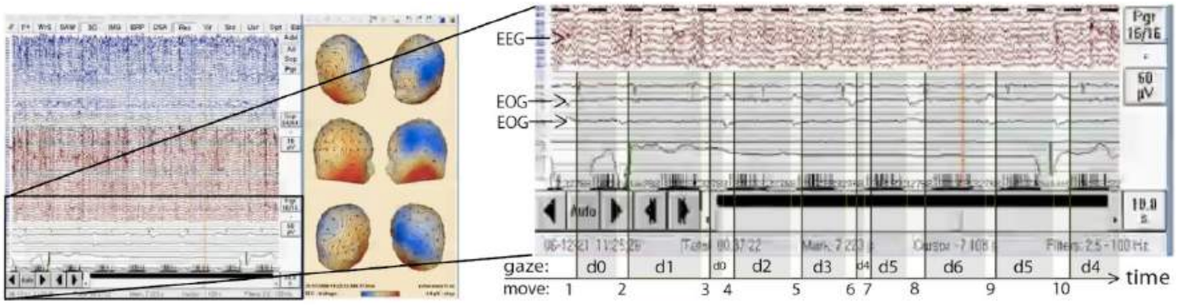

Figure 2: Time synchronizing physiological and behavioral data sets using EOG

A key premise of the approach I've taken to *educational* neuroscience is that theories, results, and methods of the neurosciences, cognitive neuroscience and psychophysiology in particular, can serve to augment and validate, *not replace*, traditional methods of educational research. These observations were part of a qualitative study in mathematics education research. The behavioral data provided by audiovisual data, coupled with the eye-tracking clearly indicated that an "aha!" moment occurred. So, then, what did the educational *neuroscience* tell us?

As noted above, a hallmark of the transcendental approach I've taken to educational neuroscience has been to draw upon methods, results, and findings from the neurosciences, and especially from the cognitive neurosciences. In this case, I drew upon results that clearly identify neural correlates of the "aha!" moment (Jung- Beeman, Bowden, Haberman et al, 2004; Bowden & Jung-Beeman, 2006). In two landmark experiments, Jung-Beeman, et al (2004) identified and located the neural correlates of an insight effect using EEG and fMRI. In the EEG experiment, the red line in the lower panel on the left side of Figure 3 below identifies an increase in gamma range power during moments of insight in contrast to the blue line where no insight was reported. Time zero on the horizontal scale designates the moment when participants reported the insight by pressing a button. The leftmost topographic maps of the right and left hemispheres show grand averages of EEG power distribution *prior* to the onset of the gamma burst (-1.52 to -.36ms), while the rightmost topographic maps show grand averages *during* the onset of the gamma burst, prior to the button press (-30ms to -.02ms).

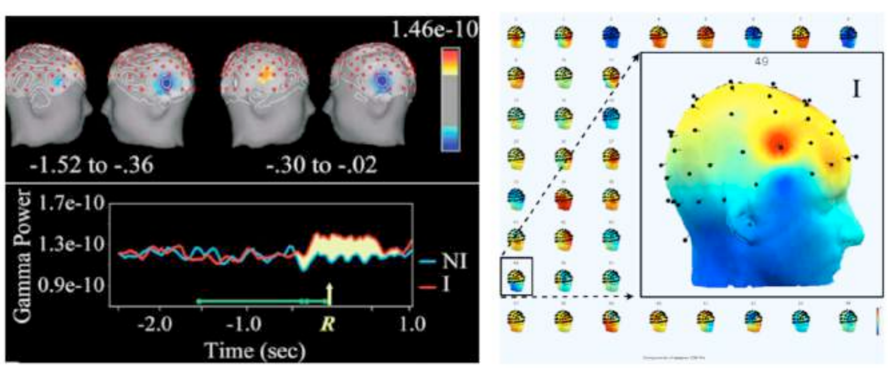

Figure 3: EEG Insight Effect, left hand side (after Jung-Beeman, et al., 2004, p. 505; Kounios & Beeman, 2009, p. 211). To the right, an independent analysis component of our EEG data corresponds to a phenomenon they identified with the EEG Insight Effect.

Jung-Beeman et al's fMRI experiment (upper panel on the left-hand side), cross-validated and located the effect in the anterior superior temporal cortex (ASTC). The question for us, given the behavioural evidence we had of an "aha!" moment, was whether an increase in EEG gamma power was evident in the vicinity of our participant's ASTC. Independent component analysis (Delorme &

Makeig, 2004; Makeig, Bell, Jung, & Sejnowski, 1996) was used to isolate different sources within our EEG data, and found the component illustrated on the right side of Figure 3.

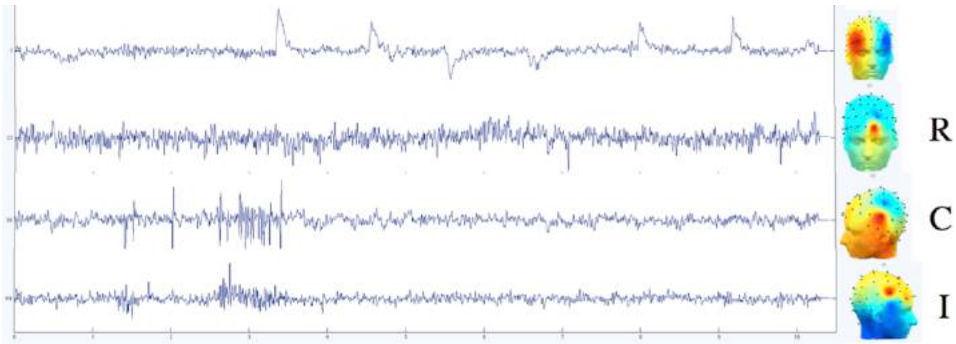

Figure 4: Independent components extracted from EEG data

Cutting to the quick here, Figure 4 (above) illustrates four independent components of EEG data acquired in my lab from the participant over this approximately 10 second interval are presented in Figure 3 below. From the top, the first component captures and isolates the participant's lateral eye movement. The spikes correspond to the vertical displacements from the EOG data (P7 in Figure 1). Second from the top in Figure 3 is an EEG component, labeled R, illustrating on-going activity in the participant's slightly left dorsolateral Prefrontal Cortex (dlPFC) associated with spatial reasoning, working memory (Knauff, Mulack, Kassubek, et al, 2002), and implicated in integrating verbal and spatial representations (Barbey, Koenigs, & Grafman, 2013). Third from the top, labeled C, is sourced in proximity to Broca's and Wernicke's areas in the left hemisphere, responsible for speech and comprehension respectively. Most germane here is the bottom component labeled I in which the burst of energy in the gamma range is evident in close vicinity to the ASTC, associated with the insight effect.

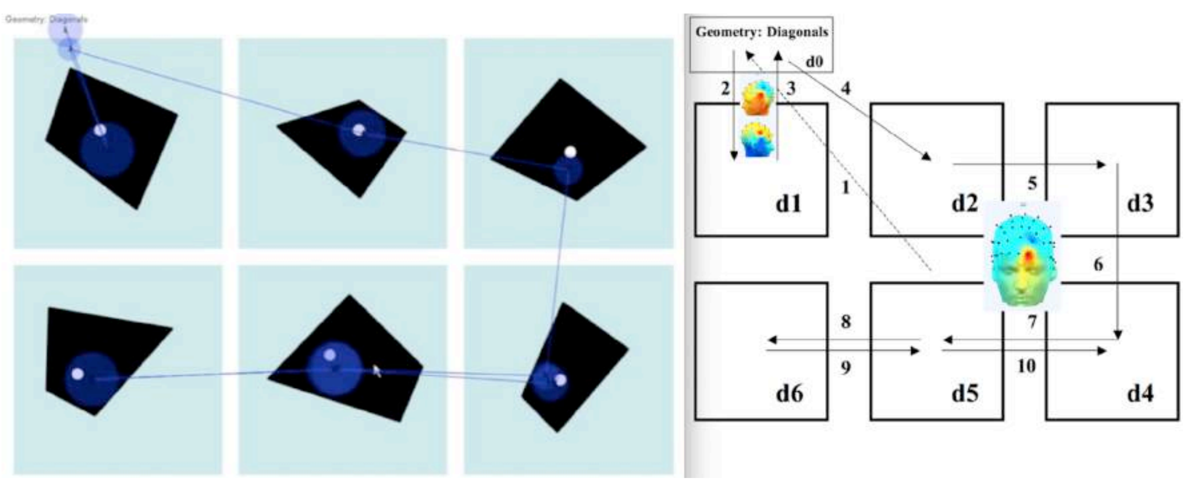

Figure 5: Detailed eye-tracking of the "aha!" moment. The behavioral eye-tracking data on the left side of this figure was time synchronized with the EOG data (Figure 2)

The left-hand side of Figure 5 (above) illustrates the eye-tracking data. After having been given two previously unsuccessful opportunities to identify the "odd ball" in this slide the participant's gaze was initially oriented toward the centre of the screen when this slide reappeared for his consideration for the third time (now with prompt terms revealed which had been previously masked). Hence, his first action was to immediately move his eyes directly toward the prompt phrase "Diagonals". The blue lines on the left-hand side of Figure 5 track his eye movements, while the blue circles indicate the locations where he held his gaze. The larger the circle, the longer the gaze interval. Eye movements and eye gazes are schematized on the right-hand side of Figure 5. The participant's eye movements (with higher frequency saccadic jitter filtered out) are sequentially indicated by the numbers 1 through 10, whereas the area of the prompt phrase is designated as d0, and the six diagrams d1 through d6, in the order in which they were first viewed by the participant.

It is clear that the participant read the word "Diagonals" silently at d0, then, as he shifted his gaze to d1 he took a breath (see P9 in Figure 1) and articulated the word "diagonals" (as evidenced in the voice recording P11 in Figure 1). As he did so, as the idea of diagonals associated with the word became the focal point of his intentional consciousness, his gaze returned to d0, presumably as confirmation (verification) at about the 2.5s mark into the onset of the presentation of the slide. He then continued quite systematically and relatively quickly to shift his gaze to d2, d3, and d4. When he came to d5, it is evident that his gaze lingered a little longer. He then continued to d6, then returned to d5, at which point he clicked his tongue (see P11 in Figure 1), took a breath (P9 in Figure 10), and then exclaimed "Ahhh!" as he continued back to d4. The participant went on to describe his insight as follows:

> Okay, yes, I see this quite differently now [than he was seeing this slide during his unsuccessful attempts to identify the oddball]. This, this one, um, in particular [referring specifically to this slide] I see very differently. I can see, if I mentally imagine a line [while looking at d1 and moving his cursor diagonally from the upper left corner to the lower right corner, then from the left corner to the right corner] connecting the diagonal edges [sic], I can see that this dot [while looking and pointing to the white dot in the centre of d1] is on that line. This dot [looking now at d2] is also on that line, this dot [d3] is on that line, this dot [d6] is on that line, this dot [d5] is not, and this dot [d4] is on that line. So here [d0], when I see the word "diagonals", it definitely prompted me for what to look for, and I clearly see that this one [d5] is the one, is the only one that the dot is not on the diagonal.

So, when exactly was his "aha!" moment? Clearly, as illustrated in Figure 4, there was an attunement of sorts for our participant regarding the C and I components of his brain activity as recorded by EEG. Given that the C component was a neural correlate of comprehension as he read the term "diagonals" and that the I component was a neural correlate of insight as he connected that term to the criterion he had been seeking to identify the oddball figure, the R component appears to correlate with his assessing of the validity of that insight.

Koestler notes: "The sudden activation of an effective link between two concepts or percepts, at first unrelated, is a simple case of 'insight'" (1967, p. 590). Does component I signal a spontaneous bisociative connection or link between, in this case, the participant's comprehension of 'diagonal' and the synthesis of that comprehension with the perception of the dot on the diagonal (d1 in Figure 5) coupled with his unfolding realization that 'diagonal' was indeed the criteria the participant had been seeking to identify the oddball (d5 in Figure 5)? The eye-tracking and audiovisual data, in tandem with results from the EEG data appears to support this interpretation.

There is widening acceptance and growing evidence that various modalities of consciousness, and mind more generally, are manifest within the dynamic fluctuations of the electromagnetic field generated by neuronal activity (e.g., Jones, 2013, 2017). Exactly how characteristics of mind, such as the binding of subjective experience into a coherent and stable whole, our sense of identity and privacy of thought, let alone how other matters of thought and perception, memory and foresight, creativity and insight, are so embodied remain to be satisfactorily resolved, and remain topics of on-going investigation.

As for the future of educational neuroscience, it seems more likely to me, after a number of years of promoting *educational* neuroscience in the transcendental sense that I have indicated above, whereby new philosophical frameworks are forged that are inclusive of lived human experience, that educational *neuroscience* will continue to prevail. That is, I see much of the past, present, and future of educational neuroscience unfolding as an applied cognitive neuroscience, elucidating biological underpinnings of mental processes.

Cognitive neuroscience, approached from a "hard" scientific orientation, has the luxury of focusing on various aspects of brain behavior in terms of neural structure, mechanisms, processes, and functions. On the other hand, neuroscience approached from a more humanistic orientation would have the luxury of not having to be concerned with trying to explain, or explain away, the lived experience of learners solely in terms of biological mechanisms or computational processes underlying brain behavior (Campbell, 2010).

I think educational researchers, at least those who think the brain actually does have something to do with informing our understandings of cognition and learning, would like to be informed by biological mechanisms and processes underlying learning, and perchance also have access to methods of cognitive neuroscience. As an educational researcher, however, my *primary* focus is not on the biological mechanisms and processes underlying or associated with cognition and learning. Rather, it is on the lived experiences of teaching and learning, along with the situational contexts and outcomes of those experiences.

The above considerations perhaps still hold out some hope for the possibility of a more humanist-oriented *educational* neuroscience, as a new area of *educational* research that is both informed by the results of cognitive neuroscience, and has access to the methods of cognitive neuroscience, specifically conscripted for the purposes of educational research into the lived experiences of embodied cognition and learning (ibid.).

One may speculate, if not fully anticipate, that at some point in the future, such matters will become sufficiently resolved to be of great *practical* significance for education. Consider the following possibilities: Dry electrodes arrays that can be comfortably worn by students like ball caps, capable of transmitting high spatial and temporal resolution EEG or MEG signals from each student in a classroom wirelessly to a central console, analysed for specific aspects of cognitive activity, and made available to the teacher in real time.

Although there are serious ethical issues associated with realising such a scenario, used in a responsible and sensitive manner, such a possibility could provide teachers with unprecedented insight into formative assessment and student learning. Moreover, such tools could provide invaluable information for the teacher regarding overall student engagement and effectiveness of their teaching in real time. Whether such a scenario will benevolently unfold as so envisioned, there can be little doubt that the neurosciences will continue to inform our understandings of cognitive phenomena such as insight and the "aha!" moment, along with many other aspects of cognition and learning at the nexus of mind and brain. How far into the future must we wait? Perhaps not too much longer.

EYE-TRACKING MATHEMATICAL REPRESENTATIONS – FINDING LINKS BETWEEN VISION AND REASONING

COMPRENDIENDO LAS REPRESENTACIONES MATEMÁTICAS CON MÉTODOS DE RASTREO OCULAR – UNA APROXIMACIÓN BASADA EN LA TEORÍA

Eye-tracking studies need adequate theoretical frameworks for producing insights about mathematics learning. The current study uses eye-tracking to investigate the effectiveness of tables and diagrams for supporting covariational reasoning amongst elementary students (n = 60). The theoretical framework emphasizes the cognitive functions of representations. Students showed more covariational reasoning around diagrams. The fixations showed that tables concentrated students' attention on the dependent variable data, whereas diagrams distributed students' attention evenly across the numeric and visual elements of the task. According to the theoretical framework, tables did not constrain a covariational interpretation of numerical data, whereas diagrams effectively constrained covariational interpretations, disrupting recursive tendencies and promoting the construction of a mental model of covariation.

Keywords: Representations and Visualization, Research Methods, Cognition, Algebra and Algebraic Thinking

Eye-tracking methods have much potential for studying mathematical thinking and learning. However, more work is necessary for developing conceptual frameworks to guide the design of eye-tracking studies and interpret eye movement metrics (Strohmaier et al., 2020). Here we report research that illustrates an attempt to make conceptual connections between low-level vision mechanisms and abstract mathematical reasoning. The study reported below investigated how external visual representations (VRs) might influence the reasoning of pre-algebraic elementary students while solving tasks that are widely used in the functional approach to early algebra, presented in tabular and diagrammatic formats. Conceptual frameworks of learning with multiple representations allowed us to formulate and respond to research questions with theoretically-driven interpretations of eye movement data.

Generalization and representation in Functional Thinking

The Functional Thinking (FT) approach to early algebra uses the function concept to articulate ideas such as variable, covariation, generalisation, and symbolic notation. FT research algebra relies heavily on tabular tasks to investigate and support generalization processes. The study reported below addresses a task that require students to define missing instances of a dependent variable, e.g., completing missing cells in a function table.

Learners might use at least three approaches for solving tabular tasks (Smith, 2008): (1) Recursive patterning involves attending to variation in sequences of values, (2) a covariational approach means analysing simultaneous change in two or more quantities, and (3) a correspondence approach emphasizes the relation between pairs of variables. The use of covariational and correspondence approaches indicate a notion of function based on covariational reasoning (Thompson & Carlson, 2017), which entails the conception of two quantities varying simultaneously with an invariant relationship between the values of the quantities, and every value of one quantity determines exactly one value of the other quantity.

Most elementary students struggle to transit from recursive approaches to covariational reasoning while working with tables (Tanışlı, 2011; Wilkie, 2016). The focus on recursion might result from an interaction between a natural the tendency to seek univariate patterns and the visual properties of tables. Consequently, other visual representations, such as diagrams, could ease covariational reasoning by disrupting recursive tendencies. However, research about representational factors in functional thinking is scarce, so the question remains open: How do different visual representations influence students' reasoning during functional thinking tasks?

Approaches to learning with multiple representations

We consider tabular tasks and diagrammatic tasks as cognitive tools that display information to achieve mathematical insight, and not necessarily to depict mathematical objects (Giardino, 2017). Therefore, we draw from the Design, Functions and Tasks (DeFT) framework to learning with multiple representations by (Ainsworth, 2006), which addresses the learning potential of multi-representational systems from a design perspective, considering representational features such as modality and number of representations as design parameters, as well as other dimensions to analyse the effectiveness of multiple representations, namely tasks and functions.

Tabular tasks and diagrammatic tasks are equal in design because both are in the visual modality and combine text with VRs. Tables and diagrams are also equivalent in the task dimension because these representations are common in the elementary classroom and, therefore, students know how to "read them". Pre-algebraic elementary students learn to relate tables or diagrams to the functional thinking domain while working in functional tasks. However, tasks and diagrammatic tasks are different in the functions dimension.

The DeFT framework outlines three cognitive functions of multiple representations. *Complementary functions:* In multi-representational tasks, the representations should complement each other by differing in the information each contains and the processes that each support. *Constraining functions:* Multiple representations help learning when one representation constrains the interpretation of a second representation. VRs can constrain text because text is ambiguous and VRs are specific (Schnotz, 2005); *Constructing functions:* Multiple representations support effective learning when learners integrate information from representations to achieve insights that could be difficult to achieve with only one representation. In tasks that include text and VRs, each representation is processed by parallel mechanisms resulting in complementary mental models that are mapped onto each other (Schnotz, 2005), thereby extending current knowledge and facilitating deeper understandings.

Representational functions of tabular tasks

Tables are semi-graphical representations that support learning by arranging information to exhibit facts or relations in a compact manner, and by directing attention to unsolved parts of a problem (Cox & Brna, 1995). In the tabular functional tasks reported in the literature (e.g., Tanışlı, 2011), graphic components such as cells, rows and columns, comply with the complementary function by representing mathematical relations that texts cannot represent. For example, columns represent variables, rows represent ordered pairs, and empty cells represent missing instances of the dependent variable. Tables comply with the constraining function by positioning numbers in a way that constrains their interpretation from a covariational reasoning perspective. The constructing function happens when the processing of numerical data produces a mental model of quantities, and the processing of the visual layout produces a mental model of covariation. The mapping of these mental models prompts insights about the invariant rule governing the relationship between quantities.

Representational functions of diagrammatic tasks

Diagrams represent objects with pictorial components that express conceptual relations spatially, and can be idealized or instantiated in some context (Belenky & Schalk, 2014). Diagrams give fast access to meaning, facilitate the comprehension of complex information, and elicit previous knowledge (Tversky, 2011). Diagrams effectively show physical layouts and how things work or are put together, organize information, make abstract ideas concrete, and allow the use of spatial skills (Winn, 1991). We have made explorations with diagrammatic functional tasks of shadow-casting phenomena (Xolocotzin et al., 2018). In these tasks numerical data is complemented by pictorial components representing a pole and its shadow, making an explicit representation of covariation and correspondence between the quantities pole height and shadow length. The pictorial components constrain a relational interpretation of numerical data. For example, the pictorial representations of the pole and its shadow are visually connected, facilitating the interpretation of numerical data from a covariational reasoning perspective. Diagrammatic tasks might comply with the constructing function by facilitating the integration of a mental model of quantitative properties extracted from numerical data, e.g., variation, with the mental model of shadow-casting phenomena, which is relational by nature.

Previous paper-based study

Before the eye-tracking study, we assessed the effects of diagrammatic and tabular tasks with a paper-and-pencil study conducted with 1145 students in Grade 4, Grade 5 and Grade 6, recruited from 16 public schools located in central Mexico. Because the schools are public, they must follow the official mathematics curriculum, which does not include algebraic content. We studied different representational versions of a functional task that required students to identify missing instances of a dependent variable. The task presents two number sets. The first set has 6 numbers of the independent variable. The second set has 3 known numbers and 3 unknown numbers of the dependent variable. Students must figure out the rule governing the relationship between the two variables to identify the missing numbers. There were four options to choose from: (1) functional, (2) recursive, (3) First instance, which is consistent with a rule that only applies to the first pair of data, thereby denoting lack of generalization, and 4) random, which presents three numbers defined randomly. Four versions of the tasks were generated by manipulating two factors: Representation (table or diagram), and context (with context or without context), see Fig. 1. The diagrammatic tasks, either with context of without context, generated more functional responses than tabular tasks. However, this effect was larger in the contextualized version of the diagrammatic task. We also observed that Year 5 students were the most sensitive to the effects of context. We considered these results as evidence that diagrams ease covariational reasoning.

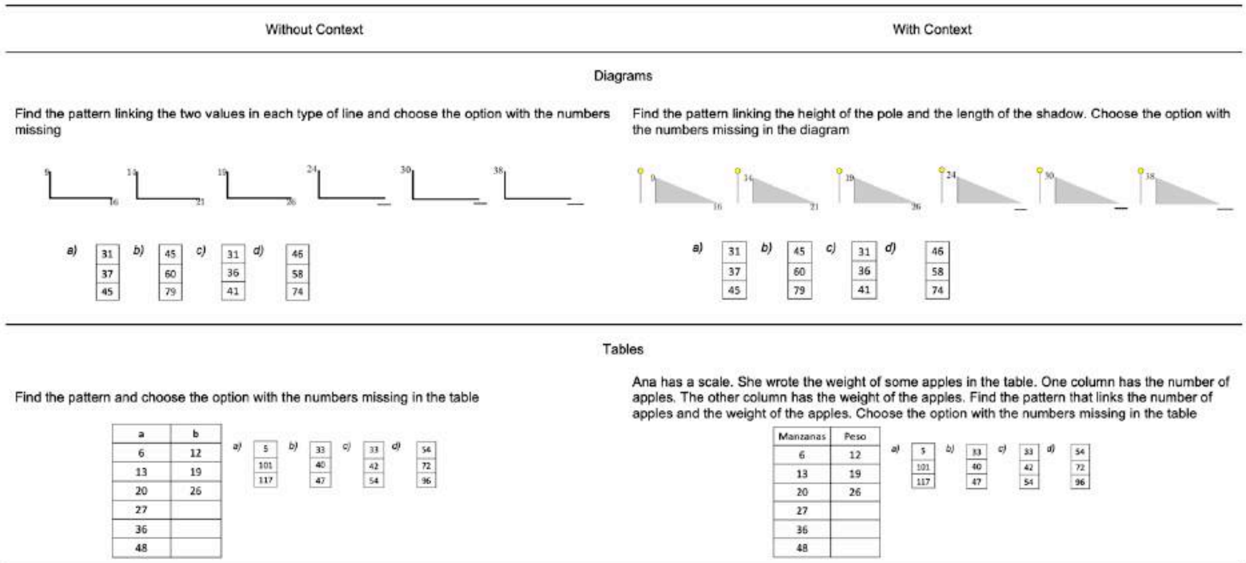

Figure 1 Examples of the tasks employed in the paper-based study.

Overview of the current study

The previous paper-based study suggested that diagrammatic tasks are more effective than tabular tasks at easing covariational reasoning. Albeit informationally equivalent, diagrams seemed to facilitate retrieval of functional information. In line with the DeFT framework, we hypothesized that diagrams are more effective than tables for complying with the functions of multiple representations, which opened our research question: How do diagrammatic tasks and tabular tasks comply with functions of multiple representations such as constraining and constructing? To answer this question, we analyzed students' eye movements to gain insights about the effects of tables and diagrams on students' attention.

Method

Participants

A total of 60 students in Grade 4 (n = 20), Grade 5 (n = 20) and Grade 6 (n = 20) from a public elementary school participated in the study. All students participated on a voluntary basis, with informed consent from parents and school authorities. Three participants failed to reach accuracy levels due to unforeseen circumstances, e.g., spectacles not allowing registration of the participants' eye. Therefore, their data were discarded, leaving a sample of 57 students.

Apparatus and stimuli

The data were collected with a portable eye-tracker Tobii Pro X2-30, with a 30 Hz sampling rate, 0.4 precision (binocular), and 0.32 gaze precision (binocular). Both eyes were tracked. This model allows robust detection of individuals' eye movements, even with unrestricted movement. The eye-tracker was mounted below the screen of a Dell Inspiron 5000 15 inch laptop, which display was set at 60 Hz refresh rate and 1366 x 768 resolution. The distance between the eye-tracker and the edge of the table was held constant at 60 cm.

The stimuli were a series of functional tasks presented in either tabular or diagrammatic format. The tasks were replicated from the "with context" of the previous study (See Fig. 1). Tabular tasks were grounded on a situation involving apples and their weight. The diagrammatic tasks were grounded in a shadow-casting situation involving the height of a pole and the length of its shadow cast. There were 12 tabular tasks and 12 diagrammatic tasks. In each type of task, there were four items involving sums, four items involving subtractions, and four items involving multiplications. The same as in the previous study, each task required the identification of a relationship between two quantities, and selecting one of four response options: functional, recursive, first instance, or random.

Experimental design

The experiment employed a factorial design involving the within-subjects factor representation (table/diagram) and the between-subjects factor Grade (4/5/6). The factor representation was counterbalanced within each Grade. The tasks were presented in fixed order: sums, substractions, and multiplications.

Procedure

Students were tested individually in the school IT suite. They were instructed as follows: We would like you to please help us solving a task. It is important that you know that the results do not have any relation with your grades. Do you have any question? the results are very important for us because we are studying how students solve some mathematics activities. Please, pay attention and do your best effort.

Results and discussion

The behavioural results replicated the previous study, that is, students chose the functional response more in diagrammatic tasks [F (1, 56) = 4.038, $p < .05$, $\eta^2 = .022$]. The eye tracking data, interpreted under the DeFT framework, allowed us to explain this result. Eye-trackers produce a range of eye-movement metrics. We wanted to know which areas components of tables and diagrams were more noticeable for students. Therefore, we used fixation time, which indicates difficulty in extracting information, or that the object is more engaging in some ways (Poole & Ball, 2006). We defined a series of analogous areas of interest (AOIs) corresponding with key components of the tasks, see Fig. 2. One set of AOIs contained data; A1 and A2 show contained the first and second half of the independent variable. A3 contained the first half of the dependent variable, and A4 contained the unknown second part of the dependent variable. A second set of AOIs contained contained the response options, functional, recursive, instance, and random.

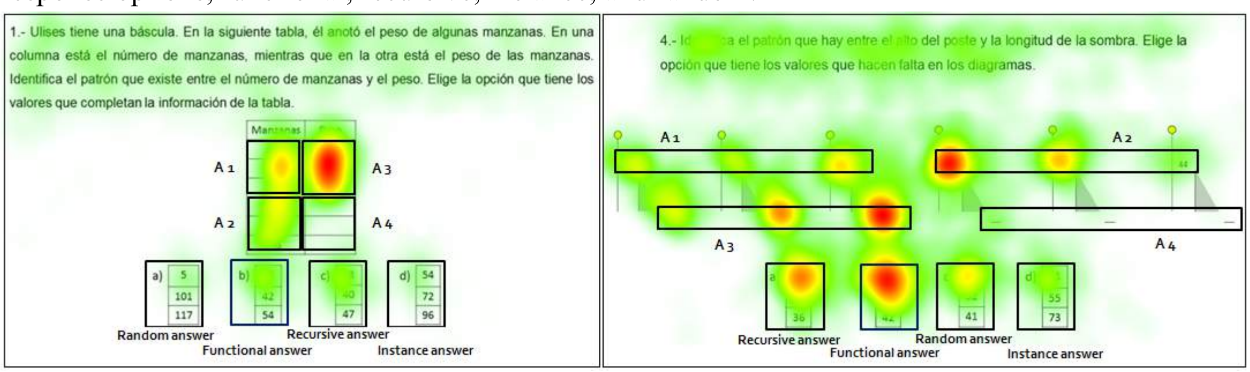

Figure 2 Ares of Interest in Tabular tasks and Functional tasks with an overlay heatmap of fixation duration

The analysis of the data AOIs revealed that students fixated more on AOI3 while solving tabular tasks, which contained the known numbers of the dependent variable, whereas in diagrammatic tasks students fixated evenly across the data AOIs [F (3, 162) = 20.541, $p < .001$, $\eta^2 = .085$]. As for responses AOIs, students fixated more on functional responses while solving diagrammatic tasks [F (3, 162) = 40.209, $p < .001$, $\eta^2 = .108$]. The DeFt framework allows an interpretation of these results. Figure 2 illustrates how students engaged more with AOI A3, which indicates the spatial layout of cells and columns, fails comply with its intended function of constraining a covariational interpretation of numerical data. Therefore, students are unable to integrate the mental model of quantitative properties extracted from the data, with a mental model of covariation. Therefore, they did not achieve the necessary insight for inhibiting the tendency to look for recursive patterns. This might explain why students engaged equally with recursive and functional responses. In contrast, diagrams disrupted the tendency to focus on recursion, and made students to expand the breadth of their attention, and engaged equally with data and probably other elements of the task. This might indicate that they considered all sources of pictorial and numeric information, moreover, pictorial components seemed to constrain a covariational interpretation of data. We argue that diagrammatic tasks allowed the construction and integration of a mental model of quantitative properties extracted from numerical data, and a mental model of a relational situation, extracted from the graphic elements of the task. In this way, students gained covariational reasoning insight and, therefore, engaged more with functional responses.

General conclusion

Eye-tracking research in mathematics education is growing steadily (Strohmaier et al., 2020). However, the release the full potential of these methods for gaining insights about mathematical learning, it is necessary to use theoretical frameworks that allow plausible interpretations of eye-movement data. The presented study aimed to illustrate the benefits of theory-driven interpretations of eye-movement data.

In our first paper-based study, we found that diagrammatic tasks were more effective at easing covariational reasoning than diagrammatic tasks. However, this result could not be explained from paper-based data. So, we had the output but were unable to empirically explain the process leading to such output. We addressed this issue with eye-tracking methods because the cognitive mechanisms involved in learning from visual representations cannot be observed directly. Moreover, these mechanisms rely heavily on unconscious vision processes which operation cannot be intentionally controlled by individuals.

The DeFT framework allowed us to make theoretically-informed accounts of the ways in which tables and diagrams are expected to support covariational reasoning. By analyzing tabular tasks and diagrammatic tasks under the DeFT framework, we identified that these representations were similar in the dimensions design and tasks, but different in the functions dimension. Therefore, we hypothesized that diagrams were more effective for supporting covariational reasoning in the first study because this representation complied more effectively with functions such as complementing textual information, constraining textual information, and constructing insights.

The behavioural results replicated the paper-based results, diagrammatic tasks were more effective for supporting covariational reasoning. The patterns of fixation duration confirmed our hypothesis. Diagrammatic tasks distributed the individuals' attention evenly across the visual display of the task, and directed their attention to recursive and functional responses evenly. In contrast, the tabular task concentrated individuals' attention on the first part of the dependent variable, and directed their attention to recursive only.

An interpretation of results from a cognitive load framework would have been problematic. Diagrams should have produced less functional answers because they have more information and require more cognitive resources than tables. The DeFT framework offered a more parsimonious interpretation of these results. The layout and structure of tables seemed unable to constrain a covariational interpretation of textual data such as task instructions and numerical data, thereby favoring a recursive interpretation of the data. In contrast, diagrams effectively constrained a covariational interpretation of data, disrupting the natural tendency to seek recursive patterns, and allowing the production and integration of a mental models of data's numerical properties with a mental model of covariation.

MENTAL MATHEMATICS IN THE CLASSROOM: CONTENT, PRACTICES AND PAPERT'S *MATHLAND*

Jérôme Proulx
Université du Québec à Montréal
proulx.jerome@uqam.ca

This lecture reports on aspects of a larger research programme focused on studying mental mathematics in elementary and secondary mathematics classrooms. It specifically addresses an unplanned aspect that became salient through the work conducted in these classrooms. In this research programme, mental mathematics sessions are designed on a variety of mathematical topics (e.g., algebra, geometry, measurement, statistics, trigonometry, fractions), where students are given short amounts of time to solve tasks given orally and/or on the board, without the use of paper-and-pencil or any material aids. Whereas the central objectives centers on inquiring into the nature of the strategies students engage in to solve the tasks, more seem to be happening in these sessions. In particular, students' solutions and strategies to the task given in the mental mathematics context led to numerous questions, discussions, follow-up explorations, and so forth, by students, which in turn enabled the emergence of significant mathematical issues. This raised interest in investigating these (additional and unplanned) mathematical issues. This represents the core of this lecture, which focuses on the nature of the mathematics (in terms of content and of practices) that frequently unfolds in the mental mathematics sessions conducted. Using an illustrative extract from a mental mathematics session on analytical geometry in a Grade-10 classroom (15-16 years old), the analysis outlines how not only mathematical content is being worked on through these mental mathematics sessions, but also how mathematical practices are being enacted by students. This raises issues about the nature of the environment that these mental mathematics session plunge students into, one that could be tentatively, and boldly, aligned with Papert's concept of mathland.

Keywords: Mental Mathematics, *Didactique des Mathématiques*, Mathematical Practices, Problem Solving, Curriculum Enactment, Geometry and Geometrical and Spatial Thinking

> Being a mathematician is no more definable as knowing a set of mathematical facts than being a poet is definable as knowing a set of linguistic facts. Some modern mathematical education reformers will give this statement a too easy assent with the comment: 'Yes, they must understand, not merely know'. But this misses the capital point that being a mathematician, again like a poet, or a composer, or an engineer, means doing rather than knowing or understanding. (Papert, 1972, p. 249)

Preliminary note: the nature of my research work in *didactique des mathématiques*

My research work is in *didactique des mathématiques*. What does this mean and how does it impact on the nature of the work I conduct? As Douady (1984) expresses, research work in *didactique des mathématiques* investigates the processes and conditions for the production, transformation, communication and acquisition of mathematics, which is not to be reduced to the quest of finding effective teaching methods for mathematical notions. In other words, research work in *didactique des mathématiques* focuses on studying how mathematics happens and advances; which includes its teaching. Brousseau (1991) adds an important aspect to this, mainly that it is a "Science concerned with the production and communication of mathematical knowledge in how these productions and communications are *specific* to mathematics" (*my translation*). What comes out of this is that mathematics and its specificities are central to research work conducted in *didactique des mathématiques*. Hence, questions about mathematics education are addressed *through* mathematics,

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

that is, where the *didacticien des mathématiques* is concerned with mathematical experiences and activities in how they are representative, specific and aligned with mathematics themselves. As an example, the interest in problem solving for a *didacticien des mathématiques* is not because doing problem-solving helps learn this or that mathematical concept or because it could contribute to better students' success in mathematics, but mainly because mathematics is defined as a problem-solving endeavor (e.g., Brown & Walter, 2005; Halmos, 1981; Papert, 1972, 1996; Polya, 1957). This is why *didacticiens des mathématiques* undertake studies on problem-solving or argue for its significance: because problem-solving is constitutive of mathematics as a discipline.

Research work in mental mathematics

My research programme is focused on studying mental mathematics in elementary and secondary mathematics classrooms. In this research work, sessions are designed and conducted on a variety of mathematical topics (e.g., algebra, geometry, statistics, measurement, trigonometry, fractions), where classroom students are given short amounts of time to solve tasks given orally and/or on the board, without the use of paper-and-pencil.

Mental mathematics can be defined along the existing research literature, e.g., following Hazekamp's (1986) view, as the solving of mathematical tasks through mental processes without paper-and-pencil or other material aids available. To this one can add that there are frequently time constraints to producing an answer, as well as the fact that questions are often asked orally. The mental mathematics sessions conducted usually follow the same structure, similar to what Douady (1994) suggests by carefully establishing a respectful climate that ensures thay students' share and listen to solutions:

(1) A task is offered orally or on the board;
(2) Students listen and solve the task mentally;
(3) When time is up, students are asked to explain their answer (adequate or not) in detail to the classroom, taken in note on the board (and in some cases students themselves come to the board to explain it);
(4) Other students who solved differently (or thought of solving differently) are invited to offer their answers; once all is said and done, another task is given.

It is often reported that the strategies used to solve mental mathematics tasks differ from those usually referred to in a paper-and-pencil context. Butlen and Pézard (1992), for example, report that the practice of mental mathematics can enable students to develop new and economical ways of solving arithmetic problems that traditional paper-and-pencil contexts rarely afford, because the latter are often focused on techniques that are too time-consuming for a mental mathematics context. These economical ways of solving are said to have the potential to open varied and alternative mathematical routes for handling the concepts under study (e.g., Alain, 1932; Murphy, 2004; Plunkett, 1979; Reys & Nohda, 1994; see also Proulx, 2019). Thus the central objectives of this research on mental mathematics is to inquire into the nature of the mathematical activities (strategies, ways of solving, ideas, reasoning, etc.) that students engage in to solve these tasks.

This said, as these mental mathematics sessions were conducted in classrooms, it became quite apparent that much more than strategies and solutions was happening in these sessions. In effect, the answers given by students and the strategy shared to arrive at them becomes some kind of natural occasion for other students to question or comment them, if they are not convinced or do not understand them. This leads to numerous interactions between students and the Principal Investigator (PI) (and the regular classroom teacher), where students ask important questions about the mathematics at play, which in turn would often lead students to engage in subsequent investigations about these issues (through questions, discussions, follow-up explorations, etc.; see also Cobb et al., 1994, on this). In addition, the sharing of numerous strategies leads invariably to discussions about these strategies, where the various strategies and their answers are compared and discussed by the PI and students concerning their effectiveness, links, (dis-)advantages, possible extensions to other tasks, and so forth. Even if from the outset this was not the scientific objective of the research, this phenomenon became intriguing. And from a *didactique des mathématiques* orientation, some attention was given to how all this was contributing to the advancement of mathematics with students.

Advancement of mathematics: content and practices

The advancement of mathematics can be addressed along two dimensions. The first is relative to the advancement of *mathematical content*. Mathematics is filed with content, from number to geometry and algebra, to name a few, through various algorithms, formulas, procedures, methods, definitions, theories and theorems about them. Analyses of the advancement of content in classrooms focuses on the development of this content with students, that is, on their understandings and reasoning relative to this mathematical content. Having said this, as Papert's above quote insists, mathematics is not only about its content; it is an activity that is done and takes shape in action (see also Brown & Walter, 2005; Hersh, 2014; Lockhart, 2009; Schoenfeld, 2020). Mathematics is about doing mathematics; mathematics is a practice. Another dimension thus concerns *mathematical practices*. This second dimension of the advancement of mathematics in classrooms is about the development of mathematical practices in students, that is, how these emerge, unfold, progress, and so forth, as mathematics is being explored and produced.

In other words, mathematics is composed of content and practices, where this mathematical content is explored and engaged with. Intertwined with the advancement of content, the emergence and development of mathematical practices thus acts as a fundamental dimension to consider in relation to mathematics. It is also along these lines that Lampert (1990a) raises the relevance of working on a double agenda, that is, simultaneously on *of* and *about* mathematics:

> This meant that I needed to work on two teaching agendas simultaneously. One agenda was related to the goal of students' acquiring technical skills and knowledge in the discipline, which could be called knowledge of mathematics, or mathematical content. The other agenda, of course, was working toward the goal of students' acquiring the skills and disposition necessary to participate in disciplinary discourses, which could be called knowledge about mathematics, or mathematical practice. (p. 44)

Both these dimensions of content and practices have been salient in the mental mathematics sessions conducted. This research, strongly grounded in Papert's work (e.g. 1972, 1980, 1993, 1996; see also Barabé & Proulx, 2017), compelled investigations of mathematical practices. Papert is indeed quite adamant on the importance of the development of mathematical practices, where mathematics is not something given and fixed, but is alive and a source of ongoing investigations in order to enrich students' experiences and culture in mathematics (see, e.g., 1993, 1996). This idea also relates to Bauersfeld's (1995, 1998) notion of plunging students into a "culture of mathematizing", where mathematical practices unfold and take shape through interactions and investigations.

Participants in a culture of mathematizing are seen as authors and producers of mathematical knowledge, understandings and meanings. In the establishment and development of such a culture, where mathematical practices unfold and concepts and methods are explored and worked on, students are encouraged to generate ideas, questions and problems, to make explicit and share understandings and solutions, to develop explanations and argumentations to support the solutions and strategies put forth, to negotiate proposed meanings, to share and explore various ways of understanding problems, concepts, symbolism, and representations, and to assess and validate other's understandings and ways of doing (see e.g. Bartolini Bussi, 1998; Bednarz, 1998; Borasi, 1992, 1996; Brown & Walter, 2005; Cobb & Yackel, 1998; Lampert, 1990a; Schoenfeld, 2020; Voigt, 1985, 1994). From these practices, a number of elements can be outlined to characterize and analyze the advancement of mathematics.

- *The emergence of a community of validation*. Central to a mathematics-producing practice are participants who are engaged in explaining, discussing, arguing, and validating mathematical understandings and meanings (Boaler, 1999; Borasi, 1992; Hersh, 1997; Krummheuer, 1995; Lakatos, 1976; Lampert, 1990a).
- *The role, relevance and development of mathematical languages, symbolisms and conventions*. Mathematical symbolism, languages and conventions, and their development, are used to express mathematical understandings, explanations, arguments, etc., and play a major role in the emergence of mathematics and mathematical thinking (Bednarz et al., 1993; Byers & Erlwanger, 1984; Byers & Herscovics, 1977; Lampert, 1990b; Lockhart, 2017).
- *The role given to errors and how they are handled*. Errors play and have played a fundamental role in the emergence of mathematical thinking and understanding. The way they have been handled has enable new ways of seeing and understanding mathematics, leading to unpredicted or as yet not thought of avenues (Borasi, 1996; Hadamard, 1945).
- *The solving and posing of problems*. Doing mathematics is an activity of posing and solving problems of many kinds (Bkouche, Charlot & Rouche, 1992; Brown & Walter, 2005; Hersh, 1997; Lang, 1985; Polya, 1945), where explorations of mathematical content have contributed to the development of additional mathematical content.
- *The authorship, ownership and responsibility in mathematics*. Doing mathematics imposes an active engagement. People doing mathematics do not conceive of themselves as mere consumers or receivers of mathematics, but as producers and even authors of mathematics (Papert, 1996; Povey & Burton, 1999; Schoenfeld, 1994). Mathematics confers a double sense of responsibilities (Borasi, 1992, 1996), where people doing mathematics are responsible for the mathematics they produce and also responsible for producing mathematics.

As scientific interest arose about these dimensions relative to the advancement of mathematics in the mental mathematics sessions conducted, the following question oriented the inquiry: *In what ways is mathematics advancing in the mental mathematics sessions, under both its mathematical content and practices dimensions?* As a way of showing how the advancement of mathematics happened in the sessions, an extract taken from one session is presented. This extract is then looked into in relation to how mathematics content and practices advance, as a way of offering an initial illustration of what it can mean to analyze the advancement of mathematics in these mental mathematics sessions.

Extract from a mental mathematics session

The extract is taken from a session led by the PI in a Grade-10 classroom of about 30 students, who were working on analytical geometry in relation to distances (points, midpoints, lines, etc.) and had been initiated to usual algebraic formulas. One of the tasks given to students was "Find the distance between (0,0) and (4,3) in the plane" (given orally, with points drawn on a Cartesian plane on the front board); they had 15 seconds to answer without recourse to paper and pencil or any other material. When time was up, students were invited to share and justify their solutions to the group. The following is a synthesis of the strategies engaged in and the discussions, questions, and explorations that ensued.

The first strategy referred to applying the usual distance formula ($D=\sqrt{(x_1-x_2)^2+(y_1-y_2)^2}$), leading to 5 as a distance. A second strategy suggested drawing a triangle in the plane, with sides 3 and 4, for then finding the hypotenuse by using Pythagoras (Figure 1a).

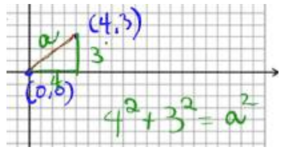

Figure 1a – Drawing the right triangle

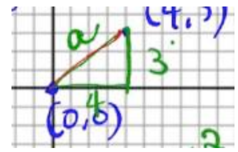

Figure 1b – Close-up on the triangle

Another student then suggested a third strategy, coming to the board to trace a red segment to count directly on it from (0,0) to (4,3) as in Figure 1b. Starting from (0,0), she counted "the number of points" to arrive at (4,3), counting the number of whole-number coordinate points from (0,0) to (4,3). While doing this at the board, she suddenly stopped and mentioned that her red segment did not go through the points she envisaged, which made the counting difficult. The PI then traced another segment going through square diagonals linking two separate points, which could enable counting the number of (whole-number) coordinate points from one point to the next (giving 4 as a distance, Figure 2). The student agreed that for this case, it would work.

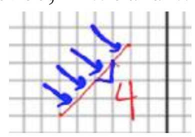

Figure 2 – Line drawn through square diagonals

The PI then asked if the measure obtained with square diagonal lengths was identical to that obtained with the side of the square (drawing  on the board).

> One student asserted that both lengths were not identical, because the diagonal of the square was not of the same length as the square's side. Another explained that both lengths were different, because the hypotenuse is always the longer side in a triangle. Finally, a student claimed that the diagonal was longer because it faces the wider angle.

The PI then asked if that last assertion about facing the wider angle was always true, and if so why (drawing on the board a random right triangle ).

> One student, pointing at the triangle, stated that it was indeed the case in this drawn triangle. Another student explained that in a triangle the bigger the angle the longer the opposite side, mentioning that if the side-hypotenuse had been longer, the opposite angle would have been wider. And, because the sum of the (measures of the) angles in a triangle is 180^o, then the 90^o angle is always the wider one, the other 90^o being shared between the remaining two angles.

Using the drawing of the triangle, the PI simulated the variation of the right angle toward an obtuse one and traced the resulting side obtained, showing how it would become longer (drawing  on the board). He then moved it toward producing an acute angle, asking students if their "theory" about opposite side of the angle worked for any angle, like acute ones.

> One student asserted that it works for isosceles triangles, with equal sides facing equal angles, and another mentioned that it is the same for the equilateral triangle, because it is "everywhere the same" with same angles and same side lengths.

The PI explained that these ideas about the diagonals being longer than the side underlined the fact that this initial strategy amounted to counting diagonals, that is, the number of diagonals of a unit square. And, that this offered a different sort of measure for the (same) distance between the two points: one in terms of units and one in terms of diagonals. A student added that if one knows the value of the diagonal (e.g. 1.2 or else), then one could find the number of unit squares for the diagonal-segment by multiplying by that factor.

One student offered a fourth strategy to find the distance, suggesting using the sine law with angles of 45^o. The PI asked the student how he knew that both angles were 45^o in the triangle. As skepticism grew in the classroom, the PI suggested that students inquire, in small groups or individually, if the triangle's angle were 45^o or not, and to be able to convince others. After 5-6 minutes of exploration, students were invited to share their findings.

> One student explained that on her exam checklist there is an isosceles right triangle with 45^o angles. Thus with this triangle of side length of 4 and 3, one cannot directly assert that it is 45^o because it is not an isosceles triangle as its sides are not equal. Another student illustrated on the board that if one "completes" the initial triangle into a rectangle ( , see Figure 3a), then the hypotenuses of both triangles are the rectangle's diagonal which cuts it in two equal parts and thus cuts its angle in two equal 45^o parts.

As the PI highlighted that the two arguments were opposed, one student replied not agreeing with the last argument, drawing on the board a random rectangle with its diagonal (Figure 3b), and asserting that in this rectangle *it was not certain* that the angle was divided into two equal parts. Another student added that because the sides of the triangle were not identical (of 3 and 4), then the diagonal would not necessarily cut the 90^o angle in two equal parts of 45^o.

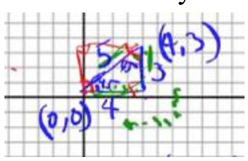

Figure 3a – The "completed" rectangle

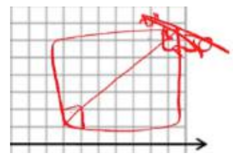

Figure 3b – The "counter" rectangle

The PI highlighted that this last argument reused aspects of the precedent "theory" that the longer side faces the wider angle in the triangle. Hence, following this, a longer side needed to face a wider angle. Then a counter-example was offered to the group.

> The student who made reference to the checklist asserted that sometimes in their exams right triangles did not have 45^o angles, for example, one with 32^o and 58^o; coming to the board to draw it (Figure 4). She completed her drawing to create a rectangle, explaining that the diagonal cuts as well this rectangle in two parts, but that the angles obtained are not of 45^o.

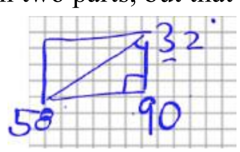

Figure 4 – The triangle counter-example with angles of 32^o and 58^o, and the rectangle

The PI asserted that this offered a counter-example, with a type of right triangle frequently met that did not have angles of 45^o.

> One student added that because all sides were different, then their associated angles would be different, the longer side needed to face a wider angle, which would lead to different angles.

The PI then highlighted the work of one student who drew a square in his notebook to assess the 45^o situation. Drawing a triangle of sides 3-4-5, he extended the cathetus of 3 toward one of 4 to create a 4x4 square. Then, because in the previous unit-square the angles were of 45^o, in this 4x4 they were 45^o as well (Figure 5). Comparing hypotenuses of both triangles, it illustrated that in the initial 3-4-5 right triangle, the angle is smaller than the right triangle of side 4 and 4. All this led students to appear to agree that the angle was not 45^o, ending the explorations (and leading the PI to offer another task for the students to solve).

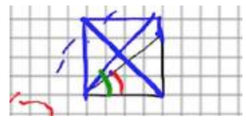

Figure 5 – Comparing triangles within a square

Analysis of the advancement of mathematics

A *didactique des mathématiques* analysis of this extract in relation to the advancement of mathematics underlines issues of mathematical content and of mathematical practices. First, mathematical content is significantly present in this extract through the explorations undertaken. Some mathematical content is engaged with more superficially or in an isolated way, without requiring subsequent exploring and mostly being referred to: Pythagoras' relation, distance formula, hypothenuse, angles (acute, obtuse, right), triangles (various types, and isosceles and equilateral). These are not explored in depth, but are mobilized during the session and play an important part in it. Other mathematics content takes a more important place, enabling or representing some mathematical advances in the session through deeper explorations than the former: the sum of the measures of the angles of a triangle is 180^o, the possibility of having two different measures for the same distance, the relationship between the rectangle's diagonal, and the bisector of its angles. Finally, some content appears at the heart of the explorations in the session, thought of and recurrently being engaged with by students: the difference between the (measure of the) square diagonal and (the measure of) its side, and the relation between and variation of one side of the triangle and its opposite angle. There would obviously be more to outline, and along much subtler lines, but what is significant is the magnitude of the mathematical content worked on, mobilized, and continually explored with the students.

Second, students are enacting a variety mathematical practices, which participate in the environment where the mathematical content is taking shape. In sum, the mathematical contents engaged with in the session are grounded in these mathematical practices:

- *The emergence of a community of validation*. The investigation of the 45^o angle is an example of how a community of validation was established, in which students offered conjectures, argued and counter-argued on the ideas suggested, justified their claim, developed elements to prove it, engaged in reflections to establish what works and does not, and why, etc. The mathematical "truths" were not passively received from outside, from an external authority, but were debated and worked on to develop consensus.
- *The role, relevance and development of mathematical languages, symbolisms and conventions*. Although complex to analyse from a short extract, it is possible to seize some of the symbolisms and representations that took shape in it. For example, the manner of drawing rectangles and triangles with a "cut" to argue about the value of their angles is representative of a strong symbolization that became established in the group, that evolved, and that was used throughout the session. Thus, from a triangle (), students were led to "complete" it to make a rectangle (), enabling them to discuss and explore what happens with the rectangle's and triangle's angles. It is this specific symbolic representation that is used in Figures 3b and 4 to argue and counter-argue about the rectangle's diagonal and the division in half of the 90^o angle. This "invented" representation to symbolize the relationship between rectangles and triangles regarding their angles contributed to the mathematical understandings, and was often reused by students in the session.
- *The role given to errors and how they are handled*. Errors have played a productive role in the session, provoking additional questions and explorations. For example, the third strategy about measuring the distance between the points through the diagonal of the unit-square has

unleashed important questioning on the difference between the diagonal and the side of the square, and has led to the idea that it is possible to have different measures for the same distance. The suggestion that the triangle had a 45^o angle also provoked the investigation about triangles' angles and sides, as well as rectangles' sides and diagonals. None of these assertions, even when erroneous, were criticized and all were taken seriously: they were respected as authentic mathematical productions and enabled deeper understandings of the mathematics at play.

- *The solving and posing of problems*. Throughout the session, questions were asked and sub-problems emerged, unpredicted and contingent on the ongoing explorations undertaken (e.g. diagonal of the unit-square; the 45^o angle; the diagonal splitting the 90^o angle into two equal parts). Students raised and engaged intensely in these questions and sub-problems. It is through these questions and problems that the main part, if not the entirety, of the mathematical content was explored and deepened.
- *The authorship, ownership and responsibility in mathematics*. Students took an active part in the investigation through a number of mathematical assertions and proposals (through strategies, answers, questions, disagreement, explanations, etc.). In this sense, they took ownership of the ideas produced and were engaged in producing them. This double-responsibility took place as students were not passive in the session, but contributed to it with their own ideas. As an example, students' spontaneous use of the front board shows how they felt compelled to share their ideas and participate in the explorations to reach a consensus: they show ownership over this consensus and do not appear to wait for someone else to reach it for them, interacting with others and the PI, raising issues, arguing, questioning, responding, etc.

Another mathematical practice also comes out of this extract, and one considered of significance in mathematics. It is related to what Papert (1980, 1993) calls *theorizing*. In the discussions about the difference between the measure of the diagonal and the side of the square, an important theory was suggested by students: the bigger side of the triangle faces its bigger angle. First, this theory was mainly an assertion, some sort of conjecture. But, after some questions raised by the PI (*Does it work all the time? / What happens if the angle changes? / etc.*), it was increasingly confirmed by and through students' justifications. This theory was then used by others, and as much by the students than by the PI, to address the issues about the 45^o angle: if the measure of one side of the triangle is not the same as another, then neither can be the opposite! Throughout the session, this theory took shape and strengthened, giving rise to a number of side assertions, in the form of corollaries, like the following:

Corollary 1: In a triangle, the smallest angle is always opposed to the smallest side.
Corollary 2: In a triangle, the smaller an angle is, the smaller its opposite side is.
Corollary 3: In an isosceles triangle, both equal angles are opposed to both equal sides.
Corollary 4: In an equilateral triangle, angles are the same, linked to sides of same length.
Corollary 5: Since the sides are not equal, its angles are not equal either.
Corollary 6: Since the sides are of different length, they opposed angles of different size.

And the list could go on. Without always being stated explicitly, the arguments and explanations related to the initial theory, that justified it, underlined these ideas and strengthened them. This made the theory increasingly accepted by students and the PI, to the point of being used itself as an argument. It is in this sense that this theory, and its corollaries, became established during the session, and became "proven". It can be seen as some kind of proof by use, which is shown to be truthful through its efficient functionality and recurrence (Hersh, 2014). *The proof of the pudding is in the eating!* The establishment of theories thus acts here as an additional mathematical practice being put forth in the session.

Concluding remarks

The above analysis could be deepened and refined. However this sketch, albeit rapid, is significant: it illustrates how mathematics not only advanced in relation to its content, but also relative to its practices, and how both content and practices are intermingled in this advancement, going hand in hand, participating in the unfolding of the other. Content arises through mathematical practices, which in turn are geared toward specific contents. The need to talk about triangles and their angles as content gave rise to a specific *symbolisation* to represent it, which in turn helped to make sense of triangles, rectangle and their angles. The need to understand the 45^{o} angle as content, and the skepticism that it caused, led the *community of validation* to take shape, helping in return to give stronger meaning to the 45^{o} angle. The notion of the measure of the side of a square and its diagonal made emerge a question about their difference, becoming a *sub-problem* to inquire into, which led not only to understandings about their difference in the square, but also gave rise to the *theory* of the triangle's angle and its relation to its opposite side. And the list could go on, for each dimension of mathematical practices outlined, each linked to aspects of mathematical content covered in the session.

This extract is only a short glimpse into the nature of the work conducted regularly with groups like these in mental mathematics settings. As these mathematical practices continually unfolded, sessions after sessions and with different group of students, one cannot but be seized by how students plunged deeply into aspects at the heart of Bauersfeld's (1995, 1998) culture of mathematizing. The mathematical ideas emerge, are alive and flow dynamically. The students are strongly engaged, compelled to contribute, enthusiastic in responding to one another and to the ideas shared, and so forth.

However, above all, this was not staged nor planned. Mental mathematics sessions are usually designed to gather and then analyse students' strategies about various mental mathematics tasks. But classrooms are what they are, and students are who they are: asking them to solve mental mathematics tasks made emerge lots of questioning from them, and between them, about the mathematics. The tasks then became springboards for inquiry or "seeds" for explorations (Borasi, 1992, 1996; Schoenfeld, 2020), as opportunities for developing not only mathematical content but also mathematical practices. This is why the mental mathematics environment that students seem to be plunged into appeared to be worth reflecting on.

Although Papert never profoundly developed this concept, one is compelled to wonder if this environment of exploration happening in the mental mathematics sessions could represent, at least a little, what he had in mind with his *mathland*. Here, for example, is one quote taken from *The Children's machine*:

> It is thoroughly embedded in our culture that some of us have a head for figures while most don't, and accordingly, most people think of themselves as not mathematically minded. But what do we say about children who have trouble learning French in American schools? Whatever the explanation of their difficult, one certainly cannot ascribe it to a lack of aptitude for French – we can be sure that most of these children would have learned French perfectly well had they been born and raised in France. […] In the same way, we have no better reason to suppose that these children who have trouble with math lack mathematical intelligence than to suppose that the others lack "French intelligence". We are left with the question: What would happen if children who can't do math grew up in a Mathland, a place that is to math what France is to French? […] while what happened in the regular math class was more like the learning math as a foreign language. […] In the math class, where knowledge is not used but simply piled up like the bricks forming a dead building, there is no room for significant experimenting. (Papert, 1993, p. 64)

However bold, asserting that the mental mathematics environment in which students are plunged, for which the Grade-10 extract is an illustration of, could be aligned with a form of *mathland* has a nice ring to it. And, this ring leads one to become attentive to the strength of the engagement and the richness of the explorations undertaken. It seems to orient the focus, as Papert insisted, on doing mathematics more than on knowing mathematics. In this sense, doing mental mathematics becomes more about inquiring than about knowing facts (see PME-NA research report in Proulx, 2014, 2015a; or others e.g. in Proulx 2013, 2015b, 2019).

Although at first a curiosity, inquiring into the environment of the mental mathematics sessions seemed to help draw out both these content and practices dimensions, and their intertwinement in the advancement of mathematics in the sessions. And it might be where Papert's *mathland* fits in well, that is, in an environment where mathematics grows as much in terms of content as in terms of practices.

CONSTRUCTION OF ARITHMETIC-ALGEBRAIC THINKING IN A SOCIO-CULTURAL INSTRUCTIONAL APPROACH

CONSTRUCTION D'UNE PENSÉE ARITHÉMICO-ALGÉBRIQUE DANS UNE APPROCHE SOCIOCULTURELLE DE L'ENSEIGNEMENT

Fernando Hitt
Université du Québec à Montréal
hitt.fernando@uqam.ca

We present the results of a research project on arithmetic-algebraic thinking that was carried out jointly by a team in Mexico and another in Quebec[1]. The project deals with the concepts of variable and covariation between variables in the sixth grade at the elementary level and the first, second, and third years of secondary school – namely, children from 11 to 14 years old. We target secondary students (first year or K7) in this article. Our objective relates to the development of a gradual generalization in arithmetic-algebraic thinking in a socio-cultural approach to the learning of mathematics. We experimented with investigative situations using a paper-and-pencil approach and technology. We analyze the emergence, in this context, of a visual abstraction, the production of institutional and non-institutional representations, a sensitivity to contradiction, and, finally, the concepts of variable and of covariation between variables.

Key words: gradual generalization, socio-cultural approach, arithmetic-algebraic thinking.

Introduction: Steps of the Project

The project presented herein has been ongoing since 2008, carried out jointly by a team in Mexico and another in Quebec. The experimentation was done at the primary and secondary levels as well as in a pre-service teacher education program.

- Step 1: studies of the concept of function (Hitt, Gonzâlez & Morasse, 2008; Hitt & Gonzâlez-Martîn, 2015; Hitt & Quiroz, 2019; Passaro, 2009) among students in Secondary 2 and 3 (aged 13-15 years, K8 and K9 equivalents)
- Step 2: a study of the generalization of the concepts of variable and of covariation between variables in relation to arithmetic-algebraic thinking among Secondary 1 students in Quebec (aged 12-13 years, K7 equivalent) (Hitt, Saboya & Cortés, 2017, 2019a, 2019b) and among Secondary 3 students in Mexico.
- Step 3: studies of the concepts of variable and covariation between variables and of the generalization (in the transition from primary to secondary levels) related to arithmetic-algebraic thinking among 6th grade elementary students with learning difficulties in Mexico (11-12 years of age, K6 equivalent) (Hitt, Saboya & Cortés, 2017a, 2017b; Saboya, Hitt, Quiroz & Antoun, 2019).

Páez's (2004) doctoral thesis worked on teacher training with a teaching method based on collaborative learning, scientific debate, self-reflection, and the process of instutionalization (ACODESA) (see Hitt, 2007).

In order to use the same method in our project, which targeted elementary and secondary students, we had to use, in Step 1 of the project, the results obtained among Secondary 2 and 3 students to create theoretical tools which would allow us to better analyze students' spontaneous representations and their role in the resolution of non-routine situations.

[1] Joint project: Carlos Cortés (UMSNH); Samantha Quiroz (UAC); Fernando Hitt; and Mireille Saboya (UQAM).

(2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Step 2, which is the focus of this paper, will allow us to better understand the processes of abstraction[2] that trigger a generalization among students (in Secondary 1 in Quebec) in the transition from elementary to secondary levels as well as the construction of a cognitive structure related to arithmetic-algebraic thinking (which we elaborate further below).

We are currently in the process of analyzing the results of Step 3.

Theoretical framework: Socio-Cultural Approach to Learning

Our approach to the construction of knowledge is based on the notion of activity from Leontiev's (1978) activity theory. According to Leontiev, activity, mediated by mental reflection that situates a subject in the objective world, follows a system of social relations. Leontiev holds that an individual's activity depends on their place in society and their life circumstances (idem, p. 3). Further, activity is intimately related to a motive: "different activities are distinguished by their motives. The concept of activity is necessarily bound up with the concept of motive. There is no such thing as activity without a motive" (idem, p. 6). Hence, the activity of an individual in a society has a central role in the "subject-activity-object" relation (known as Leontiev's triangle) which, in turn, is part of a system of relations within the given society.

> It stands to reason that the activity of every individual depends on his place in society, on his conditions of life… The activity of people working together is stimulated by its product, which at first directly corresponds to the needs of all participants. (p. 3-6)

Engeström (1987, 1999) analyzes Leontiev's triangle as a model of the relation between subject, object, and artefact-mediation, and concludes that Leontiev's triangle does not capture all elements and relations of a system:

> I am convinced that in order to transcend the oppositions between activity and process, activity and action, and activity and communication, and to take full advantage of the concept of activity in concrete research, we need to create and test models that explicate the components and internal relations of an activity system… To overcome these limitations, the model may be expanded. (p. 29-30).

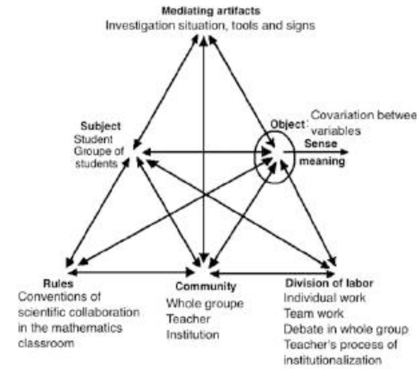
Voloshinov's (1929/1973) ideas about the construction of sign emphasize the importance of the collaborative work that enriches Leontiev and Engeström's theoretical approach: "[t]he reality of the sign is wholly a matter determined by that communication. After all, the existence of the sign is nothing but the materialization of that communication. Such is the nature of all ideological signs" (p. 13)

Building on the ideas above, we adapted Engelström's model (see Figure 1) while adhering to the ACODESA teaching method (Hitt, 2007). The mathematics classroom is viewed as a microsociety whose various members are the teachers, the students, the institution, and the tools used in the co-construction of knowledge through the resolution of investigative situations (physical materials, school textbooks, computers, etc.).

Collaborative work, communities of practice, and even societies, according to Engeström (1999), Legrand (2001), Leontiev (1978), and Wenger (1998), among others, involve a motive, rules, a division of labour among members, a mediation of artefacts, and interaction among the various actors (see Figure 1). In our case, given a mathematical task, we are interested in the co-construction of students' knowledge through the evolution of their representations in the context of an ACODESA method of teaching.

---

[2] The following is a translation of the definition of abstraction in the Larousse dictionary: an intellectual operation which consists in isolating by thought a characteristic of an object and considering it independently of the other characteristics of that object.



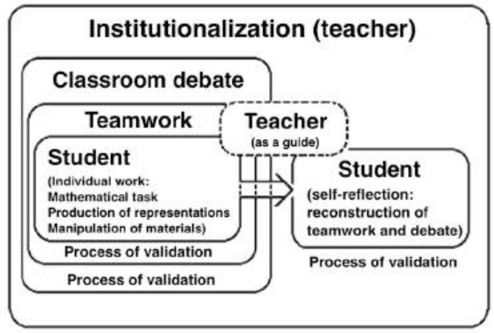


Figure 1. Engeström's (1999) model adapted to have covariation between variables as object; the various phases of the ACODESA method of teaching

Local Theoretical Framework and First Elements of Arithmetic-Algebraic Thinking

Given that we are primarily interested in the co-construction of knowledge, we searched for theoretical elements specific to moments of understanding or to the epistemic actions of Pontecorvo & Girardet (1993):

a) Higher-level methodological and metacognitive procedures; and

b) explanation procedures used for the interpretation of particular elements of the task.

To better understand the epistemic actions taking place during the resolution of a mathematical task, we use Rubinshtein's (1958) notions (cited in Davidov, 1990, p. 93-4) about the distinction between "visual empirical thought" and "abstract theoretical thought." In our project, just as in Rubinshtein and his group's, we are interested in the *gradual generalization* that occurs in a collaborative process of learning. For Davidov (idem), generalization is a process: "[i]f we mean the *process* of generalization, then the child's transition from a description of the properties of a particular object to finding and singling them out in a whole class of similar objects is usually indicated" (p. 5).

In the previous century, research about the transition from arithmetic to algebra focused on the concepts of epistemological obstacle (Vergaud, 1988), cuts (Filloy & Rojano, 1989), and gaps (Herscovics & Linchevski, 1994). Today, a change of paradigm purports that cognitive difficulties can be overcome (by a majority of students) with appropriate teaching. The discussion is one of a *continuum* rather than a *rupture* (Hitt, Saboya, and Cortés, 2017a). In this new paradigm, three types of approaches have emerged:

- "Early Algebra," which is based on a functional thinking approach with "an early inclusion of algebraic symbols as a valuable tool for early algebraic thinking" (Carraher, Schliemann, & Brizuela, 2000; Kaput, 1995, among others);
- "Algebraic nature of arithmetic" (Fujii 2003, among others); and
- a "development of algebraic thought" which acts as a support from which to delve deeper into arithmetic (Davidov, 1990; Kilpatrick, 2011; Radford, 2011a, 2011b, among others).

The Early Algebra approach prioritizes the use of institutional algebraic symbols to express covariation between variables and functions (tables of values and algebraic notations of the type $n \rightarrow n + 3$, for example). The second approach is similar to the first, albeit with a broader focus on the use of algebraic symbols in classical arithmetic tasks (see below in Section 3.2). However, the third approach relates to the use of general mathematical notions such as intuition, abstraction, and generalization in a socio-cultural learning of mathematics.

We situate ourselves in this third, socio-cultural type of approach (Engeström 1987, 1999; Leontiev, 1978; Voloshinov, 1929/1973) to the learning of mathematics (Radford's Theory of Objectification, 2011b). We propose the development of complex intuitive ideas by considering, for example, mathematical visualization (including "visual empirical thought" and "abstract theoretical thought," Rubinshtein, 1958), generalization (Davidov, 1990; Radford, 2011a), and the promotion of sensitivity to contradiction (Hitt, 2004) in mathematical activity. We worked on these general notions in elementary and secondary schools; specifically, we worked on the notions of variation and covariation between variables with the aim of developing arithmetic-algebraic thinking in students.

The notion of arithmetic-algebraic thinking is related to the development of a cognitive structure that we wish to promote in students, a structuring structure (a *habitus*) in the sense of Bourdieu (1980): the conditioning associated with a particular class of living conditions produces habitus, systems of durable and transposable dispositions, structured structures predisposed to function as structuring structures (p.88-89).

In our project, we attempt to show how to develop a structuring structure related to arithmetic-algebraic thinking in a mathematics classroom that is viewed as a microsociety.

Co-construction of Knowledge and a Sensitivity to Contradiction in the History of Mathematics

Szabó's (1960) studies of the history of mathematics detail elements that, during the Golden Age of the Greek civilization, contributed to the transformation of an empirical-visual mathematics into a definition-based on an axiomatic deductive science. We highlight the following elements:

a) The socio-political progress of the Greeks that allowed for the development of the art of rhetoric, polemical discussion, and critical thinking;

b) the influence of the philosophy of Parmenides of Elea and his disciple, Zeno of Elea (and, in particular, his paradoxes), on the Pythagoreans, who had an interest in mathematics; and

c) a "sensitivity to contradiction" when confronted with mathematical results developed by the Babylonians and the Egyptians, which did not always agree (e.g. the area of the disc).

Indeed, Szabó (idem) shows that Thales of Miletus' results were obtained in an empirical-visual manner. Szabó (idem) also gives the example of Plato's (4th century B.C.) Socratic dialog, Meno, which deals with the doubling of the area of a unit square. At the end of the dialog, a slave builds a square on the diagonal of the original unit square. It is easy, visually, to see that the surface area of the new square is double that of the first.

Parmenides' philosophy on the existence of being excludes non-being and provides the first reflections on logic and on the law of excluded middle. Szabó believes Parmenides influenced the Pythagoreans and that they, in turn, influenced mathematics, creating not only critical thinking but also a sensitivity to contradiction in mathematics. Szabó states:

The earliest Greek mathematicians, the Pythagoreans, borrowed the method of indirect demonstration from the Eleatic philosophy; consequently, the creation of deductive mathematical science can be attributed to the influence of the Eleatic philosophy. (p. 46)

Unfortunately, many of the Greeks' documents have been lost. Nevertheless, historians point to Euclid's Elements, which record the content of the Pythagoreans' books (Books VII, VIII, IX, and X). In Euclid's Elements, it is common to find theorems proved by contraposition. Vitrac (2012) confirms that indirect demonstrations (known as reduction to absurdity) are not uncommon in Euclid's Elements; they appear in a hundred or so propositions (p. 1).

One of Szabó's main assertions is that the transformation of mathematics into a deductive science (from the 5th century B.C. to the 3rd century B.C.) was accompanied by a transformation of mathematics into an anti-illustrative science. The visual demonstration of the duplication of the surface area of a unit square did not have a place in the new approach in Euclid's Elements. In Euclid, the illustration did not play a role in the visual demonstration process, but rather as an aid to the formal demonstration.

Historians report that the birth of algebra as a discipline was developed by the Persian al-Khwarizmi (790-850). Hence, while algebra did not originate with the Greeks, they did lay the groundwork for critical thinking, mathematical logic, indirect proof, and a sensitivity to contradiction. This type of thinking is, historically, an important precursor to the development of algebra.

How can we draw inspiration from the history of mathematics in the classroom? How can these historical elements of different cultures be integrated into the mathematics classroom?

Sensitivity to Contradiction in the Construction of Arithmetic-Algebraic Thinking

Research from the 1980s offers a glimpse into students' difficulties in solving algebraic problems. We consider, as an example, Fujii's (2003) study of the success rates among elementary and high-school students in the United States and in Japan in solving the following two problems:

Problem 1. Mary has the following problem to solve: "Find value(s) for x in the expression: x + x + x = 12" She answered in the following manner. a. 2, 5, 5; b. 10, 1, 1; c. 4, 4, 4 Which of her answer(s) is (are) correct? (Circle the letter(s) that are correct: a,b,c)	Problem 2. Jon has the following problem to solve: "Find value(s) for x and y in the expression: x + y = 16" He answered in the following manner. a. 6, 10; b. 9, 7; c. 8, 8 Which of his answer(s) is (are) correct? (Circle the letter(s) that are correct: a, b, c) State the reason for your selection.

> It is also important to note that it is rare for students to get both problems correct, which was also consistent with the data for both countries [USA and Japan]. Let me select the Athens (GA) 6th, 8th and 9th graders from the American data, simply because these students have a common educational environment. The percentages of correct answers for 6th, 8th, and 9th grade are 11.5%, 11.5% and 5.7% respectively. For Japanese students, the correct response from 5th, 6th, 7th, 8th, 10th and 11th grades are 0%, 3.7%, 9.5%, 10.8%, 18.1% and 24.8% respectively (Fujii, 1993).

These problems help distinguish between students with a *conception* of the role of a variable in an algebraic expression and those who had formed the *concept* of a variable.

By analyzing the tasks Fujii (2003) proposes, we see they had been designed as assessment tools (to detect the conceptions students had formed). The design of a task meant to promote learning based on students' conceptions, however, is a whole other matter. In what follows, we present two examples of sensitivity to contradiction.

First example. Sensitivity to contradiction in the process of solving the following:

a) Solve this inequality: $0.2(0.4x + 15) - 0.8x \leq 0.12$
b) Verify that $x = 10$ is an element of the solution set.

In designing this activity, we took into account Brousseau's (1997) notion of epistemological obstacle in the learning of decimal numbers: an error that results when knowledge that, in other situations, had been valid and effective proves to be erroneous in a new situation. In this case, an error occurs when knowledge about multiplication of natural numbers is applied to multiplication of decimal numbers. We take advantage of this error to promote a richer mathematical structure: a sensitivity to contradiction. Here is an example of a student's work:

$$0{,}2 \times 0{,}4 = 0{,}8$$

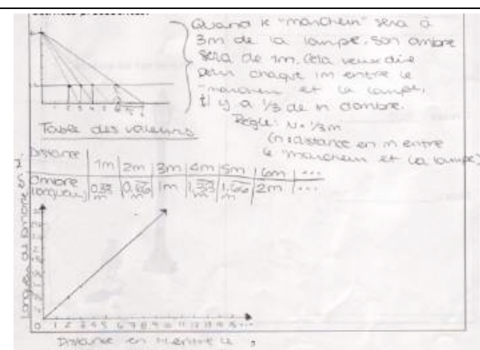
$$0{,}2 \times 15 = 0{,}30$$

	Question 3. Study of the inequality: $(0.2)[0.4x + 1.5] - 0.8x \leq 0.12$ a) For which values of x is the inequality satisfied? The inequality is satisfied for 	b) Verify that the inequality is satisfied for $x = 10$: 
We note the student made the mistakes anticipated by the researcher. The student had proposed the solution "st [solution] = 0,12," but after addressing question b), the student noticed the contradiction. The student retraced his steps to resolve the contradiction in part a). He spotted and overcame the cognitive contradiction, even if, formally, the contradiction remained in item b). This shows the student is sensitive to contradiction.

Second example. The *Shadow Situation* was one of five situations proposed in a month-and-a-half-long experiment with students in their third year of high-school. The five (sequential) situations were worked on in connection with the ACODESA method and with the goal of developing the concepts of covariation between variables and of function (Hitt & González-Martín, 2015; Hitt & Morasse, 2009). The following is a translation of the Shadow Situation given to students:

> Suppose we have a source of light with a height of 6 meters (a street light). We consider the shadow formed when a when a person who is 1.5 meters tall walks down the street. We are interested in the relationships between the quantities involved.
>
> 
>
> *Are some of the quantities dependent on one another? Which ones?*
> Select two quantities that depend on one another and describe the phenomenon with the various representations you used in previous activities.

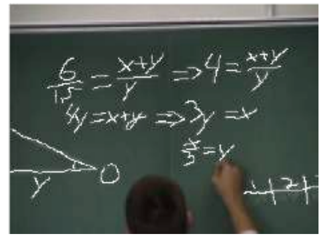
Phase 1: Individual work. Two girls work on their own[3] to understand the task. One of them represented the situation through a proportional drawing. Starting with an empirical-visual thought, she found a relationship between the quantities "distance travelled by the person" and "length of the shadow."



Phase 2: Teamwork (Prusak, Hershkowits, & Schwarts, 2013, suggest groups of two to three). The two girls produce a verbal description of a relationship, an algebraic expression, and a graphical representation of the situation.

---

[3] Translation of text in top right corner of image: [w]hen the "walker" will be at 3m from the lamp, his shadow will be 1m. This means that for every 1m between the "walker [sic] and the lamp, there is 1/3 of a m of shadow.
*Rule: N * 1/3m (n [*sic*]: distance in m between the "walker [*sic*] and the lamp)*
Table of values, first row: distance; table of values, second row: shadow (length)
*Graph, x-axis: distance in M [*sic*] between [*sic*]; graph, y-axis: length of the shadow in M [*sic*]*



Phase 3: Classroom debate. One group of students failed to find an answer due to algebraic errors. Upon seeing the two girls' results, this group manages to construct an algebraic approach by using similar triangles.

Phase 4: Self-reflection. The instructor collects everything the students produced and re-assigns them the situation as homework, this time with the instruction to re-create the work done in class. The following is what one of the girls (mentioned above) produced as a reconstruction of what had been discussed in class:

Reconstruction of work done in teams	Reconstruction of the classroom debate
  [4]  [5]	(1) (2) (3)  [6]

She reconstructed with no difficulty what she had done numerically and visually with her team-mate. Unfortunately, when she wanted to reconstruct the boys' algebraic process, she made a mistake and failed to come up with a solution. In her drawing (the one on the right), she expressed a feeling of unease in the face of a contradiction she couldn't overcome. This shows she had formed a sensitivity to contradiction. From a cognitive standpoint, *a sensitivity to contradiction is an awareness of contradiction accompanied by a sense of unease, and its resolution by a sense of happiness.*

These examples demonstrate the importance of students' spontaneous representations. Given these findings on students' spontaneous representations, Hitt and Quiroz (2019) proposed the notion of ***socially-constructed representation***, one which materializes through the evolution of students' functional-spontaneous representation as it emerges in individual work and is then discussed in a team, in large groups, and in self-reflective work. According to Hitt and Quiroz (2019, p.79),

> [a] socially-constructed representation is one that emerges in individuals when given a non-routine activity; the actions in the interaction with the situation have functional (mental, oral, kinesthetic, schematic) characteristics and are related to a spontaneous (external) representation. The representation is functional in the sense that the student needs to make sense of the situation, and it is spontaneous because it naturally occurs in an attempt to understand and solve the non-routine situation. [Translation]

The Investigative Situation (the Task): Key Element in the Co-Construction of Mathematical Knowledge

The theories of didactical situations (Brousseau, 1998), of "problem solving" (Mason, Burton, & Stacey, 1982; Schoenfeld, 1985), and of Realistic Mathematical Education from Freudenthal (1991) have prompted changes in curricula worldwide. There is a break from the classical approach – that is, from "definition-theorem-exercises and problems" instruction. Situational problems, problems in general, and contextualized problems have a fundamental role to play in the new approach. In light of these theories, task design is viewed as central for overcoming cognitive barriers. A new era came for

[4] Translation: Rule: LoS [Length of Shadow] = n * 1/3

[5] In this table of values, the entries in the first row correspond to "n (dis) [distance]" and those in the second row to "LdO [Longueur de l'Ombre, or Length of Shadow]."

[6] Translation of items (1), (2), and (3) in the image: (1) 6 divided by 1.5 gives 4, so we can reduce. To get rid of the division, multiply y. (2) Homothety of the big triangle to the small one. (3) (I don't know anymore ☹)

the organization and role of the task in mathematics instruction, in situational problems related to creativity, and in mathematical modelling (Blum, Galbraith, Henn, & Niss, 2007; Hitt & González-Martín, 2015; Hitt, Saboya, & Cortés, 2017; Hitt & Quiroz 2019; Lesh & Zawojewski, 2007; Margolinas, 2013).

The activities we designed are related to the ACODESA teaching method in a socio-cultural approach to mathematics instruction. We call our activities "investigative situations":

> An **investigative situation** consists of different tasks that follow the steps of the ACODESA method. The tasks attempt to promote, first and foremost, the emergence of non-institutional or institutional representations, empirical-visual thinking related to diversified thinking (that is, divergent thinking), conjecture, prediction, and validation. In second and third stages (teamwork and classroom debates), we try to promote abstract thinking that includes sensitivity to contradiction as well as an evolved version of the representations and characteristics formed in the first stage. In a fourth stage, students re-construct what had been done in class so as to solidify the knowledge they had formed. Finally, the teacher reviews students' various solutions and presents the institutional position vis-à-vis the content considered in the situation. [Translation]

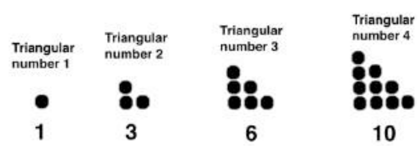
The design of investigative situations follows an organization such as that outlined in Hitt, Saboya, and Cortés (2017b).

Variation and Covariation between Variables: an Example with Polygonal Numbers

We now present the first step of an investigative situation that involves polygonal numbers and which is targeted towards students in their first year of high-school. This step consisted of five questions to be solved with paper and pencil. The second step had students use technology to validate their conjectures. In total, the situation was eight pages long. The following is a translation from French:

Step 1 (Individual work, followed by teamwork; paper-and-pencil approach)

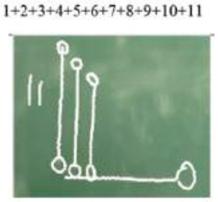
A long, long, long, long time ago (around 520 B.C.), a mathematician called Pythagoras founded a school on an island in ancient Greece. He and his students were fascinated by both numbers and geometry. One of their ideas consisted of representing numbers by geometric figures. They called these *polygonal numbers*. For example, they noticed that certain numbers could be represented by triangles. Thus, 1, 3, 6, and 10 are the first four triangular numbers since they can be represented by points arranged in triangles as follows:



1) Observe these numbers carefully. What is the fifth triangular number? Represent it. Explain how you did this.
2) How do you think a triangular number is constructed? What do you observe?
3) What is the 11th triangular number? Explain how you found its value.
4) You must write a SHORT email to a friend describing how to calculate the triangular number 83. Describe what you would write. YOU DON'T HAVE TO DO ANY CALCULATIONS!
5) And how would you calculate any triangular number? (We want a SHORT message here as well.)

Teams' Responses to Questions 1, 2, and 3

1+2+3+4+5+6+7+8+9+10+11

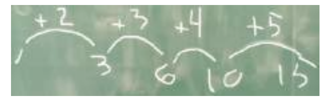


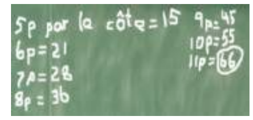
11+10+9+8+7+5+4+3+2+1

In this first step, we wanted to promote empirical-visual thinking (Rubinshstein, 1973) and generalization (Davidov, 1990; Radford, 2011). Students (in teams G1 and G3) naturally shifted from a visual approach to an arithmetic procedure (an epistemic action). For example, to calculate T_{11}, they wrote 1+2+3+4+5+6+7+8+9+10+11.

Team G2 first moved from a concrete visual approach to a more general visual approach and then to an arithmetic procedure (an epistemic action). Hence, for T_{11}, they wrote 11+10+9+8+7+6+5+4+3+2+1.

We note the abandonment of the iconic representation by one student (from team G4) who, during the classroom debate, switched from a detached visual approach to the polygonal configurations to an iterative calculation which he had not discussed with his teammates (what Rubinshtein would term theoretical abstract thinking). Team G4 used this final strategy, along with Excel, to tackle the fifth question of the second step of the investigative situation.





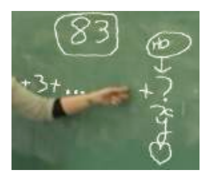
This shift shows the importance of teamwork and of Yan's reflection as he organized his thoughts (in what Vygotsky, 1932/1962, would call inner speech) so as to communicate them to the group (Voloshinov's construction of sign). Yan needed to make himself understood by the rest of the class.

Team Responses to Questions 4 and 5 and First Classroom Debate

The following are the responses given by each team in the first classroom debate:

	Team's response to question 4	Team's response to question 5
G1	We add all the numbers from 1+2+3... all the way to the number of points on the side.	We add all the numbers from 1+2+3... all the way to the number of points on the side.
G2	Add up the numbers from 1 to 83.	You add up the numbers from there?
G3	You have to do 83+82+81… all the way to 1.	Calculate the last diagonal column and calculate by doing -1 to the number. E.g. 15th, 15+14+13… etc.
G4	You have to do; 1+2+3+4+5+6+7+8… +83 and this will give you the answer.	You put the same number on the other sides and then you add up 1+2+3+4+5+6… until you get to your number and your answer is the triangular number.

During the classroom debate, the researcher asked what answers had been written in response to question 5 (see responses above), which asked for a short message describing how to find any triangular number. The students first suggested the sum "1+2+3 all the way to your number." The researcher intervened: how can I write a number I don't know? Different proposals emerged. The first was to write "?" ; afterwards, they proposed "x" or "y." The teacher asked whether a heart could be used: "♥." One student replied that they could use anything that wasn't a number.



The students transitioned from empirical-visual thinking to abstract arithmetic-algebraic thought. The variable was first expressed in words: "all the way to your number." Then, it was expressed as "?," then, as "x" or "y," and, finally: "we can use anything that isn't a number."

Output produced by team G4 (during teamwork and during the classroom debate)			
Teamwork and spontaneous generalization	Surprise at finding a decimal number as T_{100} and team discussion towards generalization (with Excel)	General computation of a triangular number presented to the rest of the class	Generalization obtained through classroom debate
(83+1)÷2= 42 42x 83 =	100 ((100+1)÷2=5x X x 100 =	(46+1)÷2 = 47 ÷ 2 =23,5 46x23,5=1081	(x+1)÷2=y y·X=

We note that each abstraction came with a certain type of generalization. The processes of abstraction were of the following types: *visual abstraction, arithmetic abstraction, emergence of the concept of a variable, emergence of the concept of covariation between variables*.

45 Days Later: Phase of Self-Reflection (Reconstruction)

During this step, Yan, the student who found an algebraic expression for triangular numbers, tried to remember his formula but got it wrong. He wrote: ***(Row*2)-1=y*** and ***(Row*y=triangular number***. During the pentagonal number activity which we had given him as a challenge, he wrote that ***Row*(Row + (Row * 0.5 – 0.5)) = pentagonal number***. He found this expression by using the same strategy he had used 45 days beforehand to deal with triangular numbers. This expression is equivalent to the institutional one: $P_n = \frac{n(3n-1)}{2}$.

During this process of self-reflection, another student obtained the following in response to the question about triangular numbers: ***Odd number: (row + 1) ÷ 2 * row = triangular number.*** This expression is equivalent to $T_n = \frac{n(n+1)}{2}$ (when restricted to odd numbers).

Conclusions

In this paper, we wanted to show the various elements needed for the construction of arithmetic-algebraic thinking. Building on a few ideas from the history of mathematics, from a socio-cultural theory of learning, and from the ACODESA teaching method, we have shown that for the construction of arithmetic-algebraic thinking, various elements of the mathematics classroom need to be taken into account: the role of the task (investigative situations) in the acquisition of knowledge, communication in the classroom, mathematical visualization, the role of non-institutional and institutional representations, generalization, conjecture, sensitivity to contradiction, validation, and proof.

Our approach seeks to develop and enrich an association between arithmetic and algebra (*a habitus*) so as to promote the construction of a structuring structure, in the sense of Bourdieu (1980), that is related to arithmetic-algebraic thinking and which supports not only algebra, but also an enrichment of the cognitive structure of arithmetic tasks.

Further, we observed the emergence of the concepts of variable and of covariation between variables through the process of co-construction of knowledge.

The results of our studies have encouraged us to experiment new investigative situations (following the ACODESA method) in grade 6 classrooms. So far, we have suggested five investigative situations of different types and which require electronic tablets: Marcel's Restaurant, The El Dorado Jewelry Shop, Windows, The Garden and the Pumpkins, and Rectangles and Disks. We are currently analyzing the results.

CONSTRUCTION D'UNE PENSÉE ARITHÉMICO-ALGÉBRIQUE DANS UNE APPROCHE SOCIOCULTURELLE DE L'ENSEIGNEMENT

CONSTRUCTION OF ARITHMETIC-ALGEBRAIC THINKING IN A SOCIO-CULTURAL INSTRUCTIONAL APPROACH

Fernando Hitt
Université du Québec à Montréal
hitt.fernando@uqam.ca

Dans cet document, nous présentons les résultats d'un projet de recherche sur la pensée arithmético-algébrique, qui a été réalisé conjointement par une équipe au Mexique et une autre au Québec[7]*. Le projet porte sur le concept de variable et de covariation entre variables dans les classes de 6e année du primaire, 1re, 2e et 3e du secondaire, à savoir les enfants de 11 à 14 ans. Nous allons ici cibler les élèves de 1re secondaire. Notre objectif porte sur le développement d'une généralisation graduelle liée à la pensée arithmético-algébrique dans une approche socioculturelle de l'apprentissage des mathématiques. Nous avons expérimenté avec des situations d'investigation dans une approche papier-crayon, puis avec la technologique. Dans ce contexte, nous analysons : l'émergence d'une abstraction visuelle, la production de représentations institutionnelles et non institutionnelles, une sensibilité à la contradiction et, enfin, l'émergence de la notion de variable et de covariation entre variables.*

[7] Projet en collaboration : Carlos Cortés (UMSNH); Samantha Quiroz (UAC); Fernando Hitt et Mireille Saboya (UQAM).

Mots-clés : Généralisation graduelle, approche socioculturelle, pensée arithmético-algébrique.

Introduction (étapes du projet)

Le projet que nous vous présentons ci-dessous a été réalisé conjointement par une équipe du Mexique et un autre du Québec dès 2008. L'expérimentation a été faite au primaire, au secondaire et à la formation des maîtres.

- 1re étape : Étude du concept de fonction (Hitt, Gonzâlez & Morasse, 2008; Hitt & Gonzâlez-Martîn, 2015; Hitt & Quiroz, 2019; Passaro, 2009) chez les élèves de 2e et 3e secondaire (13-15 ans équivalentes à K8 et K9).
- 2e étape : Étude de la généralisation liée à la notion de variable et de la covariation entre variables en lien avec la pensée arithmético-algébrique chez les élèves du 1re secondaire au Québec (12-13 ans équivalente à K7) (Hitt, Saboya & Cortés, 2017, 2019a, 2019b), et 3e secondaire au Mexique.
- 3e étape : Étude des notions de variable, de covariation entre variables et de la généralisation (transition primaire-secondaire) en lien avec la pensée arithmético-algébrique chez des élèves en difficulté d'apprentissage de la 6e année du primaire au Mexique (11-12 ans équivalente à K6) (Hitt, Saboya & Cortés, 2017a, 2017b; Saboya, Hitt, Quiroz et Antoun, 2019).

Dans sa thèse de doctorat, Páez (2004) a travaillé à la formation des maîtres avec une méthode d'enseignement basée sur l'apprentissage collaboratif, le débat scientifique, l'autoréflexion et le processus d'institutionnalisation (ACODESA) (voir Hitt, 2007).

Afin de pouvoir utiliser la même méthode dans notre projet, mais cette fois avec des élèves au primaire et au secondaire, nous avons dû, pendant la 1re étape du projet, construire des outils théoriques avec les résultats obtenus auprès d'élèves de 2e et 3e secondaire. Ces outils nous permis par la suite de mieux analyser les représentations spontanées des élèves et leur rôle dans la résolution de situations non routinières.

La 2e étape, celle à laquelle nous allons nous attarder, va nous permettre de mieux comprendre les processus d'abstraction[8] qui d'déclenchent une généralisation chez les élèves (1er secondaire au Québec) dans la transition primaire-secondaire et sur la construction d'une structure cognitive liée à la pensée arithmético-algébrique (nous allons préciser plus loin).

Nous sommes présentement en train d'analyser les résultats de la 3e étape.

Cadre théorique général (approche socioculturelle de l'apprentissage)

Notre approche sur la construction des connaissances est basée sur la notion d'activité de Leontiev (1978) liée à sa théorie de l'activité. Selon Leontiev, l'activité, médiatisée par la réflexion mentale, qui a comme fonction d'orienter le sujet dans le monde objectif, obéit au système des relations dans la société. Pour Leontiev, l'activité de chaque individu dépend de sa place dans la société, de ses conditions de vie (idem, p. 3). Selon Leontiev, l'activité est intimement liée à un motif : « different activities are distinguished by their motives. The concept of activity is necessarily bound up with the concept of motive. There is no such thing as activity without a motive » (idem, p. 6). Ainsi, l'activité d'un individu dans une société, a un rôle central dans la relation « subject-activity-object » (connue actuellement comme le triangle de Leontiev) et celle-ci est une partie d'un système de relations dans cette société.

> It stands to reason that the activity of every individual depends on his place in society, on his conditions of life… The activity of people working together is stimulated by its product, which at first directly corresponds to the needs of all participants. (p. 3-6)

[8] La définition d'abstraction du dictionnaire Larousse est : Opération intellectuelle qui consiste à isoler par la pensée des caractères de quelque chose et à le considérer indépendamment des autres caractères de l'objet.

Engeström (1987, 1999) analyse le triangle de Leontiev comme un modèle de la relation entre le sujet, l'objet et les artefacts de médiation, et conclut que le triangle de Leontiev ne montre pas les différents éléments du système et ses relations :

> I am convinced that in order to transcend the oppositions between activity and process, activity and action, and activity and communication, and to take full advantage of the concept of activity in concrete research, we need to create and test models that explicate the components and internal relations of an activity system… To overcome these limitations, the model may be expanded. (p. 29-30).

Les idées de Voloshinov (1929/1973) sur la construction du signe : "The reality of the sign is wholly a matter determined by that communication. After all, the existence of the sign is nothing but the materialization of that communication. Such is the nature of all ideological signs" (p. 13), accentuent l'importance du travail collaboratif qui enrichit l'approche théorique de Leontiev et d'Engeström.

En nous appuyant sur les idées précédentes, nous avons adapté le modèle d'Engeström (voir Figure 1) tout en respectant la méthode d'enseignement ACODESA (Hitt, 2007). La classe de mathématiques est considérée comme une microsociété dont les différents acteurs sont les maîtres, les élèves, l'institution et différents types d'outils à utiliser pendant la co-construction des connaissances à travers la résolution de situations d'investigation (matériel physique, manuels scolaires, ordinateurs, etc.).

Selon Engeström (1999), Legrand (2001), Leontiev (1978), Wenger (1998), entre autres, dans un travail collaboratif, ou dans une communauté de pratique, ou même dans une société, il doit y avoir un motif, des règles, une division du travail entre les membres, la médiation des instruments, et une interaction entre les différents acteurs (voir Figure 1). Dans notre cas, étant donné une tâche mathématique, nous sommes intéressés à la co-construction des connaissances des élèves à travers l'évolution de leurs représentations en suivant la méthode d'enseignement ACODESA.

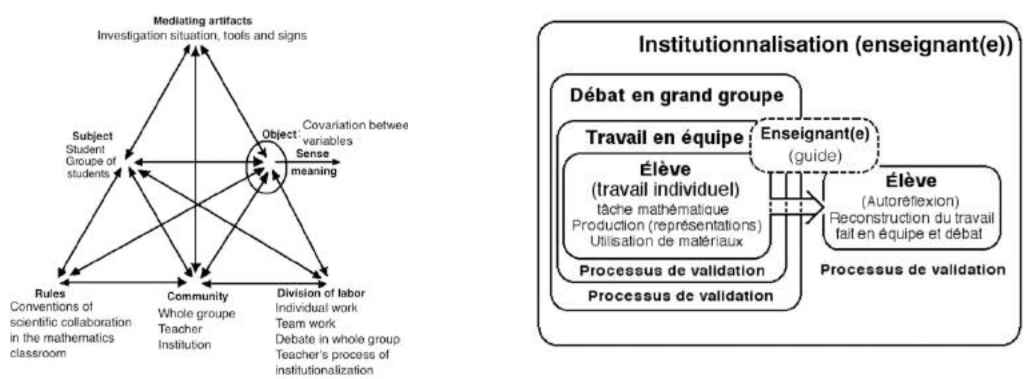

Figure 1. Adaptation du modèle d'Engeström (1999) ayant comme objet la covariation entre variables et les différentes phases de la méthode d'enseignement ACODESA

Cadre théorique local et premiers éléments de la pensée arithmético-algébrique

Étant donné que nous nous intéressons particulièrement à la co-construction des connaissances, nous avons cherché des éléments théoriques spécifiques sur les moments de compréhension ou d'actions épistémiques de Pontecorvo & Girardet (1993) :

a) [A] higher level methodological and metacognitive procedures,
b) Explanation procedures used for the interpretation of particular elements of the task.

Pour mieux comprendre les actions épistémiques lors la résolution d'une tâche mathématique, nous allons utiliser les notions de Rubinshtein (1958) (cité par Davidov, 1990, p. 93-94) sur la distinction entre « visual empirical though » et « abstract theoretical though ». Dans notre projet tout comme Rubinshtein et son équipe, nous sommes intéressés *à une généralisation graduelle* dans un processus d'apprentissage collaboratif. Pour Davidov (idem), la généralisation c'est un processus : If we mean the *procces* of generalization, then the child's transition from a description of the properties of a particular object to finding and singling them out in a whole class of similar objects is usually indicated. (p. 5)

Au siècle dernier, les recherches portant sur la transition de l'arithmétique à l'algèbre étaient centrées sur la notion d'obstacle épistémologique (Vergaud, 1988), coupure (Filloy & Rojano, 1989) ou écart (Herscovics & Linchevski, 1994). Aujourd'hui, il a eu un changement de paradigme qui supporte l'idée que les difficultés cognitives peuvent être surmontées (par une grande majorité des élèves) par un enseignement approprié. On parle d'un *continuum* au lieu d'une *rupture* (Hitt, Saboya et Cortés, 2017a). Trois types d'approches se sont manifestés dans ce nouveau paradigme. Ce sont :

- « Early Algebra », basée sur une approche de la pensée fonctionnelle avec « un early inclusion of algebraic symbols as a valuable tool for early algebraic thinking » (Carraher, Schliemann & Brizuela, 2000; Kaput, 1995, entre autres) ;
- « Algebraic nature of arithmétique » (Fujii 2003, entre autres);
- « Développement d'une pensée algébrique » qui donne un support pour approfondir l'arithmétique (Davidov, 1990; Kilpatrick, 2011; Radford, 2011a, 2011b, entre autres).

L'approche Early Algebra donne une priorité à l'utilisation de symboles algébriques institutionnels pour exprimer la covariation entre variables et les fonctions (table de valeurs, notations algébriques de la forme $n \rightarrow n + 3$ par exemple). La 2^e^ approche est similaire à la 1^re^, mais avec un domaine plus élargi sur l'utilisation de symboles algébriques dans les tâches classiques de l'arithmétique (voir plus loin, section 3.2). Par contre, le 3^e^ est liée à l'utilisation des notions mathématiques globales comme l'intuition, l'abstraction et la généralisation dans une apprentissage socioculturelle des mathématiques.

Nous nous situons plutôt dans cette 3^e^ approche de type socioculturel (Engeström 1987, 1999; Leontiev, 1978; Voloshinov, 1929/1973) de l'apprentissage des mathématiques (théorie de l'objectivation de Radford, 2011b). Nous proposons le développement d'idées intuitives complexes, en prenant en considération, par exemple, la visualisation mathématique (en incluant « visual empirical thought » et « abstract theoretical thought », Rubinshtein, 1958), la généralisation (Davidov 1990; Radford 2011a) et la promotion d'une sensibilité à la contradiction (Hitt, 2004) dans l'activité mathématique. Ces notions générales, nous les avons travaillées à l'école primaire et secondaire, spécifiquement avec les notions de variation et de covariation entre variables, avec l'objectif de développer chez les élèves une pensée arithmético-algébrique.

Cette notion de pensée arithmético-algébrique est liée au développement d'une structure cognitive que l'on veut promouvoir chez les élèves, structure structurante (un *habitus*) dans le sens de Bourdieu (1980):

> Les conditionnements associés à une classe particulière de conditions d'existence produisent des habitus, systèmes de dispositions durables et transposables, structures structurées prédisposées à fonctionner comme structures structurantes… (p. 88-89)

Notre projet essaie de montrer comment développer cette structure structurante dans la classe de mathématique vue comme une microsociété en relation à la pensée arithmético-algébrique.

La co-construction des savoirs et la sensibilité à la contradiction dans l'histoire

Les recherches de Szabó (1960) sur l'histoire des mathématiques fournissent les éléments qui ont participé à la transformation pendant la période d'or des Grecs d'une mathématique empirico-visuelle en une science déductive basée sur des définitions et des axiomes. Nous retiendrons :

a) L'avancée sociopolitique des Grecs qui leur a permis de développer l'art de la rhétorique, la discussion polémique et la pensée critique,

b) L'influence de la philosophie de Parménide d'Élée et de son disciple Zénon d'Élée (avec ses paradoxes) sur les pythagoriciens qui s'intéressaient aux mathématiques.

c) La « sensibilité à la contradiction » face aux résultats mathématiques développés par les Babyloniens et les Égyptiens, et qui ne concordaient pas toujours (par exemple l'aire du disque).

En effet, Szabó (*idem*) nous montre que les résultats de Thalès de Milet avaient été obtenus de manière empirico visuelle. Szabo (*idem*) nous donne aussi l'exemple du dialogue de Ménon de Platon (IV^{e} siècle av. J-C.) traitant de la duplication de l'aire d'un carré unitaire. À la fin du dialogue, un esclave construit un carré sur la diagonale du carré unitaire original. On peut facilement constater visuellement que l'aire de ce nouveau carré est le double de l'aire du premier.

La philosophie de Parménide sur l'existence de l'être exclut le non-être, et fournit les premières réflexions sur la logique et le principe du tiers exclu. Szabo pense que Parménide a eu une influence sur les pythagoriciens et qu'ils ont à leur tour influencé les mathématiques, créant non seulement une pensée critique, mais aussi une sensibilité à la contradiction en mathématiques. Szabó affirme:

> The earliest Greek mathematicians, the Pythagoreans, borrowed the method of indirect demonstration from the Eleatic philosophy; consequently, the creation of deductive mathematical science can be attributed to the influence of the Eleatic philosophy. (p. 46).

Malheureusement, de nombreux documents des Grecs ont été perdus; cependant, les historiens nous informent que dans les Éléments d'Euclide se trouve le contenu des livres conçus par les pythagoriciens, qui ont été transformés par Euclide (livres VII, VIII, IX et X). Dans les Éléments d'Euclide, il est habituel de trouver des théorèmes prouvés par contraposition. Vitrac (2012) affirme: Les démonstrations indirectes (dites par réduction à l'absurde) ne sont pas rares dans les Éléments d'Euclide; ils apparaissent dans une centaine de Propositions (p. 1).

L'une des principales thèses de Szabó est celle que la transformation des mathématiques en science déductive (du V^{e} siècle av. J-C., au III^{e} siècle av. J-C.), s'est également transformée en science anti-illustrative. La démonstration visuelle sur la duplication de la surface d'un carré unitaire n'avait plus sa place dans la nouvelle approche dans les Éléments d'Euclide. Avec Euclide, la figure a joué un rôle d'aide à la démonstration formelle et non aux processus visuels de démonstration.

Les historiens nous signalent que la naissance de l'algèbre en tant que discipline a été développée par le perse al-Khwarizmi (790-850). Cela nous montre que bien que l'algèbre ne soit pas originaire des Grecs, ils ont jeté les bases de la pensée critique, de la logique mathématique, de la preuve indirecte et d'une sensibilité à la contradiction. Ce type de pensée est historiquement important avant le développement de l'algèbre.

Comment s'inspirer de l'histoire de la mathématique dans la classe? Comment intégrer ces éléments historiques des différentes cultures dans la classe de mathématiques?

Sensibilité à la contradiction dans la construction de la pensée arithmético-algébrique

Les résultats des recherches des années 1980, nous ont donné un aperçu des difficultés des élèves face à la résolution de problèmes de type algébrique. Nous allons prendre comme exemple Fujii (2003) qui montre les pourcentages de réussite des élèves du primaire et du secondaire des États-Unis et du Japon par rapport à deux problèmes :

Problem 1. Mary has the following problem to solve: "Find value(s) for x in the expression: x + x + x = 12" She answered in the following manner. a. 2, 5, 5; b. 10, 1, 1; c. 4, 4, 4 Which of her answer(s) is (are) correct? (Circle the letter(s) that are correct: a,b,c)	Problem 2. Jon has the following problem to solve: "Find value(s) for x and y in the expression: x + y = 16" He answered in the following manner. a. 6, 10; b. 9, 7; c. 8, 8 Which of his answer(s) is (are) correct? (Circle the letter(s) that are correct: a, b, c) State the reason for your selection.

It is also important to note that it is rare for students to get both problems correct, which was also consistent with the data for both countries [USA and Japan]. Let me select the Athens (GA) 6th, 8th and 9th graders from the American data, simply because these students have a common educational environment. The percentages of correct answers for 6th, 8th, and 9th grade are 11.5%, 11.5% and 5.7% respectively. For Japanese students, the correct response from 5th, 6th, 7th, 8th, 10th and 11th grades are 0%, 3.7%, 9.5%, 10.8%, 18.1% and 24.8% respectively (Fujii, 1993).

Ces problèmes permettent de différencier les élèves qui ont une *conception* du rôle de l'inconnue dans une expression algébrique de ceux qui ont construit le *concept* d'inconnue.

En analysant les tâches proposées par Fujii (2003), nous voyons que celles-ci ont été conçues pour l'évaluation (détection des conceptions). Construire une tâche pour promouvoir l'apprentissage à partir des conceptions des élèves est tout autre chose. Voici deux exemples sur la sensibilité à la contradiction.

Premier exemple. Sensibilité à la contradiction dans un processus de résolution de :

a) Résoudre l'inégalité: $0,2\ (0,4x + 15) - 0,8x \leq 0,12$
b) Vérifier que $x = 10$ est un élément de l'ensemble solution.

Dans l'élaboration de cette activité, nous avons tenu compte de la notion d'obstacle épistémologique de Brousseau (1997) sur l'apprentissage des nombres décimaux. L'erreur est conçue comme une connaissance qui a été efficace, valable dans d'autres situations, mais qui s'avère erronée dans une nouvelle situation. Dans ce cas, c'est la connaissance de la multiplication des nombres naturels qui appliquée aux nombres décimaux va entrainer une erreur. Nous profitons de l'erreur pour promouvoir une structure plus riche de la mathématique : la sensibilité à la contradiction. Voici un exemple d'une production d'un élève :

$$0,2 \times 0,4 = 0,8$$

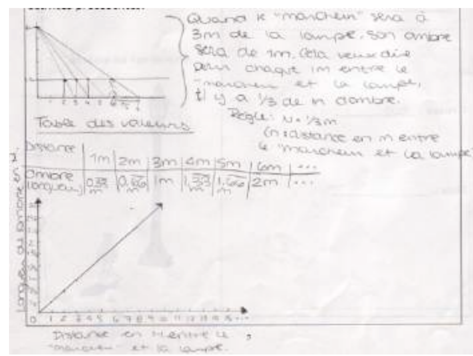
$$0,2 \times 15 = 0,30$$

Question 3. Étude de l'inégalité : $(0,2)[0,4x+15] - 0,8x \leq 0,12$ a) Pour quelle valeur de x, l'inégalité est elle satisfaite? $0,8x + 0,30 - 0,8x \leq 0,12$ $- 0,72x \leq 0,12 - 3$ $0,72x \geq 2,88$ $x \geq \frac{2,88}{0,72} = 0,4$ l'inégalité est satisfaite pour $x \geq 0,4$ $[0,4 ; +\infty[$	b) Vérifier que l'inégalité est satisfaite pour $x=10$. $(0,2)[0,4 \times 10 + 15] - 0,8 \times 10 \leq 0,12 \Leftrightarrow$ $0,2 [4+15] - 8 \leq 0,12 \Leftrightarrow$ $0,8 + 0,30 - 8 \leq 0,12 \Leftrightarrow$ $1,10 - 8 \leq 0,12 \Leftrightarrow$ $- 6,1 \leq 0,12$

On peut remarquer que l'élève a commis les erreurs anticipées par le chercheur. L'élève est arrivé à proposer la solution St [Solution] = 0,12, mais à la question b), l'élève a remarqué la contradiction. L'élève est revenu sur ses pas pour résoudre la contradiction en a). Il est sorti de la contradiction cognitive, contradiction qu'il a repérée, même si formellement la contradiction continue dans l'item b. Cela montre que l'élève est sensible à la contradiction.

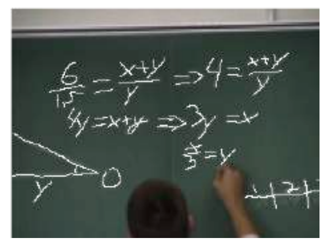
Deuxième exemple. *Situation sur les ombres* : Cette situation était l'une des 5 situations proposées lors d'une expérimentation d'une durée d'un mois et demi, avec des élèves de 3^e^ secondaire. Les 5 situations (enchainées) ont été travaillés en lien avec la méthode ACODESA, avec la finalité de faire développer les concepts de covariation entre variables et de fonction (Hitt et González-Martín 2015, Hitt et Morasse 2009) :

> Supposons que nous avons une source lumineuse d’une hauteur de 6 m (un lampadaire). Nous observons l’ombre sur le sol lorsqu’une personne de 1,5 m de hauteur marche dans la rue. Nous nous intéressons aux relations entre les grandeurs en jeu.
>
> 
>
> *Existe-t-il des grandeurs qui sont dépendantes les unes des autres? Lesquelles?*
> Sélectionne deux grandeurs qui sont dépendantes l’une de l’autre et décris le phénomène à l’aide des différentes représentations que tu as utilisées dans les activités précédentes.



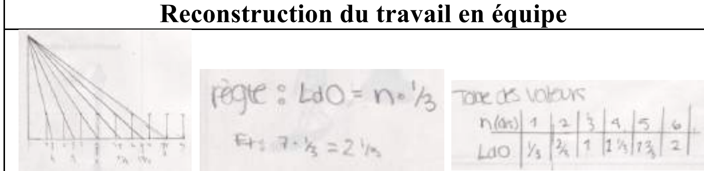
Phase 1 : Travail individuel. Deux filles travaillent individuellement pour comprendre la tâche. L’une d’elles a représenté la situation par un dessin proportionnel. À partir d’une pensée empirique visuelle elle a trouvé une relation entre les grandeurs « distance parcourue par la personne » et « mesure de l’ombre ».

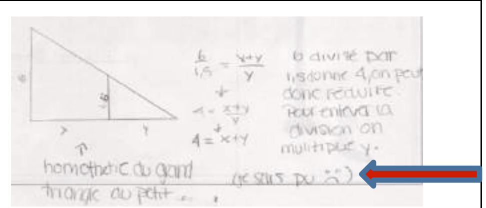
Phase 2 : Travail en équipe (Prusak, Hershkowits et Schwarts 2013, suggèrent des équipes de deux ou trois personnes). Les deux filles parviennent à construire : une relation verbale, une expression algébrique et une représentation graphique de la situation.



Phase 3 : Débat en grand groupe. Une équipe d’élèves n’est pas parvenue à trouver la réponse à cause d’erreurs algébriques. À la vue du résultat des deux filles, ils ont réussi à construire une approche algébrique en utilisant des triangles semblables.

Phase 4 : Autoréflexion. Le professeur collecte alors toutes les productions des élèves, puis leur remet la même situation à faire en devoir avec pour consigne de reconstruire tout le travail réalisé en classe (4[e] phase). Voici la reconstruction de ce qui avait été débattu en classe par l’une des filles dont on a parlé.

Reconstruction du travail en équipe	Reconstruction du débat en grand groupe
	




Elle a reconstruit, sans difficulté, ce qu’elle avait fait de façon numérique et visuelle avec sa coéquipière. Malheureusement, quand elle a voulu reconstruire le processus algébrique des garçons, elle a fait une erreur sans arriver à la solution. Dans son dessin, elle a exprimé (voir dessin à droite) un sentiment de gêne face à une contradiction de laquelle elle ne pouvait pas se sortir. Cela montre que cette fille a développé une sensibilité à la contradiction. D’un point de vue cognitif, *la sensibilité à la contradiction est la prise de conscience d’une contradiction, accompagnée d’un sentiment de malaise, et son dépassement d’un sentiment de bonheur*.

Les exemples nous montrent l’importance des représentations spontanées des élèves. À partir de ces résultats sur les représentations spontanées des élèves, Hitt et Quiroz (2019) ont proposé la notion de ***représentation socialement construite***, qui est liée à l’évolution de la représentation fonctionnelle-spontanée chez les élèves quand celle-ci a émergé dans le travail individuel, puis a été discutée à l'intérieur d'une équipe, en grand groupe et dans un travail d'autoréflexion. Selon Hitt et Quiroz (2019, p. 79) :

> **Définition.** Une RF-S est une représentation qui émerge chez les individus dans la pratique, face à une activité non routinière : les actions liées à l'interaction avec la situation ont des caractéristiques fonctionnelles (mentales, orales, kinesthésiques, schématiques) et sont liées à une représentation spontanée (externe). La représentation est fonctionnelle dans le sens où l'élève a besoin de donner un sens à la situation et qu'elle est spontanée, car elle s'exprime naturellement dans l'action quand on essaye de comprendre et de résoudre la situation non routinière.

La situation d'investigation (la tâche) comme élément clé dans la co-construction du savoir mathématique

La théorie des situations didactiques (Brousseau, 1998), celle du « problem solving » (Mason, Burton & Stacey, 1982; Schoenfeld, 1985) et de la mathématique réaliste de l'école de Freudenthal (1991) ont provoqué un changement dans les curriculums du monde entier. L'approche classique, à savoir l'enseignement « définition-théorème-exercices et problèmes » a été brisée. Les situations-problèmes, les problèmes en général et les problèmes en contexte ont pris alors une place fondamentale dans cette nouvelle approche. À partir de ces théories, on retiendra l'élaboration de la tâche comme élément central pour le dépassement d'un obstacle cognitif.

Une nouvelle ère est apparue pour l'organisation et le rôle de la tâche dans l'enseignement des mathématiques, les situations problèmes liées à la créativité et à la modélisation mathématique (Blum, Galbraith, Henn & Niss, 2007; Hitt et González-Martín, 2015; Hitt, Saboya et Cortés, 2017; Hitt et Quiroz 2019; Lesh & Zawojewski, 2007; Margolinas, 2013).

Dans notre cas, les activités que nous avons développées sont liées à la méthode d'enseignement ACODESA, dans une approche socioculturelle de l'apprentissage des mathématiques. Nous les avons appelées les « situations d'investigation ».

> **Situation d'investigation**. La situation est constituée de différentes tâches que suivent les étapes de la méthode ACODESA. Les tâches essayent de promouvoir premièrement, l'émergence des représentations non institutionnelles ou institutionnelles, une pensée visuelle empirique liée à une pensée diversifiée (pensée divergente), à la conjecture, à la généralisation, à la prédiction et à la validation. Dans un deuxième et troisième temps (travail en équipe et grand groupe), on essaye de promouvoir une pensée abstraite où la sensibilité à la contradiction est une partie ainsi comme une évolution des représentations et caractéristiques de la première étape. Un quatrième temps est envisagé pour promouvoir une connaissance plus stable avec une reconstruction de ce qui avait était fait en classe. Finalement, l'enseignant(e) fait un retour sur les différentes solutions des élèves et présente la position institutionnelle par rapport au contenu envisagé dans la situation.

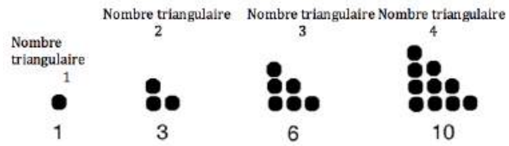
L'élaboration des situations d'investigation suit une organisation comme celle signalée dans Hitt, Saboya et Cortés (2017b).

Variation et covariations entre variables (un exemple avec les nombres polygonaux)

Nous allons présenter ici la 1re étape d'une situation d'investigation portant sur les nombres polygonaux et destinée à des élèves de la 1re année du secondaire. Cette étape était composée de 5 questions à résoudre papier-crayon. Dans la 2e étape était envisagée l'utilisation de la technologie pour valider leurs conjectures. Au total la situation comptait 8 pages.

1re étape (Travail individuel, suivi de travail en équipe, approche papier-crayon)
Il y a très, très, très, longtemps (vers l'an 520 av. J.-C.), un mathématicien du nom de Pythagore fonda une école dans une île de la Grèce antique. Ses élèves et lui étaient fascinés à la fois par les nombres et par la géométrie. Une de leurs idées consistait à représenter les nombres par des figures géométriques. Ils

appelèrent ces nombres : les nombres polygonaux. Par exemple, ils s’aperçurent que certains nombres pouvaient être représentés par des triangles. Ainsi, 1, 3, 6 et 10 sont les quatre premiers nombres triangulaires parce qu’on peut les représenter par des points disposés en triangles comme ci-dessous :

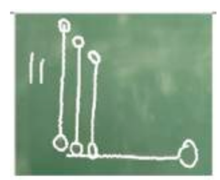


2) Observe bien ces nombres. Quel est le cinquième nombre triangulaire ? Représente-le. Explique la façon dont tu as procédé.
2) D’après toi, comment construit-on un nombre triangulaire ? Qu’observes-tu ?
3) Quel est le 11e nombre triangulaire ? Explique comment tu fais pour trouver sa valeur.
4) Tu dois écrire un courriel COURT à un ami pour lui décrire comment procéder pour calculer le nombre triangulaire 83. Décris ce que tu lui écrirais. TU N’AS PAS À FAIRE LES CALCULS!
5) Et pour calculer n’importe quel nombre triangulaire, comment ferait-on (on veut encore ici un message COURT).

Production des équipes aux questions 1, 2 et 3

1+2+3+4+5+6+7+8+9+10+11

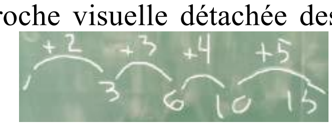
Dans cette 1re étape, nous voulions développer la pensée empirique visuelle (Rubinshtein, 1973) et la généralisation (Davidov, 1990; Radford, 2011). De façon naturelle, les élèves (équipe G1 et G3) sont passés d’une approche visuelle à une procédure arithmétique (action épistémique). Par exemple, pour le calcul de T_{11} ils ont écrit 1+2+3+4+5+6+7+8+9+10+11.

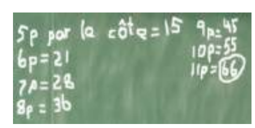


11+10+9+8+7+5+4+3+2+1

L’équipe G2 est passée d’une approche visuelle concrète à une approche visuelle plus générale, et ensuite à une procédure arithmétique (action épistémique). Ainsi pour le T_{11} ils ont écrit 11+10+9+8+7+6+5+4+3+2+1.

Nous pouvons noter l’abandon de la représentation iconique par un élève (équipe G4) qui, pendant la présentation en grand groupe, est passé d’une approche visuelle détachée des configurations polygonales à un calcul itératif qu’il n’avait pas discuté avec les membres de son équipe (pensée théorique abstraite selon Rubinstein). L’équipe G4 a utilisé cette dernière stratégie pour résoudre la 5e question de la 2e étape avec Excel.



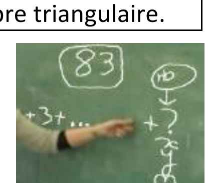


Ce passage montre l’importance du travail en équipe et la réflexion de l’élève Yan pendant qu’il organisait ses idées (dialogue intérieur selon Vygotsky 1932/1962) pour les communiquer à tout le groupe (construction du signe de Voloshinov). Yan avait besoin de se faire comprendre par le reste de la classe.

Réponses en équipe aux questions 4 et 5 et premier débat en grand groupe

Voici les réponses (travail en équipe) donnés par les différents groupes.

	Réponses à la question 4 par équipe :	Réponses à la question 5 par équipe:
G1	On additionne tous les nombres de 1+2+3… jusqu’au nombre de points sur le côté.	On additionne tous les nombres de 1+2+3… jusqu’au nombre de points sur le côté.
G2	Additionner des nombres de 1 à 83.	Tu additionnes les nombres de là ?
G3	Tu dois faire 83+82+81… jusqu’à 1.	Calcul la dernière colonne diagonale et calcul en faisant -1 au nombre. Ex. 15ème, 15+14+13… etc.
G4	Tu dois faire; 1+2+3+4+5+6+7+8… +83 et ça va te donner la réponse.	Tu mets le même nombre sur les autres côtés et ensuite tu additionnes 1+2+3+4+5+6… jusqu’à ce que tu arrives à ton nombre et ta réponse est le nombre triangulaire.



Dans une discussion en grand groupe, la chercheure demande les messages écrits pour répondre à la question 5 (voir réponses plus haut) : Message court pour n’importe quel nombre triangulaire. Les élèves ont d’abord proposé l’addition

« 1+2+3 jusqu'à ton nombre ». Intervention de la chercheure : Comment écrire le nombre que je ne connais pas? Différentes propositions ont émergé. La première était d'écrire « **?** », après ils ont proposé « **x** » ou « **y** ». La chercheure a demandé si un cœur pourrait être écrit : « ♥ ». Un élève a répondu : « On peut mettre n'importe quoi qui n'est pas un chiffre ».

Ce qu'on peut souligner c'est que les élèves sont passé d'une pensée empirique visuelle à une pensée abstraite arithmético-algébrique. La variable a été exprimée premièrement en mots : « jusqu'à ce que tu arrives à ton nombre », après comme « **?** », ensuite comme « **x** », ou « **y** », et finalement : « On peut mettre n'importe quoi qui n'est pas un chiffre ».

Production de l'équipe G4 (travail en équipe et présentation en grand groupe)			
Travail en équipe et généralisation en acte	Surprise d'obtenir un nombre décimal avec T_{100} et discussion en équipe vers la généralisation (Excel)	Présentation en grand groupe du calcul général d'un nombre triangulaire	Généralisation dans le débat en grande groupe
(83+1)÷2= 42 42x 83 =	100 (100+1)÷2=X X x 100 =	(46+1)÷2 = 47 ÷ 2 =23,5 46x23,5= 1081	(x+1)÷2=y y·x=

On peut remarquer que pour chaque abstraction, il y a un certain type de généralisation. Les processus d'abstraction ont été du type : *Abstraction visuelle, abstraction arithmétique, émergence de la notion de variable, émergence de la notion de covariation entre variables.*

Après 45 jours, à eu lieu la phase d'autoréflexion (reconstruction)

Lors de cette étape, Yan, l'élève qui avait trouvé l'expression algébrique pour les nombres triangulaires, a essayé de se rappeler de sa formule, mais s'est trompé. Il a écrit : ***(Rang*2)-1=y*** et ***Rang*y=nombre triangulaire***. Dans l'activité sur les nombres pentagonaux que nous lui avons ajoutée comme défi, il a écrit : ***Rang*(Rang + (Rang * 0,5 − 0,5)) = nombre pentagonal***. Expression qu'il a trouvée en utilisant la même stratégie que celle utilisée 45 jours avant pour les nombres triangulaires. Expression équivalente à l'expression institutionnelle : $P_n = \frac{n(3n-1)}{2}$.

Dans ce processus d'autoréflexion, une élève a obtenu à la question sur les nombres triangulaires : « ***Nombre impair : (rang + 1) ÷ 2 * rang = nombre triangulaire***. » Expression équivalente (avec restriction aux nombres impaires) à : $T_n = \frac{n(n+1)}{2}$.

Conclusions

Dans ce document, nous avons voulu montrer les différents éléments nécessaires pour la construction d'une pensée arithmético-algébrique. Basés sur quelques idées de l'histoire des mathématiques, d'une théorie socioculturelle de l'apprentissage et d'une méthode d'enseignement ACODESA, nous avons montré la nécessité de prend en compte différents éléments dans la classe de mathématiques pour une construction d'une pensée arithmético-algébrique; à savoir : le rôle de la tâche (situations d'investigation) dans l'acquisition des connaissances, la communication dans la classe, la visualisation mathématique, le rôle des représentations non institutionnelles et institutionnelles, la généralisation, la conjecture, la sensibilité à la contradiction, la validation et la preuve.

Notre approche cherche à développer et enrichir une articulation entre l'arithmétique et l'algèbre (*un habitus*) avec l'intention de promouvoir la construction d'une structure structurante dans le sens de Bourdieu (1980) liée à la pensée arithmético-algébrique qui donne non seulement un support à l'algèbre, mais aussi un enrichissement de la structure cognitive de l'arithmétique.

Nous avons aussi pu constater dans ce processus de co-construction des connaissances, l'émergence de la notion de variable et de la covariation entre variables.

Les résultats de nos recherches nous ont amenés à vouloir expérimenter des nouvelles situations d'investigation (en suivant la méthode ACODESA) en 6e année du primaire. Nous avons proposé 5 différents types de situations d'investigation avec l'utilisation de tablettes électroniques : Le restaurant de Marcel ; La bijouterie El Dorado ; Les fenêtres ; Le jardin et les citrouilles et Rectangles et disques. Nous sommes en train d'analyser les résultats.

UNDERSTANDING TEACHERS' PROFESSIONAL DEVELOPMENT THROUGH THEIR INTERACTIONS WITH RESOURCES: A MULTILINGUAL PROJECT

Luc Trouche
French Institute of Education, Ecole normale supérieure de Lyon, France
Luc.Trouche@ens-lyon.fr

The Documentational Approach To Didactics (DAD) aims to study teachers' professional development through their interactions with their resources for/from teaching. It has been introduced in the French community of didactics of mathematics in 2007, then extended at an international level. It has been introduced as an entry in the Encyclopedia of Mathematics Education in 2020. The DAD-Multilingual project (2020-2021) is dedicated to gather and confront the translations of this entry towards 14 languages. The project main goals are: making available – for students as well as for researchers - a presentation of DAD in various languages; deepening the DAD concepts themselves in thinking their possible instantiations in different languages; questioning the translation processes; and questioning the notion of resource itself, resource for/from teaching. The lecture presents this project, and draws some lessons from its first steps.

Keywords: Documentational approach to didactics; Cross-cultural studies; Teacher Education – In-service / Professional Development; Teacher Knowledge; Teaching Tools and Resources.

In this lecture, we want to present an on-going project dedicated to better understand mathematics teachers' professional development through the lens of their interactions with a diversity of resources. In the first part, we will introduce the so-called Documentational Approach to didactics (DAD), which has been developed for about 10 years. In a second part, we will present the DAD-Multilingual project, aiming to deepen this approach through its adaptation towards different social, curricular and linguistic contexts. In the third part, we will present the feedback of the scientific committee of this project, allowing to better situating the scope of the project and the ways for its development. In the fourth part, we will present the preliminary results, and will conclude in drawing some perspectives.

DAD, towards a 'resource' approach to mathematics education.

The documentational approach to didactics (DAD) has been introduced by Ghislaine Gueudet and Luc Trouche (Gueudet & Trouche, 2009), and has been developed further in joint work with Birgit Pepin (Gueudet, Pepin & Trouche, 2012). We will just introduce here the main concepts of this approach; more information may be found in the DAD entry (Trouche, Gueudet & Pepin, 2020) of the second edition of the Encyclopedia of Mathematics Education edited by Stephen Lerman.

DAD is originally steeped in the French didactics tradition in mathematics education (Artigue et al., 2019), where concepts such as *didactical situation*, *institutional constraint* and *scheme* are central. At the same time it also leans on socio-cultural theory, including notions such as *mediation* (Vygotsky, 1978) as constitutive of each cognitive process. Moreover, the approach has also been developed due to the emerging digitalization of information and communication, which asks for new conceptualizations. This digitalization and the development of Internet had indeed strong consequences: ease of quick access to many resources and of communication with many people. This necessitated a complete metamorphosis of thinking and acting, particularly in education: new balances between *static* and *dynamic* resources, between *using* and *designing* resources, between *individual* and *collective* work (Pepin, Choppin, Ruthven, & Sinclair, 2017). Taking into account these phenomena, DAD proposed a change of paradigm by analyzing teachers' work through the lens of "resources" for and in teaching: what they prepare for supporting their classroom practices, and what is continuously renewed by/in these practices. This sensitivity to *resources* meets Adler's (2000) proposition of "think[ing] of a resource as the verb re-source, to source again or differently" (p. 207). Retaining this point of view, DAD takes into consideration a wide spectrum of resources that have the potential to resource teacher activity (e.g. textbooks, digital resources, email exchanges with colleagues, or student worksheets), resources *speaking to the teacher* (Remillard, 2005) and supporting her/his engagement in teaching.

During the interaction with a particular resource, or sets of resources, teachers develop their particular *schemes of usage* of these resources. The concept of "scheme" (Vergnaud, 1998) is central in DAD. It is closely linked with the concept of "class of situations", which are, in our context, a set of professional situations corresponding to the same aim of the activity (for example, introducing a given mathematical property for a given grade). For a given class of situations, a teacher develops a more or less stable organization of his/her activity, that is a scheme. A scheme has four components:

- The aim of the activity;
- Rules of action, of retrieving information and of control;
- Operational invariants, which are elements, often implicit, of knowledge guiding the activity;
- Possibilities of inferences, meaning of adaptation to the variety of situations.

Over the course of his/her activity, a teacher enriches his/her schemes, e.g., integrating new rules of actions, or s/he can develop new schemes. Schemes are likely to be different for different teachers, although they may use the same resources, depending on their dispositions and prior knowledge.

The resources and the scheme, developed by a given teacher for facing a given class of situations, make up a document. The process of developing a document has been coined *documentational genesis* (Figure 1). The 'use' of resources is an interactive and potentially transformative process. This process works both ways: the affordances of the resource/s influence teachers' practice (that is the *instrumentation* process), as the teachers' dispositions and knowledge guide the choices and transformation processes between different resources (that is the *instrumentalisation* process). Hence, the DAD emphasizes the dialectic nature of the teacher-resource interactions combining instrumentation and instrumentalisation. These processes include the design, re-design, or 'design-in-use' practices (where teachers change a document 'in the moment' and according to their instructional needs).

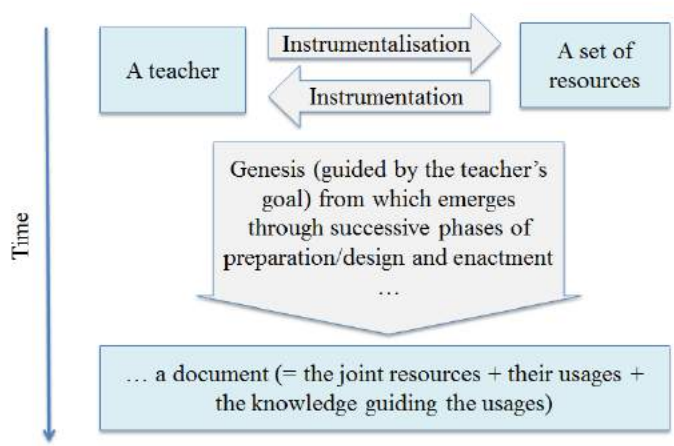

Figure 1. A representation of a documentational genesis

The set formed by all the resources used by the teacher is named his/her *resource system*. These resources are associated with schemes of usage, forming documents. The documents developed by a teacher also form a system, called the *document system* of the teacher. Its structure follows the structure of the class of situations composing the professional activity of the teacher. When teachers share their documentation work, for example in a group preparing lessons collectively, they may also develop a shared resource system (Gueudet, Pepin & Trouche, 2012). Nevertheless, the different members of the group can develop different schemes for the same resource, resulting in different documents.

We have then presented the main concepts grounding DAD. Since its introduction, this approach has been used in a variety of contexts, in Ph.D. and research projects. The Re(s)source international conference, held in 2018 in Lyon (https://resources-2018.sciencesconf.org/), gathering 130 people from 30 countries, gave a good image of the extension of the French original field. This cultural and linguistic diversity was understood as a potential richness for deepening the concepts at stake:

- One of the sessions of the young researchers workshop, held during this conference, was dedicated to « Naming systems1 used by secondary school teachers to describe their resources and their documentation work », meaning the structured set of words used by teachers, in their own language, for describing their resource systems;
- And, in my final conference (Trouche, 2019), among the 10 research programs that I proposed for developing DAD, two of them addressed linguistic issues: the first one, "Conceiving a DAD living multi-language glossary", and the last one "Contrasting naming systems used by teachers in describing their resources and documentation work, towards a deeper analysis of teachers' resource systems."

These reflections, among others, lead to the DAD-Multilingual project.

The DAD-Multilingual project, deepening a theoretical approach through its adaptation to a diversity of contexts

We describe here the origin of the project, the actors involved, and the translating processes. Any project is actually born from the convergence of a set of phenomena; and responds to a set of needs. It is indeed the case for the DAD-Multilingual project, being:

- The result of my personal experience, as a French native speaker having to go back and forth between English and French: introducing first DAD in French (Gueudet & Trouche, 2008), then in English (Gueudet & Trouche 2009); writing in English the entry DAD for the Encyclopedia of Mathematics Education (Trouche, Gueudet, & Pepin, 2020), then translating it in French (Trouche, Gueudet, Pepin, & Aldon, 2020). Doing so, I had in mind the Tuareg proverb: "travelling is going from oneself to oneself through others"…
- The result of my PhD supervisions experience: I realize, for example, that students from some countries had never the occasion to express themselves, in the frame of their studies, in their own language: "In spite of the numerous calls from education and language specialists, many countries still use the languages of wider communication instead of their native languages […] As a result, students are often required to learn subject material in the language of a former

1 The notion of "naming system" was inspired by the Lexicon project. "[This project involved] nine countries (Australia, Chile, China, Czech Republic, Finland, France, Germany, Japan, USA), and in each country a team of mathematics education researchers and experienced mathematics teachers. In this project, we consider that our experiences of the world and reflection on those experiences are mediated and shaped by available language, and that the use of English as *lingua franca* for international communication substantially limits what can be expressed and shared. The goal of the project is thus to document and compare the naming systems employed in mathematics teacher communities in the nine countries to describe the objects and events in their classrooms, in order to expand on the variety of constructs available for the purpose of theorizing about classroom practice and for identifying the characteristics of accomplished practice" (Artigue et al., 2019). But while the Lexicon project looked at the naming systems used to describe classroom activities, the young researchers workshop looked at the naming systems used to describe teachers' interactions with resources, before, during, and after class.

power; a language in which they may not be proficient "(Quigley et al., 2011). The DAD-Multilingual project appears then as a necessity for addressing equities issues;

- The result of interacting with researchers in various contexts (Algeria, Brazil, China, Japan, Lebanon, Mexico, Netherlands, Norway, or Senegal): these interactions have evidenced the fact that dealing with DAD in each new context (theoretical, cultural, curricular a well a linguistic) leads to new questions and potential enrichment. As it was said for didactics (Arcavi et al., 2016), DAD "goes travelling"…
- The result of developing an approach grounded on teachers' work with resources, involving naturally a diversity of supports and languages;
- The result of working over a long period with Ghislaine Gueudet and Birgit Pepin, committed both in international projects, Birgit having herself a long experience of crossing linguistic boarders…

These interactions evidenced also the need for enlightening the complex metaphoric structure developed by DAD, that could appear as a characteristic of the French community of mathematics education: "Despite the broad dispersion and wide-ranging accomplishments of didactique over the past decades, it has not had the influence outside the Francophone world that one might have expected […] part of the communication problem is that didactique carries some heavy baggage stemming largely from the language it employs and its metaphors in particular […] Didactique, in creating a precise vocabulary for its work, has made extensive use of the fundamental metaphoric structure identified by Pimm [1988, 2010], generating terms that need careful exegesis before they are used. Anglophones may find that English versions of those terms come laden with extra baggage that makes them difficult to interpret correctly." (Jimmy Kilpatrick in Arcavi et al., 2016)[2].

Finally, the presentation of DAD in the Encyclopedia of Mathematics Education gave us (Ghislaine, Birgit and me) the opportunity of a conceptual reversal. Each Encyclopedia, since Diderot and d'Alembert's work (1760), rests on a fundamental objective: making available all the knowledge of the world in a given place (a series of books) and a given language. Our project, reversing this objective, was to make available a small piece of knowledge in a diversity of languages, with the idea that this diversity will contribute to better understand the piece of knowledge at stake. Thus was born the DAD-Multilingual project (https://hal.inria.fr/DAD-MULTILINGUAL, aimed at adapting the Documentational Approach to Didactics entry into a diversity of languages.

The translating process involved 14 languages (in addition to English), actually the languages represented in the Re(s)source 2018 international conference (Gitirana *et al.* 2018): Arabic, Chinese, French, German, Greek, Hebrew, Hungarian, Italian, Japanese, Norwegian, Portuguese, Spanish, Turkish and Ukrainian. These 14 languages offer both elements of proximity (as for the roman languages: French, Italian, Portuguese and Spanish) and elements of distance, for example between European languages and Chinese one, leading to conceptualize differences of languages and of thought (Jullien, 2015).

The goals of the project, as announced on its website (https://hal.inria.fr/DAD-MULTILINGUAL), are the following ones:

- Making available a presentation of DAD in various languages, allowing the students and the researchers interested to refer to it in their own language;
- Deepening the DAD concepts themselves in thinking their possible instantiations in different languages;
- Questioning the translating process itself;

[2] Thanks to Tommy Dreyfus who, after his reading of a preliminary version of this paper, draws my attention on this Kilpatrick's contribution.

- Beyond the frame of DAD, questioning the notion of 'resource', resource for/from teaching;
- Designing (in a later step) a multilingual glossary of DAD.

The project involves a set of translators, reviewers (at least one translator and one reviewer for each language) and a scientific committee (see § 3). It would be excessive to say that they formed a community at the start of the project. Actually, there is not a DAD community, no regular event or specific journal allowing labelling such a scientific group. Since its beginning, in 2009, DAD develops as an « approach », with blurred boundaries, acting as a theoretical workshop for studying teachers-resources interactions, complementing or questioning already well established theoretical frameworks. During these 10 years, DAD has attracted PhD students, and researchers, in the frame of projects around mathematics teaching resources: e.g., in France, ReVEA (https://www.anr-revea.fr); in Europe, MC2 (http://www.mc2-project.eu); internationally, the French-Chinese joint project MaTRiTT (http://ife.ens-lyon.fr/ife/recherche/groupes-de-travail/matritt-joriss). The translators and reviewers have a diversity of links to DAD: interested as prospective users, or effective users, or co-designers (in particular, PhD students have enriched DAD with new concepts in their theses). They all are native speakers for the targeted language of a given translation; and they are sometimes go-between different languages, for historical reasons (e.g., Arabic-French in Lebanon) or PhD reasons (e.g. Chinese students having done their PhD in a frame of a co-supervision, using French and Chinese for collecting data; and English for writing their thesis), or a mix of these reasons (see Window 1).

Window 1 - The translator-reviewer pair in the Spanish language case

The translator was Ulises Salinas-Hernández, and the reviewer Ana Isabel Sacristán. Both have been members of the Department of Mathematics Education in Cinvestav-IPN (Mexico):

- Ulises obtained his PhD from Cinvestav; then has been doing a two-year post-doctorate at the ENS de Lyon with Luc Trouche, reflecting on theoretical networking, crossing DAD and the semiotic approach (Radford, 2008). His stays at ENS de Lyon gave him the opportunities to contrast the naming systems used by Mexican and Chinese teachers (Wang, Salinas & Trouche, 2019);
- Ana Isabel did her PhD at the University of London with Richard Noss and partially with Celia Hoyles. She has a long history of interacting with Luc Trouche, first at the ENS de Lyon during a three-month scientific stay in 2012, as well as in Cinvestav during a two-month scientific stay of Luc Trouche in 2017; these interactions gave rise to several papers (e.g., Trouche, Drijvers, Gueudet & Sacristan, 2013).

These close interactions have allowed flexible discussions on the translating process. This is a specific case for the translator-reviewer pair, and other cases can be found in the project, more or less close to DAD history.

The method of the translating process was as follows:

- English was the interface language (of course, this could constitute a bias for the on-going discussions);
- From the beginning, it was clear that the objective was not to produce a translation that was as close as possible to the original text, but instead to: make DAD understandable in a specific cultural, curricular and linguistic context (that means bridging it, if possible, with other frames well known of the targeted audience); enrich DAD in questioning its concepts when translating it;
- Issues that arose in the translating process were shared by each translator-reviewer pair, who had to fill, in English, a 'Translating issues report'. For such a report, a model was proposed (see Window 2), but such a model could be adapted according to the needs of the translator-reviewer pair.

Window 2 – The model (to be adapted) for the Translating issues report

Language: Translator: Reviewer:

Sources: English version and other linguistic versions?

- In a few lines, could you describe the main issues that emerged when translating the DAD entry or when interacting with the reviewer? Issues linked to the context (social, cultural, or curricular); issues linked to the concepts at stake; issues linked to the vocabulary
- Certain concepts raised difficulties, or discussions between the translator and the reviewer. We suggest that you explain these difficulties, and the choices you have made, for the notions of resource, document and for about three other notions, which seemed more particularly complex: Possible translations, and associated definitions (in English) - Final choice, and motivation - Scientific references using this word in the targeted language
- Other issues that you would like to share

Each translation was considered as an element of a collection, integrated in a French scientific Open Archive website (see Window 3).

Window 3 – The presentation of the Chinese translation on the Open Archive Website

文献纪录教学论

摘要

文献纪录教学论是数学教育百科全书的入门词条(Trouche, Gueudet & Pepin 2018)。词条于 2020 年更新(Trouche, Gueudet & Pepin 2020)。本文是中文译本，是 14 种语言译本之一（https://hal.archives-ouvertes.fr/DADMULTILINGUAL）。

文献纪录教学论是数学教育领域的一种教学理论。该理论创立的初衷是通过研究教师和资源之间的互动（包括使用和设计）来理解教师专业发展。本文主要阐述该理论的起源，理论背景，核心概念和相关的方法论。为达到理据结合的效果，我们将结合不同的研究项目作为案例诠释上述内容。本文面向的读者群是研究者，以及对入门文献纪录教学论有兴趣的非专家型读者（比如硕士研究生）。

Abstract

The 'Documentation Approach to Didactics' is an entry of the Encyclopedia of Mathematics Education (Trouche, Gueudet & Pepin 2018). This entry has been updated in 2020 (Trouche, Gueudet & Pepin 2020). This article is a Chinese adaptation of this updated version. It is part of a collection, gathering such adaptations in 14 languages (https://hal.archives-ouvertes.fr/DADMULTILINGUAL).

The documentational approach to didactics is a theory in mathematics education. Its first aim is to understand teachers' professional development by studying their interactions with the resources they use and design in/for their teaching. In this text we briefly describe the emergence of the approach, its theoretical sources, its main concepts and the associated methodology. We illustrate these aspects with examples from different research projects. This synthetic presentation is written for researchers, but also for non-specialists (e.g. master students) interested in a first discovery of the documentational approach.

This website (https://hal.inria.fr/DAD-MULTILINGUAL) gives access to the presentation of the project and its actors; to the set of translations; to the set of Translating issues reports; and to different resources aimed to support the translating processes (most of them coming from the scientific committee); and to the analyses produced over the project (as this current lecture!).

What we have learnt until now from the feedback of the scientific committee

The scientific committee was at the beginning composed of 5 persons: Jill Adler, Nicolas Balacheff, Rongjin Huang, Janine Remillard and Kenneth Ruthven. They were called upon due to their knowledge in, and interest of: the international community of mathematics education; the resource approach to mathematic education; the semantic issues at stake in each translating process; or/and the interactions between different cultures and languages. From the beginning of the project, they were asked to comment on the way the project was organized (e.g., the model of 'Translating issues report', improved thanks to their comments), and to propose references that could support the reflections on the translating processes. Their full comments can be found on the project website (https://hal.inria.fr/DAD-MULTILINGUAL/page/translation-issues), where we underline what appear as their main contributions.

Kenneth Ruthven draws attention to the source language, with four fundamental questions:

- Why not retain key terms from the source language?
- Why not 'mark' key terms in some way to indicate the specialized usage intended (e.g., reSource)?
- Why not 'mark' key terms in some way to clarify the metaphor (e.g., resource-scheme-document, abbreviated, say, to res-sch-doc)?
- Does a concept (as 'resource system' see Ruthven 2019) need a sharper definition before it can become a key term of DAD? And would that sharper definition point to a more precise term (or phrase)?

In such cases, the support of dictionaries (e.g., the Cambridge Dictionary https://dictionary.cambridge.org/dictionary/ and the already accepted translated terms in the specialized domain (e.g., such as the case of 'scheme' in the field of psychology) should be followed.

Nicolas Balacheff recalls that "The issue of language is not just a question of words, as is too often stated, but of expression and the circulation of meaning" (Balacheff, 2018). The minimal condition for doing this work should be to complete the choice of translated terms with authority quotes attesting to their use, and allowing taking into account the "finesse" of the concepts.

Jill Adler considers that the focus on DAD concepts as isolated words is too narrow. She suggests to take into account the context in which these concepts are used (see also Arcavi et al., 2016; Pepin, 2002; Setati, 2003), and raised the issue of the link between teachers' discourse-resources (Adler, 2012), and the theoretical discourse analyzing them.

Janine Remillard, building on her experience in the Math3Cs project (Remillard, 2019), evokes Osborn's (2004) discussion of different types of equivalences in cross-cultural research and Clarke (2013)'s notions of validity when doing cross-cultural research. Like Jill Adler, she underlines the importance of the context, pointing to how the words themselves are "the tip of the iceberg". For facing these issues, the translation team needs to develop what Andrews (2007) calls *prerequisite intersubjectivity*, leading to a shared understanding of the core concepts (see also Pepin et al., 2019). In this perspective, the design of a multilingual glossary of key terms seems crucial – this is actually one of the objectives of the DAD-Multilingual project, already evoked at the Re(s)source 2018 conference (Trouche, 2019).

For taking into account the link between the cultural context, teachers' words, and the conceptualization of their interaction with resources, the coordinators of the project invited Michèle Artigue, involved in the Lexicon Project (see footnote 1), to join the scientific committee, and so it became composed of 6 persons. Until now, this scientific committee is only composed of members of the mathematics education community: other scientific fields could be, of course, considered (e.g., linguistics, computer science, anthropology, cultural studies…); perhaps to be discussed in a later stage of the project?

Some preliminary results

As I write the presentation of this lecture (August 20th 2020), the project is still on-going. 11 translations (of over 14) have been completed, and the three remaining translations will be achieved before the end of September. This is the first *productive* result of the project, corresponding to its first aim.

Regarding its *constructive* results – what do we learn from the translating process itself – the Translating Issues Reports, still under progress, as well as the interactions within the project, allow drawing some preliminary lessons.

First of all, each translation gave rise to very active processes, often mobilizing several sources, and more actors than the translator and the reviewer. For example, for the Turkish translation, the English and French versions were used, and the translation process was an opportunity to introduce, and to discuss the approach with doctoral students:

> About the translation, we checked the translation together but it seems it is not possible to finish it at the end of the April. Because the sentence type and the explanations are very different from English and French. Doctoral students also find the translation problematic and we are revising it according to their feedback (email from Burcu Nur Basturk, on April 13th 2020)

Second, each translation appeared as a complex process, involving several levels: vocabulary, scientific expressions, and structure of the sentences, as detailed in the Japanese report (Window 4).

Window 4 – Extract of the Japanese Translating issues report

Takeshi Miyakawa and Yusuke Shinno

After reading all through the translated text of the DAD entry, we found that the text was not really the one we usually write by ourselves in Japanese. One may find that this is the translation, not the original text. This would be due to the difficulties of translation at different levels.

First, at the level of vocabulary, there are many technical terms, which are not used in the ordinary language. We had to create an appropriate Japanese term for the English or French term. This difficulty is not only for the technical terms used in DAD, but also those used in the mathematics education, in the scientific papers in general, or in the ordinary language. For the technical term, we used sometimes the English phonetic expression, and other times the Japanese translated terms. The most difficult term we discussed a lot was the name of approach "Documentational approach to didactics". Even the usual term "approach" was not easy for us to translate.

The use of technical terms is also related to the context of scientific research. In the research on mathematics education in Japan, the scholars often try to use the terms which are comprehensible to others and actually use much less number of technical terms than in the didactics of mathematics in France. Japanese scholars therefore may be surprised with the use of technical terms in this text and sometimes might be uncomfortable with it.

There were also many difficulties of translation at the level of sentence. In Japanese language, the order of terms in a sentence is very different from French and English: for example, the verb is given at the end of the sentence; the subject is not sometimes given; and so forth. Due to this, we had to often split a sentence into several sentences. Further, we consider that the context in which the original English text was written would be a factor that makes our translation alien from the Japanese ordinary text. Some English sentences, which seem self-explanatory would not clearly explain the claim, and Japanese readers may feel the lack of sentences that complement the claim, since they are in the other context.

Third, translating DAD needed to think more globally on the theoretical background of this approach, and on the existing, or not, bridges towards the targeted language, requiring, sometimes, to go through a third language, such as Russian in the case of Ukrainian. In this perspective, the objects and methodologies have to be questioned (see Window 5).

Window 5 – Extract of the Ukrainian Translating issues report

Maryna Rafalska and Tetyana Pidhorna

There are no translations of the works of G. Brousseau, G. Vergnaud, and Y. Chevallard in Ukrainian. Thus, we faced the difficulties in translating the main notions used in their theories (e.g. “milieu”, “scheme”, “operational invariants”, “savoir à enseigner” and “savoir enseigné”, etc.). For the translation in Ukrainian of the notion of scheme we used Ukrainian articles [11, 12] that refer to the work of J. Piaget and the Russian translations of J. Piaget works [10]. We also used the Russian translation [12] of Rabardel's instrumental approach for translating the notions of instrumentation, instrumentalisation, and instrumental genesis. The Russian terms were translated in Ukrainian using the dictionaries that provide the meaning of these words and then we found the Ukrainian analogues (also using the dictionary to confirm that the meanings of found words are the same).

Translating the DAD showed us the differences in research objects and methodologies in different cultural contexts, e.g. French didactics of mathematics and Ukrainian method of teaching and learning mathematics (metodika navchannya matematiky). Thus, we noticed that in Ukrainian method of teaching and learning mathematics much less attention, compared to French didactics of mathematics, is given to the study of psychological constructs (e.g. scheme) that influence on teachers' choices as well as to transposition of mathematical knowledge in different institutions. The main accent in Ukrainian method of teaching and learning mathematics is given to the development of advanced methodical systems (systems of methods, forms and tools of teaching and learning of mathematics) and evaluation of their effectiveness via pedagogical experiments. Metodika has more practical objectives than didactics. For example, it aims to bring the answer to the following questions: what to teach (content), how to teach (what methods, 151organizational forms to use, tools), how to evaluate the teaching/learning results, etc.

Житомир. – Житомир : Вид-во ЖДУ ім. Івана Франка, 2011. – С. 13 – 18.

Fourth, the evidence of central concept, such as ‘resource’, was called into question: “Understanding resource as something re-sourcing teachers' activity” can be transferred easily into French, or Italian, but is doesn't work in other languages, such as Portuguese:

> ‘Recurso’ (in Portuguese) is a word composed by the juxtaposition of the prefix «re» and the noun «curso», the first means repetition and the second a path already used, which is the meaning of the Latin recursus (NEGRI, 2007, p. 9). Therefore, recursar (verb in Portuguese) is unusual to give the same meaning of the verb re-source (in English). For that, we used the verb *reabastecer* ou *realimentar* with the idea of ‘source again’ (extract of the Portuguese Translation issues report, by Katiane Rocha, Cibelle Assis and Sonia Igliori)

It appeared, then, that there is a need to give a sharper definition of the critical concepts of DAD (see Ruthven's comment, § 3).

Fifth, thinking of *adaptation* instead of *translation* leads to establish links between DAD and frames already existing in a given culture, offering new opportunities to rethink the terrain of DAD; e.g.:

- The links between the instrumental and the documentational genesis through the lens of the mathematics laboratory for the Italian adaptation (Trouche, Gueudet, Pepin, Maschietto, & Panero, 2020);

- The potential links between the concept of instrumentalisation and the Guided Discovery Approach (Goztoniy, 2019), in the case of the Hungarian translation.

Finally, at this stage of the DAD-Multilingual project, these results appear quite promising regarding its aims: deepening the DAD concepts themselves in thinking their possible instantiations in different languages; questioning the translating process itself; questioning the notion of resource itself, resource for/from teaching. These results concern the 'resource' approach to mathematics education, beyond the community of mathematics education, and, beyond, the scientific fields interest in teacher education, cross-cultural studies, and translating processes.

Perspectives

I would like, as a conclusion, to imagine some perspectives, to be discussed with the actors of the project, perspectives internal to each language, crossing the languages or at a general level.

Each translation-adaptation could live its life in different natural ecosystems: being published in journals, discussed in scientific communities, being used in various research projects (for analyzing teachers interactions with resources, particularly their naming systems, in a variety of contexts), or teaching programs, and crossed with existing approaches. A given language could correspond to diverse cultural, national, or social contexts, e.g. the Spanish adaptation (in Mexico vs. in Spain), the Portuguese adaptation (in Brazil vs. in Portugal), or the Arabic one (in Lebanon vs. in Algeria or Morocco), English constituting a specific case (UK, USA, Australia or India). And, for a given language and a given country, the research context (at University level) and the teaching context (at schools levels) could provide different ecosystems where words and notions may follow their own trajectories. These appropriation processes, at a larger scale, would lead probably to updating each translation, and new issues to be addressed to/by the 'original' DAD frame.

The existing collection of translations opens also different perspectives; for example:

- Confronting the translating techniques, as detailed by Quigley et al. (2011) in the case of the English to Chinese translation:

  "*borrowing* (the source language word is transferred directly to the target language), *literal translation* (word-for-word translation), *transposition* (translating the words while paying attention to linguistic differences such as placement of adjectives before or after nouns), *modulation* (a technique often adopted when literal or transposition translation results in a utterance that, though grammatically correct, appears abnormal or awkward), and equivalence (a technique similar to modulation often used in idioms, proverbs, and phrases) […] in order to accurately translate documents, all these techniques must be used. Furthermore, translation through modulation and equivalence requires great attention to cultural, lexical, grammatical, and syntactic aspects of the text.

- Using the diversity of Translating issues reports for a mutual enrichment of each of them, leading towards an updated version of these reports and of the related translations;
- Organizing a new stage in interactions between pairs of languages using their proximity, or origin, for example Spanish-Portuguese, French-Italian, German-Norwegian, Chinese-Japanese, Greek-Ukrainian, Arabic- Hebrew…;
- Using the translated frame for analyzing data in the corresponding language;
- Proposing a special issue of a journal in mathematics education dedicated to the project, its results, issues and perspectives;
- Organizing working groups around concepts, leading towards a common glossary.

Finally, we could imagine a last stage of coming back to the original English presentation of the DAD entry, for updating and perhaps enlarging its scope in the perspective of the 'Resource Approach to Mathematics Education', as described by Gueudet, Pepin, & Trouche (2019).

These perspectives, of course, have to be questioned and enriched by the scientific committee, and discussed within the actors of the project, emerging as a community of (conceptual) enquiry (Jaworski, 2005). In this time of pandemic, sheltering at home, and cultivating a regular social distance, I would like to conclude with a personal statement: such a project, crossing the linguistic and cultural boarders, opens (at least for me) a breathing space, allowing to re-source, really, our conceptualization of teachers' work.

Acknowledgments

- To Ghislaine Gueudet, Birgit Pepin, Ana Isabel Sacristán, and Tommy Dreyfus for their careful rereading and helpful advices;
- To all the participants to the DAD-Multilingual project.

RESEARCH COLLOQUIA

CONCEPTIONS AND CONSEQUENCES OF WHAT WE CALL ARGUMENTATION, JUSTIFICATION, AND PROOF

Michelle Cirillo
University of Delaware
mcirillo@udel.edu

Kristen N. Bieda
Michigan State University
kbieda@msu.edu

Since PME-NA 2015, a working group has explored how argumentation, justification, and proof are conceptualized in the extant mathematics education literature and the consequences of these conceptualizations. We feature work from a forthcoming book in which scholars have critically examined the consequences of using particular conceptions of argumentation, justification, and proof as lenses for examining classroom practice from elementary through tertiary grade levels. Session participants will have opportunities to analyze data sets across grade bands and reflect on chapter authors' analyses of those data sets. Discussants will explore implications regarding how definitional choices impact both research and teaching practice. During the final session, we consider the next phase of the working group's focus for future PME-NA conferences.

Keywords: Reasoning and Proof; Advanced Mathematical Thinking; Teacher Knowledge

Theoretical Backgrounds

Although there is a large and growing body of research in mathematics education focused on argumentation, justification, and proof (Cirillo et al., 2015), the definitions and conceptualizations of these terms differ according to the perspective of the researcher, the focus of the research, and the particular data being analyzed (Reid & Knipping, 2010). Consequently, these differences cause inconsistencies in the literature. For example, there are debates about whether argumentation and proof are deeply intertwined or fundamentally separate activities, and there are inconsistencies related to students' success and difficulties with proof (Stylianides et al., 2017). Unpacking and making sense of these kinds of inconsistencies and debates has been a core focus of the Argumentation, Justification, and Proof working group.

History of the Working Group

The *Conceptions and Consequences of What We Call Argumentation, Justification, and Proof* Working Group (AJP-WG) met for the first time during the 37th Annual Meeting of the North American Chapter of the Psychology of Mathematics Education (PME-NA) in 2015. The group then met for three additional years in 2016, 2017, and 2018. The AJP-WG sessions were well-attended each year, and the group is active in between meetings. For example, following the 2015 and 2016 meetings, AJP-WG members published white papers to disseminate the group's work during the sessions (i.e., Cirillo et al., 2016; Staples et al., 2017). Following the 2018 meeting, AJP-WG members began work on an edited book. Across the authoring teams of the AJP-WG papers, the white papers, and the book, over 40 scholars have been involved in the group's work, including many graduate students. The goal of this colloquium is to share ideas from the forthcoming book (Bieda, Conner, Kosko, & Staples, forthcoming), which have developed during previous PME-NA AJP-WG sessions.

Areas of Discussion and Plan for the Research Colloquium

Each day will feature presentations from two chapter authors who analyzed the same grade level classroom transcript from different perspectives (e.g., justification and proof). Prior to author presentations, participants will have opportunities to review each transcript (i.e., the data set) and

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

make their own observations. Participants will consider implications of the authors' definitional choices and conclusions with respect to research, working with teachers, or both.

Day 1: Opening Session and Focus on the Elementary Grades

The goals for the first session will be to (1) share the origins and evolution of the AJP-WG that motivated this research colloquium (2) introduce the aims and structure of the edited book that resulted from past efforts of the AJP-WG, and (3) have a set of book authors, whose chapters focused on justification and proof in the elementary grades, share reflections from their analyses. To achieve these goals, we anticipate the following organizational structure: M. Cirillo will lead Activities 1 and 2 [30 minutes] and K. Bieda will facilitate a review of the data set used by elementary section authors in the book [30 minutes]. Then, E. Thanheiser and C. Walkington will co-present major findings from their analyses of the elementary data set [20 minutes]. Finally, we will facilitate audience questions and discussion [10 minutes].

Day 2: Focus on the Middle Grades

The goals for the second day will be to explore the middle grades data and author analyses and to preview the data set for Day 3. K. Bieda will facilitate groups in reviewing the middle grades data set used by the book section authors [30 minutes]. Then, C. Gomez and K. Lesseig will share major findings from their analyses of the middle grades data set [20 minutes]. We will then facilitate audience questions and discussion [10 minutes]. Last, D. Plaxco will facilitate groups in reviewing the data set featured in the tertiary (post-secondary) book chapters [30 minutes].

Day 3: Focus on the High School and Tertiary Grades and Next Steps for Working Group

The goals for the third day will be to explore and reflect on the author analyses at the high school and tertiary levels, reflect on the implications of analyses across the presentations, and brainstorm about future working group foci as suggested by implications of the work presented across the three days. First, M. Cirillo will share findings from the Cirillo and Cox high school synthesis chapter which explores the findings of three authors who analyzed a common transcript through the lenses of argumentation, justification, and proof. Similarly, D. Plaxco will share major findings from analyses of the tertiary data set [30 minutes]. We will facilitate questions and discussion [10 minutes]. Then, A. Ellis will share reflections on the set of presentations featured during Day 1-3 of the colloquium [30 minutes]. We will then facilitate a conversation about potential topics for future PME-NA working groups based on implications from the analyses presented across the three days of colloquium sessions.

Our research is guided by the question: 'How might we observe, document, display, and analyze data from a collective systems perspective?' In this colloquium, we will examine our current work involving the development of new methodological tools that address the research question.

Keywords: Research Methods

Introduction

Over the past 25 years, the research colloquium leaders have individually and in subgroups, been theorizing about, as well as collecting, analyzing, and reporting on data related to collective action in mathematics classrooms (e.g., Davis & Simmt, 2006; Martin, McGarvey & Towers, 2011; Martin & Towers, 2011; McGarvey & Thom, 2010; Proulx, Simmt & Towers, 2009; Thom & Glanfield, 2018). While our work has contributed to meaningful insights into mathematical understanding of learners and teachers, we realized that the methodological tools developed and used were limited due to the vast and intricate range of dynamic interactions (Martin, McGarvey & Towers, 2011; Simmt, 2011). This led us to working systemically on the mutual concern: How might we observe, document, display and analyze data from a collective learning systems approach? Building on our previous PME(NA) working group, NCTM research symposium, and PME research forum, in this colloquium we will present our work to date and provide opportunities for the participants to learn about, try out, and discuss the methodological tools we have developed.

Theoretical Background of the Research

We situate this research within a complex systems framework to inquire into how relationships between the parts of a system give rise to new and unanticipated collective behaviours of the larger system. We conceive mathematics classes as dynamic complex collectives; that is, mathematics classes emerge and evolve from the inextricable layering and entanglement of biological, social, societal, and environmental subsystems (Davis & Sumara, 2006; Davis & Simmt, 2003). Events within such systems may be unpredictable in foresight, but are potentially understandable in hindsight. As such, complex systems present "collective possibilities that are not represented in any of the individual agents" (Davis & Simmt, 2003, p. 140). In contrast to considering classroom interactions as strictly a series of distinct contributions by individuals, we recognize that teacher actions and decision making are often not based on the multitude of individual actions, but rather, on a teacher's sense of the class as a whole of which the teacher is a part (Burton, 1999; Towers, Martin & Heater, 2013).

Previous Engagement with Methodological Tools Work

At the 2015 PME(NA) Conference the research colloquium leaders offered a working group on "Collective learning: Conceptualizing the possibilities in the mathematics classroom" (McGarvey et. al., 2015). Participants discussed the theoretical and methodological concerns as well as practical implications related to mathematics class as a collective. Following the working group, we directed

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

our attention on the metaphor of "vital signs" to guide the development of tools for observing the collectivity of mathematics classes. Similar to how health professionals monitor bodily systems, we explored how a mathematics class might also have *multiple vital signs*; that is, when monitored simultaneously, such signs afford robust insight into the systemic viability. Here, a suite of "classroom vital signs" were proposed to distinguish between different forms of collective classroom activity while pointing to key elements of dynamic engagement. At the 2017 NCTM Research Conference, we described the potential of vital signs as both a metaphor and tools to inquire into collective learning (McGarvey et. al., 2017) in a research symposium. In 2018, at the International PME conference, we facilitated a Research Forum on the "Vital signs of collective life in the classroom" where we shared our research team's efforts to develop methodological tools for observing the class as a collective (McGarvey et. al., 2018). To date, we have created six new tools with which to observe, track, and identify new patterns within the collective activity of mathematics classes. In this colloquium, three tools will be explicitly examined: Tool 1) ideational networks; Tool 2) dynamics of ideas; and Tool 3) classroom board activity.

Proposed Layout for Research Colloquium

<u>Session 1:</u> 15 min. introduction to the purpose and importance of the methodological research; 10 min. presentation about the development of Tool 1 to date; 20 min. for participants to observe the tool in action and dialogue about its use; 35 min. for participants to exchange ideas and collaboratively work with the tool; and 10 min. for closing remarks, discussion of future implications, and applications for mathematics education research.
<u>Session 2:</u> 20 min. overview of the Dynamical Model/Theory for the Growth of Mathematical Understanding (Pirie & Kieren, 1994) and presentation on the integration of it and the development of Tool 2 to date; 20 min. for participants to observe the tool in action and dialogue about its use; 40 min. for participants to exchange ideas and collaboratively work with the tool; 10 for closing remarks, discussion of future implications, and applications for mathematics education research.
<u>Session 3:</u> 10 min. presentation about the development of Tool 3 to date; 15 for participants to observe the tool in action and dialogue about its use; 25 min. for participants to exchange ideas and collaboratively work with the tool; 30 min. for participants to experiment with applying different combinations of the three tools and explicate the multiple perspectives they afford when observing them simultaneously "all at once"; 10 min. for closing remarks, discussion of future implications, and applications for mathematics education research.

Acknowledgments

We acknowledge the Social Sciences and Humanities Research Council of Canada for financial support as well as the members of our research team who are not able to be a part of the colloquium: Brent Davis (University of Calgary), Lyndon Martin (York University), and Elaine Simmt (University of Alberta).

In this new working group, we will bring together those interested in sharing knowledge, information, insights, and current work related to implementing and researching content-focused coaching in mathematics. There are many variations of content-focused coaching currently referenced in the field which has led to a lack of clarity about how this coaching model is being implemented and researched. This working group is an opportunity for those engaged in the work of developing and/or researching coaching models to collectively explore (a) variations of content-focused coaching, (b) challenges in implementing content-focused coaching, including ways to support coaches, and (c) needs and future work for content-focused coaching in mathematics. We intend for this working group to continue into future PME-NA conferences as we build on this initial collaboration to impact our individual work and the field at large.

Keywords: Teacher Education-Inservice/Professional, Instructional Leadership, Research Methods

Content-focused Coaching in Mathematics

Coaching has become a widespread method of professional development for teachers (Campbell & Griffin, 2017). One particular form of coaching, content-focused coaching, has been shown to be a promising practice to impact teachers' instructional practices and student learning (e.g., Gibbons & Cobb, 2016; West & Staub, 2003). Content-focused coaching has two primary goals: (a) increasing the teacher's knowledge of a specific content area, such as mathematics, and (b) building the teacher's knowledge of effective instructional practices related to a specific content idea through a personalized, embedded program (Cobb & Jackson, 2011).

Researchers in multiple countries have highlighted the benefits of content-focused coaching (e.g. Becker, Waldis, & Staub, 2019; Gibbons & Cobb, 2016; Kreis, 2012; Kreis & Staub, 2011; Murawski, 2019). In Switzerland, for example, researchers found content-focused coaching to be beneficial for both prospective and practicing teachers, emphasizing the applicability of the model to other contexts (Becker et al., 2019, Kreis, 2012; Kreis & Staub, 2011). Similar coaching models have been used in Canada (e.g. Bengo, 2016), showing positive influences on teacher practice. The variability of contexts in which content-focused coaching is implemented in terms of demographics, teaching conditions, and teaching experience, highlights the need for collective exploration of content-focused coaching.

In addition, there is not a shared understanding in the field about how to define content-focused coaching, how to implement and support content-focused coaching programs, and how to study the actions of content-focused coaches and impact on teachers' practice. As a result, there are high-levels of variability in the ways mathematics coaches interact with teachers (e.g. Ellington, Whitenack, & Edwards, 2017) and inconsistent empirical findings when researching the effectiveness of coaching (e.g. Campbell & Griffin, 2017).

As a collective team, the proposal authors have extensive experience implementing content-focused coaching as a part of larger professional learning programs for teachers. The team has developed and supported content-focused coaches in both face-to-face and online contexts. We are currently researching the actions of content-focused coaches in an online environment and the impact of these actions on teachers' practices (see Author, 2019).

The intent of this working group is to build on and connect the knowledge and experiences of participants in order to establish a more robust understanding of content-focused coaching and to identify opportunities for future work. Participants will have an opportunity to collectively explore three themes: (a) variations of content-focused coaching, (b) challenges in implementing content-focused coaching, including ways to support coaches, and (c) needs and future work for content-focused coaching in mathematics.

Working Group Organization and Strategy

Each session of the working group will draw on the experiences of the authors and the participants related to content-focused coaching, with a different focus for each session based on the themes noted above.

The first session will invite discussion on two of the three themes: exploring variations of content-focused coaching to generate a common understanding, and exploring challenges in implementing content-focused coaching, including ways to support coaches. We will launch the session with the authors sharing their background and experiences to provide a foundation for discussion related to what constitutes content-focused coaching. We will then engage participants in small and full group discussions with the goal of generating a more cohesive understanding of the critical components of content-focused coaching. Attendees will then work in small groups to identify challenges in implementing content-focused coaching. We will share and discuss current work to overcome these challenges with the goal of networking around effective implementation of content-focused coaching.

Session Two will include brief presentations from several participants' work related to content-focused coaching. Participants will then engage in small group discussions on the third theme - what more needs to be known about content-focused coaching. Specifically, discussions will be guided by the following: (a) what has been/is being studied related to mathematics content-focused coaching, and, (b) what are areas of need for further contributions to the field. These discussions will culminate with groups creating questions relating to common research challenges and possible future research based on gaps in the literature. These questions will provide an extended opportunity for discussion with an *Open Space Protocol* structure. The Open Space Protocol provides time and space for participants to generate new knowledge about a particular question with which they find relevant. The process draws on the talent that will be in the room and positions participants to discuss questions important to their work within a supportive and structured environment.

In Session Three, we will use the Open Space Protocol to continue the conversations from the previous day in two more rounds of small group discussions. Attendees will be encouraged to move groups, if they desire, at the end of each round. To support follow-up and ongoing collaboration of participants, group notes and documents will be shared and distributed via a Google Folder that will be set up for this working group. This shared folder will provide a shared space for future collaborations and writing projects within the working group members.

The material is based upon work supported by the National Science Foundation under Grant DRL-1620911.

The central aim of the EMIC Working Group is to connect, engage, and inspire colleagues in this growing community of discourse around theoretical, technological, and methodological developments for advancing the study of embodied cognition for mathematics education. This year, our fifth at PME-NA, we also will convene on Day 3 with the WG on Mathematical Play. Our community of scholars will use these sessions to continue to broaden the range of activities, practices, and emerging technologies that contribute to mathematics teaching and learning as well as to research on these phenomena.

Keywords: Cognition; Embodiment and Gesture; Informal Education; Learning Theory

Empirical, theoretical, and methodological developments in embodied cognition and gesture studies support the continuation of the regularly held Embodied Mathematical Imagination and Cognition (EMIC) Working Group for PME-NA. The central aim of EMIC is to attract, engage, and inspire colleagues in a growing community of discourse for advancing the study of embodied cognition for mathematics education, including mathematical reasoning, instruction, assessment, technology design, and learning in and outside of formal settings.

Views of learning as embodied experiences have grown from several developments in philosophy, psychology, anthropology, education, and the learning sciences that frame human communication as multimodal interaction, and human thinking as multimodal simulation of sensory-motor activity (e.g., Lave, 1988; Nathan, 2014; Wilson, 2002). Four ideas exemplify the plurality of ways EMIC is relevant for the study of mathematical understanding: (1) *Grounding abstractions in perceptuo-motor activity as an alternative to amodal symbol systems;* (2) *Cognition emerges from perceptually guided action*; (3) *Mathematics learning is always affective*, never detached from body-based feelings and interpretations; (4) *Mathematical ideas are conveyed via multimodal forms of communication, e.g., gestures, drawing, and objects.*

The interplay of multiple perspectives is vital for the study of embodied mathematical cognition to flourish. While there is significant convergence of theoretical, technological, and methodological developments in embodied cognition, there remain questions to be addressed through formulating and applying experimental design principles. We aim to: (1) synthesize the work of leading scholars into a theory of EMIC; (2) identify and negotiate focal ontologies and parameters that capture our theoretical, methodological, and technological variability; (3) curate and disseminate evidence-based design principles to enhance mathematics education and broaden participation in STEM fields; and (4) articulate a research agenda in embodied design.

Past Achievements, Current Organizers, and the Future of EMIC

This is the 5th year of the EMIC WG. Several activities and website have emerged to connect scholars and provide resources, https://www.embodiedmathematics.com. Two NSF workshops for researchers and instructors grew from this: "The Future of Embodied Design for Mathematical Imagination and Cognition" (May 20-22, 2019); and "EMIC: Professional Development for Undergraduate Mathematics Instructors" (June, 2021). An edited book is planned for the "Research in Mathematics Education" Series and an article is under review for *Frontiers in Education* Research Topic: "Futures of STEM Education."

As the WG matures, we are broadening the set of organizers to represent a range of institutions, perspectives, and applications. This enriches the WG experience and the long-term viability of the community. The organizers not included in the authorship list are listed here: Candace Walkington, Southern Methodist University; Carmen J. Petrick Smith, University of Vermont; Hortensia Soto, University of Northern Colorado; Ivon Arroyo, University of Massachusetts-Amherst; and Martha W. Alibali, University of Wisconsin-Madison.

EMIC 2020: Embodiment in Mathematics for Inclusion

Embodiment is an effective way to promote inclusive mathematics education research and practices. This year we will explore how embodied mathematics can bridge cultural divides and raise awareness of inclusion for those with different physical and perceptual abilities (Abrahamson et al., 2019). To demonstrate growth and relevance, we will also join the Mathematical Play WG on Day 3 to integrate EMIC and Play research and practice.

On Day 1 we will discuss the goals for PME-NA 2020 to bridge divides that arise across those with different physical and perceptual abilities. As is customary with EMIC, we will anchor this to mathematical activities (e.g., making human-scale polyhedra). For a portion of the time, participants will collaborate without sight, to identify how our bodies offer effective ways to engage. This will invite us to identify principles of inclusive pedagogy and activity design. This will be connected to the 4 EMIC themes: Grounding, emergence, affect, and multimodality.

On Day 2, we will explore mathematical collaboration when participants cannot rely on a shared language. In order to challenge the norms of mathematical activities (e.g., Bagh Chal from Nepal), we will include puzzles and games that are foreign to majority cultures.

On Day 3, EMIC will meet with the Math Play WG to consider overlapping interests and questions. The organizers of both WGs led a joint conference proposal that is currently under review, and Day 3 will be our first overt synthesis of the two bodies of work. The session will include small activity groups with Math Play participants who want to think about their work as embodied and EMIC participants who want to think of their work as math play opportunities. After, we will review Days 1 and 2, we consider how our themes overlap, ways to enhance future PMENA conferences, as well as the broader ways that embodiment, imaginative thinking, and play can be used to promote inclusivity. We will conclude by discussing continued engagement and dissemination opportunities available with both the EMIC and Math Play communities.

Students' construction, coordination, and abstraction of units underlie success across multiple mathematics domains. This working group aims to facilitate collaboration between researchers and educators with the particular aim of extending research on units coordination and construction across age groups, learning differences, and mathematical contexts.

Keywords: Cognition, Learning Theory, Number Concepts and Operations

Theoretical Background, Purpose, and History

Units coordination and construction refers to the number of levels and type of units children can construct and bring into a situation (Steffe & Olive, 2010). Children at young ages begin counting when first constructing *pre-numerical units* (relying on perceptual material and/or physical actions) with which to use as material for future activity (Steffe & Cobb, 1988). These units are first constructed through children's external activity before becoming *internalized* (imagined actions) and then *interiorized* (able to anticipate relationships between levels of units). In Steffe's 2017 plenary for PME-NA, he substantiated particular needs for investigating how children develop operations when constructing and coordinating units. The working group began at PME- NA 2018, with the aim of facilitating collaboration amongst researchers and educators sharing Steffe's concerns about (a) the need for supporting units construction and coordination for all learners and (b) the need for accompanying learning trajectories (curricula) appropriate for students' current level of units across grade levels.

Working Group Goals and Strategies, Past and Present

In the first year of the working group, goals included generation of related research topics of interest to PME-NA attendees, including the role of units coordination in early childhood education, special education, and secondary and post-secondary education (including teacher-education). Products included the creation of a website for organizing and collecting tasks used for assessing students' units coordination links to research papers addressing particular topics relating to units coordination: https://unitscoordination.wordpress.com/ At the second working group meeting at the 41st PME-NA (2019), novice and experienced researchers described inferences of students' units activity and shared perspectives of the affordances and constraints of assessing units coordination using particular tasks and settings. Our goals for the 2020 working group are to (1) continue to build on the productive discussions from the 2019 and 2018 working group meetings relating to issues of assessments of units coordination in different settings (within classrooms, via written instruments, via clinical interviews, and via individual or paired-student teaching experiments) as well as (2) to continue to bridge efforts to emerging research connecting units coordination across mathematical domains.

(2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Session 1: Shared Understanding of Units Coordination and Construction

GOAL: Participants (new and returning) will come to shared understandings of the main ideas of units construction and coordination as well understandings of differences in theoretical and conceptual perspectives. ENGAGEMENT: Prior to the working group, we will administer an entry survey of participants to determine interests and goals for collaboration. In the first day's meeting, participants will reflect on their own actions to solve tasks used to assess and support units construction and coordination and discuss in small groups how tasks from the literature afford students' units construction and coordination and associated mental operations. Subgroups will come together and discuss their understandings of relationships between student actions and task features when assessing and supporting students' units construction/coordination.

Session 2: Emerging Connections between Units Coordination and Subitizing, Units Coordination and Reasoning about Rates

GOAL: Explore and bring to focus the role of emerging research investigating connections between units construction and coordination across age groups and mathematical contexts (e.g., STEM fields, cognitive science fields). ENGAGEMENT: Participants will form three groups, one focused on units construction and coordination with young children (and their subitizing activity), one focused on units coordination with adult learners (and their reasoning about rate of change), and one focused on units coordination of elementary students with identified with learning (i.e., working memory) differences. Building on the discussions from the first session, participants will explore video-recordings of clinical interviews and teaching experiments and discuss theoretical and pragmatic connections between these constructs and describe their inferences and wonderings in these contexts by sharing their analyses in a shared google doc.

Session 3: Reflection and Taking Action

GOAL: Reflect on connections and embark on planning collaborations of interest to participants. ENGAGEMENT: During the first 30 minutes, we will discuss the results from the previous session as a whole group. Then, form small groups for each of these goals: (1) collaborations within participants' research projects (2) creation of content for the webpage and (3) identification of target journals and outlets or grants and funding sources. Administer exit survey of participants' interests and goals for collaboration.

WORKING GROUP: DIDACTIC CONTRASTS BETWEEN CALCULUS AND ANALYSIS

GRUPO DE TRABAJO: CONTRASTES DIDÁCTICOS ENTRE CÁLCULO Y ANÁLISIS

Fabio Augusto Milner
Arizona State University, USA
fmilner@mainex1.asu.edu

José Ramon Jiménez Rodríguez
Universidad de Sonora, Mexico
jimenez@mat.uson.mx

A new Working Group is proposed. In other forums, both PME and ICMI, working groups have worked and focused on the analysis of problems in teaching and learning Calculus and Analysis, both at the pre-university and university levels, but those did not start from a clear characteriza-tion and explicit statement of the differences that could exist between these two areas of mathematical knowledge and, consequently, without full awareness of the implications that this distinction could have for both educational research and teaching. This is precisely the theme that is intended to be the focus here. It is intended that the Working Group will be working until it reaches a certain maturity of the ideas that it plans to discuss.

Keywords: Precalculus, Calculus, Curriculum Analysis

Objective of the Working Group

Identify and characterize the conceptual, epistemological and didactic differences between Calculus and Mathematical Analysis, to guide both the specific problems of educational research, and the selection of content in pre-university or university Calculus courses for non-mathematicians.

Strategy

Promote the exchange of ideas and discussion among invited experts, as well as among the participants, around the issue raised and the stated goal. This work will be supported by the presentation of a base document for discussion, prepared by this new Working Group's proposers.

Invited researchers

Luis Moreno Armella, Cinvestav, Mexico
Irene Biza, U. of East Anglia, UK
Fernando A. Hitt Espinoza, University of Quebec at Montreal, Canada
Anatoli Kouropatov, David Yellin and Levinsky College of Education, Israel
Patrick W. Thompson, Arizona State University, USA
Tin Lam Toh, National Institute of Education, Singapore
Laurent Vivier, University of Paris Diderot, France

Coordinator of the Working Group

Fabio Augusto Milner, Arizona State University

Theoretical referents

From the theoretical referents provided by the Ontosemiotic Approach to Cognition and Mathematical Instruction (Godino and Batanero, 1994), researchers have been making different efforts to characterize both Mathematical Analysis and Differential and Integral Calculus, distinguishing the problem situations addressed by each of them, as well as the mathematical objects that are used and emerge in the historical development of each of these two areas of mathematical knowledge. In particular, emphasis has been placed on identifying and characterizing some of the mathematical practice systems and primary objects (problem situations, language, procedures, properties, arguments and concepts) in each of these two disciplines.

However, it is important to systematize and organize the partial results of these efforts in three directions. First, it is important to try to identify and characterize the greatest number of contrasts between Calculus and Analysis, so that the distinction is as complete as possible. Secondly, it is important to analyze these contrasts from the point of view of the cognitive abilities and professional needs of the students (pre-university and university) who enroll in a Calculus course. The second direction concerns directly the curricular design of the Calculus course. Thirdly, and this seems fundamental to us, it is important to identify, in light of these contrasts, the new psycho-pedagogical, epistemological and didactic questions that educational research will have to address but has not yet done it for lack of such clarification.

In a broader context, this panoramic distinction is also important in that it will allow us to clarify the vision with which we intend to introduce elementary ideas related to Calculus in early education, and particularly in secondary schools.

Participation dynamics

It is hoped that the participants of the Working Group (at least some of them), after analyzing the base document, will be able to contribute short essays related to the three aspects of the topic for analysis and discussion, as well as enrich the contributions of others.

Group work organization

The organization of the group work is planned in two stages. In the stage prior to PMENA 2020, researchers who have been working along the lines of the proposed theme will be contacted and invited to join the group, become familiar with the base document and prepare their essays or contributions, which will be made available to the group in the first week of October 2020. In the second stage, during the meeting, three 90-minute sessions will be structured to present the essays and discuss them. To conclude, a final presentation will be made by those in charge of the Working Group, who will summarize what has been achieved and outline the tasks for the future.

In order to make the Group's work as productive as possible, the discussion and analysis sessions will be structured based on the three lines mentioned above as follows:

First Session. Need for a clear and systematic distinction of didactic contrasts between Calculus and Mathematical Analysis. Epistemological, cognitive and didactic problems that emerge from this distinction.

Second Session. Curricular impact that this distinction would have on pre-university and university courses in Calculus for non-mathematicians. General outline of the main characteristics of these courses. Early Calculus curriculum.

Third session. Reorientation of educational research towards new psycho-pedagogical, epistemological and didactic problems that emerge as a result of the didactic reconceptualization of Calculus and Mathematical Analysis.

GRUPO DE TRABAJO: CONTRASTES DIDÁCTICOS ENTRE CÁLCULO Y ANÁLISIS

WORKING GROUP: DIDACTIC CONTRASTS BETWEEN CALCULUS AND ANALYSIS

Fabio Augusto Milner
Arizona State University, USA
fmilner@mainex1.asu.edu

José Ramon Jiménez Rodríguez
Universidad de Sonora, Mexico
jimenez@mat.uson.mx

Se propone un nuevo Grupo de Trabajo. En otros foros, tanto de PME como de ICMI, han funcionado grupos de trabajo centrados en el análisis de la problemática de la enseñanza y el aprendizaje del Cálculo y el Análisis, tanto en el nivel preuniversitario como universitario, pero sin partir de una caracterización clara y explícita de las diferencias que podrían existir entre estas dos áreas del conocimiento matemático y, en consecuencia, sin plena consciencia de las implicaciones que dicha distinción podría tener tanto para la investigación educativa como para la enseñanza. Esta es precisamente la temática que se pretende abordar. Se intentará sostener dicho Grupo de Trabajo hasta lograr la maduración de las ideas que en él se planea discutir.

Palabras clave: Precálculo, Cálculo, Análisis Matemático

Objetivo del Grupo de Trabajo

Identificar y caracterizar las diferencias conceptuales, epistemológicas y didácticas entre el Cálculo y el Análisis Matemático, para guiar tanto la problemática específica de investigación educativa, como la selección de contenidos de un curso de Cálculo preuniversitario o universitario para no matemáticos.

Estrategia

Promover el intercambio de ideas y la discusión entre expertos invitados, así como entre los participantes, en torno al tema planteado y su objetivo. Se apoyará dicho trabajo mediante la presentación de un documento base para la discusión, elaborado por quienes proponen este nuevo Grupo de Trabajo.

Investigadores invitados

Luis Moreno Armella, Cinvestav, Mexico
Irene Biza, U. of East Anglia, UK
Fernando A. Hitt Espinoza, University of Quebec at Montreal, Canada
Anatoli Kouropatov, David Yellin and Levinsky College of Education, Israel
Patrick W. Thompson, Arizona State University, USA
Tin Lam Toh, National Institute of Education, Singapore
Laurent Vivier, University of Paris Diderot, France

Coordinador del Grupo de Trabajo

Fabio Augusto Milner, Arizona State University

Referentes teóricos

A partir de los referentes teóricos proporcionados por el Enfoque Ontosemiótico de la Cognición y la Instrucción Matemáticos EOS (Godino y Batanero, 1994), los investigadores han estado haciendo distintos esfuerzos para caracterizar tanto al Análisis Matemático como al Cálculo Diferencial e Integral, distinguiendo las *situaciones problema* que aborda cada uno de ellos, así como los *objetos matemáticos* que se emplean y emergen en el desarrollo histórico de cada una de estas dos áreas del conocimiento matemático. En particular, se ha puesto énfasis en identificar y caracterizar algunos de los *sistemas de prácticas matemáticas* y de los *objetos primarios* (situaciones problema, lenguaje, procedimientos, propiedades, argumentaciones y conceptos) en cada una de estas dos disciplinas.

Es importante, sin embargo, sistematizar y organizar los resultados parciales de estos esfuerzos en tres direcciones. En primer lugar, es importante tratar de identificar y caracterizar el may,or número de contrastes entre Cálculo y Análisis, a fin de que la distinción sea lo más completa posible. En segundo lugar, es importante analizar dichos contrastes desde el punto de vista de las posibilidades cognitivas y de las necesidades profesionales de los estudiantes (preuniversitarios y universitarios) que se inscriben en un curso de Cálculo. Esto último concierne de manera directa al diseño curricular del curso de Cálculo. En tercer lugar, y esto nos parece fundamental, es importante identificar, a la luz de dichos contrastes, las nuevas cuestiones psicopedagógicas, epistemológicas y didácticas que la investigación educativa deberá abordar y que no la hecho por falta de dicha clarificación.

En un contexto más amplio, esa distinción panorámica también es importante por cuanto permitirá precisar la visión con la que se pretenden introducir ideas elementales relacionadas con el Cálculo en la enseñanza temprana, y particularmente en la escuela secundaria.

Dinámica de participación

Se espera que los participantes del Grupo de Trabajo (al menos algunos de ellos), luego de analizar el documento base, puedan aportar ensayos breves relacionados con los tres aspectos del tema motivo de análisis y discusión, así como enriquecer las contribuciones de los demás.

Organización del trabajo del Grupo

Se planea organizar el trabajo del grupo en dos etapas. En la etapa previa a la realización de PMENA 2020, se contactará a investigadores que han estado trabajando en la línea de la temática propuesta y se los invitará a integrarse al grupo, familiarizarse con el documento base y preparar sus ensayos o aportes, que pondrán a disposición del grupo en la primera semana de octubre de 2020. En la segunda etapa, durante la celebración del encuentro, se estructurarán las tres sesiones de 90 minutos para la presentación de los ensayos y la discusión de los mismos. Para concluir se realizará una presentación final a cargo de los responsables del Grupo de Trabajo, quienes harán un balance de lo conseguido y esbozarán las tareas para el futuro encuentro.

A fin de que el trabajo del Grupo resulte lo más productivo posible, las sesiones de discusión y análisis se estructurarán con base en las tres líneas arriba mencionadas como sigue:

Primera Sesión. Necesidad de una distinción clara y sistemática de los contrastes didácticos entre el Cálculo y el Análisis Matemático. Los problemas epistemológicos, cognitivos y didácticos que emergen de dicha distinción.

Segunda Sesión. El impacto curricular que dicha distinción tendría sobre los cursos preuniversitarios y universitarios de Cálculo para no matemáticos. Esbozo general de las principales características de dichos cursos. El currículo de Cálculo temprano.

Tercera Sesión. La reorientación de la investigación educativa hacia los nuevos problemas psicopedagógicos, epistemológicos y didácticos que emergen como resultado de la reconceptualización didáctica del Cálculo y el Análisis Matemático.

The Gender and Sexuality in Mathematics Education Working Group convened in 2018 and 2019. Over the past two working group sessions, working group members have (1) shared historical and contemporary research related to the topics of the working group; (2) clarified language related to gender and sexuality; (3) developed understandings related to language and its influence on methods, results, and interpretations; (4) explored how gender and sexuality are experienced by students and teachers, and studied by researchers, in international contexts; and (5) developed research relationships among participants to explore relevant ideas. Based on the discussions from past working groups, during the 2020 Working Group, we will strengthen our understanding of these topics by examining underlying theories of gender and sexuality and the affordances of these theories on both research and practice.

Keywords: Gender and Sexuality; Equity and Diversity; Affect, Emotion, Beliefs, and Attitudes

The Gender and Sexuality Working Group has met during the two previous PME-NA conferences. These meetings have resulted in a shared foundational knowledge of the research area and has helped us develop understandings related to how language choices in gender and sexuality influence research methods, results, and interpretations. The goal of the 2020 working group is to expand our communal knowledge on utilizing theories of gender and sexuality within our work in mathematics education. In order to reach this goal, this year's working group is organized to provide participants with opportunities to develop deeper understandings of theories from gender and sexuality studies—with a focus on conceptions of identities.

Theoretical Background

The previous Gender and Mathematics Working Group contributed significant understandings regarding girls' and women's experiences in mathematics (See Forgasz, Becker, Lee, & Steinthorsdottir, 2010). Early research in this area focused on biological sex-based disparities in mathematics achievement (Lubienski & Ganley, 2017). Subsequently, the field shifted to study gender, via the sociocultural factors that influence girls' achievement and participation in mathematics (Leyva, 2017). In response to calls for clarity in the way that mathematics education researchers define and operationalize gender (Damarin & Erchick, 2010), theories of gender as performative (Butler, 1993) are now being employed in mathematics education research (i.e., Chronaki, 2011; Darragh, 2015; Gholson & Martin, 2019). Conceptualizing gender as performative repositions gender as an aspect of identity that is interactionally (re)produced. Researchers who investigate identity in mathematics education have also tended to draw on a variety of epistemological traditions (Darragh, 2016; Langer-Osuna & Esmonde, 2017). While identity categories have been problematized in feminist theories, queer theory has deconstructed the concept of identity. Some researchers have proposed a gender-complex education in which the existence of queer students is reflected in curricula (Rands, 2013; Rubel, 2016). The 2020 working group will focus on bridging theories of identity and gender to more fully understand their affordances and limitations when applied to teaching and learning mathematics. We will also discuss newer methodologies for research in mathematics education from feminist and queer theories (Mendick, 2005b; Rands, 2009).

Organization and Structure of the Working Group

The organization and structure of the working group were created to maximize participation, while focusing on topics that prior participants have expressed interest in discussing further. In the working group sessions over the past two years, participants have implicitly explored notions of identity as narrative and the construction of mathematics as a masculine domain (Mendick, 2005a), and explicitly sought ways to collect stories avoiding a gender binary. By discussing the topics for the 2020 working group, participants will extend their understanding of gender, sexuality, and identities. On Day 1, summaries of feminism and queer theory will be provided. On Day 2, specific notions of identity and its relation to performativity will be discussed.

Day 1: Feminism and Queer Theory

The working group will begin with a 20-minute presentation by Ana Dias and Weverton Pinheiro about the history of feminism and queer theory. Based on their research and collaborative conversations, they will summarize the theoretical underpinnings from these two theories as well as include examples of how these ideas have been used in mathematics education research. After the presentations, Ana and Weverton will facilitate an activity (15 minutes) to review research from these traditions and lead a discussion (50 minutes) about feminism and queer theory in mathematics education research. The major focus of these activities will be based on the *Political Grammar of Feminist Theory*. In the activities, participants will explore feminist progress, loss, and return (Hemmings et al., 2011), and the perspective of queer theory. Day 1 will end with a preview of the topics and activities for Day 2.

Day 2: Identity and Performativity

The themes for Day 2 are identity and performativity. The impetus for these topics is the 2019 working group discussion in which participants began questioning whether these concepts are compatible. Brent Jackson will give a 20-minute discussion that extends the topic from Day 1 to include how the notions of identity and performativity have been used in feminism and queer theory. Brent will also address the implications of their use in mathematics education research. Brent will then facilitate an activity (15 minutes) regarding methods that employ varying constructs of identity and performativity in mathematics education research. To conclude the session, Brent will lead a discussion (50 minutes) on the topics from the two days and address how the ideas apply to working group members' current research or new research ideas that have been provoked from the past activities. Working group leaders will then elicit comments and recommendations for how to structure Day 3 to help participants achieve their own goals and work toward the goals of the working group.

Day 3: Working Group Plans

Based on the interests of participants, Day 3 will be organized as whole-group discussion, small break-out groups, or a combination. By the end of Day 3, the group as a whole will have generated a plan to continue working together toward the working group goals.

In the proposed working group, we will build from the foundation of the past two years' working groups as well as our members' continuing collaborations with researchers outside of this group. Specifically, we propose three days of activity, each focused on different aspects of developing the body of mathematical play research. We have planned the three following foci: adapting existing mathematical tasks and curricula to increase opportunities for play (Day 1); the reverse, adapting voluntary play activity to support mathematical learning (Day 2); and developing synergistic dialogue with members of the EMIC research community through an intra-working-group discussion session (Day 3).

Keywords: Teaching tools and resources; Affect, emotion, beliefs and attitudes, Informal education

Understanding mathematical play at all ages is an important, yet under-investigated domain within mathematics education research (e.g., Holton et al., 2001; Wager & Parks, 2014). Over the past three years, members of this Mathematical Play working group have developed a community of colleagues focused on identifying and characterizing productive theoretical lenses and methodological approaches to investigate students' mathematical play. Central to this work has been the emergent characterization of mathematical play as (1) voluntary engagement in cycles of mathematical hypotheses with occurrences of failure (Authors), (2) often spontaneous and self-directed toward a player's emerging goals (e.g., Wager & Parks, 2014), and (3) supported or discouraged through physical or digital interactions (e.g., Authors; Sinclair & Guyevskey, 2018). In preparation for this year's working group proposal, our co-organizers have focused on situating our work based on the degree to which it might be characterized as pure play as well as the degree to which it can be characterized as structured mathematical instruction. This focus is consistent with what Wager and Parks (2014) discuss as two seemingly contrasting ideologies: groups advocating an increased focus on teacher-directed instruction and scholarship confirming that children learn best in play-based environments (p. 223). Wager and Parks (2014) also point to calls to identify practices that bridge the two ideologies, and this proposal is a direct response.

In order to address the existing theoretical divide between play and instruction, we will discuss and collaborate around theory and results from several projects that participating researchers might situate along the dimensions of play and instruction. These conversations will focus on how specific activities and instructional interventions might support shifts along those dimensions. That is, we will

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

focus on two shifts: how might an education researcher who has traditionally situated their work around more traditional mathematical tasks alter their existing instructional approaches to afford greater opportunities for play? And the complement: how might educators shift their interactions with students in a play setting to better support meaningful mathematical development?

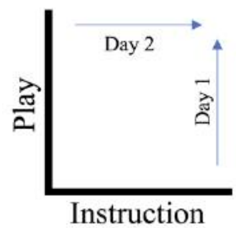

Figure 1: Graphic organization of two shifts we will explore – increasing the playfulness of high instructional tasks (Day 1) and increasing the instructional utility of high play tasks (Day 2)

Continuing the success of the last two years of the Mathematical Play PME-NA Working Group, we have developed the following overarching goals for this year's working group: (1) to engage participant researchers in conceptualizing the two shifts illustrated in Figure 1; (2) to share and discuss existing projects that are making or have made these shifts, specifically identifying frameworks and perspectives to support such shifts; and (3) to summarize these conversations and promote a synergistic dialogue with the EMIC working group.

Day 1 will center around examples of projects that originated as instructional activities but have shifted or are shifting toward more playful activities for students (Authors, Authors). Working group leaders will briefly introduce their projects and engage working group participants in tasks from their existing research projects. This will focus on identifying and discussing what play frameworks might be productive for supporting such transitions. The group will synthesize this discussion as a starting point to conceptualize how educators might incorporate playful activity within their existing instructional programs.

On Day 2, we will take a contrasting perspective as we explore design and facilitation practices that leverage mathematical play for learning. Leaders will engage group members in interactive play and board game activities with a focus on the mathematics that players draw on during their play. Leaders will then guide whole-group discussions to identify facilitation practices and pedagogical approaches to support meaningful learning in mathematical play.

On Day 3 the mathematical play working group will meet with the EMIC working group (Nathan et al., 2017) to explore areas of overlapping interest and potential convergence. Members of both groups will engage in intra-working-group conversations to highlight common theoretical and methodological approaches and identify opportunities for synergistic dialogue (i.e., mathematical play as an embodied way of learning, design considerations for embodied mathematical play, etc.).

Narrative inquiry, self-study, and autoethnography (i.e., self-based methodologies) are becoming a more common choice of mathematics teacher educators (MTEs). This has opened new possibilities and challenges for early career MTEs as they try to disseminate their findings in mathematics education journals. Building from our working group at PME-NA 2018 and 2019, we respond to the need for creating a community where MTEs can feel supported in their study design, implementation, representation of findings, and publication using self-based methodologies. This year, we continue our focus on mentoring and scholarship on self-based methodologies. We invite English- and Spanish-speaking MTEs with research projects in any stage of preparation to join us in discussions meant to promote growth, sustainability, and continued insight into the use of self-based methodologies.

Keywords: Mathematics Teacher Educators, Research Methods, Narrative Inquiry, Self-study, Autoethnography

Context and Significance

Building from Hamilton, Smith, and Worthington (2008), we have adopted the language of *self-based methodologies* (Chapman et al., 2020) to refer to narrative inquiry (Clandinin & Connelly, 2000), self-study (LaBoskey, 2004), and autoethnography (Ellis & Bochner, 2000). These research methodologies focus on self-understanding based on personal professional experiences and are often used in teacher education (e.g., Grant & Butler, 2018; Grant, 2019; Kastberg et al., 2019; Ross, 2003; Sack, 2008; Samaras & Freese, 2009). In mathematics education, self-based methodologies are growing in use in journals (e.g., Chapman, 2011; Chapman & Heater, 2010; Cox et al., 2014; Grant & Butler, 2018; Kastberg et al., 2018; Kastberg et al., 2019) and conferences (Brand, & Jung, 2019; Clark et al., 2019; Cox & D'Ambrosio, 2015; Gallivan, & Rumsey, 2019; Kinser-Traut, 2018; Kosko, 2019; Lischka et al., 2018; Lischka et al., 2019; McGraw & Neihaus, 2018; Richardson & Zhou, 2019; Towers et al., 2019; Truxaw & Rojas, 2019). Yet, using self-based methodologies is still less widespread in the mathematics education field. Our goal is to keep growing our international community of MTEs, in which they feel sustained and empowered in their use of self-based methodologies.

History of the Working Group

Over the past two years, we have been building a community with the goal to support each other and to expand our network of MTEs who use self-based methodologies (Suazo-Flores et al., 2018; Suazo-Flores et al., 2019). After receiving positive responses from conference attendees in North America, our goal now is to diversify our membership by providing spaces for Spanish-speaking

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

MTEs who want to learn, or are already using, self-based methodologies. We resonate with Whitcomb et al. (2009) call for creating spaces where MTEs feel energized. Over the last two years we have felt energized, which motivates us to continue providing spaces at conferences where MTEs who use self-based methodologies feel sustained and empowered in their professional practices (Jaworski & Wood, 2008). We think organizing such spaces contributes to the diversification in the use and acceptance of self-based methodologies (Bullock, 2012; Stinson & Walshaw, 2017).

Plan for the Working Group

We anticipate that many of the attendees at PME-NA 2020 will be Spanish speaking MTEs. Therefore, our working group will be facilitated in both Spanish and English. Given the personal nature of studies conducted under self-based methodologies, we will work on creating an atmosphere of trust and care. Day 1 will be a professional development day where the audience will learn about (1) communities of practice, (2) focus, (3) characteristics, (4) methods, and (5) professional growth in these methodologies. On Day 1 MTEs will also start drafting questions or topics they would like to explore. On Day 2, participants who have used self-based methodologies will be invited to share their work so that MTEs, who are new to such methodologies, can ask questions. We envision Day 2 also as an opportunity for the presenters to receive feedback on their ongoing work. On Day 3, MTEs will work in small groups where they can feel vulnerable and receive more personal feedback. MTEs who are new to these methodologies will continue planning inquiries to puzzling questions or topics of their interest using self-based methodologies. We will conclude our time together on Day 3 with the group planning for future meetings and projects, so that we keep nurturing each other in the use of self-based methodologies.

Conclusion

As MTEs increasingly use self-based methodologies, communities are needed to support their research practices including study design, implementation, representation of findings, and publications in mathematics education journals. This working group intends to be such a community, where over time MTEs feel supported and sustained in their use of self-based methodologies.

Goals:

There are three goals for this new working group: 1) To create a community of mathematics teacher educators (MTEs) who are (or are interested in) collaboratively teaching mathematics for social justice (TMfSJ) in their university content and/or methods classes. 2) To collaboratively select/develop/modify TMfSJ tasks and implement those in mathematics content/methods classes. 3) To research the implementation of TMfSJ tasks in content and methods classes.

Strategies to Reach Those Goals:

The organizers have all (to some level) incorporated TMfSJ into their teaching. At a recent workshop, many of the organizers collaborated on designing one task to implement in both content and methods courses focused on understanding gentrification across the United States and also locally in each collaborator's own city/area. This collaboration was highly beneficial and led us to envisioning this working group. Our goal is to create a community of MTEs who will collaboratively develop and implement TMfSJ tasks in their university courses and research the implementation for (in no particular order): (a) preservice teacher (PT) learning about the mathematics, (b) PT learning about the sociopolitical context, (c) impacts 'on PTs' view of mathematics and/or teaching mathematics, and (d) the potential for TMfSJ in university methods or content courses to ignite a call for action.

Background:

Children and youth in schools today are increasingly aware of and grapple daily with the social injustices that pervade our world. Mathematics educators face a moral and ethical imperative to support students in their struggles to make sense of and fight against these injustices (Stinson, 2014). Incorporating social issues into the mathematics curriculum offers one way to both deepen students' mathematics knowledge and encourage the application of mathematics to understand and potentially change their world (Frankenstein, 2009). The Teaching Mathematics for Social Justice framework (TMfSJ) includes two critical interrelated ideas. First, school mathematics can be used to teach and learn about issues of social and economic justice. Second, mathematics can be taught through the study of social justice issues - the development of mathematical literacy itself being an important social justice issue (Gutstein, 2003; Raygoza, 2016). A growing body of research shows how TMfSJ lessons can support PK-12 students to learn mathematics, interrogate social justice issues, and deep positive mathematics identities (e.g. Chao & Marlowe, 2019; Esmonde, 2014; Gutstein, 2003; Turner, Gutiérrez, Simic-Muller, & Díez-Palomar, 2009).

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Given the power of TMfSJ with PK-12 students, some MTEs seek to integrate TMfSJ tasks into their courses in order to give PTs, who have little or no experience with TMfSJ, opportunities to experience integrated learning of mathematics and social issues and to consider the relevance of TMfSJ to their local communities and instructional possibilities in their future classrooms. Research on TMfSJ in mathematics teacher education tends to focus on PT or teacher learning about the pedagogical conceptions and practices of TMfSJ (e.g. Bartell, 2013; Jong & Jackson, 2016). PTs, however, also need opportunities to develop mathematical knowledge (Ball, Thames, & Phelps, 2008) and political knowledge (Gutiérrez, 2017) for teaching mathematics generally and to enact TMfSJ, specifically. Little attention has been paid to the potential for TMfSJ in mathematics content and methods courses impact PTs' mathematics learning, understanding of social issues, and mathematics identities as well as their teaching practices. In other words, we seek to develop a research program that explores PTs learning not only *about* TMfSJ but also *through* TMfSJ.

Given the complexity of social issues and the challenge of using mathematics in authentic ways, TMfSJ proves more effective through multiple iterations over time (Harper, 2019). Accordingly, TMfSJ with PTs cannot happen in a single class. Instead, we seek to explore these ideas across content and methods courses at multiple spaces so that we can describe the complexity of these and other issues with our future teachers (and hopefully with their future students). This is especially true for content courses which allow elementary PTs to experience such tasks from a learner's perspective and to learn to read and write the world themselves. PTs can then build upon this in methods courses to explore the pedagogical practices for TMfSJ.

Many PTs enter their coursework believing that mathematics is neutral or universal (Greer, Verschaffel, & Mukhopadhyay, 2007; Keitel & Vithal, 2008). MTEs must address the fact that mathematics can never be neutral and no classroom is a neutral space (Frankenstein, 1983; Gutiérrez, 2013; Yeh & Otis, 2019).TMfSJ offers a means of engaging PTs in building their sociopolitical consciousness about the political implications of mathematics and how math can be leveraged to read and write the world (Gutstein & Peterson, 2005) from both a content and teaching methods perspective.

In some cases MTEs have met resistance from PTs when integrating social justice issues into the mathematics curriculum (Aguirre, 2009; Ensign, 2005; Felton-Koestler, Simic-Muller, & Menéndez, 2012; Rodríguez & Kitchen, 2004). However, MTEs have also found that they are able to broaden PTs' perspectives about mathematics and mathematics teaching (Bartell, 2013; Ensign, 2005; Felton & Koestler, 2015; Leonard & Moore, 2014; Mistele & Spielman, 2009) when PTs are given opportunities to engage in TMfSJ tasks during teacher preparation. This aligns with Gutstein's (2003) goal of supporting students in developing their sociopolitical consciousness, and possibly a stronger sense of agency and identity. Given the possibilities for TMfSJ to impact both PT and PK-12 student learning and mathematics identity in similar ways, PME-NA offers an ideal community for spearheading this work by bringing together experts in both student and teacher learning.

Participant Engagement

Session 1: Successes and struggles implementing TMfSJ tasks: 1) Organizers will present (30 minutes) on how they have used TMfSJ tasks in their classrooms. 2) Participants and organizers discuss the successes and struggle in implementing TMfSJ tasks. 3) Towards the end of the session, organizers will introduce one context to focus on for the next two sessions (e.g. gentrification) as well as an online media platform for continued participation with this group.

Session 2: Entry points for TMfSJ tasks: 1) We will discuss various entry points (focus on math and social issue) for TMfSJ tasks. 2) We will collaboratively engage in the use of one context in our classes and potential tasks that could go with that context. 3) Participants will share their own experiences and how they may envision using such a context in their class.

Session 3:1) We (in small groups) will collaboratively create/adapt TMfSJ task(s) to participants' localized contexts to use in their teaching. Participants will leave with a more nuanced understanding of TMfSJ tasks/implementation. 2) We will set up structures to follow up via online media after implementations. 3) The goal will be to meet at next year's PME-NA.

The concepts and practices of the discipline of statistics are crucial for engaging in government and society in the current information age. These concepts and practices are also a part of the school mathematics curriculum to help prepare students to be able to think and reason statistically in their daily lives. The relevance to learning statistics and the importance of its concepts and practices know no boundaries, as statistics is part of the human endeavor to make sense of the world we live in. In spite of this, due to sociopolitical forces, ideas, resources, and research often do not cross political and social boundaries. The goal of this group is to begin to break down some of those boundaries of isolation to create spaces for collaboration and leveraging our shared understandings for positive change. A particular focus given the location of the conference is to break down political and social barriers sharing ideas and resources.

Keywords: Data Analysis and Statistics, Cross-cultural Studies

Creating opportunities for students to engage in statistical investigations to learn statistical concepts and become attuned to statistical practices is crucial for mathematics educators (Franklin et al., 2007, 2015) making it relevant for PME-NA. The centrality of context to statistical inquiry makes its practices powerful for students to make sense of their world (Cobb & Moore, 1997; Wild & Pfannkuch, 1999). During the 2019 PME-NA Conference the goal of the statistics education working group was to create a space for those interested in researching issues around the teaching and learning of statistics to meet, discuss, synthesize past research, and begin to strategize ways of leveraging multiple perspectives and expertise to identify and address current challenges in statistics education. The goals of this year's group are still in a similar vein, but we want to take advantage of the location of the conference in Mexico to collaborate and discuss statistics education across political and social boundaries to share ideas and resources.

Education systems are very contextualized, which can lead scholars to focus on their specific context. One of our goals is to share challenges and insights that statistics educators have from the contexts that they work in to consider similarities and differences and to learn from one another. Such sharing is important because though North America includes Canada, Mexico, and the United States the political powers in those countries create obstructions physically, emotionally, psychologically, and discursively between their citizens and those of the other countries, which have isolating effects. However, people move back and forth across those made up boundaries spreading ideas and culture. Therefore, in education, a social science, we face some of the same challenges. Because of our contextual differences, we have also likely tackled challenges in different ways based on the resources we had available. Furthermore, based on differences in language and power structures we have likely faced different challenges that we may be able to help one another. Through sharing our experiences, we share insights on how to tackle common challenges, reflect on what we are missing in our work, consider important challenges for us to tackle together, reflect on what needs we have, and consider what help and support we can give. We plan to develop a mechanism for the communities to share and support one another with ideas, resources, data, and social and political experiences. We also hope to share ideas about ways we can talk about real-world controversial issues in our classrooms that are relevant to the lives of our students safely and critically – a very important aspect in all mathematics classrooms, but essential in statistics classrooms due to the nature of exploring and analyzing relevant data. Finally, we aim to find ways to share ideas across languages and cultural communities and find ways to break down barriers to the English dominant scholarship.

Theoretical Framing

To frame the work of the working group we draw from Communities of Practice (CoP; Lave & Wenger, 1991; Wenger, 1998). All of the authors are members of various CoP's relevant to the focus of the working group including those of statistics, statistics education, and mathematics education. We also come from different communities, particularly in the contexts we work within. We view this working group as a space were we come together to share challenges and lessons learned as well as consider our roles as boundary crossers and how we and the resources we produce might break down some of the boundaries of the communities we are situated and the communities we are interconnected by. This framing is consistent with past work of the authors in considering how CoP's can be used with teacher professional development (Gómez-Blancarte & Viramontes, 2014) and organizing researchers (Tauber et al., 2019).

Table 1: Plan for Active Engagement of Participants

Session	Activities
Session 1: Sharing	• Participant introductions. • Brief presentations of selected projects from authors' various contexts to highlight challenges in statistics education research to begin discussions. • Participants share their context for statistics education and challenges. • Identify similarities and differences in contexts and challenges. • Discuss how we can collaborate and what we hope to gain.
Session 2: Discussing	• Group discusses insights we have collectively on the similarities in contexts and challenges identified during the first session. • Group discusses resources they have to tackle the challenges identified. • Group will discuss what would be helpful and sustainable mechanisms for sharing ideas and resources beyond the conference.
Session 3: Planning for Action	• Participants brainstorm ways of tackling challenges different from their own identified during the first session to bring new ideas to bear. • Participants create a plan of collaboration for after the conference, research ideas, analyzing data together, writing together, etc.
After conference: Action	• Group continues to collaborate to implement the ideas and share resources based on connections made during the conference. • Group members begin longer term research collaborations.

We describe how we supported middle-school students developing meanings for quadratic growth by bringing together three theoretical framings and designing a task sequence grounded in that framework. Specifically, this framework was assembled from the research on students' quantitative and covariational reasoning, Realistic Mathematics Education, and the theory of designing for mathematical abstraction. We present data from a teaching experiment to highlight how this task sequence supported students as they imagined constant increases in the amounts of change in one quantity, a kind of change they later understood to be a defining characteristic of quadratic growth. We conclude with a discussion of our findings and how our integration of the three frameworks proved useful to design a productive task sequence.

Keywords: Algebra and Algebraic Thinking; Middle School Education; Design Experiments

Quadratic relationships are an important topic in middle-school through college mathematics. In this study, we build on prior work (e.g., Ellis & Grinstead, 2008; Ellis 2011a, 2011b; Hohensee, 2016) that provides accounts of middle and high school students developing productive meanings for quadratic relationships via their quantitative and covariational reasoning. Whereas students in these studies leveraged numeric quantitative reasoning, we were interested in designing a task sequence that supported them in both non-numeric and numeric reasoning to develop meanings for quadratic growth. Hence, our goal is to address the research question: *How can middle-school students leverage non-numeric and numeric quantitative and covariational reasoning to develop meanings for quadratic growth?*

In what follows, we outline our operationalization of quadratic growth grounded in students' quantitative and covariational reasoning, and then describe a task sequence we developed with principles of Realistic Mathematics Education (RME) and designing for abstraction in mind. We highlight how this task sequence was productive in supporting students developing productive meanings for quadratic growth. We conclude by highlighting how the three theories interacted to inform the task design and development.

Quantitative Reasoning, Covariational Reasoning, and Quadratic Change

As conceptual entities, meanings for quantities can and do differ from individual to individual. Therefore, it is critical to attend to a *student's* meanings for quantities. Accordingly, Steffe, Thompson, and colleagues' stance on quantitative reasoning (Steffe, 1991; Smith III & Thompson, 2008; Thompson 2008) underscores the thesis that as students construct quantities in order to make sense of their experiential world (Glasersfeld, 1995), teachers and researchers cannot assume that students maintain understandings of quantities that are compatible with teachers' and researchers' intentions.

Quantitative reasoning can involve numerical and non-numerical reasoning (Johnson, 2012), but the essence of quantitative reasoning is non-numerical (Smith III & Thompson, 2008). Building on these

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

prior descriptions of quantitative reasoning, Carlson et al. (2002) described covariational reasoning as entailing a student coordinating two quantities with attention to the ways the quantities change in tandem. They specified mental actions that allow for a fine-grained analysis of students' activity. The mental actions include coordinating *direction of change* (area increases as base length increases; MA2) and *amounts of change* (the *change* in area *increases* as base length *increases in equal successive amounts*; MA3). Whereas researchers (Johnson, 2012; Moore, 2016; Paoletti & Moore, 2017) have described productive ways high school and college students can engage in reasoning compatible with Carlson et al.'s mental actions, few studies have explored the possibility of middle-school students enacting these mental actions in productive ways (e.g., Ellis, 2011a). We pay particular attention to MA3 as critical to students developing meanings for quadratic relationships, and we characterize a productive meaning for quadratic change to entail a student understanding that as one quantity changes by equal amounts, the amounts of change of the second quantity increase (or decrease). Further, and consistent with meanings described by others (Ellis, 2011a, 2011b; Lobato et al., 2012), these amounts of change increase (or decrease) themselves by a constant amount. Hereafter, we refer to these constant amounts of change of the first amounts of change as a constant AoC of AoC.

Ellis (2011b) provides evidence that middle-school students are capable of engaging in such reasoning. In her examination of middle-school students' ways of reasoning about heights, lengths, and areas of a growing rectangle, she describes how the students numerically and pictorially represented the first and second differences to identify a constant second difference, which later supported them in developing meanings for quadratic change. Building on and extending this work, we are interested in exploring whether we can support students in first identifying constant AoC of AoC non-numerically prior to reasoning numerically to develop meanings for quadratic growth.

Designing for Mathematical Abstraction with RME Principles in Mind: An Example Task

We begin by outlining important aspects of RME and designing for mathematical abstraction that informed the task development. Then we introduce the *Growing Triangle Task*.

RME is an instructional theory that aims to find ways to connect what students already know to what they do not yet know (Gravemeijer, 2008). RME's emphasis is on opportunities for students to re-invent mathematics by organizing experientially real situations (Cobb et al., 2008; Gravemeijer, 2008). Tasks are experientially real to students if they can engage in personally meaningful mathematical activity; they need not refer to some 'real-world' situation or context.

By having students engage in an experientially real context, we intend to support their *horizontal mathematization*, a process that refers to a student's development of meanings for a specific context. A student's initial *model of* (Linchevski & Williams, 1999) the situation is specific to the context but should support her in developing informal strategies and representations that will be useful as she begins to generalize to other contexts. After beginning to mathematize the situation, a student can start the progressive process of *vertical mathematization,* which entails extending her informal mathematical representations or activity into more normative representations or activity. Thus, horizontal mathematization is preparation for vertical mathematization. Vertical mathematization may involve using conventional notations such as making a drawing, table, or graph (Cobb et al., 2008; Gravemeijer & Doorman, 1999). As students gather more experiences with similar problems, their attentions may shift towards mathematical relations and strategies which helps them develop further mathematical relations and a resulting shift from *models of* a context to *models for* a mathematical idea. This shift allows the students to use the model in a different manner (Gravemeijer, 2008) thereby becoming a *model for*. We describe in the Task Design section how we imagine this transition occurring in the context of quadratic growth.

Our operationalization of quadratic change emphasizes the importance of students constructing AoC of AoC as a quantity unto itself and then identifying constant AoC of AoC. We leveraged 3D-printing to design physical manipulatives we conjectured could support the students in both of these endeavors. As Greenstein (2018) noted, "The faithful mental representation of objects is critical, because conceptual thought proceeds from representational thought and representational thought proceeds from perception" (p. 3). Hence, leveraging principles of *designing for mathematical abstraction* (Pratt & Noss, 2010), we devised the physical manipulatives with the intention of making several quantities of interest, including AoC of AoC, available to students for abstraction through their sensorimotor engagement with those manipulatives (Piaget, 1970). We describe these manipulatives in the next section.

The Growing Triangle Task

We designed the *Growing Triangle Task* (https://bit.ly/2YTjwmj) with principles of RME, designing for abstraction, and theories of students' quantitative and covariational reasoning in mind. In this task sequence, students first interact with a dynamic GeoGebra applet showing an apparently smoothly growing scalene triangle (Figure 1a). Our intention is to provide students an experientially real context so that they could develop a *model of* the growing triangle situation. To support the students in attending to the triangle's area and base length (i.e., reasoning covariationally), we highlighted the base length of the triangle in pink and the area in green. The area and base length grow (apparently) smoothly as the longer slider increases (apparently) smoothly. With AoC in mind, we included a second smaller slider which allows students to increase the increment by which the pink length increases (e.g., to equal integer chunks versus apparently smoothly). We have the 'trace' option available so that students can visually identify the increasing AoC of area in the applet (i.e. the increasing size of the consecutive trapezoids shown in Figure 1b).

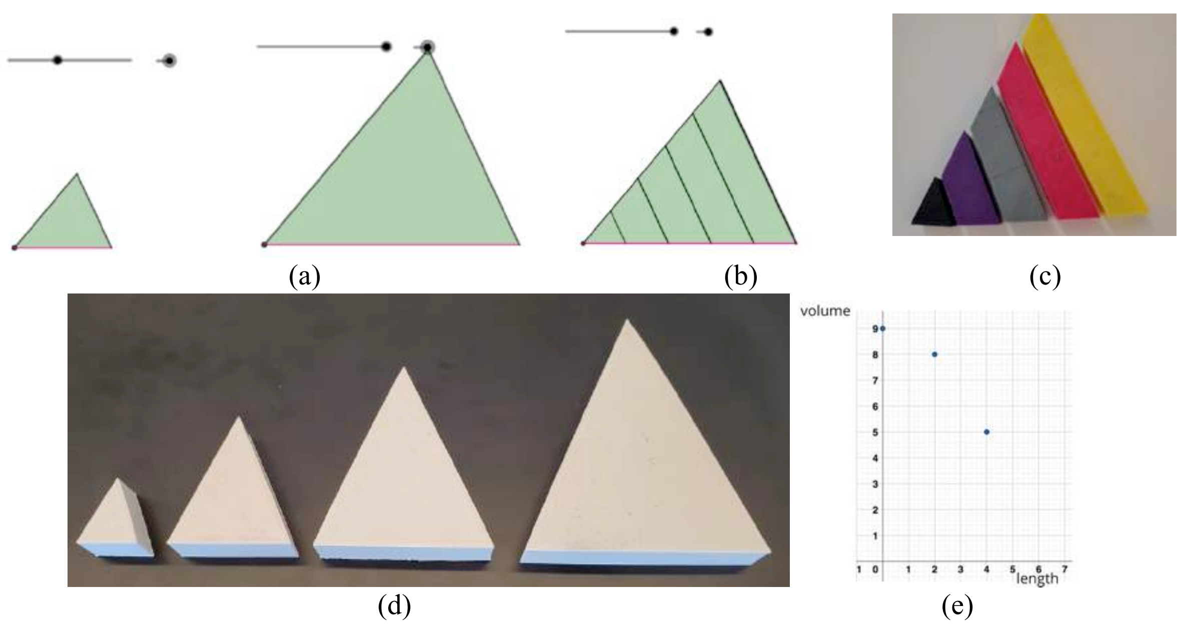

Figure 1: (a/b) Several screenshots of the *Growing Triangle Task* shown in applet, (c/d) images of manipulatives and (e) new task for vertical mathematization

We conjectured that although the visual representation provided by the applet may support students in identifying the increasing AoC (MA3), it was unlikely to support them in identifying the constant AoC of AoC. Hence, with designing for abstraction (Pratt & Noss, 2010) in mind, we 3D-printed a set of manipulatives that consisted of four consecutive gray triangles (Figure 1d) to represent the growing triangle at four equal integer increases of the base length and five AoC blocks (one triangle in black, and four trapezoids, Figure 1c). Thus, these designs make these representations of increase in the amount added to each triangle to get to the next consecutive triangle available to students through their mediated engagement with them. Figure 2b demonstrates this potential for abstraction: by stacking the physical representations of change on top of each other, students can construct non-numerical interpretations of the constant AoC of AoC. After doing so, we will ask them to create a table of values for the relationship to explore if (and if so, how) they identify the constant AoC of AoC in this representation.

After developing a *model of* the Growing Triangle situation, the next step is to support students in extending this model by developing a *model for* constant AoC of AoC (i.e., by continuing the process of vertical mathematization). To do this, we presented them with several graphs, each with three points, and the instructions, "For each of the following, we know the differences in the amounts of change of volume are constant with respect to the length of a side. Complete each graph". In the ensuing activity, after students determined additional points using the constant AoC of AoC, they will be introduced to a normative definition for quadratic growth to further support their vertical mathematization: "Whenever the *amounts of change* change constantly (i.e. we have a second constant difference), the relationship is *quadratic*." Additionally, we consider that this activity may support students in developing more sophisticated meanings for other polynomial relationships. In such cases, these relationships and their related properties will be discussed (e.g., cubic growth has a constant third difference, etc.).

Methods, Participants, and Analysis

To examine the potential of supporting students in developing meanings for quadratic change, we conducted a teaching experiment (Steffe & Thompson, 2000) situated in a whole-class setting. The teaching experiment occurred in a middle school that hosts a diverse student population (over 75% of the students are of color; 75% are entitled to free or reduced-price lunch), in the northeastern United States. The class was selected from a convenience sample. The teacher of the school's only accelerated 8th grade geometry course[1] invited the research team to explore new activities with her students. We taught five class sessions, with each session scheduled for 76 minutes. We covered a variety of topics in these sessions (see Table 1), with the focus of this paper being the fifth session. The class had eight students who worked in three groups on large whiteboards during class time. We video- and audio-recorded two of the groups (one group of three and one pair), capturing their utterances, motions, and written work. For brevity's sake, we focus this report on the group of Neil, Aaron, and Nigel (pseudonyms).

Adopting a radical constructivist perspective (Glasersfeld, 1995), we contend that a student's mathematics is inaccessible to us as researchers. Hence, to analyze the qualitative data, we performed conceptual analyses (Thompson, 2008) to generate and test models of each student's mathematics so that these models provided viable explanations of his observable words and actions. With the goal of building viable models in mind, we analyzed the records from the teaching episodes using open (generative) and axial (convergent) approaches (Strauss & Corbin, 1998). Specifically, we watched all videos to identify instances that offered insights into each student's meanings. Using these instances, we generated tentative models of each student's mathematics, which we compared to researcher notes taken during on-going analysis. We tested these models for viability by searching for supporting or contradicting instances in his other activities. When evidence challenged our

[1] Most students in the school take algebra in 8th grade. The terminology is used to be consistent with the school's name for the course.

models, we revised hypotheses to explain each student's meanings and returned to prior data with these new hypotheses in mind to modify previous hypotheses. This process resulted in viable models of each student's mathematics.

Table 1: Whole class teaching experiment sequence

Session	Task	Content topics for students to develop
1 & 2	Faucet Task (see Paoletti, 2018)	Coordinate Systems, graphs, and graphing
3	Triangle Task (Part I)	Non-linear change
4	Triangle/Rectangle Task (Paoletti, Vishnubhotla, & Mohamed, 2019)	Comparing non-linear and linear change, Systems of Relationships
5	Triangle Task (Part II)	Extending non-linear change to quadratic change
6	Post-test	

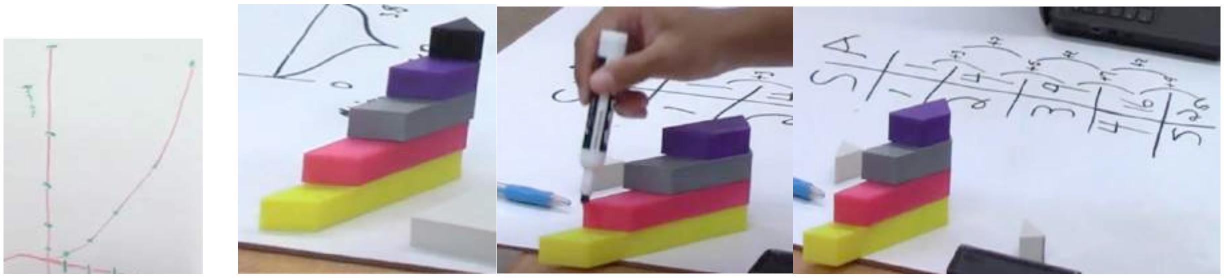
Results

In this section, we first highlight the students reasoning non-numerically about the quantities in the *Growing Triangle Task*. We then present the students' activity with manipulatives, which facilitated their identifying constant AoC of AoC (i.e., an instance of horizontal mathematization). We then characterize how the students develop a *model of* constant AoC of AoC when they are presented with a new task (shown in Figure 1: (a/b) Several screenshots of the *Growing Triangle Task* shown in applet, (c/d) images of manipulatives and (e) new task for vertical mathematization e), and how that *model of* transitions into a *model for* quadratic growth. We conclude with examples of student work on the post-test to characterize the extent to which students engaged in vertical mathematization.

The Growing Triangle Task: Horizontal Mathematization

Introducing the *Growing Triangle Task* on Day 3, the teacher-researcher (TR) distributed the manipulatives to the class intending to support the students in differentiating between the total area of the triangle and the changes in area for each increase in base length. To support the students developing meanings for area and change in area, the TR began with the first triangle (shown in Figure 1c) and added the first change. He asked the class, "When I add another unit of side length, is the amount of area I'm gonna add, is it the same amount, more, or less?" Neil responded, "More." The students were then asked to open up the applet on a laptop and begin making observations about the changes in the triangle. As they watched the applet play, the three students discussed how the changes were growing. When the TR asked, "So initially do we have a big jump, a small jump, medium jump?" Both Aaron and Neil simultaneously responded, "Small." As the TR asked what happened for the next two jumps, Neil responded, "It gets larger… even larger." In this activity, Neil's quantitative understanding of area was elicited as he described it growing by increasing amounts (MA3). After this interaction, Neil plotted points accurately representing this relationship between area and base length (Figure a). We infer Neil was reasoning covariationally as he leveraged non-numeric images of total area and AoC of area in the situation to graphically represent each quantity and the resulting relationship.

Whereas the focus of Day 3 was on supporting students in identifying increasing AoC, on Day 5 we returned to the triangle task with the intention of supporting students in imagining constant AoC of AoC in this context. Because the students had already identified increasing AoC of area with respect to side length, the TR asked the students to consider, "How do the amounts of change compare to one another?" The TR requested the students "play around with the manipulatives and explore." Neil and Nigel began to stack the trapezoidal manipulatives on top of one another in consecutive amounts (shown in Figure b). The following conversation ensued:



(a) (b) (c) (d)

Figure 2: (a) One group's graph; (b/c) students notice a constant second difference and use manipulatives to identify it; and (d) table displaying students' work

Neil: [*Places yellow trapezoid on bottom then places pink trapezoid on top*] Ooh! Look, look, it's a quadrilateral [*pointing to the piece at the end of yellow trapezoid not covered by the pink trapezoid, seen in Figure b*].

Aaron: Mmhmm. [*Agreeing*]

Neil: Right, look, if we do it again. [*Nigel places gray trapezoid on top of the pink trapezoid*] Same size [*pointing to quadrilaterals created by the difference in the yellow and pink trapezoids and pink and gray trapezoids to indicate these amounts are the same*]. Put that one on [*Nigel places the purple trapezoid on top of the stack*] Same size [*referring the quadrilateral formed by the difference in purple and grey trapezoids*].

TR: So what did you notice?

Neil: It's like, this quadrilateral [*pointing to quadrilateral shown by the differences Figure b*] keeps going I guess, it's added on to that [*pointing to each layer of the stack of trapezoids*].

TR: That, that piece we're adding on to the amounts of change is always the same? [*Nigel nods in agreement as TR speaks*]

Neil: [*as TR is completing his remark*] Yeah.

In this conversation, Neil characterized the amount being added to each trapezoidal AoC manipulative as equal (i.e. constant AoC of AoC). We conjectured from activity (e.g., adding consecutive trapezoids to the stack), agreement throughout the conversation, and their later activity, that Nigel and Aaron also understood that the relationship between area and side length exhibited constant AoC of AoC. We provide evidence for this shortly.

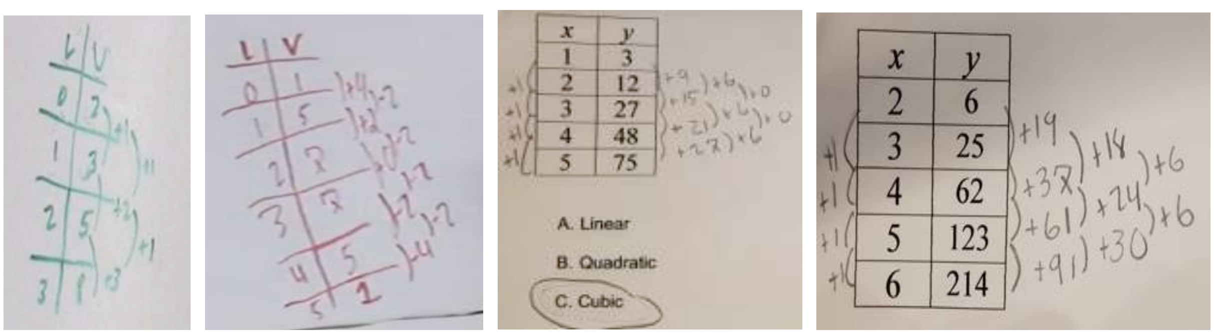
Beginning vertical mathematization for AoC of AoC

After identifying non-numeric constant AoC of AoC using informal representations, the TR prompted the students to create a table of values as a way to normatively represent such a relationship (i.e., an instance of vertical mathematization). His goal was for students to consider how the constant AoC of AoC would impact the numeric values in the table. The TR designated the smallest gray triangle as having an area value of one, and with this value of one, the students identified the purple trapezoid as having an area of three units and the total area of the resulting triangle as composed of four units. Similarly, when adding the pink trapezoid to the total area, Neil identified the area of the pink trapezoid as "seven," then immediately described the total area as "seven plus nine," with nine being the total area of the previous triangle. We infer Neil understood that in order to find a new total area he must first identify the AoC of area from the previous base length to the new base length and add that AoC-value to the previous total area. Using this reasoning, the three students completed their table (shown in Figure 2d).

To build on the students previously identifying non-numeric constant AoC of AoC, the TR asked the students how the values they had identified for the trapezoidal AoC manipulatives (i.e. first difference), and the differences in these (i.e. second difference), were represented in their table. As part of this process, the students identified the differences with Aaron notating with arrows and values (e.g., '+3', '+5') the AoC from one consecutive area to the next (seen in Figure d). As Aaron identified several AoC-values and notated them besides the corresponding total area values in the table, he spontaneously described how the constant AoC of AoC was represented to his peers. Pointing to the '+3' and '+5" written adjacent to the table, he said, "It's two" and then pointed to the quadrilateral made by differences of the AoC pieces (Figure c). We infer Aaron was connecting their informal identification of the constant AoC of AoC with the manipulatives to the changes in the AoC represented in their table.

Moving to a *model for* constant AoC of AoC

After each group identified the constant AoC of AoC in the table, we provided them with new tasks (example shown in Figure 1d) representing volume and length values for some new hypothetical situation. Indicative of the students engaging in extending their *model of* the *Growing Triangle Task* to a more general *model for* constant AoC of AoC, on the first task Aaron drew a table with the coordinate values, found the first AoC in the second quantity ('+1", "+2"), then identified an AoC of AoC value of '+1". Using the constant second difference, Aaron found the next first difference ('+3', shown in Figure 3a) and used this value to determine the next volume-value of eight. In the second task, Nigel engaged in compatible activity with a second difference value of '-2' (Figure 3b). We infer the students leveraged a meaning for constant AoC of AoC to calculate values of new points in a given relationship (i.e. a shift to a *model for* constant AoC of AoC). After engaging in this activity, we concluded the class episode by introducing the definition of quadratic (as well as cubic) growth as described above to extend students' understandings of a relationship that contains a constant second difference as quadratic.



(a) (b) (c) (d)

Figure 3: (a/b) Samples of students' vertical mathematization; post-test questions with students' work on (c) quadratic and (d) cubic relationships

Evidence of a *model for* quadratic growth

We present data from a post-test given on Day 6 as evidence of the three students extending their *models for* constant AoC of AoC to *models for* quadratic growth. The post-test included two tables (shown in Figure 3.c/d), with options linear, quadratic, cubic, or exponential. Given the first table (as shown with Nigel's work in Figure 3c), Neil and Aaron found a constant second difference and identified the relationship as quadratic. Nigel's work indicates he also successfully found a constant second difference, but then moved on to find a constant third difference of '+0' and concluded that the relationship was cubic. One possible explanation is that Nigel may not have noticed the constant second difference prior to finding the constant third difference; if this were the case, and Nigel had noticed the constant second differences, we conjecture he likely would have chosen quadratic. This conjecture is based in part on his response addressing the second table in which he and the other two students identified a constant third difference (shown in Figure 3d) to conclude the growth was cubic. Hence, we infer each student has at least begun to develop *models for* quadratic (and cubic) growth.

Discussion and Implications

To conclude, we highlight how we were able to draw from theories on students' quantitative and covariational reasoning (Carlson et al., 2002; Smith III & Thompson, 2008), designing for mathematical abstraction (Pratt & Noss, 2010), and RME instructional theory (Gravemeijer, 2008) to support students building *models for* quadratic growth (and potentially *models for* other polynomial growth as well). These findings extend previous examinations of middle-school students developing meanings for quadratic change (e.g., Ellis, 2011a) by describing how they leveraged their non-numeric quantitative and covariational reasoning to identify constant AoC of AoC before representing such relationships numerically.

We intend for our description of the task design and sequence to highlight ways in which these theories can work together to inform the design of a task sequence that is responsive to students' reasoning activity. For example, designing for mathematical abstraction supported us in developing manipulatives that we conjectured could support students constructing quantities, including total area, AoC of area, and AoC of AoC of area in ways compatible with our intentions. Further, these manipulatives supported students' non-numeric and numeric quantitative and covariational reasoning as well as their engagement in the mental actions described by Carlson et al. (2002). Connecting RME to the other theories, we note how the 3D-printed manipulatives were critical as the students transitioned to vertical mathematization as they identified constant AoC of AoC. Similarly, we highlight how the students leveraged their quantitative and covariational reasoning as they moved from *models of* the *Growing Triangle Task* to *models for* constant AoC of AoC, and further to *models for* quadratic growth.

We highlight the productive meanings for quadratic growth the three students described here developed as part of this study, and offer this research as both an existence proof and starting point for future researchers interested in exploring how to support larger populations of middle-school students in leveraging non-numeric and numeric quantitative and covariational reasoning to develop important mathematical ideas including quadratic and cubic growth. Integrating activities like these with activities described by Ellis (2011a), for example, may support students in developing more productive meanings for AoC and quadratic growth. Future researchers may be interested in exploring this possibility.

UNIT TRANSFORMATION GRAPHS: A CASE STUDY

Anderson Norton

We introduce a methodology for diagramming the ways students use sequences of mental actions to solve mathematical tasks. We studied 12 pre-service teachers as they solved a set of fractions tasks, ranked by cognitive demand. We present the unit transformation graphs for one of those pre-service teachers, to illustrate how she experienced and met cognitive demand across the fractions tasks. Specifically, the graphs illustrate how sequencing mental actions places demands on working memory and how units coordination structures can offload some of that demand.

Keywords: Cognition; Learning Theory; Number Concepts and Operations; Problem Solving.

Prior mathematics education research from a Piagetian perspective has identified students' construction and transformation of units as central to their development of number, extended to rational numbers and even algebraic reasoning as generalized arithmetic (Hackenberg, 2013; Steffe & Cobb, 2012; Steffe & Olive, 2010). The present study was motivated by a desire to explicitly identify mental actions that undergird the construction and transformation of units in the context of fractions. For example, students might construct 1/7 as a unit, which has a one-to-seven relationship with a whole unit. This relationship might be established by the mental action of partitioning a continuous whole into seven equal parts. Conversely, the relationship could be reversed by iterating a 1/7 part seven times to reproduce the whole. Thus, partitioning and iterating constitute reversible and composable mental actions that can be used to construct a 1/7 unit and transform it back into the whole unit (Wilkins & Norton, 2011).

The purpose of this paper is to introduce a methodology for modeling students' mathematics by explicitly identifying the sequences of actions and unit structures they use to solve mathematical tasks. Unit transformation graphs (UTGs) account for the constraints of working memory in sequencing actions, as well as the power of unit structures in offloading demands on working memory. We share the case study of a pre-service teacher (PST) with relatively high working memory and the ability to assimilate and operate on two-levels of units. Findings (and the UTGs themselves) illustrate how students might use their units coordinating structures to chunk sequences of actions into single units, thus reducing the cognitive demands of mathematical tasks.

Theoretical Framework

Mathematics educators have begun to explicitly account for students' actions in building models of their mathematical reasoning. Recent examples include activity-effect relations (Tzur & Simon, 2004) and the Learning Through Activity framework (Simon Placa, Avitzur, & Kara, 2018). Similar to those models, UTGs explicitly identify the mental actions students use to construct and transform units, but have two distinguishing features. First, they account for the role of working memory in sequencing actions. Second, they explicitly account for the role of unit coordinating structures in reducing demands on working memory.

Mental Actions for Constructing and Transforming Units

Following Piaget (e.g., Beth & Piaget, 1966), we characterize mathematical actions (operations) as mental actions that are potentially reversible and composable. We are particularly concerned with operations students use to construct and transform units. For example, a student might construct a unit by isolating a collection of items, treating them as identical, and taking them as a whole—a

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

mental action called unitizing (Steffe, 1991). Students might also unitize a continuous span of attention, whether it be time, length, area, or volume. Once constructed, units can be transformed into other units: students might iterate a unit, making copies of it and integrating the copies within a new composite unit (a unit composed of units); or they might partition a unit into equal parts, forming smaller units.

Steffe (1992) originally defined a units coordination as a distribution of the units within one composite units across the units of another composite unit. For example, in determining the value of 7 times 4, a student might distribute seven 1s across the four 1s that comprise 4, making a sequence of four units of seven units of 1. This definition orients our thinking about how units might be transformed into other kinds of units, but we include additional transformations as units coordinations. The aforementioned operations of unitizing, partitioning, iterating, and distributing are all potentially reversible and composable, and all can be used to transform units into other units. In addition, disembedding enables a student to remove a unit, or collection of units, from a composite unit, without destroying the composite unit (Steffe, 1992). The student maintains the composite unit while considering some of its parts as units separate from that composite unit.

Sequencing Operations in Working Memory

Students might need to perform a long sequence of operations to solve a mathematical task. In our framework, the cognitive demand of the task would increase with the length of this sequence. This perspective aligns with Pascual-Leone's (1970) characterization of working memory as a mental-attentional operator (the M operator). "Working memory involves the process of holding information in an active state and manipulating it until a goal is reached" (Agostino, Johnson, & Pascual-Leone, 2010, p. 62). It is a limited resource used to implement mathematical problem solving strategies (Bull & Lee, 2014; Swanson & Beebe-Frankenberger, 2004) and one that predicts children's mathematical achievement (Blankenship et al, 2018; De Smedt et al, 2009).

In the context of mathematical problem solving, Pascual-Leone (1970) characterized this limited capacity (M-capacity) as "the number of separate schemes (i.e., separate chunks of information) on which the subject can operate simultaneously using his mental structures" (Pascual-Leone, 1970, p. 302). Commensurate with other measures of working memory, Pascual-Leone (1970) found that adults can typically hold in mind 5-7 schemes at once. In numerical contexts, such as solving fractions tasks, schemas might refer to the operations students use to construct and transform units. A student might hold in mind a sequence of seven such operations, but fractions tasks may involve multiple levels of units (e.g., the whole, unit fractions, measures of a unit fraction) with many transformations between them. A student might offload some of that demand on working memory through the use of figurative material, such as drawings or notations, or by assimilating some of the units and unit transformations into existing cognitive structures: units coordinating structures.

Units Coordinating Structures

In the absence of structures for assimilating multiple levels of units, each unit or unit transformation (e.g., partitioning a whole into n equal parts) would place separate demands on working memory. However, those units and the operations that transform them can be organized within units coordinating structures (Boyce & Norton, 2016; Hackenberg, 2007; Ulrich, 2016). The rectangle on the right side of Figure 1 represents a two-level structure for coordinating units—one that would organize the previously-described one-to-seven relationship between a whole unit and the unit fraction, 1/7. Note that the structure contains two units and a pair of reversible mental operations between them: the whole can be transformed into seven equal parts by via the operation of partitioning; and this mental action can be reversed by iterating one of those parts seven times, reproducing the whole. This unit coordinating structure acts as a single unit that can be used to assimilate two units and an action (in either direction), thus reducing cognitive demand from three to one.

Figure 1: Units coordinating structures

The mathematical power of units coordinating structures is well documented (Boyce & Norton, 2019; Hackenberg, 2007; Tillema, 2013). For example, Hackenberg and Tillema (2009) demonstrated that students who can assimilate three levels of units are able to reason through fractions multiplication problems in ways that other students cannot, including students who can assimilate two levels of units. This power can be explained, at least in part, by reduced demands on working memory. When units are assimilated into existing structures, working memory is freed to focus on ever more complex tasks. This structuring and offloading also explains the sense in which mathematics builds upon itself.

Methods

The data collected and analyzed for this paper is part of a larger project investigating the cognitive development of mathematics, behaviorally and neurologically. This paper reports on results from video recorded behavioral data.

Data Collection

Participants consisted of PSTs at a large university in the mid-Atlantic United States. All participants were enrolled in one of two sections of the same mathematics course—Mathematics for Elementary School Teachers—taught by the same instructor. PSTs comprise a special population of participants for the study because they practice metacognitive skills in the context of solving elementary school mathematics tasks. Specifically, they are encouraged to explain their reasoning when solving tasks. Twelve PSTs agreed to participate in the interviews.

Interviews lasted about 75 minutes and occurred in three parts: an assessment of their available structures for coordinating units (e.g., two-level structures like the one shown on the right side of Figure 1) using interview tasks from prior studies with middle school students (Norton et al, 2015); an assessment of working memory using backward digit span with digits read aloud (Morra, 1994); and the fractions tasks. Using the units coordination and working memory assessments from the first two parts of the interview, a subset of ranked fractions tasks was selected for each PST. Tasks were ranked by cognitive demand based on the number of unit constructions and transformations that might be required to solve the task, without reliance on units coordinating structures. We intended for initial tasks to impose low cognitive demand on PSTs and for later tasks to impose high cognitive demand, so generally, PSTs assessed with lower M-capacity began with simpler (lower ranked) tasks. Table 1 presents the four tasks on which we focus in this report.

Table 1: Fractions tasks (adapted from Hackenberg & Tillema, 2009)

Task #	Rank	Task Description
5	8	Imagine this [drawing a rectangle] is 5/9 of a whole candy bar. So, how could you make 1/9 of the whole candy bar from what you have?
6	10	Imagine a rectangular cake that is cut into 15 equal pieces. You decide to share your piece of cake fairly with one other person. So, how much of the whole cake would that person get?

8	12	Imagine you are at a party and a cake is cut into nine equal pieces. Two people show up to the party late and you decide to share your piece of cake with them. So, what fraction of the whole cake do the latecomers get together?
10	14	Imagine cutting off 1/4 of 5/6 of a cake. So, how much is that of the whole cake?

Data Analysis

Data analysis reported here consists of real-time and retrospective analysis of PSTs' responses to the fractions tasks. During the interview, we assessed PSTs' abilities to solve the tasks without using figurative material in order to determine whether to continue to more challenging (higher ranked) tasks. The interview continued with higher and higher ranked tasks until we inferred that the PST was unable to produce correct or confident solutions. In some cases, PSTs were explicit about their own perceived limitations; e.g., "I have no idea" or "my brain is confused now."

After all interviews were completed, the team began retrospective analysis of the behavioral video data. The videos were analyzed, PST by PST, moving from lowest ranked to highest ranked tasks. For each task, the video analysis consisted of two main parts: the first consisted of classifying the demand of the task for the students, and the second consisted of creating a UTG for the PST's actions in solving the task. A constant comparative analysis was used throughout both parts of analysis to promote consistency.

Analysis of the videos was done together by the research team with at least two of the three team members present. Each task was assigned a classification for the cognitive demand of the task, based on behavioral indicators during the PST's response to the task. Cognitive demand was coded as Low, High, or Over, depending on how challenging the task seemed to be for the PST in managing the units and unit transformations involved in solving the tasks. The Low code indicates that the PST's response was quick and confident. The High code was used when the PST struggled presumably operating near the limits of their M-capacity, as indicated by expressed doubt, rehearsing the task's solution, and requests for the task to be repeated. The Over code indicates that the task was beyond the students' ability to solve without figurative material or help from the interviewer.

Once cognitive demand codes were assigned for each task, the research team went back and watched the video again in order to build a UTG for each task's solution, illustrating the sequence of actions (operations) the PST used to reach a solution. The graphs serve as explanatory models for the PSTs' observed behavior in solving tasks by drawing on cognitive resources. Using the constant comparative method, we iteratively returned to prior graphs to ensure the models were consistent across tasks and PSTs. Adjustments were made to prior graphs as new features emerged in newer graphs.

Results

We chose to focus on PST 22 because she was one of two PSTs with the highest assessed M-capacity (7), and of those two, was the only PST operating at the lower stage of units coordination (constructing two-level unit structures but not three-level unit structures). Here, we analyze her responses to the four tasks shown in Table 1.

Task 5

PST 22 exhibited Low cognitive demand in solving Task 5. As soon as the task was posed, she responded, "well if you have five-ninths of it, taking away four ninths would give you one-ninth because five minus four is one." The UTG shown in Figure 2 illustrates the mental actions we inferred PST 22 used in solving the task.

PST 22 seemed to rely on a part-whole understanding of fractions. Rather than structuring 1/9 as a one-to-nine size relation between the 1/9 part and the whole, PST 22 seemed to partition the whole into nine parts (P_9) and, reversibly, take their unitized collection as the whole (U_9). The PST needed to disembed five of those parts from the whole (D_5) to establish 5/9 as five parts out of nine equal parts in the whole. Then, taking away four of those five parts, through a second use of disembedding (D_1), would leave 1/9 as one out of nine equal parts in the whole. As such, PST 22 would experience Task 5 as having an M-demand of 3, well below her M-capacity of 7.

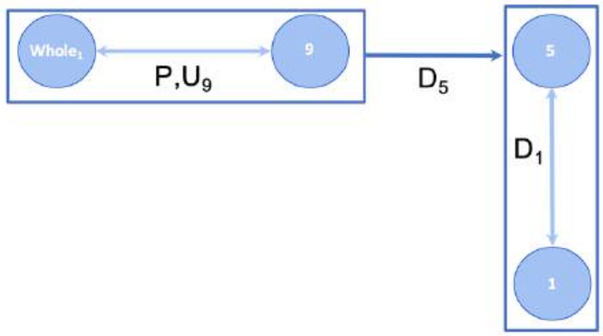

Figure 2: Making a unit fractional part from a non-unit fractional part (Task 5)

Tasks 6

Tasks 6 involved finding a fractional value (relative to the whole) when taking a unit fraction of a unit fraction. With the composition of two fractions, these tasks should impose additional cognitive demands, relative to Task 5. These increased demands are indicated in the PSTs' behavioral responses to the tasks, but behavioral indicators did not meet the threshold of High cognitive demand and, so, we categorized them as Low.

PST 22's response to Task 6 was immediate: "You get one fifteenth of the cake and split that in half. My first thought was one-thirtieth of the cake, because [makes splitting motion with hands in the air] splitting that in half, like if you were to split every piece of fifteen in half, then that would be like one thirtieth of the entire case." She seemed to imagine partitioning each one of the fifteen original parts into two parts to produce 30 parts in the whole. This mental action aligns with the distributing operation ($T_{2:15}$), but the production of 30 equal parts would be essential for PST 22's understanding of 1/30 as one out of 30 equal parts in the whole. We take such responses as indication PST 22 used her units coordinating structures to assimilate fractions as parts out of wholes. As indicated by the UTG (Figure 3) PST 22 experienced an M-demand of 4 for this task.

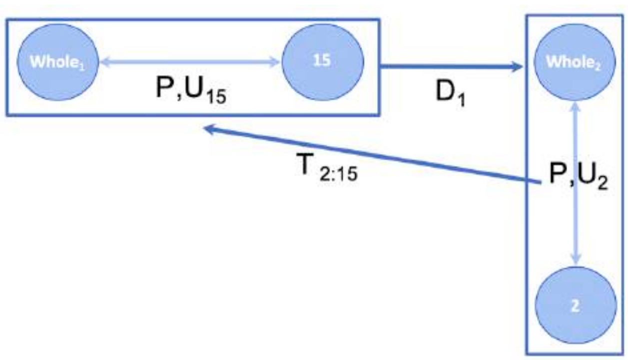

Figure 3: Finding a unit fraction of a unit fraction (Task 6)

Task 8

With the introduction of a non-unit fraction, Task 8 would also introduce one more unit and one more action to coordinate, increasing cognitive demand by 2 over Task 6. Indeed, the UTG for PST 22's response to Task 8 (not shown) would be structurally identical to the one for Task 6 (Figure 3), except it would include an additional action of disembedding two units from 27 (D_2) and the resulting unit of 2/27. Increased demand became evident in PST 22's response, which we took as indication of High demand.

PST 22: So, it's split up into nine equal pieces. So, then, you would split one ninth into…Two people come, but you still have a little bit? So, that… So, you would split that up into three. So, then I… Well, I guess you would do one ninth times two thirds to get how much they equal, like how much both their pieces would be. And then whatever that is, I guess it would be… two over… two eighteenths? Wait, that doesn't seem right. [pauses for five seconds] I feel like… I mean, I guess… You take those nine pieces, splitting that one ninth into thirds. But to find out how much two of those thirds are, you'd multiply one ninth by two thirds… Or no. You'd… you'd multiply the one ninth by one third, and then just do that twice? I don't know if that'd give you the same answer.

Researcher: Okay. Uh, let's… Maybe I can help you.

PST 22: Okay.

Researcher: If you want me to be your calculator again, I'll do it.

PST 22: [begins to draw on table with finger] So, you do one ninth, which divided by three, so you could times it by one third. So, then you'd have one over um… [pauses for five seconds.] Oh wait… [whispers to self] Three times nine, that's twenty-seven. Oh no, one over twenty-seven. And then you multiply that by two… to get two-thirds or to get two parts of the thing… So, then I guess… What's one over twenty-seven times two? Is that just two-twenty-sevenths? Okay.

Researcher: Nice, I like the way you reasoned through it. Yeah.

PST 22: Okay. I was like, because I was thinking one over twenty-seven times two over one and I was like I guess that's just two, twenty-sevenths.

This response indicates that PST 22 tried to rely on the standard algorithm for multiplying fractions but struggled to reconcile it with prior reasoning. She began as she had in Task 6, partitioning the whole, disembedding one of those parts, and then partitioning it into smaller parts. However, in contrast to Task 6, she then began referring to a fraction multiplication, 1/9 times 2/3. Fraction multiplication might have helped her keep track of the additional unit involved in this task (the 2 in 2/3), but she was not sure that the multiplication of fractions would generate the correct result. Her concerns were heightened when she mistakenly multiplied 9 times 2, instead of 9 times 3, to produce two eighteenths: "that doesn't seem right." So, she reverted to operating on the 9 units, partitioning them into thirds, which she was then able to reconcile with 1/9 times 1/3. Thinking of the task as the multiplication problem, 1/9 times 2/3, then did work for her by maintaining the 2 in two-thirds: "and then you multiply that by 2 to get two-thirds, or to get two parts of the thing."

We found PST 22's persistence in response to Task 8 impressive and indicative of her high M-capacity. Ultimately, she reasoned with parts out of the whole ("two parts of that thing"), as she had before, but was able to meet the cognitive demands of the task by organizing her operations around the fraction multiplication algorithm. So, while the task was highly demanding for her, we see evidence for how algorithms, when made meaningfully related to (or reconciled with) operations, can offload the demands of mathematical reasoning.

Task 10

For Task 8, the PSTs needed to distribute the new partitioning (thirds) across the nine units making up the whole, and then take two of the resulting parts (1/27ths). For Task 10, she needed to distribute fourths across both the five parts in five-sixths and the six parts in the whole. The increased demands caused PST 22 to lose track of the six parts making up the whole. Figure 5 presents the UTG for this response.

PST 22: You're cutting off one fourth of five sixths of a cake?
Researcher: Yes.
PST 22: [uses hands to show number of pieces on the desk and begins talking to self] So, you'd have, so you'd have six pieces…and out of those five…you want to cut off one fourth of that. Um…I guess you would…I mean I guess you could split those five pieces into four and get one of those, but I'm trying to think like numbers-wise what that would...I. well… [pauses for seven seconds] I guess of those five pieces you could…Split them into…Like you could get a…Split them into twenty pieces because five times four is twenty and then, um, you would take one fourth of that… I guess it would be five pieces. Yeah, it would be five pieces of that twenty to find the one fourth of the five sixth. Is that, do I need to explain it more?
Researcher: Okay, uh let's…
PST 22: Which would be, do you want me to draw it? [reaches towards paper]
Researcher: Well tell me the final answer and then we can draw it.
PST 22: Um, oh gosh it would be… [pauses for four seconds] Splitting twenty, it would be five…Well it would be five twentieths, which would equal one fourth, so like five of those, but then I don't know how to figure that out into sixths. I think that's my…
Researcher: Yeah that's cool, I like the way you're reasoning. Let's draw it, and I think you will figure it out.

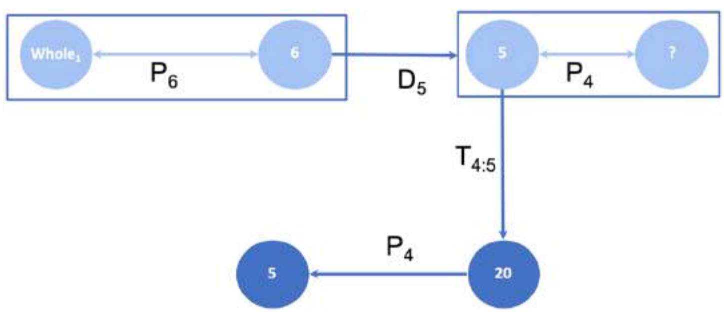

Figure 4: Finding a unit fraction of a non-unit fraction (Task 10)

Once again, PST 22 seemed to conceptualize the initial fraction (5/6) as a part-whole relation, partitioning the whole into six equal parts and disembedding five of them. This inference is supported by the PST's verbalization, "so you'd have six pieces…and out of those five." As PST 22 tried to find one-fourth of 5/6, she operated only on the five disembedded parts and lost track of the sixth part making up the whole. Thus, rather than fourthing 5/6, as originally intended, she ended up distributing four parts into each of the five parts, producing 20 parts, and taking one-fourth of those 20 parts instead.

Discussion

In line with the stated goals of PME-NA, we aimed to elucidate the psychological aspects of learning mathematics. Specifically, UTGs integrate the psychological construct of working memory with a construct from mathematics education research—units coordination—to explain how mathematics arises through the coordination of students' own mental actions (Beth & Piaget, 1966). The case study of PST 22's solutions to a ranked set of fractions tasks demonstrate the explanatory power of UTGs.

With an assessed working memory of 7, PST 22 would have experienced even Task 5 as highly demanding; her solution to the task involved four units and three transformations between them. However, PST 22 assimilated some of those units and transformations into two-level structures, thus chunking them into single two-level units so that she experienced Low cognitive demand. As a theoretical construct, chunking has its roots in cognitive psychology (e.g., Pascual-Leone, 1970), but UTGs illustrate how chunking can take a particular form in mathematics, as units coordinating structures (Steffe, 1992; Hackenberg, 2007).

Offloading cognitive demand with unit structures afforded PST 22 the ability to account for additional units and transformations in progressively more demanding tasks. In looking at the UTGs across the four tasks (as illustrated in Figures 2-4), we see how PST 22 introduced additional transformations (such as distributing) and units to solve Tasks 6 and 8, until she reached her threshold, with 7 units/transformations. Having reached that threshold, she was not able to proceed in solving Task 10, but we might imagine ways that she might further structure units into chunks to increase her mathematical power.

Acknowledgments

We thank the Adaptive Brain & Behavior Destination Area at Virginia Tech for their support of this project. We also thank undergraduate researcher, Rachael Stryker, for her contributions.

This research project focuses on identifying the difficulties that children between 6 – 7 years-old have in learning natural numbers, when working a teaching model with a Von Neumann formal mathematical basis. In this study, we present the analysis of the experimentation with a first-grade class in the construction of zero and one numbers, contrasting the results with a case of the clinical interview. Our methodological theoretical framework is the Local Theoretical Model (LTM) and its four components: Formal, Cognitive, Communication and Teaching. With the theoretical contribution of each component, the categories of analysis are designed to observe and explain difficulties in the use of the Mathematical Sign System (MSS) involved in the construction of the first natural numbers, using iteration and the recursive process.

Keywords: difficulties, learning, natural numbers.

Research Problem

Learning numerical notions remains a concern in research and education policies. This project has been developed under the perspective of Educational Mathematics, stating that the learning difficulties that elementary school children have are not found in what the teacher does nor in the students, but in mathematics itself. Therefore, you have to know in depth the mathematical basis of what is taught.

In the curriculum of Mathematics primary education in Mexico (SEP, 2011) the development of numbers is focused on the use of cardinality in different contexts in contrast to that of ordinality. From the first degree, the number zero is used as a figure in the quantity representation and as an empty column, but there is no conceptual treatment. The lack of a mathematical conceptualization in teaching natural numbers as the basis of the arithmetic structure is accompanied by teaching practices that continue with the tradition of mechanization, memorization and exercise of the oral and written number sequence, and of algorithms of addition and multiplication.

From the formal point of view, Cantor and Peano contributed to the conceptualization of natural numbers. For Cantor, it is through the cardinality relations of the sets (Mosterín, 2000, pp. 105-108). While Peano proposes an axiomatic that involves a formal conceptualization of numbers (Op. Cit. pp. 54-55). However, this goes against how children cognitively process the first actions to order the world. It is considered essential to begin the learning of natural numbers with the construction of the number zero as it is a contribution to mathematical conceptualization and a contribution that goes beyond the numbering system, independent of the debates on its origin.

Therefore, the orientation of this work is to look at learning and observe learning difficulties from a formal mathematical proposal. According to Filloy, Puig & Rojano (2008), the analysis provided by the formal component indicates that difficulties must be sought in the most primitive mathematical actions. For the learning of natural numbers, we found these actions in the iteration. Hamilton & Landin (1961) introduce us to the construction of natural numbers based on the works of the logician

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

mathematician Von Neumann, who uses the theory of sets and summarize the axiomatic of Peano in the principle of finite induction and iteration; each number is constructed from a finite number of iterations; order is implicit by the same construction.

The research questions are 1) What elements of the formal model in the terms referred to by Hamilton & Landin (1961) should we consider designing a Teaching Model that translates into specific activities for children aged 6 to 7? 2) What difficulties emerge when children work from the construction of the number zero and one, based on that teaching model?

To answer these questions, we propose as a general objective to identify students' learning difficulties in the construction of the numbers zero and one, in the framework of a teaching model based on Von Neumann.

The particular objectives are 1) Design and implement a teaching model by translating the Formal Model into sequences of specific activities, for the construction of the first natural numbers. 2) Identify and explain the difficulties that children 6 to 7-year old's have, when working with a Von Neumann's-based Teaching Model.

Theoretical Framework

The LTM (Filloy, et. al. 2008) is a theoretical and methodological framework for the experimental observation on research in Educational Mathematics. LTM relies on Peirce's semiotic approach (1987) to make sense of MSS, a theory for the interpretation of experimental observations. MSS focuses its attention on the production of intertexts through the reading/transformation of mathematical texts in relation to other texts. This allows users to produce meaning and mathematical meaning to communication processes that occur in classrooms, when activity sequences are implemented for a particular purpose. The sense of the local focuses the analysis on a specific phenomenon through the four components: formal, cognitive, communication and teaching.

The design of this LTM has been structured according to the four components

Formal. Von Neumann Model (Hamilton & Landin, 1961) proposes a logic of construction that requires MSS involved in natural numbers, starting with zero: "Zero is the empty set; i. e., $0 = \emptyset$", it continues with the number one as the set containing element zero: "$1 = \{0\} = \{\emptyset\}$". From this moment on, enter the successor definition:

> The set $x \cup \{x\}$ is the *successor* of the set x. If y is a set and if there is a set x such that y is the successor of x, then y is a successor. For each set x, the successor of x is x'. Thus, $1 = 0', 2 = 1'$, 3=2', etc. (Op. Cit. p. 77).

Each ordinal is the set of all the ordinals that precede it. Each of these sets is $\in -$ordered by the same construction, where for all x and for all y at least one of the following conditions is met: $x \in y, x = y, or\ y \in x$. Natural numbers are defined as "n is a $\in -ordered$ every nonempty subset of n has a leading element, if $x \in n$ then $x \subset n$, if n is not empty then *n* is a successor if $x \in n$ and x is not empty then x is a successor" (Op. Cit. 1961, p. 81). To count a set A is a one-to-one correspondence $\varphi: [1, n] \to A$ between $[1, n]$ y A, where $n \in N$." Cardinality is: If n is the result of a count of A, then A has n elements, or the number of elements in A is *n,* or the cardinality of A is *n*. We also denote the cardinality of A by $\#\ (A)$. (Op. Cit. pp. 99-101).

The sum is given, naturally when obtaining the successor, by iteration and starting from n, is $n + 1$. When *n* is a set, then the sum is the union of disjoint sets: $A \cup B$ and if m and n are their cardinals respectively, then $m + n$.

Cognitive. Based on the contributions of the theory of activity (Talizina, 2001) we expect to identify difficulties that obstruct (OB) students' competence in the use of MSS involved in the construction of natural numbers due to the ways in which children aged 6 to 7, have learned to use natural numbers in everyday life. These obstructions can hinder the transition from action to cognitive operation to foster the conceptual numerical development of zero, one and the notion of a successor.

Communication based on semiotics (Peirce, 1987), we analyzed induction, deduction and abduction arguments as processes of signification (ASP). The categories are built with significant relations to interpret what children do and say in the production of meaning and processes of the significance of the actions they perform in numerical activities. This is the Sense Endowment (SD). The logic of using MSS is related to iteration and recursion processes in the construction of natural numbers.

Teaching. It is understood as a collection of concrete texts that the students can understand, so that they gradually convert concrete texts into abstract texts, with a conventional mathematical meaning. Researchers designed a Teaching Model to translate Von Neumann's formal model into specific activities with the use of manipulative material.

Methodology Design and implementation of the Teaching Model. The design of the activities was carried out according to the mathematical definitions of the Von Neumann sequence according to Hamilton & Landin (1961, pp. 74 – 112), we have called them principles (Pi):

P_1: Beginning the construction with zero. The name of the empty set is zero.

P_2: Building the number one as a successor to zero number. Using the recursive process $0 = \emptyset$; $1 = \{\emptyset\}$; $2 = \{\emptyset, \{\emptyset\}\}$; $3 = \{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}$; and so on. Keys are replaced with bags, as shown in Figure 1.

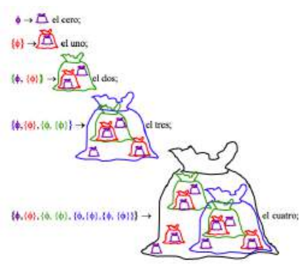

Figure 1: Recursive number processing, using sachets

P_3: One successor has been called *the following*.

P_4: Definition of Set n, as natural number.

P_5: Counting and cardinality.

P_6: Addition.

The use of a semi-straight has been included to represent the order of the numbers, from the interval definition "If $a, b \in N, [a, b] = \{x \mid x \in N \text{ and } a \leq x \text{ and } x \leq b\}. [a, b]$ is the interval of a to b." (Op. Cit. 1961, p. 97).

We selected two sequences of activities of the teaching model to present them in this work briefly described as follows:

Guess I am (P_1). -The empty set as the number zero.

- Teacher asks the students to look at an empty clear plastic bag and say what it contains (possible answers: nothing and empty).
- Teacher asks the students how to name this empty bag. The intention is to relate the notion of numbers to the bags to refer to bag/number.
- Students are asked by what number the empty bag can be named with.
- When students name the word zero, they are asked to identify the label of the number zero and paste it on the outside of the bag.
- Teacher asks students if they already know this number and what they think it is useful for.
- Teacher asks where students can paste it on the semi-straight (drawn on the board).

Can we build the next one? (P_2, P_3). - Construction of the successor.

- Once the empty set is related and named as number zero, the teacher asks: Can we build the next one? (The next is number one, it's the bag/number that contains item zero).
- Teacher takes another empty bag and asks students how they can build the next one. Teacher asks who the empty bag is, so that they name it as zero, they are asked to stick the zero label outside this empty bag/number and put it in the new bag named as number one; then stick the label for item one outside the bag.
- They are asked where to paste it in the semi-straight (it is expected to be after zero, building the sense of linear order).
- With this logic of construction, the successors are built, reflecting on each construction, who is before, who is after, who is in all numbers, who has no ancestor, who contains each bag/number.

This teaching model was used in the first phase when working with a first-grade class from a public school in Mexico City. Based on quantitative (written exercises) and quantitative (performance in each session) the students were classified into three strata High, Medium and Low. We selected one student from each stratum to participate in the clinical interview. The second phase was carried out in the next school year, with the application of the clinical interview.

The results of the analysis of model experimentation were published in (Rodríguez, et. al 2018) and (Rodríguez, et. al. 2019a, 2019b). Due to the space available in this report, we expose only a fragment of a group session and a snippet of Daniel's interview (low stratum).

Observation of the empirical experience with analysis categories. In the analysis of the experimentation of the Model, we identified recurring difficulties in the children's performances. These difficulties are grouped into three axes 1) The use of pragmatic/intuitive and spontaneous knowledge, that is, difficulties in identifying zero as a number; identify the successor and ancestor of any number. 2) Semantic use of numbers in rendering and counting actions, that is, difficulties in recognizing the number zero as an empty set, recognizing that zero is the only number belonging to any successor, identifying zero as the point of origin in the straight, and recognizing that every successor contains all his previous ones. 3) Syntactic use in operations, that is, difficulty using the form $a \cdot 10 + b$.

To understand and explain the difficulties and based on the theoretical framework, there are three categories of analysis designed, Cognitive Trends that constitute obstructions for learning (OB); Induction, Deduction and Abduction Arguments as Significance Processes (ASP) and, Significant Relations Indicators for Sense Endowment (SD).

Finally, to contrast whether the difficulties continue, or new ones appear, the clinical interview took place and it was interpreted based on the same categories of analysis.

The following is assigned as follows: Teacher (M), Children All (N_s), Nicole (N_e), N_1, N_2... refers to any child except those whose initial letter is the name of a specific child, Interviewer (E) and Daniel (D).

Fragment of dialogue of the activity sequence, "Guess I am":

M: What's with the bag? [Teacher shows the empty bag].
N1: Nothing [The teacher inserts some objects into the bag and then empties it in front of them].
M: How does the bag look?
N2: Empty.
M: How do we know that my bag is empty?
A: Because it has nothing in it.
F: If you don't put something in it, you have nothing.
E: If it is empty it is not heavy.

Ne: If you put something in it, then it's full.
E: Or by numbers.
M: What did you say?
Ns: By numbers.
M: And, what number do you think should be here?
Ns: One, two, three... [Labels shown from numbers 0 to 9].
N3: A zero.
M: Who's that number?
Ns: Nothing.
Ns: Zero.
M: Who wants to go to the front to look for number zero and stick it onto the bag?
K: Here it is [Karen chooses the label with number zero].
M: Where do I put it? [The teacher displays the bag/number zero, to place it on the semi-straight painted on the board].
F: At the end [Points to the left end of the straight but use the word end].
M: At the end?
F: Ah! At the beginning! [He corrects his answer].

Fragment of dialogue of the activity sequence, "Can we build the next one?"

M: Can we build the next one?
N_s: The one.
M: How are we going to build the next one?
Ne: Take another bag and put one on it.
M: What do we have here? [showing the empty bag].
N_s: Empty.
M: Empty, but I need...
N_s: The one.
M: How are we going to do it because this bag is empty?
N_s: Put the one on it! [The teacher inserts the bag of the zero that was previously built and asks them].
M: How many bags are inside? (...)
N_s: One. (...)
M: What number was formed here?
N_s: One.
M: Why is it one Emiliano?
E: Because the one comes first.
M: Nicole…
Ne: Because the one goes after the zero.
M: Where do I put it?
N_s: In first place.
M: Who's in the first one? [points to zero that is placed on the straight].
N_s: A zero number.
E: You pass it for the second [he refers to the right of the zero, on the straight].

Analysis of these fragments. "*Guess I am".* - In this fragment we observe the difficulties of identifying zero as an empty set and as the origin point on the straight. The zero as an empty set is observed in the action of inserting objects into the bag/number and removing them, children were able to relate the void to words: "nothing, empty, full, put in, take out, heavy" (A, F, E, Ne). This can be interpreted as SD-related actions, which allow an approach to the notion of zero as empty. (A) makes inductive reasoning (ASP) by using the word "nothing" to justify the vacuum, giving meaning (SD) to the absence of elements, which gave a pattern for his peers to follow the meaning of the notion of emptiness. When (F) verbally states, "Because if you don't put something in, you have nothing," he's making a deduction (ASP), allowing (E) to relate the weight to the vacuum, and (Ne) reasons inductively (ASP). Later, faced with the question of being able to name the empty bag, the answer to (E) allows us to observe that this is abductive reasoning (ASP), when proposing the use of numbers. However, for the rest of the group, it is a difficulty, which can be understood to be caused by a cognitive (OB) from their experiences with numbers, they have learned to repeat the number sequence starting with the one (Ns). While (N_3) manages to follow the idea of (E) and chooses the number zero, which can be understood as abductive reasoning (ASP).

The (F)'s difficulty in identifying zero as the origin point in the semi-straight, could be, because this student was sitting in front of the right end of the semi-straight. This cognitive (OB), of perception, made it difficult for him to establish a reversibility relation, to focus his attention on the semi-straight as an object and not only on visual perception. When the teacher questions it, he allows (F) to correct his answer.

Can we build the next one? In this fragment, we see difficulties to recognize that zero is the only number belonging to any successor and in recognizing that every successor contains his former. Children identify that the successor to zero is one, so we can say that they are making sense of the expression "the next one". However, the difficulty remains when children do not give meaning to the construction, they consider they need only the label of number one (N_2) "Take another bag and put the one on it", (N_s) "Put one on it!" This difficulty is constant in the first lines of the activity, because children do not make sense of the recursive process. They do not recognize that the bag/number one must contain at least one item. It is understood that this difficulty is due to a cognitive obstruction (OB) from how they have learned that numbers are only the oral and written repetitions of the counter sequence from one. The action of (M) by inserting the empty bag labeled with the number zero and asking them about the number that was formed, allowed some children to observe that it is number one, when it contains element zero (N_s): "One, one". But, for most children, they continue to associate it with label one: (E) "Because one is first," thus, observing that this difficulty is an (OB) with the use of reversibility relations to identify that the one's ancestor is zero; just as the zero's successor is the one. With the deductive argument (ASP) of (N_e): "One goes after zero", leads to (E) correcting his answer, using an inductive argument (ASP) when the teacher asks where to place it: "You move it to the second one".

Clinical interview. The objective was to compare whether the difficulties that occurred during the experimentation of the model continue or new ones appear.

Fragment of the dialogue in the sequence of activities: "Guess I am":

E: What do you have in the bag?
D: Nothing.
E: Nothing and how's the bag?
D: Empty.
E: How do you know it's empty?
D: Because it has nothing in it.
E: How can you say it has nothing?
D: It would be a little bit heavy.
E: How can we represent this bag that has nothing, that is empty? [Daniel keeps thinking for a few seconds, unanswered. So, the interviewer shows him the material he has on the table: a semi-straight, transparent rubber bags of different sizes, number labels in flexible plastic]. Can I use any of these?
D: This [Daniel points to the zero-number label heap].
E: What is this?
D: Zero. [Daniel sticks the number zero label on the front of the bag].

E: Now that we know that this bag is empty and that it is the number zero, where do we place it on the line?
D: Here [Daniel points to the left end of the straight].

Fragment of the dialogue in the sequence of activities: Can we build the next one?

E: What's next?
D: The one.
E: What do I need to make the number one?
D: A number inside.
E: Who's going to be that element inside?
D: The one?
E: Who was before the one?
D: Ah, zero!
E: Zero, so what do you have to do?
D: Grab a... [Daniel takes another empty bag, sticks the number zero label and inserts it into the new bag/number one].
E: What name am I going to give you?
D: The one. [Daniel points and takes a number one label and sticks it on the new bag/number one].
E: All right! Where are you going to put it in the straight?
D: Here [Daniel places it to the right of the bag/number zero].

Analysis of the fragments of the clinical interview. *Guess I am.* In this excerpt, we can observed that (D) relates the empty set to the number zero, by expressing, "it would be a little bit heavy", a deductive argument (ASP) that evoked the experience of the group session in the last school year, which, can be understood as a sense endowment (SD) to relate the notion of vacuum to the zero number, but it is not conventional yet. But D doubts when the teacher asks him how to name the bag/empty number, so (E) points out and asks, "Can I use any of these?", giving the guideline for (D) to choose any of the number labels. When he places it on the left end of the semi-fully, he is making sense (SD) of zero as the starting point of the construction and overcoming that difficulty.

Can we build the next one? - It is observed that there is an endowment of meaning (SD) when recognizing that the next number of the number zero is number one. The answer "A number that is inside" to the interviewer's question: "What do I need to make it number one?" can be understood as a deductive argument (ASP) to make sense (SD) to the notion of a successor. However, when the interviewer asks "Who is that element inside?", evidence of D's insecurity, he answers with another question "The one?", which can be interpreted as a difficulty to produce a sense of use of the recursive process to recognize that every successor contains all of the above. The question of E "Who was before", allows D to evoke the construction process, remembering that the number zero is the one that should be inside the bag/number one: immediately takes a smaller bag and labels it with the number zero, inserts it into the new bag/number one. With these actions, we understand that D makes sense of the use of MSS through recursion. He places the bag/number one in the semi-straight of the bag/number zero, consolidating the sense of order by the same construction.

Final discussion.

We close this space by emphasizing that the general objective is to identify learning difficulties when taught with von Neumann's formal mathematical model for the construction of natural numbers and the logics of using the MSS involved in that task.

During the experimentation, it was possible to check that the influence of the ways in which they have acquired numerical notions makes it difficult to understand and use recursion, but they do not constitute an obstacle. In the clinical interview, the recurring difficulties reappear, which are overcome in less time, making efficient use and making sense of MSS through iteration and recursion (elementary actions for the conceptualization of natural numbers).

For the results obtained, it seems valuable to recover the formal mathematical tradition in teaching from the first grades of elementary education, allowing children to participate in the construction of natural numbers, which gives them the possibility to consolidate generalization, as the basis for solid arithmetic thinking.

Finally, we consider that the conceptual work of numbers with children aged 6 to 7 is not trivial, memoristic or operational; but it can make it easier to develop the concept before symbolism. What this work seeks is to cultivate abstract thinking, which allows children to access higher levels of mathematical knowledge.

Este Proyecto de investigación se ha centrado en identificar dificultades que tienen los niños (6 – 7 años) en el aprendizaje de los números naturales, cuando se trabaja un modelo de enseñanza con una base matemática formal de Von Neumann. En esta comunicación, se presentará el análisis de la experimentación con un grupo de primer grado, en la construcción de los números cero y uno; contrastando los resultados con un caso de la entrevista clínica. Nuestro marco teórico metodológico son los Modelos Teórico Locales (MTL) y sus cuatro componentes: Formal, Cognitivo, Comunicación y Enseñanza. Con el aporte teórico de cada componente se diseñon las categorías de análisis para observar y explicar dificultades de uso del Sistema Matemático de Signos (SMS) involucrado en la construcción de los primeros números naturales, usando la iteración y el proceso recursivo.

Palabras clave: dificultades, aprendizaje, números naturales.

Problema de investigación

El aprendizaje de las nociones numéricas, sigue siendo una preocupación en la investigación y en las políticas educativas. Este proyecto se ha desarrollado bajo la perspectiva de la Matemática Educativa, planteando que las dificultades de aprendizaje que tienen los niños de la escuela elemental, no está en lo que hace la maestra/o, ni en los alumnos; sino en la matemática misma, por lo que hay que conocer con profundidad la base matemática de lo que se enseña.

En la currícula de Matemáticas educación primaria en México (SEP, 2011) el desarrollo de los números está centrado en el uso de cardinalidad en diferentes contextos; en contraste con el de ordinalidad. Desde el primer grado, el número cero se usa como cifra en la representación de cantidades y como columna vacía, pero no hay un tratamiento conceptual. La carencia de conceptualización matemática en la enseñanza, de los números naturales como base de la estructura aritmética, se acompaña de prácticas docentes que continúan con la tradición de la mecanización, memorización y ejercitación de la secuencia numérica oral y escrita, y de algoritmos de adición y multiplicación.

Desde el punto de vista formal Cantor y Peano contribuyeron a la conceptualización de los números naturales. Para Cantor es a través de las relaciones de cardinalidad de los conjuntos (Mosterín, 2000, pp. 105-108). Mientras que Peano propone una axiomatica que involucra una conceptualización formal de los números (Op. Cit. pp. 54-55); pero va en contra de las maneras en que los niños procesan cognitivamente las primeras acciones para ordenar el mundo. Se considera fundamental iniciar el aprendizaje de los números naturales con la construcción del número cero, por ser una aportación que va más allá del sistema de numeración, independiente de los debates sobre su origen.

Por lo anterior, la orientación de este trabajo es mirar al aprendizaje y observar dificultades de aprender cuando los niños trabajan con una propuesta formal matemática. De acuerdo con Filloy, Puig & Rojano (2008), el análisis que nos brinda la componente formal nos indica que las dificultades deben buscarse en las más primitivas acciones matemáticas. Para el aprendizaje de los números naturales estas acciones las encontramos en la iteración. Hamilton & Landin (1961) nos introducen a la construcción de los números naturales con base en los trabajos del lógico – matemático Von Neumann, quien usa la teoría de conjuntos y encapsula la axiomatica de Peano en el principio de inducción finita y en la iteración; cada número es construído a partir de un número finito de iteraciones; el orden está implicito por la misma construcción; lo que permite observar las acciones matemáticas más simples al usar la *iteración*.

Las preguntas de investigación son:

¿Qué elementos del modelo formal en los términos señalados por Hamilton & Landin se deben considerar para diseñar un Modelo de Enseñanza que se traduzca en actividades concretas, dirigidas a niños de 6 a 7 años de edad?

¿Qué dificultades se pueden observar cuando los niños trabajan a partir de la construcción de del número cero y el uno, con base en ese modelo de enseñanza?

Para dar respuesta a estas preguntas, se propone como objetivo general:

Identificar dificultades de aprender la construcción del número cero y el uno, cuando se les propone un modelo de enseñanza basado en Von Neumann.

Objetivos particulares:

Diseñar e implementar un modelo de Enseñanza traduciendo el Modelo Formal a secuencias de actividades concretas, para la construcción de los primeros números naturales.

Identificar y explicar las dificultades, que tienen los niños de 6 a 7 años de edad, al trabajar con un modelo de Enseñanza con base en Von Neumann.

Marco Teórico

Los MTL (Filloy, et. al. 2008) son un marco teórico y metodológico para la observación experimental en la investigación en Matemática Educativa. Se apoyan en el enfoque semiótico de Peirce (1987) para dar sentido a los SMS, una teoría para la interpretación de observaciones experimentales. Los SMS centran la atención en la producción de intertextos a través de la lectura/transformación de textos matemáticos en relación con otros textos. Esto permite a los usuarios la producción de sentido y significado matemático a los procesos de comunicación que se producen en las aulas, cuando se implementan secuencias de actividades con un fin determinado. El sentido de lo *local*, focaliza su análisis en un fenómeno específico a través de los cuatro componentes: formal, cognitivo, de comunicación y de enseñanza.

El diseño de este MTL se ha estructurado de acuerdo con los cuatro componentes:

Formal: Modelo de Von Neumann (Hamilton & Landin, 1961) propone una lógica de construcción que precisa SMS involucrados en la construcción de los números naturales, comenzando por el cero: “El cero es el conjunto vacío; $0 = \emptyset$.”, el número uno es el conjunto que contiene al elemento cero: “$1 = \{0\} = \{\emptyset\}$”. A partir de este momento introduce la definición de *sucesor*:

> El conjunto $x \cup \{x\}$ es el sucesor del conjunto x . Si y es un conjunto y si hay un conjunto x tal que y es el sucesor de x, entonces y es un *sucesor*. Para cada conjunto x, el sucesor de x es x'. Por lo tanto, 1 = 0’, 2 = 1’, 3 = 2’, etc. (Op. Cit. p. 77).

Cada ordinal es el conjunto de todos los ordinales que le preceden. Cada uno de esos conjuntos es $\in -ordenado$ por la misma construcción, donde para todo x y para todo y se cumple al menos una de las siguientes condiciones: $x \in y$, ó $x = y$ ó $y \in x$. Se define a los números naturales como: “n es $\in -ordenado$; cada subconjunto no vacío de n pose un elemento principal; si $x \in n$, entonces $x \subset n$; si n no está vacío entonces n es un sucesor; si $x \in n$, y x no está vacío entonces x es un sucesor.” (Op. Cit. 1961, p. 81). Contar un conjunto *A* es una correspondencia uno-uno $\varphi: [1, n] \to A$ entre $[1, n]$ y A, donde $n \in N$.” La cardinalidad es Si *n* es el resultado de un conteo de *A*, entonces *A* tiene *n* elementos, o el número de elementos en *A* es *n*, o la cardinalidad de *A* es *n*. Esto también lo denotamos como la cardinalidad de *A* por *#(A)*. (Op. Cit. pp. 99-101).

La suma se da, de manera natural al obtener el sucesor, por iteración y partiendo de n, es $n + 1$. Cuando n es un conjunto, entonces la suma es la unión de conjuntos disjuntos: $A \cup B$ y si m y n son sus cardinales respectivamente, entonces $m + n$.

Cognitivo: Con base en los aportes de la teoría de la actividad (Talizina, 2001) se pretende identificar dificultades que obstruyen (OB) su competencia con el uso de los SMS involucrados en la construcción de los números naturales debido a las maneras en que los niños de 6 a 7 años, han aprendido a usar los números naturales en la cotidianeidad. Estos obstructores pueden dificultar el tránsito de la acción a la operación cognitiva para promover el desarrollo numérico conceptual del cero, el uno y la noción de sucesor.

Comunicación: Con base en la semiótica (Peirce, 1987), se analizan los argumentos de inducción, deducción y abducción como procesos de significación (APS). Con las relaciones significantes se construyen las categorías para interpretar lo que hacen y dicen los niños en la producción de sentido y procesos de significación de las acciones que realizan en las actividades numéricas, esto es la Dotación de Sentido (DS). La lógica de uso de los SMS está relacionada con los procesos de iteración y recursión en la construcción de los números naturales.

Enseñanza: Entendida como colección de textos concretos que entiendan los aprendices, con la finalidad de que gradualmente conviertan los textos concretos en abstractos, con un significado matemático convencional. Se ha diseñado un Modelo de Enseñanza traduciendo el modelo formal de Von Neumann a actividades concretas, con el uso de material manipulativo.

Metodología Diseño y ejecución del Modelo de Enseñanza. El diseño de las actividades se realizó siguiendo las definiciones matemáticas de la secuencia de Von Neumann de acuerdo con Hamilton & Landin (1961, pp. 74 – 112), las hemos llamado principios (P_i):

P_1: Inicio de la contrucción con el cero. El nombre del conjunto vacío es el cero.

P_2: Contrucción del número uno como sucesor del número cero. Uso del proceso recursivo $0 = \emptyset$; $1 = \{\emptyset\}$; $2 = \{\emptyset, \{\emptyset\}\}$; $3 = \{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}$; y así sucesivamente. Las llaves se sustituyen con bolsas, como se muestra en la figura 1.

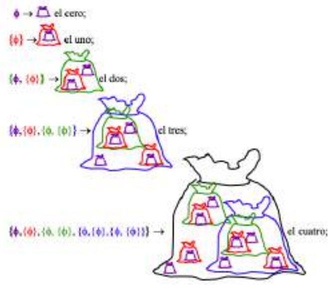

Figura 1: Proceso recursivo de los números, usando bolsitas

P_3: Un sucesor lo hemos llamado el siguiente.

P_4: Definición del Conjunto *n*, como número natural.

P_5: Conteo y cardinalidad.

P_6: Adición.

Se ha introducido el uso de una semirrecta para representar el orden de los números, a partir de la definición de intervalo "Si $a, b \in N, [a, b] = \{x\ x \in N\ y\ a \leq x\ y\ x \leq b\}. [a, b]$ es el intervalo de a hacia *b*." (Op. Cit. 1961, p. 97).

Para esta comunicación se han seleccionado dos secuencias de actividades del Modelo de Enseñanza, las cuales describiremos brevemente:

Adivina quien soy (P_1). El conjunto vacío como el número cero:

- Se les pide que observen una bolsa de plástico transparente vacía y digan que contiene, (posibles respuestas: nada y vacía).
- Se les pregunta cómo se puede nombrar esta bolsa vacía. La intención es relacionar la noción de números con las bolsas, para referirnos a bolsa/número.
- Se les pregunta con qué número se puede nombrar a la bolsa vacía.
- Al nombrar la palabra cero, se les pide identificar la etiqueta del número cero y la peguen en la parte externa de la bolsa.
- Se les pregunta si ya conocían ese número y para qué creen que sirva.
- Se les pregunta en qué parte de la semirrecta (dibujada en el pizarrón) pueden pegarla.

¿Podemos construir el siguiente? (P_2, P_3).- Construción del sucesor:

- Una vez relacionado y nombrado al conjunto vacío como número cero, se les pregunta: ¿Podemos construir el siguiente? (El *siguiente* es el número uno, es la bolsa/número que contiene al elemento cero).
- Se toma otra bolsa vacía y se les pregunta cómo se puede construir el siguiente. Se les pregunta quién es esa bolsa vacía, con la finalidad de que la nombren como *cero*, se les pide que peguen la etiqueta *cero* afuera de esta bolsa/número vacía, la introduzcan en la nueva bolsa nombrada como uno. Se les pide que peguen la etiqueta del *uno* por fuera de la bolsa.
- Se les pregunta dónde pegarla en la semirrecta (se espera que sea después del cero, construyendo el sentido de orden lineal).

- Con esta lógica de construcción, se van construyendo los sucesores, reflexionando en cada construcción, quién está antes de, quién está después de, quién está en todos los números, quién no tiene antecesor, a quién o quiénes contiene cada bolsa/número.

Este modelo de enseñanza se trabajó en la primera fase con un grupo de primer grado de una escuela pública en la CDMX. Con base en el análisis cuantitativo (ejercicios escritos) y cuantitativo (desempeño en cada sesión) los alumnos fueron clasificados en tres estratos (Alto, medio y bajo); se seleccionó un alumno representante de cada estrato para participar en la entrevista clínica. La segunda fase se realizó en el siguiente ciclo escolar, con la aplicación de la entrevista clínica.

Los resultados del análisis de la experimentación del Modelo, se publicaron en (autores 2018) y (autores 2019[a], 2019[b]). Por la falta de espacio en este reporte, sólo se presentará un fragmento de una sesión grupal y un fragmento de la entrevista de Daniel (estrato bajo).

Observación de la experiencia empírica con las categorías de análisis. En el análisis de la experimentación del Modelo, se identificaron *dificultades recurrentes* en las actuaciones de los niños. Las dificultades se agruparon en tres ejes: Uso de conocimientos pragmáticos/intuitivos y expontáneos: dificultades para identificar al cero como número; identificar al sucesor y antecesor de cualquier número. Uso semántico de los números en acciones de representación y conteo: dificultades para reconocer el número cero como conjunto vacío; reconocer que el cero es el único número que pertenece a cualquier sucesor, identificar al cero como punto origen en la semirrecta, reconocer que todo sucesor contiene a todos sus anteriores. Uso sintáctico en las operaciones: dificultades para usar la forma $a \cdot 10 + b$.

Para entender y explicar las dificultades y con base en el marco teórico, se diseñaron *tres categorías de análisis*: Tendencias Cognitivas que constituyen obstructores para el aprendizaje (OB); Argumentos de inducción, deducción y abducción como Procesos de Significación (APS) e; Indicadores de las Relaciones Significantes para la Dotación de Sentido (DS).

Por último, con el fin de confrontar a si las dificultades continúan, o aparecen otras nuevas, la entrevista clínica se aplicó e interpretó sobre la base de las mismas categorías de análisis.

Se usa la siguiente simbología: Maestra (M), Niños todos (N_s), Nicole (N_e), N_1, N_2,… cuando es un niño cualquiera y la letra inicial del nombre cuando es un niño en particular, Entrevistadora (E) y Daniel (D).

Fragmento del diálogo de la secuencia de actividades:"Adivina quien soy":

M: ¿Qué tiene la bolsa? [muestra la bolsa vacía].
N1: Nada [la maestra introduce algunos objetos a la bolsa y luego la vacía frente a ellos].
M: ¿Cómo quedó la bolsa?
N2: Vacía.
M: ¿Cómo podemos saber que mi bolsa está vacía?
A: Porque no tiene nada.
F: Por si no metes algo, no tienes nada.
E: Si está vacío no está pesado.
Ne: Si le metes algo, ya está lleno.
E: O por números.
M: ¿Cómo dijiste?
Ns: Por números.
M: ¿Y cuál creen que sea el número que debe estar aquí?
Ns: El uno, el dos, el tres, … [Se les muestran etiquetas de los números 0 al 9]
N3: Un cero.
M: ¿Quién es ese número?
Ns: Nada.
Ns: Cero.

M: ¿Quién pasa a buscar al número cero y pegarlo a la bolsa?
K: Aquí está [Karen, elige la etiqueta del número cero].
M: ¿En dónde lo coloco? [La maestra muestra la bolsa/número cero, para colocarla en la semirrecta pintada en el pizarrón].
F: Hasta el final [señala el extremo izquierdo de la semirrecta, pero usa la palabra final].
M: ¿Hasta el final?
F: ¡Ah! ¡En el primero! [Corrige su respuesta].

Fragmento del diálogo de la secuencia de actividades: "¿Podemos construir el siguiente?"

M: ¿Podemos construir el siguiente?
N_s: El uno.
M: ¿Cómo le haremos para construir el siguiente?
Ne: Tomar otra bolsa y ponerle el uno.
M: ¿Qué tenemos aquí? [Mostrando la bolsa vacía].
N_s: Vacía.
M: Vacía, pero necesito…
N_s: El uno.
M: ¿Cómo le haremos, porque esta bolsa está vacía?
N_s: ¡Póngale el uno! [La maestra introduce la bolsa del cero que se construyó previamente y les pregunta:]
M: ¿Cuántas bolsas hay adentro?
N_s: Una.
M: ¿Qué número se formó aquí?
N_s: Un uno.
M: ¿Por qué es uno Emiliano?
E: Porque el uno es primero.
M: Nicole...
Ne: Porque el uno va después que el cero.
M: ¿Dónde lo coloco?
N_s: En el primero.
M: ¿Quién está en el primero? [señala al cero que está colocado en la semirrecta].
N_s: Un número cero.
E: Lo pasas para el segundo [se refiere a la derecha del cero, en la semirrecta].

Análisis de estos fragmentos: "*Adivina quién soy*". En este fragmento se observan las dificultades para identificar el cero como conjunto vacío y como punto origen en la semirrecta.

El cero como conjunto vacío se observa con la acción de introducir objetos a la bolsa/número y luego sacarlos; pudieron relacionar el vacío con palabras: "nada, vacío, lleno, meter, sacar, pesado" (A, F, E, N_e). Esto se puede interpretar como acciones relacionadas con la (DS), los cuales permiten un acercamiento a la noción de cero como vacío. (A) hace un razonamiento inductivo (APS) al usar la palabra "nada" para justificar el vacío, dotando de sentido (DS) a la ausencia de elementos, lo que dio pauta para que sus compañeros pudieran seguir el sentido de la noción de vacío. Cuando (F) expresa verbalmente: "Porque si no metes algo, no tienes nada", está haciendo una deducción (APS) , lo que permite que (E) lo pueda relacionar el peso con el vacío, y (N_e), razona inductivamente (APS). Más adelante, ante la pregunta de poder nombrar a la bolsa vacía, la respuesta de (E) permite observar que se trata de un razonamiento abductivo (APS), al proponer el uso de los números. Sin embargo, para el resto del grupo, constituye una dificultad, que se puede entender es provocada por un (OB) cognitivo proveniente de sus experiencias con los números, han aprendido a repetir la secuencia numérica comenzando con el uno (N_s). Mientras que (N_3) logra seguir la idea de (E) y elige al número cero, lo que se puede entender como un razonamiento abductivo (APS).

La dificultad de (F) para identificar al cero como punto origen en la semirrecta, puede ser a que este alumno se encontraba sentado frente al extremo derecho de la semirrecta. Este (OB) cognitivo, de percepción, le dificultó establecer una relación de reversibilidad, para centrar su atención la semirrecta como objeto y no sólo en la percepción visual. Cuando la maestra lo cuestiona, permite que (F) corrija su respuesta.

¿Podemos construir el siguiente?.- En este fragmento se observan dificultades para reconocer que el cero es el único número que pertenece a cualquier sucesor; y que todo sucesor contiene a sus anteriores. Los niños identifican que el sucesor del cero es el uno, con lo que se puede decir que están dotando de sentido a la expresión “el siguiente”. Sin embargo, la dificultad se observa en que no le dan sentido a la construcción, consideran que sólo se necesita la etiqueta del número uno: (N_e) “Tomar otra bolsa y ponerle el uno”, (Ns) “¡Póngale el uno!” Esta dificultad es constante en las primeras líneas de la actividad, no le dan sentido al proceso recursivo. No reconocen que la bolsa/número *uno*, debe contener al menos un elemento. Se entiende que esta dificultad se debe a un obstructor cognitivo (OB) proveniente de las maneras en que han aprendido que los números es sólo la repetición oral y escrita de la secuencia contadora a partir del uno. La acción de (M) al introducir la bolsa vacía etiquetada con el número cero y preguntarles por el número que se formó, permitió que algunos niños observaran que es el número uno, cuando contiene al elemento cero (N_S): “Un uno”. Pero, para la mayoría de los niños lo siguen asociando con el primer elemento de la secuencia numérica: (E) “Porque el uno es primero”, con lo que se observa que esta dificultad es un (OB) con el uso de las relaciones de reversibilidad para identificar que el antecesor del uno es el cero; así como el sucesor del cero es el uno. Con el argumento deductivo (APS) de (N_e): “El uno va después del cero”, conlleva a que (E) corrija su respuesta, usando un argumento inductivo (APS) cuando la maestra pregunta en dónde colocarlo: “Lo pasas para el segundo”.

Entrevista clínica. Tuvo como objetivo comparar si las dificultades que se presentaron durante la experimentación del modelo continuan o aparecen nuevas.

Fragmento del diálogo en la secuencia de actividades: “Adivina quién soy”

E: ¿Qué tiene la bolsa?
D: Nada.
E: Nada y ¿Cómo está la bolsa?
D: Vacía.
E: ¿Cómo sabes que está vacía?
D: Porque no tiene nada.
E: ¿Cómo puedes decir que no tiene nada?
D: Estuviera un poco pesado.
E: ¿Cómo podemos representar esta bolsa que no tiene nada, que está vacía? [Daniel se queda pensando algunos segundos, sin contestar. Por lo que la entrevistadora le muestra el material que tiene sobre la mesa: una semirrecta, bolsas hule transparente de diferentes tamaños, etiquetas de números] ¿Alguno de estos puedo usar?
D: Este [Daniel señala el montón de las etiquetas del número cero].
E: ¿Cuál es este?
D: El cero. [Daniel pega la etiqueta del número cero en la parte frontal de la bolsa].
E: Ahora que sabemos que esta bolsa está vacía y que es el número cero ¿En dónde la colocamos en la recta?
D: Aquí [Daniel señala el extremo izquierdo de la semirrecta].

Fragmento del diálogo en la secuencia de actividades: ¿Podemos construir el siguiente?

E: ¿Cuál va a ser el siguiente?
D: El uno.
E: ¿Qué necesito para que sea el número uno?

D: Un número que esté adentro.
E: ¿Quién va a ser ese elemento que esté adentro?
D: ¿El uno?
E: ¿Quién era el que estaba antes?
D: ¡Ah, el cero!
E: El cero, entonces ¿qué tienes que hacer?
D: Agarrar una... [Daniel toma otra bolsa vacía, le pega la etiqueta del número cero y la introduce en la nueva bolsa/número uno].
E: ¿Qué nombre le voy a poner?
D: El uno. [Daniel señala y toma una etiqueta del número uno y la pega en la nueva bolsa/número uno].
E: ¡Muy bien! ¿dónde lo vas a colocar en la recta?
D: Aquí [Daniel lo coloca a la derecha de la bolsa/número cero].

Análisis de los fragmentos de la entrevista clínica. *Adivina quién soy.* - En este fragmento, se puede observar que (D) relaciona al conjunto vacío con el número cero, al expresar: "Estuviera un poco pesado", argumento deductivo (APS) que evocó la experiencia de la sesión grupal en el ciclo escolar próximo pasado. Lo que se puede entender como dotación de sentido (DS) para relacionar la noción de vacío con el número cero, pero aún no es convencional. Pero D duda cuando se le pregunta cómo nombrar a la bolsa/número vacía, se observa que duda, por lo que (E) le señala y pregunta: "¿Alguno de estos lo puedo usar?", dando la pauta para que (D) elija alguna de las etiquetas de los números. Al colocarlo en el extremo izquierdo de la semirrecta, está dotando de sentido (DS) al cero como punto origen de la construcción y superando esa dificultad.

¿Podemos construir el siguiente? - Se observa que hay dotación de sentido (DS) al reconocer que el número siguiente del número cero es el número uno. La respuesta de Daniel "Un número que esté adentro" a la pregunta de la Entrevistadora: "¿Qué necesito para que sea el número uno?", se puede entender como un argumento deductivo (APS) para dotar de sentido (DS) la noción de sucesor. Sin embargo, cuando la entrevistadora pregunta "¿Quién va a ser ese elemento que esté adentro?", se evidencia la inseguridad de D, al contestar con otra pregunta "¿El uno?", lo que se puede interpretar como dificultad para de producción de sentido de uso del proceso recursivo para reconocer que todo sucesor contiene a todos los anteriores. La pregunta de E "¿Quién estaba antes", permite que D evoque el proceso de construcción, recordando que el número cero es el que debe estar adentro de la bolsa/número uno, pues de inmediato toma una bolsa más pequeña y le pega la etiqueta del número cero y la introduce en la nueva bolsa/número uno. Estas acciones que realiza D nos permiten entender que le da sentido al uso de los SMS a través de la recursividad. A continuación, coloca la bolsa/número uno en la semirrecta a la derecha de la bolsa/número cero, consolidando el sentido de orden por la misma construcción.

Discusión final

Cerramos este espacio haciendo hincapié en que el objetivo general es identificar las dificultades de aprendizaje cuando se les enseña con el modelo formal matemático de von Neumann para la construcción de los números naturales y la lógica de uso de los SMS involucrados en dicha tarea.

Durante la experimentación se pudo cotejar que la influencia de las maneras en que han adquirido las nociones numéricas, dificulta la comprensión y uso pragmático de la recursividad, pero no constituyen un obstáculo. En la entrevista clínica vuelven a aparecer las dificultades recurrentes, mismas que son superadas en menor tiempo, haciendo un uso eficiente y dotando de sentido los SMS a través de la iteración y recursividad (acciones elementales para la conceptualización de los números naturales).

Por los resultados obtenidos parece ser valioso recuperar la tradición formal matemática en la enseñanza, desde los primeros grados de educación elemental y permitiría la participación de los niños en la construcción de los números naturales, lo que les brinda una posibilidad para consolidar la generalización, como base para un pensamiento aritmético sólido.

Finalmente, consideramos que el trabajo conceptual de los números con niños de 6 a 7 años de edad, no es una construcción trivial, memorística y operativa; pero puede facilitar el desarrollo del concepto antes del simbolismo. Lo que busca este trabajo es cultivar un pensamiento abstracto, que le permita a los niños acceder a niveles superiores de conocimiento matemático.

Researchers have identified students' difficulties reasoning about inverse functions. Through our review of this literature, three meanings stand out: a formal, 'undoing', and quantitative meaning. Using these meanings as a guide, we analyzed student work collected from a lesson on the topic of inverse functions taught by an experienced high school mathematics teacher, using a novel task. In analyzing the data, we noticed tensions between students' understanding of the context and of inverse function as treated in curricula. In this paper, we illustrate these tensions and describe potential implications for students' productive construction of the meanings of inverse function.

Keywords: Cognition, Algebra, High School Education, Representation and Visualization

Previous literature has identified that students in high school and beyond struggle with constructing productive inverse function meanings. We identify three different ways researchers discuss students' meanings for inverse relations: formal, "undoing", and quantitative. In this study, we characterize student work from a contextualized, problem-based lesson (Herbst, 2003) that our research team co-designed with an experienced high school mathematics teacher to support students in developing productive inverse function meanings in relation to the meanings characterized in the literature. In particular, we designed the lesson to support students in conceiving of and representing a quantitative relationship. The teacher who taught the lesson stated as part of their goal that students would understand that a function and its inverse function represent the same relationship and that the rule used to determine the function could be "undone" to determine the rule for the inverse function. Addressing the question "How do students reason when introduced to inverse function?", we use examples of student work and dialogue during their discussion to characterize the extent to which students exhibited these meanings of inverse function. We also highlight how the teacher's attempt to meet institutional obligations (Chazan, Herbst, & Clark, 2016) by introducing switching techniques (described shortly) during the lesson likely prompted students to move away from their initial reasoning.

Prior Literature on Students' Meanings for Inverse Relationships and Framework

We synthesize three meanings for inverse functions that are emphasized in the research literature examining the learning and teaching of inverse function: a formal meaning, an 'undoing' meaning, and a quantitative meaning. We use these meanings to categorize both the students' work from the classroom and the teachers' discussion of inverse.

Formal Meaning

Many researchers characterizing students' and teachers' meanings of inverse functions have emphasized aspects of the formal definition of inverse function: $f(f^{-1}(x)) = x$ and $f^{-1}(f(x)) = x$. This definition uses the notions of function composition (Brown & Reynolds, 2007; Even 1992; Vidakovic, 1996) and injectivity (Marmur & Zazkis, 2018; Wasserman, 2017). For example,

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Vidakovic (1996) provided a preliminary genetic decomposition of inverse function which closely resembled the formal definition. However, none of the students in her study developed inverse function meanings compatible with her genetic decomposition. Futhermore, none of the 26 pre-service teachers in Marmur and Zazkis' (2018) study noted the lack of injectivity of the function when asked to respond to a hypothetical student claiming the function $y = x^2 - 4x + 5$ had two inverse functions. The difficulties identified by Vidakovic (1996) and Marmur and Zazkis (2018) provide motivation for a continued need to explore ways to support students and teachers in developing meanings for inverse function.

Specifically, these aforementioned researchers and others (e.g., Paoletti et al., 2018) found that students' and teachers' meanings for inverse function are often constrained to engaging in specific actions in certain representations (e.g., switching-and-solving analytically, reflecting over a line graphically that may or may not result in equivalent inverse functions across these representations). For instance, Paoletti et al. (2018) noted a majority of the pre-service teachers in their study maintained disconnected meanings for inverse function that were constrained by such 'switching' techniques. Collectively, these disconnected meanings motivate a need to explore ways to support students and teachers in developing more coherent meanings for inverse function.

Undoing Meaning

Other researchers (Fowler, 2014; Martinez-Planell & Cruz Delgado, 2016; Oehrtman, Carlson, & Thompson, 2008; Teuscher, Palsky, & Palfreyman, 2018) have suggested having students develop meanings for an inverse function as "undoing" the original function process, often in lieu of focusing on formal mathematical properties of inverse function. Researchers who have adopted this stance have found that instruction emphasizing inverse functions as 'undoing' supports more students in addressing tasks relevant to decontextualized and contextualized inverse functions as compared to students who experienced instruction focused on formal definitions and switching techniques (e.g., analytically switching the x and y labels, reflecting over the line $y = x$). For example, across a sample of 3,858 college pre-calculus students, Teuscher, Palsky and Palfreyman (2018) reported that, in course sections with instruction emphasizing an undoing meaning, students accurately solved 48% of inverse function tasks compared to 32% of students whose instruction focused on switching techniques. We note that although emphasizing an 'undoing' meaning can be *more* productive when compared to emphasizing formal definitions or switching-techniques, over half of students in the former sections were still unsuccessful in addressing inverse function prompts.

Quantitative Meaning

Recently, Paoletti et al. (2018) and Paoletti (2020) have leveraged Thompson's (2011) theory of quantitative reasoning to characterize a quantitative meaning for inverse relations (and functions). A quantitative meaning for inverse relations entails a student understanding that a relation and its inverse relation represent an invariant relationship between quantities' values, regardless of how the relationship is represented. Thus, rather than foregrounding injectivity (cf. Marmur & Zazkis, 2018), a quantitative meaning entails the existence of an inverse relation regardless of whether the original or inverse represents a function. Students can determine if either relation is a function by examining if the univalence property (i.e., if for each value of one quantity there is exactly one value of the second quantity) holds for each relation.

Rather than focusing on a function and its inverse as processes that can be undone, a student with a quantitative meaning for inverse relations understands that a relation and its inverse are (or can be) represented by the same rule or graph (Paoletti, 2020). Paoletti (2020) provided an empirical example of one pre-service teacher reorganizing her unproductive inverse function meanings grounded in switching techniques, into a more productive, quantitative, meaning. By the end of the study the student, Arya, understood that a single graph or analytic rule represented a function and its inverse function and that switching techniques were used to maintain conventions commonly used in school mathematics (e.g., the independent quantity is represented by variable x on the horizontal axis). She particularly noted how confusing switching techniques were in contextualized situations as it was necessary to switch the quantitative referents of the variables when engaging in switching techniques (i.e., if in $F(C) = (9/5)C + 32$, F represents the temperature in Fahrenheit and C the temperature in Celsius, then in $F^{-1}(C) = (5/9)(C - 32)$, F represents the temperature in Celsius and C the temperature in Fahrenheit). In this paper, we present indications of other students naturally maintaining the quantitative referents of variables.

Methods

Our team worked closely with an experienced high school mathematics teacher to design a contextual problem-based lesson with the goal of introducing students to the concept of inverse function. The first step in the lesson design was for the teacher to create a problem that would provoke a need for this new idea, but that students could make progress on by drawing on knowledge and skills that they had developed previously. Next, the teacher created a detailed lesson plan that included anticipations of student work and potential scaffolds and responses to them. The teacher then implemented the lesson in which students would work with their peers in small groups and then with whole-class discussions. The teacher ended the lesson with a statement of the newly introduced idea. The final version of the problem that the teacher designed is presented in Figure 1.

Several of us that teach at [name of your school] are on a slow-pitch recreation softball team together. Your City Parks and Rec charges a “sponsor fee” of $350 to enter the league. This pays for umpire fees, softballs, grounds people, etc. In addition, individual players each have to pay a player fee of $17. Thus, **the total amount of money we need to pay the office depends on how many people we have on our team**.

1) Make a table of *Total Fee* vs. *Number of Team Members* for at least 6 points. We need at least eight people to play.
2) Write, in words, the calculation procedure you kept doing to get the total amount of money given the number of players.
3) Is this situation linear? How do you know?
4) What is the y-intercept? What does it represent in this situation?
5) Write a rule for this situation.
6) Graph this function on a piece of graph paper.

When I worked for the recreation department in My Town, near the end of the season I needed to be able to see which teams in each division still had a chance to win the league. This way, I could order enough “Champions” t-shirts for the team with the most players who had a chance to win. What I had was the inventory list that had the receipts for the amount of money each team turned in, and from that, I had to figure out the number of players they had.

Assuming this same scenario for Your City Parks and Rec, the function for the league supervisor is backwards: for him or her, ***the number of players on the team depends on the total fee.***

7) Make a table for the league supervisor that computes the number of players for teams that have paid $571, $622, $639, $673 and $724.
8) Explain in words the calculation procedure you did to compute the number of players from the total fee amount.
9) Write a rule that computes the number of players as a function of the total team fee.
10) Make a second graph on your graph paper that shows the relationship from this perspective (with the total paid as the independent variable and the number of players the dependent).

11) Compare the function from the front with that of the recreation supervisor from this side. What do you notice about how the tables, graphs, and rules are different?

Figure 1: The Softball Fees Problem

Relative to the meanings for inverse function, although the context included an injective relationship between quantities and could have led to a discussion involving composition, this introductory lesson to inverse function did not explicitly address composition. Rather, the lesson revolved around ideas of inverse function more closely related to the undoing and quantitative meanings of inverse function. In the discussion of the lesson, the teacher explicitly referred to the inverse equation as representing an "undoing" of the original function process. Moreover, in his lesson plan, the teacher described, as a mathematical goal, that "we can focus at this initial stage on simply what the relationship looks like if you want to change your perspective and have students recognize that the function and its inverse are related, but not the same" (which is consistent with an undoing meaning) and goes on to say "that the factual information [this many players equates to this much money] stays consistent regardless of what perspective you have" (which is consistent with a quantitative meaning) The teacher attended to constructing different representations for the function and its inverse and emphasized the importance of understanding that the two functions represent the same "factual information" for all representations. Thus, in this paper, we report on student work that stemmed from instruction that emphasized both an "undoing" notion of inverse function (particularly when representing the relationship between the quantities as rules) and maintaining the quantitative relationship that a function and its inverse represent.

The teacher worked at a large Midwestern public high school. He taught the lesson during three class periods to three different classes of students. The data collected from each implementation of the lesson included video recordings positioned strategically across the room to capture students' work in groups. Additionally, researchers took fieldnotes and created copies of written work from 60 students.

Our analysis focused primarily on the student work. Initially, we analyzed it using Balacheff and Gaudin's (2010) conception framework. Through this analysis, we noticed variation in the representations used—tables, rules, and graphs—by students as well as in how they operated on them in the process of finding the inverse function. We also noticed that there was an association between the representations/operations used and the students' control structure. Reflecting on these findings, literature emphasizing students' inconsistencies in representations of inverse relationships (Paoletti et al., 2018), and our own observations of students' attempts to update their work to fit the conventional ways of representing inverse relationships in each of the representations (i.e., tables with the independent variable on the left, rules in which the independent variable is represented as x, and Cartesian graphs whose horizontal axis represents the independent variable x), we shifted our attention to those pieces of student work that may present this tension. We then open-coded (Strauss & Corbin, 1994) the student work based on individual student's ways of representing inverse functions (e.g., column location of values, naming of quantities in expressions, orientations of graphs). We also analyzed the classroom video associated with the implementations of the lesson to learn what ideas about inverse functions the teacher emphasized and to confirm the use of the aforementioned conventional notation with the students. From there, attending to the idea that conventional student work would not be present in work *prior* to the class discussion, we identified key pieces of student work in which the student seemed to change the way they represented the inverse function. As we explain in the next section, these pieces of work provided insights into students' initial reasoning about representing inverse functions and the alterations they made to fit with the ways in which the teacher was asking the students to represent inverse functions. We connected the chosen pieces of student work to ways in which they did so to the aforementioned inverse function meanings. Collectively, this analysis allowed us to answer the question of how students reason when first introduced to inverse function and to identify some of the tensions that present in their different ways of representing their reasoning.

Results

We present samples of student work that provide evidence of reasoning emphasizing either an "undoing" or quantitative meaning for inverse function. Although each individual created tables, rules, and graphs, we only present specific responses relevant to specific representations of each student's work. Specifically, we describe, by type of representation, each piece of original student work and, if relevant, the updates that the students made to this work.

Reasoning with Tables

Addressing Question 7 (Figure 2), IS initially constructed a table for the supervisor that labeled the quantities "# of players" and "$" on the left and right, respectively. IS wrote the given fee values in the right-hand column, circling them. This table followed the same format as IS's first table from Question 1 (not pictured) in which IS had the number of players on the left side of the table and total fee amount on the right. To the right of that table in Figure 2 is an updated table in which the student constructed a table with switched columns (values and their associated quantitative referent). This example illustrates a student who considered their initial table as representing both a relationship and its inverse; using a single table to represent a function and its inverse aligns with the quantitative meaning for inverse function. Although students often chose different values or column labels in their tables, using the same table to address Question 1 and 7 was common. As a second example, MH preserved *x* and *y* labeling as well as the location of the quantities represented on the left and right in their table.

Figure 3 is another example of a student using the same table to address Questions 1 and 7. Moreover, KK's description of her original process for constructing her table across Questions 2 and 8 is consistent with an "undoing" meaning. Such activity may be indicative of the student understanding ways to connect her quantitative and undoing meanings for inverse function. She may understand that, while the function and its inverse represent the same relationship, in order to determine values of one quantity given a value of the second quantity, she must reverse the process by which she found values of the second quantity to determine the value of the first quantity. KK's table and descriptions also provide insight into the significant components of the table they were considering when updating their crossed-out table. Specifically, they drew several double-sided arrows on their (initial) crossed out table and, beside their redrawn table, they drew another blank table with the labels "ind" (independent) and "dep" (dependent). Comments from other students who drew new tables such as KK included a student writing "flipped around" above the new table and TK writing "should have put # of players right (y) on table." We conjecture such activity was spurned by the instructor who emphasized representing the independent variable on the left side of the table and the dependent variable on the right.

Lastly, consider the work in Figure 4 from DS. DS viewed a table as apt to represent both a relationship and its inverse. When asked to explain the calculation procedure for the supervisor, DS wrote, "You take the table from befor[e] and find the p[r]ice then writ[e] down what *x* is."

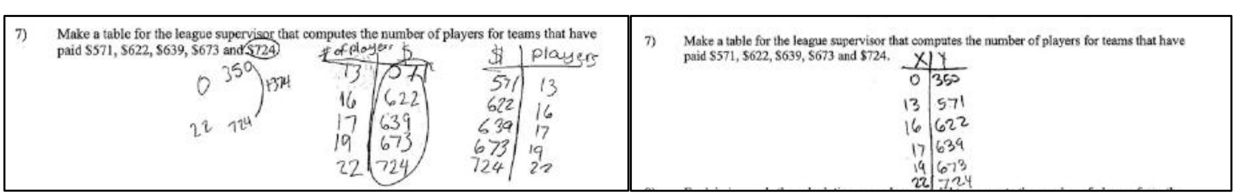

Figure 2: (left) IS's Two Tables for the League Supervisor and (right) MH's Table

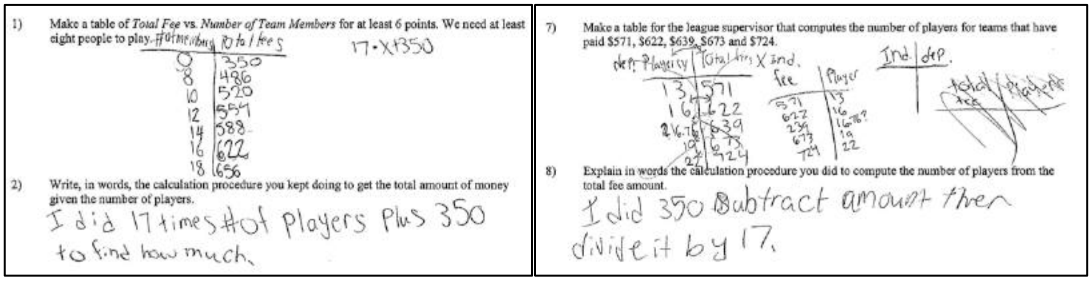

Figure 3: KK's Initial and Inverse Tables and "Undoing" Description

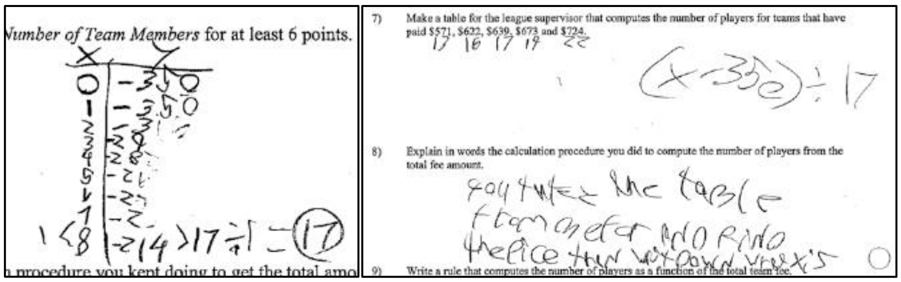

Figure 4: DS's Description of the Inverse Calculation Procedure

Reasoning with Rules

Figure 3 above provides an example of a student who provided a mathematical description of a process that undoes the original one. Perhaps due to current curricular treatments of inverse function, which emphasize the importance of representing the input quantity by the variable x on the horizontal axis, students engaging in writing a new rule to represent this undoing process may switch variables such that the independent quantity represents x and the dependent quantity represents y (or $f^{-1}(x)$). This point was raised by the teacher during the discussion. However, in students' initial work, there was variation among students' use of x, y, and their quantitative referents in their construction of a rule that computes the numbers of players as a function of the total team fee.

First—and indicative of maintaining a quantitative meaning for inverse functions—some students did not write a new rule for the inverse relationship and simply used their existing rule. For example, MH, who also did not construct a table with a different format for the inverse (Figure 2, right), used their rule "$y = 17x+350$" to substitute the given team fee values and solve for x (Figure 5). Thus, throughout their work on the task, x represents the "*number of team members*" and y represents the "*total fee*" consistently.

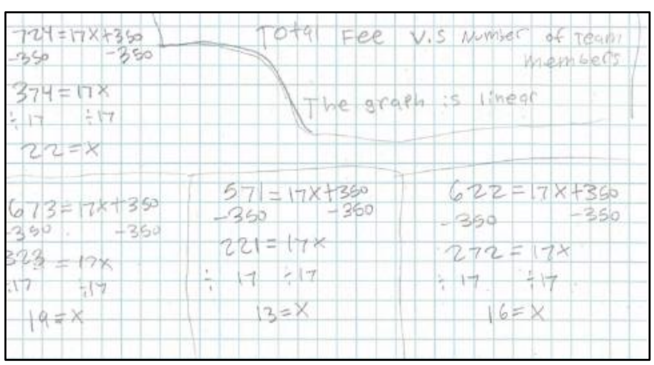

Figure 5: MH Substitution Strategy for Supervisor

Other students used their first rule and wrote a new rule in terms of the symbol representing the total team fee. For example, TK (Figure 6, left), who, like MH, did not construct a new table, had the rule "(y – 350) ÷ 17 = x". Here, y represented "Total fee" as labeled in the table. However, as seen in both MH's work and HV work, the x and y labels were not used consistently throughout individual students' work. For example, TK's initial rule, seen in Question 7 (i.e., $(y - 350)/17 = x$), maintains the quantitative referent of the variables in their table (i.e., "Total fee y"). However, when addressing Question 9, TK appears to have erased and then switched their original x and y labels in the rule used to create the table values. We conjecture this change may have been spurned by the classroom conversation based on TK's note that they "Should have put # of players right (y) on a table." Another student, HV, wrote the equation "(x – 350) ÷ 17 = y" but the labels on the table beside seem to indicate that x represented the number of players and y the total fee (Figure 6, right).

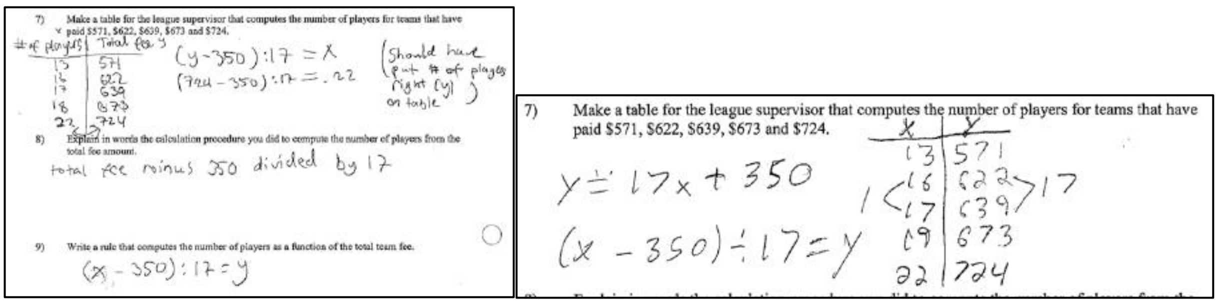

Figure 6: TK (left) and HV's (right) inconsistent use of *x* and *y*

Across the student work, we observed responses that were indicative of each of the meanings for inverse function described in the literature. Several students, like MH, exhibited a quantitative meaning for inverse function as they understood a single rule could be used to represent both a function and its inverse. Consistent with an undoing meaning for inverse function, other students, like TK, wrote a new rule that represented the opposite of the initial process that maintained the quantitative referents of the variables. Finally, several students created rules that inconsistently maintained the relationships between variables and quantitative referents, which may be indicative of their attempting to make sense of the classroom instruction that emphasized the importance of switching-and-solving.

Reasoning with Graphs

As a closing illustration, although most students constructed two perceptually different graphs with different axes labeled on the horizontal axis, nine students drew graphs (or at least labeled axes) to indicate that both requested graphs would have the same axes labels in the same locations. MX, for example, had "People" labeled on the horizontal axis for her first graph and seemed to intend for the number of people on the team to be represented on the horizontal axis for her graph for the supervisor, too (Figure 7). Like the students who only constructed one table (e.g., IS), these students seemed to indicate that a single graph orientation could represent both a relationship and its inverse.

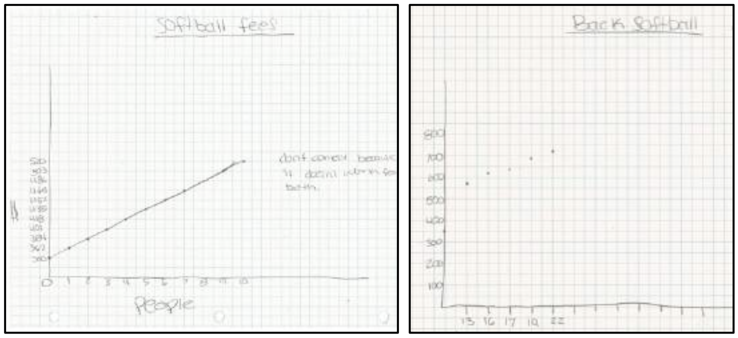

Figure 7: MX's Two Graphs with Same Axes Labels

Discussion

We use the aforementioned pieces of student work to highlight various ways in which students exhibited each of the three meanings for inverse relations present in the literature. The teacher designed the lesson purposefully to be contextualized and problem-based, and we argue reasoning with the context supported the students in understanding a relation and its inverse as representing the same quantitative relationships. The design of the task also supported an undoing meaning for inverse function. In particular, KK's work provides some evidence that these two meanings – quantitative and undoing meanings – can interplay with one another in possibly productive ways. We note that none of the student work contained the common struggles described in literature on students' inverse meanings (e.g., reflecting over a $y = x$ line on a graph, writing the multiplicative inverse of the function as the function's inverse, composing functions). We hypothesize this is because of the scaffolding of this introductory task and that the contextualization of the relationship they considered supported them in being able to reference the context to make sense of their results.

Despite the students providing several quantitative representations of their reasoning, the teacher likely felt an institutional obligation (Chazan, Herbst, & Clark, 2016) to carry out a classroom discussion in which students' reasoning, while perhaps quantitatively appropriate, needed to be amended to fit the conventional notations for inverse function. Although the teacher maintained consistent meanings for inverse function throughout this discussion, we note that students were faced with the tension of motivating changes in notation in their quantitatively appropriate work. We conjecture without having explicit conversations that allow students to reconcile the need for adjustments in their work (i.e. discussions regarding conventions), students may experience conflations (and perhaps a motivation to rely on memorizing techniques) when addressing inverse function tasks as is seen in the literature (e.g., Paoletti et al., 2018; Vidakovic, 1996). Future researchers may be interested in exploring how such conversations may be fruitful for teachers to have with students.

FRAMEWORK FOR REPRESENTING A MULTIPLICATIVE OBJECT IN THE CONTEXT OF GRAPHING

Halil I. Tasova

halil.tasova25@uga.edu

Kevin C. Moore
University of Georgia
kvcmoore@uga.edu

In this study, based on the analysis of a teaching experiment with middle school students, we propose a framework for describing meanings of a point represented on a plane in terms of multiplicative objects in the context of graphing. We classify those meanings as representing (i) non-multiplicative objects, (ii) quantitative multiplicative objects (Type-1 and Type 2), and (iii) spatial multiplicative objects. We then discuss implications of these meanings with respect to students' graphing activities.

Keywords: Cognition, Representations and Visualization, Modelling

Quantitative and covariational reasoning play a critical role in students' understanding of various ideas in mathematics (e.g., Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Ellis, 2011; Johnson, 2015). There are numerous aspects and important constructs (e.g., quantitative structure, frames of reference, and quantification) that individuals could develop in order to engage in productive, powerful quantitative and covariational reasoning (Joshua, Musgrave, Hatfield, & Thompson, 2015; Moore, Liang, Tasova, Stevens, 2019; Thompson, 2011). One of these constructs is a *multiplicative object*. Thompson, Hatfield, Yoon, Joshua, and Byerley (2017) suggested that students "must construct a multiplicative object of quantities' attributes in order to reason about their values covarying smoothly and continuously" (p. 128). Constructing a multiplicative object is also important in the context of graphing as it imparts a productive meaning to a point on a graph (Frank, 2017; Saldanha & Thompson, 1998; Thompson & Carlson, 2017). However, much is left to understand about the extent and nature of students' meanings of a point as representing a multiplicative object in the context of graphing. Therefore, in this study and against the backdrop of empirical data, we provide a framework to classify students' meanings of a point on a plane in terms of representing a multiplicative object.

What is a Multiplicative Object?

A multiplicative object can be considered a conceptual object that is formed by uniting in the mind two or more quantities' magnitudes or values simultaneously (Saldanha & Thompson, 1998; Thompson, 2011; Thompson & Carlson, 2017). The mental operation of someone who constructs a multiplicative object is similar to the operation of someone who conceives a quarter coin as being, simultaneously, a circle and silver in color. In this operation, circle and silver, as two attributes of the object, have been considered, simultaneously, as one property of a quarter coin. For a dynamic example, imagine heating the quarter coin up to the melting point of silver. As a multiplicative object, coupling the two attributes, someone could track the variation of the coin's color with the immediate and persistent awareness that, at every moment, the temperature of the coin also varies.

In the context of co-variation, Thompson (2011) represented the multiplicative object formed by uniting two quantities' variations by using the following representation: $(x_e, y_e) = (x(t_e), y(t_e))$, where $x_e = x(t_e)$ represents a variation in the values of x, where t_e represents variation in t through conceptual time over the interval $[t, t+e)$. He explained that in order for students to reason covariationally, they must unite x_e and y_e by constructing (x_e, y_e), which simultaneously represents the two. Note that the corresponding representation of this conceptual object in graphical context would be a point in a coordinate plane. We next discuss the role of conceiving a point as a multiplicative object in developing meanings for graphs.

Multiplicative Objects in the Context of Graphing

Despite the notion that graphing is critical for understanding various ideas in STEM fields (Rodriguez, Bain, & Towns, 2019; Kaput, 2008; Leinhardt, Zaslavsky, & Stein, 1990), students face a number of challenges (e.g., graphs as pictorial objects) in interpreting and making sense of graphs (Clement, 1989; Leinhardt et al., 1990; Moore & Thompson, 2015). Thompson and Carlson (2017) conjectured that part of these students' difficulties were grounded in being unable to conceive points on a graph as multiplicative objects, and several researchers have provided evidence to this claim (e.g., Frank, 2016, 2017; Stalvey & Vidakovic, 2015; Stevens & Moore, 2017; Thompson et al., 2017). Given this evidence, conceiving points as multiplicative objects might be an integral part of constructing productive meanings for graphs, and thus a student's construction of points should not be taken for granted.

We note that students' meanings of points on a plane can be considered as a representation of multiplicative object if students conceive a point by engaging in multiplicative operation—the operation of uniting and holding in mind two attributes of an object (i.e., quantities) simultaneously—as defined by Inhelder and Piaget (1964). Inhelder and Piaget first introduced the role of a multiplicative operation to characterize children's thinking when classifying 2-atrribute objects (e.g., objects grouped according to shape and color, as described above). They reported two different ways of children's thinking, both of which lead to normative responses when identifying a missing element in a matrix arrangement (see Figure 1). One is based on twofold symmetries that involve relying on perceptual configuration of the matrix arrangement and treating it as an incomplete pattern. For example, squares are symmetric over the horizontal axis of the diagram, so the blank space should include a circle. Similarly, red objects are symmetric over the vertical axis, so the blank space should include a blue circle. The other way of thinking is based on a multiplicative operation on a logical structure with reasoning about objects and coordinating two classes. For example, classifying the given three objects simultaneously in terms of shape and color, then identifying two elements of squares already belong to the classification of red or blue, noting the given element of circle belongs to red, and then joining circle and blue to construct the missing element.

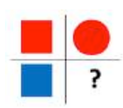

Figure 1. A matrix diagram designed based on the narratives of Inhelder & Piaget (1964).

We rely on these two types (e.g., perceptual features vs. reasoning about attributes) to classify students' meanings of points as representing non-multiplicative objects or representing multiplicative objects. In addition, we note that Inhelder and Piaget (1964) illustrated that an arrangement does not have to be in a matrix form for a child to think of objects in terms of two attributes. Inhelder and Piaget reported students could coordinate multiplicative classes without needing objects in a matrix form, and in our work, we illustrate that students could conceive points as representations of multiplicative objects without needing points represented in a Cartesian coordinate system (see spatial multiplicative object of the following framework). In other words, we considered that representing a multiplicative object is not restricted to plotting a point on a coordinate plane in the normative sense; it is about conceiving a point as a simultaneous representation of the two attributes of the same object.

Role of Multiplicative Objects in Emergent Shape Thinking

Moore and Thompson (2015) introduced the notion of *emergent shape thinking* to describe a person who envisions a graph "*simultaneously* as what is made (a trace) and how it is made (covariation)"

(p. 785). Constructing a graph from this perspective involves (1) representing two quantities' magnitudes and/or values varying on each axis of a coordinate system, (2) creating a point as a representation of a multiplicative object uniting those two quantities' magnitudes or values as a single object, and (3) generating a graph by conceiving the process of a multiplicative object leaving a trace when moving within the plane in ways invariant with the two covarying quantities. As we elaborate on different types of representing multiplicative objects, our framework informs the process in which a student could develop emergent shape thinking, which researchers (e.g., Frank, 2017; Moore, Stevens, Paoletti, Hobson, & Liang, 2019) have shown it is a productive way of thinking about graphs.

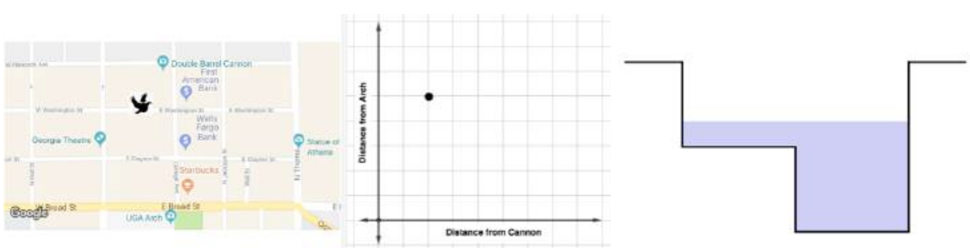
Method

Our work here stems from a semester-long teaching experiment (Steffe & Thompson, 2000) that occurred at a public middle school in the southeast United States. We recruited four seventh-grade students (age 12). Our goal was to investigate students' thinking involved in conceiving and representing various quantitative relationships. In this paper, we focus on two of the four students, Zane and Ella, since their meanings for points were consistent within their representational system and clearly described by them throughout the teaching experiment. We believe it is important to document these ways of thinking in order to add nuances to our models of students' conception of points in a graphing activity in terms of multiplicative objects.

The first author was the teacher-researcher (TR). We recorded all sessions using two video cameras to capture students' work and their gestures and a screen recorder to capture their activities on the tablet device. We transcribed the video and digitized students' written work for on-going and retrospective conceptual analyses (Thompson, 2008). Our analysis relied on generative and axial methods (Corbin & Strauss, 2008), and it was intended to develop working models of students' thinking based on their observable and audible behaviors.

Tasks

Before conducting the teaching experiment, the TR developed an initial sequence of tasks by considering particular design principles focused on graphing covarying quantities (e.g., Frank, 2017; Moore & Thompson, 2015; Stevens, Paoletti, Moore, Liang & Hardison, 2017; Thompson & Carlson, 2017). The TR revised and implemented those tasks based on on-going inferences and analysis of Zane and Ella's thinking. Each task was designed with a dynamic geometry software and displayed on a tablet device.



(a) (b) (c)

Figure 2. (a) The map of Downtown Athens, (b) Coordinate system with a point, and (c) A diagram of the pool

The Crow Task. The situation includes a map of Downtown Athens with a movable crow and fixed seven locations: UGA Arch (hereafter Arch), Double-Barreled Cannon (hereafter Cannon), First American Bank, Georgia Theater, Wells Cargo Bank, Statue of Athena, and Starbucks (see the map in Figure 2a). We also presented a Cartesian coordinate system whose horizontal axis is labeled as distance from Cannon and vertical axis is labeled as distance from Arch (Figure 2b). Students can control the crow freely by dragging it and see how the corresponding point in the coordinate plane changes (go to https://bit.ly/PMENA42 for the digital version of the tasks).

The Swimming Pool Task. This task was adapted from Swan (1985). We presented students a dynamic diagram of a pool (Figure 2c), where they could fill or drain the pool by dragging a point on a given slider. We designed the task to support students in reasoning with the inter-dependence relationship between two continuously co-varying quantities: amount of water (AoW) and depth of water (DoW) in the pool.

Framework for Representing a Multiplicative Object

In this framework, we describe students' meanings for a point in terms of multiplicative objects. We classify those meanings as representing (i) non-multiplicative objects, (ii) quantitative multiplicative objects (Type-1 and Type 2), and (iii) spatial multiplicative objects.

Representing a Non-Multiplicative Object

In this section, we illustrate a characterization of students' meanings for points on a coordinate system as contra-indication of representing a multiplicative object. Building off of limited number of studies (i.e., David, Roh, & Sellers, 2018; Frank, 2016, 2017; Thompson & Carlson, 2017; Thompson et al., 2017), this characterization emerged as we identified students correctly plotting points in the plane by carrying out a certain procedure (e.g., over and up), but the meaning of these points included solely an ordered pair of numbers and/or a location in the plane that did not symbolize or unite two quantities' magnitudes and measures.

Note that there are different students' meanings that could be classified as a non-multiplicative object. Aforementioned researchers have exemplified some of those meanings. For example, Thompson et al. (2017) argued that calculus students viewed the point (2, *f*(2)) in a coordinate plane as a value of the function, instead of the relationship between the value of the function (i.e., *f*(2)) and the value (i.e., 2) for which the function was evaluated. Similarly, David et al. (2018) reported that some students treated the output of the function as the location of the coordinate point in the plane, rather than on the vertical axis (i.e., *location-thinking*). Those students—and consistent with those in Thompson et al.'s study—did not think of 2 as a measure of a magnitude located on the horizontal axis and they did not think of *f*(2) as a measure of a magnitude located on the vertical axis in a canonical Cartesian plane.

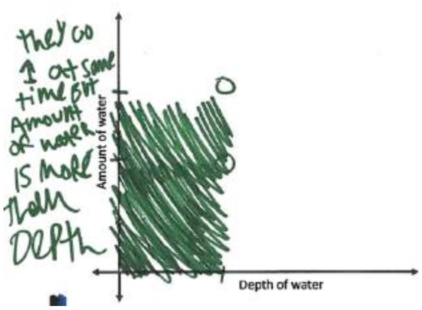


Figure 3. Ella's first draft.

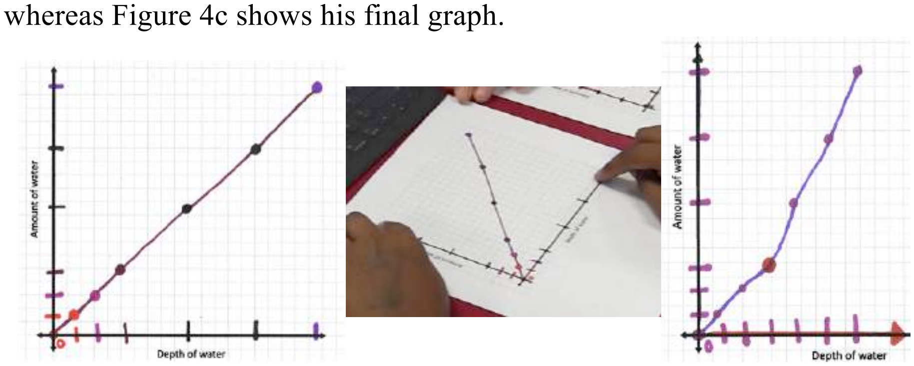
For an empirical example from our data set that falls under this category, we present Ella's graphing activity in Swimming Pool Task. We asked Ella to sketch a draft of a graph that represents the relationship between AoW and DoW as the pool fills up. She began by inserting two tick marks on each axis as an indication of AoW and DoW. As seen in Figure 3, she noted, as we fill the pool up, both tick marks go up along the axis at the same time and wanted to place the tick mark for AoW further along the vertical axis than the tick mark for DoW since she thought "amount of water is more than depth."

Then, Ella drew a small circle in the plane to show "where those two things [*tracing her finger horizontally from the tick mark on the vertical axis to the circle in the plane, then vertically down from the circle in the plane to the tick mark on the horizontal axis*] meet here." Then, she shaded the rectangular area in the plane, what she called "a box" (see Figure 3), to show "a bunch of water." When asked to explain what the small circle meant for her in terms of the pool situation, Ella said, "I don't know what it means" and further she explained "that is just like the dot between [*tracing her finger horizontally from the tick mark on the vertical axis to the circle in the plane*] here [*tracing her finger vertically down from the circle in the plane to the tick mark on the horizontal axis*] so I can just make this box [*pointing to the shaded area in the plane*]." We infer that Ella was able to plot a point in the plane respective of the tick marks that she placed on each axis. However, Ella conceived the point as a landmark to draw "the box," which was a contraindication of *representing* a multiplicative object. Although Ella reasoned about the attributes when placing the two tick marks on the axes and used those tick marks in order to generate the point (i.e., the circle in Figure 3), Ella's meanings of the point didn't include uniting the attributes of an object (i.e., AoW and DoW) in the plane; instead Ella conceived the point in terms of a mark as a part of a procedure to set the corner for the box.

Representing a Quantitative Multiplicative Object (QMO)

In this category, we describe meanings of students who construct and/or interpret a single point in the plane in relation to two quantities whose magnitudes or values represented on each axis. We illustrate this category by using Zane's graphing activity in the Swimming Pool Task.

We asked Zane to sketch a graph that shows the relationship between AoW and DoW as the pool fills up. Zane started with drawing tick marks on each axis. Zane referred to the quantity's magnitude by drawing a line segment from the origin to the tick mark on the axis to articulate his meanings of tick marks. Moreover, Zane simulated the quantities' variation by tracing his fingers along the axis as we played the animation to fill the empty pool (Figure 4b). After inserting tick marks, Zane plotted points for each related tick marks correspondingly (see his color-coded points and tick marks in Figure 4a), then he connected those points with line segments in the plane. Figure 4a shows Zane's earlier graph whereas Figure 4c shows his final graph.



(a) (b) (c)

Figure 4. (a) Zane's draft, (b) Zane moving his fingers on axes, and (d) Zane's final graph

To gain more insights into how he conceived his plotted points, we asked Zane to show the point on his graph representing when the pool is full. Zane first pointed to the far right and top purple tick marks on each axis (see Figure 4a, see also Figure 4b), and he then pointed to the corresponding purple point in the plane (see Figure 4a). Taken together with his description of a dot—"the dot represents both amount of water and depth of water"—his actions suggest that he could associate two tick marks (i.e., indication of quantities' magnitudes for Zane) on each axis to the corresponding point in the plane, which is an indication of representing a QMO.

So far, we demonstrated Zane's meanings of a single point in the plane. We, now, classify the instances of representing QMO in two ways in relation to conceiving a graph (e.g., a line drawn in the plane) when students represent a relationship as two quantities vary: (1) as a path or direction of movement of a dot in the plane, and (2) as a trace of the point consisting of infinitely many points, each of which showing the relationship of two varying quantities. We illustrate those types below.

Type-1 QMO. Type 1 includes students who envision points as a circular *dot* that represents two quantities' magnitudes or values simultaneously and envision that points on a graph (e.g., a line) do not exist until they are physically and visually plotted. Therefore, those students conceive the graph as representing a direction of movement of a dot on a coordinate plane. We illustrate by continuing to discuss Zane's graphing activity identified above.

We asked Zane whether his graph (see Figure 4c) showed every single moment of how the two quantities varied in the situation, Zane claimed no because one would need to stop the animation and plot an additional point in order to show the desired moment and state of the quantities. We infer that, for Zane, his line did not have points until they are visually plotted. He needed to physically plot additional points to represent moments in between two available points, even if there is a line connecting them. When questioned what the line segments that he drew in between dots meant to him, Zane responded that the line shows "where the dots go." By go, he meant a dot moving from one plotted point to the next plotted point, but not in a way that preserved an invariant relationship between those two points.

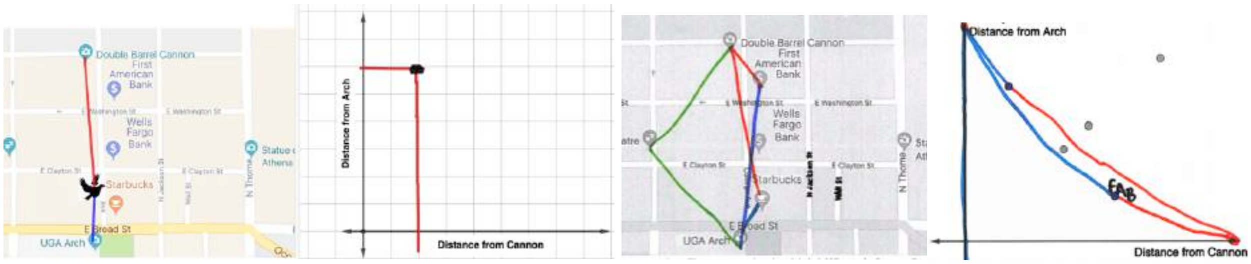
Therefore, despite his success in being able to conceive of a point as a multiplicative object, Zane assimilated his graphing activity as one dot moving along a line path instead of one dot generating infinitely many points by leaving a trace. We claim that his meaning for points and lines played a critical role in Zane's construction and constrained him from conceiving a graph as an emergent, in-progress trace (i.e., the third component of emergent shape thinking).

Type-2 QMO. Type 2 describes students who could envision a point as an abstract object that represents two quantities' magnitudes or values simultaneously, and envision a graph (e.g., a line) as composed of infinitely points, each of which represent two quantities' values or magnitudes, which is an indication of emergent shape thinking. We did not have data in our current study to show an empirical example of a student reasoning emergently (see Moore & Thompson, 2015, for an illustration).

Representing a Spatial Multiplicative Object (SMO)

This category emerged as we coded instances where the students assimilated a "point" in the plane as an object/location by focusing on the object's quantitative properties and engaging in quantitative reasoning (e.g., gross comparison of two quantities' magnitudes). Students who represented a SMO determined the object's *location* by coordinating and representing two (measurable) attributes of the object (e.g., the crow's distance from Arch and Cannon) *in* the plane, as opposed to representing those attributes on the axes of the plane. That is, they represented the two attributes considering the object's (i.e., the point in the plane) distance from each axis or from a certain location in each axis of the coordinate plane.

For an illustration, we present a moment from Zane's activity in a version of the Crow Task. In the previous version, Zane assimilated the given black point in the plane (see Figure 2b) as the crow. In this version, we hided the given point and asked Zane to plot a point that represents the crow's DfA and DfC when the crow is in a place on the map as seen in Figure 5a. Zane began drawing a horizontal line segment starting from the vertical axis to a certain place in the plane and drew a vertical line segment from that place to the horizontal axis (see Figure 5b). Making connection to the blue and red bars appearing on the map (Figure 5a), he referred to the horizontal line segment in the plane saying “the crow’s distance form Arch is shorter” and referring to the vertical line segment in the plane, he said “the crow’s distance from Cannon is longer.” Then, he plotted the black dot (seen in Figure 5b) where these line segments intersected.



(a) (b) (c) (d)

Figure 5. (a) and (b) Zane’s activity, (c) and (d) Ella’s activity

We infer that to *locate* the black dot (i.e., the crow for him) in the plane, Zane represented the crow’s distance from Arch as the distance from the vertical axis and the crow’s distance from Cannon as distance from the horizontal axis. Note that this activity is consistent with Zane’s earlier activity where he assimilated the axis of the coordinate system as Arch and Cannon. Although the position of the point he plotted is not normative in terms of a canonical quantitative coordinate system (Lee, Hardison, & Paoletti, 2018), this activity was valid for Zane as he was assimilating the black dot in the plane as the crow, and imagining Arch in place of the vertical axis and Cannon in place of the horizontal axis itself.

Note that our emphasis in this framework is not on students’ use of coordinate systems (cf. Lee, Hardison, & Paoletti, 2018; Paoletti, Lee, & Hardison, 2018); instead we categorize students’ meanings of points in terms of multiplicative objects represented in a space that may or may not be classified as any type of coordinate system that we, as researchers, know. For example, Zane’s graphing activity (Figure 5b) may suggest he *seemed* to be engaging in plotting a point as a multiplicative object in a *spatial coordinate system* (according to Paoletti et al., 2018), where Zane established a frame of reference considering the horizontal axis and the vertical axis as a reference point to represent the crow’s distance from Cannon and Arch, respectively. However, conceiving a point as SMO should not directly imply representing the relationship on a spatial coordinate system. Considering Ella’s activity in Downtown Athens Task (see Figure 5c and 5d), we infer that Ella essentially formed, from our perspective, a two-center bipolar coordinate system based on gross comparisons between the two quantities’ magnitudes. That is, she conceived Arch and Cannon as a location on the vertical and horizontal axis, respectively, implied by the labels (see orange dots on each axis in Figure 5d). Then, she made sense of the rest of the space by coordinating the radial distances between “places” in the plane and “Arch” and “Cannon” on each axis. For example, Ella labeled a point as FAB in the plane (see Figure 5d) indicating First American Bank. To justify why FAB, referring to the orange and blue line segments that she drew *in the plane* (Figure 5d), she said “the orange is shorter, and the blue is longer.” Referring to the line segments on the map (see Figure 5c), she added, “over here, like the same thing” showing FAB is closer to Cannon and farther from Arch in the map as well as in the plane.

Discussion

In this study, we illustrated different ways students’ graphing activity involved multiplicative objects when graphing quantitative relationships. We believe outlining such a framework is important as researchers can be more attentive to those meanings students hold for their representational activity. In this section, we discuss the different implications of these ways of representing multiplicative objects on students' graphing meanings.

QMO VS. SMO

We perceive that the goal for students who conceive a point as a SMO is locating the object in the space, which is why the primary attention is the plane rather than the axes. To locate the object on the space, students represent the quantities' magnitudes in the space by committing to a reference, such as the axis itself or a location on the axis, and where those magnitudes meet determines the location of the object (e.g., the crow, bike, or First American Bank). The meaning of this point on the space is different than students' meanings who conceive a point as QMO as they represent quantities' magnitudes on the axis and form the point by taking two orthogonal magnitudes along the axis and creating projections. In turn, the space is inconsequential beyond creating the point by joining the projections when engaging in representing QMO. For that reason, students who produce a graph by tracing a SMO will perform different actions (e.g., moving different directions on the space) than others who produce a graph by tracing a QMO. Interestingly, those two graphs produced by tracing a SMO and a QMO will be exactly the symmetry of each other over the line of $y = x$ in case of Zane's activity. Despite the fact that students construct non-normative graphs when tracing a SMO, their form of reasoning is productive in terms of completing the goal of the activity as they perceive it. Their activity should be considered as a different way of graphing relationships because it still requires students engage in quantitative coordination in a non-normative way. Calling this type as "spatial" should not imply dismissing the role of quantitative coordination in students' reasoning.

Type 1 and Type 2

To produce a graph via reasoning emergently, students trace a point and anticipate a graph including infinitely many points, each of which is a representation of a multiplicative object; a point as a multiplicative object is sustained throughout conceiving the emergence of the trace. Given the importance of reasoning emergently in developing productive meanings for graphs, by distinguishing two types of representing a QMO (i.e., Type 1 and Type 1), we note that conceiving a point as a multiplicative object is necessary, but not sufficient in envisioning "graphs as composed of points, each of which record the simultaneous state of two quantities that covary continuously" (Saldanha & Thompson, 1998, p. 298). As we illustrated above, students whom we classify engaging in representing Type 1 QMO can conceive a point in terms of multiplicative object, but they do not imagine a trace being produced as representative of that multiplicative object. Given there are numerous students (i.e., about 89% of secondary students [N=1798], as reported in Kerslake, 1981) not conceiving of infinitely many points on a line and believing there is no point on a line until they are plotted (Mansfield, 1985), it becomes important for us to be able to determine which type of multiplicative object the students forming and representing. In doing so, we can inform our instruction to foster and support students in developing productive meanings for graphs.

A CONCEPTUAL ANALYSIS OF THE EQUAL SIGN AND EQUATION –THE TRANSFORMATIVE COMPONENT

Yufeng Ying
University of Georgia
yy16186@uga.edu

Mathematics education scholars have generally classified students' conception of the equal sign as either operational or relational. Adding to these conceptions, Jones (2008) introduced the idea of substitutional conception. Building off these scholars, I introduce a form of understanding the equal sign that includes a transformative equivalence component and extends the conceptions of the equal sign to conceptions of equations.

Keywords: Algebra and Algebraic Thinking, Cognition.

Introduction

Students' algebra achievement acts as a gatekeeper that affects their future academic success and employment (Rech & Harrington 2000; Ladson-Billings, 1998). As a result, students' understanding of algebra continues to attract attention from mathematics educators (Kieran, 1992; National Council of Teachers of Mathematics[NCTM] 2000; Wagner & Kieran, 1989). Researches have established that students' conception of the equal sign is fundamental to their learning of algebra (Knuth et al., 2006; McNeil & Alibali, 2005; Falkner et al., 1999). Consequently, aiding students in building a productive understanding of the equal sign may not only support students learning of algebraic concepts but also foster social equity. Building on such belief, this paper proposes one cognitive model for giving meaning to the equal sign.

The paper begins with a detailed summary of two important papers in which the authors separately addressed elementary school students' understanding of the equal sign and middle school students' understanding of the equal sign (Behr et al., 1980; Knuth et al., 2006). Both studies, although focused on students of different school ages, suggested a differentiation between an "operational" and a "relational" (or "equivalent") understanding of the equal sign, and such differentiation has been echoed by other researchers (Carpenter et al., 1999; Baroody & Ginsburg, 1983; McNeil et al., 2006; McNeil, 2008; McNeil et al.,2011). In general, an operational conception involves interpreting the equal sign as an announcement of the result of an arithmetic calculation, and the relational conception interprets the equal sign as indicating a mathematical equivalence (Knuth et al., 2006). After summarizing these perspectives, I introduce Jones's (2008) notion of the substitutive conception of the equal sign, which further divides the "relational understanding" into "substitutive relational" and "sameness relational." Following this cursory literature review, I explain the theoretical rationale for this paper and introduce a conceptual analysis—named *the transformative model*—along with a brief empirical result. The model extends the question from understanding students' conception of the equal sign to understanding their conception of equation, and it contributes a "*transformative equivalence*" component to previous discussions.

Background

The equal sign was not introduced until 1557 by Recorde, and it was universally applied around 1700. In the field of mathematics, it is not the only symbol that represents an equivalent relationship, and indeed it is a special symbol that only represents a certain category of mathematical equivalence (Molina et al., 2009). Therefore, one can reasonably assume that students' understanding of the equal

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

sign might be as varied in both meaning and sophistication as its development across the history of mathematics.

One of the earliest works in studying students' understanding of equal sign can be found in Behr and his colleague's (1980) research, in which the authors studied elementary students' conception of the equal sign. One major finding is that students (around 6-7-year-old) hold a fixed belief that the equal sign has to appear after the operation symbol. For example, some students in their study read the expression "8=5+3" as "five plus three equals eight." Furthermore, students generally rejected a sentence in the form "$\square = 2 + 4$" but instead changed it to "$\square + 2 = 4$" or "$2 + 4 = \square$". One interpretation of them was that students had an inclination in using an "action" sentence rather than a non-action sentence. In such a case, the authors argued that students conceived the equal sign as a "do something signal," and one could only have an equal sign when there was an operation appears on the left (p.16). In other words, students did not conceive the equal sign as suggesting two equivalent expressions but an operation symbol. In the study, some students even changed expression "4=6+1" to "4=6+10" and saying 4 and 6 made 10. The authors further postulated that some students were merely treating equal symbols as symbols to connect numbers.

The aforementioned study provides evidence that many primary school students do not have a flexible way of using the equal sign and frequently see it as an operation signal, and McNeil and Alibali (2005) revealed similar patterns among high school and college students. Following this result, Knuth and his colleagues (2006) conducted a quantitative study on middle school students' conceptions of the equal sign. Based on their findings, they argued that middle school students lack "relational understanding" (or equivalence understanding) of the equal sign, and this influenced students' success in solving algebra problems.

Knuth et al. (2006) used two problems in their study. In the first problem, students were required to give an explicit description of the meaning of the equal sign. In the second problem, students were required to solve algebra problems such as "4m+10=70". The authors found that students who explained the equal sign with a relational description (i.e., equal sign means the same as) were more likely to solve the algebra problem correctly than students who explained the equal sign with a non-relational description (i.e., equal sign is a sign connecting the answer to the problem). The authors also illustrated that the students who gave relational descriptions were more likely to use algebraic methods in solving the later problem; the authors defined algebra methods as methods that involved algebraic manipulation (i.e., performing the same transformation on each side of the equation), and non-algebra methods are guessing and trying or direct arithmetic (i.e., 70-10=60, 60÷4=15). The authors further showed that both correlations hold when controlling for students' general mathematic abilities, that relatively few students hold a relational view, and that the percentage of students who hold such view did not increase significantly when students moved from grade 6 to grade 8. The authors suggested such a lack of progress might be related to the lack of explicit focus on the meaning of the equal sign in the curriculum.

The findings from these studies are consistent. In listed studies, we observe students may either understand equal sign as a "do something signal," which aligns with an operational meaning, or as "a sign of equivalent relation," which supports students to use algebraic method in solving it. In both studies, we also observe students with the operational conception have difficulties in doing algebra flexibility. Based on these studies, one can further conjecture that a student, if holds an operational conception, will likely avoid using algebraic methods since an algebraic method requires operations on each expression, but he/she may not want the right-side expression to involve an operation.

Adding to these researches, Jones and his colleague (Jones, 2008; Jones et al., 2012) studied the substitutive conception of the equal sign. They define the substitutive conception as realizing both sides of the equation can be used to substitute each other when needed. These studies are resonated with the study of "relational thinking" developed by Carpenter et al. (2005). In short, the key idea that concerns those researchers is that given "16+37=53", students should be able to evaluate "16+39" without doing a direct calculation but utilizing the possible connections between these two expressions. More importantly, Jones and his colleague (2012) argued there is a cognitive difference between "seeing two entities as equivalent" and "being able to interchange equivalent expressions when beneficial," and scholars frequently over-emphasized the sameness component and risks neglecting the substitute component. Jones (2008) found that while making substitutions, students were oblivious to the correctness of the equation. For example, when a student needed to replace 77, some picked 77=11+33. Jones et al. (2012) also observed cases where students realized that both sides of the equation are the same but did not substitute them in problem-solving. Though only a few numbers of researchers have studied this substitutive conception, studies in relational thinking have shown similar findings that it is challenging for students to relate both sides of the equal sign in solving problems (Molina & Ambrose, 2006, 2008). Therefore, the difference between recognizing the equivalence and being able to utilize such equivalence as a means for substitution should be marked.

Theoretical Rationale

Kaput (2000) proposed a movement to "algebrafying" the K-12 curriculum where he encouraged students to engage in algebraic reasoning. Carpenter and Levi (2000) answered with a proposal in re-conceptualization some mathematical topics taught in the primary grade. Following both proposals, I provide a re-conceptualization of the equal sign and equations such that students can reason with them more flexibly. The previous studies on students' conception of the equal sign offer a solid grounding for this re-conceptualization, but they share two potential limitations.

One limitation of previous research is their lack of clarity in classifying students' conception, or as Mirin (2019) argued, the differentiation between "operational" and "equivalent" is sometimes unclear. For instance, a primary school student who accepts the notion of 3=4-1 is considered as presenting a relational conception in Behr et al.'s study, but he/she can still have difficulties in solving equations with algebraic strategies when he/she moves into middle school. More importantly, there are inconsistencies between students' conception of the equal sign and their problem-solving strategies. For instance, in Knuth at al.'s (2006) study, 33 students in grade-eight used the algebra method in solving the problem, but only 31 students showed relational understandings. More surprisingly, 43 grade-seven students provided a relational definition to the equal sign, but only one student used the algebra method in problem-solving. These results suggest students' conception of the equal sign is not fully predictive of their performance in solving algebra problems. Especially in high school and above, it is likely that few students will not realize that equal sign represents an equivalence or do not believe in the legitimacy of 3=3, but their algebraic skills regarding equations can still be lacking. Therefore, to effectively extend the study of the equal sign to all k-16 education, especially for the high school and college students, it might be beneficial to reframe students' conception of the equal sign as students' conception of equation. In short, students' conceptions of equation are dependent on their conception of the equal sign, but student's conception of the equal sign is not fully predictive to their use of equation. Such expansion will bring issues, which we will address later.

The second limitation is that most studies on students' conception of the equal sign were conducted under the context of single equation solving but lacks research on modeling students' thinking within a system of equations. For instance, given the equation $x^2 + 2x = 1$ and ask students to evaluate $x + 1$. Besides using the standard procedure of solving for x and plugging, a student can also solve the question by re-writing the original equation as $x^2 + 2x + 1 = 2$ and taking square roots on both sides. The standard solve-and-plug method requires an equivalent understanding of the equal sign, but the later method further requires students to perform a transformation on both sides of the equation. Building off Jones's argument, I believe there is also a cognitive difference between "realizing the sameness or the substitutive nature of both sides of the equation" and "being able to transform both sides of equations flexibly in problem-solving." One could argue that those algebra skills are beyond the scope of understanding the equal sign. I contend that they are not beyond such a scope because there is an inherent kinship between students' making meaning for an equation and making meaning for the equal sign, a point we will revisit later.

The Transformative Model

In response to these potential limitations, I describe a first-order conceptual model (named the transformative model) on students' understanding of the equation as follows: In the first level, students conceive an equation as a call to execute an operation or calculation with an answer. In the second level A, students see the equation as representing the sameness of two expressions; in the second level B, students conceive equation as two parts that stay equivalent under some algebraic operation; In the second level C, students see equation as two parts that are interchangeable and used as means for substitution. In the third level, students see equation as a piece of information that only display a specific equivalent relationship explicitly but also includes a lot of implicit but inferable equivalent relationships that can be used in problem-solving. The third level is what I named the transformative equivalence conception (or transformative conception).

This model is of first-order as it is developed through analyzing my own thinking. It has two salient characteristics: Firstly, it incorporates the aforementioned research on students' conceptualization of the equal sign but extends such notion to the study of equation. Such extension is not a dramatic deviation from previous research on the equal sign, as many of them collected their data through observing students' solving equations (Alibali et al., 2007; Knuth et al., 2008). The other characteristic, which is also the central focus of this model, is the inclusion of the transformation component: conceiving equation as a piece of information that only display a specific equivalent relationship explicitly but also includes implicit but inferable equivalent relationships that can be used in problem-solving. I now use the following example to illustrate the above meanings:

Given $x^2 - 3x + 1 = 0$, find the value of $3x^3 - 8x^2 + x - 1 + \frac{3}{3x}$.

Notice to solve this problem, besides the common method of solving for x and then plugging the value, students will be benefitted from substituting "$x^2 - 3x + 1$" by 0. Students may also want to further conjecture the equations "$x^3 - 3x^2 + x = 0$" and "$x - 3 + \frac{1}{x} = 0$" from "$x^2 - 3x + 1 = 0$", and use these two new relationships to substitute x^3 and $\frac{3}{3x}$ in problem-solving. Here, I argue being able to recognize "$x^2 - 3x - 1$" as substitutivity equivalent to 0, and being able to conjecture a new equation and then recognize "$\frac{1}{x}$" $is\ substitutive\ equivalent\ to$ "$3 - x$" are cognitively different. I also postulate the second equivalence is more difficult to recognize since producing equation such as "$x - 3 + \frac{1}{x} = 0$" requires students to multiplicatively compare both expressions with respect to x, which is represented by dividing by x. Though dividing a variable to both sides is a common mathematical practice, it is often done to reduce the order or perform cancellation. However, since here dividing x will not accomplish either goal, students are less likely to use such a strategy as I illustrate in a subsequent section.

The model is also constructed with a partial hierarchical order, but it is not a linear progression where students gradually find new properties of equation. Instead, this model is an "emancipation process," where students gradually become less and less constrained to lower-level understandings. For instance, for students who solve "$x + 7 = 12$" with algebraic method in Knuth et al. (2006) study, when they subtracted 7 on both sides, they have performed a transformation, but their use of transformation can still be unnecessarily restricted and they might still be unable to perform other types of transformation in different questions. Therefore, though the model is hierarchical, the hierarchy is determined by the extent of how restricted students are using equations in problem-solving. Similarly, as Jones et al. (2012) suggested, students' development of different conceptions of equal sign does not follow a strict order, and one might develop substitutive conception before mastering an equivalent conception. Therefore, I put several conceptions as parallel, and the ordering in my model is certainly tentative rather than deterministic.

Methodology and Method

In considering my methodology, I follow radical constructivism and believe our knowledge is constrained by our experience in the sense that we do not have direct access to external realities or absolute truth (even assuming they exist). Consequently, each student constructs their own conceptualizations of mathematical ideas through their unique experiences. We do not have direct access to their understandings, but we can build hypothetical models of students' knowledge (Glaserfeld, 1995). Thompson (2013) reminded us of the importance of attending to students' meaning in mathematical activities and ensuring students understand mathematical objects productively. Conceptual analysis, as elaborated by Silverman and Thompson (2008), is then an approach in which researchers will model productive meanings of a concept such that those meanings are well connected with other mathematical ideas or students' life experiences. Educators, ideally, can then use those models to analyze students thinking and guide students to more productive understandings.

Following these beliefs, I conducted several semi-structurted clinical interviews with pre-service teachers and tried to identify possible ways that students are using or can use in conceptualizing the equal sign and equations. Research has reported the similarities between pre-service teacher and high school students in terms of their mathematics performance in non-college math topics (Moore & Carlson, 2012; Carlson, Oehrtman, & Engelke, 2010). In short, though the participants here represent a convenience sample, the results are applicable to a broader population. Here I will focus on my interview with Meki, who was a second-year undergraduate student registered in our math education pre-service teacher program. She has completed several college-level math courses but not high-level analysis courses. In the interview, I asked Meki to go through six algebra problems and explained her thinking, and most problems are algebraic questions that have multiple approaches but will be solved most efficiently by transforming the given equation and then using the substitution method. The interviews try to examine how i) interviewees' conceptualization of the equation is consistent/inconsistent with my conceptual model, especially regarding the transformative component; ii) what are the affordances and constraints of my conceptual model in modeling students' conceptualization of equation, especially regarding the transformative component.

Empirical Result

In this section, I report Meki's answer on two problems with detail. The first problem asks the student to evaluate $\frac{1}{x}+\frac{1}{y}$ when presented with the claims that $xy = 1; x + y = 1.$ Meki solved the problem by realizing $\frac{1}{x}+\frac{1}{y}=\frac{x+y}{xy}$. However, when I asked about her thinking, she said that she did so as she felt there was no way to directly substitute the equations (pointing to equations $xy = 1; x + y = 1$) into the unknown expression, and she explained that there was no "xy" or "$x + y$" appeared in the equation. I then intervened directly and told her that there was a way of doing direct substitution; she, after some thought, realized the other solution which was substituting 1 by "xy" and change the expression $\frac{1}{x}+\frac{1}{y}$ to $\frac{xy}{x}+\frac{xy}{y}$ which equals $x + y = 1$. When I asked her why she didn't think of such substitution in the first place, she replied, "yeah, normally you don't put more variables into solve, cause you try to solve and get rid of the variable and find the numbers."

Meki displayed a substitutive conception of equation since she was comfortable in evaluating $\frac{x+y}{xy}$ by substitution, and also she mentioned that she started the problem by looking for some substitution. However, from the quote, I argue that her substitutive conception might be restricted in the sense that she normally does not substitute numbers by symbols. Therefore, I hypothesize that she lacks a transformative conception, and her use of equations is not flexible. Though this result does not directly substantiate the difference between the transformative conception and other conceptions, it at least suggests that a student with substitutive conception can still experience unnecessary restrictions in the potential ways of using the substitution method.

I then gave Meki the following problem, which was similar to the one I introduced earlier, and the difference is we had $\frac{3}{3x}$ in previous problem but $\frac{3}{a^2-1}$ here (which are equivalent)

Given $a^2 - 3a + 1 = 0$, find the value of $3a^3 - 8a^2 + a - 1 + \frac{3}{a^2-1}$.

In dealing with the expression $3a^3 - 8a^2 + a$, Meki started by extracting a common factor "a," and rewrote the expression into the form $a(a^2 - 3a + 1 + 2a^2 - 5a)$, which she then simplify as $a(a^2 - 5a)$. She then failed to make too much progress beyond. She mentioned she could do this trick again twice (referring to the trick of finding"$a^2 - 3a + 1$" in the expression and the substitute it by 0), but she tried some mental calculation and gave it up. In dealing with the term $\frac{3}{a^2+1}$, she rewrote it as $\frac{3}{a^2-3a+1+3a}$. She explained that since the expression "$a^2 + 1$" has two terms that were the same as the given equation's, she wanted to introduce some new terms to make it zero. It is important to mark here that she said she did not foresee the result would be $\frac{3}{3a}$, but she was trying to get rid of the two terms and had less term in the denominator.

Here I argue that Meki was using the substitutive conception, and she was working very hard to substitute the expression a^2-3a+1 by 0 in the exact form to the unknown expression, and she did not realize that one can also generate other ways of substituting (e.g. $a^3 = 3a^2 - a$) in solving the question. Though the problem can be solved by repetitively using direct substitution, the mental effort that is required in such a process was huge, and students are likely to give up. A student with a transformative conception may, however, have a very different approach to doing this problem. One approach that I observed from my cohorts was creating a "tool column" where he made a column of all equivalent forms such as $a^3 = 3a^2 - a$, and used these forms when he felt he needed it. Notice in such an approach, the student was still substituting one side of the equation with the other side, but such substitution requires a prior transformation of the original equation, and Meki seemed to be reluctant to perform it.

After I told Meki the answer and gave explicit hints on these potential equivalent equations, the students solved the problem without too many struggles. When reflecting on her thinking, she mentioned that she never did anything like that, and she said: "I was thinking a lot of it like taking things like this (circling the original equation) as it was instead of moving terms around." Her explained insistence in substituting the whole equation in its original form again suggested her use of substitution is restrictive, and a transformative conception of the equation is cognitively different from a substitutive conception.

When doing other problems, Meki presented similar thinking patterns where she is comfortable in making substitutions, but her use of the substitution method is unnecessarily restrictive. There were also some interesting findings that I noticed when I asked my cohort to experiment with some of the problems: For example, one of my cohorts realized $a^3 = 3a^2 - a$ and simplified most terms, but he struggled about $\frac{3}{3a}$. When I asked if he could conclude anything about $\frac{1}{a}$ from the given equation, he believed he could not. Certainly, by being able to simplify the higher-order terms, he displayed transformative conception, but his transformative conception does not fully support all forms of transformation (e.g., he did not notice here $\frac{1}{a} = 3 - a$).

Behr et al. (1980) summarized students' operational conception as "an extreme rigidity about written sentences, an insistence that statements be written in a particular form, and a tendency to perform actions (e.g., add) rather than to reflect, make judgments, and infer meaning." (p.16), and he named the flexible part as relational conception. Similarly, students can hold a relational conception but present the same rigidity in using algebraic methods in solving problems, which implies a lack of Jones's substitution conception. Furthermore, the student can also hold a substitution conception but present the same rigidity in using substitution, which implies a lack of the transformative conception. The case of Meki serves as a proof of such an argument where students show substitution conception but with unnecessary rigidity in the ways of substituting.

Conclusion and Compromise

Students' conception of the equal sign is important, but a differentiation between an "operational" and a "relational" is too broad to explain the wide spectrum of students' performance on operating with the equation. Consistent with Jone's finding that students can observe the equivalence between two sides of the equation while not substituting each side when helpful, I found some students can substitute each side but only perform substitutions in limited ways. In general, this study points out the variety of operations that exist in operating with equations, and students suffer from unnecessary restrictions in performing them as their conceptualization of how an equation could be operated in problem-solving is incomprehensive.

Here are two important questions to revisit: why include a transformative component of the equation into the study of the equal sign? How such an extension to the conception of equation may bring issues? For the first question, it is an observation that most studies of the equal sign are generalized through studying students' meaning of how an equation can be written/operated in problem-solving. Indeed, it is hard to imagine how one student can develop a conception of the equal sign without experiencing different ways of writing/manipulating equations. Besides, such a conception is tightly related to Jones' substitution conception, as both concern the potential ways of utilizing equations in problem-solving, and both believe there is a nonnegligible and important cognitive difference between understanding the equivalence and utilizing such equivalence in problem-solving. For the second question, since the conceptualization of equation goes beyond pure algebraic context (e.g., one may argue a complete conceptualization of equation has to contain the idea of function, as function is a special "equation" or a collection of an infinite number of "equations"), the provided conceptual analysis is incomplete. The model is created independently from concerning the students' conception of variables, the cognitive gap between arithmetic and algebra, and the rich real-life or mathematical contexts that an equation can be embedded. I concede all these factors are important points that a fully comprehensive study of equation should include. Certainly, this model is not claiming a complete analysis of students' conception of equation. Nevertheless, the primary aim of building such a model, which is to support emphasizing and studying the transformative property of equation in teaching and learning, should remain intact.

To contextualize this study into the broader field of education theory, I argue it echoes the general belief in fostering students' critical thinking and creativity as it relates to their mathematical learning. Adopting Ennis's (1996) definition of critical thinking with its emphasis on reflectiveness and making a choice from what to believe and what to do, the transformative conception may support creative reasoning and critical thinking since it invites students to think and consider all possible ways of writing an equivalent relation. Cobb(1998) raised an argument that viewing Mathematica learning as an "acculturation," and through providing more flexibility in problem thinking, the transformative conception may help students to conquer certain fixed norms in solving equations and experience the creative culture from the mathematics society (such as avoiding thinking substitution as only using numbers to replace symbols). Under such a perspective, mathematics equations and expressions become Lego blocks that students can play with and make creations accordingly, but if and only if there are multiple ways of playing, students have motivations to consider different possible mathematical operations, and what information can different equivalent expression produce. In such a way, students are potentially engaging with mathematics critically, creatively, and authentically.

MENTAL CONSTRUCTIONS OF INVARIANT SUBSPACE DEVELOPED BY AN APOS TEACHING DESIGN

CONSTRUCCIONES MENTALES SOBRE SUBESPACIO INVARIANTE DESARROLLADAS EN UNA PROPUESTA DE ENSEÑANZA DESDE LA TEORÍA APOE

We present some of the preliminary results of a project about how the concept of eigenspace can be learned as special invariant subspace. The study is based on the theoretical and methodological elements of the APOS framework. Specifically, we present the part of the preliminary genetic decomposition, obtained from the theoretical analysis, corresponding to the concept of invariant subspace; as well as the criteria for classifying and contrasting the mental structures proposed in the genetic decomposition with those manifested during and after the instructional stage by eight students of Mathematics who participated in the study.

Keywords: Advanced Mathematical Thinking, Algebra and Algebraic Thinking, Technology, Design Experiments

The application of the concept of eigenspace and the link it has with various key concepts of Linear Algebra have guided various investigations regarding its learning. Wawro, Watson, and Zandieh (2019) point out that students find it difficult to argue when linear combinations of eigenvectors are eigenvectors, showing confusion to distinguish between a base for a given eigenspace and elements of such subspace; They conclude that: " A focus on eigenspaces as subspaces has the potential to mitigate these challenges and help students see connections across the linear algebra course" (p. 1122). Therefore, a study was carried out with the purpose of *analyzing the cognitive structures that a student might need for the learning of eigenspaces as invariant subspaces*, so that the cognitive demand of this task can be clarified. Some preliminary results about the difficulties in developing such mental constructs are presented below.

APOS theoretical framework

The APOS framework was chosen since it is a cognitive theory that allows a structural analysis on the learning of mathematical concepts and poses specific relationships between the cognitive analysis of mathematical learning and the design of teaching materials and experiments (Oktac, Trigueros & Romo, 2019). The model defines these stages as mental structures and classifies them as *Action, Process, Object* and *Schema* (hence the acronym APOS), which arise from the application of specific mental mechanisms: *internalization, encapsulation, coordination, reversal, de-encapsulation* and *thematization* (Arnon et al., 2014).

With an **Action** structure, an individual performs transformations to previously constructed *Objects* and its main characteristic is that each step of the transformation must be carried out explicitly, in a given order, by the individual and needs to be guided by external instructions. The **Process** structure comes from the *internalization* of an Action in a Process or by the *coordination* of different Processes into a new one. In the first case, the same operation is performed as the Action that is internalized, but in the individual's mind, achieving control over the transformation; in the second, the interaction of different processes leads to the development of a new one that in a certain way includes both. When it is possible to apply transformations onto the Process and such transformations can be constructed, the Process has been *encapsulated* in an **Object**. The **Scheme** structure has a

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

different nature from the previous three, as it develops as a network of Action, Process and Object structures, as well as relationships between them; for example, a differential calculus scheme can be described as network centered on the concept of function (Arnon et al., 2014). The specific focus of this work leads us to study the first types of constructions and not include the development of Schemes.

The hypothetical model that explains the set Actions, Processes and Objects, as well as the mental mechanisms that a person could need for the construction of a specific mathematical concept is called *genetic decomposition*.

Methodology

Research in the APOS framework is commonly carried out following its *research cycle*, which consists of three components: *theoretical analysis, design and implementation of instruction,* and *data collection and analysis* (Arnon et al., 2014, p. 94). From the theoretical analysis a preliminary genetic decomposition is obtained, the teaching design generates sequences that seek to facilitate the mental structures and mechanisms proposed in the genetic decomposition; and from the collection and analysis of data, the *preliminary* genetic decomposition and the teaching design are obtained. Preliminary results of each methodological phase are presented below.

Theoretical analysis

Based on a review of various Linear Algebra books (Axler, 2015; Frieldberg, Insel & Spence, 1982) and research related to learning the concept of eigenspace (Sierpinska et al., 1999; Soto & García, 2002; Thomas & Stewart, 2011; Gol Tabaghi & Sinclair, 2013; Wawro et al., 2019), it was concluded that the need to compare a vector subspace with its image implied thinking that the image of an eigenspace satisfies that its image is the same subspace or the zero subspace. Likewise, that for the development of a conception of eigenspace as invariant, it was relevant that conceptions of both concepts were constructed first and that relations between eigenspaces and invariant subspaces were later determined.

It was determined that for the learning of *invariant-eigenspace*, students were required to have previous conceptions of *generated subspace*, *linear transformation*, and *eigenvalues and eigenvectors*.

In the preliminary genetic decomposition, the construction of eigenspace starts from invariant subspaces, followed by invariant one-dimensional and then *larger* subspaces (2 and 3 dimensions), eigenspaces, and then relationships between these structures are analyzed. The proposed concepts for invariant subspace are described below.

The **Action A_1** consists of manipulating the *spanning vector Object*, a single vector that spans a one-dimensional subspace, by applying a linear transformation (defined from $\mathbb{R}^2 \to \mathbb{R}^2$), identifying cases in which the image of the subspace is itself or the zero subspace. When Action A1 is repeated for different subspaces and different linear transformations, the reflecting on the results allows the internalization into **Process P_1.** This process allows the observing, assuming or arguing that the subspace generated by some vector is invariant without having to manipulate specific cases of subspaces or linear transformations.

Process P_1 is coordinated with the *spanned subspace Process* to obtain **Process P_3**, with this Process it is expected that students can identify that the images of the generators of an invariant subspace are not necessarily scalar multiples of themselves; to argue that the invariant subspaces are those subspaces that satisfy that the generators of the *image subspace* can be expressed as a linear combination of the spanning vectors of the subspace and recognize that the image of the generator set of the subspace does not generate the invariant subspace if the null subspace is different from the zero subspace.

Design and implementation of instruction

The ACE Teaching Cycles proposed from APOE were taken as a reference. These cycles are made up of three stages that give the cycle its name: *Activities* to initiate the development of mental structures; *Class discussions* to promote mental mechanisms; and *Exercises* to reinforce the mental constructions developed by the students (Arnon et al., 2014, p.58).

The design consists of four ACE type sequences. In sequence 1, students are familiarized with the graphic representations of the concepts and with the use of GeoGebra applets, additionally, previous conceptions about the concepts of generated subspace and linear transformations are evaluated. In sequence 2, the development of Action A1 and Process P1 is promoted; this paper refers to the second sequence. For the activity phase, an applet was designed available at: bit.ly/g-act1. The activity begins with the graphic exploration of the image of a one-dimensional subspace, line *l*, which can be modified by changing the spanning vector of the subspace. Each of the buttons T_1, T_2, T_3, T_4 and T_5, is associated with a different linear transformation and they are distributed by teams, while the group discussion is focused on the similarities and differences between the five cases.

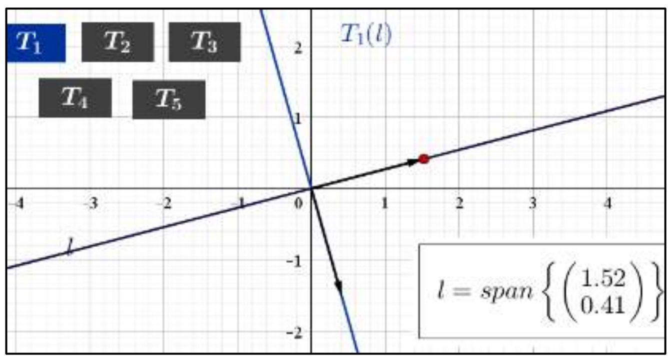

Figure 1 Sequence 2 GeoGebra applet

The implementation of the sequences here reported was carried out with eight students of the Bachelor of Mathematics enrolled in a second Linear Algebra course, the data and analysis shown below correspond to sequence 2, whose implementation was carried out in 3 sessions of 50 minutes.

Data collection and analysis

The student worksheets collected in the implementation stage complemented with notes and recordings of the class discussions constitute the data analyzed. A non-comparative case study was carried out, which sought to contrast the proposed structures from the theoretical analysis with those expressed by the students in their written productions. The following table shows a couple of student responses to a problem in the exercise section designed to assess Action A_1 conception.

Table 1 Differences in the development of conception Action A1.

Let $P_2(\mathbb{R})$ be the vector space of grade 2 or lower polynomials with real coefficients, and $T: P_2(\mathbb{R}) \to P_2(\mathbb{R})$ a linear transformation such that $T(p) = p'$. Determine if a) $P_2(\mathbb{R})$ and b) $span\{x^2\}$, invariant subspaces under T	
Student **E1** set $p(x) = a + bx + cx^2$ and calculated the image of vector p, realizing that $T\big(p(x)\big) \in P_2(\mathbb{R})$ and concluding that the subspaces was invariant. In b), following a similar procedure, compared αx^2 with $span\{x^2\}$ and concluded that the subspace was not invariant because $T(\alpha x^2) = 2\alpha x \notin span\{x^2\}$.	Student **E3** set $p(x) = a_0 + a_1 x + a_2 x^2$, calculated its image and concluded that: "it is T-invariant because T(p) is a polynomial with grade equal or lower than 2, for each $p \in P_2(\mathbb{R})$". However, for b) he took an arbitrary αx^2, calculating that $T(\alpha x^2) = \alpha 2x \in P_2(\mathbb{R})$, finally concluding that, since for every $u \in span\{x^2\}$, $T(u)$ was a polynomial of grade 2 or lower.
Action	Pre-action

Student E1 can apply the definition for the specific subspace, determining whether or not it is met; this implies that she can determine for specific cases that the subspace is invariant if its image is the same subspace or the zero subspace. E1 resorts to a previous conception of set containment that involves thinking that given two sets A and B, $A \subseteq B$ if and only if for any $a \in A$ it is satisfied that $a \in B$, which is considered part of Action A_1 . In the case of E3, the initial procedure performed by the student is correct, however, the student does not recognize that in order to conclude that the subspace is or is not invariant, he must determine if $T(\alpha x^2) \in span\{x^2\}$. In his answer, he also does not write explicitly which is the subspace that is invariant under the transformation; the absence of this part of the action classifies it as an action in progress or pre-action.

Similarly, the responses for the other conceptions of the genetic decomposition are analyzed for its evaluation.

Discussion and preliminary conclusions

In general terms, the evaluation of sequence 2 allowed evaluating both the proposed mental structures from the theoretical analysis, as well as the design and implementation of teaching corresponding to Action A_1 and process P_1. The continuation of the analysis will allow evaluating the rest of the genetic decomposition and the teaching design.

The classification of the responses in terms of the concepts shown allowed us to identify the correctly developed mental structures and those that were emerging, as in the pre-action cases, in some cases showing they were not compatible with the preliminary genetic decomposition.

Regarding the Activities problems, the student responses were mostly classified as compatible with the described mental structure linked to them, although in several cases the structures are manifested in a developmental stage (Arnon et al., 2014, p. 139), this was primarily observed in responses in which the work was based on graphical representations, the students seemed to understand and be able to work the situation according to the required mental structure, however they found it difficult to give a sufficiently clear argument that would validate what they said; students showed better arguments when situation were stated in algebraic representations. This difficulty was associated with the fact that the students who participated in the study were unfamiliar with the graphic representations.

Se presentan algunos de los resultados preliminares de un proyecto en el que se analiza cómo se puede aprender el concepto de espacio propio como subespacio invariante especial. El estudio se sustenta en los elementos teóricos y metodológicos del marco APOE. Específicamente, se muestra la parte de la descomposición genética preliminar correspondiente al concepto de subespacio invariante, así como los criterios utilizados para el análisis de datos que permitieron clasificar y contrastar las estructuras mentales propuestas en la descomposición genética con las manifestadas durante y después de la etapa de instrucción por ocho estudiantes de la licenciatura en Matemáticas que participaron en el estudio.

Palabras clave: Pensamiento Matemático Avanzado, Álgebra y Pensamiento Algebraico, Tecnología, Experimentos de Diseño

Los campos de aplicaciones del concepto de espacio propio y el vínculo que tiene con diversos elementos del Álgebra Lineal han guiado diversas investigaciones sobre su aprendizaje. Wawro, Watson y Zandieh (2019) señalan que a los estudiantes se les dificulta argumentar cuándo combinaciones lineales de vectores propios son vectores propios, mostrando confusión para distinguir entre una base del espacio propio con los elementos del subespacio; concluyen que: "un enfoque en los espacios propios como subespacios tiene el potencial de mitigar estos desafíos y ayudar a los estudiantes a ver las conexiones a través del curso de álgebra lineal" (p. 1122). Por lo anterior, se realizó un estudio con el propósito *analizar las estructuras cognitivas que un estudiante podría necesitar en el aprendizaje de espacios propios como subespacios invariantes*, de manera que se pueda aclarar la demanda cognitiva de esta tarea. Se presentan a continuación algunos resultados preliminares acerca de las dificultares para desarrollar tales construcciones mentales.

Marco teórico APOE

Se eligió el marco APOE ya que es una teoría cognitiva que permite un *análisis estructural* sobre el aprendizaje de los conceptos matemáticos y plantea relaciones específicas entre el análisis cognitivo del aprendizaje matemático y el diseño de materiales y experimentos de enseñanza (Oktac, Trigueros & Romo, 2019). El modelo define estas etapas como estructuras mentales y las clasifica como *Acción, Proceso, Objeto* y *Esquema* (de aquí las siglas APOE), que surgen de la aplicación de mecanismos mentales específicos: *interiorización, encapsulación, coordinación, reversión, desencapsulación y tematización* (Arnon et al., 2014).

La estructura **Acción** el individuo realiza transformaciones sobre Objetos previamente construidos y se caracteriza porque cada paso de la transformación debe realizarse explícitamente por el individuo y necesita ser guiado por instrucciones externas. La estructura **Proceso** es desarrollada a partir de la *interiorización* de una Acción en un Proceso o por la *coordinación* de distintos Procesos. En el primer caso, se realiza la misma operación que la Acción que se está interiorizando, pero en la mente del individuo, logrando la toma de control sobre la transformación; en el segundo la interacción de Procesos distintos conlleva al desarrollo de uno nuevo que de cierta manera incluye a ambos. Cuando es posible aplicar transformaciones sobre el Proceso y se pueden construir tales transformaciones, el Proceso ha sido encapsulado en un **Objeto**. La estructura de **Esquema** tiene una naturaleza distinta a las tres anteriores, al desarrollarse como una red de estructuras Acción, Proceso y Objeto, así como relaciones entre éstas; por ejemplo, se puede describir un esquema de Cálculo diferencial como centrado en el concepto de función (Arnon et al., 2014). El enfoque puntual del presente trabajo nos lleva a estudiar los primeros tipos de construcciones y no incluir el desarrollo de esquemas.

El modelo hipotético que explica el conjunto Acciones, Procesos y Objetos, así como los mecanismos mentales que una persona podría necesitar para la construcción de un concepto matemático específico es llamado *descomposición genética*.

Metodología

Las investigaciones en el marco APOE se realizan comúnmente siguiendo su *ciclo de investigación*, el cual consta de tres componentes: *análisis teórico, diseño e implementación de enseñanza y recolección y análisis de dato*s (Arnon et al., 2014, p. 94). Del análisis teórico se obtiene una descomposición genética preliminar, el diseño de enseñanza genera secuencias que buscan favorecer las estructuras y mecanismos mentales propuestos en la descomposición; y de la recolección y análisis de datos se obtiene la valoración de la descomposición genética preliminar y el diseño de enseñanza. Se presenta a continuación resultados preliminares de cada etapa metodológica.

Análisis teórico

A partir de la revisión de diversos libros de Álgebra lineal (Axler, 2015; Frieldberg, Insel & Spence,1982) e investigaciones relacionadas con el aprendizaje del concepto de espacio propio (Sierpinska et al., 1999; Soto & García, 2002; Thomas & Stewart,2011; Gol Tabaghi & Sinclair, 2013; Wawro et al., 2019) se concluyó que la necesidad de comparar el subespacio con su imagen implicaba pensar en que la imagen del espacio propio satisface que su imagen es el mismo subespacio o el subespacio cero. Así mismo, que para el desarrollo de una concepción de espacio propio como invariante era relevante que se construyeran primero concepciones de ambos conceptos y que después se determinaran relaciones entre espacios propios e invariantes.

Se determinó que para el aprendizaje del concepto de *espacio propio invariante* se requería que los estudiantes tuvieran concepciones previas de subespacio generado, transformación lineal y valores y vectores propios.

En la descomposición genética preliminar se proponen concepciones para el aprendizaje de espacio propio partiendo de subespacios invariantes. Se construyen concepciones sobre subespacios invariantes unidimensionales y de dimensión mayor, espacios propios y luego se analizan relaciones entre estas estructuras. A continuación, se describen las concepciones propuestas para subespacio invariante.

La concepción **Acción $\mathbf{A_1}$** consiste en manipular el *Objeto de vector generador*, mediante la aplicación de una transformación lineal (definida de $\mathbb{R}^2$ en $\mathbb{R}^2$), identificando casos en los que la imagen del subespacio es él mismo o el subespacio cero. Cuando la Acción A_1 se repite para diferentes subespacios generados y diferentes transformaciones lineales, reflexionando sobre los resultados, se puede interiorizar en un **Proceso $\mathbf{P_1}$** que permite observar, suponer o argumentar que el subespacio generado por algún vector es invariante sin tener que manipular casos específicos de subespacios o transformaciones lineales.

El Proceso P_1 se coordina con el *Proceso de subespacio generado* para obtener el **Proceso $\mathbf{P_3}$**, con este Proceso se espera que los estudiantes puedan identificar que en general las imágenes de los generadores del subespacio invariante no son necesariamente múltiplos escalares de sí mismos; argumentar que los subespacios invariantes son aquellos subespacios que satisfacen que los generadores del subespacio imagen se pueden expresar como combinación lineal del conjunto generador del subespacio y reconocer que la imagen del conjunto generador del subespacio no genera al subespacio invariante si el subespacio nulo es diferente del subespacio cero.

Diseño e implementación de enseñanza

Se tomaron como referencia los *Ciclos de enseñanza ACE* propuestos desde APOE. Estos ciclos se componen de tres etapas que dan nombre al ciclo: ***A**ctividades* para iniciar el desarrollo de las estructuras mentales; *Discusiones de **C**lase* para promover los mecanismos mentales; y ***E**jercicios* para reforzar las construcciones mentales desarrolladas por los estudiantes (Arnon et al., 2014, p.58).

El diseño consiste en cuatro secuencias de tipo ACE. En la *secuencia 1* se familiariza a los estudiantes con las representaciones gráficas de los conceptos y con el uso de applets en GeoGebra y se valoran concepciones previas sobre los conceptos de subespacio generado y transformaciones lineales. En la *secuencia 2*, se promueve el desarrollo de la Acción A_1, Proceso P_1 y Proceso P_2; el documento se refiere a esta segunda secuencia. Para la actividad se diseñó un applet disponible en: bit.ly/g-act1. La actividad inicia con la exploración gráfica de la imagen de un subespacio unidimensional, la recta l, que puede modificarse al cambiar el vector generador del subespacio. Cada uno de los botones T_1, T_2, T_3, T_4 y T_5, está asociado a una transformación lineal distinta y se distribuyen por equipos para luego discutir grupalmente las semejanzas y diferencias entre los cinco casos.

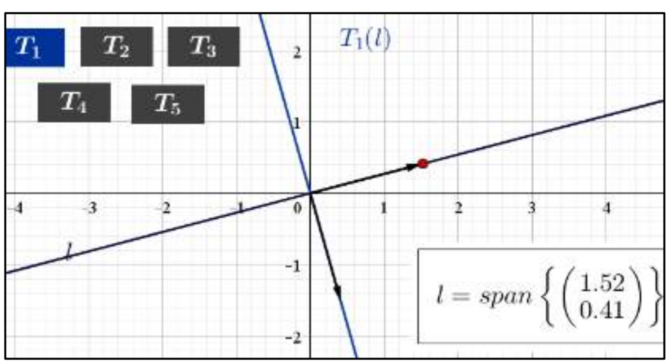

Figura 1 Applet de la Secuencia 2

La implementación de las secuencias que aquí se reporta se realizó con ocho estudiantes de la Licenciatura en Matemáticas inscritos a un curso de Álgebra Lineal II, los datos y el análisis que se muestra a continuación corresponden a la secuencia 2, cuya implementación se llevó a cabo en 3 sesiones de 50 minutos.

Recolección y análisis de datos

Se analizan las hojas de trabajo de las estudiantes, recolectadas en la etapa de implementación, complementando con notas y grabaciones de las discusiones de clase. Se realizó un estudio de caso no comparativo, con lo cual se buscó contrastar las estructuras propuestas a partir del análisis teórico con las manifestadas por los estudiantes en sus producciones escritas.

En la siguiente tabla se muestran un par de respuestas de estudiantes ante un problema de la sección de ejercicios diseñado para evaluar la concepción Acción A_1.

Tabla 1 Diferencias en el desarrollo de la concepción Acción A_1.

Sea $P_2(\mathbb{R})$ el espacio vectorial de los polinomios de grado menor o igual a dos, con coeficientes reales y $T: P_2(\mathbb{R}) \to P_2(\mathbb{R})$ una transformación lineal tal que $T(p) = p'$. Determine si a) $P_2(\mathbb{R})$ y b) $span\{x^2\}$, son subespacios invariantes bajo T	
La estudiante **E1**, tomó $p(x) = a + bx + cx^2$ y calculó la imagen del vector, llegando a que $T(p(x)) \in P_2(\mathbb{R})$ concluyendo que el subespacio era invariante. En b) realizó un procedimiento similar, comparando αx^2 con $span\{x^2\}$ y concluyó que el subespacio no era invariante porque $T(\alpha x^2) = 2\alpha x \notin span\{x^2\}$.	La Estudiante **E3**, en el caso a) tomó $p(x) = a_0 + a_1 x + a_2 x^2$, cálculo su imagen y concluyó: "Es T-invariante ya que $T(p)$ es un polinomio de grado menor a dos $\forall\, p \in P_2(\mathbb{R})$". Sin embargo, para el caso b) consideró un elemento arbitrario del subespacio αx^2, llegando a que $T(\alpha x^2) = \alpha 2x \in P_2(\mathbb{R})$ finalmente concluyó que se trata de un *T-invariante,* debido a que para todo $u \in span\{x^2\}$, $T(u)$ era "un polinomio de grado menor a 2".
Ejemplo de Acción	Ejemplo de Pre-acción

La estudiante E1 puede aplicar la definición para el subespacio específico, determinando si éste satisface o no la definición; esto implica que puede determinar para casos específicos que el subespacio es invariante si su imagen es el mismo subespacio o el subespacio cero. Se observa que E1 recurre a una concepción previa de *contención* que involucra pensar que dados dos conjuntos A y B, $A \subseteq B$ si y solo si para cualquier $a \in A$ se satisface que $a \in B$, lo cuál se considera parte de la Acción A_1. En el caso de E3, el procedimiento inicial realizado por la estudiante es correcto, sin embargo, la estudiante no reconoce que para poder concluir que el subespacio es o no invariante debe determinar si $T(ax^2) \in span\{x^2\}$, en su respuesta tampoco escribe explícitamente cual es el subespacio que es invariante bajo la transformación; la ausencia de esta parte de la acción lo clasifica como acción en desarrollo o pre-acción.

De manera similar se analizan las respuestas para las demás concepciones de la descomposición genética para su evaluación.

Discusión y conclusiones preliminares

En términos generales la valoración de la secuencia 2 permitió evaluar tanto las estructuras mentales propuestas a partir del análisis teórico, como el diseño e implementación de enseñanza correspondiente a la Acción A_1 y proceso P_1. La continuación del análisis permitirá evaluar el resto de la descomposición genética y el diseño de enseñanza.

La clasificación de las respuestas en términos de las concepciones mostradas permitió identificar las estructuras mentales correctamente desarrolladas y las que estaban emergiendo, como en los casos de pre-acciones, en algunos casos de forma no compatible con la descomposición genética preliminar.

En relación con los reactivos de las secuencias, las respuestas mayormente se clasificaron como compatibles con la estructura mental descrita, aunque en varios casos las estructuras se manifiestan en etapa de desarrollo (Arnon et al., 2014, p. 139), esto se observó primordialmente en respuestas en las que se trabajaba con las representaciones gráficas, los estudiantes parecían entender y poder trabajar la situación de acuerdo con la estructura mental requerida, sin embargo les costaba dar una argumentación suficientemente clara que validará lo que decían; los estudiantes mostraron mejores argumentaciones cuando el trabajo que se solicitaba involucraba representaciones algebraicas. Esta situación se asoció a que los estudiantes que participaron en el estudio se encontraban poco familiarizados con las representaciones gráficas.

The purpose of this study is to investigate the range of strategies fifth graders used to solve a word problem involving fraction multiplication. We report a detailed qualitative analysis of elementary students' written work (N = 1472). The results demonstrate that students collectively use a wide range of strategies for fraction multiplication. Implications for teaching and learning are discussed.

Keywords: Number Concepts and Operations; Rational Numbers; Assessment and Evaluation

Perspectives

Kieren (1976) stated five subconstructs to define fractions: part-whole, ratio, quotient, operator, and measure (see also, Behr et al., 1992). A comprehensive understanding of the rational numbers demands students to be familiar with interpretations of various subconstructs as well as understand their interaction (Ball, 1993; Behr et al., 1983; Lamon, 2007, 2012; Ni, 2001). Teaching the algorithm for multiplying fractions seems easy (Johanning, 2019; Reys et al., 2007) but the conceptual underpinnings are complex (Tirosh, 2000; Tsankova & Pjanic, 2009). Usually, additive operations require dealing with one fractional unit, while multiplicative operations involve interaction between multiple units. A problem like 'Ben has 1/3 of a cup of sugar. He sprinkles 1/2 of the sugar onto brownies. How much sugar does Ben sprinkle?' requires – (i) coordination in the units involving '1/3 cup a sugar' with '1/2 of the 1/3 cup' and (ii) choice of a specific arithmetic operation.

This study explores students' conceptions on fraction multiplication for a contextual problem. The results might guide elementary teachers to design strategic problems to capture the implicit conceptions of their students' reasoning. This paper describes the patterns in students' responses to capture the reasons for selecting a specific option by examining their written work. The main question guiding our research is *What is the range and distribution of strategies that students use to approach and solve a fraction multiplication problem?*

Context

We designed a task to address the Grade 5 standard (CCSS.MATH.CONTENT.5.NF.B.4) focusing on students understanding of multiplication related to multiplying a fraction by a fraction (Figure 1). The question included two fractions with different meanings: the fraction 5/8 representing a certain length and functioning *as a measure* of the distance between Levi's home and his school and the fraction 2/3, functioning *as a ratio* between the distance he has walked and the school-home distance. The distractors for this question were purposefully designed to assess the participants choice of operation: (a) 1/24 is the result of subtracting; (b) 10/24 can be obtained by multiplying and is the correct response; (c) 16/24 can be obtained after finding equivalent fractions with a common denominator; and (d) 31/24 can be obtained by adding.

7. Levi lives $\frac{5}{8}$ mile from school. After he walked $\frac{2}{3}$ of the way to school, he met Marta. How far, in miles, had Levi walked when he met Marta?

A. $\frac{1}{24}$ miles B. $\frac{10}{24}$ miles C. $\frac{16}{24}$ miles D. $\frac{31}{24}$ miles

Figure 1: The Problem

Data and Methods

The data is drawn from a larger study from a representative sample of fifth-grade students (*N* = 1427) in a Midwestern State. Participation was voluntary, and students were given 15 minutes to work on eight multiple-choice questions. For this paper, we have focused on one question involving fraction multiplication (Figure 1). The written work of the students was examined using qualitative software, MAXQDA version 18.1.1 (VERBI Software, 2016).

Qualitative Analysis of Students' Written Work

Research suggests that students' written work provides valuable evidence of their mathematical strategies, reasoning, and confusions (Brizuela, 2005; Kamii et al., 2001). We used thematic analysis (Braun & Clarke, 2006) to code students' written work. To ensure consistency, two coders coded one class (*n* = 57) during a training session to identify similarities in students' work and developed a list of themes. Certain pragmatic agreements were made, for example, the code of 'no written work' was used both for blank entries and if the student scratched out or erased their written work. As another example, the code 'unclear explanation' was used if something were written but a clear idea could not be deciphered. The coders used the initial codebook to code three classes individually and agreed on 100% of the cases after discussion. The final codebook had five themes each with several sub-themes (Table 1). Each code was defined in a code book along with prototypical examples to create consistent use.

Results

The unit of analysis for this part of the study is a *student's response to one specific item on fraction multiplication*. To address the research question, we first present the distribution of themes and then summarize the information captured from these themes.

Table 1: List of Themes with Distribution of The Students

	=1472	%
Code 10 Students who selected option 10/24 (**correct response**)	**435**	**9.55**
• 10A: Used multiplication as operator ('*' or '.' or 'of')	157	0.67
• 10A(a): Reduced the fraction to 5/12	36	2.45
• 10A(b): Used multiplication as second operator choice	7	0.48
• 10B: Used drawings	2	0.14
• 10C: Used "wrong" or "no" arithmetic operator	13	0.88
• 10D: Incorrectly written work	2	0.14
• 10E: No written work	145	9.85
• 10F: Unclear explanation	41	2.79
• 10F(a): Showed understanding of making the same denominators	14	0.95
• 10F(b): Subtract fractions and select the one with same multiples	6	0.41
• 10F(c): Added fractions as 7/11 or 7/24	11	0.75
• Guess	1	0.07

Code 1 Students who selected option 1/24	**414**	8.13
• 1A: Made the denominators same and subtracted both	125	8.49
• 1A(a): Subtracted fractions but did not write ‘-’ in their work	36	2.45
• 1A*: Made the denominators same, flipped the numbers and subtracted	119	8.08
• 1B: Unclear explanation	54	3.67
• 1B(a): Subtracted fractions and have written 3/5 as answer	6	0.41
• 1B(b): Used other/multiple operations	6	0.41
• 1C: No written work	68	4.62
Code 16 Students who selected option 16/24	**247**	6.78
• 16A: Made denominators same; selected the one with large numerator	60	4.08
• 16A(a): Compared fractions but used ‘-’ in their written work	10	0.68
• 16B: Unclear explanation	36	2.45
• 16B(a): Used multiple/other operators	11	0.75
• 16B(b): Transformed either 5/8 to 15/24 or 2/3 to 16/24	17	1.15
• 16C: No written work	113	7.68
Code 31 Students who selected option 31/24	**158**	0.73
• 31A: Made the denominators same and added both	97	6.59
• 31A(a): Added fractions but did not write ‘+’ OR wrote ‘-’	22	1.49
• 31B: Unclear explanation	9	0.61
• 31B(a): Added numbers as 7/11	2	0.14
• 31C: No written work	28	1.90
Code O Other Responses	**218**	4.81
• O(A): Students have written ‘what’ or ‘IDK’ or ‘guessed’ or ‘?’	2	0.14
• O(B): No response with unclear or clear written work	23	1.56
• O(C): No response and NO written work	193	3.11

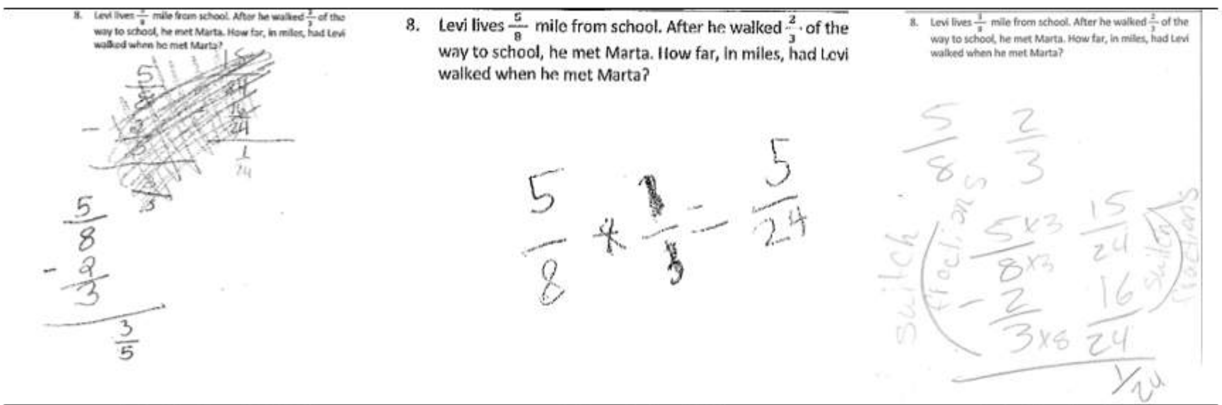
N: Number of Students; %: Percentage of Students

The students’ written work revealed their comprehension and conception of a fraction multiplication word problem. Around 435 students (29.55%) chose the correct option 10/24, but 62 (4.21%) of them had unclear explanations. Some students did not use the multiplicative operator as their first choice and employed a ‘guess and check’ strategy solving the task, e.g., making the denominator values the same, adding the fractions, etc. as their first attempt (**Code 10A(b)**, n = 7, 0.48%). **Code 10C** depicts the students (n = 13) who have either not used any or used ‘-’ as an arithmetic operator between 5/8 and 2/3. The reason of their selecting their operation is unknown to us but suggests avenues to be explored in the future using interviews.

Some students (**Code 10F(b),** n = 6, 0.41%) wrongly subtracted the fractions 5/8 and 2/3 as 3/5, and selected 10/24 (Figure 2(a)). A potential reason for this selection can be that the students might have realized that 3 and 5 are respective factors of 24 and 10. There is speculation in this inference but the best judgment we can make from their work. However, this code supported the idea of revisiting previously learned concepts because even if the subtracting fractions is a fourth-grade standard (CCSS.MATH.CONTENT.4.NF.B.3.A), misconceptions were visible in their present work. Similar reasoning has also been captured in **Code 1B(a)** (*n* = 6, 0.41%).

Some students demonstrated an advanced level of understanding by treating fractions as an operator. They considered 2/3 as 2*(1/3), multiplied 5/8 with 1/3 to get 5/24, and then doubled the output (Figure 2(b); **Code 10A**, n = 157, 10.67%). This shows a sophisticated level of reasoning as students changed the fraction into a unit fraction and then doubled it.

Many students chose the option 1/24 (**Code1;** *n* = 414, 28.13%) suggesting that they relied on a part-whole understanding of fractions. Students subtracted 5/8 and 2/3 after making the same denominator; this only makes sense if they were treating both as a distance. **Code1A*** (*n* = 119, 8.08%), an extension to **Code1A** (related to subtracting both fractions, *n* = 161, 10.94%), reflected a unique attribute of understanding where students made the denominators the same for both fractions and switched their order (Figure 2(c)). This code indicated students may have applied the rule of always subtracting the smaller number from the larger number. Similar reasoning was captured by **Code 31** (*n* = 158, 10.73%) where students interpreted this to be an addition problem.



(a) Code 10C(d) (b) Code 10A (c) Code 1A*

Figure 2: Examples of the Students' Work for Specific Codes

A few codes call for teachers' attention, for instance, **Code 16B(b)** (*n* = 17, 1.15%) depicts students using only one fraction to deduce the answer. One of the students mentioned, "I think it is 16/24 because 1/3 = 8/24 and he is 2/3, so you add and get 16/24". We also found that there were students who performed the correct calculation and obtained 5/12 but did not select any option, captured in the **Code O(B)**. Such students might have forgotten to mark an answer choice or potentially did not recognize equivalence between 5/12 and 10/24.

Discussion

The qualitative analysis of the students' written work helped in recognizing and identifying the strategies involved in answer choices. We find it plausible that students selected incorrect options because to answer correctly requires one to understand the different meanings of fractions and how to interpret the product (Wyberg et al., 2012). Instead, students often rely on their understanding of whole numbers (Tsankova & Pjanic, 2009; Wu, 2001). However, whole number strategies are not appropriate for finding the product of two fractions. The analysis shows that many students added or subtracted directly which implies they treated both fractions in the question (5/8 of a mile and 2/3 of the distance) as a measure. The students in this sample may lack understanding of a fraction as a ratio.

Previous researchers mentioned that instruction in the elementary classrooms is dominated by the part-whole interpretation of fractions (Ni & Zhou, 2005; Olanoff et al., 2014). Such instruction does not provide the conceptual understanding necessary to solve a problem involving fractions with a ratio meaning. We speculate that reinforcing the conceptual meaning behind all fraction sub-constructs might improve students' facility with fraction operations.

STUDENTS' UNDERSTANDINGS OF THE TRANSFORMATIONS OF FUNCTIONS

Camille S. Burnett
Prairie View A&M University
csburnett@pvamu.edu

The goal of this study is to describe students' understandings of the transformations of functions in different representations based on an analysis of pilot interviews with two ninth and two twelfth grade students from the same urban public high school in Massachusetts, which serves a diverse community. Interview responses indicated that the students were unable to identify explicitly the type of transformation that described the relationship between two functions. Analyses of the interviews revealed that a student's flexibility in the use of representations of and approaches towards functions is an indicator of their understanding of functions and, therefore, that the ninth grade students interviewed have a less sophisticated understanding of functions than do the twelfth grade students interviewed.

Keywords: Algebra and Algebraic Thinking

Purpose of Study

Functions, as proposed by Schwartz and Yerushalmy (1992; Doorman & Drijvers, 2011; Schwartz, 1999; Zandieh et al., 2017), can be viewed as one of the fundamental objects of mathematics, and appears at all levels of the mathematics curriculum ranging from patterns in elementary school to real analysis in college mathematics. Landmark studies about the concept of function include, but are not limited to: (1) theoretical models on the development of the function concept; (2) teaching experiments that apply general theories to the specific concept of function; (3) students' and teachers' conceptions of functions; and (4) the use of technology in functions-based mathematics classes (e.g., Dubinsky & Harel, 1992b). The current study falls under the third category above, which includes more recent studies such as Ayalon and Wilkie (2019), Dubinsky & Wilson (2013), and Ronda (2015). It aims to contribute to this line of research by specifically analyzing and describing students' *understandings* of the *transformations* of functions in *different representations*. Thus far, researchers have identified that students experience difficulties with transformations of functions when asked to (a) visualize the transformations because of processing challenges with horizontal and vertical translations (Eisenberg & Dreyfus, 1994); (b) identify, graph and use transformations to solve problems because they have not interiorized the concept of function (Lage & Gaisman, 2006); and (c) translate functions because of cognitive and pedagogical obstacles (Zazkis et al., 2003). This study will describe some of the difficulties students encounter with transformations of functions, in particular, when asked to state the relationship, based on a transformation, between two given functions.

Theoretical Framework

Representations of Functions

There are various ways to represent a function. This study considers the algebraic, graphical, and tabular representations, which frequently occur in a high school math curriculum. The term algebraic representation refers to expressions or equations containing numbers and variables connected by mathematical operations. The term graphical representation refers to the Cartesian coordinate system, and the term tabular representation refers to a table of values displaying an input and an output.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Conceptions of Functions

The most predominant distinction used for describing one's concept of a function is *process* versus *object*. A *process* conception of a mathematical concept is "a form of understanding of a concept that involves imagining a transformation of mental or physical objects that the subject perceives as relatively internal and totally under her or his control" (Dubinsky & Harel, 1992b, p. 20). An *object* conception of a mathematical concept is "a form of understanding of a concept that sees it as something to which actions and processes may be applied" (Dubinsky & Harel, 1992b, p. 19). One method for identifying one's conception of function is to consider one's approach towards functions, as is done in this study. One can have a pointwise or a global approach towards a function (Bell & Janvier, 1981; Janvier, 1978). For instance, if given the algebraic representation of a function and asked to create the graph, then a pointwise approach is to plot discrete points, and a global approach is to sketch the graph (Even, 1998).

Conceptions and Representations of Functions

A students' understanding of the concept of function can vary depending on the representation (Dubinsky & Harel, 1992a; Moschkovich et al., 1993). This is likely because the tabular representation is composed of discrete data points and requires a pointwise (process) approach, and the algebraic and graphical representations can be manipulated discretely (pointwise/process) or in their entirety (global/object). Further, to be able to translate between representations is associated with being able to transition between approaches (Even, 1998), and it is important to be able to move flexibly between representations and understandings (Moschkovich et al., 1993).

Methods

Participants

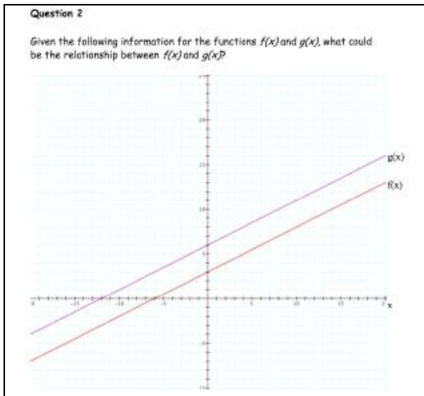
The participants included two high-performing ninth graders (Student 9-1 and 9-2) and two high-performing twelfth graders (Student 12-1 and 12-2), from the same public high school in an urban center in Massachusetts, which serves a diverse community. The ninth graders were learning basic algebra principles such as order of operations, as well as statistical concepts such as box plots; the twelfth graders were learning about polynomial functions and their characteristics. The students were selected by their mathematics teachers to participate in this pilot study based on their excellent grades and high skill level in their current mathematics class.

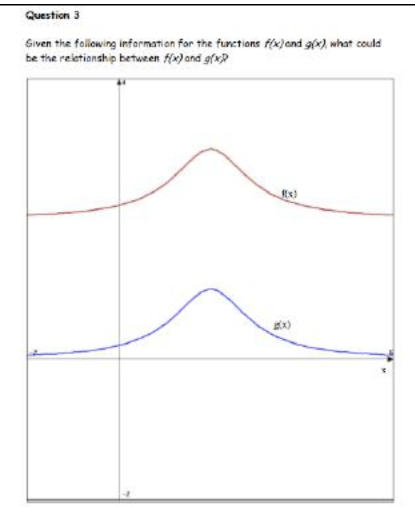
Individual Interviews

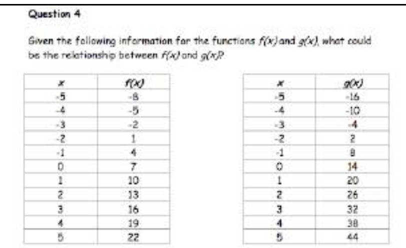
The individual interviews piloted seven questions pertaining to the definition of a function, and the transformations and comparisons of functions in different representations; however, this paper will focus only on the responses to the three interview questions regarding the transformations of functions (Questions 2, 3, and 4 – see Figure 1). In these questions, the participants were asked to state the relationship between the two given functions. The interviews were videotaped and lasted between 15 and 60 minutes, depending on the participant.

Analysis

The participants' responses to Questions 2, 3, and 4 were analyzed based on Figure 2, which was adapted from Moschkovich et al.'s (1993) study, and includes Even's (1998) approaches to functions – pointwise or global. If a participant's response was considered accurate, then it was coded with a 1, and if it was not, then it was coded with a 0. Also, the "most anticipated" response cells appear in boldface for each participant. The "most anticipated" responses were chosen based on two criteria: (1) it was in the representation in which the question was posed, and (2) it used an approach aligned with the representation. More specifically, for the second criterion, the graphical representation tends to evoke the object conception of function (Schwartz & Yerushalmy, 1992), while the tabular representation relies on discrete data points and, therefore, is more closely related to the process conception of function. Thus, each participant could have a "most anticipated" response, as well as accurate, non-anticipated responses.







Question 4

Given the following information for the functions f(x) and g(x), what could be the relationship between f(x) and g(x)?

x	f(x)
-5	-8
-4	-5
-3	-2
-2	1
-1	4
0	7
1	10
2	13
3	16
4	19
5	22

x	g(x)
-5	-16
-4	-10
-3	-4
-2	2
-1	8
0	14
1	20
2	26
3	32
4	38
5	44

Note: Functions can be expressed in other representations, and relationship is a translation.	Note: Functions cannot be expressed in other representations, and relationship is a translation.	Note: Functions can be expressed in other representations, and the relationship is a dilation.

	Representation		
Approach	*Tabular (T)*	*Graphical (G)*	*Algebraic (A)*
Pointwise			
Global			

Figure 2: Framework for Examining Representations and Approaches to Functions

Results

Response Samples

Question 2. Student 9-2 was unsure as to what the question was asking and kept referring to the graphs as being representative of information usually seen in a table or as an equation. The student then pointed out that the two lines are parallel, and deduced the slope of each function from their respective graphs, which was found to be the same. The student continued to examine the two functions and pointed out that they both have different x- and y-intercepts, and finally concluded, "They're both the same, I guess. They're both the same lines…just in different positions … One's higher, and one's lower. They're placed…they're the same…the same two lines…just placed different on the axis."

Question 3. Student 12-1 started by examining the graphs and stating that if the functions were expressed in tabular form, then the x-values would be the same for each function, but the output values would be different by a power or a multiple. The student showed great difficulty in explaining the relationship but was able to say, "The difference between the y-axis on either graph is going to be the number that you are going to be ... adding or multiplying to [g(x)]."

Question 4. Student 12-2 displayed high confidence in responding to the question and stated that "There's…you can find the difference between the two if you have this, and you say, …g(x)…, …x and y table is, um…in order to get that, all you have to do is multiply by two. Then, you would…then you could easily find g(x). And, you could plot it out. And, you could discover the, um…the slope…and the y-intercept. And, you could find out the equation."

Response Summary

The analysis of the participants' responses to Questions 2, 3, and 4 is summarized in Table 1.

Discussion

Interview responses indicated one significant observation in terms of students' understandings of *transformations*: the students were unable to identify explicitly the type of transformation that described the relationship between any of the pairs of functions but were able to use other descriptive words for the same. More specifically, none of the students used the terms translation, dilation, or transformation in response to any of the questions. Instead, they used words such as "higher" or "lower" on the graph to describe a translation, and "multiplied" to describe a dilation, which indicates a lack of mathematical vocabulary. Also, Student 12-1 was unable to specifically determine if the functions in Question 3 represented a translation or a dilation, which indicates a lack of understanding of transformations. These observations regarding difficulties with transformations need to be substantiated with more research.

Analysis of the interviews highlighted two significant findings in terms of students' *understandings* of functions in different *representations*: (1) students were able to be flexible between representations for functions, moving from one to another even though the question they were answering was presented in a single type of representation; and (2) students were able to be flexible between approaches towards and conceptions of functions, providing evidence that they could approach single questions and functions embedded in them in both a pointwise (process) and global (object) way. Given our assumption that moving across representations of functions and adopting both pointwise and global approaches towards functions provides evidence for students' flexibility and therefore greater sophistication in their understandings about functions ((Even 1998; Moschkovich et al. 1993), these findings lead us to the preliminary conclusion that the ninth grade students interviewed have a less sophisticated understanding of the concept of function than do the twelfth grade students interviewed because neither ninth grade student exhibited any flexibility between representations and only one exhibited flexibility between approaches. This preliminary conclusion needs to be substantiated with further research.

DIDACTIC SEQUENCE FOR THE LEARNING OF PLACE VALUE IN SECOND GRADE ELEMENTARY STUDENTS IN A MULTIGRADE SCHOOL

SECUENCIA DIDÁCTICA PARA EL APRENDIZAJE DEL VALOR POSICIONAL EN ALUMNOS DE SEGUNDO CICLO DE PRIMARIA DE UNA ESCUELA MULTIGRADO

This study addresses the teaching of mathematics in a multigrade school through the design of a didactic sequence for the learning of place value. Based on the theory of didactical situations and didactic engineering, we designed a sequence of six didactic situations on place value that was implemented on a group of second grade elementary students (ages 8-9). The sequence encourages students to perform numerical decomposition, decimal grouping, and number ordering with different numeric ranges, to construct meanings about place value in a game-oriented way.

Keywords: teaching activities and practices, elementary education, rural education.

Background

In a multigrade elementary school, students from different grades are grouped in a classroom to be taught by the same teacher. These schools are in geographically inaccessible and sparsely populated communities, where the number of students is small and, therefore, it is not feasible to have a full-organization school. Teachers in these schools also perform management and administrative tasks (INEE, 2019).

Various studies reveal the difficulties faced by teachers and students in multigrade schools in the learning and teaching process; for example, the reduced time for teaching as teachers must perform management, administrative or janitorial functions. It is common for traditional teaching methods to predominate in these schools due to the lack of a suited curricular proposal for this modality (Reséndiz, Block and Carrillo, 2017).

Nonetheless, it has also been noted that the multigrade modality has favorable characteristics for learning, such as the possibility for students to learn from their peers as well as a greater flexibility to assign tasks to students based on their level of performance. However, for these features to become really favorable for learning, teachers must possess teaching and organizational strategies (Block, Ramirez and Reséndiz, 2015).

According to Santos (2011), the teaching events that occur within multigrade classrooms point to diversity; that is, the diversification of teaching activities, with criteria of concurrency and complementarity, abandoning unique, synchronized, and standardized didactic practices. At the same time, it is possible to observe the circulation of knowledge, which means going beyond the formalities of school grades for knowledge to flow.

This study focuses on the teaching of mathematics in primary education in multigrade classrooms, specifically on the learning of place value in the Decimal Numbering System (DNS). DNS is an instrument of measure of other mathematical learnings, so understanding the DNS is decisive in the subsequent school trajectory of students (Terigi and Wolman, 2007).

Understanding the DNS promotes the development of numerical sense, skill and reflection in arithmetic operations, mental calculation and estimates (Angulo, 2017; Galicia and Uzuriaga, 2015). The concept of place value is indispensable for the construction of the DNS. Place value is the value that a digit takes according to the position it occupies within the number (units, tens, hundreds).

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

For the understanding of the DNS se should favor the understanding of all figures in a quantity to assign a name to the figures according to the order of location, that is, the value that each figure acquires within a number to represent the quantity described (Gallego and Uzuriaga, 2015).

In order for students to understand place value within a quantity, we proposed that a teaching sequence be designed to encourage students to discover the rules underlying the DNS. The question guiding this research is: How to promote the learning of place value in second cycle students (third or fourth grade) of a multigrade elementary school? Therefore, our goal is to design and implement a teaching sequence that favors this learning.

Theoretical Framework

The design of the didactic sequence is based on elements of the theory of didactic situations (Brousseau, 2007) and didactic engineering (Artigue,1995).

The design of didactic situations and the manipulation of teaching variables such as numerical range, allows us to approach a medium through which students interact with place value in all its complexity. According to Terigi and Vulture (2013) in the usual teaching of the DNS, the numbers are taught one by one, starting with the digits and respecting the order of the series. Ranges are established to sequence the teaching of numbers according to the years of schooling of the students: from 1 to 100 in first grade, up to 1000 in second, and so on. Since the beginning and along with the presentation of number 10, the notions of units and tens are incorporated. Therefore, one hypothesis that is incorporated into the design of didactic situations is that students can identify regularities and discover the recursion of the grouping, if an interaction with the SND through wide numerical ranges is allowed. Didactic situations, therefore, favor decimal grouping, numeric decompositions, number ordering and comparison, in different numeric ranges.

Some didactic sequences are designed and taught in a game-oriented environment, that is, games involving numbers. Fuenlabrada, Block, Balbuena and Carvajal (1992) state that "a good game allows you to play with little knowledge but, to start winning systematically, it requires the building of strategies

that imply the need of greater knowledge" (p.5). Therefore, didactic situations in a game-oriented context allow students to approach the situation with the knowledge they possess on place value and for meaning to be built through the construction of strategies.

Methodology

For the design of the didactic situations that make up the sequence, we used the phases of the didactic engineering (Artigue, 1995).

Situation 1 *Cashier 1* (Fuenlabrada, Block, Balbuena and Carvajal, 1992) consists of a set of dice and chips where students, organized into teams, take turns to throw the dice and ask a student playing the role as a Cashier for different color chips according to the number they obtain. Blue chips represent units, red ones represent tens, and yellow ones represent hundreds. Students must group the chips by tens and they trade their chips so as to obtain the yellow chip. The student who first gets the yellow chip wins.

In scenario 2, *Cashier 2*, students play with a board with blue, red and yellow chips. They add up 5 numbers that the *Cashier* shows them and record the sums on the board marking with the blue chip the position of the units, the tens with the red ones and the hundreds with the yellow ones. Whoever gets the sum of the five numbers correct wins.

Situation 3, *Math Bingo,* (Perez, 2016), is a game in which students have a card with several 5-digit numbers and they must place the value of one digit in one of those numbers. A number from 0 to 9 is drawn out of a tombola and, at the same time, place value: units, tens, hundreds, thousands, or tens of thousands is picked out of a deck of cards. The student will recognize the place and place a mark in one of the numbers to indicate the position.

Situation 4, *Broken Calculator 1*, (Galvez, Navarro, Riveros, Zanocco, 1994) is about students playing with a calculator, typing only the keys 1, 0, +, to create a number. In this situation students play with a number range from units to hundreds (1-999), so that the student can play without complications.

In situation 5 called *Decomposed Calculator 2,* a numerical range of hundreds to tens of thousands (100-99000) is worked to observe the procedures of students when facing the numbering system without restrictions.

Finally, in situation 6 *Clothes Line,* students compare numbers, previously selected, so that they can choose between the largest or smallest. Whoever has the highest or lowest number wins, depending on which one they chose at the beginning of the game. Students will then place the numbers on a rope sorted as they are directed, from highest to lowest or vice versa.

A multigrade rural primary school was chosen in the state of Guanajuato, Mexico, for the implement of the sequence. The school has four teachers who attend all students. The classroom is made up of third grade (8-year-old) and fourth grade (9-year-old) students

The community in which the school is located has a population of 311. The locals work in the fields or manufacturing factories.

A first approach to the group was made and an initial didactic situation of another topic was applied in order to identify the characteristics of the students and their level of participation with the researcher. The implementation of the teaching sequence is currently being carried out, recording each situation in audio and video for its subsequent analysis.

Discussion and results

The teaching sequence is intended to engage students in various contexts in which they can build meanings of about place value. As the research is in the implementation stage, here we identify some procedures of students that show how the sequence functions.

The use of teaching materials such as chips, calculators, bingo boards and dice, allows students to experience new ways of approaching mathematical activities. The situation that is created, in terms of the theory of didactic situations, stimulates the senses of the students and allows them to interact with their peers, building and validation their solution strategies.

The knowledge, procedures and skills developed by students is not determined by their age, which is associated with their school level. The curriculum indicates that the contents and learning in fourth grade (9-year-olds) are different because the level of complexity is higher, for example, the number ranges are wider than in third grade (8-year-olds). Nonetheless, the interaction between different grade students in the same classroom does not impede the construction of knowledge (Santos, 2011). On the contrary, students interact in a natural way and their arguments are validated collectively. Knowledge is generated in a didactic situation, designed from the curricular contents of the two levels.

The results of this study are located in the field of didactics of mathematics in multigrade schools and aim to contribute to improve teaching in this educational context.

Este estudio aborda la problemática de la enseñanza de las matemáticas en la escuela multigrado a través del diseño de una secuencia didáctica para el aprendizaje del valor posicional. Con base en la teoría de situaciones didácticas y la ingeniería didáctica, se diseñó una secuencia de seis situaciones didácticas sobre el valor posicional, que se implementó con un grupo de alumnos de segundo ciclo de primaria (8-9 años). La secuencia promueve que los alumnos realicen actividades de descomposición numérica, agrupación decimal y orden de los números, con disntintos rangos numéricos, para construir significados sobre el valor posicional, en un contexo lúdico numérico.

Palabras clave: actividades y prácticas de enseñanza, educación primaria, educación rural.

Antecedentes

En la escuela primaria multigrado se agrupan dos o más grados escolares, en un mismo grupo, para ser atendidos por un mismo docente. Estas escuelas están presentes en comunidades geográficamente poco accesibles y con escasa población, en las que el número de alumnos es reducido y no viable contar con una escuela de organización completa. Los docentes de estas escuelas también realizan tareas directivas y administrativas que la gestión escolar implica (INEE, 2019).

Diversas investigaciones revelan las dificultades en los procesos de enseñanza y aprendizaje en estas escuelas, por ejemplo, la reducción de tiempos de enseñanza, pues los docentes realizan funciones directivas, administrativas o de aseo escolar. Es común que predominen los métodos tradicionales de enseñanza debido a la falta de una propuesta curricular para esta modalidad (Reséndiz, Block y Carrillo, 2017).

También se ha señalado que la modalidad multigrado tiene características favorables para el aprendizaje, como la posibilidad de que los alumnos aprendad unos de otros, o la mayor flexibilidad para asignar tareas a cada uno en función de su nivel de desempeño. Para que estas características se vuelvan realmente favorables para el aprendizaje, es necesario disponer de estrategias didácticas y de organización que lo hagan posible (Block, Ramírez y Reséndiz, 2015).

De acuerdo con Santos (2011), los acontecimientos didácticos que ocurren al interior de las aulas multigrado apuntan a la diversidad, esto es, la diversificación de actividades de enseñanza, con criterios de simultaneidad y complementariedad, abandonando las prácticas únicas, sincronizadas y uniformizadas en sus mecanismos. Al mismo tiempo, es posible observar la circulación de los saberes, lo que supone abrir las formalidades de los grados escolares para que los saberes fluyan.

La problemática de este estudio se centra en la enseñanza de las matemáticas en la educación primaria en aulas multigrado, específicamente en el tema de valor posicional del Sistema de Numeración Decimal (SND). El SND constituye el instrumento de mediación para otros aprendizajes matemáticos, por lo que el aprendizaje de este objeto matemático es decisivo en la trayectoria escolar posterior de los alumnos (Terigi y Wolman, 2007).

La comprensión del SND favorece el desarrollo del sentido numérico, la habilidad y reflexión en operaciones aritméticas, cálculo mental y estimaciones (Angulo, 2017; Gallego y Uzuriaga, 2015) y el concepto de valor posicional es indispensable para la construcción del SND. El valor posicional es el valor que toma un dígito de acuerdo con la posición que ocupa dentro del número (unidades, decenas, centena).

Para la comprensión del SND se debe favorecer la comprensión de todas las cifras en una cantidad para asignar un nombre a las cifras de acuerdo al orden de ubicación, es decir, el valor que adquiere cada cifra dentro de un número para representar la cantidad descrita (Gallego y Uzuriaga, 2015).

Para que los alumnos comprendan el valor posicional de las cifras dentro de una cantidad, se propone el diseño de una secuencia didáctica que favorezca que los alumnos descubran las reglas subyacentes al SND. Por lo tanto la pregunta de esta investigación es ¿cómo favorecer el aprendizaje del valor posicional en alumnos de segunco ciclo (tercero y cuarto grado) de una escuela primaria multigrado? De modo que nuestro objetivo es el diseño e implementación de una secuencia didáctica que favorezca este aprendizaje.

Marco Teórico

El diseño de la secuencia didáctica se fundamenta en elementos de la teoría de las situaciones didácticas (Brousseau, 2007) y en la ingeniería didáctica (Artigue,1995).

El diseño de las situaciones didácticas y la manipulación de las variables didácticas como el rango numérico, permite aproximarnos a un medio en el que los alumnos interactúen con el valor posicional en toda su complejidad. De acuerdo con Terigi y Buitron (2013) en la enseñanza usual del SND, se enseñan los números uno por uno, comenzando por los dígitos y respetando el orden de la serie. Se establecen cortes para secuenciar la enseñanza de los números según los años de escolaridad de los alumnos: de 1 a 100 en primer grado, hasta 1000 en segundo, y así sucesivamente. Desde el inicio y junto con la presentación del número 10, se incorporan las nociones de unidades y decenas. Por lo tanto, una hipótesis que se incorpora al diseño de las situaciones didácticas es que los alumnos pueden identificar regularidades y descubrir la recursividad del agrupamiento, si se permite una interacción con el SND, a través de rangos numéricos amplios. El medio de las situaciones didácticas favorece agrupaciones decimales, descomposiciones numéricas, establecimiento de orden y comparación de números, en diferentes rangos numéricos.

Algunas situaciones didácticas están contextualizadas en un entorno lúdico-numérico, es decir, juegos que involucran números. Fuenlabrada, Block, Balbuena y Carvajal (1992) afirman que "un buen juego permite que se pueda jugar con pocos conocimientos, pero, para empezar a ganar de manera sistemática, exige que se construyan estrategias que implican mayores conocimientos" (p.5). Por tanto, el medio de las situaciones didácticas, en el contexto lúdico-numérico, permite que los alumnos se aproximen a la situación con los conocimientos que tienen sobre el valor posicional y a través de la construcción de estrategias ganadoras, puedan construir significados.

Metodología

Para el diseño de las situaciones didácticas que conforman la secuencia, se utilizan las fases de la ingeniería didáctica (Artigue, 1995).

La situación 1 demoninada *Cajero 1* (Fuenlabrada, Block, Balbuena y Carvajal, 1992) consiste en un juego de dados y fichas en donde los alumnos, organizados en equipos, tiran los dados por turnos y de acuerdo al número que obtienen, piden fichas de colores a quien tiene el rol de cajero. Fichas azules representan unidades, fichas rojas representan decenas y fichas amarillas representa centenas. Los alumnos agruparán de diez en diez, realizarán equivalencias entre las fichas para cambiar fichas azules por fichas rojas y fichas rojas por amarillas. Gana el alumno que obtenga primero la ficha amarilla.

En la situación 2 denominada *Cajero 2*, los alumnos juegan con un tablero, con fichas de color azul, rojo y amarillo. Suman 5 números que les muestre quien tenga el rol de cajero y registrarán las sumas en el tablero, marcando con la ficha azul la posición de las unidades, con la roja las decenas y con la amarilla las centenas. Gana quien obtenga el resultado correcto de la suma de los cinco números mostrados.

La situación 3 denominada *Bingo matemático* (Pérez, 2016), es un juego en el que los alumnos tienen una tarjeta con varios números de 5 cifras y tienen que ubicar el valor de un dígito en uno de esos número. De una tómbola de números se toma uno del 0 al 9 y, al mismo tiempo, de un mazo de tarjetas se toma el nombre de una posición: unidades, decenas, centenas, unidades de millar, decenas de millar. El alumno reconocerá y pondrá una marca en la posición indicada, en alguno de los números de su trajeta.

La situación 4 denominada *Calculadora descompuesta 1* (Gálvez, Navarro, Riveros, Zanocco, 1994) consiste en jugar con una calculadora, tecleando sólo las teclas 1, 0, +, = para formar cualquier número. En esta situación se juega con un rango numérico que abarca de unidades a centenas (1-999), para que el alumno pueda acceder a la dinámica de juego sin complicaciones.

En la situación 5 denominada *Calculadora descompuesta 2*, se trabaja con un rango numérico de centenas a decenas de millar (100-99000) para observar los procedimientos de los alumnos al enfrentarse al sistema de numeración sin restricciones.

Finalmente, la situación 6 denominada *tendedero matemático* consiste en un juego en el que los alumnos comparan números, seleccionados previamente, con la intención de que puedan elegir el mayor o menor según sea el caso. Gana quien tenga el número mayor o menor, según se elija al inicio de la jugada. Luego, los alumnos colocarán los números en un listón o cuerda, ordenados según se les indique, de mayor a menor o viceversa.

Se eligió una una escuela primaria rural multigrado en el estado de Guanajuato, México, para la implemetación de la secuencia. La escuela cuenta con cuatro docentes que atienden todos los alumnos. El segundo ciclo, agrupa a los grados de tercero (8 años) y cuarto (9 años).

La comunidad en la que se ubica la escuela tiene 311 habitantes, que en su mayoría se dedican a labores del campo y al trabajo como obreros en fábricas manufactureras.

Se realizó un primer acercamiento al grupo y se aplicó una situación didáctica inicial de otro tema, para conocer las características de los alumnos y su nivel de participación con la investigadora. Actualmente se está realizando la implementación de la secuencia didáctica, registrando en audio y video cada situación didáctica, para su posterior análisis.

Discusión y resultados

La secuencia didáctica pretende favorecer el acercamiento de los alumnos con diversos contextos en los que puedan construir significados del valor posicional. Como la investigación se encuentra en fase de implementación, se identifican hasta el momento, algunos procedimientos de los alumnos que muestran el funcionamiento de la secuencia didáctica.

Por otra parte, el uso del material didáctico como las fichas, calculadora, tableros de bingo y dados, permite que los alumnos experimenten nuevas formas de acercarse a la actividad matemática. El medio que se construye, en términos de la teoría de situaciones didácticas, estimula los sentidos de los alumnos y les permite interactuar con sus compañeros, construir y validar sus estrategias de solución.

Los conocimientos, procedimientos y habilidades que desarrollan los alumnos no están determinados por sus edades, asociadas al grado escolar. El currículo indica que son diferentes los contenidos y el aprendizaje en cuarto grado (9 años), pues es mayor el nivel de complejidad, por ejemplo, los rangos numéricos más amplios que en tercer grado (8 años). Sin embargo, la interacción entre grados en el mismo grupo no fragmenta o imposibilita la circulación de saberes (Santos, 2011). Por el contrario, los alumnos interactúan de manera natural y sus argumentaciones se validan en colectivo. Se genera una circulación de saberes en una situación didáctica, diseñada desde los contenidos curriculares de los dos grados que se atienden en el mismo grupo.

Los resultados de este estudio se ubican en la línea de investigación de didáctica de las matemáticas en multigrado y pretenden contribuir a las propuestas para mejorar la enseñanza en esta modalidad educativa.

In this research, we used the Local Theoretical Models as a theoretical and methodological frame and Pierce's theoretical perspective on semiotics. At the end of the study carried out with secondary school students, authors identified strata of intertextuality derived from the processes of semiosis, based on acts of reading/transformation of texts or reading/translation/transformation of the textual spaces proposed in the teaching model through solving verbal problems using grade two equations with an unknown, adopting the Mixed Method (geometric and algebraic), and the Cartesian Methods that include algebraic procedures with paper and pencil and a symbolic calculator with a Computation Algebraic System.

Keywords: Intertextuality, semiosis processes, sense production, verbal problems.

There are various difficulties that secondary school students face during the process of learning algebra; for instance, they fail to identify the structures underlying algebraic expression, surface structure, and systemic structure as in Kieran (1989). Also, in Filloy & Córdoba (2013), Córdoba (2016), authors assert that it is usual when working with algebraic expression, that occur several types of syntax errors, either arithmetic or algebraic, or when solving equations of grade one (EG1) and of grade two (EG2), in such a way that students cannot be considered competent users of a Mathematical Sign System (MSS) yet. They are in the process of reading the mathematical text correctly and distinguishing the allowed transformations from those that are not.

Some researchers (Gallardo, 2002; Kieran, 2006; Solares, 2007; Rojano, 2010; Martínez, 2012; Filloy & Córdoba, 2013; Bonilla, 2014; Córdoba, 2016) consider that in the transition from arithmetic to algebra it is essential that secondary school teachers recognize as fundamental that students learn the properties and relationships of the arithmetic MSS (MSS1) and that the incomplete knowledge of these implies operational difficulties with MSS of algebra (MSS2).

Purpose of the study

The purpose of the qualitative experimental study carried out by Córdoba (2016) was to observe and analyze the semiosis processes of the students (study subjects), as a result of reading/transforming mathematical texts, for the production of meaning in the process of algebraic solving of verbal problems (VP) by EG2 with an unknown.

Theoretical framework

The theoretical and methodological framework proposed by Filloy (1999), for experimental observation in Educational Mathematics, called Local Theoretical Models (LTMs), allows us to account for the processes that are developed when certain specific mathematical contents are taught within the National Educational System to some students, which must be relevant to the phenomena under study; LTMs contemplate four interrelated components and their corresponding models: 1) Teaching Model, 2) Model of Cognitive Processes, 3) Model of Formal Competence, and 4) Model of Communication. Filloy (1999) defines a Teaching Model (TM), as a sequence of texts produced by both the teacher and the student, and these texts are the result of the work of both in problem teaching situations - which are taken as spaces textual. "In algebra, textual spaces are made up of Mathematical Sign Systems whose codes and traditions come from the meanings attributed to them for their social use". (Filloy, Rojano & Puig, 2011).

From Pierce's theoretical perspective on semiotics, what is a sign? For Peirce the fundamental thing in the sign is its function, when describing the semiotic process, rather than signs, it refers to sign functions. That sign, vital, constant, and meaningful process is the semiosis. Elizondo (2012). We find it relevant to differentiate text and textual space (TS), which corresponds to the distinction between meaning and sense. It is also relevant to understand the use that teachers and students assign to mathematical text. Filloy affirms that the notion of text is introduced to be used in the analysis of any practice of meaning production. (Filloy, Rojano, & Puig, 2008; Kieran & Filloy, 1989). A text is the result of the reading/transformation made on an TS, whose purpose is to produce sense and only extract meaning in that space (Filloy, Rojano, & Puig, 2008). Textual space is a system that imposes a semantic restriction on the person who reads it; the text is a new articulation of that space, individual and unrepeatable, made by a person as a result of an act of reading. Thus, an TM as a component of an LTM (Filloy, 1999) is a succession of texts that are taken as an TS to be read/transformed into another ET as the learner gives meaning in his readings (Rojano, 2010).

The MC process involves putting a problem into equations or a process of translating the given VP statement in natural language into algebraic language. On one hand, to accomplish an analytical reading that prepares the text of the problem by producing another text that in a certain way is in course to be translated into algebraic language. On the other hand, to work at the level of expression in the algebraic language that transforms the translated text (equation) into a text that can be solved, that is, the equation in its canonical form. (Puig, 2012).

Research Method

For this research, we designed and developed an LMT composed of the four models referred to. In the TM, we recovered elements for the didactic use of syntax errors in the development of algebraic thinking. From the study of Córdoba (2005); we observed with a clinical interview with teaching (ECT) situation, the performances of nine third graders of Secondary Education in the State of Mexico; but as a matter of space we will only refer to the case of Fer, when solving VP through EG2 using pencil and paper procedures and CAS as a symbolic manipulator. It was also used their modeling through the use of a didactic material called Algebraic Puzzle proposed by Larrubia (2005), which allowed analyzing the interaction of the learners with the MSS1, the MSS2 and the TM.

Results

In his doctoral thesis, Córdoba (2016) identified three types of intertextuality strata derived from the semiosis processes; it also described three levels of competence of MSS2 use (low, intermediate and high) of each; the above, from the ECT with students, in which the author asked them to solve VP using EG2 with an unknown, which are part of the TM. Below are the general characteristics of the intertextuality strata.

The first intertextuality stratum: *Reading/writing of texts in a network of textual relationships,* refers to the acts of reading/writing of algebraic text that a specific reader does base on a network of textual relationships derived from his/her prior mathematics and linguistics experiences. In particular, in this study, emerge three levels of MSS2 use competence of learners when asked them to solve EG2 with one unknown.

The second intertextuality stratum: *Reading/transformation of superficial structure of algebraic texts,* refers to the way the learners solve the given EG2 (complete and incomplete) from the recognition of shallow structure. Learner performed algebraic transformations between algebraic texts at the level of algebraic expression; this also require the learner to identify the shallow structure of the equation and its transformation from the factored form to the canonical form or vice versa.

The third intertextuality stratum: *Reading/translating/transformation of text,* refers to the algebraic resolutions of a VP through EG2 with one unknown; in this regards, it is common to use MC, defined as the process to pose a problem as an equation, which implies the process of translation and the algebraic transformations describe in second intertextuality stratum.

A brief description and analysis of a clinical interview episode with teaching, conducted by the Researcher (R) with Fer (F), is included to exemplify the third intertextuality stratum "Reading/translation/transformation of texts" in the resolution of a VP.

R: The square of the number plus the triple of the same number gives us fifty-four. What is that number and how do you state the equation?

F: Well, the first number is equis, and plus three times the same number, then it would be three equis! [writes with a certain separation x and 3x on the board, stays watching and mentions...] but as it says, the square of a number, we raise to the square equis, plus three equis equal to fifty-four [he writes $x^2 + 3x - 54 = 0$], the equation is square equis plus three equis equal to fifty-four, but if the fifty-four we pass it on the other side and match it with zero, then we would have... [he writes $x^2 + 3x - 54 = 0$ and continued the solving process by factoring the second-degree trinomial written on the first equation member until the two equis ($x_1 = -9$, $x_2 = 6$)].

R: Well, you obtained two values, one positive and one negative and the question of the problem is: What is the number? However, the VP refers: the square of a number plus the triple of the same number gives us fifty-four. What value do you consider adequate? [Fer stays thinking]

F: I will try first by substituting the value of six in the equation $(x)^2 + 3x = 54$, [he writes $(6)^2 + 3(6) = 54$, $36 + 18 = 54$ and obtains $54 \equiv 54$, then he doses the same with value -9, and concludes by saying that he value sought is six].

In this episode you can see significant progress towards algebraic syntax, his personal intertexts allow him to make an efficient reading of the proposed problem statement. He verbally evokes how he carries out his reasoning, which allow him to pose a EG2 with one unknown that represents the translation. The student's semiosis process shows his competence in the use of MSS2 at a high level; he also formulates the correct answer of the problem because he proved the equality of the equation by substituting the values of the unknown. The above fives sense to the algebraic procedures carried out.

Conclusions

The teaching model used in this study allowed to enhance the semiosis processes, the intertextuality and the production of meaning in the study subjects from the manipulation of Algebraic Puzzle pieces, that were useful for concrete modeling of the equations written in its canonical form $ax^2 \pm bx \pm c = 0$, where $a, b, c \in Z$, and thus provide meaning and senses to equivalent equations syntactically obtained from this solving process with pencil and paper, that the competent user of the MSS2 wrote in its factored form $(x \pm a)(x \pm b) = 0$, or by CAS.

The results presented are not conclusive. It is necessary to carry out studies that deepen the reading/transformation processes and the consequent production of meanings by the students, through the design of a teaching model that allow them to evolve towards the construction of the algebraic syntax around the MC of EG2 resolution, based on their intertexts during the semiosis processes that students use as competent users of the MSS2 to solve those VP posed.

INTERTEXTUALIDAD Y PROCESOS DE SEMIOSIS EN LA RESOLUCIÓN ALGEBRAICA DE PROBLEMAS VERBALES

INTERTEXTUALITY AND SEMIOSIS PROCESSES IN THE ALGEBRAIC RESOLUTION OF VERBAL PROBLEMS

Juan Manuel Córdoba Medina
Escuela Normal Superior del Estado de México
juancordoba1974@gmail

Eugenio Filloy Yagüe
Matemática Educativa – Cinvestav IPN
smmeef@aol.com

En esta investigación se utilizó como marco teórico y metodológico los Modelos Teóricos Locales y la perspectiva teórica sobre semiótica de Pierce. Al final del estudio realizado con estudiantes de secundaria se identificaron estratos de intertextualidad derivados de los procesos de semiosis, con base en actos de lectura/transformación de textos o de lectura/traducción/transformación de los

espacios textuales propuestos en el Modelo de Enseñanza para la resolución de Problemas Verbales mediante Ecuaciones de Grado dos con una incógnita, empleando el Método Mixto (geométrico y algebraico) y el Método Cartesiano que incluye procedimientos algebraicos con lápiz y papel, y una calculadora simbólica con un Sistema Algebraico Computacional.

Palabras clave: Intertextualidad, procesos de semiosis, producción de sentido, problemas verbales.

Son diversas las dificultades que enfrentan los estudiantes de secundaria en su proceso de apredizaje del álgebra, por ejemplo, no identifican las estructuras subyacentes a las expresiones algebraicas: estructura superficial y estructura sistémica en términos de Kieran (1989), por otra parte en Filloy & Córdoba (2013), Córdoba (2016), se afirma que es común que se generen diversos tipos de errores de sintaxis al manipular expresiones matemáticas, ya sean aritméticas o algebraicas, o bien, en la resolución de ecuaciones de grado uno (EG1) y ecuaciones de grado dos (EG2), de tal forma que, aún no se les puede considerar usuarios competentes del Sistema Matemático de Signos del Álgebra (SMS2), están en proceso de leer los textos matemáticos de manera correcta y distinguir las transformaciones permitidas de las que no lo son.

Algunos investigadores (Gallardo, 2002; Kieran, 2006; Solares, 2007; Rojano, 2010; Martínez, 2012; Filloy & Córdoba, 2013; Bonilla, 2014; Córdoba, 2016) consideran que en la transición de la aritmética al álgebra es necesario que los profesores de secundaria contemplen como fundamental que sus estudiantes aprendan las propiedades y relaciones del SMS de la aritmética (SMS1), y que el insuficiente conocimiento de éstas se traduce en dificultades de operatividad con el SMS2 y con ello, la lectura/transformación de textos algebraicos

Propósito del estudio

El propósito del estudio experimental de corte cualitativo realizado por Córdoba (2016), fue observar y analizar procesos de semiosis de los estudiantes (sujetos de estudio), como resultado de la lectura/transformación de textos matemáticos, para la producción de sentido en el proceso de la resolución algebraica de problemas verbales (PV) mediante EG2 con una incognita

Marco Teórico

El marco teórico y metodológico propuesto por Filloy (1999), para la observación experimental en Matemática Educativa, denominado Modelos Teóricos Locales (MTL's), permite dar cuenta de los procesos que se desarrollan cuando se enseñan dentro del Sistema Educativo Nacional determinados contenidos matemáticos concretos a unos estudiantes dados, los cuales deben ser pertinentes para los fenómenos que son objeto de estudio; los MTL's contemplan cuatro componentes interrelacionados y sus correspondiente modelos:1) Modelo de Enseñanza 2) Modelo de los Procesos Cognitivos, 3) Modelo de Competencia Formal y 4) Modelo de Comunicación. Filloy (1999), define un Modelo de Enseñanza (ME), como una secuencia de textos producidos tanto por el profesor como por el alumno, y esos textos son el resultado del trabajo de ambos en situaciones de enseñanza problema —que se toman como espacios textuales—."En álgebra, los espacios textuales están constituidos por Sistemas Matemáticos de Signos cuyos códigos y tradiciones provienen de los significados atribuidos a ellos por su uso social". (Filloy, Rojano & Puig, 2011).

Desde la perspectiva teórica de Pierce en relación con la semiótica ¿qué es un signo? Para Peirce lo fundamental en el signo es su función, al describir el proceso semiósico, más que a signos, se refiere a funciones sígnicas. Ese proceso sígnico, vital, constante y significante es la semiosis. Elizondo (2012). Es pertinente hacer una distinción entre texto y espacio textual (ET), la cual se corresponde con la distinción entre significado y sentido, es importante comprender el uso que dan los profesores y los estudiantes a los textos matemáticos. Filloy afirma "… la noción de texto se introduce para ser utilizada en el análisis de cualquier práctica de producción de sentido." (Filloy, Rojano, & Puig, 2008; Kieran & Filloy, 1989). Un texto es el resultado de la lectura/transformación hecha sobre un ET, cuyo propósito es producir sentido y solamente extraer el significado inherente a dicho espacio. (Filloy, Rojano, & Puig, 2008). El espacio textual es un sistema que impone una restricción semántica a la persona que lo lee; el texto es una nueva articulación de ese espacio, individual e irrepetible, hecha por una persona como resultado de un acto de lectura. Así, un ME como componente de un MTL (Filloy, 1999), es una sucesión de textos que son tomados como un ET para ser leído/transformado en otro ET conforme el aprendiz da sentido en sus lecturas (Rojano, 2010).

El proceso del MC implica poner un problema en ecuaciones, o bien, un proceso de traducción del enunciado del PV dado en lenguaje natural al lenguaje del álgebra, implica: por un lado, la lectura analítica, que prepara el texto del problema elaborando otro texto que en cierta manera está preparado para ser traducido al lenguaje del álgebra, y por otro, un trabajo en el nivel de la expresión en el lenguaje del álgebra que transforma el texto traducido (la ecuación) a otro texto que se sabe resolver; es decir, la ecuación en forma canónica (Puig, 2012).

Método de investigación

En esta investigación se diseñó y desarrollo un MTL integrado por los cuatro modelos referidos, en el ME se retomaron elementos para el uso didáctico de los errores de sintaxis en el desarrollo del pensamiento algebraico, a partir del estudio de Córdoba (2005); se observaron en situación de entrevista clínica con enseñanza (ECE), las actuaciones de nueve estudiantes de tercer grado de Educación Secundaria en el Estado de México; pero por cuestión de espacio solo nos referiremos al caso de Fer, al resolver PV mediante EG2 utilizando procedimientos con lápiz y papel y CAS como manipulador simbólico, además se recurrió a la modelación de éstas, mediante el uso de un material didáctico denominado Puzzle Algebraico propuesto por Larrubia (2005), esto permitió analizar la interacción de los aprendices con el SMS1, el SMS2 y el ME.

Resultados

En la tesis doctoral de Córdoba (2016), se identificaron tres tipos de estratos de intertextualidad derivados de los procesos de semiosis, también se describen tres niveles de competencia de uso del SMS2 (bajo, intermedio y alto) de cada tipo, lo anterior, a partir de las ECE con estudiantes, en las que se les propuso resolver PV mediante EG2con una incógnita, los cuales forman parte del ME, a continuación se exponen características generales de los estratos de intertextualidad:

El primer estrato de intertextualidad: *Lectura/escritura de textos en una red de relaciones textuales*, se refiere a los actos de lectura/escritura de textos algebraicos que hace un lector concreto con base en una red de relaciones textuales derivadas de sus experiencias matemática y lingüística previas; se observaron tres niveles de competencia de uso del SMS2 de los aprendices cuando se le pide resolver EG2 con una incognita.

El segundo estrato de intertextualidad: *Lectura/transformación de la estructura superficial de textos algebraicos,* se refiere a la manera en que los aprendices resuelven las EG2 (completas e incompletas) dadas, a partir del reconocimiento de su estructura superficial. Las transformaciones algebraicas se realizan entre un textos algebraicos en el nivel de la expresión algebraica, esto requiere también que el aprendiz identifique la estructura superficial de la ecuación y su transformación de la forma factorizada a la forma canónica o viceversa.

El tercer estrato de intertextualidad: *Lectura/traducción/transformación de textos*, se refiere a la resolución algebraica de PV mediante EG2 con una incógnita, al respecto es común recurrir al uso del MC, definido como el proceso de poner un problema en ecuaciones, que implica el proceso de traducción y las transformaciones algebraicas definidas en el segundo estrato de intertextualidad.

Se incluye una breve descripción y análisis de un episodio de entrevista clínica con enseñanza, realizada por el Investigador (I) con Fer (F), para ejemplificar el tercer estrato de intertextualidad "Lectura/traducción/transformación de textos" en la resolución de un PV.

I: El cuadrado de un número más el triple del mismo número nos da cincuenta y cuatro. ¿Cuál es ese número? y ¿cómo plantearías la ecuación?

F: ¡Pues, el primer número es equis, y más el triple del mismo número, entonces sería tres equis! [escribe con cierta separación x y $3x$ en el pizarrón, se queda observando y menciona…] pero como dice, el cuadrado de un número, elevamos al cuadrado equis, más tres equis igual a cincuenta y cuatro [escribe $(x)^2 + 3x = 54$], la ecuación es equis cuadrada más tres equis igual con cincuenta y cuatro, pero si el cincuenta y cuatro lo pasamos del otro lado y lo igualamos con cero, entonces nos quedaría…[Escribe $x^2 + 3x - 54 = 0$ y continuó con el proceso de resolución factorizando el trinomio de segundo grado escrito en el primer miembro de ecuación hasta encontrar los dos valores de equis ($x_1 = -9$, $x_2 = 6$)].

I: Bueno obtuviste dos valores, uno positivo y otro negativo y la pregunta del problema dice: ¿cuál es el número? Sin embargo, el PV refiere: el cuadrado de un número más el triple del mismo número nos da cincuenta y cuatro. ¿Qué valor consideras adecuado? [Fer se queda pensando]

F: Probaré primero sustituyendo el valor de seis en la ecuación $(x)^2 + 3x = 54$ [escribe $(6)^2 + 3(6) = 54$, $36 + 18 = 54$, obteniendo $54 \equiv 54$, después hace lo propio con el valor de -9, concluye diciendo que el valor buscado es seis].

En este episodio se puede observar un progreso significativo hacia la sintaxis algebraica, sus intertextos personales le permitieron realizar una lectura eficiente del enunciado del problema propuesto, evoca de manera verbal cómo realiza su razonamiento, esto le permite plantear la EG2 con una incógnita que representa la traducción correspondiente; los procesos de semiosis del estudiante dan cuenta de su competencia de uso del SMS2 en un nivel alto, así mismo, enuncia la respuesta correcta del problema, con base en haber realizado la comprobación de la igualdad de la ecuación sustituyendo los valores obtenidos de la incógnita, lo anterior, dota de sentido a los procedimientos algebraicos efectuados.

Conclusiones

En particular el ME utilizado en este estudio, permitió potenciar los procesos de semiosis, la intertextualidad y la producción de sentido en los sujetos de estudio, a partir de la manipulación de las piezas del Puzzle Algebraico, siendo útil para modelar de manera concreta las ecuaciones escritas en su forma canónica: $ax^2 \pm bx \pm c = 0$ donde $a, b, c \in Z$ y con ello, dar significado y sentido a las ecuaciones equivalentes obtenidas en dicho proceso de resolución de manera sintáctica con lápiz y papel, y que son escritas por el usuario competente del SMS2 en su forma factorizada: $(x \pm a)(x \pm b) = 0$, o bien, por el propio CAS.

Los resultados expuestos no son concluyentes, se requiere realizar estudios que profundicen más en los procesos de lectura/transformación y la consecuente producción de sentido por parte de los estudiantes, diseñando un ET que les permita evolucionar hacia la construcción de la sintaxis algebraica alrededor del MC de resolución de EG2, teniendo como base el uso de sus intertextos personales durante los procesos de semiosis a los cuales recurren para resolver como usuarios competentes del SMS2, los problemas verbales que se les propongan.

EXAMINING STUDENTS' REASONING ABOUT MULTIPLE QUANTITIES

Nicole Panorkou
Montclair State University
panorkoun@montclair.edu

Erell Germia
Montclair State University
germiae1@montclair.edu

In this report, we discuss five forms of reasoning about multiple quantities that sixth-grade students exhibited as they examined mathematical relationships within the context of science. Specifically, students exhibited forms of sequential, transitive, dependent, and independent multivariational reasoning as well as relational reasoning. We use data from whole-class design experiments with students to illustrate examples of each of these forms of reasoning.

Keywords: Cognition, Algebra and Algebraic Thinking, Design Experiment, STEM/STEAM.

Variation, Covariation, and Multivariation

Reasoning about variation and covariation has been studied extensively in mathematics education as a way of supporting students' mathematics learning (e.g., Confrey & Smith, 1995; Carlson et al., 2002). More recently, we found that the use of variation and covariational reasoning also supported students' learning of science phenomena, such as the learning of gravity and the greenhouse effect (e.g. Author, 2019; Author, 2020). Science phenomena involve a complex interaction of variables and this provided a constructive space for students to reason about covariation in more complex ways. In these studies, we found that by manipulating the quantities involved in those phenomena using interactive simulations and studying what quantities are changing and how they are changing, sixth grade students exhibited some sophisticated forms of covariational reasoning. Specifically, students coordinated the direction of change of one quantity with the change in another quantity and also identified the bi-direction of change of some of those quantities. Students even discussed inverse relationships, such that as one quantity increases, the other quantity decreases, and predicted the change of one quantity if another is varied multiplicatively. While analyzing our data, we found that students also reasoned about more than two quantities changing simultaneously. Prior research on multivariational reasoning only focused on undergraduate mathematics education (Kuster & Jones, 2019). Therefore, this provided an opportunity to examine students' emerging forms of multivariational reasoning in earlier grades. This effort could eventually respond to Thompson and Carlson's (2017) call for more contributions on defining the covariation construct. Specifically, we aimed to explore: *How do sixth-grade students reason about multiple quantities as they explore complex quantitative relationships in scientific phenomena?*

Theoretical Framework

We use a *quantitative reasoning* lens (Thompson, 1994) to discuss students' forms of reasoning about multiple quantities in the context of science. We use the term *quantity* as one's conceived attribute of an object or phenomenon that is measurable, whether they have carried out that measurement or not (Thompson, 1993; 1994). In this manner, numeric or not, reasoning quantitatively involves analyzing a situation into "a network of quantities and quantitative relationships" (Thompson, 1993, p.1). Accordingly, Kuster and Jones (2019) defined multivariation as a situation with more than two quantities that change in relation to each other. They used this definition to discuss three forms of multivariational reasoning that students exhibited as they explored differential equations: dependent, nested, and independent multivariation. Specifically, they defined *dependent multivariation* as involving at least three quantities that are interdependent with each other, in which a variation in one quantity simultaneously influences the change in other interdependent quantities. They gave the example of reasoning that since P is a function of time, P' is

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

also a function of time. They defined *nested multivariation* as involving a network of quantities, where the first quantity is embedded in the second quantity and the change in the second quantity influences the change in the third quantity. For instance, when the differential equation $P' = 2P+2t$ was presented, a student used nested multivariation to explain that a change in t influenced the change in $2t$, then variation in $2t$ changed P'. Finally, they defined *independent multivariation* as involving at least two quantities that are independent to each other and affect the change in another quantity. They gave the example of reasoning that the solution function $P(t)$ is dependent on t, but the rate of change, P', is not influenced by t. Although two independent quantities (t and P') are presented, we would argue that the example does not clearly show independent multivariation because the student does not clearly state that P' influences the function $P(t)$. However, we consider the types that Kuster and Jones presented to be foundational for initiating the discussion around the different forms of multivariational reasoning in the earlier grades.

Forms of Multivariational Reasoning

In this paper, we report on the data from whole-class design experiments (DEs) (Cobb et al., 2003) conducted in three different sixth-grade classrooms, each examining a specific scientific phenomenon: the sea level rise, the water cycle, and the rock cycle. We designed a simulation to dynamically model and study each scientific phenomenon. For example, in the rock cycle simulation students could manipulate a rock's depth and study the changes in its temperature and pressure. We accompanied the simulation exploration with questions that prompted them to reason about those quantitative relationships, such as "How would you describe the relationship between the quantities?" and "How does the change in one quantity affect other quantities?" In the following paragraphs, we discuss five forms of multivariational reasoning that students exhibited (Figure 1) by providing examples of students' episodes from all three DEs.

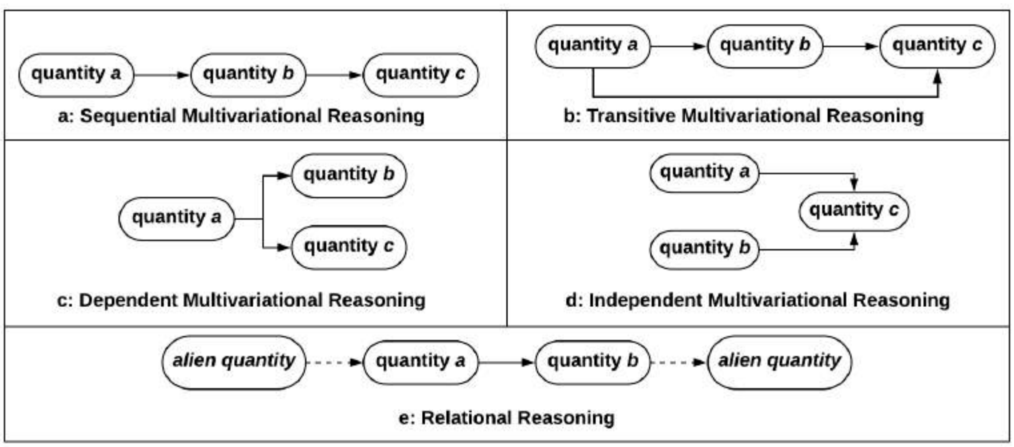

Figure 1: Forms of reasoning about multiple quantities.

Sequential Multivariational Reasoning

In students' articulations, we observed a form of multivariational reasoning that was not discussed in the Kuster and Jones' (2019) study. We refer to sequential multivariational reasoning (Figure 1a) as illustrating sequential changes in quantities, where a change in the first quantity (a) influences a change of the second quantity (b), and a change in the second quantity (b) affects a change in the third quantity (c). While exploring a simulation about sea level rise, students discussed the relationship between the global temperature rise, the height of future sea level, and the total land area. For instance, Myra explained that "The higher the global temperature, the higher the height of the future sea level, and the less the total land area." We interpret her reasoning to illustrate a sequential image of change: that the change in global temperature rise (quantity *a*) impacts the height of future sea level (quantity *b*), and that the change in height of sea level (quantity *b*) affects the change in total land area (quantity *c*).

Transitive Multivariational Reasoning

Our students also exhibited what we would define transitive multivariational reasoning (Figure 1b), a form of reasoning that supports that a change in the first quantity (*a*) leads to a change in the second quantity (*b*), and a change in the second quantity (*b*) in turn changes a third quantity (*c*), then a change in the first quantity (*a*) changes the third quantity (*c*). The difference between transitive reasoning and sequential reasoning is that the transitive reasoning involves the coordination of change in the first quantity (*a*) influencing a change in the third quantity (*c*), which is not illustrated in sequential reasoning. To illustrate this form of reasoning, we provide an example from the water cycle. The water cycle simulation presented a virtual ecosystem, in which students could manipulate the temperatures of air, mountain, land, and lake, and relative humidity and observe the change in the amount of water molecules in every phase of the water cycle. When asked to describe the relationship between evaporation and runoff, Ray stated, "If the rate of evaporation is higher, there could be higher rate of precipitation. If there's a higher rate of precipitation, there could be more runoff. So, the higher rate of evaporation, there can be more runoff." We consider Ray's coordination of the change in three quantities to illustrate transitive multivariational reasoning. In particular, Ray first explained how the change in evaporation (quantity *a*) influences precipitation (quantity *b*), and how the change in precipitation (quantity *b*) influences runoff (quantity *c*). Then he used those two relationships to reason about how a change in evaporation (quantity *a*) causes a change in runoff (quantity *c*).

Dependent Multivariational Reasoning

Our students also illustrated reasoning that we would characterize as a subset of Kuster and Jones' (2019) definition of dependent multivariational reasoning. In contrast to Kuster and Jones' definition in which all three quantities involved are interdependent, the students in our study coordinated a change in an independent quantity *a* which simultaneously affected changes in two dependent quantities *b* and *c*, while quantities *b* and *c* were not related to each other (Figure 1c). For example, when Michael was prompted to describe what he noticed as he explored the rock cycle simulation he stated, "I would say that, the deeper, the deeper you get, the higher the temperature is, and the higher the pressure is." We consider Michael's reasoning about the relationship of depth with the temperature and pressure to be dependent multivariational reasoning. Michael's language "the deeper" and "the higher" also shows an understanding of simultaneous change between the two dependent quantities (temperature and pressure) as influenced by one independent quantity (depth).

Independent Multivariational Reasoning

Our students exhibited independent multivariational reasoning, (Figure 1d), similar to Kuster and Jones' (2019) definition of coordinating a change in two independent quantities (quantities *a* and *b*) influencing the same dependent quantity (quantity *c*). For example, when Chloe and Justin were asked to use the water cycle simulation to release snow by manipulating only the air temperature and the land temperature, they reasoned that "We need both of them to be cold." Chloe explained that "if you just move for air temperature, it only snows a little bit, but if you put it with a land temperature, it starts to accumulate in the ground and it produces more." Chloe illustrated an example of independent multivariational reasoning as she coordinated the change of land temperature and air temperature as unrelated independent quantities with the change in snow as the dependent quantity.

Relational Reasoning

In addition to the above four types of multivariational reasoning, we also noticed instances where students related their explorations with quantities that were not part of the specific study. We refer to relational reasoning (Figure 1e) as the form of reasoning that connects the relationship of two quantities with a third quantity that students bring in from their prior experiences (what we refer to as an *alien* quantity). Relational reasoning can be expressed together with other forms, such as sequential multivariational reasoning. For instance, while exploring the water cycle simulation, we asked students to explain the model. Lorna connected the relationship between the amount of precipitation, runoff, and infiltration with the quantity of water that would go into the aquifers, which was not identified in the simulation or module. Lorna reasoned that "the more rain there is, there's more runoff. And the more runoff, the more water is going to go into the aquifers." Lorna first reasoned about the change in the quantity of rain with change the quantity of runoff. Then she coordinated the change in runoff with the amount of infiltrated water in the aquifer, an alien quantity to the simulation.

Conclusions

In 2017, Thompson and Carlson argued that while there are a wealth of studies employing variation and covariation as a framework for their investigations, these "do not contribute directly to defining the construct" (p. 427). Investigating how students may reason about more than two quantities makes a contribution to this call. The Kuster and Jones' (2019) study initiated a discussion about how we can define students' forms of multivariational reasoning. Our study built on their work to examine how students as young as sixth grade could reason about multiple quantities. By exploring the sequential and simultaneous variation of quantities involved in the water cycle, rock cycle, and sea level rise phenomena, students exhibited five different forms of reasoning about multiple quantities, namely sequential, transitive, dependent, and independent multivariational reasoning as well as relational reasoning.

The retrospective analysis showed that it was the students' interaction with the simulations and the probing questioning that provided a constructive space for them to study the variation in multiple quantities and reason multivariationally. Our initial goal in the study was to engineer opportunities for students to reason covariationally, therefore our tasks and questioning were restricted to only a few prompts to connect multiple quantities. In the next iteration of our design, we plan to engineer more opportunities of this type of reasoning. Through this process, we can examine the progression from covariational to multivariational reasoning and the tasks, tools, and questioning that assist students in exhibiting each specific form of reasoning about multiple quantities.

Acknowledgments

Research is mixed on whether understanding decimal magnitude supports operations with decimals or whether operations can be learned before and while students develop understanding of decimal magnitude. In the present study, we used a large scale, longitudinal design to investigate students' knowledge of decimal comparison and operation before and after decimal comparison alone was introduced in the curriculum. Student performance on a decimal comparison task did not increase, but there was an increase in performance on decimal subtraction and decimal multiplication tasks, topics which were not part of the mandated curriculum during the relevant period of instruction.

Keywords: Number Concepts and Operations, Rational Numbers, Elementary School Education, Cognition

Perspectives

Researchers examined various conceptual hurdles involved in meaningful interpretation and use of the notational system involving decimals (Resnick et al., 1989). Hiebert (1992) proposed three types of knowledge which are important to comprehend the decimal system: knowledge of the notation, knowledge of the symbol rules and knowledge of quantities and actions on quantities. The knowledge of notation comprises of "how the symbols are positioned on paper" (ibid, p. 290) rather than understanding of what '.' means or what quantities it represents. For instance, a student can compare two decimals correctly, but can have incorrect reasoning to explain their answers (see Resnick et al., 1989 for details on erroneous rules while comparing decimal numbers). The knowledge of the symbol rules prescribes on "how to manipulate the written symbols to produce correct answers" (Hiebert, 1992, p. 290). For instance, while adding and subtracting two or more decimals, the numbers need to be lined up systematically (Lai & Murray, 2015). This knowledge is analogous to Skemp's (1976) idea of instrumental understanding where an individual can manipulate mathematical syntactic symbols using appropriate rules, procedures, algorithms, etc. to produce the correct answer, even when without understanding the underlying reasons. Knowledge of quantities and actions includes the understanding of decimal numbers are representing quantities, i.e., measures of objects "…by units, tenths of units, hundredths of units, and so on" and comprehending the reasons that explain "what happens when the quantities are moved, partitioned, combined, or acted upon in other ways" (Hiebert, 1992, p. 291). Lai and Murray (2015) related the knowledge of quantities and actions on quantities with developing a comprehensive understanding of the decimal topics.

Decimal Comparison

Students build on whole number ideas when they engage with decimals, and this both helps and hinders learning. Lee and colleagues (2016) argued that due to the representational nature of decimal numbers, which is virtually indistinguishable from that of whole numbers, the students find decimal magnitude comparison tasks easier as compared to the fraction magnitude (see also, DeWolf et al., 2014; Iuculano & Butterworth, 2011). Researchers claim that students often perform well on the decimals comparison tasks by following syntactical rules (Lachance & Confrey, 2002), rather than developing a conceptual understanding of it. However, the common practice of teaching decimals as

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. an extension of the whole numbers might convey an inadequate understanding of place-value system (Fuson, 1990; Martinie, 2014).

Sequence of Decimal Instruction

In the United States, decimal instruction begins in the fourth grade with comparisons of fractions written in decimal form with denominators of 10 and 100. A decimal is regarded as the one-dimensional magnitude of a fraction (a/b = c) expressed in the form of the standard base-10 metric system (Lee et al., 2016). This continues in fifth grade with decimal operations to the hundredths place (National Governors Association Center for Best Practices, 2010). Decimal instruction then continues through middle school (Rittle-Johnson et al., 2001).

Although curricula frequently sequence decimal comparison instruction before operations, there is little research available to support this sequence. The magnitude-before-computation sequence is supported for fractions and standards and curricula appear to follow it for decimals based on the idea that fractions and decimals are closely conceptually related, even though there has been very little research on this instructional order. Arguments for teaching decimal magnitude before tackling operations between decimals numbers are formed by research that shows that children who are less comfortable with fraction magnitudes are also not as good as their counterparts at computations involving fractions (Lortie-Forgues et al., 2015). Other researchers note that students can understand decimal magnitude without being able to understand the results of computations involving decimals, which implies that understanding decimal magnitude is a prerequisite for decimal operations (Siegler & Lortie-Forgues, 2015).

Decimal Comparison and Operations with Decimals

Even though decimal magnitudes are taught first and operations second, the concepts appear to be intertwined in the minds of students. Decimals are familiar to students before they reach fourth grade to some degree because they follow some of the whole number rules, even though students often misapply those rules for comparing and computing with decimals (Ren & Gunderson, 2019; Rittle-Johnson et al., 2001; Vamvakoussi & Vosniadou, 2004). As students make sense of decimals in school, they begin to apply what they understand to computation even if they have not been explicitly taught to do so. Hiebert et al. (1991) showed that children could learn about decimal concepts and structure and still show growth on decimal computation with symbols without detailed instruction on procedures. Other research has found that intermingling work on decimal place value with decimal addition and subtraction results in strong student performance, which is opposite of the assumptions surrounding magnitude-first instruction (Rittle□Johnson & Koedinger, 2009). Given the mixed findings from past research that has mostly relied on small-scale qualitative data, in the present study, we used a large scale, longitudinal design to investigate students' knowledge of decimal comparison and operation before and after it was introduced in the curriculum. In particular, we sought to answer two research questions. (1) *How does knowledge of decimal comparison and operations with decimal change during the year in which decimals are formally introduced in the curriculum?* (2) *Are the patterns that characterize students' responses at each time point more indicative of magnitude-before-operation or intermingled learning in the decimal domain?*

Methods

The data is drawn from a larger study that included a representative sample of Grade 4 elementary teachers in Indiana. These teachers administered 8-item tests to their Grade 4 students (N = 1467) in the Fall of 2017 and Spring of 2018, and the data we report comes from three items on that test. The participation in this survey was voluntary for the students and they were given 15 minutes to work on the test. McNemar's test was used to compare the pre-test and post-test results of the same students in grade four at two different points in the school year, so we had matched pairs of subjects with a dichotomous trait of correct or incorrect for each question. We used alluvial diagrams to search for patterns in pretest and posttest responses.

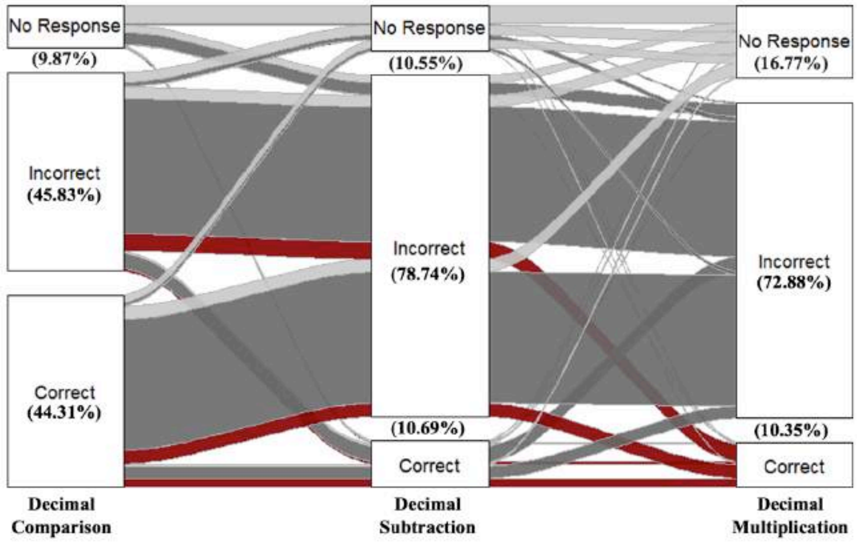

Figure 1. Pretest weighted flow of participants between response categories.

Results

An exact McNemar's test was used to compare the two conditions (correct and incorrect) on the pre- and post-test over fourth-grade fraction and decimal knowledge. The change in the number of students who correctly answered the comparison question from the pretest to the posttest was small, 44.31% to 45.07%. The analysis showed that there was not a statistically significant positive change between the pre- and post-test for ordering decimals from smallest to largest (p = 0.689). Of the 1,467 students who took the pre- and post-tests, 642 answered the ordering question correctly on the pre-test and 653 answered correctly on the post-test.

In contrast, there was a larger change in the number of students answering the decimal subtraction question correctly on the posttest from 10.67% to 28.57%, and this change was a statistically significant (p = 0.000). For decimal addition, 155 students answered correctly on the pre-test and 414 answered correctly on the post-test. For the decimal multiplication question, the increase was more modest, from 10.35% answering correctly on the pretest to 17.53% answering correctly on the posttest. Similar to the decimal subtraction problem, this increase statistically significant (p = 0.000). In the decimal multiplication question, 150 students answered correctly on the pre-test and 254 answered correctly on the post-test. The students' performance differences between the decimal magnitude question and the operation questions shows that as a group the students improved in their ability to operate on decimals without substantially increasing their understanding of decimal comparison.

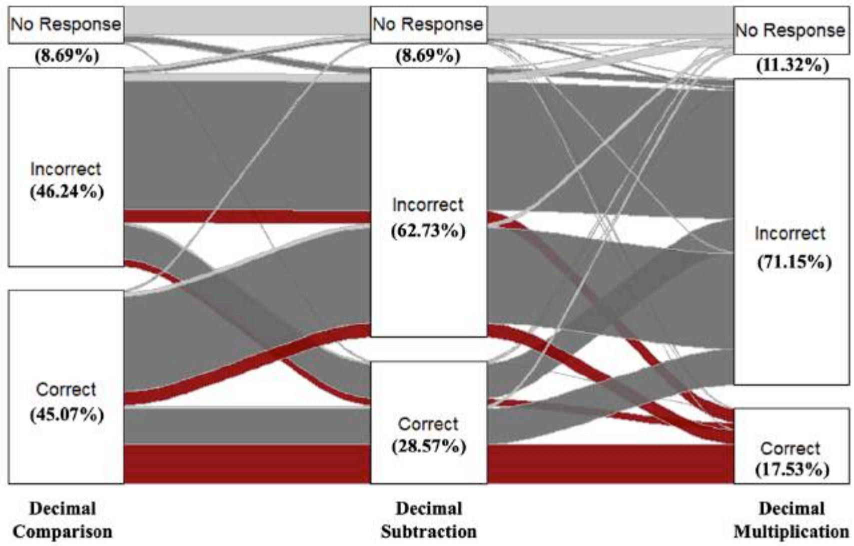

Figure 2. Posttest weighted flow of participants between response categories.

We examined the relationship between responses on these three items and compared these patterns of responses between the pretest and posttest. The alluvial diagrams below show weighted flows among the three decimal questions on the pre- and posttests from the first decimal question about comparing decimals, through the subtraction question, and then to the multiplication question. These diagrams illustrate how responses to decimal items early in the test were related to responses later in the test at each time point. In particular, although the number of students who answered the comparison question did not significantly increase at posttest, a much larger portion of those students went on to answer the two operation questions at posttest than at pretest (see large ribbon at the bottom of Figure 2).

Discussion and Implications

We expected that fourth grade students would show more growth on decimal comparisons than decimal operations in fourth grade because decimal comparison is a fourth-grade standard and decimal operations are a fifth-grade standard. Students were presumably receiving more instruction on magnitude comparisons than on decimal operations. What we saw instead was that growth in decimal comparisons was not statistically significant yet growth in decimal operations (subtraction and multiplication) were statistically significant. Furthermore, by comparing the patterns between items at each time point we noticed that a majority of the students who answered the multiplication question at posttest also answered the comparison and subtraction problems, suggesting most of the change from pre to post was driven by a cohort of students who solidified their understanding of operations during the year in which comparison was taught. These findings confirm at scale what other researchers have found in small, qualitative studies; namely, that the conceptual development of both comparisons of magnitude and operations happen concurrently rather than sequentially.

LEVEL-ZERO COVARIATIONAL REASONING IN SECONDARY SCHOOL MATHEMATICS

José Ramón Jiménez-Rodríguez
University of Sonora, México
jimenez@mat.uson.mx

Based on the results from a research project currently in progress, we outline the hypothesis that exhaustive mathematical study of the behavior of a single variable quantity (E1VQ) constitutes, by itself, a whole cognitive structure (in the Piagetian sense) underlying the development of variational thinking, and that it can and should be fully addressed in secondary education, during and in parallel with the study of representation of numbers and quantities on the number line (a variable quantity – a number axis). This would allow the student to develop a series of conceptual (qualitative) images and quantitative mathematical tools that allow identifying, describing and naming the basic types of variational behavior of a variable quantity.

Keywords: Algebra and algebraic thinking, variable quantities, variational thinking.

Introduction

The ideas addressed in this work are the collateral product of a research project that aims to contribute arguments of a historical, epistemological and cognitive nature in efforts to reconceptualize the teaching of Calculus for non-mathematicians (Jiménez et al., 2020). These ideas point, on the one hand, to the need to promote early development of a variational way of thinking in secondary and high school students, and on the other, to rethink the vision under which the variational approach is embodied in the curriculum of these educational levels. These ideas are presented here as working hypotheses that require a great subsequent effort in educational research, either to corroborate, reject and modify them, or to develop a greater knowledge.

Variational Thinking Conception

The research literature has long documented the difficulties that many students experience in understanding and constructing Cartesian graphs and developing a variational way of thinking (Radford; 2009a, 2009b). In our opinion, one of the epistemological roots of such difficulties consists in the very interpretation of what *variational thinking* is. It is a term whose meaning has not yet been established in a clear and concise way, not to say precise and rigorous, as is typical of scientific work. Different research groups, affiliated with different theoretical approaches, assume their particular interpretation of the meaning of this notion (Vasco, 2010).

In this work, the term ***variational thinking*** refers to the type of mathematical thinking required to understand variation and *change in progress* (Thompson, Ashbrook, & Milner, 2016), and it develops and evolves as the study of such phenomenology occurs. This way of thinking is both *qualitative* (it implies the construction of dynamic images of variation and the reasoning about them, as well as the development of a language that reflects this dynamism) and *quantitative* (it has to do with numerical calculations, techniques and algebraic expressions).

By its nature, the way of thinking that a mathematical study of change in progress requires is a complex entity that we can conceive of as consisting of two components that Thompson and Carlson (2017) have respectively called *variational reasoning* and *covariational reasoning*. These are complementary aspects of the same type of mathematical thinking, which have to do with the mathematical conceptualization of variable quantities.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Variational Reasoning

Variational reasoning consists of two critical moments. The first is to understand that variable quantities actually *vary*, that is, their numerical values change. Consequently, it is a *dynamic* way of thinking. Thus, this first moment, characterized by the fact of perceiving or conceiving, in a given situation of change, the intervention of one, two, three, four, etc., variable quantities (one of which may be time), and to inquire how they change in order to form dynamic mental images of their ways of changing, to create mathematical tools to represent and quantify such changes, to develop an appropriate language for describing those changes, and much more, is what constitutes the essence of variational reasoning.

There is an important aspect in conceptualizing a variable quantity that has an intuitive connotation. It is the fact that the numerical value a variable quantity takes at each moment is unique: it is not possible for a variable quantity to take two or more different numerical values at the same moment. This essential characteristic of the behavior of variable quantities is known as the *uniqueness principle*.

The second crucial moment in variational reasoning is in some sense an aesthetic appreciation: when a variable quantity changes, it does so smoothly. This "smoothness" is a quality of the processes of change in progress called *continuity*. Time runs smoothly from one instant to the next in an interval; an athlete running moves smoothly from one point to another in the path, and the height of the liquid changes smoothly as a container fills (or empties). The whole process is continuous, since it is continuous at every moment. Usually the process of change-in-progress is continuous, in the sense that it changes smoothly from one state to the next.

The *principle of continuity* is not exclusive to the movement of objects or filling/emptying of containers, but applies to all natural processes. As a process develops, it does not omit any state in its becoming. If the process is in one state at a certain time, and in another state at a different time, then it assumes all states between these two.

In summary, variational reasoning has to do with the mathematical conceptualization of continuous variation of a single variable quantity, this variation having a temporal background.

Covariational Reasoning

The second important stage in variational thinking is to make explicit the fact that in the analyzed situation there are at least two variable quantities present, whose numerical values change simultaneously, and are also related in some way. In this case, the ability to *coordinate* the joint change of these numerical values is crucial for the next level of analysis. Carlson et al. (2002) call this more complex way of thinking as *covariational reasoning*, and characterize it as the set of all "cognitive activities involved in the coordination of two variable quantities while considering how they change in relation to each other". In other words, covariational reasoning about quantities implies the consideration and/or construction of dependency relationships between numerical values of at least two variable quantities that change simultaneously and jointly.

The Early Development Of Covariational Reasoning: Level-Zero

It follows from the previous descriptions that covariational reasoning is cognitively and mathematically much more complex than variational reasoning and that, in order to develop in students the ability to reason covariationally, it is not only desirable but above all it is also ***necessary*** to previously develop their more elemental ability to reason variationally, that is, to reason mathematically about a single variable quantity. Despite this, educational research seems to assume as an unquestionable fact that variational reasoning is simple, unproblematic, natural and spontaneous, and that we should not be concerned with its development. In the overwhelming majority of research work on the subject, the student is involved from the very first moment with mathematical tasks typical of the level of covariational reasoning. The results of our own research point in another direction, suggesting that mastering mathematical work with variable quantities on the number line seems to be a fundamental prerequisite for subsequent work with two number lines in the Cartesian plane. In other words, variational reasoning is related to mathematical work with a single variable quantity on the number line, while elementary covariational reasoning is related to mathematical work with two variable quantities on the Cartesian plane.

Although we know that variable quantities never appear separately in the phenomena of the world in which we live in, isolating and studying them in this way seems to us a justified didactic decision, for several reasons. First, it is a relatively simpler cognitive task, since it does not require the explicit coordination of two variable quantities.

The second argument for first addressing the analysis of a single variable quantity, isolated from the others, is based on the historical development of scientific methodology itself. A methodological strategy to understand complexity is to consider simpler cases of it. The number line is a simpler object than the Cartesian plane.

Our third and main argument is that the basic mathematical ideas required for the coordination of two variable quantities can and should be developed in depth in this simplified, foregoing, hypothetical case (the study of a variable quantity in isolation from the others). Unfortunately, there is no place here to show that this is possible and that it does indeed contain great mathematical richness. In another work (Jiménez et al., work in progress) we argue that, in particular, it is possible to form and develop the mathematical images, tools and terminology necessary to describe and conceptualize the seven basic variational behaviors (uniform growth, accelerated growth, decelerated growth, uniform decrease, accelerated decrease, decelerated decrease, and zero growth or decrease), with a level of complexity similar to that of the case of covariation. Likewise, it is possible to approach some of the advanced ideas of Calculus, such as a first approach to derivatives of higher order and the Fundamental Theorem of Calculus. An outline of such approach is presented in Jiménez et al. (2020).

A cardinal statement of this work is the thesis that *exhaustive mathematical study of the behavior of a single variable quantity* (E1VQ) constitutes, by itself, a whole cognitive structure (in the Piagetian sense, 1968) on which the further development of covariational reasoning relies. A deep understanding of the behavior of a single variable quantity, its description in mathematical terms and its dynamic graphic representation on the number line are relevant and structural for the formation and development of variational thinking, both from a mathematical and a cognitive point of view. In particular, they are fundamental for understanding, interpreting, endowing with meaning and constructing graphs in the Cartesian plane. This is the initial step in the development of variational thought. Given that the process of development of covariational reasoning, according to the terminology proposed by Carlson et al. (2002), has been described in terms of five levels (called L1, L2, L3, L4 and L5), we have decided to name *level-zero* (L0) the corresponding stage of emergence and development of variational reasoning described above.

Related to this, it is sensible to assume that the development in students of a dynamic image of the variable, as well as of a dynamic meaning for it, is possible only relying on a specific mathematical work on the number line, provided that such mathematical work involves the representation of variable quantities and not only of numbers (Jiménez et al., 2020). However, as Thompson and Carlson (2017) rightly pointed out:

> ... there is relatively little research on students' meanings and understandings of number lines. Psychological research in this regard portrays number lines as nebulous objects on which researchers presume that people do informal arithmetic (...), the main interest being by what method people use it to determine sums, products, and so forth. Mathematics education research seems to see the target idea of a number line as being relatively unproblematic and

> focuses on using it as an instructional aid, helping students understand how to locate numbers on it, or using it as a tool in reasoning (...). In both cases, number lines seem to be taken by researchers as lines full of numbers. (Thompson and Carlson, 2017)

The study of the number line is certainly included in the school curriculum, but unfortunately not from the variational point of view. Students learn how to represent numbers by points on the number line, and to associate points with numbers (the coordinates), to identify line segments (intervals), etc. This mathematical work is essentially static in nature. But they never learn how to *represent variable quantities on the number line*, much less how to developn it in dynamic graphic images associated with the different basic variational behaviors, or how to develop and use mathematical tools that allow them to deepen the analysis of the behavior of variable quantities. The number line itself is not a constructed object; it is presented to students as a prefabricated object.

This does not imply that the mathematical work on the number line stipulated by the current curriculum is unnecessary and must be eliminated. On the contrary, it is adequate and necessary, although clearly ***insufficient*** to favor the formation and development of variational reasoning in students. For the latter, it will be necessary to incorporate another type of mathematical work on the number line, of a dynamic nature, related to graphic representation of variable quantities. This implies engaging in a deeper reflection on the construction of the number line itself.

Acknowledgments

The author thanks the support of the Division of Exact and Natural Sciences of the University of Sonora under Research Project USO315006052 that gave birth to this work. Likewise, he thanks the comments, observations and critical suggestions of his colleagues on the Project team, Fabio Augusto Milner (Arizona State University), Agustín Grijalva Monteverde, María Teresa Dávila Araiza and César Fabián Romero Félix, of the University of Sonora.

This paper reports the manner in which primary school students from a Mexican public school, having just learned to validate the truth-value of numerical equalities (e.g., 8+2+16=10+12+4) based on two algebraic strategies, that is, transforming both sides of the equality to a third common form, and rewriting one side of the equality in the same form as the other side – both strategies being based on decomposing, composing, and recomposing the numbers – tended to favor the first strategy as their primary approach for validating numerical equalities. This tendency suggests that, although the students have developed an algebraic thinking based on structure sense in arithmetic, the second strategy would appear to be less consolidated than the first.

Keywords: Algebra and algebraic thinking; Structure sense in arithmetic; Decomposing, composing, and recomposing numerical expressions and equalities.

Background

Algebraic thinking in primary-grade students has been studied from different perspectives, although an emphasis on generalization has prevailed. Recently, it has been proposed that, in addition to generalizing, seeking and expressing structure is an important part of this kind of mathematical thinking (Kieran, 2018). Regarding the structural, some studies have focused on observing regularities in numerical equalities (e.g., Pang & Kim, 2018; Schifter, 2018). However, according to Mason, Stephens, and Watson (2009), structural thinking involves more than observing regularities. In this sense, Martínez-Hernández and Kieran (2018, 2019, in press), in their studies on structure sense in arithmetic, have reported on the strategies that primary school students use to validate numerical equalities. They found that these students tended at first to use computational strategies to validate numerical equalities of the form $a+b=c+d$ (Martínez-Hernández & Kieran, 2018); however, they were also able to use *ad hoc* strategies on the same kind of equalities, based on decomposing the given numbers (Martínez-Hernández & Kieran, 2019). According to Martínez-Hernández and Kieran (in press), the students were able to transition from an arithmetical thinking expressed by computational strategies to an algebraic thinking expressed by the decomposition, composition, and recomposition of the given numbers, using two strategies: (i) transforming both sides of a numerical equality to a third common form; and (ii) rewriting one side of a given equality in the form of the other side. Based on the emergence of these two strategies, the following question is posed: Which of these two strategies do the students tend to use in order to validate numerical equalities for which they previously used computational or ad hoc strategies?

Theoretical Framework

Early algebra has been characterized from different perspectives (e.g., Carraher & Schliemann, 2007; Kieran, 2018), but all of them recognize the algebraic character of arithmetic. According to Kieran (2004), algebraic thinking in the early grades involves the development of ways of thinking within activities for which the letter-symbolic could be used as a tool, or alternatively within activities that could be engaged in without using the letter-symbolic at all, for example, noticing structure. Recently, Kieran (2018) has emphasized and suggested that more attention be paid to the structural.

Structure in Numbers and Numerical Operations

According to Kieran (2018), the learning of high school algebra has included a focus on the structural aspect (e.g., Hoch & Dreyfus, 2004, Linchevski & Livneh, 1999) much more so than has been the case for early algebra. Kieran suggests that structure sense in arithmetic entails more than attending to the basic field properties. Structure sense in arithmetic involves looking through mathematical objects and decomposing and recomposing them in several structural ways. Based on Freudenthal (1983, 1991, cited in Kieran, 2018), Kieran proposes that the structure in numbers and in numerical operations is explained by the fact that the number system constitutes an order structure, in which, for each pair of numbers, a third number, for instance, its sum, can be assigned, thereby constituting an addition structure. Similarly, the multiplicative structure can be defined. Accordingly, expressing structure sense in arithmetic implies being aware of the different structural forms that numbers and numerical operations can take, for example, observing that the number 989 can be rewritten equivalently as 9x109+8 and as 9x110-1, also as $9x10^2+8x10^1+9x10^0$, among others.

In this way, Kieran (2018) suggests promoting in students, from the early grades, various experiences with equivalence of numerical expressions through the structuring processes of decomposing, composing, and recomposing. And, in line with Freudenthal who describes different means of structuring according to a variety of structures and properties, numbers and numerical operations can be decomposed and recomposed to show equivalence without calculation and involving properties related to, for example, the addition structure and the properties of equality. Thus, validating the truth-value of numerical equalities such as 67+86=68+85 by decomposing, composing, and recomposing the involved numbers implies re-expressing them in different forms, such as 67+86=60+7+1+85 and 68+85=60+7+1+85, and so it is true that 67+86=68+85.

Method

Participants

In the study, three students (S1, S2 and S3) from a Mexican public school participated, ages between 11 and 12 years. When data were collected, the students had just finished primary school. The three participants are the same students that were reported in Martínez-Hernández and Kieran (2018, 2019, in press).

Task Design and Data Collection

The study involved the design of four tasks. The focus in this paper is the fourth task, which asked students to indicate the truth-value of three numerical equalities (10+7=5+12, 530+200=300+430, and 8+2+16=10+12+4), without calculating the total of each side. The structure of the task for each of the equalities is the following:

- A true numerical equality is presented
- Students are asked to show, without calculating the total of both sides, that the equality is true.
- Students are asked for an explanation of their procedure.

The data were collected through a group interview, conducted by the first author of this paper. During the interview, each student was given the printed task sheet, which they first worked on individually for each given equality, followed by a group discussion of their answers. During the full interview, students had the opportunity to use the blackboard to explain their approaches.

Results and Discussion

When students had finished answering with respect to the veracity of the three equalities (10+7=5+12, 530+200=300+430, and 8+2+16=10+12+4) and after developing the two strategies based on decomposing, composing, and recomposing the given numbers [i.e., (i) looking for a third common form, observed when they validated 530+200=300+430 and 8+2+16=10+12+4; and (ii) transforming one side of the equality into the same form of the other side, which was observed when they validated 8+2+16=10+12+4 (see Martínez-Hernández & Kieran, in press)], they were asked to validate the equalities 10+7=5+12 and 530+200=300+430 once again. The reason for this was that the students had not used the above strategies to validate the initial equality 10+7=5+12 – they had first relied upon a computational strategy, which was followed by an *ad hoc* decomposition that had not involved an attempt to have the same numbers on both sides (see Martínez-Hernández & Kieran, 2019).

Episode 1

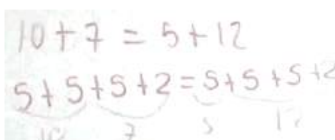
To investigate which of the two strategies based on structure sense would be used by the students, the Interviewer (I) asked them to show the veracity of the first given equality. See this episode in the following excerpt.

I: Let me go back to the first two equalities [Writes on the board 10+7=5+12]. How can it be re-expressed?

S1 and S3: Me, me, [Both want to go to the blackboard].

I: S1, go ahead, please. How could you tell this is true, without adding?

S1: [Writes on the board 5+5+5+2=5+5+5+2, see Fig. 1, left]. This [pointing to the 5+5 at the left side of the equality] I would take from the 10. This [pointing to 5+2 on the left side] from the 7. This [pointing to the 5 on the right side from the equality] from 5, and this [pointing to 5+5+2] from the 12.



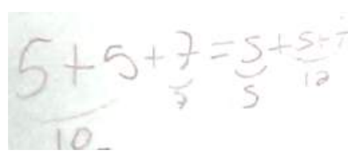


Figure 1: S1's decomposing strategy (left) and S3's (right)

As observed in Fig. 1 (left), S1 decomposes both sides of the equality into a third common form (5+5+5+2), and explains where each number comes from. In the same way, S3 proposes another decomposition (Fig.1, right) based on the same idea – also explaining where each number comes from in the rewritten equality.

Episode 2

In reaction to the students' behavior described in Episode 1, the interviewer asks them directly about the possibility of transforming the left side into the right side (or vice versa). The following excerpt presents the unfolding of the episode.

I: Finally, I am going to redo [Writes 530+200=300+430 on the board]. Can it be rewritten? You have already done this, but tell me how to do it in another way. This [Referring to the expression 530+200], for example, can it be rewritten in this way [pointing to the expression 300+430]? Or this [pointing to 300+430] in this way [pointing to 530+200]? How would you do it?

S3: Oh, yes, yes!

I: Go ahead S3

S1: Transforming

I: Tell us S1. Transforming how?

S1: By doing just as S2 and S3 just did [Referring to the strategy to validate 8+2+16=10+12+4; see Martínez-Hernández & Kieran, in press)]

S3: [Goes to the blackboard] I subtract 200 from this one [pointing to 530] to make it into 300, and add the 200 to this one [pointing to 200] to make it 430. Hold on, no! 230 [Finally writes the equality 300+430=300+430, see Fig. 2, left].

I: This [pointing to the left side 300+430 written by S3], where did it come from?

S3: From 530, I subtract 230 and add it to 200, so I get 430.

Figure 2: Rewritten equality by S3 (left); interpretation of his strategy (right)

As observed in the excerpt and in Fig. 2 (left), S3's strategy can be interpreted as follows: The left side is decomposed into 300+230+200 and then recomposed as 300+430; note that he does not have to transform the right side (see Fig. 2, right). The strategy in Episode 2 is based on a simultaneous relation that is discerned between both right and left sides of the given equality, which is not the case for the strategy in Episode 1. In other words, this strategy does not involve an arbitrary decomposing and recomposing of the left side; rather it is guided by the form of the right side.

Conclusions

According to the results, on the one hand, students tend to look for a third common form, by decomposing both sides of an equality (Episode 1) in order to validate the truth-value of numerical equalities. Hence, this strategy replaces the initial computational strategy that was spontaneously used by them at first (see Martínez-Hernández & Kieran, 2018). On the other hand, the Episode 2 strategy emerged from explicit interviewer intervention. As indicated by Martínez-Hernández & Kieran (in press), this second strategy would seem to be cognitively more demanding than the first one. In any case, both strategies go beyond that of simply observing regularities in equalities (e.g., Pang & Kim, 2018; Schifter, 2018) and therefore offer new findings with respect to the development of structure sense in numerical activity. As seen in the example of S3's work (Fig. 2), his way of decomposing, composing, and recomposing the numbers to transform one side of the equality into the form of the other side illustrates not only relational thinking based on structure sense but also the structural approach proposed by Kieran (2018) that involves looking through mathematical objects and expressing them in different structural forms. As a final comment, we envisage expanding the research so as to study the ways in which students understand the similarities and differences of their strategies.

Université du Québec à Montréal
kieran.carolyn@uqam.ca

Este reporte da cuenta sobre cómo alumnos de primaria de una escuela pública Mexicana, una vez que son capaces de validar la veracidad de igualdades numéricas (e.g., 8+2+16=10+12+4) a partir de dos estrategias: transformar ambos lados de la igualdad en una tercera forma común, o reescribir un lado de la igualdad en la forma del otro lado–ambas relacionadas con la descomposición, composición y recomposición de los números– tienden a utilizar la primera de éstas como su opción inicial de validación de igualdades numéricas. Tal comportamiento de los alumnos indica que si bien muestran un razonamiento de tipo algebraico basado en un sentido de estructura en aritmética, su segunda estrategia no está suficientemente consolidada.

Palabras clave: Álgebra y pensamiento algebraico; Sentido de estructura en aritmética; Descomposición, composición y recomposición de expresiones e igualdades numéricas.

Antecedentes

El pensamiento algebraico en edades tempranas ha sido estudiado desde diferentes perspectivas, aunque ha imperado un énfasis en la generalización. Recientemente, ha sido propuesto que, además de lo general, el sentido de estructura es también parte importante de este tipo de pensamiento matemático (Kieran, 2018). Sobre lo estructural, algunos estudios se han enfocado en la observación de regularidades en igualdades numéricas (e.g., Pang & Kim, 2018; Schifter, 2018). Sin embargo, de acuerdo con Mason, Stephens y Watson (2009), un pensamiento estructural es mucho más que tal característica. En este sentido, Martínez-Hernández y Kieran (2018, 2019, en prensa), sobre el sentido de estructura en aritmética, han reportado estrategias de validación de igualdades numéricas que muestran alumnos de primaria. Los alumnos suelen utilizar estrategias de cómputo para validar igualdades numéricas de la forma $a+b=c+d$ (Martínez-Hernández & Kieran, 2018) y son también capaces de utilizar estrategias *ad hoc* para validar el mismo tipo de igualdades, basados en la descomposición de números (ver Martínez-Hernández & Kieran, 2019). En Martínez-Hernández y Kieran (en prensa) se muestran cómo los estudiantes transitan de un pensamiento aritmético manifestado en estrategias de cómputo hacia un pensamiento de tipo algebraico basado en un sentido de estructura; manifestado en la descomposición, composición y recomposición de los números, a través de dos estrategias: (i), transformar ambos lados de una igualdad numérica en una tercera forma común, y (ii) reescribir un lado de la igualdad en la forma del otro lado. A partir de estas, surge la siguiente pregunta: ¿Cuál de las dos estrategias aplican para volver a validar igualdades en las que previamente utilizaron estrategias de cómputo o bien aplicaron una estrategia *ad hoc*?

Marco Teórico

El algebra temprana ha sido caracterizado desde distintas perspectivas (e.g., Carraher & Schliemann, 2007; Kieran, 2018), en todas se reconoce el carácter algebraico de la aritmética. Sobre el pensamiento algebraico en edades tempranas, Kieran (2004) menciona que éste trata sobre el desarrollo de formas de pensamiento en actividades en las cuales el aspecto simbólico-literal puede usarse como herramienta, o alternativamente, en actividades que no requieren lo simbólico-literal, por ejemplo, observar la estructura. Recientemente, Kieran (2018) ha enfatizado y sugerido una mayor atención al aspecto estructural.

La Estructura en los Números y en las Operaciones Numéricas

De acuerdo con Kieran (2018) en el aprendizaje del álgebra, la importancia del aspecto estructural ha sido tomado en cuenta con amplitud (e.g., Hoch & Dreyfus, 2004; Linchevski & Livneh, 1999, Mason, Stephens & Watson, 2009), no así en el caso del álgebra temprana. En este sentido, Kieran propone que el sentido de estructura desde la aritmética implica mucho más que la estructura numérica basada en las propiedades de campo. El sentido de estructura en aritmética involucra observar a través de los objetos matemáticos, descomponerlos y recomponerlos en diferentes formas estructurales. Con base en planteamientos de Freudenthal (1983, 1991, citado en Kieran, 2018), Kieran propone que la estructura en los números y las operaciones se explica en el hecho de que el sistema de los enteros constituye una estructura de orden, en la cual, a cada par de enteros, un tercer número, por ejemplo su suma, les puede ser asignado, constituyendo así una estructura aditiva. De manera similar se define una estructura multiplicativa. Así, manifestar un sentido de estructura en aritmética implica ser consciente de diferentes formas estructurales que los números y las operaciones numéricas pueden tomar, por ejemplo, observar que el número 989 se puede reescribir como 9x109+8, 9x110-1, o bien como $9\text{x}10^2+8\text{x}10^1+9\text{x}10^0$, entre otras.

De esta manera, Kieran (2018) sugiere promover en los alumnos, desde los primeros grados escolares, la experiencia de la equivalencia de expresiones numéricas a través de la descomposición, recomposición y sustitución. En línea con Freudenthal, quien describe diferentes formas de estructurar, acorde a la variedad de estructuras y propiedades, los números y las operaciones numéricas pueden ser descompuestas y recompuestas para mostrar la equivalencia sin realizar cálculos y considerando propiedades relacionadas, por ejemplo, la estructura aditiva y las propiedades de la igualdad. De esta manera, para validar la veracidad de igualdades como 67+86=68+85 mediante la descomposición, composición y recomposición de los números involucrados implica re-expresarla en diferentes formas, por ejemplo: 67+86=67+1+85 y 68+85=60+7+1+85, por lo que 67+86=68+85 es verdadera.

Método

Participantes

Participaron en el estudio tres alumnos (S1, S2 y S3) de sexto grado de primaria de una escuela pública de México, de entre 11 y 12 años de edad; quienes al momento de la toma de datos estaban culminando su educación primaria. Los tres alumnos son los mismos participantes reportados en Martínez-Hernández y Kieran (2018, 2019, en prensa).

Diseño de la Tarea y acopio de datos

El estudio incluyó el diseño de cuatro Tareas. La aquí analizada corresponde cuarta, esta versa sobre mostrar la veracidad de tres igualdades sin calcular el total de cada lado (10+7=5+12, 530+200=300+430 y 8+2+16=10+12+4). La estructura de la Tarea para cada igualdad es:

- Una igualdad numérica es presentada
- Se solicita a los alumnos mostrar, sin calcular el total en ambos lados de la igualdad, que la igualdad es verdadera
- Se les solicita una explicación de su procedimiento

La recopilación de datos se llevó a cabo mediante una entrevista grupal, conducida por el primer autor (E, en adelante) de este reporte. Cada alumno contó con la tarea impresa, en la cual, los alumnos trabajaron primero de manera individual para cada igualdad dada, seguido por una discusión grupal de sus respuestas. En todo momento los alumnos tuvieron la oportunidad de pasar a un pizarrón para explicar sus procedimientos.

Resultados y Discusión

Al terminar los alumnos de responder sobre la veracidad de las tres igualdades (10+7=5+12, 530+200=300+430 y 8+2+16=10+12+4) y después de que desarrollaron dos estrategias basadas en la descomposición, composición y recomposición de los números de las igualdades dadas [i.e., (i) sobre la búsqueda de una tercera forma común, observada cuando validan 530+200=300+430 y 8+2+16=10+12+4, (ii) transformación de un lado de la igualdad en la misma forma del otro lado, observada cuando validan 8+2+16=10+12+4 (ver Martínez-Hernández & Kieran, en prensa)] les fue solicitado validar de nuevo las igualdades 10+7=5+12 y 530+200=300+430. Ello se debe a que no utilizaron tales estrategias para validar la igualdad inicial 10+7=5+12 – en esta, emplearon primero una estrategia de cómputo, y después, una estrategia de descomposición *ad hoc*, en la cual no buscan los mismos números en ambos lados (ver Martínez-Hernández & Kieran, 2019)

Episodio 1

Para indagar cuál de las dos estrategias, basadas en un sentido de estructura, podrían emplear los alumnos, el entrevistador (E) les solicita mostrar de nuevo la veracidad de la primera igualdad propuesta en la tarea, tal como se muestra en la siguiente transcripción.

E: Déjenme regresar a las primeras dos igualdades [Escribe en el pizarrón la igualdad 10+7=5+12]. ¿Cómo se puede re-expresar?

S1 y S3: Yo, yo, [A la vez manifiestan su interés por pasar al pizarrón].

E: S1, pasa por favor. ¿Cómo le harías para decir que sí es verdadera, sin hacer la suma?

S1: [Escribe en el pizarrón 5+5+5+2=5+5+5+2, ver Fig. 1, izquierda]. Éste [señala el 5+5 del lado izquierdo] lo agarraría del 10. Éste [señala el 5+2 del lado izquierdo] del 7. Éste [señala el 5 del lado derecho de la igualdad] del 5, y éste [señala 5+5+2] del 12.

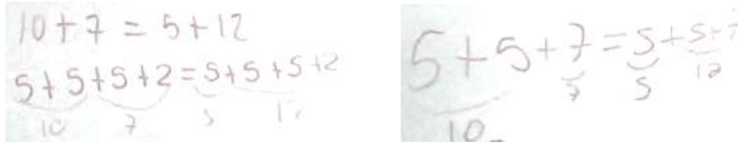

Figura 1: Estrategia de descomposición por S1 (izquierda) y S3 (derecha)

Como se observa en la Fig. 1 (izquierda), S1 descompone ambos lados de la igualdad en una tercera forma común (5+5+5+2), y explica de dónde surgen cada uno de los números de ésta. De la misma forma, S3 propone otra descomposición (Fig. 1, derecha), bajo la misma idea explica dónde surgen los números de la igualdad reescrita.

Episodio 2

Dado el comportamiento de los alumnos descrito en el episodio 1, el entrevistador les cuestiona directamente por la posibilidad de transformar el lado izquierdo en el derecho (o viceversa), esto se observa en la siguiente transcripción.

E: Finalmente, voy a escribirla [Escribe en el pizarrón la igualdad 530+200=300+430]. ¿Esa se puede reescribir? Ya lo hicieron ustedes, pero díganme otra forma más. ¿Esto [Refiriéndose a la expresión 530+200], por ejemplo, se puede reescribir de esta manera [señala la expresión 300+43] o esto [señala 300+430] de esta manera [señala 530+200]? ¿Cómo lo harían?
S3: ¡Ah, ya, ya! [Expresión coloquial de afirmación]
E: Pasa S3
S1: Transformando
E: Dinos S1, ¿transformando, cómo?
S1: Sería lo mismo que hizo S2 y S3, hace rato [Refiriéndose a la estrategia para validar la igualdad 8+2+16=10+12+4, ver Martínez-Hernández & Kieran, en prensa)]
S3: [Pasa al pizarrón] Le quito 200 a éste [señala el 530] para hacerlo 300 y se lo paso a este [señala el 200] para hacerlo para hacerlo 430. ¡Ah no! 230 [Finalmente escribe la igualdad 300+430=300+430, ver Figura 2 izquierda]
E: ¿Esto [señala es lado izquierdo 300+430 escrito por S3] de dónde salió?
S3: Del 530 le quito 230 y se los doy al 200, para que me resulte 430.

Figura 2: Igualdad reescrita por S3 (izquierda) interpretación de su estrategia (derecha)

Como se puede observar en la transcripción y en la Fig. 2 (izquierda), la estrategia desarrollada por S3 se puede interpretar de la siguiente manera: el lado izquierdo 530+200 lo descompone como 300+230+200 y después lo recompone como 300+430, mientras que el lado derecho no lo transforma (ver Fig. 2, derecha). La estrategia del Episodio 2, a diferencia de la del episodio 1, está sustentada en una relación simultánea entre los lados izquierdo y derecho de la igualdad dada. Es decir, no se trata de una descomposición y recomposición arbitraria del lado izquierdo, sino que está guiada por la forma del lado derecho.

Conclusiones

De acuerdo con los resultados, por un lado, los alumnos tienden a buscar una tercera forma común mediante la descomposición de ambos lados de una igualdad (Episodio 1) para validar el tipo de igualdades numéricas propuestas. Así, tal estrategia desplaza a la estrategia de cómputo inicialmente utilizada por ellos de forma espontánea (ver Martínez-Hernández & Kieran, 2018). Por otro, la estrategia del Episodio 2 emerge, de nuevo, a partir de la intervención explícita del entrevistador. Como se indica en Martínez-Hernández y Kieran (en prensa) esta segunda estrategia parece ser cognitivamente más demandante que la primera. En cualquier caso, ambas estrategias van más allá de observar regularidades en igualdades (e.g., Pang & Kim, 2018; Schifter, 2018), lo cual es muestran de nuevos resultados sobre el sentido de estructura en aritmética. Así, el trabajo de S3 (Fig. 2), la forma en que descompone, compone y recompone los números, para transformar un lado de la igualdad en la misma forma del otro, es un ejemplo de un pensamiento relacional basado en un sentido de estructura y de la aproximación estructural propuesta por Kieran (2018) respecto a observar a través de los objetos matemáticos y expresarlos en diferentes formas estructurales. Por ultimo, planteamos la necesidad de investigar sobre la forma en que los alumnos entienden las similitudes y diferencias de sus estrategias.

INTUITION IN LINEAR TRANSFORMATION: SOME DIFFICULTIES

LA INTUICIÓN EN LA TRANSFORMACIÓN LINEAL: ALGUNAS DIFICULTADES

Osiel Ramírez-Sandoval
Universidad Autónoma de Ciudad Juárez
osiel.ramirez@uacj.mx

An individual interview was conducted with five students who successfully completed a mathematics degree in Mexico. An instrument was applied that contained situations of both linear and non-linear transformations in the graphic and algebraic environment. The results were analyzed under the theoretical framework of Fischbein (1987) on intuition and intuitive models. It was obtained that the interviewed students have a universe of linear transformations that are known in the school context as a prototype. Students exclude the existence of a linear transformation in the geometric environment, when they fail to build said transformation under the composition of the range of prototype models.

Keywords: Advanced Mathematical Thinking, Algebra and Algebraic Thinking, Cognition, Representations and Visualization

Objective

The purpose of the research was to identify the intuitive models that some Bachelor of Mathematics students retain regarding Linear Transformations in R^2 (in the sense of Fischbein, 1987); It also sought to demonstrate the conceptions that students have regarding this concept. It was hypothesized that the universe that some students have regarding Linear Transformations in R^2 is reduced to rigid movements of the plane.

Theoretical framework

In the present work we are going to consider the term intuition as an instinctual knowledge, not as a method, not as a source of knowledge, but as a type of cognition. To make this approach clearer, Fischbein mentions the following examples:

> One intuitively admits that the shortest path between two points is the straight line, that each number has a successor, that the whole is greater than each of its parts, that a body must fall if it is not supported. (Fischbein, 1987)

These statements are accepted almost immediately, without the need to perform any formal test, that is; We can say that self-evidence is part of a characteristic of intuitive knowledge, but it is remarkable that there is a whole universe of statements or propositions that are not accepted so immediately, for example: if the product of the slopes of two lines is equal to one, then; these are perpendicular, or that $a^0 = 1, a \neq 0$ or the mathematical expression $\frac{n(n+1)}{2}$ generates the sum of the first n natural numbers.

> Intuition is not the primary source of truth, certainty and knowledge but this seems to be so, because this is exactly its role: to create the appearance of certainty, to attribute to various interpretations and representations a character of intrinsic certainty and unquestionable (Fischbein, 1987).

Students develop their intuition, because they resort to representations of mathematical objects. "Mental objects (concepts, operations and statements) must achieve a kind of intrinsic consistency and direct evidence, similar to the real one, external to material objects and events, if the reasoning process is a genuinely productive activity" (Fischbein, 1987) . In this way, mental representations are

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. not the product of memorization; but to the repeated experiences that the subject has had in the concept construction process: obstacles, conflicts, etc.

General characteristics of intuitive cognitions

Fischbein (1987) considers that at every level of mathematical reasoning, one must consider mainly three basic aspects.

1. *The formal aspect*: Which is essentially given by the structure logical-deductive mathematics, such as axioms, definitions, theorems and proofs.
2. *The algorithmic aspect*: Which refers to the procedures, the development of a approach until reaching the solution.
3. *The intuitive aspect*: That refers to the degree of acceptance of the concepts, mathematical propositions or statements, as something evident or true.

The research is particularly interested in the implicit models that students can develop in relation to the concept of linear transformation and the consequences of these models in learning the same concept.

Methodological elements

Five students (Saulo, Miguel, Max, David and Hugo) who graduated from the Bachelor of Mathematics at the Higher School of Physics and Mathematics of the National Polytechnic Institute in Mexico were interviewed. The interview was conducted individually on different dates over the course of a week. At the time of the interviews, each of the students belonged to a master's program in different institutions and specialties, with a common core in mathematics. It should be noted that the students were chosen for their good training and good performance in mathematics, since in this research we intend to identify those intuitive models that persist, and that are not necessarily strictly related to cognitive difficulties, etc.

The bibliography to which they referred when they were questioned about the textbook brought in during their training corresponds to the book on Linear Algebra published by the authors Hoffman & Kunze (1987), however they have consulted other authors such as Grossman (2012), Lang (1974) and Lay (2007).

The method

Once the instrument to be used was established, an a priori analysis was carried out, which hypothetically posed the possible arguments and situations to be presented during the interview. Once this analysis was carried out, we proceeded to the interview stage. The interviewer had the task of bringing, posing and explaining the situations that arose during the development of the interview, and one of his main tasks consisted of confronting the environments where the student had opposing or other people's arguments, which suggested a deeper analysis. Finally, the a priori analysis is contrasted with the a posteriori analysis, to obtain the following results.

Results

In one of the initial activities of the instrument, it requested the following:

a) Provide an example of a linear transformation.
b) Argue why the transformation you proposed is linear.

Both the student Saulo and the student Max provide examples very similar to those approached in a Linear Algebra course (see Figure 1 and Figure 2), since they are characteristic of those presented in textbooks.

Sea $T: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ / $T(x,y) = (2x, 2y)$

Figure 1. Saulo's production, following the example of TL.

$T: \mathbb{R}^2 \rightarrow \mathbb{R}^2$

$T(x,y) = (x+y, x-y)$

Figure 2. Max production, to the example of TL.

Fischbein (1987) considers this type of intuitive cognitions to be algorithmic in appearance; which refers to the procedures, the development of an approach until reaching the solution. The strategy used by the students (Saulo and Max) corresponds to first setting the definition of Linear Transformation and then applying it to their proposed examples until their demonstration is completed, with great skill in algebraic treatment. Attached to a priori analysis, this type of results are those expected by teachers, since they correspond to some exercises in textbooks or the first examples that are addressed to illustrate the concept of Linear Transformation. (Grossman, 2012, p.500).

Miguel provides the example of the Linear Identity Transformation (see Figure 3.), and applying his definition verifies the linearity of the transformation. It does not specify vector spaces, nor does it specify the membership of scalars to a field, as in the definition of Linear Transformation that you provided; highlights the notation used by the student presenting the definition with a “f ” referring to the function, thus also taking x & y as vectors, as a real analysis notation.

$$f(x) = x$$

$$\begin{aligned} f(\alpha x + \beta y) &= \alpha x + \beta y \\ &= \alpha f(x) + \beta f(y). \end{aligned}$$

Figure 3. Miguel's production, following the example of TL.

In the a priori analysis, this possible response by the student was warned, when conceptualizing Linear Transformations as functions in the context of their calculus courses.

For his part, the student David, argues that:

> David: There are several examples, we can start, to define the simplest transformation, which is the constant, in general the simplest functions are the constants, the ones that map all the space in a number here (indicating the counter-domain) but in this case , to be linear, it cannot be any constant. Given the structure we gave for the linear transformation, it can easily be verified that if the linear transformation is constant, then:

$$T(v) = 0 \quad \forall\, v \in V$$

Figure 4. David's production, following the example of TL.

David demonstrates his mathematical maturity by fluently providing the example of the Zero Linear Transformation. Very similar to the one shown in the textbook that he carried in his studies; "The zero transformation, defined by $0_\alpha = 0$, is a linear transformation from V to V" (Hoftman & Kunze, 1971, p.67).

It is evident that in his mathematical reasoning, David shows the formal aspect, in the sense of Fischbein (1987), which is essentially given by the logical-deductive structure of mathematics, such as axioms, definitions, theorems and demonstrations, this situation is reflected throughout the entire interview. David is very much akin to the implicit (or tacit) model:

A fundamental characteristic of a mental model is its structural entity. A model, like a theory, is not a simple isolated rule, rather a global, unitary, meaningful interpretation of a phenomenon or a concept. . . . of an implicit model is its concrete, practical nature, even if the model is an abstract construction. (Fischbein, 1987)

Of the students interviewed; the one that Fischbein (1987) classifies as an intuitive model was also observed when the following activity was requested.

a) Provide an example of a nonlinear transformation
b) Argue why the transformation you proposed is not linear.

The student Hugo does not provide any algebraic expression, as the rest of the interviewed students do; He takes Galileo's transformations, to illustrate the non-linearity of transformation

> Hugo: . . . well, here I'm going to use something like this. . . Galileo transformations, for example, are linear transformations, when. . . in fact they are valid for: when a reference system moves with respect to the other and in each of the two it is realized. . . for example the position of a particle or of a body in general, then this. . . and the Galileo transformations are linear transformations, but that only applies when the speed with which a system S 'moves with respect to another system S is constant (write), right now I don't remember what they are. . . how are the Galileo transformations established, but. . . if to this system S ', which moves with respect to the system S, we make this speed be different, not constant, that is, it has a acceleration, the resulting transformation is going to be a non-linear transformation, it is going to carry a term due to the acceleration, it is going to carry a square there. For that reason, it would be non-linear and that would also be the argument. . . Besides, if we check the calculations for this a bit, we would surely obtain a non-linear expression. . . and therefore it would not fulfill the two properties that a linear transformation must satisfy.

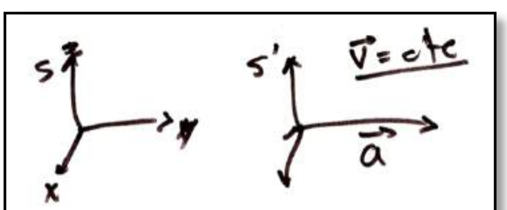

Figure 5. Hugo production, to the example of Nonlinear Transformation.

> An intuitive model is not necessarily a direct reflection of a certain reality, very often it is based on an abstract interpretation of that reality. The graph of a function is an intuitive model of that function and the function, for its part, is the abstract model of a true phenomenon […] Intuitive models that use conventional, graphical means are generally called diagrams. (Fischbein, 1987)

Conclusions

We observed that all the students showed a complete management of the concept of linear transformation, reaffirming their good training and performance in the area of mathematics, proof of this was that they all provided definitions of the concept of linear transformation presented in textbooks or that were acquired in their linear algebra courses, they also showed examples and counterexamples of linear transformations; It should be noted that all of these were different.

We verify that the students immediately identify a prototype linear transformation (expansions, contractions, rotations, reflections and the combination of them) in both environments. However, in the geometric part where the figures show a fixed vector, the students cannot identify the linear transformation, differing from the corresponding situation in the algebraic stage, which led to a confrontation of their arguments.

LA INTUICIÓN EN LA TRANSFORMACIÓN LINEAL: ALGUNAS DIFICULTADES

INTUITION IN LINEAR TRANSFORMATION: SOME DIFFICULTIES

Osiel Ramírez-Sandoval
Universidad Autónoma de Ciudad Juárez
osiel.ramirez@uacj.mx

Se realizó una entrevista individual a cinco estudiantes que cubrieron satisfactoriamente una licenciatura en matemáticas en México. En ella; se aplicó un instrumento que contenía situaciones de transformaciones tanto lineales, como no lineales en el ambiente gráfico y algebraico. Los resultados se analizaron bajo el marco teórico de Fischbein (1987) sobre la intuición y los modelos intuitivos. Se obtuvo que los estudiantes entrevistados, disponen de un universo de transformaciones lineales que son conocidas en el contexto escolar como prototipo. Los estudiantes excluyen la existencia de una transformación lineal en el ambiente geométrico, cuando no logran construir dicha transformación bajo la composición de la gama de modelos prototipos.

Objetivo

La investigación tuvo como propósito el identificar los modelos intuitivos que conservan algunos estudiantes Licenciatura en Matemáticas en cuanto a las Transformaciones Lineales en R^2 (en el sentido de Fischbein, 1987); asimismo se busco evidenciar las concepciones que poseen los estudiantes respecto a éste concepto. Se tuvo como hipótesis, que el universo que poseen algunos estudiantes respecto a las Transformaciones Lineales en R^2 se reduce a movimientos rígidos del plano.

Marco Teórico

En el presente trabajo el término intuición vamos a considerarlo como un conocimiento instintivo, no como un método, no como una fuente de conocimientos, sino como un tipo de cognición. Para hacer más claro este acercamiento, Fischbein menciona los siguientes ejemplos:

> Uno admite intuitivamente que el camino más corto entre dos puntos es la línea recta, que cada número tiene un sucesor, que el todo es más grande que cada una de sus partes, que un cuerpo debe caerse si no esta sostenido. (Fischbein, 1987)

Estas afirmaciones son aceptadas de forma casi inmediata, sin tener la necesidad de realizar alguna prueba formal, es decir; podemos decir que la autoevidencia forma parte de una característica del conocimiento intuitivo, pero es notable que existe todo un universo de afirmaciones o proposiciones que no son aceptadas de forma tan inmediata, por ejemplo: si el producto de las pendientes de dos rectas es igual a uno, entonces; estas son perpendiculares, ó que $a^0 = 1, a \neq 0$ ó la expresión matemática $\frac{n(n+1)}{2}$ genera la suma de los n primeros números naturales.

Una habilidad que desarrollan los estudiantes en una disciplina como las matemáticas corresponde a la intuición, la cual adquieren debido a la interacción ineludible al: conocer, comprender, construir y/o emplear objetos que no se puede acceder de manera directa, por su naturaleza abstracta. Una formación en matemáticas, no se reduce a un sistema deductivo de conocimientos, “la actividad creativa en matemáticas es un proceso constructivo en el cual los procedimientos inductivos, las analogías y las conjeturas plausibles, juegan un papel fundamental” (Gómez-Chacón, 2000, p.30). La intuición, es un término que no tiene un sentido universal en la comunidad de la matemática educativa; para ello recurrimos a la descripción propuesta por nuestro marco teórico.

> La intuición no es la fuente primaria de la verdad, certeza y conocimiento pero esto parece ser así, porque este es exactamente su papel: crear la apariencia de certeza, atribuir a diversas interpretaciones y representaciones un carácter de certeza intrínseca e incuestionable (Fischbein, 1987).

Los estudiantes desarrollan su intuición, porque recurren a representaciones de los objetos matemáticos. “Los objetos mentales (conceptos, operaciones y declaraciones) deben conseguir una especie de consistencia intrínseca y evidencia directa, similar a la real, externa a objetos materiales y eventos, si el proceso de razonamiento es una actividad genuinamente productiva” (Fischbein, 1987). De esta manera, las representaciones mentales no son el producto de la memorización; sino a las reiteradas experiencias que ha tenido el sujeto en el proceso de construcción del conceptos: obstáculos, conflictos, etc.

Características generales de cogniciones intuitivas

Fischbein (1987) considera que en todo nivel de razonamiento matemático, se deben de considerar principalmente tres aspectos básicos.

1. *El aspecto formal*: Que viene a estar dado esencialmente por la estructura lógico-deductiva de la matemática, como son los axiomas, las definiciones, teoremas y demostraciones.
2. *El aspecto algorítmico*: Que se refiere a los procedimientos, al desarrollo de un planteamiento hasta llegar a la solución.
3. *El aspecto intuitivo*: Que se refiere al grado de aceptación de los conceptos, proposiciones o afirmaciones matemáticas, como algo evidente o cierto.

La investigación se interesa particularmente los modelos implícitos que los estudiantes pueden desarrollar en relación con el concepto transformación lineal y las consecuencias de estos modelos en el aprendizaje del mismo concepto.

Elementos metodológicos

Se entrevistó a cinco estudiantes (Saulo, Miguel, Max, David y Hugo) egresados de la Licenciatura en Matemáticas en la Escuela Superior de Física y Matemáticas del Instituto Politécnico Nacional en México. La entrevista se realizó de manera individual en diferentes fechas en el transcurso de una semana. Al periodo de las entrevistas, cada uno de los estudiantes pertenecía a un programa de maestría en diferentes instituciones y especialidades, con un tronco común en matemáticas. Cabe aclarar que los estudiantes fueron elegidos por su buena formación y buen desempeño en matemáticas, ya que en esta investigación pretendemos identificar aquellos modelos intuitivos que persisten, y que no necesariamente guardan estricta relación con dificultades cognitivas, etc.,

La bibliografía a la que hicieron referencia cuando se les cuestionó sobre el libro de texto llevado en el transcurso de su formación, corresponde al libro de Álgebra Lineal publicada por los autores Hoffman & Kunze (1987), sin embargo han consultado a otros autores como Grossman (2012), Lang (1974) y Lay (2007).

El Método

Una vez establecido el instrumento a emplear, se realizó un análisis a priori, donde se planteaba de manera hipotética, los posibles argumentos y situaciones a presentarse durante la entrevista. Una vez realizado este análisis, se procedió a la etapa de entrevistas. El entrevistador tuvo la labor de llevar, plantear y explicar las situaciones que se presentaban durante el desarrollo de la entrevista, y uno de sus principales tareas consistió en confrontar los ambientes donde el estudiante tenía argumentos opuestos o ajenos, que sugerían un análisis más profundo. Finalmente se contrastan, el análisis a priori con el análisis a posteriori, para obtener los siguientes resultados.

Resultados

En una de las actividades iniciales del instrumento solicitaba lo siguiente:

a) Proporciona un ejemplo de una transformación lineal.
b) Argumenta por qué es lineal la transformación que propusiste.

Tanto el estudiante Saulo, como el estudiante Max proporcionan ejemplos muy similares a los abordados en un curso de Álgebra Lineal (ver Figura 1 y Figura 2), dado que son característicos a los presentados en los libros de texto.

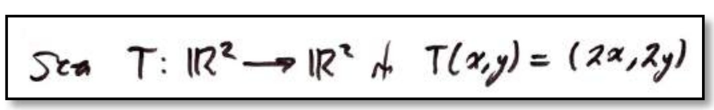

Figura 1. Producción de Saulo, al ejemplo de TL.

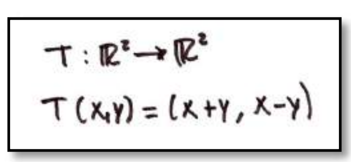

Figura 2. Producción de Max, al ejemplo de TL.

A este tipo de cogniciones intuitivas, Fischbein (1987) las considera como de aspecto algorítmico; las cuales se refiere a los procedimientos, al desarrollo de un planteamiento hasta llegar a la solución.

La estrategia que emplean los estudiantes (Saulo y Max), corresponde a situar en un primer momento a la definición de Transformación Lineal y posteriormente aplicar a sus ejemplos propuestos hasta cumplir su demostración, con gran habilidad en el tratamiento algebraico. Apegados al análisis a priori, este tipo de resultados son los esperados por los profesores, dado que corresponden a algunos ejercicios en los libros de textos o los primeros ejemplos que se abordan para ilustrar el concepto de Transformación Lineal. (Grossman, 2012, p.500).

Miguel roporciona el ejemplo de la Transformación Lineal Identidad (ver Figura 3.), y aplicando su definición verifica la linealidad de la transformación. No especifica los espacios vectoriales, como tampoco la pertenencia de los escalares a un campo, al igual que en la definición de Transformación Lineal que proporcionó; resalta la notación que maneja el estudiante presentando la definición con una "f "aludiendo a la función, así también tomando a x & y como vectores, como una notación de análisis real.

$$f(x) = x$$

$$\begin{aligned} f(\alpha x + \beta y) &= \alpha x + \beta y \\ &= \alpha f(x) + \beta f(y). \end{aligned}$$

Figura 3. Producción de Miguel, al ejemplo de TL.

En el análisis a priori se advirtió de esta posible respuesta por parte del estudiante, al conceptualizar a las Transformaciones Lineales como funciones en el contexto de sus cursos de cálculo.

Por su parte el estudiante David, argumenta que:

> David: hay varios ejemplos, podemos empezar, para definir la transformación más sencilla, que sea la constante, en general las funciones más sencillas son las constantes las que mapean todo el espacio en un número de acá (indicando el contradominio) pero en este caso, para que sea lineal, no puede ser cualquier constante. Dada la estructura que dimos para la transformación lineal, se puede verificar fácilmente, que si la transformación lineal es constante, entonces:

$$T(v) = 0 \quad \forall\, v \in V$$

Figura 4. Producción de David, al ejemplo de TL.

David evidencía su madurez matemática al proporcionar con soltura el ejemplo de la Transformación Lineal Cero. Muy semejante al que se muestra en el libro de texto que llevó en sus estudios; "la transformación cero 0, definida por $0_\alpha = 0$, es una transformación lineal de V en V" (Hoftman & Kunze, 1971, p.67).

Es evidente que en su razonamiento matemático, David evidencia el aspecto formal, en el sentido de Fischbein (1987), el cual viene a estar dado esencialmente por la estructura lógico-deductiva de la matemática, como son los axiomas, las definiciones, teoremas y demostraciones, esta situación se ve reflejada a lo largo de toda la entrevista. David está muy afín al modelo implícito (o tácito):

> Una característica fundamental de un modelo mental es su entidad estructural. Un modelo, como una teoría, no es una regla aislada simple, más bien una interpretación global, unitaria,

significativa de un fenómeno o un concepto. . . . de un modelo implícito es su naturaleza concreta, práctica, aun si el modelo es una construcción abstracta. (Fischbein,1987)

De los estudiantes entrevistados; también se observó aquel que Fischbein (1987) clasifica, como modelo intuitivo, cuando se solicitó la siguiente actividad.

a) Proporciona un ejemplo de una transformación no lineal
b) Argumenta por qué no es lineal la transformación que propusiste.

El estudiante Hugo, no proporciona expresión algebraica alguna, como lo hace el resto de los estudiantes entrevistados; él toma a las transformaciones de Galileo, para ilustrar la no linealidad de transformación.

Hugo: . . . bueno, aquí voy a usar algo que este . . . las transformaciones de Galileo, por ejemplo son transformaciones lineales, cuando . . . de hecho valen para: cuando un sistema de referencia se mueve respecto del otro y en cada uno de los dos se realiza . . . por ejemplo la posición de una partícula o de un cuerpo en general, entonces este . . . y las transformaciones de Galileo son transformaciones lineales, pero eso sólo vale cuando la velocidad con la que se mueve un sistema S' respecto de otro sistema S, es constante (escribe v = cte), ahorita de momento no recuerdo cuáles son las . . . cómo están establecidas las transformaciones de Galileo, pero . . . si a este sistema S', que se mueve con respecto al sistema S, hacemos que esta velocidad sea diferente, no sea constante, es decir, tenga una aceleración, la transformación resultante va a ser una transformación no lineal, va a llevar un término debido a la aceleración, va a llevar un cuadrado ahí. Por esa razón, sería no lineal y además ese sería el argumento . . . a parte que si nos metemos a comprobar un poco los cálculos de esto, seguramente obtendríamos una expresión no lineal . . . y por lo tanto no cumpliría con las dos propiedades que debe satisfacer una transformación lineal.

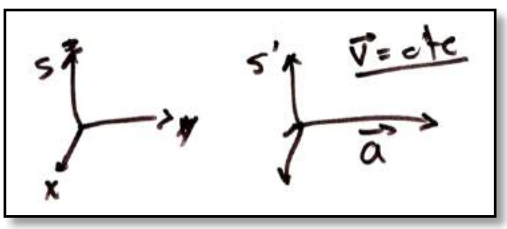

Figura 5. Producción de Hugo, al ejemplo de Transformación No Lineal.

Un modelo intuitivo no es necesariamente una reflexión directa de una cierta realidad, muy a menudo está basado en una interpretación abstracta de aquella realidad. El gráfico de una función es un modelo intuitivo de aquella función y la función, por su parte, es el modelo abstracto de un verdadero fenómeno[…] Los modelos intuitivos que usan medios convencionales, gráficos son generalmente llamados diagramas. (Fischbein, 1987)

Conclusiones

Observamos que todos los estudiantes mostraron un manejo íntegro del concepto de transformación lineal, reafirmando su buena formación y desempeño en el área de las matemáticas, prueba de ello fue que todos proporcionaron definiciones del concepto de transformación lineal que presentan los libros de texto o que fueron adquiridas en sus cursos de álgebra lineal, así también mostraron ejemplos y contraejemplos de transformaciones lineales; cabe señalar que todos estos fueron diferentes.

Comprobamos que los estudiantes identifican inmediatamente una transformación lineal prototipo (expansiones, contracciones, rotaciones, reflexiones y la combinación de ellas) en ambos ambientes.

Sin embargo, en la parte geométrica donde las figuras muestran un vector fijo los estudiantes no logran identificar la transformación lineal, difiriendo de la situación correspondiente de la etapa algebraica, lo cual desembocó en una confrontación de sus argumentos.

Transforming the teaching practice involves the adoption of new methods that must engage teachers in reflecting on their practice (CSE, 2004; Day, 1999). The roles of the researcher are multiplying. His quest to understand the teaching/learning activity is mirrored by a concern to examine the teaching profession from more than just a normative standpoint, thereby contributing to the reflection on actions and participating in the decisions that will guide their interventions (Bednarz, 2009). Influenced by historical and cultural theories (Radford, 2011; Engestrom, 1999) and more specifically by the concept of contradiction, our communication illustrates our way of "grasping" the awareness process and the coming into being of generality layers linked to the development of algebraic thinking occurring in the various classrooms of the teachers we are supporting and acting as trainers with them.

Keywords: Algebra and algebraic thinking, Teacher knowledge, Mathematical knowledge for teaching, Teaching activities and practices.

Background of the action research

Training mechanisms targeting the prescriptive training of teaching approaches are not obtaining the expected benefits (Bednarz & Proulx, 2010; Tardif, Lessard & Gauthier, 1998). Rather, the transformation of the teaching practice involves the appropriation and integration of new methods that must engage teaching professionals in reflecting on their practice (CSE, 2014; Day, 1999). The role of the researcher is thus changing. His quest to understand the teaching activity is mirrored by a concern to examine the teaching profession from more than just a normative standpoint, thereby contributing to the reflection on actions and participating in the decisions that will guide the interventions of the professionals (Bednarz, 2009).

From 2013 to 2017, we conducted an action research involving more than twenty high school teachers and academic advisors. The main objective: reflect together and improve the teaching practices aiming at the development of algebraic thinking among junior high school students (students aged 12 to 15). This research is the continuation of other studies (Kaput, 1998; Squalli, Mary & Marchand, 2011) suggesting to rethink classroom interventions fostering algebraic learning even before introducing literal language. To do this, different approaches (e.g. generalization to identify formulas and introduction to analytical reasoning through problem solving) promoting the introduction of algebra were considered and tested over the four years.

Reflecting on the development of algebraic thinking

Throughout this co-development work between the participants and the research team, the expression of a mathematical activity that we reformulated in terms of acting was the first step in inviting the participants to reconceptualize algebraic thinking as sensitive thinking as defined by Radford (2011). It is thereby considered a social process in the coming into being of historical and cultural methods and is mediated through gestures, the body, signs and artefacts provided to the student. These semiotic means are constituent parts of the thinking process. More specifically, the

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

three conditions linked to the development of algebraic thinking that we address like Radford (2014) were discussed regularly in such a way as to recognize their expression among students and to influence teaching to foster their emergence. These conditions are: 1) *Reason about the indeterminacy*, or the ability to exploit problems involving not-known numbers such as unknows, variables or parameters; 2) *Denotation*, which refers back to the use of signs (alphanumeric or non-conventional signs, gestures, natural language or a mix of those) to name, symbolize what is considered to be not-known; 3) *Reason analytically*, or treating indeterminate number(s) as though they were known and operate on them. The background of this project constantly brought us back to this desire to foster, among students, both the use of the letter without it being imposed by teachers and the development of algebraic expressions whose meaning could be made clear to their peers.

Following the presentation of the various roles that we, as researchers, played as part of the action research, this communication illustrates how the study and coming into being, among teachers, of certain contradictions inherent to the teaching of algebraic generalization help to enrich discussions with teachers on the way in which to introduce algebraic generalization.

Diversification of the roles of the researchers according to their objectives

Just like teachers and academic advisors, research assistants and researchers are here conceptualized as subjectivities expressing themselves in a common project whose goal is to develop algebraic thinking. The objectives of the researchers influence the intentionality of their activity and are:

- Support our participants and collectively reflect on the development of algebraic thinking among students
- Document algebra teaching/learning through the study of certain moments experienced in our participants' classrooms
- Document the support activity

These objectives thereby influence the different roles played as researchers. This text fosters the distinction of these roles although they were more often than not expressed in an overlapping way.

Table 1: Roles and tasks of the researchers

Roles	Tasks
Trainer	· Develop training activities · Host the training sessions · Share examples experienced in class by one of us while we were high school teachers · Plan and prepare the training days (methods, tools, etc.) · Anticipate / identify the learning obstacles and intervene if necessary · Manage the group in such a way as to facilitate professional learning · Evaluate the progress or achievement of the training objectives · Identify the needs and priorities
Classroom session investigator	· Observe and study the algebra teaching/learning activities as they take place in the classrooms · Produce and communicate research results that shed light on certain aspects of the activities studied
Educational resource investigator	· Study the educational kits provided to teachers and academic advisors

Investigator on the co-development activity between the participants and research team	· Observe and study the co-development activity between the participants, professional and research assistants as they evolve mainly on the discussion and training days and targeting the development of algebraic thinking among junior high school students · Produce and communicate research results that shed light on certain aspects of the activity studied
Support worker	· Develop and maintain collaboration relationships with the teachers, academic advisors, professional and research assistants · Offer (or make sure to offer when the research professional is involved) educational support to the teachers and academic advisors between the training days · Help find solutions to the problems perceived

Adaptation from Lessard (2008) and Gagnon (2010)

The activity theory as a tool for the researcher investigating the co-development activity between the participants and research team

As such, to report on the method we used to support and study the teaching/learning activity targeting the introduction of algebra in our teachers' classrooms and its transformation under the influence of the project, it seems useful to recall that the principles of the perspective used inevitably steer the production of data, its interpretation and more specifically, our way of conceptualizing the actions of the researcher in her different functions. The assumptions of the social, historical and cultural theories feed this text: the ways in which people do things, think and are are considered social practices that are mutually constitutive part of the culture in which they live and that must account for past similar activity forms (historical and genetic perspective). Phenomena must be studied holistically rather than isolating certain elements that would not account for the links they have between themselves (Langemeyer & Roth, 2006). As such, the activity is considered to be the smallest analysis unit allowing for researchers to give meaning to the participant coming into being process through the actions taken by the participants. To better grasp the activity concept, one must understand its dialectic (ideal, material) nature. According to Leontiev, a subject's (teacher, academic advisor or researcher) activity is always geared toward an object/a motive. The goal of this activity is reflected in the actions. In the special case of learning, Roth and Radford note that:

> "[…] students cannot know the object/motive of the learning activity: the object/motive itself has to be the outcome of the learning activities so that others – e.g. teachers – have to take on the regulative function that in other productive human activities exists in the known object/motive" (Roth & Radford, 2011, p.16).

As written by Radford (2015), student activity is the materialization of cultural archetypes seen in "actions, words, perceptions, gestures, symbols, reasoning (p.338)". Our role as trainers also calls us to insert methods linked to the historical and cultural development of algebraic thinking in the support activity of our participants and make the aspects of teaching/learning to consider when looking at it from an educational perspective come into being. As such, if for Roth and Radford (2011) the challenge of the learning activity for students is precisely that they recognize the object/motive through their own actions, we will see that the same goes for researchers who commit to contributing to the training of teachers and academic advisors.

Roth and Radford (2011) invite us to consider thought from an anthropological (its origins) and ontogenical (the conditions of its existence) perspective. On the one hand, thought is conceptualized as *praxis cogitans*. Thought is not static; it is activity and movement. Considered a potential, it reveals itself, is reflected in a singular and becomes/is a purpose/activity of consciousness. Radford (2011) then speaks of thought/activity as an awareness-building processes he called objectification. On the other hand, this awareness-building process depends on one's social existence. Researchers add that these individual and collective awareness-building processes are mutually constitutive.

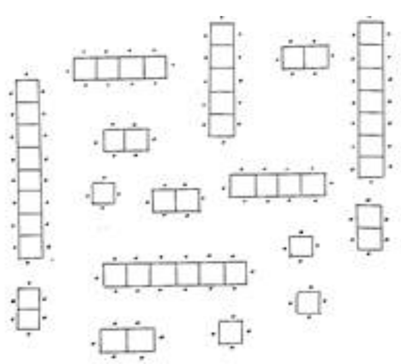
The concept of contradiction

Historical and cultural theories invite us to conceptualize activity as movement. Object/motive motivates an individual's activity; the object of the activity is materialized/reflected in his actions. This flow is considered to be the effect of the activity itself. Taking the work of linguists as an example, Roth (2012) illustrates the meaning to give to any activity. Our language changes in its uses. As written by Bakhtin (1981), a language dies as soon as it is no longer used. Every time a word is used, its meaning reifies itself, changes, much like the language itself is transformed by the use of a word. Thus, words, signs, in a dialectical approach, are not a single unique entity (Roth, 2014). In their uses, they carry and exhibit an internal contradiction that becomes apparent in the various ways in which people use signs. According to Roth and Radford (2011), these internal contradictions refer back to conflictual aspects that coexist dialectically in a phenomenon. Other work uses the concept of contradiction, but it is instead conceptualized differently. This is the case for the work of Engeström (2001) and Potari et al. (2018). The latter studies and distinguishes the activity of different communities (e.g. Department, teachers) considered as distinct systems. They then identify the contradictions in the contrary practices, the different choices between teachers or between a teacher and an external source (a researcher, manual or program). It is then said that the study of contradictions stemming from two systems can create learning opportunities and thereby transform the actions and goals of an activity. The transformation activity must then be looked at from a collective standpoint, all the while taking into account the different mediating factors (subject, tool, rules, community, division of work…) that influence this same activity.

Some elements of methodology

As part of this action research, the collaborative sessions with the teachers and academic advisors were all filmed. During these sessions, the project participants familiarized themselves with certain tasks, had analyzed videos of teachers facilitating these tasks and had attended the presentation of some theoretical content by the researchers, namely Radford's (2003) typology of generalization, which we will not refer to here. Also, the experiments conducted in the teachers' classrooms were also filmed. Transcriptions of these recordings were made. As part of this communication, we will discuss the experiments that followed the training session during which *Marcel's restaurant* situation was presented to the teachers (see Figure 1).

Marcel, a restaurant owner, has single tables in his restaurant. He places these tables one beside the other to be able to seat his clients when they arrive. He has tables of different sizes: large, small, medium…



Marcel would very much like not having to count the clients coming in every time to decide at which table to seat them. Can you help him find a way to quickly calculate the number of clients that can be seated at a table, regardless of the size of the table? Our owner lives far so he will be waiting for you to write to him about this.

Write him a **message with words** that would indicate a way to quickly find out how many people he can seat at a table, for any table.

Messages are long to read for Marcel so rewrite your message but this time as a text message so that he can read it quickly.

Figure 1. Marcel's restaurant situation

Before being able to discuss the potential and inherent intentions of the situation, the teachers had to solve it. So, for the first question, different word messages are possible. There are lots of good messages such as: 1) There are 2 people per table facing each other and one person at each end of the table; 2) 3 people can be seated at the end tables and 2 people facing each other for each table between these two tables; 3) We place one person per table and another person on one end of the table and we do this twice (we notice a symmetry), incorrect messages are also possible. These messages are formulated in context; here the motives presented are an essential support to the problem-solving process. In the second question, the purpose is to bring students to move on to symbolization, which helps to illustrate a size (here the number of tables) concisely and briefly.

Reflection on the contradictions recognized in the teachers' experiments

Through this situation, the goals of the researchers are to give meaning to symbolism through the emergence of symbolization that will be specific and spontaneous to each student. By not imposing the use of a sign (letter or other) in particular, we can expect a variety of symbolizations to represent the same variable. Other than this work on symbolization, the purpose is also to motivate the use of various algebraic expressions that will be equivalent and that will bring some flexibility in the way in which to perceive the pattern. This method opens the door to a work on equivalent expressions.

After the training session, numerous teachers experimented with this situation in their classroom to set out what they had observed in their students during the next meeting. Upon their return, the trainers observed diversity in the teachers' ways of doing things (see Table 1).

Table 2. The teachers' different ways of doing things for *Marcel's restaurant*

Stéphane	Annie	Alexandre
Stéphane considers this situation to be the first he uses to introduce algebra in his classroom. He referred back to it several times over the next few weeks. Especially, when he discussed the recognition of proportionality situations (words, value table and graph). During the first period, in teams of two, his students must find two different formulas expressed with algebraic symbols. The teacher validates the formulas obtained and invites a few teams to come explain them in front of the class by coordinating their explanations of the table visual. During the next class, the teacher focuses on the representation of the formulas taken from two representation	Annie mentions having dealt with the chapter on "geometric and numerical patterns" before. The students thus learned to extract formulas by studying the additive recurrence in the progression of different patterns. The teacher introduced the situation proposed with the intention of having the different messages she wishes to obtain in words or as a symbolic form extracted. During the problem solving, she also invites her students to build a value table to extract a formula. She is disappointed by the lack of variety of formulas.	This situation is the first that the teacher uses to introduce algebra according to him; however, he says that he started working on the translation of comparison relations only during games at the end of some periods. For this situation, the teacher promotes the emergence of different messages that are based on a study of the pattern. When returning to whole class, the focus is put on validating each message expressed in words by relying on the visual of the situation. He is therefore concerned with coordinating the visual with words. Following the first period, use of symbolism is decreased. Alexandre focuses on the potential of the formulas expressed in words to predict the maximum number of

registers: value table and graph. The teacher's purpose is to express the links existing between these three registers: table, graphic and symbolic.		people that can be seated according to the number of tables.

It can be noted that although the teachers all orchestrated *Marcel's restaurant* situation, the generalization activity or, more specifically, the coming into being process experienced by the students differs in each of the classrooms depending on what the teachers value in terms of the development of algebraic thinking. As trainers, we gave ourselves the role of documenting the teaching/learning activity lived in each of the participating teachers' classrooms. Here we can document the various facets of the same object (see Table 1). That said, the role of trainer is much more than that; it is about facilitating a group discussion on the different intentions driving the teachers when the experiment was set up and on the activities lived. While acknowledging the potential of these different methods, it is about going back to the initial intentions targeted (motive of the activity) by the trainers and set out during the previous meeting. It is also about making the teachers see the various facets (meaning of the letter, emergence of algebraic expressions whose meaning differs depending on the students' objectification process, generalization levels recognized…) of algebraic thinking that develops in each classroom.

In Alexandre's class, the trainers recognize the importance to giving meaning to algebraic expressions. They strive to make the teachers see all the work completed by the teacher to help his/her students coordinate the verbalization of the generalization messages extracted from the visual provided. They then make this contradiction (idealized/materialized in the classroom activity) be seen, which can be better explained by associating the generalization levels of Radford (2003). The whole class discussion in Alexandre's classroom is thus mainly in terms of contextual generalization. The latter still includes references to the specificities of the context objects and their characteristics in terms of the spatial and temporal situation. The generalization messages remain contextual in that their designation mode still depends on spatial properties. As specified by Radford (2003), the "arguments" or "variables" are no longer numbers, but generic objects that are designated by generic terms such as "the figure" or "the next figure". Other contradictions are felt by the trainers during the presentation of the approaches of Stéphane and Annie but they are somewhat different. Indeed, adding a value table in the situation (Annie's approach) limits the expressions extracted by the students, which the teacher observed. There are two levels of tension. On the one hand, it is no longer about working on the different possible symbolizations and a variety of expressions that mean something to the students; here, looking for a rule seems to be a priority. On the other hand, the generalization work undertaken by the students seems to be glossed over by the application of a procedure (for each table added, there are two more people so we write "times two" in the formula). This contradiction was a driving change for the teacher who became aware of it herself when she compared the activity in her classroom with that of her peers.

As for Stéphane's approach, the trainers did not intervene in the same way given that the intentions targeted are met. The focus is put on the work involving the representation registers; it is then about making aware the teachers that converting an expression in another register and coordinating the various significations is a daunting task for the students who are beginning to learn about algebraic generalization. It is not about telling the teachers that what they are doing is wrong or that there is a contradiction, in the sense of Engestrom (2001), according to "our trainer system", but rather about helping them look at the different facets that mesh together when it comes to reflecting on the work of algebraic generalization.

Conclusion

The study of the teaching/learning activities in the different classrooms of the teachers we are supporting illustrates the teachers' different methods that, although stemming from the same situation, have different motives. In our investigator role, we study the materialization of the expression of algebraic thinking in each class as contradictions between what the teachers aim and the materialized activity. In our role as trainers, it is by relying on these different ways of doing that, we make apparent different facets of algebraic thinking but which nevertheless shape it differently.

Studying certain contradictions that we are looking to make visible in our role as trainers allows the teachers to learn how to recognize the emergence of the different facets that influence the expression of algebraic thinking.

Acknowledgements

The data and results presented in the text come from an action research whose title is "Co-construction, trial, analysis and sharing of educational situations aiming to foster arithmetic/algebraic transition". This project was funded as part of the program supporting the continuing education of school personnel (Chantier 7), of the Ministère de l'Éducation, du Loisir et du Sport (2013-2017).

La transformation de la pratique enseignante implique un travail d'appropriation de nouvelles manières de faire qui doit engager les enseignants dans un travail réflexif sur leur pratique (CSE, 2004; Day, 1999). Les rôles du chercheur se multiplient. Sa recherche de compréhension de l'activité d'enseignement/apprentissage se voit doublée d'un souci de dépasser le regard normatif sur ce que font les enseignants pour ainsi contribuer à la réflexion sur les actions et prendre part aux décisions qui guideront leurs interventions (Bednarz, 2009). Sous l'influence de théories historico-culturelles (Radford, 2011; Engestrom, 1999) et plus particulièrement du concept de contradiction, notre communication illustre notre manière de «saisir» le processus de prise de conscience et de mise en apparence de couches de généralité associées au développement de la pensée algébrique qui a cours dans les différentes classes des enseignants que nous accompagnons et d'agir en tant que formatrices auprès d'eux.

Mots-clés: Algebra and algebraic thinking, Teacher Knowledge, Mathematical Knowledge for Teaching, Instructional activities and practices.

Mise en contexte de la recherche-action

Les dispositifs de formation qui visent une formation prescriptive d'approches de l'enseignement ne connaissent pas les bénéfices escomptés (Bednarz & Proulx, 2010; Tardif, Lessard & Gauthier, 1998). La transformation de la pratique enseignante implique plutôt un travail d'appropriation et d'intégration de nouvelles manières de faire qui doivent engager les professionnels de l'enseignement dans un travail réflexif sur leur pratique (CSE, 2014; Day, 1999). Le rôle du chercheur est alors en mutation. Sa recherche de compréhension de l'activité enseignante se voit doublée d'un souci de dépasser le regard normatif sur ce que font les enseignants pour ainsi contribuer à la réflexion sur les actions et prendre part aux décisions qui guideront les interventions des professionnels (Bednarz, 2009).

De 2013 à 2017, nous avons mené une recherche-action impliquant plus d'une vingtaine d'enseignants et des conseillers pédagogiques du secondaire. L'objectif premier : réfléchir ensemble et améliorer les pratiques d'enseignement visant le développement de la pensée algébrique chez les élèves du premier cycle du secondaire (élèves de 12 à 15 ans). Cette recherche est le prolongement d'autres études (Kaput, 1998; Squalli, Mary & Marchand, 2011) suggérant de repenser les interventions en classe qui favorisent l'apprentissage de l'algèbre avant même l'introduction au langage littéral. Pour ce faire, différentes approches (p.ex. généralisation en vue de dégager des formules et introduction au raisonnement analytique par la résolution de problèmes) favorisant l'introduction de l'algèbre ont été abordées et expérimentées au courant des quatre années.

Réfléchir le développement de la pensée algébrique

Au fil de ce travail de coélaboration entre les participants et l'équipe de recherche, l'expression d'une activité mathématique que nous avons reformulée en termes d'agir fut le prélude invitant les participants à reconceptualiser la pensée algébrique en tant que pensée sensible telle qu'elle est définie par Radford (2011). Elle est ainsi considérée en tant que processus social de mise en apparence de manières de faire historico-culturelles et est médiatisé par les gestes, le corps, les signes et les artefacts que l'on met à la disponibilité de l'élève. Ces moyens sémiotiques sont des parties constitutives de la pensée. Plus spécifiquement, les trois conditions associées au développement de la pensée algébrique que nous reprenons de Radford (2014) furent régulièrement discutées de manière à reconnaitre leur expression chez les élèves et à teinter l'enseignement de manière à favoriser leur émergence. Ces conditions sont : 1) *Raisonner sur l'indéterminé*, soit cette capacité à exploiter des problèmes qui implique des nombres qui ne sont pas connus; 2) *Dénoter* qui renvoie à l'usage de signes (signes alphanumériques ou non conventionnels, gestes, langage naturel ou mélange de ce qui précède) pour nommer, symboliser ce qui est considéré comme étant inconnu ; 3) *Raisonner analytiquement*, soit traiter les quantités indéterminées comme si elles étaient connues et opérer sur celles-ci. La trame de fond de ce projet nous renvoyait constamment à ce désir de favoriser chez les élèves, d'une part, le recours à la lettre sans qu'elle ne soit imposée d'emblée par les enseignants et, d'autre part, à l'élaboration d'expressions algébriques dont la signification saurait être explicitée à leurs pairs.

Suite à la présentation de la variété des rôles que les chercheures que nous sommes avons joués dans le cadre de la recherche-action, la présente communication illustre comment l'étude et la mise en apparence auprès des enseignants de certaines contradictions inhérentes à l'apprentissage de la généralisation algébrique contribuent à enrichir les discussions avec les enseignants sur des manières d'introduire la généralisation algébrique.

Diversification des rôles des chercheures selon leurs objectifs

Au même titre que les enseignants et les conseillers pédagogiques, les assistants de recherche et les chercheures sont ici conceptualisés en tant que subjectivités qui s'expriment dans un projet commun dont l'objet est le développement de la pensée algébrique. Les objectifs des chercheures colorent l'intentionnalité de leur activité et sont :

- Accompagner nos participants et réfléchir collectivement au développement de la pensée algébrique chez les élèves
- Documenter l'activité d'enseignement/apprentissage de l'algèbre par l'étude de certains moments vécus dans les classes de nos participants
- Documenter l'activité d'accompagnement

Ces objectifs teintent ainsi les différents rôles assumés en tant que chercheures dont ce texte favorise leur distinction bien qu'ils s'exprimaient plus souvent qu'autrement en superposition.

Tableau 1: Rôles et tâches des chercheures

Rôles	Tâches
Formateur	· Concevoir des activités de formation · Animer les formations · Partager des exemples vécus en classe par l'une de nous alors que nous étions enseignante au secondaire · Planifier et préparer les journées de formations (méthodes, outils, etc.) · Anticiper / identifier les obstacles à l'apprentissage et intervenir si nécessaire · Assurer une gestion de groupe facilitant un apprentissage professionnel · Évaluer la progression ou l'atteinte des objectifs de formation · Identifier les besoins et les priorités
Investigateur des séances de classe	· Observer et étudier les activités d'enseignement/apprentissage de l'algèbre telles qu'elles se déroulent dans les classes · Produire et communiquer des résultats de recherche qui éclairent certaines composantes des activités étudiées
Investigateur des ressources didactiques	· Étudier les ensembles didactiques mis à la disposition des enseignants et des conseillers pédagogiques
Investigateur de l'activité de coélaboration entre participants et équipe recherche	· Observer et étudier l'activité de coélaboration entre les participants, la professionnelle et les assistantes de recherche telle qu'elle évolue principalement dans les journées d'échange et de formation et visant le développement de la pensée algébrique chez les élèves du 1er cycle. · Produire et communiquer des résultats de recherche qui éclairent certaines composantes de l'activité étudiée.
Accompagnateur	· Développer et maintenir des relations de collaboration avec les enseignants, les conseillers pédagogiques, la professionnelle et les assistantes de recherche · Offrir (ou s'assurer d'offrir lorsque la professionnelle de recherche est mise à contribution) un soutien pédagogique aux enseignants et conseillers pédagogiques entre les journées de formation · Contribuer à la recherche de solutions aux problèmes perçus

Adaptation de Lessard (2008) et Gagnon (2010)

La théorie de l'activité un outil pour le chercheur investigateur de l'activité de coélaboration entre participants et équipe de recherche

Ainsi, pour rendre compte de notre manière d'accompagner et d'étudier l'activité d'enseignement/apprentissage visant l'introduction de l'algèbre dans les classes de nos enseignants et sa transformation sous l'influence du projet, il s'avère utile de rappeler que les principes de la perspective retenue orientent inéluctablement la production de données, leur interprétation et plus spécifiquement notre manière de conceptualiser l'agir du chercheur dans ses différentes fonctions. Les postulats des théories socio historico-culturelles alimentent ce texte: les manières de faire, de penser, d'être des individus sont considérées comme des pratiques sociales qui sont consubstantielles de la culture dans laquelle ils vivent et qui doivent rendre compte de formes d'activités semblables passées (perspective historico-génétique). Les phénomènes doivent être étudiés de façon holistique plutôt que d'en isoler certains éléments qui ne rendraient plus compte des liens qu'ils entretiennent entre eux (Langemeyer & Roth, 2006). L'activité est ainsi considérée comme la plus petite unité d'analyse permettant aux chercheurs de donner du sens au processus de mise en apparence des participants à travers leurs actions posées. Pour mieux saisir le concept d'activité, il est nécessaire de comprendre sa nature dialectique (idéale, matérielle). Au sens de Leontiev, l'activité d'un sujet (enseignant, conseiller pédagogique ou chercheur) est toujours dirigée vers un objet/motif. L'objet de cette activité se matérialise dans les actions. Dans le cas particulier de l'apprentissage, Roth et Radford notent que :

> «[…] les élèves ne peuvent pas connaître l'objet/motif de l'activité d'apprentissage : cet objet doit être le résultat de l'activité d'apprentissage dans laquelle les autres – p.ex. les enseignants – assurent une fonction de régulation permettant l'expression d'autres activités humaines dans l'objet de l'activité d'apprentissage [traduction libre]» (Roth & Radford, 2011, p.16).

Comme l'a écrit Radford (2015), l'activité des élèves est la matérialisation d'archétypes culturels qui se donnent à voir dans « l'agir, le parlé, le perçu, le gesticulé, le symbolisé, le raisonné (p.338) ». Notre rôle de formatrices convoque aussi une responsabilité d'insérer dans l'activité d'accompagnement de nos participants des manières de faire associées au développement historico-culturel de la pensée algébrique et de rendre apparentes des facettes de l'enseignement/apprentissage à considérer lorsqu'on porte un regard didactique sur celle-ci. Ainsi, si pour Roth et Radford (2011) le défi de l'activité d'apprentissage pour les élèves est précisément qu'ils reconnaissent l'objet/motif à travers leurs propres actions, on verra qu'il en va de même pour les chercheurs qui se donnent le mandat de contribuer à la formation d'enseignants et de conseillers pédagogiques.

Roth et Radford (2011) nous invitent à considérer la pensée sous ses dimensions anthrolopologique (ses origines) et ontogénique (ses conditions d'existence). D'une part, la pensée est conceptualisée comme *praxis cogitans*. La pensée n'est pas fixe, elle est activité, elle est mouvement. Considérée comme potentialité, elle se dévoile, se matérialise dans un singulier et devient/est objet/activité de conscience. Radford (2011) parle alors de pensée/activité en termes de processus de prise de conscience qu'il a appelé objectivation. D'autre part, ce processus de prise de conscience n'est possible qu'à condition d'exister socialement. Les chercheurs ajoutent que ces processus de prise de conscience individuel et collectif sont mutuellement constitutifs.

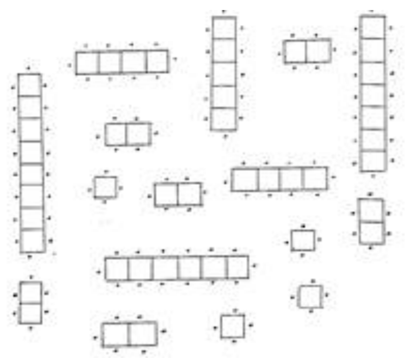
Le concept de contradiction

Les théories historico-culturelles nous invitent à conceptualiser l'activité en tant que mouvement. Le motif motive l'activité d'un individu, l'objet de l'activité se matérialise dans ses actions. Ce flux est considéré comme l'effet de l'activité elle-même. Prenant l'exemple des travaux de linguistes, Roth (2012) illustre le sens à donner à toute activité. Notre langue change dans ses usages. Comme l'écrit Bakhtin (1981) un langage meurt dès qu'il n'est plus utilisé. À chaque fois qu'un mot est utilisé, son sens se réifie, change tout comme la langue est elle-même transformée par l'usage d'un mot. Ainsi, les mots, les signes, sous une approche dialectique, ne sont pas une seule et unique entité (Roth, 2014). Ils portent et arborent, dans leurs usages, une contradiction interne qui se manifeste elle-même dans les différentes manières dont usent les individus des signes. Ces contradictions internes renvoient, selon Roth et Radford (2011) à des aspects conflictuels qui coexistent dialectiquement dans un phénomène. D'autres travaux recourent au concept de contradiction, mais il est plutôt conceptualisé différemment. C'est le cas des travaux d'Engeström (2001) et de Potari et al. (2018). Ces derniers étudient et distinguent l'activité de différentes communautés (p.ex. Ministère, enseignants) considérées comme des systèmes distincts. Ils identifient alors des contradictions dans les pratiques contraires, les choix différents entre enseignants ou entre un enseignant et une source externe (un chercheur, un manuel ou un programme). On avance alors que l'étude de contradictions émergeant entre deux systèmes peut créer des opportunités d'apprentissage et ainsi transformer les actions et buts d'une activité. Il s'agit alors de s'intéresser à l'activité de transformation d'un point de vue collectif tout en tenant compte de différents éléments médiateurs (sujet, outil, règles, communauté, division du travail…) qui influencent cette même activité.

Quelques éléments de méthodologie

Dans le cadre de la présente recherche-action, les séances de collaboration avec les enseignants et conseillers pédagogiques ont toutes été filmées. Dans le cadre de ces séances, les participants au projet s'étaient familiarisés avec certaines tâches, avaient analysé des vidéos d'enseignants qui animaient ces tâches et avaient assisté à la présentation de quelques contenus théoriques exposés par les chercheuses, notamment la typologie de la généralisation de Radford (2003) que nous n'exposerons pas ici. De même, les expérimentations qui ont eu lieu dans les classes des enseignants furent aussi filmées. Des transcriptions de ces enregistrements ont été effectuées. Dans le cadre de cette communication, nous discuterons des expérimentations qui ont succédé la séance de formation où la situation *Le Restaurant de Marcel* a été présentée aux enseignants (voir figure 1).

Marcel, le propriétaire du restaurant, dispose de tables simples dans son restaurant qu'il place l'une à côté de l'autre pour pouvoir placer ses clients lorsqu'ils arrivent. Il dispose ainsi de différentes tables de toutes sortes de grandeurs : des grandes, des petites, des moyennes…



Marcel aimerait bien ne pas avoir à compter à chaque fois les clients qui arrivent pour décider autour de quelle table il les place. Pourrais-tu l'aider à trouver une manière de calculer vite le nombre de clients qu'on peut asseoir autour d'une table, et ce, quelle que soit la grandeur de la table? Notre propriétaire habite loin alors il attend que tu lui écrives à ce sujet.

Écris-lui un **message en mots** qui lui indiquerait une manière de faire pour trouver vite combien de personnes il peut asseoir autour d'une table, et ce, pour n'importe quelle table.

Les messages sont longs à lire pour Marcel, réécris tes messages cette fois-ci sous forme de texto pour qu'il puisse les lire rapidement.

Figure 1. La situation du restaurant de Marcel

Avant de pouvoir discuter du potentiel et des intentions inhérentes à la situation, les enseignants ont eu à la résoudre. Ainsi, pour la première question, différents messages en mots sont possibles. On peut penser à de bons messages comme : 1) Il y a 2 personnes par table face à face et une personne à chaque extrémité de la table; 2) On peut asseoir 3 personnes sur les tables des extrémités et deux personnes face à face pour chacune des tables qui se situe entre ces deux tables; 3) On place une personne par table et une autre personne à une des extrémités de la table et on fait ceci deux fois (on voit une symétrie), des messages erronés sont également possibles. La formulation de ces messages se fait en contexte, les motifs présentés sont ici un support essentiel à la résolution. Dans la deuxième question, l'intention est d'amener les élèves à passer à la symbolisation, celle-ci permettant d'illustrer de façon concise et succincte une grandeur, ici le nombre de tables.

Réflexion sur des contradictions reconnues dans les expérimentations des enseignants

À travers cette situation, les intentions des chercheures sont de donner du sens au symbolisme en misant sur l'émergence d'une symbolisation qui sera propre et spontanée à chaque élève. En n'imposant pas l'usage d'un signe (lettre ou autre) en particulier, on peut s'attendre à une variété de symbolisations pour représenter la même grandeur. Outre ce travail autour de la symbolisation, l'intention est également de motiver le recours à différentes expressions algébriques qui seront équivalentes apportant une flexibilité dans la façon de voir des motifs. Cette façon de faire ouvre la porte sur un travail sur les expressions équivalentes.

Après la séance de formation, plusieurs enseignants sont allés expérimenter cette situation en classe en vue d'expliciter ce qu'ils avaient observé chez leurs élèves lors de la prochaine rencontre. Lors du retour, les formatrices ont observé une diversité dans les manières de faire des enseignants (voir tableau 1).

Tableau 2. Différentes manières de faire d'enseignants pour le *Restaurant de Marcel*

Stéphane	Annie	Alexandre
Cette situation est considérée par Stéphane comme étant la première qu'il utilise en classe pour introduire l'algèbre. Il reviendra sur celle-ci à plusieurs reprises durant quelques semaines. Il la réinvestit lorsque vient le temps d'aborder la reconnaissance de situations de proportionnalité (mots, table de valeurs et graphique). Lors de la première période, en équipes de deux, ses élèves doivent trouver deux formules différentes qui sont exprimées à l'aide de symboles algébriques. L'enseignant valide les formules obtenues et invite quelques équipes à venir les expliquer à l'avant en coordonnant leur explication du visuel des tables. Au cours suivant, l'enseignant axe sur la représentation des formules dégagées dans deux registres de représentation : table de valeurs et graphique. L'intention de l'enseignant est d'exprimer les liens existants entre ces trois registres : table, graphique et symbolique.	Annie mentionne avoir traité le chapitre «des suites» auparavant. Les élèves ont donc appris à dégager des formules en étudiant la récurrence additive dans la progression de différents motifs. L'enseignante introduit la situation proposée en ayant comme intention de faire dégager différents messages qu'elle souhaite obtenir en mots ou sur forme symbolique. Lors de la résolution, elle invite aussi ses élèves à construire une table de valeurs pour dégager une formule. Avec déception, elle partage ne pas avoir eu une diversité de formules.	Cette situation est la première qu'utilise l'enseignant pour introduire l'algèbre selon lui. Il dit avoir toutefois avoir amorcé un travail sur la traduction de relations de comparaison uniquement dans des jeux de fin de période. Pour la présente situation, l'enseignant favorise l'émergence de différents messages qui s'appuient sur une étude du motif. Lors du retour en grand groupe, l'attention est portée sur la validation de chacun des messages exprimés en mots en s'appuyant sur le visuel des motifs. Il a ainsi le souci de coordonner le visuel avec les mots. Suite à la première période, le recours au symbolisme est minoré. Alexandre met l'accent sur le potentiel des formules exprimées en mots pour prédire le nombre maximal de personnes qui peuvent s'asseoir selon le nombre de tables.

On peut remarquer que bien que les enseignants aient tous orchestré la situation du *Restaurant de Marcel*, l'activité de généralisation ou plus spécifiquement le processus de mise en apparence vécu par les élèves diffère dans chacune des classes selon ce que les enseignants valorisent au sujet du développement de la pensée algébrique. Comme formatrices, nous nous sommes données comme rôle de documenter l'activité d'enseignement/apprentissage vécue dans chacune des classes des enseignants participants. On peut ici documenter les différentes facettes d'un même objet (voir tableau 1). Mais le rôle de formateur va plus loin, il s'agit d'animer une discussion de groupe sur les différentes intentions qui ont animées les enseignants lors de la mise sur pied de l'expérimentation et sur les activités vécues. Tout en reconnaissant le potentiel de ces différentes manières de faire, il s'agit de revenir aux intentions ciblées au départ (motif de l'activité) par les formatrices et explicitées lors de la rencontre précédente. Il s'agit aussi de faire voir aux enseignants les différentes facettes (sens de la lettre, émergence d'expressions algébriques dont le sens diffère selon le processus d'objectivation des élèves, niveaux de généralisation reconnus…) d'une pensée algébrique qui se développe dans chacune des classes.

Ainsi dans la classe d'Alexandre, les formatrices reconnaissent l'importance accordée à donner du sens aux expressions algébriques. Elles s'attardent à faire voir aux enseignants tout le travail réalisé par l'enseignant pour aider ses élèves à coordonner la verbalisation des messages de généralisation dégagés au visuel fourni. Elles font alors voir cette contradiction (idéale/matérialisée dans l'activité de la classe) qui peut mieux s'expliquer dans l'association des niveaux de généralisation de Radford (2003). Le retour en grand groupe animé dans la classe d'Alexandre reste donc principalement au niveau de généralisation contextuelle. Celle-ci comporte encore des références aux particularités des objets du contexte et de leurs caractéristiques en référence à la situation spatio-temporelle. Les messages de généralisation restent contextuels au sens où leur mode de désignation dépend encore des propriétés spatiales. Comme le spécifie Radford (2003), les «arguments» ou «variables» ne sont plus des nombres, mais des objets génériques qui sont désignés par des termes génériques tels que «la figure», «la prochaine figure». D'autres contradictions sont ressenties par les formatrices lors de la présentation des approches de Stéphane et d'Annie mais elles ne sont pas du même ordre, de la même nature. En effet, l'ajout d'une table de valeurs dans la situation (approche d'Annie) limite les expressions dégagées par les élèves, ce qu'a pu observer l'enseignante. Des tensions sont de deux ordres, d'une part, il ne s'agit plus ici de travailler sur les différentes symbolisations possibles et sur une diversité d'expressions qui sont porteuses de sens pour les élèves, la recherche d'une règle semble prendre le pas. D'autre part, le travail de généralisation engagé par les élèves semble escamoté par l'application d'une procédure (à chaque table qui s'ajoute, il y a deux personnes de plus donc on inscrit «fois deux» dans la formule). Cette contradiction a été moteur de changement chez l'enseignante qui en a elle-même pris conscience en comparant l'activité de sa classe avec celle de ses pairs.

Dans le cas de l'approche de Stéphane, les interventions des formatrices ne sont pas du même ordre puisque les intentions visées sont rencontrées, mais l'accent est mis sur le travail autour des registres de représentation. Il s'agit alors de faire voir aux enseignants que l'exercice de convertir une expression dans une autre registre et d'y coordonner les différentes significations est une tâche exigeante pour les élèves qui amorcent leurs apprentissages au sujet de la généralisation algébrique. Il ne s'agit pas de dire aux enseignants que ce qu'ils font est incorrect ou qu'il y a contradiction, au sens d'Engestrom (2001), selon «notre système formatrice», mais plutôt de les aider à percevoir les différentes facettes qui s'enchevêtrent lorsqu'il s'agit de réfléchir au travail de généralisation algébrique.

Conclusion

L'étude des activités d'enseignement/apprentissage qui ont cours dans les différentes classes des enseignants que nous accompagnons illustre différentes manières de faire d'enseignants qui, bien que partant d'une même situation, ont des motifs différents. Dans notre rôle de chercheures investigatrices des séances de classe, nous étudions la matérialisation de l'expression de la pensée algébrique dans chaque classe soit cette expression de contradictions entre ce que les enseignants visent et ce qui se matérialise. Dans notre rôle de formatrice, c'est en nous appuyant sur ces différentes manières de faire que l'on rend apparentes différentes facettes qui colorent toutes l'expression d'une pensée algébrique mais qui la façonnent toutefois de façon différente.

Remerciements

Les données et résultats présentés dans le texte proviennent d'une recherche-action dont le titre est «Co-construction, mise à l'essai, analyse et partage de situations didactiques visant à favoriser la transition arithmétique/algèbre». Ce projet a été subventionné dans le cadre du programme de soutien à la formation continue du personnel scolaire, Chantier 7, du Ministère de l'Éducation, du Loisir et du Sport (2013-2017).

THE ALLOCATION OF SENSE TO THE QUOTATIVE DIVISION OF FRACTIONS

LA ASIGNACIÓN DE SENTIDO A LA DIVISIÓN CUOTATIVA DE FRACCIONES

This research paper is part of a doctoral study under development. In this research report, we analyze the cognitive and operative processes that first graders in secondary school perform in assignments involving division of fractions. The study includes some contributions from researchers who have adopted the problem solving about division of fractions tasks through the quotative model, as well as the use of different levels for coordination of units proposed by Hackenberg (2007). Tasks here presented include problems solving through canonical and pictorial algorithms, and form part of a questionnaire that was thoroughly analyzed, by contrasting the arithmetic-symbolic notations and the expressions of the language.

Keywords: Division of fractions, canonical and pictorial algorithm.

Introduction

In the semantic analysis carried out in this research report focused on measuring how much a part fits in the given hole, that Fischbein, Deri, Sainati, Sciolis (1985) called a quotative model of division and recognized the pictorial algorithm by Kieren (1985), we intend to make sense of dividing fractional numbers using a didactic support that makes feasible its comprehension and achieves good results in the applied tasks; otherwise, if only the canonical algorithm is applied the operation of division of fractions will be mechanic. This situation is illustrated below with an example.

Operations that students carry out can not be restricted to operational-algorithm use of fractional number; on the contrary, we intend that they help to achieve a semantic interpretation through a pictorial algorithm proposed in each task. We consider that the use of the pictorial algorithm is substantial in the present research work because through it we can observe the steps students follow when facing diverse problematic situations posed and there is no doubt about first graders' competency in Telesecondary schools (an educational modality in Mexico that is taught to the most remote places through television images) to solve tasks in which division of fraction is involved within the quotative model.

Research question and objectives

Mexican students' assessments in secondary school are applied through an official test called Early Warning System (Sistema de Alerta Temprana-Sisat, 2018). For now, results are not quite positive for first graders in Telesecondary modality, which take us to investigate which are the performance and strategies students use to face problematic situations that involve the quotative division of fractions?

General aim:

Identify through the pictorial algorithm, the different strategies used by that first graders in Telesecondary to give sense to the quotative division of fractions to understand why it is divided, by recognizing how much a fraction fits in another fraction.

Theoretical framework

Rational numbers have been a fairly broad research topic around the world, just to mention some of the most outstanding authors such as Kieren (1983), who define several subconstructs to understand the meaning of fractional numbers. Streefland (1991) highlights realistic models where operational and conceptual operation of rational numbers is necessary. Vergnaud (1988) came up with theorems in action, which will help us to analyze the students' conceptual difficulties when solving the proposed tasks. Fischbein et al. (1985) defines the quotative division that is essential in the present research work. Tirosh (2000) emphasizes the semantic and operative elements that required to solve a division of fraction task, but much students lack them. Valdemoros (2004) points out how semantic contents are vital to achieve the transition from natural language to an arithmetic language, all which is necessary to define with considerable accuracy regarding quotative division of fractions.

Students' limitations regarding the division of fractions have been documented over the last decades, as well as those limitations that the in-service teachers also show, as Izsák (2012) reports, who express how most of in-service teachers can solve tasks involving division of fractions through a canonical algorithm, but they have serious difficulties to solve such tasks when this type of number appears in problematic situations in the division of fractions. This situation also occurs in secondary students. Izsák (2012) shows a task from Armstrong & Bezuk (1995), in which teachers accepted that the required situation to solve it was a multiplication of fractions, but when asked to explain their thought or draw diagrams to unify the algorithmic-canonical result to that of pictorial one (by using geometric representations) and understand what kind of unit were using in each case, teachers showed many difficulties to recognize their cognitive conflicts, this situation that also arises in secondary students and it is one of the fundamental reasons that lead us to investigate about such problematic.

To construct a quotative model for dividing fractional numbers, the different levels of unit coordinations proposed by Hackenber (2007) are taken into account; although, the focus of the paper is the construction of improper fractions, its original contributions of how students carry out the coordination of different levels of units for the construction of proper fractions is fundamental to this research work.

The correct identification of appropriate reference units (Schwartz, 1988) for each fraction is fundamental for solving tasks that involve the division of fractions; and the coordination of unit structures in the three levels mentioned in the previous paragraph, are essential for understanding the mathematical knowledge, all of this through drawing geometric models, diagrams and other pictorial elements that students use to appropriate the arithmetic of rational numbers.

Method

Participants

There were 28 first graders belonging to a scholar group which we applied a questionnaire in a Telesecondary school located on the boundary of the state capital of Puebla. The school was selected because the teacher of the group showed great interest in the didactic treatment about knowledge of fractional numbers.

Socio-Cultural Situation

The school has 198 students divided into six groups (2 groups for each grade). The school has the Service and Support Unit for Regular Education, what is in charge to assist students with low school achievement; it also has institutional support resources such as the Internet, food service, psychological attention, library, civic and sports activities.

Methodological instruments

We designed a questionnaire for the first graders in Telesecundaria. It consisted of eight tasks that involved mathematical problems about the division of fractions. For each task, we provided two ways of solving it, canonical and pictorial algorithms (tasks should be solved in both ways). The following is one of the tasks: How many parts of ½ meter of a wooden board can I obtain in 2 wooden boards if each board measures 2 meters? Toño achieved the first result through the canonical algorithm. He operated $2 \div \frac{1}{2} = 4$ parts in each wooden board. The second solution came through the pictorial algorithm; Pepe represented his operation with two rectangular figures divided into four parts each and said ½ meter of wood fits 4 times in each wooden board. Students solved another task equal to the previous explained, but the fraction unit was 1/3.

Analysis of collected data

In this research paper, we consider those answers that used both models of solving because from these models we can build appropriated meanings for the operations the students carried out, in particular the quotative meanings. Andrea's answer was right. In her first answer, she operated $2/1 \div 1/3 = 6/1 = 6$. In her second answer, she drew two rectangular figures divided into 3 parts each one, so her answer to the task was: 6 parts.

As we can observe in Andrea's answer, she formed a structure of two levels of unit coordination, where a two-unit range is divided into three equal parts. This answer allowed us to determine that Andrea understood the quotative meaning of the division of fractions by using two levels of unit coordination.

Results

The students could solve tasks in the questionnaire by using those strategies they considered appropriate; however, when the solution involves the use of the pictorial algorithm this allows us to determine in which moment and circumstances students constructed the different levels of unit coordination, which in turn allows us to know if the reasoning used is correct or there are some deficiencies in their development.

The students in first grade gave only one answer through the canonical algorithm. They had difficulties to explain each of their answers, though they were correct, their interpretation of results was unreliable and their oral explanations were inconsistent. So, the didactic interview with feedback (Valdemoros, 2004, Valdemoros, Ramirez and Lamadrid, 2015) and the group interview (Werscht, 1993), which will be carried out soon, will be of great help in clarifying the students' conceptualizations that participate in this research.

Conclusions

The first graders' performance in the Telesecondary modality can be observed in the tasks included in the questionnaire; unfortunately, results are a little favorable because most of the students tried to solve tasks by changing the fractional numbers to decimal numbers. Others seemed not to have previous knowledge regarding the pictorial algorithm, which at the end was inconvenient and in some cases caused serious conflicts of interpretation of the proposed tasks. To solve these inconveniences, we propose to carry out a series of didactic interviews with feedback (also described as a didactic interview) applied to some of the students in first grade as well as to apply a group interview in the following phase of the research. Currently, the theoretical-methodological and empirical design of the collective interview is in process.

El presente trabajo de investigación forma parte de un estudio doctoral en desarrollo; en este reporte de investigación analizamos los procesos cognitivos y operatorios que presentan los alumnos de primero de secundaria para realizar tareas en las que se involucra la división de fracciones. En el estudio se incluyen aportaciones de investigadores que adoptan la resolución de tareas de división de fracciones por medio del modelo cuotativo, así como la utilización de los distintos niveles de coordinación de unidades propuestos por Hackenberg (2007). Las tareas que se presentan en este estudio incluyen la resolución de problemas por medio de los algoritmos canónico y pictórico. Dichas tareas fueron integradas en un cuestionario, el cual se analizó de forma exhaustiva, por medio del contraste entre las notaciones aritmético-simbólicas y las expresiones de la lengua que acompañaron a las primeras.

Palabras clave: División de fracciones, algoritmos canónico y pictórico.

Introducción

El análisis semántico realizado en el presente documento de investigación se centra en la medición del cuánto cabe una parte en el todo dado, denominado por Fischbein, Deri, Sainati, Sciolis (1985) como modelo cuotativo, a través del algoritmo pictórico (Kieren, 1985), con el cual pretendemos otorgar sentido a la división de números fraccionarios, dando un tratamiento didáctico que facilite su comprensión y la obtención de buenos resultados en las tareas a resolver; ya que si sólo se aplica el algoritmo canónico estaremos haciendo mecánica la operación de división de fracciones, más adelante se ilustra con un ejemplo esta situación.

Las operaciones realizadas por los alumnos no pueden quedar restringidas al uso operacional-algorítmico de los números fraccionarios, sino por el contrario, se pretende que puedan facilitar una interpretación semántica por medio del algoritmo pictórico propuesto en cada una de las tareas a realizar. Consideramos que el manejo del algoritmo pictórico es substancial en el presente trabajo de investigación, ya que a través de él podemos observar los pasos que sigue cada estudiante ante las diversas situaciones problemáticas planteadas, y no dudamos de la capacidad de los alumnos de primero de telesecundaria (modalidad educativa en México que se imparte hasta los lugares más alejados, a través de imágenes televisivas) para resolver las tareas en las que se involucra la división de fracciones, a través del modelo cuotativo.

Pregunta de investigación y objetivos

La evaluación que se elabora en México para los alumnos de secundaria se realiza a través de la prueba oficial denominada Sistema de Alerta Temprana (Sisat, 2018), los resultados obtenidos hasta ahora son poco favorables en los alumnos de primero de telesecundaria, lo que nos permite preguntar, ¿cuál es el desempeño y las estrategias que utilizan los alumnos de primero de telesecundaria frente a situaciones problemáticas en las que se involucra la división cuotativa de fracciones?

Objetivo general:

Identificar, por medio del algoritmo pictórico, las distintas estrategias que utilizan los alumnos de primero de telesecundaria para otorgar sentido a la división cuotativa de fracciones para comprender por qué se divide, a través de reconocer cuánto cabe una fracción en otra fracción.

Marco teórico

Los números racionales han tenido un tratamiento de investigación bastante amplio alrededor del mundo, con autores muy reconocidos de distintos países, sólo por mencionar algunos de los más destacados como Kieren (1983), define a lo que llama subconstructos para entender las significaciones de los números fraccionarios. Streefland (1991) destaca los modelos realistas en los que es necesario el manejo operativo y conceptual de los números racionales. Vergnaud (1988) propone los teoremas en acción, los cuales nos servirán para analizar las dificultades conceptuales de los alumnos al resolver las tareas propuestas. Fischbein et al. (1985) define la división cuotativa que es central en este trabajo de investigación. Tirosh (2000) hace énfasis en los elementos conceptuales y operatorios que necesitan los estudiantes para resolver una tarea de división de fracciones, pero que en muchas ocasiones carecen de ellos. Valdemoros (2004) señala cómo los contenidos semánticos son de vital importancia para realizar la transición del lenguaje natural al lenguaje aritmético, lo cual en nuestro estudio es necesario definir con la mayor claridad respecto a la división cuotativa de fracciones.

Las limitaciones de los alumnos de secundaria con respecto a la división de fracciones se han documentado durante las últimas décadas, así como las limitaciones que tienen también los futuros profesores como lo reporta Izsák (2012), quien identifica cómo la mayoría de los maestros en servicio pueden resolver tareas en las que se involucra la división de fracciones a través del algoritmo canónico y, sin embargo, tienen serias dificultades para resolver dichas tareas cuando este tipo de números se presentan en situaciones problemáticas de división de fracciones, esta misma situación se presenta en alumnos de secundaria. Izsák (2012) propone una tarea extraída de Armstrong y Bezuk (1995), en la cual los maestros reconocieron que la situación requerida para resolverla era una multiplicación de fracciones, pero cuando se les solicitó que explicaran sus pensamientos o dibujaran diagramas para unificar la solución algorítmica-canónica con la pictórica (mediante el uso de representaciones geométricas) y comprender qué tipo de unidad se estaba utilizando en cada caso de la situación problemática, presentaron muchas dificultades para reconocer sus conflictos cognitivos, circunstancia que se presenta también en los alumnos de secundaria y es uno de los motivos fundamentales que nos llevaron a indagar sobre esta difícil problemática.

El modelo cuotativo de división de números fraccionarios se realiza aquí tomando en consideración los distintos niveles de coordinación de unidades propuestos por Hackenberg (2007), aunque el foco de atención del artículo es la construcción de fracciones impropias, es central en este trabajo de investigación su aportación original de cómo los estudiantes realizan la coordinación de los distintos niveles de unidades para la construcción de fracciones propias.

La correcta identificación de unidades de referencia (Schwartz, 1988) apropiadas para cada fracción es fundamental para la resolución de las tareas que implican división de fracciones, y la coordinación de estructuras de unidades en los tres niveles mencionados en el párrafo anterior, son esenciales para la comprensión del conocimiento matemático, todo esto a través de modelos geométricos dibujados, esquemas, y demás elementos pictóricos que utilizan los alumnos para apropiarse de la aritmética de los números racionales.

Método

Participantes

Se aplicó un cuestionario a 28 alumnos de primero de telesecundaria ubicada en la periferia de la capital del Estado de Puebla, la escuela fue seleccionada porque la maestra titular del grupo muestra gran interés por la apropiación de conocimientos de los números fraccionarios.

Entorno socio-cultural

La escuela seleccionada tiene un total de 198 alumnos repartidos en seis grupos (2 grupos de cada grado), cuenta con una Unidad de Servicio y Apoyo a la Educación Regular, la cual se encarga de atender a los alumnos que presentan bajo aprovechamiento escolar. La institución dispone además de recursos de apoyo institucional como: servicio de internet, comedor, asistencia psicológica, biblioteca escolar y de grupo, actividades cívicas y deportivas.

Instrumentos metodológicos

Se aplicó un cuestionario a los alumnos de primero de telesecundaria, con ocho tareas en las que se involucraban situaciones problemáticas de división de fracciones; en cada una de las tareas se proporcionaron dos formas de solución, los algoritmos canónico y pictórico (ambas debían ser resueltas). La tarea propuesta fue la siguiente: ¿cuántas partes de 1/2 de metro de tabla de madera, puedo obtener en 2 de tablas de madera, si cada tabla mide 2 metros? La primera solución se presentó por medio del algoritmo canónico, Toño realizó la operación de $2 \div 1/2 = 4$ partes en cada una de las tablas. La segunda solución se expuso a través del algoritmo pictórico, Pepe representó su operación con dos figuras rectangulares divididas en 4 partes cada una y dijo 1/2 metro de madera cabe 4 veces en cada una de las tablas. La tarea a realizar por los alumnos fue la misma que se expuso al principio del párrafo, solo se modificó la fracción unitaria a 1/3.

Análisis de datos recopilados

La postura del presente trabajo de investigación es tomar en cuenta aquellas respuestas que utilizaron los dos modelos de solución propuestos en el ejemplo, ya que a partir de estos modelos podemos construir significados apropiados para las operaciones realizadas por los alumnos, en especial los significados cuotativos. La respuesta de la alumna Andrea fue correcta, ya que su primera respuesta fue realizar la operación de $2/1 \div 1/3 = 6/1 = 6$. La segunda respuesta de Andrea fue dibujar dos figuras rectangulares divididas en 3 partes cada una, por lo que su respuesta a la tarea fue: 6 partes.

Como se observa en la respuesta de Andrea, forma una estructura de dos niveles de coordinación de unidades, en la que un intervalo de dos unidades se divide en tres partes iguales; esta respuesta nos permite determinar que Andrea entendió el significado cuotativo de la división de fracciones, utilizando dos niveles de coordinación de unidades.

Resultados

Los alumnos pueden resolver las tareas propuestas en el cuestionario aplicado utilizando las estrategias que consideren más apropiadas, sin embargo, cuando la solución implica la utilización del algoritmo pictórico nos permite clarificar en qué momento y circunstancias se apropian de los diferentes niveles de coordinación de unidades, lo que a su vez nos permite conocer si el razonamiento utilizado es correcto o si tienen algunas deficiencias en su apropiación.

Los alumnos que solamente dan una respuesta a través del algoritmo canónico, tienen serias dificultades para explicar cada una de sus respuestas, ya que aunque tengan una solución correcta, su interpretación del resultado es poco confiable y su explicación verbal tiene muchas inconsistencias, por lo que la entrevista didáctica y con retroalimentación (Valdemoros, 2004, Valdemoros, Ramirez y Lamadrid, 2015) y la entrevista colectiva (Werscht, 1993), a realizar próximamente, serán de gran ayuda en el esclarecimiento de las conceptualizaciones de los alumnos seleccionados.

Conclusiones

El desempeño de los alumnos de primero de telesecundaria se ve reflejado en las tareas propuestas en el cuestionario aplicado, desafortunadamente los resultados son poco favorables, debido a que la mayoría de los alumnos intentó resolver las tareas cambiando los números fraccionarios a números decimales y otros, al parecer, no tenían conocimientos preliminares concernientes al algoritmo pictórico, lo que a la postre resultó inconveniente y en algunos casos causó graves conflictos de interpretación de las tareas propuestas. Para resolver este tipo de inconvenientes, se propone una serie de entrevistas didácticas y con retroalimentación (también descrita como entrevista didáctica) para llevar a cabo en la siguiente fase de la investigación con algunos alumnos seleccionados, así como la aplicación de una entrevista colectiva. El diseño teórico-metodológico y empírico de la entrevista colectiva se está elaborando actualmente.

We report progress from a longitudinal study focused on identifying expressions of mathematical generalization articulated by students at early ages through the design of 17 tasks that are organized into structured blocks, comprising numerical sequences and everyday situations. We present the results obtained with respect to solving numerical sequences.

Keywords: Algebraic thinking, Primary education.

Purpose of the Research

We present preliminary results of a study focused on the analysis of expressions of mathematical generalization that arise in early ages, particularly among students ranging between 10 and 12 years of age when solving generalization mathematical tasks. It is expected that expressions of generalization shown by students in a natural and incipient way will be refined as they develop their capacity for generalization, which could contribute to development of algebraic thinking at later levels.

Reference Framework

Generalization is a topic of interest to various researchers and is analyzed from different perspectives (e.g. Radford, 2000, 2002; Rivera, 2006, 2018; Schliemann, Carraher y Brizuela, 2012). The approach in this study is based on the contributions of John Mason regarding the ability possessed by students to generalize, and how that ability can be developed through mathematical tasks that lead them to articulate generality.

Expressing the regularities that are observed in a generalization task is a reference to algebraic work, albeit incipient, that arises in students. Mason, Graham, Pimm and Gowar (1999) are of the opinion that expressing generality is a very important process, because it contributes to the acquisition of algebraic language. This process can be considered a continuous spiral of actions (Mason, 1996), which is summarized as the *manipulation* (first action) of particular examples to *obtain meaning* (second action) of what is happening in them, in order to *articulate* generalities (third action), and express them in some useful mathematical form.

Manipulation (of physical, mental or symbolic objects) provides the basis for detecting patterns, relationships, generalities, etc. Discovering what is happening allows one *getting a sense of* some characteristic or property of the objects that are being manipulated, which allows one to *articulate* and manifest the expression of generality. When this occurs, such an expression becomes a new entity that can be manipulated and used to find other properties, allowing it to continue ascending the spiral and starting a new cycle of actions. But when resolution is difficult, and the conjectures are wrong, the sensible thing is to return to the corresponding cycle of actions and *manipulate* more examples in order to be able to ascend.

Likewise, Mason et al. (1999) consider three stages in the generalization process: seeing, saying and recording. “Seeing” refers to the mental identification of a schema, structure or relationship. Seeing generalities means that students can identify key factors and combine them to produce a rule that

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

works; this can happen after a certain time, working with a number of particular examples until the identification of something common is achieved. "Saying", either to oneself or to someone in particular, is to articulate in words what has been recognized. Before saying the observed generalities, there is an expression of what occurs in particular cases. "Recording" a pattern or relationship leads to symbolization and written communication, which is not easy to do. The register can involve a variety of formats: drawings, word drawings, mostly words and some symbols, or mostly symbols with some words (Mason et al., 1999).

Method

The study is qualitative and descriptive in nature (Cohen, Manion y Morrison, 2007). It is longitudinal and done in cohort as the same students are followed through two school cycles, beginning in grade five of primary school. The study plan for both cycles corresponds to 2011. Identifying regularities in numerical sequences in order to find nearby missing terms or to continue the sequence (Secretaría de Educación Pública, 2011) is one of the expected learning outcomes for grade five, but generalization is not promoted. Textbooks for grades four through six include one or two activities involving these types of number sequences. Participants were deemed to have no experience with generalization tasks at the time of the study.

Design of Mathematical Tasks

17 tasks were designed for the two school cycles, which were organized in four blocks with a structured order involving a gradual transition from number sequences to everyday situations. Blocks I and II correspond to numerical sequences, Blocks III and IV to everyday situations. The analysis of responses corresponding to Blocks I and II is reported here.

Block I (numerical sequences 1-8). The mathematical structure underlying these sequences corresponds to the functions $f(x) = x$, $f(x) = 2x$, $f(x) = 2x - 1$, $f(x) = x^2$, $f(x) = 3x$, $f(x) = x + 3$, $f(x) = 4x$, $f(x) = x + 4$. Each sequence is presented through a dotted figure and the corresponding figure number. Inductive reasoning (*manipulation* of particular cases) is fostered with the intention of having students identify the correspondence relationship between the number of points and the figure number (*get a sense of*) to *articulate* the correspondence rule (generalization). When students, using the first elements of the numerical sequence, can find nearby elements, it can be said in terms of Mason (1999), that they perceive generality. By requesting considerably distant elements, the articulation of the generalization rule is promoted. As students manipulate particular cases, they are expected to "see" the corresponding structure or relationship, identifying what remains and what varies so as to articulate the generalization rule that characterizes each task. In each subsection, a figurative, numerical or explanatory record is requested. Figure 3 is an example of the numerical sequence in Block I, they all have a similar format, the variant lies in the function involved.

Block II (numerical sequences 9-10). The mathematical structure of these sequences corresponds to the functions $f(x) = 2x$, $f(x) = x + 2$. Each sequence is presented in a table that includes numerical terms along with the number that corresponds to the term, omitting the figurative (Figure 1). An inductive reasoning is also fostered, and the registry stage is highlighted during the resolution of the task. The tasks in both blocks are aimed at analyzing the articulation of the (written) ideas that lead to the generalization rule, but in this Block II, the request for a rule is made explicit. Subsection e) encourages students to suggest a number (it could be near or far); according to Mason (1999) these assignments tend to stimulate in students the scope of the generality they are expressing.

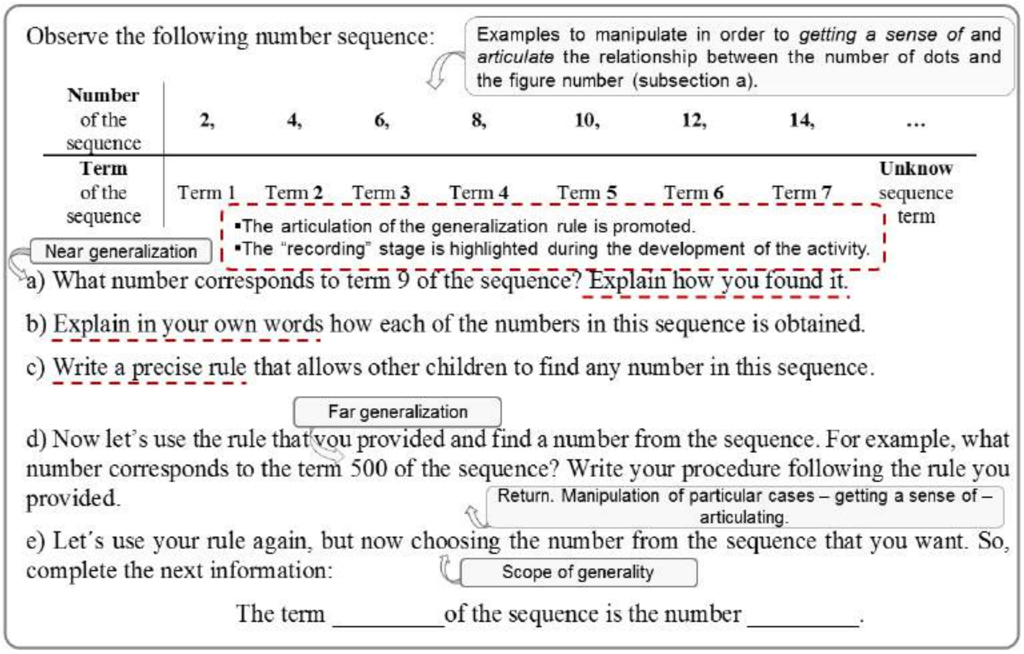

Figure 1: Task 9. Block II

Participants, Application and Analysis of Responses

The participants were 25 students from a public school located in Tekit, Yucatán, Mexico. A printout of each task was provided, students worked individually and there was no intervention by the researcher. The analysis is carried out individually to identify the expressions of generalization by student and by block, given that the tasks in each block have common characteristics. Figure 2 provides the scheme designed for the analysis of Block I responses under the Mason (1996) spiral of actions.

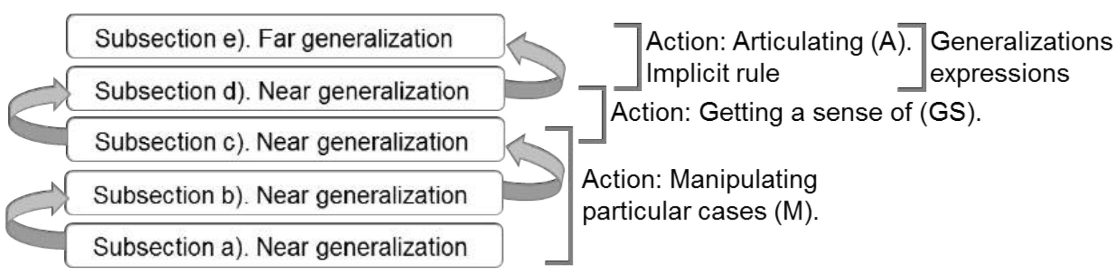

Figure 2: Maison (1996) spiral of actions in the tasks of Block I

Figure 3 provides an example of the analysis of the responses of Student 10 (S10) in Task 2 of Block I. Table 1 shows the summary of the analysis of actions that were recognized in this task by 25 students. We can see that S10 correctly constructs figures 5, 6 and 7 (part a), demonstrating the adequate manipulation of the particular cases, both figuratively and numerically (part b). The manipulation of increasingly distant examples (parts c and d) can be interpreted as getting a sense of generality, which leads to articulation and concise expression of the rule of correspondence between the number of points and the number in the figure (part e). The rule is recorded in natural language, using words (without drawings or symbols). In an analogous way, the responses of the tasks in Block II are analyzed with the corresponding scheme.

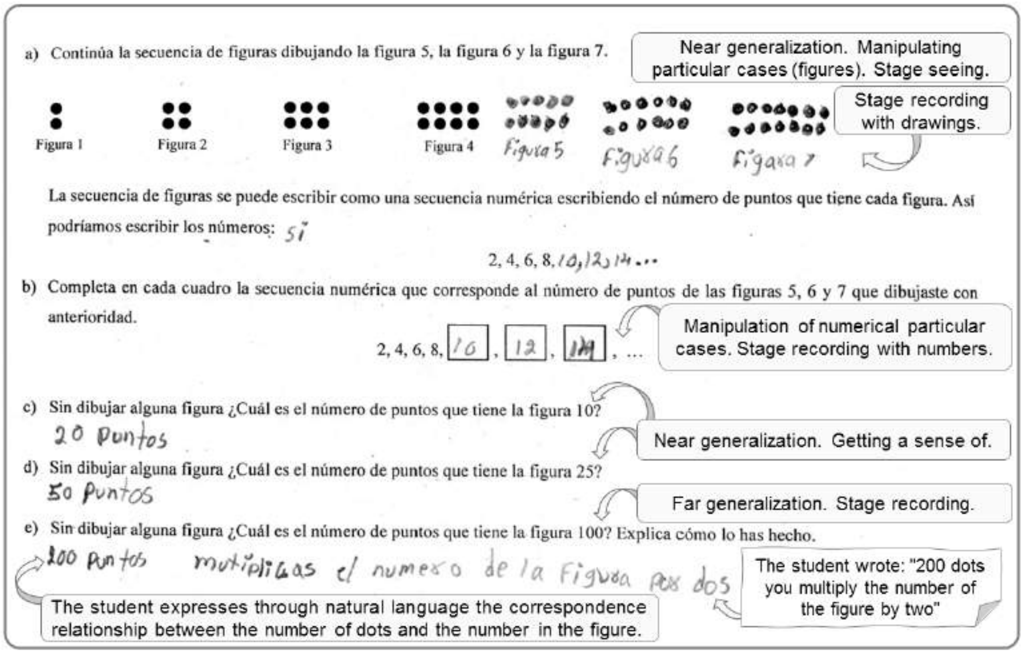

Figure 3: Analysis S10 responses in Task 2 of Block I

Table 1: Summary of actions in Task 2 of Block I

Note: S=Student; M=Manipulating; GS= Getting a sense of; A= Articulating; NA=No answer; Blank space=Student fail any of the M-GS-A actions.

Results and Preliminary Conclusions

Students provide evidence of their ability to generalize by identifying, in numerical sequence tasks, those details that remain unchanged and those that change. Also, they can identify regularities and patterns, read and interpret tabular registers and above all articulate expressions of generalization. These expressions were communicated through numerical answers, words or words with some arithmetic symbols, which resulted in 5 categories: 1) expressions that state only the regularity of the pattern, that is, the variation between the terms; 2) numeric expressions that arise from using previous results, being correct only for the functions of the form $f(x) = ax$; 3) generalized number, that is, the generalization is expressed only for the requested number; 4) expressions that incipiently state what happens with the relationship between the two variables involved and 5) expressions denoting generalization considering any term (such as the one reported in Figure 3). In the next phase of the study, we will analyze the stage "saying" using the expressions of generalization done by interviewing the 25 students when they solve everyday context tasks. Finally, in our opinion the work provides references on the development of algebraic thinking and language that can contribute to the teaching of basic education.

Se reportan avances de una investigación longitudinal cuyo interés se centra en identificar las expresiones de generalización matemática que articulan los estudiantes en edades tempranas a través del diseño de 17 tareas organizadas en bloques estructurados que comprenden secuencias numéricas y situaciones cotidianas. Se presentan los resultados obtenidos en la resolución de las secuencias numéricas.

Palabras clave: pensamiento algebraico, educación primaria.

Propósito de la Investigación

Se presentan resultados preliminares de un estudio cuyo propósito es analizar las expresiones de generalización matemática que se manifiestan en edades tempranas, particularmente en estudiantes de 10 a 12 años cuando resuelven tareas matemáticas de generalización. Se considera que las expresiones de generalización que manifiestan los estudiantes de manera natural e incipiente se irán refinando conforme vayan desarrollando su capacidad de generalización, lo que podría contribuir al desarrollo de un pensamiento algebraico en niveles posteriores.

Marco de Referencia

La generalización es de interés para diversos investigadores y es analizada desde diferentes perspectivas (p.ej. Radford, 2000, 2002; Rivera, 2006, 2018; Schliemann, Carraher y Brizuela, 2012). En esta investigación el enfoque se apoya en las contribuciones de John Mason respecto a la capacidad de generalizar que poseen los estudiantes, y cómo ésta puede ser desarrollada mediante tareas matemáticas que los conduzcan a articular la generalidad.

Expresar las regularidades que se observan en una tarea de generalización es referencia del trabajo algebraico, aún incipiente, que surge en los estudiantes. Mason, Graham, Pimm y Gowar (1999) consideran que expresar la generalidad es un proceso importante porque contribuye a la adquisición del lenguaje algebraico. Este proceso puede considerarse como una espiral continua de acciones (Mason, 1996), la cual se resume en la *manipulación* (primera acción) de ejemplos particulares para *obtener sentido* (segunda acción) de lo que está ocurriendo en ellos, con el fin de *articular* generalidades (tercera acción) y expresarlas en alguna forma matemática útil.

La *manipulación* (de objetos físicos, mentales o simbólicos) proporciona las bases para detectar patrones, relaciones, generalidades, etc. Descubrir lo que está sucediendo permite *obtener sentido de* alguna característica o propiedad de los objetos que se están manipulando, lo que da lugar a *articular* y manifestar la expresión de generalidad. Cuando esto ocurre, tal expresión se convierte en una nueva entidad que puede ser manipulada y usarse para encontrar otras propiedades, lo que permite continuar ascendiendo en la espiral empezando un nuevo ciclo de acciones. Pero cuando la resolución resulta difícil, y las conjeturas son erróneas, es sensato regresar al ciclo de acciones correspondiente y *manipular* más ejemplos para poder ascender.

Asimismo, Mason et al. (1999) consideran tres etapas en el proceso de generalización: ver, decir y registrar. “Ver” se refiere a la identificación mental de un esquema, estructura o relación. Ver generalidades implica que los estudiantes puedan identificar factores clave y combinarlos para producir una regla que funcione; esto puede ocurrir después de cierto tiempo, trabajando con un número de ejemplos particulares hasta que se logra la identificación de algo común. El “decir”, ya sea a uno mismo o a alguien en particular, es articular en palabras aquello que se ha reconocido. Antes de decir las generalidades observadas se suele decir qué ocurre en casos particulares. “Registrar” un patrón o relación conduce a la simbolización y la comunicación escrita, lo cual no es fácil de realizar. El registro puede involucrar una variedad de formatos: dibujos, dibujos con palabras, la mayor parte palabras y algunos símbolos o la mayor parte de símbolos con algunas palabras (Mason et al., 1999).

Método

El estudio es de naturaleza cualitativa y de corte descriptivo; es longitudinal y de cohorte (Cohen, Manion y Morrison, 2007) en virtud de que se realiza un seguimiento a los mismos estudiantes durante dos ciclos escolares, empezando en quinto grado de primaria. El plan de estudios de ambos ciclos corresponde al año 2011, entre los aprendizajes esperados en quinto grado se encuentra la identificación de regularidades en sucesiones numéricas para encontrar términos faltantes cercanos o continuar la sucesión (Secretaría de Educación Pública, 2011) pero no se promueve la generalización. Los libros de texto de cuarto a sexto grado incluyen una o dos actividades para trabajar con ese tipo de secuencias numéricas. Se considera que los participantes no contaban con experiencia sobre tareas de generalización al momento del estudio.

Diseño de las tareas matemáticas

Se diseñaron 17 tareas para los dos ciclos escolares, organizadas en cuatro bloques con un orden estructurado que conlleva ir gradualmente de secuencias numéricas a situaciones cotidianas. Los

Bloques I y II corresponden a secuencias numéricas, los Bloques III y IV a situaciones cotidianas. Se reporta el análisis de respuestas correspondientes a los Bloques I y II.

Bloque I (secuencias numéricas 1-8). La estructura matemática que subyace a estas secuencias corresponde a las funciones $f(x) = x$, $f(x) = 2x$, $f(x) = 2x - 1$, $f(x) = x^2$, $f(x) = 3x$, $f(x) = x + 3$, $f(x) = 4x$, $f(x) = x + 4$. Cada secuencia se presenta mediante una figura con puntos y el número de la figura correspondiente. Se promueve un razonamiento inductivo (*manipulación* de casos particulares) con la intención de que los estudiantes identifiquen la relación de correspondencia entre el número de puntos y el número de figura (*obtener sentido de*) para *articular* la regla de correspondencia (generalización). Cuando los estudiantes, apoyándose en los primeros elementos de la secuencia numérica puedan encontrar elementos cercanos se puede decir en términos de Mason (1999) que ellos perciben generalidad. Al solicitar elementos considerablemente distantes se promueve la articulación de la regla de generalización. Se espera que a medida que manipulen los casos particulares "vean" la estructura o relación correspondiente, identificando aquello que permanece y lo que varía para articular la regla de generalización que caracteriza a cada tarea. En cada inciso se solicita hacer un registro de tipo figurativo, numérico o explicativo. La Figura 3 es un ejemplo de secuencia numérica del Bloque I, todas poseen un formato similar, la variante radica en la función involucrada.

Bloque II (secuencias numéricas 9-10). La estructura matemática de estas secuencias corresponde a las funciones $f(x) = 2x$, $f(x) = x + 2$. Cada secuencia es presentada mediante una tabla que incluye términos numéricos y el número que le corresponde al término, omitiendo lo figurativo (Figura 1). Nuevamente se promueve un razonamiento inductivo y se destaca la etapa registrar durante la resolución de la tarea. En las tareas de ambos bloques se pretende analizar la articulación de las ideas (escritas) que llevan a la regla de generalización, pero en este Bloque II, se hace explícita la solicitud de una regla. El inciso e) promueve que los estudiantes propongan un número (éste puede ser cercano o lejano), Mason (1999) expresa que estas encomiendas tienden a estimular en ellos el alcance de la generalidad que están expresando.

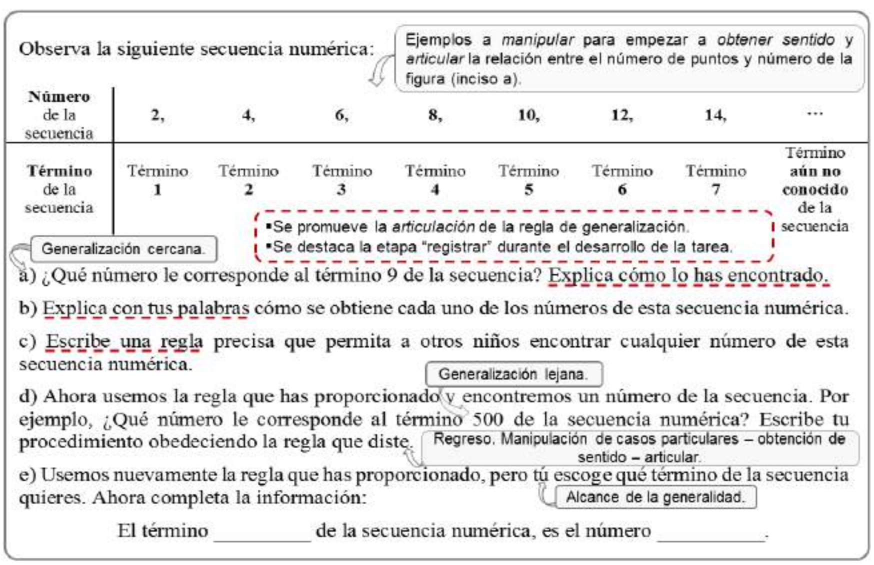

Figura 1: Tarea 9. Bloque II

Participantes, aplicación y análisis de las respuestas

Participaron 25 estudiantes pertenecientes a una escuela pública ubicada en Tekit, Yucatán, México. Cada tarea fue entregada impresa, los estudiantes trabajaron de manera individual y no hubo intervención por parte del investigador. El análisis se realiza individual para identificar las manifestaciones de generalización en cada estudiante y por bloque, en virtud de que las tareas de cada bloque presentan características comunes. En la Figura 2 se presenta el esquema diseñado para el análisis de las respuestas del Bloque I bajo la espiral de acciones de Mason (1996).

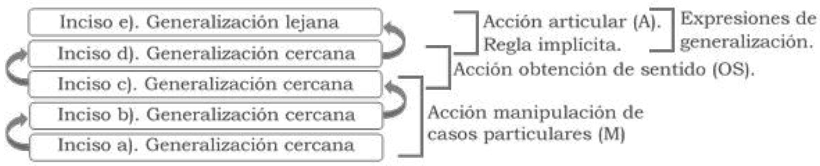

Figura 2: Espiral de acciones de Maison (1996) en las tareas del Bloque I

La Figura 3 presenta un ejemplo del análisis de las respuestas del Estudiante 10 (E10) en la Tarea 2 del Bloque I. La Tabla 1 muestra el resumen del análisis de acciones que se reconocieron en los 25 estudiantes en dicha tarea. Se puede identificar que E10 construye correctamente las figuras 5, 6 y 7 (inciso a) evidenciando la manipulación adecuada de los casos particulares tanto figurativa como numéricamente (inciso b). A medida que manipula ejemplos cada vez más distantes (incisos c y d) se puede interpretar que va obteniendo sentido de la generalidad, lo que le conlleva articular y expresar de manera concisa la regla de correspondencia entre el número de puntos y el número de la figura (inciso e). El registro de la regla lo realiza en lenguaje natural, mediante palabras (sin dibujos, ni símbolos). De manera análoga se analizan las respuestas de las tareas del Bloque II con el esquema correspondiente.

Resultados y Conclusiones Preliminares

Los estudiantes proporcionan evidencia de su capacidad para generalizar al identificar en las tareas con secuencias numéricas aquellos detalles que permanecen invariantes y los que cambian. También, pueden identificar regularidades y patrones, leer e interpretar registros tabulares y sobre todo articular expresiones de generalización. Dichas expresiones fueron comunicadas mediante respuestas numéricas, con palabras, o palabras con algunos símbolos aritméticos, encontrándose 5 categorías: 1) expresiones que enuncian solo la regularidad del patrón, es decir, la variación entre los términos; 2) expresiones numéricas que surgen de usar resultados anteriores, siendo correctas solo para las funciones de la forma $f(x) = ax$; 3) número generalizado, es decir, se expresa la generalización sólo para el número solicitado; 4) expresiones que enuncian de manera incipiente lo que ocurre con la relación entre las dos variables involucradas y 5) expresiones que denotan generalización considerando un término cualquiera (como la que se reporta en la Figura 3). En la siguiente fase de la investigación se analizarán las expresiones de generalización obtenidas en la etapa "decir" al entrevistar a los 25 estudiantes durante la resolución de las tareas de situaciones cotidianas. Finalmente, se considera que el trabajo proporciona referentes acerca del desarrollo del pensamiento y lenguaje algebraico que pueden contribuir en la enseñanza de la educación básica.

Even famous mathematicians, such as Pascal and Diophantus, rejected the possibility of negative integer solutions to algebraic equations (Bishop et al., 2011, 2014; Dehaene, 1997; Gallardo, 2002). Historical struggles make sense when we look at the limitations of physical models and instructional models for integers (Martínez, 2006; Peled & Carraher, 2008; Schwarz et al., 1993–1994; Wessman-Enzinger, 2019). Consider modelling 2 – -5 with discrete chips. Although this is possible with two-colored chips or tiles (Flores, 2008) and using concepts of zero pairs (e.g., Dickman & Bofferding, 2017), it is not necessarily intuitive and has constraints (Murray, 2018; Vig et al., 2014). These challenges in the physical embodiment of negatives integers extend to thinking and learning about multiplicative situations (e.g., -4 × -5). It is important to understand the ways that children use and extend their previous whole-number to negative integers in order to best support their thinking in our classrooms.

Theoretical Framing: Division with Integers

Cognitively guided instruction illustrates problem types and strategies for thinking about division (Carpenter et al., 2015). We can describe *partitive division* as having a total amount, dividing that amount by a certain number of groups, and determining the amount per group (total ÷ number of groups = amount per group). We can describe *measurement division* as having a total amount, dividing that total by the amount per group, and determining the number of groups (total ÷ amount per group = number of groups). These two-problem types, partitive and measurement division, are well-accepted in the field (e.g., Jansen & Hohensee, 2016; Nueman, 1999). Children's *direct modeling strategies,* as they solve division problems, often align with these problem types (e.g., Carpenter et al., 2015; Mulligan & Mitchelmore, 1997). Despite constraints with the physical embodiment of the negative integers (Martínez, 2006), direct modeling can be productive for students to extend their whole number reasoning to multiplication with negatives (Carpenter & Wessman-Enzinger, 2018).

When children engage in solving addition and subtraction problems with negative integers, they construct a variety of productive strategies, including drawing on analogies (Bishop et al., 2014, 2016, 2018; Bofferding & Wessman-Enzinger, 2018; Wessman-Enzinger, 2019; Whitacre et al., 2017). For example, they productively compare -2 + -3 to 2 + 3 with analogical reasoning (Bishop et al., 2016, 2018; Bofferding, 2010, 2011; Whitacre et al., 2017). Yet, sometimes these analogies break down for multiplication (Carpenter & Wessman-Enzinger, 2018)—a student incorrectly determined -4×-2 is -8 with a logical analogy to $4 \times 2 = 8$.

The work reported in this research brief extends the discussion on children's thinking about negative integers by highlighting the ways two Grade 5 children reasoned with analogies and direct modeling with integer division.

Methods

Alice and Kim, from a rural Midwest school in the United States, participated in a 12-week teaching experiment (Steffe & Thompson, 2000) centered on integer addition and subtraction. The children in this study became accustomed to exploring mathematical ideas, struggling, and sharing their invented thinking. The session described here departed from the study on addition and subtraction and is an exploratory session on division. I wondered how children would *construct* integer division. In this session, two of the fifth-graders, Alice and Kim, worked together on three different division open number sentences with negative integers for fifty minutes. The three division problems they discussed in this session included: -24 ÷ ☐ = -2, ☐ ÷ -3 = -10, and -21 ÷ ☐ = 7. Teaching experiment methodology draws on using conceptual analysis, which requires examining the thinking of individuals iteratively (Thompson, 2008).

Results and Discussion

Alice and Kim used analogical thinking and direct modeling strategies that drew mostly on partitive thinking as they solved division problems with negative integers. Their ways of thinking, as well as affordances and constraints, are addressed in this section.

Analogical Thinking with Integer Division

Alice and Kim solved 24 ÷ ☐ = -2 first in the session. Both Alice and Kim’s inaugural approach of this open number sentence included constructing analogies to 24 ÷ 12 = 2 and reasoning that -24 ÷ -12 = -2. Alice shared, “I think it’s -12 because twenty-four divide by twelve is two. And, these two are negative (pointing at -24 and -2), so I thought that this would have to be negative.” And, Kim shared, “Yeah. There’s both negatives (shrugs). I just compared it to something easier. I just did 24 divide by twelve.”

For ☐ ÷ -3 = -10, Alice and Kim made analogies again. They compared ☐ ÷ -3 = -10 to 30 ÷ 3 = 10. Kim reasoned, “You can multiply these two (points at -10 and -3 on the paper), but in a negative way, in the negative side. So, three times ten is thirty, so just add the negative symbol onto it.” Alice and Kim both reasoned that -30 is the solution to ☐ ÷ -3 = -10 to because 30 ÷ 3 = 10.

There are similarities in analogical reasoning across these integer division number sentences; Alice and Kim compare both to fully positive integer number sentences. Children often draw on analogies productively for both addition and subtraction with negative integers. In fact, problem types like -2 + -5 and -6 – -3 are readily solved by children who see negative integers for the first time by comparing -2 + -5 to 2 + 5 and -6 – -3 to 6 – 3 (e.g., Bofferding, 2011; Whitacre et al., 2017). Note the structural similarities between these analogies: addition and subtraction with negatives are compared to fully positive numbers sentences, but result in correct solutions. Therefore, it is not surprising that Alice and Kim applied an analogy that worked well for integer addition and subtraction to these open number sentences with division, -24 ÷ ☐ = -2 and ☐ ÷ -3 = -10. However, this structurally similar analogy (comparing 24 ÷ 12 = 2 to -24 ÷ ☐ = -2) does not result in the correct solution.

Although the analogies described above did not support correct solutions, Alice solved -21 ÷ ☐ = 7 correctly using an analogy. Alice thought the open number sentence -21 ÷ ☐ = 7 was challenging division open number sentence type; Alice wrote “nope” and the solution -3 (-21 ÷ -3 = 7) and Kim wrote “wung it!” and the solution 3. Kim reasoned that the solution to -21 ÷ ☐ = 7 is 3. She made an analogy similar to what she did previously, comparing -21 ÷ 3 to 21 ÷ 3. Kim noticed something different in the structure, as she wrote “wung it” and shared uncertainty.

Alice suggested the correct solution of -3 when solving -21 ÷ ☐ = 7. Alice was unsure of her solution and verbalized her struggle. She, for example, wrote “nope” on her paper conjecturing, “it’s wrong.” She shared the challenge with the structure of this integer division problem: “I mean it doesn’t make sense that a negative divided by a negative would equal a positive.” Alice compared -

21 ÷ ☐ = 7 to -21 ÷ 3 = -7 and 21 ÷ 3 = 7, conjecturing -21 ÷ -3 = 7. Although unsure about -3 a solution, she maintained a strong confidence the answer is not 3, stating how numbers like -21 and 21 are different.

One challenge analogical reasoning that analogies that work well for integer addition and subtraction (comparing -2 + -3 to 2 + 3), to not readily extend to integer division (comparing -24 ÷ -12 = -2 to 24 ÷ 12 = 2). An affordance of analogical reasoning is that Alice was able to comparing -21 ÷ ☐ = 7 to 21 ÷ 3 = 7 and know that solution could be negative.

Direct Modeling: Partitive and Measurement Thinking with Integer Division. Alice used a direct modelling strategy for -24 ÷ ☐ = -2 when prompted to explain her analogical reasoning above. Both Kim and Alice used direct modeling strategies for justifying their analogies as they solved ☐ ÷ -3 = -10. For the last open number sentence in the session, -21 ÷ ☐ = 7, both Kim and Alice used analogical reasoning only.

Alice drew out tallies and groups, a component of direct modeling, because she wanted to justify the analogy she made when first solving -24 ÷ ☐ = -2. The transcript below illustrates the Alice's discussion about her tallies and group in Figure 1:

> I did two rows (pointing at tallies). They both had… they are negatives. And, there's two (draws two circles around groups of tallies). … Because if it was positive twelve, then this would be (points at the -2) … I don't know. … I did twenty-four (shows drawing with 24 tallies) and what I did is twelve and twelve and it makes two (points at two groups of 12 tallies in the drawing).

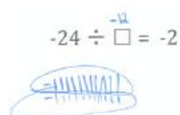

Figure 1: Alice's use of direct modeling when solving -24 ÷ ☐ = -2

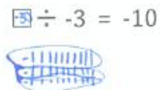
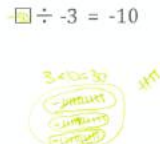
Alice created a total of 24 tallies, stating "they are negatives." As she made these 24 tallies, she placed them in two groups—she drew on a partitive division reasoning. Each of her groups has 12 tallies (see Figure 1), which represents -12. Alice actually illustrated -24 ÷ -12 = +2 with her direct modeling, and even refers to "two groups" (+2) instead of -2. She used partitive division because she doles out the tallies into two groups using how many tallies are in each group (12 tallies, or -12) as the unknown. For Alice, the number of groups was known, using +2 instead of -2, from the open number sentence. She stated that the amount in each group was unknown in -24 ÷ ☐ = -2, putting tallies in two groups and counting the tallies after.

One challenge that Alice faced is that her drawing is well-suited for -24 ÷ -12 = +2, instead of -24 ÷ 12 = -2. A second challenge that Alice encountered is making sense of what -2 groups with partitive division entails; indeed, -2 groups used in this way has physical has constraints. The physical constraints could potentially be why Alice states +2 groups instead of -2 groups. Suppose Alice used partitive reasoning and direct modeling in a way that resulted in the correct solution for -24 ÷ ☐ = -2. How could Alice physically take the existing 24 tallies that represent -24 and put the +12 tallies into -2 groups? Having -2 groups seems a bit ridiculous. However, in this case Alice could have used a direct modeling strategy with measurement division and it could have worked. For example, if Alice, instead, took her -24 tallies and looked for an unknown number of groups (12) that have -2 each in them, this could have worked. Using Alice's strategy with tallies, she could have started making groups of negative two or two tallies. If she did this, there would be 12 groups.

Both Alice and Kim drew on direct modeling strategies when justifying their analogies as they solved ☐ ÷ -3 = -10 (see Figure 2a and 2b, respectively). Both of their drawings produced for this open number sentenced used a direct modelling strategy similar to what Alice created (see Figure 1).



(a)



(b)

Figure 2: Alice and Kim’s use of direct modeling when solving ☐ ÷ -3 = -10

The following excerpt of transcript highlights how Kim discussed her drawing in Figure 2b:

> Um, I did three groups. I did three groups. The negatives is, is the negatives symbol which it tells us that the answer is going to be a negative. These numbers are negatives. I did three groups of ten tally marks in each. Like how you do tally marks regularly, like three, four, and equal five. I did that. I screwed up, but it doesn’t matter though. …These circles represent three groups. … Negative thirty is all of these combined together (motions around drawing). … Um, once you add all these up it equals negative thirty. And, you divide by negative three. …If you add all these up, it equals thirty, you can just divide it by three because of the three groups….The negative ten is in each of these (points at the tallies in the groups). I screwed up there’s six in each of these, but there’s supposed to be five.

Alice and Kim both used partitive reasoning for division, where they interpreted dividing by -3 as indication that there are +3 groups (not -3). They put ten tallies in each group, which represents -10 (albeit Kim has groups of 6 tallies instead of 5, but she counts them as five and recognizes the extra tallies). Both Alice and Kim determine that the solution is -30 to ☐ ÷ -3 = -10 by counting the total amount of “negative” tallies they have.

Kim interpreted the “÷ -3” in ☐ ÷ -3 = -10 as the number of groups positive three groups (+3), which is a challenge whether you use partitive division or measurement division. Number sentences like -24 ÷ ☐ = -2, can be supported by the students’ partitive reasoning if they twelve groups of -2. But, is partitive or measurement division intuitive with ☐ ÷ -3 = -10? The open number sentence ☐ ÷ -3 = -10 differs from -24 ÷ ☐ = -2 in the sense that the positive number (i.e., ☐ or 30) is the dividend. Analogical reasoning may be more productive for ☐ ÷ -3 = -10.

Concluding Remarks

This qualitative description of thinking about integer division highlights affordances and constraints of both analogies and direct modeling with integer division. Analogies for whole number addition and subtraction do not extend readily, but can be used productively. Although direct modeling had limitations with partitive division for -24 ÷ ☐ = -2, Alice’s direct modeling highlighted the potential of measurement thinking with this particular open number sentence. Yet, both partitive and measurement definitions of division have limitations for number sentences like ☐ ÷ -3 = -10—highlighting potential for analogical reasoning.

FOUNDATIONAL ALGEBRAIC REASONING IN THE SCHEMES OF MIDDLE SCHOOL STUDENTS WITH LEARNING DISABILITIES

Jerry A. Woodward
Ball State University
jawoodward@bsu.edu

During the course of a three-month teaching experiment, two middle school students with learning disabilities were found to form operations foundational to algebraic reasoning as they constructed mathematical equivalence schemes. In particular, the students' schemes were considered to be algebraic because they contained the cognitive roots of the distributive property, quantitative unit conservation, and solving linear equations of the form ax=bc with whole number solutions (where a, b, and c are whole number constants). The algebraic character of the students' operating was based on the extent to which the students operated on the structure of their additive and/or multiplicative schemes as they solved tasks that required them to create equivalence between two multiplicative compilations.

Keywords: Algebra and Algebraic Thinking, Number Concepts and Operations, Special Education

Introduction

The purpose of this paper is to demonstrate how the equivalence schemes of students with learning disabilities can be considered algebraic. Additionally, I suggest the algebraic character of such schemes is rooted in how students create and coordinate composite units. This study is grounded in the work of early algebra researchers who have focused on the algebraic character of student's ways of operating prior to a formal algebra course (cf. Blanton & Kaput, 2005; Carraher, Schliemann, Brizuela, & Earnest, 2006; Hackenberg & Lee, 2015). Research in the area of early algebra has become crucial for schools as the number of students who encounter algebra in middle school has increased substantially in the last twenty years.

At the same time, opportunities to be included in grade-level general education have grown for middle school students with learning disabilities due to education policy (Every Student Succeeds, 2015; Individuals with Disabilities Education Act, 2004) (Hord et al, 2019). But access is not enough. Hord et al. (2019) explains that for students with learning disabilities to be successful in middle school and as they progress to formal algebra in high school, they will need to make sense of complex algebraic concepts (Bouck, 2017; National Council of Teacher of Mathematics (NCTM), 2000). This report addresses how the whole number operations of students with learning disabilities can form the foundation for reasoning algebraically and learning complex algebraic concepts. Specifically, I focus on how the cognitive roots for the distributive property, quantitative conservation, and solving linear equations of the form ax=bc (where a,b, and c are whole number constants) can be found in relational equivalence schemes.

Relational Equivalence Schemes and Algebraic Reasoning

The schemes and reasoning I investigated were not formal algebraic schemes, but rather, the multiplicative and equivalence schemes of students that form the underpinnings for formal algebraic concepts. From an ontogenetic perspective, this means schemes are described as algebraic if they can later be reorganized into algebraic schemes (Hackenberg, 2006; Steffe, 2001). In this section, I first describe schemes of mathematical equivalence (Woodward, 2016). I then discuss formal algebraic ideas related to the equivalence schemes: the distributive property, quantitative unit conservation, and solving linear equations.

Mathematical Equivalence Schemes

Students have the opportunity to construct equivalence schemes when they are asked to produce equality between related multiplicative compilations. For example, a student may be told that person A has 3 baskets of apples with 4 apples in each basket, while person B has 8 baskets of apples with 4 apples in each basket. They are then asked to make it so that each person has the same amount of apples. In this case the two multiplicative compilations differ by the number of composite units (CU) (3CU of 4 singletons and 7CU of 4 singletons), but they also could differ by the size of the CUs (3CU of 4 singletons and 3CU of 5 singletons). There are many solution methods to such a task, including some that indicate a student is engaged in unidirectional thinking as they focus on transforming only one quantity. Others, though, suggest a student is considering relationships between quantities across the compilations as well as notions of balance between them.

I have identified two schemes that students construct while solving tasks like those mentioned in the previous paragraph, a Relational Equivalence (RE) scheme and a Quantitative Relational (QRE) scheme (Woodward, 2016). RE and QRE both incorporate additive balancing operations that support creating equivalence between the two multiplicative compilations. When operating with an RE scheme, a student first multiplicatively produces the totals of 1s from each compilation (3x4=12; 7x4=28 in the example above). They then find the difference in 1s between the totals (28-12=16) and create equivalence by operating on the totals with some or all of the 1s in the difference. For example, they may halve the difference between the two compilations and then re-distribute the 1s (16/2=8; 12+8=28-8).

When a student constructs a QRE, they can operate in the same way, but they can also do more. Instead of operating on 1s, they may choose to focus on the CUs. They can lift their operations on 1s to operations on CUs that require anticipation of multiplicative structures. A student operating with a QRE may first produce a difference in CUs between the two compilations (7CU-3CU=4CU). They then can create equivalence via additive operations on the CU. For example, they may re-distribute the CUs in the difference (4CU/2=2CU, 3+2=7-2) or transform the CU in one of the original compilations to create equivalence (3CU+4CU=7CU).

In this paper I argue that these two schemes are of particular importance because they can provide valuable insight into how students can engage with the distributive property, quantitative unit conservation, and solving linear equation prior to a formal introduction. Moreover, they may be able to provide a path to generate these ideas from students' whole number operating.

Distributive Operations

Researchers have described how students exhibit operations needed for the formal distributive property in algebra, $a(b+c)=ab+ac$ where a, b, and c are real numbers, in whole number (e.g., McClintock et al., 2011; Tzur et al.; 2009) and fractional situations (e.g., Hackenberg & Lee, 2015; Hackenberg & Tillema, 2009). In the case of whole numbers, McClintock et al. (2011) demonstrated a student's use of a distributive operation as the student found the difference between two multiplicative compilations. For example, when presented with two multiplicative compilations such as 19 boxes of candy with 6 pieces of candy in each box and 15 boxes of candy with 6 pieces of candy in each box, a student could anticipate the multiplicative structure of each compilation and identify 4 boxes of candy as the difference. Implicitly included in their mental operations is the underlying quantity of 6 pieces of candy in each box. It is distributed over each set of composite units. The student could mentally anticipate the units-coordination in each of the three sets of composite units without enacting them. For such a student, 19 groups of 6 minus 15 groups of six is the same as 4 groups of 6.

Distributive operations have also been described in fractional reasoning. Hackenberg & Tillema (2009) provided evidence of a student's distributive operation as they multiplied two fractions. The student produced a fractional amount of each unit and then added them together to produce a fractional amount of the sum of the units. For example, when asked to find 1/5 of 4/7 of a mile, a student may first partition 4/7 into 4 units of 1/7 and then partition each 1/7 mile into 5 units. In doing so, they distribute the 1/5 across the 4 units of 1/7 miles. They can then solve the problem by adding 4 copies of 1/5 of 1/7 [1/5(4/7) = 1/5 (1/7+1/7+1/7+1/7)]. Whether the situation is multiplicative or fractional, the key is that the student anticipates the result of distributing one unit across another. Such an anticipatory scheme is considered to be algebraic because it can be reorganized into the formal algebraic idea of the distributive property (Hackenberg & Tillema, 2009).

Quantitative Unit Conservation

Olive and Cağlayan (2008) described *Quantitative unit conservation* as a "coordination of coordinated quantities" (p.271). Quantitative unit conservation emphasizes how quantities found in numerical or algebraic tasks often not only need to be coordinated locally within an equation, but also need to be coordinated across the whole equation. Writing and solving systems of equations, for example, requires schemes constituted by complex relationships that also focus on relating the underlying quantities in the task.

Suppose a student is asked to deposit \$1,000 between two bank accounts from banks A and B, where Bank A provides an interest rate of 4% and bank B has a rate of 6%. If a goal is set to earn 5% interest, two equations could be written and then solved via methods for systems of equations. A possible equation relating the interest earned from each account to the total interest could be $.04x+.06y=.05\text{x}1{,}000$ (x is the amount invested at bank A and y is the amount invested at bank B). However, it is not uncommon for a student to leave off the \$1,000 and only write $.04x+.06y=.05$. The cause of this can be linked to quantitative unit conservation. A student may focus on equating the percentages instead of considering the global coordination of the quantities and the need to equate quantities of money.

Solving Linear Equations

Hackenberg describes how the equation $ax=b$, where a and b are real numbers and x is an unknown, can be thought of as a statement of division (2006). Similarly, the equation $ax=bc$, where a, b, and c are real numbers, can also be thought of a statement of division (once b and c are coordinated multiplicatively). This is not the only way, though, to conceptualize the equation $ax=bc$. For the purposes of my study, the equation $ax=bc$, where a, b, and c are whole numbers, can be thought of as a statement of equivalence. Many researchers have espoused the need for children to view the equal sign as a relational qualifier (e.g., Baroody & Ginsburg, 1983; Kieran, 1981; Knuth, Stephens, McNeil, & Alibali, 2006) when solving linear equations in formal algebra. When a QRE scheme is formed, a scheme of balance is constructed that can be reorganized into a relational understanding of the equal sign.

Furthermore, in the special case where a, b, and c are whole numbers and x is also a whole number, students who do not have fractional reasoning available can still enlist their multiplicative schemes to find a solution if they view the equal sign as a relational qualifier. For example, when solving the equation 4x7=__x14, a student who sees the equal sign as a unidirectional symbol may write 28 or 392 in the blank provided because they multiply the 4 and 7 or all three of the numbers. A student with a relational scheme of equivalence, in contrast, can reason the left side is equal to 28, which is equal to 2 times 14. Moreover, a student with a QRE scheme can reason 4 times 7 is like having 4 groups with 7 in each group, and doubling the group size from 7 in each group to 14 in each group means the number of groups must be halved from 4 groups to 2 groups if equivalence is to be maintained. Whether the unknown is symbolized as a blank space or a letter, a QRE scheme provides a foundation to create meaning for the operations needed to solve the equation.

Conceptual Framework

Examination of students' operations and schemes in my study was grounded in the reflection on activity-effect relationship (*Ref*AER*) framework (Simon et al., 2004; Tzur & Simon, 2004). *Ref*AER* is a refinement of constructivist scheme theory (Piaget, 1985; von Glasersfeld, 1995) that provides a lens for interpreting how a student forms a new conception through two types of reflections on their mental activity (Simon, Tzur, Heinz, & Kinzel, 2004). The definitions of schemes and operations are those described by von Glasersfeld (1995). Schemes are comprised of mental actions, or operations, and consist of three parts. The first part requires an experiential situation; with the caveat that the experiential situation is nothing more than the student's perception of what is offered. As they perceive the situation, the student sets a *goal* as to what activity to engage in. The second and third parts of a scheme are, respectively, the specific mental activity that is called up by the experience (and attached goal) and the student's expected result.

In addition to equivalence schemes, constructs integral to this study were children's multiplicative reasoning and number schemes. The Explicitly Nested Number Sequence (ENS) (Steffe & Cobb, 1988) and the Generalized Number Sequence (GNS) (Steffe, 1994) provide a distinction for the students' operations on CUs. In each, the student can make sense of the nested relationship between compilations with like units. For example, 7 CUs of 4 (7 baskets of 4 apples) and 6 CUs of 4 (6 baskets of 4 apples) are embedded within 13 CUs of 4 (13 baskets of 4 apples). Additionally, a student with GNS can anticipate a multiplicative structure made up of abstract, iterable units (four 1s distributed over each of the 7 CU) prior to operating with it (Steffe, 1994).

Methodology

Over two and a half months, a pair of 8th graders, Joe and Javier, participated as a pair in 14 teaching episodes taught by the author as part of a teaching experiment. The videotaped teaching sessions occurred twice per week and lasted 30 to 45 minutes. A witness-researcher was present for each of the sessions. Data analysis was conducted during the planning and evaluations of teaching sessions and also retrospectively. During the ongoing analysis, critical events were identified, discussed, and used to build second-order models (Steffe & Thompson, 2000) of the students' ways of operating. These models informed decisions as to which tasks and prompts to select for subsequent episodes. The tasks and prompts had a two-fold purpose: to facilitate the construction of new conceptions or to test the anticipatory nature of current conceptions. In the retrospective analysis, video segments and students' written work were used to make inferences about the ways of operating of the students and the algebraic character of their operating.

Joe was selected for the study for two reasons. First, he was attending twice-weekly pull-out sessions for math with a special education teacher. This was because he was identified by school personnel to be a student with a learning disability in reading who needed additional support with areas of math such as solving word problems. The school psychologist identified the Wechsler Intelligence Scale for Children (WISC) and the Wechsler Individual Achievement Test Second Edition (WIAT-II; Wechsler, 2005) as the two main assessments used by the school to identify students with learning disabilities. The second reason Joe was selected was that a base-line assessment revealed he was operating with at least an Explicitly Nested Number Sequence (ENS) (Steffe & Cobb, 1988).

Javier was also purposefully selected for two reasons. The first was his identification by school personnel to be a student with a mild cognitive disability. He received mathematics instruction in a self-contained classroom with a special education teacher. Secondly, Javier was considered to be operating with a Tacitly Nested Number Sequence (TNS) (Steffe & Cobb, 1988). Javier did not operate at the same level as Joe, but he was paired with Joe and part of the study because he was able to multiplicatively coordinate quantities fluently in multiplicative and divisional contexts.

Data Excerpts

In this section I describe how both Joe and Javier enlisted their equivalence schemes to solve a particular task. Javier operated on the structure of his additive schemes as he enlisted an RE scheme (Woodward, 2016). Joe went further and operated on the structure of his multiplicative schemes as he created equivalence using his QRE scheme. During their 10^{th} session on May 15th, Joe and Javier were given the task of creating equality between the following two multiplicative compilations: Javier buys 19 bags of candy with 6 pieces of candy in each bag. Joe buys 15 bags of candy with 6 pieces of candy in each bag. An additional constraint of *no written work allowed until after they had a solution* was imposed by the researcher in an attempt to provoke Javier and Joe to move past initially coordinating the two quantities in each compilation to produce a total of 1s.

To solve the task, Joe thought for only a couple of seconds and then wrote:

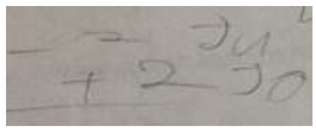

Figure 1: Joe Operates on Composite Units to Create Equivalence.

Unifix cubes were provided to the students in the form of 19 groups comprised of 6 cubes and 15 groups also comprised of 6 cubes. It was common for the students to be asked to demonstrate their solution with cubes after solving the task. At this point I asked Joe about his solution in Figure 1. Joe's response was, "Yeah, I was thinking about bags." Joe then proceeded to demonstrate his solution by moving 2 groups of 6 from the 19 groups to the 15 groups so that each compilation became 17 groups of 6. From Joe's explanation, I inferred he operated on the composite units *between* the compilations. Joe anticipated the multiplicative structures that would be formed if he coordinated the two quantities in each compilation. Such anticipation took the form of a re-presentation to himself of a quantity of composite units with identical sizes from each compilation. Joe was operating with iterable composite units (Steffe, 1994), and so the structures of these two compilations were essentially the same except that there were more composite units in the larger compilation. This understanding enabled Joe to reflect on their relative sizes and to conceptualize the smaller compilation as nested in the larger compilation (15 boxes of 6 nested within 19 boxes of 6). For Joe, the difference in composite units was a way to describe the difference between the two compilations.

Next Joe enlisted his additive schemes as he found the difference in composite units between the two compilations (19-15=4 boxes). His operating to find the difference was predicated on his anticipation that the difference in composite units also described the difference between the total 1s. This anticipation was available to him because the "4 boxes" signified 4 composite units with 6 single units in each that could be coordinated to produce a total of 1s if he chose to enact the coordination. To create equality, Joe increased the smaller compilation (15 boxes with 6 candies per box) by half the difference (4 boxes with 6 candies per box) and decreased the larger total (19 boxes with 6 candies per box) by half the difference. Joe had previously enlisted similar operating, but it was on 1s and not composite units. He re-distributed half the *composite units* in the difference (2 boxes) to the larger compilation (19 boxes) and the other half (2 boxes) to the smaller compilation (15 boxes).

At the end of the task, the students were also asked to write an equation representing their solution. Joe's equation (see Figure 2 below) again provided evidence that the single units (6 cubes per box) were still available to him even though he had operated solely on composite units throughout the process.

Equation: $19 \cdot 6 - 12 = 15 \cdot 6 + 12$

Figure 2: Joe Represents His Solution with an Equation.

It was a requirement for the equations to contain the original quantities from the task. This meant the 6 pieces of candy in each bag needed to be present. When Joe wrote 19 times 6 and 15 times 6, he recognized they represented a quantity of 1s. For the equation to make sense, the two bags from the difference that were re-distributed also then had to be a quantity of 1s. Joe accomplished this by converting the 2 bags of 6 into 12 pieces of candy. Doing so enabled the equation to make sense globally with each representing a quantity of 1s that were equivalent.

Javier also created equality between the two compilations, but he relied on his prowess with multiplying two numbers rather than operations on the multiplicative structures. He first mentally produced the totals (19 boxes of candy with 6 pieces of candy per box=114 pieces and 15 boxes of candy with 6 pieces of candy per box=90 pieces). Next, he added 10 to 90 and subtracted 10 from 114. He produced two new totals of 100 and 104. Javier purposely added a quantity of 1s to the smaller total (90+10) and subtracted a quantity of 1s from the larger total (104-10). I inferred he performed this operation because he anticipated that enacting his additive schemes would bring the two totals closer together by increasing the smaller total and decreasing the larger total. Moreover, when his transformations did not immediately produce equality, Javier continued operating on the smaller quantity to increase it and bring it into balance with the larger quantity. He finished by adding 4 more to 100 so that both totals were now equal to 104. In other sessions, Javier demonstrated that he could continue with more successive operations on both quantities if necessary.

Javier operated on two levels of units, the composite units and the units they contained. Moreover, the composite units were not abstract in nature. This meant he could not *anticipate the results of coordinating the units or the multiplicative structures* they would produce. Thus, he had no opportunity to operate on or with the multiplicative structures. Even when given compilations with large numbers and constrained to mental calculations, Javier computed the totals first and then operated on 1s.

Discussion

In this section I describe how I considered Joe's schemes to be algebraic, while Javier's schemes were algebraic to a lesser degree.

Distributive Operations

Joe operated on CUs as he subtracted 19 boxes of candy minus 15 boxes of candy to yield 4 boxes of candy. Joe mentally anticipated the units-coordination in each of the three sets of CUs involved in the computation as the unit rate of 6 pieces of candy in each box was distributed over each set of CUs. Hence, Joe's mental operations implicitly included the underlying quantity of 6 pieces of candy in each box. He reasoned that 19 groups of 6 minus 15 groups of 6 is the same as 4 groups of 6. I would symbolize this distributive reasoning as 19x6-15x6=(19-15)x6=4x6. Additionally, to produce equality he added two boxes to the smaller compilation and subtracted two boxes from the larger compilation. His reasoning was that 19 groups of 6 minus 2 groups of 6 is the same as 15 groups of 6 plus 2 groups of 6. This reasoning can be symbolized as 19x6-2x6=(19-2)x6=15x6+2x6=(15+2)x6. Again, this representation illustrates the distributive property as 6 is distributed across the quantities.

Joe operated on and with the multiplicative structures of the two compilations provided. His reasoning took on an algebraic character as he enlisted his additive schemes to operate *on* the anticipated multiplicative structure as he found the difference in composite units between the two compilations (19-15=4 boxes). To create equality, Joe also inserted the multiplicative structure of the compilations and the difference into the structure of his equality scheme. The multiplicative structure was readily available to him prior to operating because of his GNS. Joe's reasoning was algebraic because he operated on the structure of his equality scheme *with* the multiplicative structures of the difference (as quantities of composite units) and the existing compilations.

Quantitative Unit Conservation

Joe also exhibited quantitative unit conservation. He demonstrated such reasoning with his equation (see figure 1) and when he described his solution to the ask. After Joe grabbed two groups of cubes from the larger compilation and moved them to the smaller one, he stated, "I take these 2, and then I give them to me. And then they'd be equal. But I just can't say 2. I have to label. So I just put 12." Joe's explanation indicated that he coordinated quantities *within the equation* and *across the whole equation* when generating relationships between the quantities. The key coordinating quantities within an equation and across the whole equation was anticipating the multiplicative structure and operating on the composite units. Joe operated on the composite units (19-2 and 15+2) within the equation. At the same time, he considered the relationship of the multiplicatively coordinated quantities that also contained the unit rate (6 cubes per tower) across the equation. As he demonstrated his solution with the concrete objects (Unifix cubes), the 1s that comprised the composite units were present and available when he needed to include them in his equation. Joe's explanation of his use of the word "two" indicated that he was aware of the need to coordinate the quantities across the equation. Joe reasoned that 19·6-2 was not equal to 15·6+2 because the underlying total of 1s was not equal. As he equated the composite units, he also recognized the totals in 1s needed to be equal. His reasoning was algebraic as it formed the cognitive root of quantitative unit conservation.

Solving Linear Equations

The relational equivalence schemes constructed by both Joe and Javier can serve as a basis for developing a relational understanding of the equal sign. In the discussion above, I illustrated how they both enlisted relational equivalence schemes as they operated on either 1s or composite units simultaneously. This can be contrasted with a student who only operates on one quantity at a time and creates equality by transforming one quantity into the other, a unidirectional scheme of equivalence.

When Javier initially operated on both quantities simultaneously, he purposely added a quantity of 1s to the smaller total (90+10) and subtracted a quantity of 1s from the larger total (104-10). This operation was performed because he anticipated that enacting his additive schemes would bring the two totals closer together by increasing the smaller total and decreasing the larger total. Moreover, when his transformations did not immediately produce equality, Javier continued operating on the smaller quantity to increase it and bring it into balance with the larger quantity. Javier also demonstrated that he was able to do successive operations on both quantities if necessary.

Javier's reasoning was algebraic because he operated with the structure of his additive scheme on the structure of his equality scheme as he operated on both quantities simultaneously. Moreover, he anticipated that the results of his operations could be used for further operating. As Javier created equality via successively smaller transformations, he anticipated a relationship between these transformations and a single, larger transformation. He provided evidence for this anticipation by describing adding 14 to 90 rather than adding 10 and 4. Adding 14 was a single transformation that was a sum of the two smaller transformations of adding 10 and adding 4.

Furthermore, I suggest their RE and QRE schemes form the cognitive roots for symbolizing and solving linear equations of the form $ab=xc$ (where a, b, and c are constants and x is an unknown). Javier could use his relational scheme in conjunction with his operations on tacit composite units to solve *ax*=*bc*. He could multiplicatively produce the total from *ab*, next guess a value for x, then multiplicatively produce the total from *xc* to check to see if matches the total from *ab*. If the totals do not match, he could repeat the process. Without operating with the multiplicative structure of *ab* and *xc*, this would be the primary method available to Javier.

I also suggest Joe could operate with the multiplicative structure of *ab* and *xc* to solve the equation. He could anticipate the multiplicative coordination of the quantities *a* and *b*. He could then reflect on the relationship of this coordination to the multiplicative coordination of quantities *x* and *c*, even though *x* was yet to be determined. He could then solve for *x* via reasoning about *multiplicative relationships* between the multiplicative structures of the compilations *ab* and *xc*. For example, if *c* was twice as large as *b*, Joe could reason that *x* must be half as large as *a*. The key differences between his reasoning and Javier's would be his operations with abstract composite units and his anticipation of the multiplicative structure.

Conclusion

This research demonstrates how the algebraic reasoning of middle school students with learning disabilities is afforded and constrained by their whole number operations. It also provides examples of how students with learning disabilities can operate on and with the structure of their schemes while engaging in complex algebraic reasoning. Finally, this research also supports Hackenberg's reorganization hypothesis (2016) for algebraic reasoning within the context of whole number operations.

“H IS NOT A NUMBER!” EXAMINING HOW NUMBER INFLUENCES VARIABLE

Karen Zwanch
Oklahoma State University
karen.zwanch@okstate.edu

Students' conceptions of variable do not always support normative interpretations of equations, and research links limited conceptions of variable to operations on composite units (i.e., units of units). This study examines how one ninth grade Algebra 1 student, Alex's, concept of number is related to his conceptions of variables when writing and interpreting linear equations and expressions. Alex had constructed an advanced tacitly nested number sequence (aTNS). An aTNS is the third stage out of five in the number sequence hierarchy, and indicates that he operates on composite units but does not reason multiplicatively. Analysis links the cognitive structures that define Alex's aTNS to his applied conceptions of variable, and finds that non-normative conceptions of variable manifest due to limitations operating on composite units. Being constrained to additive reasoning limited Alex's use of variables in multiplicative situations.

Keywords: Algebra and Algebraic Thinking; Number Concepts and Operations

Understanding how symbols are used in mathematics is critical to students' success, but algebra curriculum tends to focus more on manipulating symbols than it does on the meaning of symbols (Sherman, Walkington, & Howell, 2016). Letters are particularly difficult for students (Bush & Karp, 2013) because they can represent one number (e.g., e); one unknown quantity (as when solving for x); a “pattern generalizer” (e.g., representing odd numbers as $2n + 1$; Usiskin, 1988, p. 9); or a varying quantity (e.g., $A = l \cdot w$; Baroody, 1998). Students must discern these four uses of letters in algebra in order to make sense of algebraic expressions and equations.

With these four meanings in mind, it is unsurprising that variable misconceptions have been well documented. Knuth, Alibali, McNeil, Weinberg, and Stephens (2005) categorized the ways in which students in grades six through eight conceived of variables. The categories included conceiving of variables as representing multiple values, a specific value, or an object. In this study, the percentage of students who responded that n represents multiple values in an expression like $3n$ increased from less than 50% in sixth grade to more than 75% in eighth grade.

MacGregor and Stacey (1997) similarly documented higher instances of variable misconceptions in later years of schooling (years 8-10) compared to earlier (year 7). Stacey and MacGregor's (1997) research also generated categories for students' misconceptions, including: abbreviated word, alphabetical value, numerical value, use of different letters, letter ignored, labels, variable equals one, and general referent. They found that interference from new learning and poor instruction may account for increased variable misconceptions in older students.

Hackenberg, Jones, Eker, and Creager (2017) have studied the mental structures that support students' conception of variable. They found that operating on composite units (i.e., units of units) supports students' conception of variable as an unknown because a quantitative unknown consists of a composite unit containing an unknown number of units of one. This directly ties students' conceptions of variable to their operations on composite units. Zwanch (2019, 2020) also found that operations on composite units and multiplicative reasoning are related to students' interpretations of linear equations. The present study examines how an Algebra 1 student's conceptions of variable are related to his concept of number.

Theoretical Framework

Students’ units construction and coordination (Ulrich, 2015, 2016) specifies that the levels of complexity with which they interpret and operate on number is related to their ability to create different levels of units. These levels of units inform students’ number sequences (Steffe & Olive, 2010; Ulrich, 2016b), which are the “recognition template of a numerical counting scheme. … [C]hildren use their number sequences to provide meaning for number words” (Steffe & Olive, 2010, p. 27).

Tacitly Nested Number Sequence (TNS)

The TNS is the second of five in the number sequence hierarchy (Steffe & Olive, 2010). TNS students construct composite units in mental activity. To construct composite units in activity means that TNS students interpret a number word, such as “seven,” as seven individual units, or counting acts (Ulrich, 2015). Thus, “seven” is thought of as the seven numbers from one through seven, or from 34 through 40, for instance. TNS students can engage in mental activity to construct a composite unit of seven, but can neither operate nor reflect on the composite unit.

Advanced Tacitly Nested Number Sequence (aTNS)

In the number sequences, an aTNS is the third stage out of five, and it is characterized by assimilatory composite units (Ulrich, 2016b). An *assimilatory composite unit* allows students to interpret a number word, such as “seven,” as a single unit containing seven individual units of one (i.e., seven is one unit of seven units), and supports operations on composite units (Ulrich, 2016a). This means that aTNS students can construct a third level of units in mental activity (e.g., 21 as a unit containing three units of seven). Following activity, the third level of units decays leaving aTNS students to reflect on 21 as a composite unit containing 21 units of 1. An assimilatory composite unit advantages aTNS students’ numerical reasoning over TNS students, but aTNS students remain limited to additive reasoning.

Explicitly Nested Number Sequence (ENS)

An ENS is the fourth stage in the number sequence framework (Ulrich, 2016b; c.f. Steffe & Olive, 2010). Like aTNS students, ENS students also assimilate with composite units and can construct three levels of units in mental activity. However, ENS students have also constructed multiplicative reasoning that supports them in thinking of seven, for instance, as a unit that is seven times the size of a unit of one.

This research study examines an aTNS student’s conception of variable. Specifically, this research asks: (1) What concepts of variable does the student apply when writing and interpreting linear equations and expressions? and (2) In what ways does operating on composite units but not reasoning multiplicatively support or limit his concept of variable?

Methods

This study was conducted in a middle and high school in the rural southeastern United States. 326 students across grades six through nine were given a survey. The purpose of the survey was to attribute a number sequence to each student (Ulrich & Wilkins, 2017). Based on the number sequences attributed by survey analysis, 18 students participated in semi-structured clinical interviews. Each student was interviewed on two days, for approximately 45 minutes each day. The first portion of the interviews confirmed the students’ number sequence. Questions were taken from the methods of Ulrich and Wilkins (2017). The next portion of the interviews characterized student’s algebraic reasoning. Tasks will be described in the results.

The participant reported here was a ninth grade, Algebra 1 Part 2 student named Alex (a pseudonym). Algebra 1 Parts 1 and 2 was a two-semester course that covered the content of high school algebra. Alex was a tenacious problem solver and was quick to explain his thinking. Alex was identified as an aTNS student by the survey.

Results & Analysis

Alex reasoned about a variable as an object on four of the 11 algebra tasks. One such task asked him to write an equation to represent the following situation: “This week the soccer team scored three fewer points than they did last week.” In this situation, he was told that last week’s and this week’s scores were unknown. Alex wrote $LW - 3$, and this explanation followed:

> Alex: Last week minus three. … Last week minus three equals fewer? I don’t know. Fewer points? … [If] last week they scored 10 and this week they scored less than three, that would be, like, seven.
> Interviewer: … Can we put a variable on that side of the equation?
> Alex: Yeah. $7p$ for points. (Writes $LW - 3 = 7p$)
> I: So does that work, then, if they scored, let’s say five points last week?
> Alex: … Five minus three equals two. Ok, think. It’d be two points this week. (Writes $LW - 3 = 2p$ on the next line.)

Alex was able to conceive of LW, which stood for last week’s score, as an unknown quantity in the context of the expression $LW - 3$. Consistent with Hackenberg et al.’s (2017) conclusion that an unknown comprises a composite unit, Alex’s aTNS supported his conception of LW as a composite unit containing an unknown number of units of one. His aTNS also supported additive operations on LW, evidenced by the expression $LW - 3$.

Alex could not, however, think of $LW - 3$ as an entity equal to a second unknown. He said that it equaled fewer points. To conceive of $LW - 3$ in relation to this week’s score, Alex needed to construct a three-level unit structure. This was supported by Alex’s additive operations on composites, however, following the mental operations, the third level of units decayed leaving Alex to reflect only on $LW - 3$ as representing “fewer points.” Then, Alex initiated a numerical example in which $LW = 10$. Substituting specific numbers for unknowns decreased the complexity of the unit structure, allowing Alex to think about $LW - 3$ as $10 - 3$, which he could equate to seven. When asked to incorporate a second variable, however, he said, “$7p$ for points.” This is evidence of his conception of p as a label on 7, rather than an unknown.

Finally, the interviewer attempted to perturb Alex’s thinking by asking if the equation $LW - 3 = 7p$ would work if the team scored five points last week. Alex was not perturbed, however, and wrote a second equation rather than recognizing the limitation of the equation he had written. This is evidence that conceiving of the additive relationship between two unknowns is beyond the limits of Alex’s algebraic reasoning. His aTNS supported conceiving of one variable as an unknown, and supported additive operations on the unknown; it did not support his normative inclusion of a second unknown into the equation because an aTNS does not support reflection on a third level of units.

At another point during the interview, Alex was asked to represent the weight of a $\frac{1}{24}$ share of a candy bar, given that the candy bar weighed h ounces (adapted from Hackenberg & Lee, 2015). Alex determined two numerical examples (24:1 and 48:2), but he could not think about h as the unknown weight of the candy bar.

> Interviewer: [Can you] represent the weight of just your piece if the whole thing weighs h?
> Alex: h is not a number!
> Interviewer: (Surprised) You said, “h is not a number?”
> Alex: Yeah! That’s not a number!

Later, Alex redirected the discussion back to h. When asked if he understood the task, he said, “Yes and no. The ‘no’ is how you got a number from a letter. … I don’t think you can say that. You can’t say that a candy bar equals h ounces, cause it’s not a number.”

The candy bar task is different because it required Alex to conceive of the multiplicative relationship between two unknowns. In a multiplicative context he could not conceive of h as an unknown because he could not construct and reflect on the three-level unit structure representing the relationship between the whole candy bar and his piece. This is a limitation of his aTNS that manifested differently on the multiplicative task than on the additive tasks. Rather than Alex conceiving of the variable as an object, he insisted that the variable not be present at all, and that the relationship can only be represented numerically. Reasoning about numerical examples instead of unknowns reduced the complexity of the unit structure, thereby allowing Alex to construct and reflect on 24 units of 1, rather than h as 24 units of an unknown number of ones.

Discussion

Alex is a ninth grade aTNS student in the second semester of an algebra class. Regardless, he could not write one-step equations to represent additive or multiplicative relationships. The first research question asked what concepts of variable Alex demonstrated. When writing additive expressions, Alex reasoned about a variable as an unknown, but when asked to reason about the relationship between the expression $LW - 3$ and this week’s score, Alex reverted to numerical examples and interpreted variables as objects.

The inability to establish the relationship between two variables when writing an equation is a persistent difficulty for high school algebra students (Bush & Karp, 2013), and the results of the second research question provide a theoretical lens to understand the complexity that contributes to this difficulty for aTNS students. aTNS students assimilate with composite units and can perform additive mental operations on composite units. Such operations supported Alex’s expression writing. However, the results of the mental operations decay following activity. This manifested behaviorally in Alex’s inability to reflect on the relationship between the expression and the second unknown. To compensate for this limitation, Alex reverted to numerical examples, and interpreted the variables in his equations as labels on numbers.

On the candy bar task, Alex did not introduce a variable at all. Hackenberg and Lee (2015) found that students who assimilate with composite units and reason multiplicatively may represent the unknown weight of the smaller piece of the candy bar as $\frac{h}{24}$. Alex was not able to write $\frac{h}{24}$, and concluded that “h is not a number!” This illustrates the manner by which aTNS students, who assimilate with composite units and are constrained to additive reasoning, may be more limited in comparison to their peers who assimilate with composite units and reason multiplicatively (i.e., ENS students).

On the tasks presented here, Alex reasoned with non-normative concepts of variables or did not include variables. These results bring to light the importance of studying not only students’ operations on composite units as prerequisite cognitive structures to their algebraic reasoning, but also their construction of additive versus multiplicative reasoning. Furthermore, Alex’s solutions demonstrate that he is capable of reasoning algebraically to some extent. Thus, research should continue to examine the ways in which algebra instruction can productively support aTNS students’ concept of variable and their additive and multiplicative operations on variables.

Keywords: Algebra and Algebra Thinking, Teaching tools and resources

Mathematics teachers use many resources to prepare and teach their classes. Official syllabi or academic texts might be a part of them, but as said by Kajander & Lovric (2009) "most teachers still use the textbooks as their primary resource" (p. 173). In this regard, analysing textbooks is important not only for identifying the author's meaning on the different mathematical objects but also, to be aware of the possible conflicts that may araise while using them. This study identifies the promoted epistemic and teaching paths, and possible semiotic conflicts, of a lesson on linear equations in the textbook *Matemáticas 1* by Block, D., García, S., & Balbuena (2018).

The Ontosemiotic Approach (OSA) (Godino, Batanero, & Font, 2007) proposes types of primary mathematical objects: language, situations, concepts, propositions, procedures, and arguments. In this regard, the *epistemic path* is defined as the distribution of these six components along the didactic episode. From this perspective, the *teaching path* describes the actions that the teacher (or, in this case, the textbook) is doing: motivating, assigning, regulating, or evaluating. Also, a *semiotic conflict* is "any disparity or difference of interpretation between the meaning ascribed to an expression by two subjects" (p. 133).

This study analyzes lessons where linear equations are studied, which correspond to sequences 5 and 12. Each sequence is divided into 4 and 3 lessons, respectivly, and, at the end of each sequence, there is a section titled "math lab", where review activities are proposed.

In every unit of analysis, we determine the primary objects that are studied and the order in which they appear, giving as a result the *epistemic path* promoted by the textbook. Also, we identify possible *semiotic conflicts* and the *teaching path* promoted in the study of linear equations.

In this poster we will share findings adressing the following objectives:

a) Identify the primary objects studied in each unit of analysis.
b) Describe the epistemic path promoted by the textbook.
c) Identify possible semiotic conflicts in each unit of analysis.
d) Describe the teaching path promoted by the textbook.

All of them, in the context of the study of linear equations in the aforementioned textbook.

A PROPOSAL FOR TEACHING MATHEMATICS TO HIGH SCHOOL STUDENTS FROM MODELING APPROACH

UNA PROPUESTA DE ENSEÑANZA DE LAS MATEMÁTICAS PARA ALUMNOS DE PREPARATORIA DESDE LA MODELIZACIÓN

Armando Agustín Chavez-Salazar
Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional
armando.chavez@cinvestav.mx

Keywords: Modeling, High School Education, Algebra and Algebraic Thinking.

The teaching proposal resulting from the study is based on Sadovsky´s (2005) modeling perspective. According to this, mathematical modeling refers to a process that integrates knowledge of a diverse nature and encompasses mathematical tasks, which is divided into several parts: recognizing a problematic, choosing a theory to deal with it and producing new knowledge about it; perspective in which the role of context in modeling problems is highlighted. Likewise, the use of digital technology (GeoGebra) was incorporated into the proposal from the standpoint that it allows observing and establishing, in a simpler way, relationships between the various elements of a problem, compared to working only with pencil and paper.

The research question was as follows: What role does the context of problems, the use of technology and teacher interventions play in promoting students' mathematical modeling work? To answer this, a didactic sequence was designed on problems using algebraic language in mathematical modeling supported by digital technology, which is based on Segal and Giuliani´s (2008) proposal. A previous analysis was made, then a pilot survey was implemented, based on this, the problems were adjusted.

The sequence was implemented to a group of 22 senior students in area I (physical-mathematics) of the National Preparatory School No. 8 in Mexico City. The sequence consisted of three problems, distributed in three sessions of 50 minutes (distributed in two days). Video recordings were used to record group work, teacher interventions and their interactions with students; also, a pair of students was recorded each day. Students were given sheets with the problems and white sheets so they can reflect their work. In general, the activities were designed to be work in pairs and with support of technology: two applets designed in GeoGebra for problems 2 and 3.

In general, the roles played by the context, the use of technology and the teacher's interventions to promote the mathematical work of the students were appreciated. The context favored the evocation/establishment of relationships between the elements of the problems and the appropriation of the context of the problems. The use of technology allowed them to analyze the problems (observe relevant characteristics for the resolution) and obtain approximations of the answers. The teacher's interventions helped students evoke certain knowledge related to the problems, which allowed them to solve them. In this way, it was observed how these elements (context, use of technology and interventions) were intertwined and favored the mathematical work of the students.

UNA PROPUESTA DE ENSEÑANZA DE LAS MATEMÁTICAS PARA ALUMNOS DE PREPARATORIA DESDE LA MODELIZACIÓN

A PROPOSAL FOR TEACHING MATHEMATICS TO HIGH SCHOOL STUDENTS FROM MODELING APPROACH

Armando Agustín Chavez-Salazar
Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional
armando.chavez@cinvestav.mx

Palabras clave: Modelación, Educación Media Superior, Álgebra y Pensamiento Algebraico.

La propuesta de enseñanza, producto del estudio realizado, está sustentada en la perspectiva de modelación de Sadovsky (2005). De acuerdo con ésta la modelación/modelización matemática se refiere a un proceso que integra conocimientos de diversa naturaleza y que abarca el quehacer matemático, el cual se encuentra dividido en varias partes: reconocer una problemática, elegir una teoría para tratarla y producir conocimiento nuevo sobre dicha problemática; perspectiva en la que se resalta el papel del contexto en los problemas de modelación. Asimismo, se incorporó en la propuesta el uso de tecnología digital (GeoGebra) bajo la postura de que ésta permite observar y establecer, de manera más sencilla, relaciones entre los diversos elementos de un problema, a comparación de trabajar únicamente con lápiz y papel.

La pregunta de investigación fue la siguiente: ¿qué papel juegan el contexto de los problemas, el uso de la tecnología y las intervenciones del docente para promover el trabajo de modelización matemática de los estudiantes? Para contestarla se diseñó una secuencia didáctica de problemas sobre el uso del lenguaje algebraico en la modelización matemática apoyada en tecnología digital, la cual se basó en la propuesta de Segal y Giuliani (2008). Asimismo, se realizaron un análisis previo y, luego, un levantamiento piloto, a partir de los cuales se ajustaron los problemas.

La secuencia se implementó en un grupo de 22 estudiantes de sexto año de área I (físico-matemáticas) de la Escuela Nacional Preparatoria No 8 en la Ciudad de México. Constó de tres problemas distribuidos en tres sesiones de 50 minutos (distribuidas a su vez en dos días). Se usó video para registrar el trabajo grupal, las intervenciones del docente y sus interacciones con los estudiantes; asimismo se grabó a una pareja de estudiantes cada día. Se dieron hojas con los problemas y hojas blancas para que los estudiantes reflejaran su trabajo de manera escrita. Las actividades fueron diseñadas para trabajarse en parejas y con apoyo de tecnología: dos applets diseñados en GeoGebra para los problemas 2 y 3.

En general, se apreciaron los papeles que jugaron el contexto, el uso de la tecnología y las intervenciones del docente para promover el trabajo matemático de los estudiantes. El contexto favoreció la evocación/establecimiento de relaciones entre los elementos de los problemas y la apropiación del contexto de los problemas. El uso de la tecnología les permitió analizar los problemas (observar características relevantes para la resolución) y obtener aproximaciones de las respuestas. Las intervenciones del docente ayudaron a los estudiantes en la evocación de ciertos conocimientos relativos a los problemas, los cuales les permitieron resolverlos. De esta forma se observó cómo dichos elementos (contexto, uso de tecnología e intervenciones) se compenetraron y favorecieron el trabajo matemático de los estudiantes.

After a long process of learning algebraic procedures, solving systems of linear equations (SLE) is often confused with obtaining a numerical solution, which hinders the idea of solutions of a parametric nature. Therefore, it is important to address the idea of solution in a SLE.

Proper interpretation of infinite solutions creates problems. Even when the solution exists and is unique, it may not be valid. In these cases, the use of parameters allow us to obtain valid solutions, depending on the conditions of the problem (Liern, 2018). However, this possibility is not attended to in classrooms, even though it is relatively simple to come about this situation;or example, an SLE with two equations and three unknowns.

This ongoing research suggests that once we have the resources to solve a square SLE (2x2 or 3x3) we can use a SLE that requires the use of parameters to calculate the solutions. In addition, we can compare the effect that these have on the original SLE and the graphs of the solution set.

Considering parameters as emerging variables associated with the constrains of associated problems, allows high school students to explore situations where, even though they have the solution, theycan modify it depending on the constrains, which helps students realize that parameters are a certain type of variable that modifies other variables and are manageable.

To carry out this research, we will take the point of view of the Theory of Objectivation (Radford, 2020) using computer software as a symbolic tool to solve SLE with two equations and three unknowns. This would promote the idea of a parameter as a variable, that in particular, makes others vary; allowing its interpretation both graphically and algebraically in its respective domain of solution to take the most appropriate decision making of the problems posed.

PARÁMETROS EN SISTEMAS DE ECUACIONES LINEALES

PARAMETERS AND SYSTEM OF LINEAR EQUATIONS

Luis Enrique Hernández
Centre for Research and Advanced Studies
luisenri.hernadez@cinvestav.mx

Claudia Acuña Soto
Centre for Research and Advanced Studies

Keywords: Álgebra y algebraico, Pensamiento de la educación preparatoria, Sistema de ecuaciones lineales

Tras un largo proceso de aprendizaje de los procedimientos algebraicos, resolver sistemas de ecuaciones lineales (SEL) se confunde con frecuencia con la obtención de una solución numérica, lo que obstaculiza la idea de soluciones generales de naturaleza paramétrica, por lo que es de importancia en abordar la idea de solución en un SEL.

La interpretación adecuada de las soluciones infinitas genera problemas, pero incluso cuando la solución existe y es única, ésta puede no ser válida. En estos casos el recurso del uso de parámetros permite obtener soluciones válidas dependiendo de las condiciones del problema, Liern (2018). Sin embargo, esta posibilidad no es atendida en los salones de clase, pese a que es relativamente simple encontrar esta situación, por ejemplo, cuando tenemos un SEL con dos ecuaciones y tres incógnitas.

Esta investigación en curso plantea que una vez que se sabe cómo resolver un SEL cuadrado (2x2 o 3x3) de manera tradicional, podemos usar un SEL no cuadrados que requieren del uso de parámetros para calcular las soluciones y resolverlos, además de la ventaja de analizar el efecto que tienen éstos en el SEL original, así como el análisis de las gráficas del conjunto solución.

El considerar los parámetros como variables emergentes asociadas a las restricciones de los problemas asociados, permitiría a los estudiantes de preparatoria explorar situaciones en las que, si bien se tiene la solución, ésta puede modificarse dependiendo de las restricciones y lo utilizado; esto contribuye a que el estudiante se dé cuenta de la idea de que los parámetros son cierto tipo de variables que modifican otras variables y que podemos manejar.

Para llevar a cabo esta investigación tomaremos el punto de vista de la Teoría de la Objetivación (Radford, 2020) usando un software de computadora como herramienta simbólica que ponga en juego los saberes necesarios para resolver SEL de dos ecuaciones y tres incógnitas. Esto motivaría el uso de parámetros, lo que propicia el encuentro con la idea de parámetro como una variable que, en particular, hace variar a otras; también permite su interpretación, tanto gráfica como algebraicamente, en un espacio solución para la toma de decisiones más adecuadas de los problemas planteados.

Algebra's role as gatekeeper is well documented in helping students build a solid foundation early is important (Stephens, 2005). For this research study, we explored: What misconceptions do elementary students display when generalizing patterns using variables to justify a hypothesis?

We used communities of practice (Wenger, 1998) as an overarching theoretical framework. We sought to engage the students in a community that would be similar to how mathematicians practice mathematics. We used this theory as a way to engage the students in joint enterprise and mutual engagement as a way to hold the participants accountable for their goals of generalizing a conjecture through the use of variables.

Two students, one in Grade 4 and one in Grade 5, participated in three semi-structured, task-based interviews (Goldin, 2000). Each interview lasted approximately sixty minutes. During the interviews, students worked on the unsolved mathematical task called The Graceful Tree Conjecture. They examined graceful labelings of four different classes of tree graphs including: Stars, Paths, Caterpillars, and Comets. We encouraged the students to develop a justification or generalize a pattern for each of the classes to document that all graphs in the given class could be labeled gracefully. All of the students' work was collected and the interviews were video recorded. All the interviews were transcribed and analyzed. For analysis, we documented each instance where students attempted to use a variable to create a generalized pattern or discussed the use or meaning of a variable.

When attempting to create a generalization the students displayed several misconceptions about variables. First, when discussing where the biggest number for would be, they were able to label it as BN. Later, one student said that if it was the biggest number it would have to be infinity rather than the largest number in the set. Second, when attempting to label one less than the biggest number they wanted to label it as SB for second biggest. We pushed them to further their thinking and were hoping for a label of b-1. One student said they could label it as A or negative A because that is one less than B. The other student said it would be E because it is like half of the biggest and if you cut the humps off B it would become E, so E is half of B. Third, when discussing if the smallest number was one (which we always used one as the smallest number in our set), one student said the smallest number is not one, but should be -9999…. These misconceptions need to be addressed for students to later be successful in algebra courses.

ELEMENTARY ALGEBRAIC THINKING WITH PATTERNS IN TWO VARIABLES

Adam R. Scharfenberger
The Ohio State University
scharfenberger.6@osu.edu

Leah M. Frazee
Central Connecticut State University
frazee@ccsu.edu

Keywords: Algebra and Algebraic Thinking, Elementary School Education

Usiskin (1999) described four conceptions of algebra: Algebra as Generalized Arithmetic, Algebra as a Study of Procedures for Solving Certain Kinds of Problems, Algebra as the Study of Relationships among Quantities, and Algebra as the Study of Structures. The Algebra as the Study of Relationships among Quantities conception relates to the NCTM (2000) Algebra Standard expectation that students "understand patterns, relations, and functions" (p. 37). Algebraic thinking "includes being able to think about functions and how they work, and to think about the impact that a system's structure has on calculations" (Driscoll, 1999, p. 1). Analyzing students' algebraic thinking with patterning tasks in two variables allows researchers to understand how students think about functions, how they work, and how the representation provided in the question impacts student thinking about the structure of the problem. In this study, one elementary student solved patterning problems in two variables with different representations during a task-based interview (Goldin, 2000).

Preliminary findings suggest that this student used different reasoning strategies when given pattern problems in two different representations. On a task consisting of a visual pattern of figures growing in an arithmetic sequence, the student visualized how the growth occurred in each successive figure. The student used the rate of growth to compute the size of the figure at future iterations. In the context of this task, the evidence suggests that the student was thinking covariationally (Confrey & Smith, 1994) about the relationship between the increase in figure size and increase in figure number.

When presented with a task showing a linear relationship between values in an input-output table of numbers, the student was asked to determine the output value when the input value was 38. Upon receiving this question, the student intensely looked at the problem before stating:

> Oh, I see it now. Okay, so I see if you multiply this by – each number [points at all the numbers in the left input column] by two and add 1, that's the number on this side [points at all the numbers in the right output column]. So take 15 for example. 15 times 2 is 30, plus 1 is 31 and that is in the out. [15 and 31 correspond to each other in the table. 15 being in the input column and 31 being in the output column].

The student used this mapping between the numbers in the input column and the output column to determine 38 corresponds to 77. In this context, the student used a correspondence approach (Confrey & Smith, 1994) to determine the output when the input was 38.

In conclusion, both tasks contained the same structure as linear functions. However, the student thought differently about how the functions "worked" when given a visual pattern of growth as opposed to when given an input-output table. This student showed the capacity to reason through covariation and correspondence while the context of the problem may have influenced the approach. The poster presentation will provide evidence and vignettes from the task-based interview.

Keywords: Number Concepts and Operations, Problem Solving

Fischbein (1987) describes intuition as a type of cognition that allows attributing intrinsic certainty to knowledge in order to develop a reasoning endeavor. An intuitive knowledge is not necessarily grounded on a logical reasoning. It was desired to observe if third grade students have intuitive notions about proportion even if they hadn't received formal instruction on this subject, and if these ideas prevailed on sixth grade students that had already received this lesson. To address this purpose, we suggested the following research question: which strategies are used by third and sixth grade students to solve ratio comparation problems?

Grounded theory, that was used to elaborate the current research, is a qualitative methodology that proposes to build theory from data. One of the analytic tools proposed by this theory is constant comparisons which consist in coding, grouping and categorizing data (Corbin & Strauss, 2014). The work was developed with 33 third grade and 25 sixth grade students that went to the same elementary school. Four ratio comparison problems like the next one composed the instrument: Pedro blows up 16 balloons in 8 minutes, Juan blows up 20 balloons in 40 minutes, which child blows up more balloons in less time?

Table 1: Approaches and Strategies Used by Students

Approach	Description	Strategies	%3rd	%6th
1. Meaningless	Use of sums and products with no sense	Algorithmic	1	19
2. Absolute	Comparison of only one of two variables (e.g. balloons with balloons)	Univocal comparison	79	6
3. Comparative	Comparison of all the variables by different methods without achieving the correct result	Equivalences chart	0	8
		Incipient notion of proportionality	16	0
4. Proportional	Students get correct results by conventional methods	Constant of proportionality	0	17
		Equivalent ratio	4	28
		Unitary value	0	22

In order to classify the results, it was considered that each element of the proportional relation was a variable: in this case balloons and minutes were two different variables. The students strategies were categorized into four different mutual exclusive bottom-up approaches. The first approach was considered the furthest from proportional reasoning (see Table 1).

Some questions arise from this research. Why was there a major proportion of sixth grade students that answered using algorithms if third grade students already presented intuitive responses with incipient notions of proportionality? How can teaching canalize and make the students intuitions contribute to achieve proportional reasoning?

Palabras clave: Conceptos de Números y Operaciones, Resolución de Problemas

Fischbein (1987) describe la intuición como un tipo de cognición que permite atribuir certeza intrínseca a un conocimiento, y a partir de éste, desarrollar un trabajo de razonamiento. Un conomiento intuitivo no necesariamente se fundamenta en un razonamiento lógico. Se pretendía observar si los estudiantes de tercero tenían nociones intuitivas acerca de la proporcionalidad incluso sin haber recibido instrucción formal en esta materia, y si estas ideas prevalecían en los estudiantes de sexto quienes ya habían recibido esta instrucción. Con este objetivo se propone la siguiente pregunta de investigación: ¿qué estrategias utilizan los estudiantes de tercer y sexto grado de primaria para resolver problemas de comparación de razones?

La teoría fundamentada, que se utilizó para elaborar la presente investigación, es una metodología cualitativa que propone construir teoría a partir de los datos. Una de las herramientas analíticas propuestas por esta teoría es la comparación constante que consiste en codificar, agrupar y categorizar datos (Corbin & Strauss, 2014). El trabajo se desarrolló con 33 estudiantes de tercero y 25 estudiantes de sexto que pertenecían a la misma escuela primaria. Cuatro problemas de comparación de razones como el siguiente conformaron el instrumento: Pedro infla 16 globos en 8 minutos, Juan infla 20 globos en 40 minutos, ¿cuál niño infla más globos en menos tiempo? Para clasificar los resultados se consideró a cada uno de los elementos de la relación de prorcionalidad como una variable: en este caso los globos y los minutos fueron dos distintas variables. Las estrategias de los alumnos se categorizaron en cuatro enfoques distintos mutuamente excluyentes de manera ascendente. El primer enfoque se consideró el más lejano al pensamiento proporcional (ver Tabla 1).

Tabla 1: Enfoques y Estrategias Usadas por los Estudiantes

Enfoque	Descripción	Estrategias	%3ro	%6to
1. Sin sentido	Uso de sumas y productos sin sentido.	Algorítmico	1	19
2. Absoluto	Comparación de una variable (e.g. globos con globos)	Comparación unívoca	79	6
3. Comparativo	Comparación de todas las variables usando diferentes métodos sin lograr el resultado correcto	Tabla de equivalencias	0	8
		Noción incipiente de la proporcionalidad	16	0
4. Proporcional	Los estudiantes obtienen el resultado correcto por métodos conveniconales	Constante de proporcionalidad	0	17
		Razón equivalente	4	28
		Valor unitario	0	22

A partir de la investigación surgieron algunas preguntas. ¿Por qué hubo una proporción mayor de estudiantes de sexto que respondió usando algoritmos si los estudiantes de tercero ya presentaban respuestas intuitivas con nociones incipientes de proporcionalidad? ¿Cómo la enseñanza puede canalizar y hacer que las intuiciones de los alumnos contribuyan a lograr un razonamiento proporcional?

THE ADVANCED TACITLY NESTED NUMBER SEQUENCE: WHY DOES IT MATTER IN THE MIDDLE GRADES?

Karen Zwanch
Oklahoma State University
karen.zwanch@okstate.edu

Keywords: Middle School Education; Number Concepts and Operations

Steffe and Cobb (1988) defined four stages of elementary students' understanding of number, which are based on the levels of units that students construct and coordinate (Ulrich, 2015, 2016a). First is the initial number sequence, marked by counting on; next is the tacitly nested number sequence (TNS), marked by double counting and constructing composite units (i.e., units of unit) in activity; third is the explicitly nested number sequence, which is defined by multiplicative reasoning; and finally, the generalized number sequence. In her work with sixth-grade students, however, Ulrich (2016b) defined an additional stage, the advanced tacitly nested number sequence (aTNS). The name is literal in its meaning: aTNS students can apply the operations of their TNS in advanced ways. Research has since identified substantial numbers of aTNS students in the middle grades (Ulrich & Wilkins, 2017; Zwanch & Wilkins, in review). This study builds on Ulrich's (2016b) definition of an aTNS by characterizing the ways in which aTNS students' numerical and algebraic reasoning typify an *advanced* TNS.

The data for this study were collected from students in grades six through nine at a small school district in the southeastern United States. 18 students (2 TNS, 8 aTNS, 6 ENS, 2 GNS) participated in two, 45-minute, semi-structured clinical interviews. Each student's number sequence attribution was confirmed, and the students' algebraic reasoning was characterized.

One characteristic use of number that distinguished aTNS students was their use of skip counting to solve multiplicative problems. TNS students construct composite units in activity (Ulrich, 2015), thus when asked to solve the bar task (Figure 1), they tended to partition the larger bar into four pieces and add 8 four times. Constructing composites in activity supported double counting, but not multiplicative reasoning. aTNS students operate on composite units (Ulrich, 2016b) making it possible for them to think about repeating composite units of eight. Accordingly, aTNS students tended to partition the larger bar into four pieces, then skip count by 8 four times. Most aTNS students stated that they had multiplied eight times four, but their behavior was inconsistent with multiplication. This shows a retrospective awareness of the multiplicative relation, but even after solving several similar tasks, aTNS students did not generalize the multiplicative nature of one bar task to the others. Algebraically, similar behaviors manifested in students' solutions to solving systems of equations. aTNS students used guess and check methods wherein the checking was heavily dependent on students' skip counting. Thus, aTNS students' operations on composite units supported their solutions to algebraic tasks in a manner that confirms their categorization of having constructed an *advanced* TNS. This also demonstrates how aTNS students' numerical and algebraic reasoning is distinct from their peers, making it necessary to consider how we support their learning in the middle grades.

WHAT MAKES A MATHEMATICS LESSON INTERESTING TO STUDENTS?

Leslie Dietiker
Boston University
dietiker@bu.edu

Rashmi Singh
Boston University
rsingh9@bu.edu

Meghan Riling
Boston University
mriling@bu.edu

Hector I. Nieves
Boston University
hnieves@bu.edu

How can we design mathematical lessons that spark student interest? To answer this, we analyzed teacher-designed and enacted lessons that students described as interesting for how the content unfolded. When compared to those the same students describe as uninteresting, multiple distinguishing characteristics are evident, such as the presence of misdirection, mathematical questions that remain unanswered for extended time, and a greater number of questions that are unanswered at each point of the lesson. Low-interest lessons did not contain many special narrative features and mostly had questions that were answered immediately. Our findings offer guidance for the design of lessons that can shift student mathematical dispositions.

Keywords: mathematics curriculum, narrative, aesthetic, mathematical story

What if mathematics lessons could be designed and enacted so they were as stimulating as *Harry Potter*, where students eagerly await the next installment? Literature is purposefully designed to capture and hold readers' attention; why not mathematical sequences? The ability to craft mathematical sequences that catch student attention and nurture a desire to continue to learn math would arguably have a positive impact on math education. That is, when a student becomes curious, they are more likely to engage with the content and increase attention, thereby increasing the potential for learning and deepening understanding (Csikszentmihalyi, 1990; Dewey, 1913; Guthrie, Hoa, Wigfield, Tonks, & Perencevich, 2005; Wong, 2007).

Despite major investment to improve mathematics curriculum, the content in most classrooms often sends the meta-message, *study this content because you need it to study related content later that you also will likely have little interest in or realize is even coming* (Chazan, 2000). Rather than provoking student imagination and curiosity in mathematics through sequencing curricular material, textbook authors rely on worldly contexts (conveying, *you should be interested in this because someday you might own a business and need to maximize profit*). Sinclair (2001) argues that this practice of relying on sources outside of mathematics to make mathematics interesting "endorses the belief that mathematics itself is an aesthetically sterile domain, or at least one whose potentialities are only realized through engagement with external domains of interest" (2001, p. 25). Drawing on Dewey's (1934) notion of *aesthetic* as a felt response to an experience rather than an attribute of an object, Sinclair asks, "Could we reverse the direction of the aesthetic flow, so that it originates in the mathematics?" (2001, p. 25).

Unfortunately, little is known about how decontextualized secondary school mathematics can be designed to be interesting and engaging. In this paper, we explore the characteristics of decontextualized secondary mathematics lessons that spur students' curiosity, captivate students with complex mathematical content, and compel students to engage and persevere, which we refer to as "mathematically captivating learning experiences" (MCLEs). The purpose of this paper is to address: *What characteristics, if any, distinguish high school mathematics lessons that students identify as interesting from those they describe as not interesting?*

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Theoretical Framework

In order to identify differences in how the mathematical ideas emerge and change as the lesson unfolds, this study interprets mathematical sequences that connect a beginning with an ending as a *mathematical story* (Dietiker, 2013, 2015b). Built from Bal's (2009) narratological framework, this interpretation foregrounds how mathematical characters are acted upon through mathematical action in mathematical settings. For example, mathematical characters are the mathematical objects brought into existence (objectified) through reference in the story, such as a function. Mathematical action describes the work of an actor (such as a student or teacher) in changing the mathematical ideas or objects of study, such as composing two functions to create a new function. Mathematical characters and actions are brought into being in a constructed "space" such as a white board or a coordinate plane, referred to as the mathematical setting.

For this study, a particularly important quality of a mathematical story is its *mathematical plot*; that is, the way it captivates and holds the interest of its audience. When a mathematical story hints of a future revelation, it may spur the formulation and pursuit of questions ("Why did the composition just end up with *x*?"), similar to how a reader of a literary story might wonder how the story will progress and continue reading. Thus, the mathematical plot describes the dynamically changing tension between what is already known and desired to be known by the participants as the story progresses (Dietiker, 2015b). It enables the description of how a mathematical sequence can generate suspense (by setting up anticipation for a result) and surprise (by revealing a different result than the one anticipated). Questions may span the entire story or may represent brief puzzles or mysteries. The progress made on each question, from when it is asked, to how students' understanding of it changes, to how it is abandoned or answered, constitutes a *story arc*. Since a mathematical story may involve answering multiple questions at any point along a sequence, multiple story arcs may arise over the course of the lesson and overlap at different intervals. The changing number of questions under pursuit by students throughout the lesson can be referred to as its *density* of inquiry.

Methods

This study identifies the distinguishing characteristics of interesting lessons that were designed and taught in the first of three design research cycles (Cobb, Stephan, McClain, & Gravemeijer, 2001; Edelson, 2002). The larger research project is an exploration of whether and how designing high school lessons as mathematical stories impact the aesthetic experiences of students. Six high school teachers, each with at least 4 years of experience, from three high schools with different curriculum and diverse demographic settings in the Northeastern region of the USA were recruited to participate in this study. The teachers worked in pairs, along with researchers, to design MCLEs for one or more of their classes. The participating courses, selected by teachers, spanned entry-level (e.g., Integrated Math 1) to advanced-level (e.g., calculus) and included both honors and non-honors. To support the design of MCLEs, the teachers attended a two-week professional development during the summer of 2018 where they learned about the mathematical story framework (Dietiker, 2015a, 2015b, 2016; Ryan & Dietiker, 2018) and participated in analyzing the mathematical plot of one lesson enactment.

An analysis of the complete set of MCLEs from the 2018-2019 school year, when compared with non-MCLEs from the same teacher and classes, revealed that the MCLEs did impact student interest measures positively (Dietiker et al., 2019). Yet, if these positive student reports are connected with non-mathematical factors (i.e., mood of the teacher, point in the semester), then the mathematical stories of the interesting lessons should not be significantly distinguishable from those of less interesting lessons. Thus, we designed the present study to learn whether the unfolding content of those lessons that students describe as interesting have characteristics are qualitatively different from those that students indicate are not interesting.

All 32 lessons generated in the 2018-2019 school year were observed by multiple researchers using the same protocol so that students would not be able to infer whether some lessons were special or not. The lessons were filmed using three video-cameras placed strategically to capture the teacher, students' facial expressions in the whole class, and the progress of a focus group of students. In addition to a central microphone, audio recorders were placed around the classroom to capture student discourse and the teacher wore a lapel mic. Immediately following each observed lesson, all participating students took a Lesson Experience Survey (LES) on their digital devices. In this survey, students were asked to rate their overall interest in the lesson on a scale of 1 to 4 and select three terms to describe their view of the lesson from 16 given descriptors, including negative, neutral, and positive options. More information about the design and testing of the LES can be found in Riling et al. (2019).

To recognize characteristics that distinguish high-interest lessons from low-interest lessons, the research team composed two groups of lessons by identifying each teacher's highest-interest and lowest-interest lessons based on students' LES responses. Pairing a low- and a high-interest lesson per class allowed both sets to include reports from the same students, rather than two groups of students who might have differing dispositions to mathematics to begin with. Only lessons with surveys from at least 10 students were included (this eliminated one lesson). We selected the lesson with the highest average interest measure for each teacher, using students' selection of positive descriptor to break ties. After selecting a teacher's high-interest lesson, the lesson for that class with the lowest average student interest level (with negative descriptors used to break ties) was selected for the low-interest group. Although the lessons were selected based on the interest level and student-selected descriptors from the LES, all lessons in the resulting "high interest group" were MCLEs and all lessons in the "low-interest group" were non-MCLEs.

To analyze the lessons in the high- and low-interest groups for their mathematical story characteristics, we first coded each for its mathematical plot. Then, we compared the mathematical plots of the two groups and identified characteristics that distinguished them. The plots relied on detailed transcripts for each lesson that included the discourse of a focal group, allowing us to note the progress those students made on the mathematical questions raised during groupwork and to include any questions the students asked while collaborating.

The transcripts were analyzed on three separate coding passes. On each pass, the research team coded separately in groups and then met to resolve differences. On the first pass, the team identified *acts* by tracking what mathematical characters, actions, and settings were in focus throughout the transcript and noting when these changed. On the second pass, the research team identified all mathematical questions that were raised, considered, and addressed throughout the lesson by a teacher, student, or some type of curriculum materials. Whereas some questions were recognized explicitly through verbal or written statements (e.g., "Find the root"), others were raised implicitly by images or situations experienced by students. Questions that were not mathematical (e.g., "Can I present my solution?") were not included.

On the final coding pass, the research team coded how what was known about each question changed across the acts of the lesson. For each question, the researchers used codes adapted from Barthes (1974) narrative theory to code contributions by teachers and students. These codes included foreshadowing of a question ("*proposal,*" marked with a 0 in the plot diagrams), when a question was raised ("*question,*" 1 when raised by a teacher and 2 when raised by a student), any explicit messages that the question would be answered ("*promise,*" 3), any progress made on answering the question ("*progress,*" 4 if made by a teacher, 5 if made by a student), and when, if ever, it was answered and thus closed ("*disclosure,*" marked with "D"). In addition to these codes, we also coded for interruptions to progress when the topic shifted so far from the question that it is no longer reasonable to assume the question may be addressed ("*suspension,*" marked with 9), or when there is a threat to progress toward an answer ("*jamming,"* marked with 8*)*. Finally, we coded any evidence of misdirection, in which lesson participants are misled in a consequential way. There are two types of misdirection: a *snare* (marked with 7) is an explicit error or lie, while an *equivocation* (marked with 6) is an encouragement to make a faulty assumption. To separately track who or what was responsible for a contribution, we also identified for each code whether the contribution came from the teacher, student, or environment (e.g., a worksheet).

These coding passes result in a comprehensive mapping of how participants within each lesson are moved to raise and answer questions, representing the mathematical plot of the lesson. For each question, the acts during which it is open (i.e., it is unanswered and it is reasonable to think that there is still a possibility of further progress on the question), along with all the codes for that question, form a story arc. The set of all story arcs describe how all of the mathematical content emerges and changes throughout the acts of the story.

Next, we qualitatively compared the mathematical plots and identified characteristics that appeared to distinguish the high- and low-interest lessons. We then compared quantitative dimensions of their mathematical plots such as number of acts, number of questions opened throughout the lesson, and story arc length. We compared the average number of coded questions per act, the average number of questions open and in progress per act ("mean density per act"), the proportion of story covered by these open questions ("mean arc length as proportion of story"), and the percentage of questions open for more than one act ("proportion of extended story arcs per total arcs"). A paired samples *t*-test was conducted to compare the mean differences between the two means of these measures for the two groups of lessons for $\alpha < 0.05$. A box plot diagram was made to compare the high- and low-interest lessons for measures.

Findings

In this section, we illustrate the differences between high-interest and low-interest lessons by describing a pair of high- and low-interest mathematical stories taught to one group of students by the same teacher. These mathematical stories are presented in present tense in the sequence in which events unfolded to highlight how what was known changed through the lesson. Next, we introduce contrasting characteristics of the stories' mathematical plots. Finally, we describe general patterns of high- and low-interest lessons, identifying characteristics of lessons that students find interesting.

This pair of lessons was selected because each contains many characteristics common to the other high- or low-interest lessons. These lessons were taught in an Algebra 2 Honors course with sophomores and juniors by Ms. Elm (pseudonym). The class had 28 students, 25 of whom participated in the study.

Low-Interest Mathematical Story

The class begins (Acts 1 through 3) with students working in partners on a "Do Now," which asks students to make sense of a newly defined operation ($a\&b = 3a - b$), including determining whether it is commutative and what its domain is. After Ms. Elm collects their work and verifies one of the answers, she reviews general principles of commutativity and domain.

In Act 4, Ms. Elm distributes a handout with questions about a range of topics, including domain, range, and percentages. The questions are multiple choice practice tasks for standardized tests. The focal group spends the rest of Act 4 working on a question about domain. In Acts 5 and 6, the group discusses a question about the range of a different function. In Act 7, they briefly complete more tasks about algebraic equations and operations.

In Acts 8 through 11, the focal group shifts to work on questions about percents. Each question is about a different aspect of percents and based in a different context: the reduced price of clothing item, what percentage one number is of another, and how much a company's profit increased.

Students engage with each other on each problem, although there is little evidence that they are challenged. The teacher concludes class by stating “we’re gonna stop there for today.”

High-Interest Mathematical Story

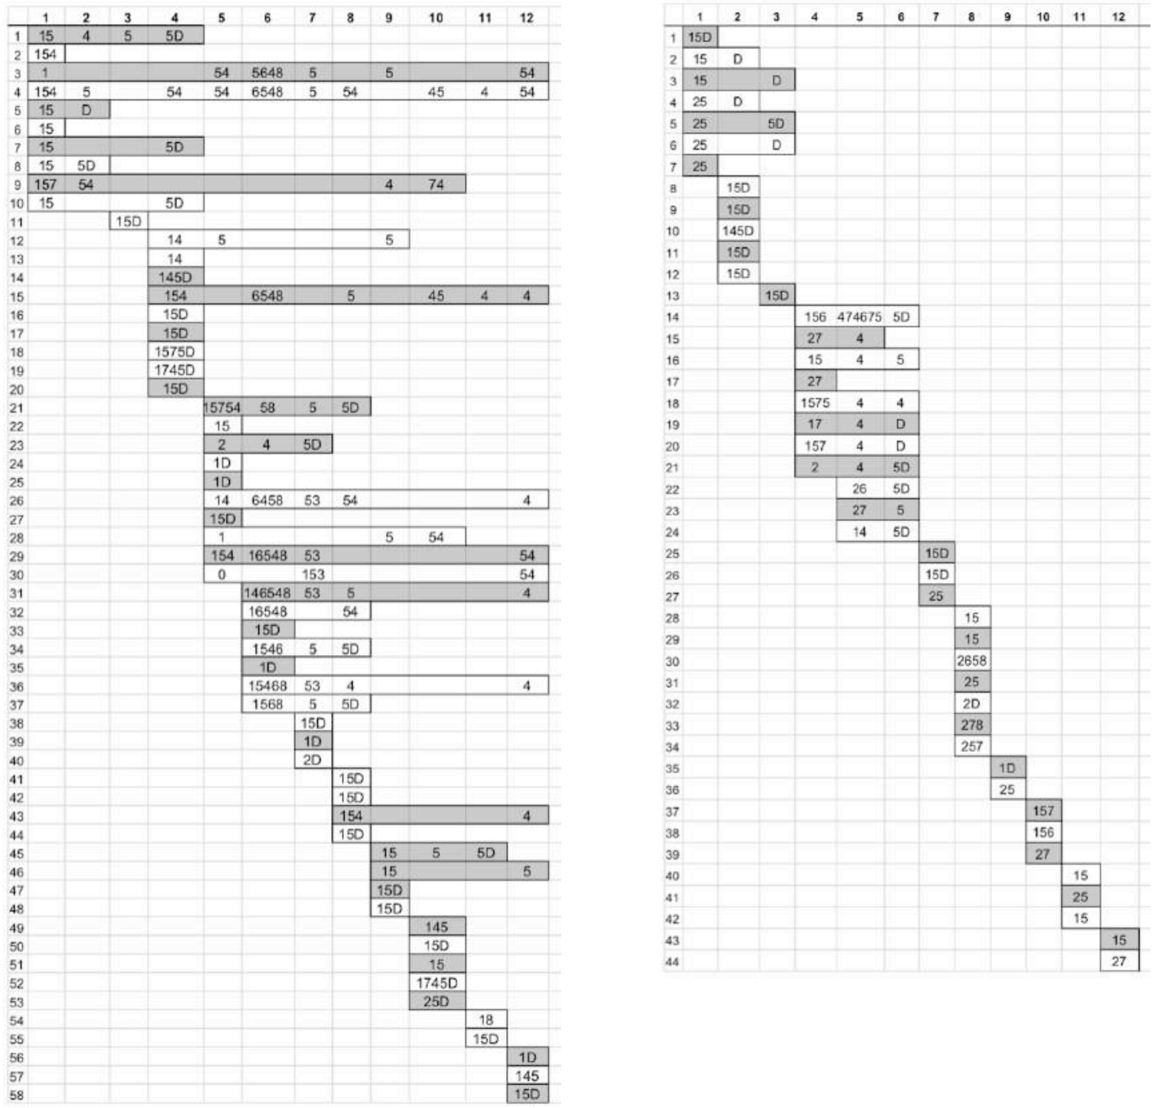
In Act 1, Ms. Elm explains that the lesson objective is to develop a strategy to identify the roots of polynomial functions. After displaying $f(x) = x^3 - 5x^2 - x + 5$ on the board and assigns each pair of students a value between –9 and 9, she challenges students to figure out whether they are “guilty as a root.” First, she asks students to predict whether their value is a root and brainstorm ways to verify their guess. The focal group, which has the value 7, predicts that they cannot be a root because “if you do factoring by grouping, you wouldn't get 7 at all.” In Act 2, Ms. Elm reviews synthetic division. In Acts 3 and 4, each group checks whether they are a root using synthetic division. The group whose value is 5 thinks they might be a root, which is confirmed. The focal group celebrates with a little dance. Next, the class finds the remaining roots (i.e. 1 and -1) by factoring the polynomial.

Students next test whether their group’s value is a root of $f(x) = 2x^3 + x^2 - 16x - 15$. In Act 5, a student says that 8 is likely a root, explaining, “this is gonna sound kinda weird, but because of the two and the sixteen.” This is the first time a student connects the polynomials’ coefficients and roots. When it turns out that 8 is not a root, another group shares that 3 is a root. In Act 6, a student suggests that since 3 is a root, then -5 might be, because the y-intercept is -15. Ms. Elm responds by saying, “that's weird right, ‘cause I actually really kind of agree here. That we need to do something to get ourselves to fifteen.” She asks groups to use synthetic division to find the remaining roots. As students begin to do so, in Act 7, a student spontaneously claims that 2.5, not 5, is another root “because the leading coefficient, you need to divide that. It's two x minus five.” Ms. Elm asks him to “hold that thought” and he reacts with contained excitement. In Act 8, the whole class finds the remaining quadratic once the cubic is divided by $x - 3$. Then, once the constant term is determined to be positive, students recognize that one of the remaining roots is not 2.5, but rather –2.5.

In Act 9, Ms. Elm elicits enthusiasm when she proposes a challenge: The class has four chances to identify the roots of $f(x) = 6x^4 + 35x^3 - 49x^2 + x + 7$. The first two choices, 6 and 7, are found to not be roots. A group proposes -7 as a root, and a student confirms it using synthetic division. In Acts 10 and 11, the class fully factors the polynomial and finds the remaining roots: 1, -⅓, and ½. In the last act, there is a growing sense during a class discussion that there is a multiplicative relationship between the coefficients and the roots. For homework, Ms. Elm asks students to reflect on how to identify polynomial roots.

The Comparison of the Mathematical Plots

These mathematical plots have several distinguishing characteristics, as can be observed in the mathematical plots of the high-interest lesson (Figure 1a) and low-interest lesson (Figure 1b). There were considerably more questions opened throughout Ms. Elm’s high-interest lesson (75) as compared with her low-interest lesson (44). Interestingly, the percentage of the story arcs that remained open for more than one act was similar in both the high-interest lesson (27 out of 75, or 36%) and the low-interest lesson (15 out of 44, or 34%). However, the average arc length of the high-interest lesson is 2.6 acts long, which constitutes 22% of the lesson and is one act longer than the average length questions remained unanswered in the low-interest lesson (1.6 acts, or 13% of the lesson).



(a) (b)

Figure 1: The Mathematical Plots for Ms. Elm's (a) High-interest Lesson and (b) Low-interest Lesson. Each row represents a story arc. See methods section for code references.

In addition, most story arcs in the high-interest lesson contain acts in which no change in what is known about the question occurs. In almost a quarter of the story arcs (18 of 75), there is at least one act with no codes at all, providing the opportunity for students to build curiosity. This also provides a sense that not all questions that are raised will be answered immediately. In contrast, in the low-interest lesson, only three questions (#3, 5, and 6) have an act during which the question is open and yet no codes appear. For all other questions (41 of 44, or 93%), every act in which the question is open contains some change.

Stark differences are also evident in the density of these lessons (see Figure 3). Since the two lessons have a different number of acts, density is graphed across the percentage of the lesson that has passed. In the high-interest lesson, the density generally increases and then remains high, providing a lasting sense of mystery. Act 1 has 10 open questions, and by Act 7, almost twice as many questions are open (19). The number of open questions remains relatively high through the end of the lesson, as students continue to pursue their ideas about how to identify the roots of a given polynomial function. There is variation in the density of both lessons, as the tension alternately increases and decreases. Yet in the high-interest lesson, this variation does not return to the initial lower level, whereas the density in the low-interest lesson remains low with temporary dips. Overall, the density in the high-interest lesson was an average of 14.25 questions per act. In comparison, the low-interest lesson had a maximum density of 10 questions and an average density of 5.7 questions per act.

Figure 2: The Density of Ms. Elm's High-interest (red) and Low-interest (blue) Lessons.

Lastly, we found differences in the occurrence of special mathematical plot codes that represent interruptions and misdirection. The mathematical plot of the high-interest lesson has more instances of *jamming* in comparison with the low-interest lesson (11 vs. 2, respectively). Additionally, the high-interest lesson has a *proposal*, offering a sense of mystery, and five instances of *promise*, offering anticipation for an answer to come, whereas low-interest lesson has neither. In addition, the high-interest lesson has twice as many *equivocations* than low-interest lesson (10 vs. 5), while the latter has twice more (12 vs. 6) *snares*. Interestingly, the high-interest lesson had more misdirection from the teacher, both in terms of *equivocations* and *snares*, than the low interest lesson (3 vs. 1 and 1 vs. 0, respectively).

Characteristics that Distinguish High-interest and Low-interest Lessons

Across all 12 lessons, we identified multiple characteristics that distinguished high- and low-interest lessons significantly. Figure 4 shows the comparative measures for high- and low-interest lessons after the measures were standardized (i.e., mean = 0, vertical axis indicates the number of standard deviations from the mean). The questions in high-interest lessons remained unanswered for significantly more acts, as shown by a higher proportion of story arcs that lasted for more than one act (what we refer to as "extended questions") ($t(5) = 3.16$, $p < 0.05$), a longer mean arc length ($t(5)= 2.85$, $p < 0.05$), and the average arc length spanning a longer portion of the lesson ("mean arc length as % of story"; $t(5)= 4.21$, $p < 0.01$). In addition, the average number of open questions per act ("mean density per act") for the high-interest lessons is significantly greater than that of the low-interest lessons ($t(5)= 3.93$, $p < 0.05$). Similarly, the average number of changes to what is known (i.e., codes) per question in high-interest lessons is significantly greater than that of the low-interest lessons ("mean total codes per question"; $t(5)= 2.96$, $p < 0.05$). We found that high- and low-interest lessons have a similar percentage of acts with codes and disclosed formulated questions. Additionally, although higher interest lessons have more formulated questions and acts than low interest lessons, this difference is not distinguishable.

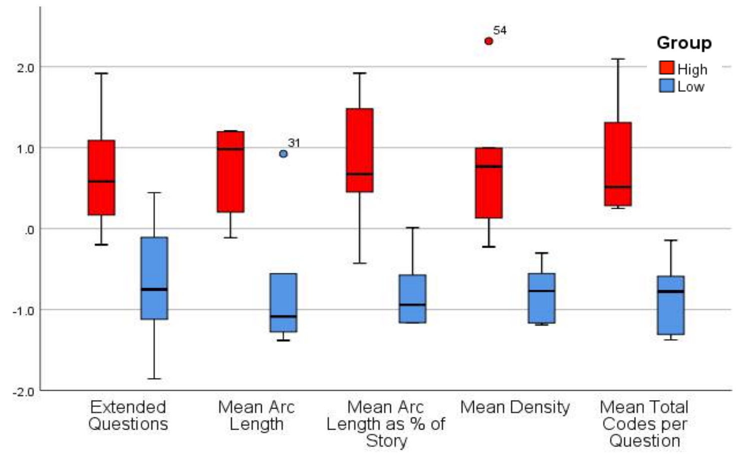


Figure 3: Comparison of Mathematical Plot Measures.

When comparing the frequency of the special mathematical plot codes by teachers (jamming, snare, equivocations, and promise), the high-interest lessons had a greater average frequency than the low-interest lessons. However, these differences were not statistically significant.

Discussion

We started this paper wondering how we can design mathematics lessons that compel students to become curious or excited. The characteristics described in this paper begin to answer this question. For example, the higher percentage of questions that are open for larger proportions of a lesson provide students extended opportunities to mathematically wonder, build understanding, and thus enjoy underlying mathematical concepts. In contrast, when questions of low-interest lessons are answered almost immediately, we are concerned that students may not have enough time to think deeply about mathematical concepts or relationships. Being confused, without the benefit of curiosity or anticipation, may hinder joy.

Knowledge of the characteristics of high-interest lessons can support educators and curriculum developers who wish to design mathematically captivating lessons that can positively impact students' experiences. For example, teachers might decide to mindfully include equivocations, which were not present in any of the low-interest lessons in our data, in order to enable surprise during their lessons. Or curriculum designers may decide to encourage teachers to delay giving answers to students, in order to permit students to wonder and anticipate for longer periods of time. Further research will hopefully uncover additional features that can be used to design reliably engaging mathematical learning experiences.

IDENTIFYING OPPORTUNITIES TO ENGAGE IN LITERACY PRACTICES: A FRAMEWORK FOR ANALYZING CURRICULUM MATERIALS

Ethan Smith
University of Delaware
etsmith@udel.edu

In this report I have created an exploratory framework to identify opportunities to engage in literacy practices within mathematics curriculum materials. This framework describes "unstructured literacy opportunities" and "structured literacy opportunities" for each of the language modalities of reading, writing, speaking, and listening. Different structures within each modality are also detailed along with connections between the modalities. The framework is then applied to Illustrative Mathematics (IM) curriculum materials to reveal patterns of how different types of literacy opportunities are addressed and connected.

Keywords: Curriculum Analysis, Communication, Classroom Discourse, Instructional activities and practices

Written and spoken language serve important functions for communicating, receiving, and retaining information. Language also manifests in complex ways. Aguirre and Bunch (2012) describe how students must navigate a myriad of language demands in mathematics classrooms, differentiating such demands into modalities of reading, writing, speaking, and listening (along with a "representing" demand critical to mathematics in particular). The authors also describe how these demands are connected to one another: writing and speaking are *productive* activities while reading and listening are *receptive*. Additionally, reading and writing are "linked" to "written mathematical conventions," while listening and speaking encompass "oral language" (Aguirre & Bunch, 2012, p. 185). This multifaceted description of language aligns well with Moschkovich's (2015) definition of academic literacy, which positions the learner as an active participant in mathematical discourse. Moschkovich explains this phrasing by stating her desire to "shift from a focus on language as words to a broader sense of *literacy* as participation in practices and discourses" (p. 45).

When literacy is seen in the Vygotskian sense as "the understanding and communication of meaning" (Moll, 1992, p. 8), its relevance to mathematics education becomes even more apparent. After all, achieving learning with understanding is considered the "Holy Grail" of mathematics education (Hiebert & Carpenter, 1992, p. 65). If literacy within written and oral language is a core conduit through which mathematical ideas are communicated, then knowing how best to engage students in literacy practices is of upmost importance.

This report extends Aguirre and Bunch's and Moschkovich's exploration of language and literacy in mathematics by focusing on a curricular rather than instructional lens. The research questions considered are: (1) In what ways do mathematics curriculum materials present opportunities to address literacy demands of reading, writing, speaking, or listening? (2) In what ways do such curriculum materials connect opportunities for reading, writing, speaking, or listening?

Theoretical Framework

A contribution of this report is a framework which describes structured versus unstructured opportunities for reading, writing, speaking, and listening in mathematics. Wiggins (2001) notes how interdisciplinary curricular materials often position one discipline as subservient to the other, which results in an "approach [that] has little to do with teaching the concepts of [either discipline]" (p. 42). Genuine integration should instead promote shared concepts and processes present across the relevant disciplines, thus leading to better understanding of both disciplines (Wiggins, 2001).

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Shanahan and Shanahan (2008) discuss in particular how generalized literacy skills are insufficient within contents such as mathematics as students advance into secondary grades. Instead, teaching in these grades should emphasize disciplinary literacy skills unique to the specialized nature of the individual content (Shanahan & Shanahan, 2008). Curricular tasks which address literacy skills in generalized or subservient ways are considered *unstructured literacy opportunities* in this framework, while tasks which address mathematics-specific literacy skills (i.e. disciplinary literacy) are considered *structured literacy opportunities*. This framework expands beyond Shanahan and Shanahan's reading focus to consider Aguirre and Bunch's (2012) language demands of reading, writing, speaking, and listening. The disciplinary focus of each type of structured literacy opportunity is also described for each modality, as the mathematical purpose of curricular activities may vary. Such modality-specific descriptions of these opportunities follow.

Unstructured reading opportunities include any written mathematical text which students may read, while structured reading opportunities are tasks which specifically address elements of reading comprehension. This includes referencing surface comprehension of syntax and text features for students (Hoffer, 2012) or metacognitive modeling of deeper comprehension (Hoffer, 2012; Kenney, 2005). With such structures in mind, the role of vocabulary within these texts is also of interest. Certain words (called academic vocabulary) have more utility across domains while also being critical to comprehending mathematical text (Hoffer, 2012; Bay-Williams & Livers, 2009), so their inclusion in written tasks could better afford such opportunities. Thus, it is worth considering whether academic text is part of a structured reading opportunity or whether it is absent (which this framework describes as *simple text*).

Structured writing opportunities are found in tasks which require written explanations or justification, as well as tasks which promote refinement of mathematical ideas through written language (Hoffer, 2012; Kenney, 2005). Although many mathematical tasks use words/phrases that imply writing (e.g. "explain", "show how you know," etc.), this alone is unstructured. Since explicit guidance around when and how to write is critical to building writing skill in mathematics (Thompson, 2008), evidence of such opportunities is a prerequisite for structured writing. Additionally, such mathematical writing can serve different purposes. Writing can act as a *summative* assessment which provides better insight into student understanding (Miller, 1991), but it can also be used *formatively* throughout the problem-solving process to better develop students' metacognitive skills than oral communication alone (Pugalee, 2001).

Unstructured listening is a ubiquitous expectation of many mathematics classrooms (Aguirre & Bunch, 2012). Hintz and Tyson (2015) refer to "complex listening" as a structure to support this demand, where mathematics sense-making is encouraged in part by "*Directing* students towards what to listen for and whom to listen to" (p. 315, emphasis in original). While listening opportunities can serve to help students internalize information for themselves (e.g. understanding what the teacher is saying), they also can be used to help facilitate responses to others' ideas within discourse (Aguirre & Bunch, 2012).

Structure can be given to speaking opportunities by directing students toward cooperative speaking (Thompson, 2008) or exploratory talk (Mercer, Wegerif, & Dawes, 1999), where students are explicitly supported in understanding how to share time and space with their peers and collaborate respectfully. While such structures drive speaking in dialogically oriented math classrooms, classrooms which adhere to direct instruction emphasize students sharing their work individually in order to receive immediate, corrective feedback from the teacher (Munter, Stein, & Smith, 2015). This shows how speaking opportunities might be structured in collaborative *or* individualized ways depending on the preferred orientation to mathematical instruction.

Aguirre and Bunch (2012) detail how language modalities of reading, writing, speaking, and listening also connect with one another. The authors note that speaking and writing share productive connections (ideas are produced) while reading and listening share receptive connections (ideas are received). Reading and writing are also both expressions of written language while speaking and listening are forms of oral language (Aguirre and Bunch, 2012). Thus, when multiple literacy connections appear in the same task, they can share connections related to student action (productive and receptive) or format (written and oral language).

Altogether these distinctions between unstructured and structured literacy opportunities, the varying types of structured opportunities, and the types of connections across language demands form the foundation of this report's framework. These are summarized in Figure 1.

Unstructured Literacy Opportunities (ULOs)

- Unstructured Reading Opportunities (UR)
- Unstructured Writing Opportunities (UW)
- Unstructured Listening Opportunities (UL)
- Unstructured Speaking Opportunities (US)

Structured Literacy Opportunities (SLOs)

- Structured Reading Opportunities (SR)
  - Academic Text (SR-A)
  - Simple Text (SR-S)
- Structured Writing Opportunities (SW)
  - Formative Writing (SW-F)
  - Summative Writing (SW-S)
- Structured Speaking Opportunities (SS)
  - Cooperative Focus (SS-C)
  - Individualized Focus (SS-I)
- Structured Listening Opportunities (SL)
  - Listening to Respond (SL-R)
  - Listening to Internalize (SL-I)

Literacy Connections

- Written Language Connections (WLC) – reading and writing practices are both present in the task.
- Oral Language Connections (OLC) – speaking and listening practices are both present in the task.
- Receptive Connections (RC) – reading and listening practices are both present in the task.
- Productive Connections (PC) – writing and speaking practices are both present in the task.

Figure 1: Opportunities to Engage in Literacy Practices

Modes of Inquiry

A curricular analysis has been conducted to test the exploratory framework of this report. The Illustrative Mathematics (IM) curriculum has been chosen for this analysis because it is well-suited for the focus of this investigation. The IM curricular overview explicitly cites Aguirre and Bunch's 2012 chapter and claims that "embedded within the curriculum are instructional supports and practices to help teachers address the specialized academic language demands in math when planning and delivering lessons, including the demands of reading, writing, speaking, listening, conversing, and representing in math" (Illustrative Mathematics, 2019b, para. 1). This suggests that the "intended curriculum" (Herbel-Eisenmann, 2007, p. 344) of IM should at the very least align with Aguirre and Bunch's model and could also reveal how these ideas play out in the transition towards the written curriculum.

Specifically, this investigation will analyze the first 6 lessons of *Unit 2: Introducing Proportional Relationship* from the 7th grade IM curriculum materials. These lessons are chosen because they emphasize multiple representations of proportional relationships, and representation is seen as a conduit which supports enactment of literacy demands and drives holistic connections across literacy opportunities (Aguirre & Bunch, 2012). Since this unit is students' first introduction to the terminology of "proportional relationship" there are also opportunities for addressing academic vocabulary in the selected lessons.

Taken together, these different aspects of the unit afford ample opportunity for a preliminary analysis of literacy opportunities. The IM lessons are broken into distinct activities, so a level of analysis smaller than the lessons themselves is appropriate: different literacy demands can be addressed in the same lesson without necessarily being connected to one another if they arise in discrete activities. Because IM activities generally break down into a "Launch" stage where a task is introduced and worked on and a "Synthesis" stage where student work or results are discussed, this study uses such task stages as the unit of analysis.

This approach created 40 task stages which were analyzed across the 6 lessons. A codebook was created which differentiated each type of opportunity and connection as summarized in the theoretical framework of this report. Reliability was established by enlisting a colleague to apply this codebook to the data set and checking for alignment with the author's results. Any initial disagreements in the data were discussed and resolved by the author and colleague. Each task stage was examined with the framework to determine whether any structured or unstructured literacy opportunities were described. When structured literacy opportunities (SLOs) were identified, they were also coded according to their appropriate sub-code (see Figure 1). The SLO results were then examined at the task level to determine if any tasks involved multiple SLOs. These tasks were coded as literacy connections as represented in Figure 1, because they provide students with opportunities to experience multiple related language modalities.

Results

The results of this analysis are presented in four main sections. The first two sections speak to the first research question regarding the ways that the Illustrative Mathematics (IM) curriculum materials address literacy opportunities of reading, writing, speaking, and listening. Results concerning structured literacy opportunities (SLOs) are examined in the first section, and these show that the curriculum materials employ multiple SLOs in every examined lesson but that productive opportunities for writing and speaking are more commonly found than receptive opportunities for reading and listening. The second section explores the unstructured literacy opportunities in these materials, and findings show that unstructured speaking and listening opportunities often appear together. The third section addresses the other research question regarding literacy connections and shows that the curriculum materials emphasize productive over receptive connections. The final section considers how the literacy practices were presented throughout the materials, noting how the way that such practices are phrased might promote an idea that SLOs should be reserved only for certain student populations.

Structured Literacy Opportunities

One overarching result of this analysis is that these curriculum materials employ structured literacy opportunities (SLOs) throughout their lessons, although with more focus on writing and speaking. Not only does every examined lesson include SLOs, but there is not a single lesson which does not employ at least 2 different SLOs. Additionally, all eight sub-codes for types of literacy opportunities were found, suggesting that these materials intentionally provide a range of opportunities to engage in literacy practices. As shown in Figure 2, 53 SLOs were coded across the tasks in these lessons. However, the different types of SLOs did not appear with equal frequency.

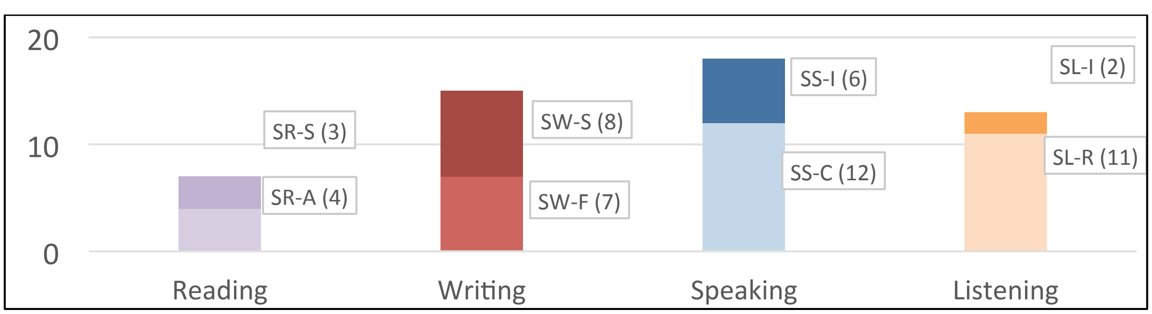

Figure 2: The frequency of each type of structured literacy opportunity with sub-codes

Structured opportunities for reading appear 7 times, writing 15 times, speaking 18 times, and listening 13 times. Despite every task being presented in the written language, reading comprehension is the least frequent structure seen in these tasks. Interestingly, listening SLOs (the other receptive modality besides reading) is the next least frequently referenced practice in these lessons. Given that most tasks in the IM curriculum materials consist of a “Launch” section with problems to complete (often with writing elements) and a “Synthesis” section grounded in discussion, it is not surprising to see high numbers of writing and speaking SLOs. What is surprising is that the receptive complements to these modalities are less frequently addressed. This becomes especially noted when looking at listening: Although there are 13 occurrences of such opportunities, 11 of these are *Listening to Respond* and 7 of those are paired with speaking SLOs. Figure 3 shows one such example from activity 5.2: The four sentence stems are structured speaking opportunities (cooperative focus) since they all orient students towards how to share time and space with their peers and collaborate respectfully (Thompson, 2008; Mercer, Wegerif, & Dawes, 1999), while “Why did you…?” and “I agree/disagree because…” are also structured listening opportunities (listening to respond) since they elevate complex listening skills (Hintz & Tyson, 2015) by directing students how to respond to specific arguments made by their partner. Given that these 7 paired routines blur the line between speaking and listening (since they emphasize discourse), this limits an explicit focus on listening. Such findings suggest that additional structures could be provided for reading and listening.

Support for Students with Disabilities

Engagement: Develop Effort and Persistence. Encourage and support opportunities for peer interactions. Prior to the whole-class discussion, invite students to share their work with a partner. Display sentence frames to support student conversation such as: “First, I _____ because ….,” “I noticed _____ so I ….,” “Why did you…?,” “I agree/disagree because….”
Supports accessibility for: Language; Social-emotional skills

Figure 3: A paired speaking and listening opportunity (Illustrative Mathematics, 2019a)

Unstructured Literacy Opportunities

This analysis also shows that unstructured literacy opportunities (ULOs) exist within in the IM curriculum materials. Such ULOs appear throughout the analyzed lessons, with unstructured speaking and listening opportunities often being paired together. As seen in Figure, there are 40 unstructured literacy opportunities coded throughout these lessons, including 4 opportunities for reading, 2 for writing, 19 for speaking, and 15 for listening . These 40 ULOs number fewer than the 53 structured practices but still represent significant numbers.

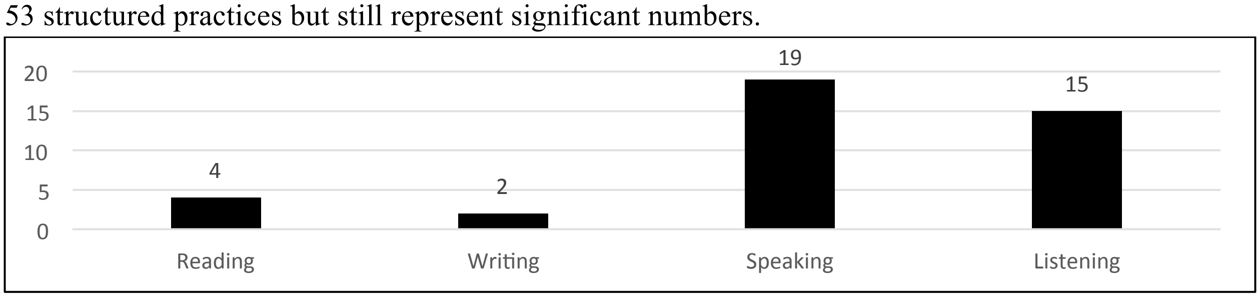

Figure 4: Frequency of unstructured literacy opportunities

24 of these instances arise from 12 pairs of listening and speaking ULOs. These unstructured pairs result from students being asked to compare or discuss with their peers (typically one partner) but without any oral language support structures (see Figure 5). Given that structured speaking and

listening opportunities *are* present throughout the IM curriculum, it is interesting that they are not consistently used when students are asked to engage in discourse. A more thorough analysis of the data could shed light on when structured speaking and listening opportunities are used versus when students are simply given unstructured speaking and listening opportunities.

Ask students to compare answers with their partner and discuss their reasoning until they reach an agreement.

Then, invite students to share how they used their equation from question 2 to answer question 3 with the whole class.

From task 4.4

Arrange students in groups of 2. Give students 6 minutes of partner work time followed by whole-class discussion.

From task 5.4

Figure 5: Unstructured speaking and listening opportunities (Illustrative Mathematics, 2019a)

Literacy Connections

The second research question for this report relates to the connections between literacy opportunities. Out of the 20 tasks explored, 14 of them had at least one connection (70% of all tasks) while 6 tasks showed two connections. Overall, 20 literacy connections were found. However, one finding of this analysis (shown in Figure 6) is that the types of literacy connections in the IM curriculum are not equally distributed. Productive connections and oral language connections both occur in 8 tasks, while written language connections only appear in 3 tasks and receptive connections do not appear at all. Additionally, 5 of the tasks include both productive and oral language connections, with each of these tasks having students write a response and then use that for discussion (see Figure 7 for such an example from activity 5.3). While this overall inconsistency is of note, the complete absence of receptive connections is especially a surprise. None of the analyzed tasks gave students structured opportunities to both read *and* listen. The limited number of written language connections (between reading and writing) further indicates that reading overall is an underutilized dimension of literacy in these materials.

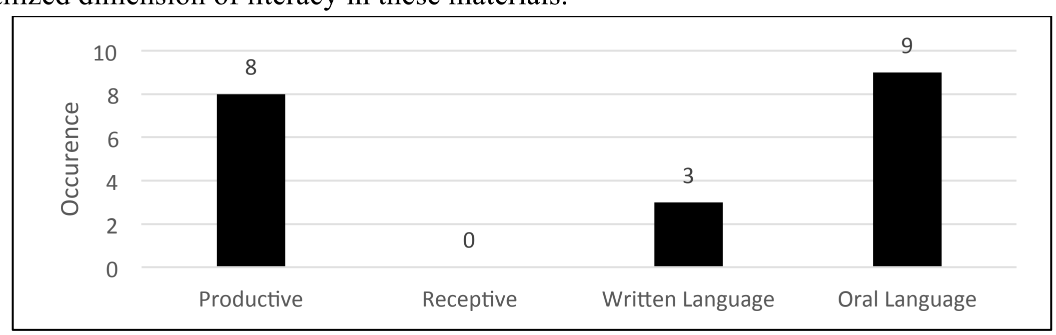

Figure 6: The number of each literacy connection that occurred in the selected IM lessons

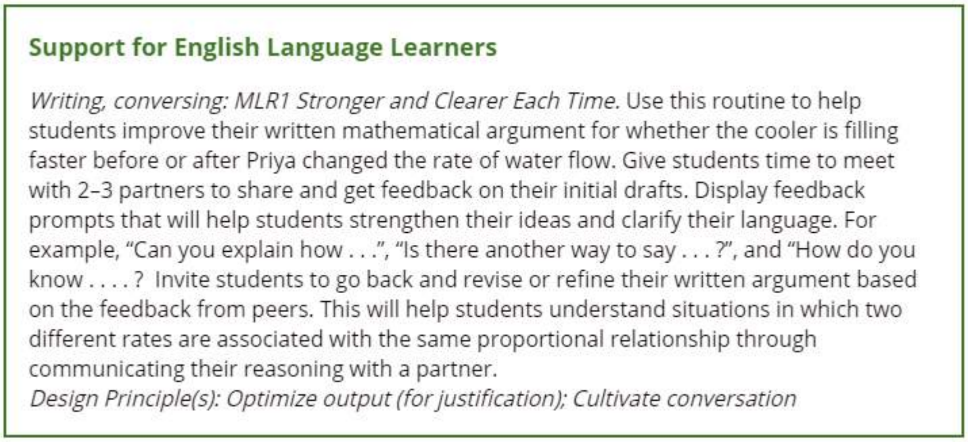

Support for English Language Learners

Writing, conversing: MLR1 Stronger and Clearer Each Time. Use this routine to help students improve their written mathematical argument for whether the cooler is filling faster before or after Priya changed the rate of water flow. Give students time to meet with 2–3 partners to share and get feedback on their initial drafts. Display feedback prompts that will help students strengthen their ideas and clarify their language. For example, "Can you explain how . . .", "Is there another way to say . . . ?", and "How do you know . . . . ? Invite students to go back and revise or refine their written argument based on the feedback from peers. This will help students understand situations in which two different rates are associated with the same proportional relationship through communicating their reasoning with a partner.
Design Principle(s): Optimize output (for justification); Cultivate conversation

Figure 7: Productive and oral language connections within a task (Illustrative Mathematics, 2019a)

Framing of Literacy Practices in the IM Curriculum

Finally, an interesting trend that arose from the analysis is the way in which the IM curricular materials address literacy demands across different student populations. Illustrative Mathematics (2019) claims to integrate support for English Language Learners (ELLs) into their curriculum through what they call "Mathematical Language Routines" or MLRs (para. 22). As shown in Figure 7, this ELL priority is clearly established by bounding every MLR in a green border and titling it "Support for English Language Learners." Additionally, some structured literacy opportunities are included in bounded boxes titled "Support for Students with Disabilities," as shown in Figure 3. The MLRs ultimately account for 27 of the 53 structured literacy opportunities coded in this analysis, representing just over half of all such findings. The "Support for Students with Disabilities" directions account for another 4 opportunities. This means that such "bounded" curricular components account for a sizeable share of the total literacy opportunities found. All other opportunities, such as that shown in Figure 8, are embedded (unbounded) within the task launch or synthesis teacher guidance. This reveals two underlying conclusions: First, the MLRs that IL states are a core part of their curricular materials *do* appear in the analyzed tasks. Second, these routines are presented with a caveat – they are for ELLs and students with disabilities. While it is certainly true that language structures support ELL students (Aguirre and Bunch, 2012) and organizational structures aid low-performing students (Kenney, 2005, p. 45), the benefits of literacy opportunities are not limited to such groups. IM themselves admit as much when they state that "these instructional supports and practices (MLRs) can and should be used to support all students learning mathematics" (Illustrative Mathematics, 2019, para. 1). Despite this, the bounded nature of such supports and their frequent placement *after* all other teacher guidance within the curriculum materials could indicate exclusivity. Exploring how practitioners interpret structured literacy practices when they are built into the overall teacher-facing task instructions versus when they are separated is a consideration for future study.

Activity Synthesis	Select students to discuss and share their solutions. Ask them to identify difficulties which might include: getting started, noticing the pattern, dividing with decimals, completing the values in the table, creating the equation. This problem increases the level of difficulty by having so much missing information, and by using decimals in the table. It is important to identify if there are parts that are confusing for students to move them forward.

Figure 8: An embedded structured speaking opportunity from task 4.3 (Illustrative Mathematics, 2019a)

Discussion

This report provides numerous avenues for discussion for educators, curriculum designers, and researchers. First, this framework's descriptive language and distinction of different types of structured literacy opportunities can act as a roadmap for addressing such structures in mathematics curriculum materials. These definitions can also serve as a tool for strengthening otherwise unstructured literacy opportunities within curriculum materials or recognizing opportunities for connecting different modalities of literacy more consistently.

This framework can also better illuminate how curriculum materials are or are not considering multiple ways in which language relates to the learning of mathematics. Because each structured literacy opportunity has two distinct sub-codes, these allow for more nuanced discussion about the curriculum. For instance, the focus on speaking in the IM curriculum materials was usually cooperative rather than individual, and the focus on listening was largely to respond to peers' thinking rather than to internalize ideas for oneself. While this fits within the dialogic orientation to teaching, it limits opportunities aligned with the direct instruction model. Such an imbalance between the two sub-codes of speaking and two sub-codes of listening (but not an *absence* of any sub-code) gives rise to worthwhile questions about curriculum design and enactment: Are only the dialogically aligned opportunities desired? Should some curricular balance exist between cooperative versus individualized speaking, or listening to respond versus listening to internalize? This is an avenue for future research to consider.

Together, this framework and its application to IM curriculum materials provides insights into the role of language and literacy within mathematics. Applied only to a small sampling of materials, the framework illustrates the ways in which literacy opportunities are being structured and connected within tasks and demonstrates just how many literacy opportunities remain unstructured in these materials. Such results give clarity to the complex manifestations of literacy in the curriculum while also pointing towards further considerations which could advance our understanding of this critical aspect of learning mathematics.

We describe results of a long-term design experiment focused on promoting mathematics learning among multilingual ninth graders classified as English Learners. The intervention at a linguistically diverse public high school in the US focused on a unit introducing concepts related to linear rates of change. We analyze results from a curriculum-aligned pre- and post-unit assessment used to document student learning across each design cycle. The main result is that students in both the Pre-Intervention and Redesigned classrooms made gains on the pre- and post-unit assessments. However, student gains on the assessments were higher in the Redesigned classrooms than in the Pre-Intervention classrooms. Additionally, on the assessment in the Redesigned classes, students classified as English Learners made larger gains than their non-EL peers, and the majority of the gains occurred on conceptually-focused items.

Keywords: Algebra and Algebraic Thinking, Design Experiments, Curriculum, Equity and Diversity

Objective

Research on the mathematics education of emerging multilingual learners[1] has shown that such students often experience procedurally-focused instruction (Callahan, 2005), are provided low cognitive demand tasks (de Araujo, 2017), and may have limited opportunities to engage in disciplinary and discourse practices (Zahner, 2015; Moschkovich & Zahner 2018). Recently, mathematics educators have engaged in design research to study how to transform the learning environment in linguistically diverse classrooms with the goal of promoting more robust forms of student learning (e.g., Chval et al., 2014; Prediger & Zindel, 2017). These design efforts have yielded promising results and frameworks for integrating mathematics and language learning. In this report, we describe results from a four-year design research effort that took place in a linguistically diverse ninth grade mathematics classes in an urban secondary school in the US. We analyze trends observed in the student responses to a curriculum-aligned assessment used to evaluate the efficacy of the design effort.

Our overarching research question is: To what extent did the design effort meet its goal of promoting student learning? In particular, we address the three specific questions

1. What was the effect of the redesign effort as measured by student response patterns on curriculum-aligned assessments?
2. How did the assessment results differ for students classified as ELs and those not classified as ELs (non-ELs)?

[1] In our research context, multilingual students who are learning the language of instruction are classified as "English Learners" (ELs). We use ELs when describing students as they are classified by the school. However, when referring to this group of students more generally, we will use "multilingual students" to highlight the assets of students learning the language of instruction.

Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

3. On what kinds of problems, conceptual or procedural, in the assessments of the Redesigned lessons did the students make the largest gains?

Framework

This design research (Cobb et al., 2003) project utilized the Academic Literacy in Mathematics (ALM) framework (Moschkovich, 2015, Moschkovich & Zahner, 2018), a sociocultural framework for analyzing and designing mathematics learning environments for emerging multilingual students. The ALM framework highlights that developing academic literacy entails developing mathematical proficiencies (in particular, procedural fluency and conceptual understanding), engaging in disciplinary practices, and participating in mathematical discourse. In our design efforts, we focused on developing students' conceptual understanding of the slope of a linear function as representing a rate of change (Lobato & Thanheiser, 2002). Based on prior research, we know that many students develop procedure-bound understandings of linear rates of change. For example, students can calculate a rate of change given a well-ordered table, but then they may struggle to interpret the rate in a given problem context (Lobato & Siebert, 2002). Therefore, one of our goals was to develop students' conceptual understanding of a linear rate of change as a multiplicative relationship between quantities.

Building on insights from prior design efforts in linguistically diverse mathematics classrooms (Chval et al., 2014; Prediger & Zindel, 2017) and the ALM framework, our redesign efforts were based on three guiding principles: (a) aligning a conceptual focus and problem contexts across the unit to minimize linguistic complexity, (b) integrating mathematical language goals linked to the conceptual focus, and (c) incorporating language supports in daily lesson activities to allow all members of a linguistically diverse classroom to engage in classroom discussions. In support of this design research effort we collected a wide array of data and we are conducting both quantitative and qualitative analyses of these data. In this report, we report on quantitative evidence of student learning measured in pre-unit and post-unit assessments. These assessments were designed by the participating teachers and researchers to align with the content of the unit, and to target both conceptual and procedural knowledge. In this sense, the assessment provides data related to the first component of the ALM framework (Moschkovich, 2015).

Data and Methods

Design Cycles

The classroom-based design research entailed three main phases and two design cycles, shown in Figure 1. In Phase I, Pre-Intervention, the researchers observed ninth grade mathematics classes at City High across a unit on linear rates of change. Students in the observed classes completed a pre-unit assessment at the start of the unit and a post-unit assessment at the conclusion of the unit. Additionally, during Phase I, the researchers conducted clinical interviews with selected students from the observed classes. Due to space restrictions, the interviews are not discussed further here.

At the conclusion of Phase I, the teachers and researchers analyzed the Phase I data with the goal of redesigning the unit on linear rates of change. The Redesigned lessons were then pilot tested in Phase II during Teaching Experiment (TE; Prediger, Gravemeijer, & Confrey, 2015). The teaching experiment lessons were taught in an after school setting, which allowed the researchers and teachers to make adjustments in the lesson designs from week to week. The TE lessons were designed using the project design principles outlined above. The teaching of the lessons in the TE was the conclusion of the first iteration of the design cycle and the start of the second iteration.

Finally, in Phase III, the team of teachers and researchers analyzed the data from the Phase II TE lessons and redesigned the unit lessons from Phase II for use during the regular school day. The participating teachers implemented the Redesigned lessons during their typical school day in Phase

III. During this second iteration of the design cycle, the classroom lessons were observed and the students in the Phase III classes completed a pre-unit and post-unit assessment (paralleling the Pre-Intervention observations from Phase I). In the results reported here, we focus on the assessments that were administered at the start and conclusion of the classroom observations in the Pre-Intervention (Phase I) and Redesigned (Phase III) units.

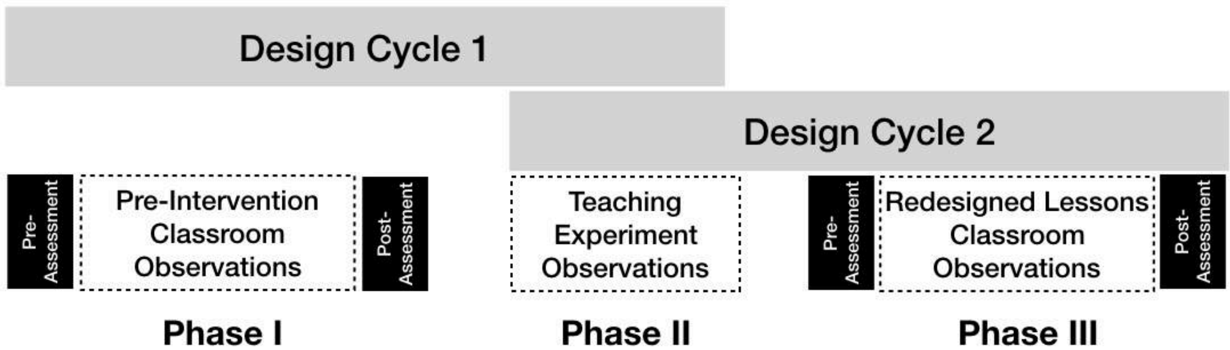

Figure 1: Overall project design and phases of design cycles.

Setting and Participants

Data collection took place in ninth grade mathematics classes at City High, a large, urban high school enrolling a linguistically diverse group of students. City High is located near the US-Mexico border, and it serves a relatively large number of recent immigrant and transborder students. Throughout the study, approximately 30% of City High students were classified as ELs, and an additional 50% of the students were formerly classified as ELs. Over 75% of the students were identified as Latinx in school demographic data, and most students classified as ELs spoke Spanish as their primary language. Additionally, the majority of City High students were from households with low socioeconomic status.

Six teachers participated in the design effort across the four-year project. In this analysis, we focus on the assessment results for the students of Mr. S because he was the only teacher who participated in all phases of the design effort. Mr. S had six years of experience at the start of the study, holds a teaching credential in mathematics, is bilingual in Spanish and English, and has taken some courses on teaching English learners in the content areas as part of his mathematics teaching certification program. He participated in the study to further develop his expertise teaching mathematics to multilingual students.

We included all students in Mr. S's focal classes who took the pre-unit and post-unit assessments during the Pre-Intervention (n=18) and Redesigned (n=28) phases of the research. We note that the assessments were designed to align with the respective units. Therefore, we were not able to use the same items on the assessments for the Pre-Intervention and Redesigned lessons. To account for these differences in the assessment design, we converted the total scores on each assessment to the proportion of correct answers.

Assessment

The pre- and post-assessments were designed by the researchers in collaboration with the teachers. In both the Pre-Intervention and Redesigned units, the assessments included a mixture of procedurally-focused items that did not require explanation, as well as conceptually-focused items characterized by prompts for explanation. Aligning with the design guidelines for the ALM framework (Moschkovich & Zahner, 2018), the focus of the intervention was developing students' conceptual understanding of rate of change. The conceptual items reflected this focus and assessment goal. Figure 2 shows an example of a procedural item (top) and conceptual item (bottom) from the Phase III assessment. In the Results section, we compare patterns of student responses to the conceptually-focused and procedurally-focused items from Phase III.

1) Deondra is saving to buy a new bike. She starts off with $10 in her account and saves $20 a month babysitting. She writes an equation that represents the total amount of money (y) she has saved in any given month (x):

$$y = 20x + 10$$

How much money did Deondra save after 6 months?

- ❑ $20
- ❑ $100
- ❑ $120
- ❑ $130
- ❑ $150

6) Connie ran 45 meters in 10 seconds. Jen ran the same speed as Connie, but Jen ran a different amount of time and distance.

a) Which of the following are possible for the time and distance that Jen ran? **Select all that apply.**

- ❑ 90 meters in 5 seconds
- ❑ 54 meters in 12 seconds
- ❑ 22.5 meters in 5 seconds
- ❑ 90 meters in 20 seconds
- ❑ 50 meters in 15 seconds
- ❑ 4.5 meters in 1 second

b) Explain: How can you check if Jen's distance and time makes the same speed as Connie?

Figure 2: A procedural item (top) and a conceptual item (bottom) from the Redesigned assessments.

The assessments were scored using a rubric by the research team. In general, students were awarded points for correct responses as well as valid explanations (on the conceptual items). For the analysis of assessment gains, we used comparisons of means and paired effect sizes (Cohen, 2013) to identify the direction and magnitude of change from the pre-assessment to the post-assessment in each phase. For the comparison of student performance on the conceptually-focused versus procedurally-focused items, we also compared means and measured paired effect sizes. We used paired effect sizes because we had both pre-assessment and post-assessment data by student. The details of these analyses are in the Results.

Results

We note a caveat at the outset of this section: we had relatively small sample sizes. These small sample sizes are a result of engaging in intensive work with a small group of teachers across multiple years. Our sample sizes were reduced by teacher turnover across study years and student absences/mobility within each design cycle. These realities, while not ideal for statistical research, are byproducts of working in our local school setting. In light of the small samples, we used Hedges' correction whenever presenting claims about growth as measured by effect sizes.

Research Question 1: What was the effect of the redesign effort as measured by student responses on the pre- and post-assessments?

To answer RQ1, we compared results of the pre- and post-assessment gains in Pre-Intervention and the Redesigned units. Table 1 shows the pre- and post-assessment mean scores along with the paired effect size to measure the magnitude of the gain.

Table 1: Pre- and post-assessment means for the Pre-Intervention and Redesigned units.

	Pre-assessment	Post-assessment	Gain	Paired effect size (Magnitude)[1]
Pre-Intervention (n=18)	0.42 (0.17)	0.57 (0.18)	+0.15	0.80 (L)
Redesign (n=28)	0.24 (0.16)	0.44 (0.19)	+0.20	1.12 (L)

Note: [1]S: |d|<0.20, M: 0.20 < |d| < 0.50, L: |d| > 0.50 (Cohen, 2013)

In summary, there was significant growth in both the Pre-Intervention and Redesigned units as measured by the pre- and post-assessments. The effect size comparing the magnitude of the pre-post gain was larger in the Redesigned unit. While the direction of the difference in effect sizes was favorable for our design effort, given the small sample size, we were not able to use a statistical test such as an ANOVA to compare the difference in effect sizes.

Research Question 2: How did the assessment results differ for students classified as ELs and those not classified as ELs (non-ELs)?

Table 2 shows the pre- and post-assessment mean scores broken out by Pre-Intervention and Redesigned Lessons and student EL classification. As with Table 1, we included a paired effect size to illustrate the magnitude of the differences (Cohen, 2013). The data in Table 2 indicate that while there was significant growth from the pre- to post-assessment scores in the Pre-Intervention unit, the effect size was larger for non-ELs (0.81) than for Els (0.58). That is, during the Pre-Intervention unit, the students who were not classified as ELs benefitted more from the business as usual teaching. During the Redesigned unit, however, the pattern in effect size was reversed. That is the effect size was larger for ELs (1.44) than for non-ELs (0.94). In terms of the mean gain scores, ELs in both the Pre-Intervention and the Redesigned lessons had larger gains than their non-EL classified peers. One interpretation of this result is that the intervention led to larger gains for ELs than non-ELs. However, this result is moderated by the fact that ELs in the Redesigned unit pre-assessment started relatively low compared to the non-ELs.

Table 2: Pre- and post-assessment mean scores by EL classification for the Pre-Intervention and Redesigned units.

		Pre-assessment	Post-assessment	Gain	Paired effect size (Magnitude)
Pre-Intervention					
	Non-EL (n=14)	0.45 (0.16)	0.59 (0.18)	+0.14	0.81 (L)
	EL (n=4)	0.33 (0.21)	0.49 (0.21)	+0.16	0.58 (L)
Redesign					
	Non-EL (n=20)	0.27 (0.17)	0.45 (0.20)	+0.18	0.94 (L)
	EL (n=8)	0.17 (0.11)	0.43 (0.19)	+0.26	1.44 (L)

RQ3: On what kinds of problems, conceptual or procedural, in the assessments of the Redesigned unit did the students make the largest gains?

Our final research question examines patterns in student responses to the pre- and post-assessments from the Redesigned unit. The assessment for the Redesigned unit included five conceptually-focused and three procedurally-focused items. Conceptually-focused items included a prompt for explanation while the procedurally-focused items were multiple-choice questions with no prompt for further explanation. To conduct the analysis of student results based on item type, we calculated a subscore for each type of item (e.g., a subscore for the three procedural items, and a subscore for the five conceptual items). Table 3 summarizes the results by type of question (Conceptual versus Procedural).

Table 3: Pre- and post-assessment mean scores by type of item for the Redesigned unit.

Type of Item	Pre mean (SD)	Post mean (SD)	Growth	Paired Effect Size (Magnitude)
Procedural	0.47 (0.22)	0.44 (0.26)	-0.03	0.12 (S)
Conceptual	0.20 (0.16)	0.44 (0.21)	0.25	1.27 (L)

Table 3 shows there was little change in the mean for the procedural items from the pre-assessment to the post-assessment. However, there were significant gains in the conceptual items. This result aligns with the focus of the redesign efforts on fostering student development of conceptual understanding related to linear rates of change.

Discussion & Conclusion

In this report we have described quantitative findings based on pre- and post- unit assessments that were used as part of a design research effort. The goal of the design research effort was to create a classroom learning environment in a linguistically diverse secondary mathematics classroom where students learn to reason about linear rates of change. The main findings presented in this report are:

1. Students in the Redesigned unit showed larger gains as measured by paired effect size with Hedges correction,

2. ELs in the Redesigned unit had larger gains when compared to their non-EL counterparts. The gains by Els in the Redesigned unit were also relatively larger than their gains in the Pre-Intervention lessons, and
3. In the assessment of the Redesigned unit, the students had more growth on the conceptually-aligned items than on the procedural items.

While we have shown that the paired effect size was larger in re-designed unit, we are not able, at this point, to make a causal claim about learning linked to our design efforts. However, we can hypothesize that some of the growth observed in our analyses can be traced back to the design principles and the instructional activities that were developed across the two design cycles. For example, in the Pre-Intervention lessons, we observed that most students had limited opportunities to solve conceptually demanding tasks during their regular mathematics classes. Therefore, in the Redesigned unit, we intentionally included conceptually demanding tasks, along with targeted linguistic supports for students classified as ELs, to allow all students in the Redesigned classroom an opportunity to solve more conceptually-focused problems. For example, during one of the Redesigned lessons students were challenged to make up a story related to a graph showing distance and time. Then they were tasked with solving non-routine problems about rates of change in other graphs. These instructional tasks, which consistently included prompts for students to explain their reasoning and justify responses, were similar to the conceptually-focused item in Figure 2.

One question that remains for our design efforts is why the students in the Redesigned unit did not show gains on the procedural items. When we ran the analysis for RQ3, we expected to see growth on both the conceptual and the procedural items. However, looking at the results in Table 3, there was little change on the procedural tasks from the pre-assessment to the post-assessment. One possible explanation for this lack of gain is that the learning opportunities within the Redesigned unit did not include many tasks focused on developing students' procedural fluency. Reflecting on the data in Table 3 prompts us to consider whether the learning tasks in the Redesigned lessons overemphasized a conceptual focus and did not include enough opportunities for students to develop procedural fluency.

Despite the limitations induced by the small sample size of this study, the results presented here highlight potential avenues for further development and research. This is of particular interest since there are relatively few studies, like the one presented here, that have engaged in design research focused on meeting the needs of linguistically diverse students. One potential follow-up study might be to use the materials developed in this project in a study with a larger number of teachers and students. Such a study, particularly one using a more controlled design, could test of the robustness of the results presented here.

Another avenue for follow-up on this research, which we are undertaking presently, is qualitative analyses of the design effort. In these analyses we are examining the forms of student reasoning that were developed during the Redesigned lessons and tracing those forms of reasoning back to the classroom learning environment. For example, we are examining the quality of student explanations on the conceptually-focused items, and then connecting the student reasoning observed on the assessments to the classroom observations (paralleling the analysis of Zahner, 2015). This analysis will allow us to understand *how* a linguistically diverse group of ninth grade students developed particular forms of reasoning about linear rates of change.

Acknowledgments

This research was supported by a grant from the National Science Foundation (#1553708) to William Zahner. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of The National Science Foundation.

We are grateful for the support of research assistants Yessika Gamala and April Zuniga and the collaboration of the teachers and students who are participating in this study.

CHARACTERIZING COHERENCE WITHIN ENACTED MATHEMATICS LESSONS

Curricular coherence has been emphasized by leaders in mathematics education as it enhances deeper understanding by enabling students to see connections between mathematical ideas. Although there are different forms of curricular coherence, the coherence of lesson has received considerably less attention. Little is known about what constitutes coherent lessons or how to measure the degree of coherence. Using the data from a larger study in which lessons are intentionally designed for coherence, we propose a tool for examining lesson coherence and describe characteristics of the lessons with different levels of coherence.

Keywords: Curriculum, Curriculum Enactment, Instructional Activities and Practices

What explains poor U.S.A. performance in mathematics according to international comparison studies? According to Stigler and Hiebert (1999), who compared enacted lessons from seven countries including the U.S.A., one of the factors that distinguishes mathematics lessons in the U.S.A. from high-performing countries is their degree of coherence. They explain:

> Imagine the lesson as a story. Well-formed stories consist of a sequence of events that fit together to reach the final conclusion. Ill-formed stories are scattered sets of events that don't seem to connect. As readers know, well-formed stories are easier to comprehend than ill-formed stories. And well-formed stories are like coherent lessons. They offer the students greater opportunities to make sense of what is going on. (p. 61)

Much of the prior research has focused more on *curricular coherence*, which refers to how mathematics topics are connected across grade levels (Schmidt, Wang, & McKnight, 2005). Coherence *within* a lesson (what we refer to as *lesson coherence*) has received considerably less attention. Our goal is to learn what constitutes a coherent lesson and to what extent one lesson's coherence differs from that of another. Using lesson data from a larger study in which lessons were intentionally designed for coherence, the present study aims to answer the following questions: When enacted lessons are analyzed for how mathematical ideas build within each lesson and how its parts are interconnected, to what extent are the lessons distinguishable? What are the characteristics of lessons in each type of lesson coherence?

Theoretical Framework

As Stigler and Hiebert (1999) suggest, mathematics curricula (i.e., lessons, units, entire courses, and so on) can be thought of as *mathematical stories* (Dietiker, 2015). Mathematical stories foreground how the mathematical content unfolds across a lesson, connecting a beginning with an ending. The sequential parts of a mathematical story form its *acts* during which students' understanding of *mathematical characters* (e.g., numbers or geometric objects), *mathematical actions* (e.g., procedures), and/or *mathematical settings* (e.g., representations) changes.

A story's coherence is the extent to which parts of stories fit with one another and come together as a whole (Richman, Dietiker, & Riling, 2019). Incoherent mathematical stories make it harder for students to see connections between lesson parts (i.e., acts) and prevent students from fully comprehending a mathematics lesson. However, it does not necessarily follow that more coherent lessons are always better; students may feel boredom during a predictable lesson.

Methods

In order to learn about types of lesson coherence, we analyzed recordings of secondary mathematics lessons expected to represent a range of coherence. The lessons were taught by six teachers from three high schools in Northeastern USA. About half of the lessons were teachers' typical lessons and the rest were designed as mathematical stories, a process that we predicted would increase coherence. Data includes video- and audio-recordings of full lessons. At the end of each lesson, consenting students completed a survey describing their experience. In order to achieve maximal variation in coherence, we identified each teacher's lessons with the most positive and negative student aesthetic reactions. We also included a lesson for which the teacher had participated in analyzing a previous enactment as a story, which we thought might result in a unique form of coherence.

Members of the research team coded independently and met for consensus throughout the coding process. The team first identified *acts* by noting changes in mathematical characters, actions, or settings (e.g., when students shift to a new task). Within each act, the team identified questions that arose. For each question, researchers marked changes in what was revealed publicly, such as when a teacher asks clarifying a question when or students shift to a new task.

In order to examine the connectivity of each lesson, we created a *coherence map* using graph theory. Nodes represent acts and edges reflect that two acts contain progress on the same question(s). Lessons were then grouped based on the connectedness of their graphs. For each level, at least two research team members examined the transcripts of the lessons to demonstrate the characteristics of each level.

Findings

We identified three levels of coherence within our data set: incoherence, partial coherence, and strong coherence. Here, we present coherence maps of lessons selected to represent each coherence level and articulate features and characteristics of each level.

Level 1: Incoherence

Two lessons analyzed contain discontinuities between topics and a lack of overarching themes across tasks. One of the lessons (see Figure 1) begins with a warm-up in which students describe properties of an operation (i.e., a&b = 3a – b). Yet, these features are not relevant to the next task, about the range of a function of x. After that, the lesson has another disconnect when the focus in Act 7 shifts to an unrelated topic (percent) without explanation. Although all tasks in Acts 7-12 are about percentages, they jump from calculating percentages of numbers to calculating prices as percent discounts, and so on. No work that students do to complete one task supports them to complete the rest. It is unlikely students will connect these tasks beyond recognizing that each is about percentages. Because these tasks are so independent, there exists no obvious sequence that would support students in building an understanding of percentages.

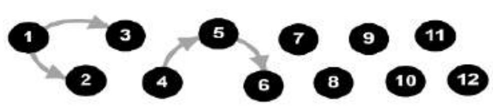

Figure 1: A Visual Model of an Incoherent Lesson

Level 2: Partial Coherence

Two of the analyzed lessons show some extent of coherence within substantial portions of the lessons. The coherence maps of such lessons contain sections with some internal connections, but no connections across sections. One of these lessons (see Figure 2) beings with students observing four graphs of systems of linear inequalities (Acts 1-6). During this activity, students work on questions like, *why are the different parts shaded?* After that, however, this question is not pursued by the teacher or students as the students work on a worksheet with other types of inequalities (e.g., one variable inequality) in Acts 8-14. In Act 15, the teacher briefly review the answers to the worksheet problems and ends the lesson. The lessons in this level include more connections between acts than the incoherent lessons do. However, these connections rely heavily on a couple of acts (e.g., Acts 6 and 15), which build some extent of coherence but not a strong amount.

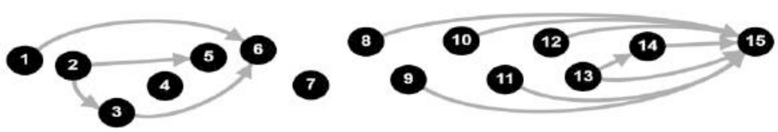

Figure 2: A Visual Model of a Partially Coherent Lesson

Level 3: Strong Coherence

Some lessons in our data set were strongly coherent. That is, a student would likely understand why they were engaged in a given activity and know how parts of the lesson connected to one another. Three sub-types of strong coherence—retroactive coherence, coherence with brief diversions, and strong coherence—are described below.

Retroactive coherence. In some highly coherent lessons, there are portions of the lesson that appear disconnected, but are later shown to be connected. These lessons are similar to partially coherent lessons in which teachers review answers at the end of the lesson, but retroactive coherence is richer because students have opportunities to make conceptual connections across ideas from the lesson. Consider a lesson with this type of coherence about repeated roots of polynomials (see Figure 3).

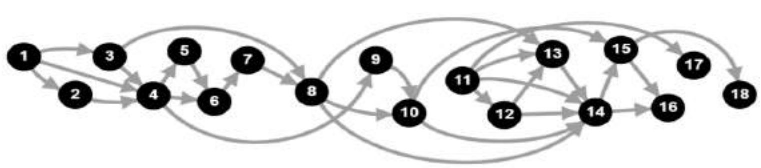

Figure 3: A Visual Model of a Retroactively Coherent Lesson

In Acts 1 through 10, students are shown a graph of a polynomial with a repeated root and work collaboratively to find its equation. In Act 11, the teacher explains that they will no longer be making progress on questions regarding the graph and distributes a new worksheet with equations to graph. In the final acts, the teacher enables students to see connections between the two seemingly distinct portions of the lesson by turning their attention to broad concepts that apply to both. Several early questions that did not refer to specific equations or graphs, but do broadly apply to them, become relevant again in Act 14. Retroactive coherence is possible because the teacher does not disclose many questions from the first part of the lesson before beginning the second part, so students may still wonder about them later on.

Coherence with brief diversions. Sometimes, most acts were connected to each other, with a few brief diversions consisting of acts that were somewhat, or not at all, connected. We found four such lessons. Two have brief diversions that appear as tails at the beginning of a lesson, typically due to teachers reviewing prior work. The others have tails later in a lesson, when teachers introduced alternate solution strategies that are not addressed as the lesson continues. An example of this second type is a lesson about exponential equations (Figure 4). In Act 15, the teacher introduces a new, efficient way of solving for x in the equation $1.04^x = 2$. The teacher asks students to think of way to find x that would be more efficient than the predominant solution strategy (i.e., guessing and checking) used in the lesson. He then solves the problem using the new method (i.e., taking the logarithm of both sides and using the power property to solve for x).

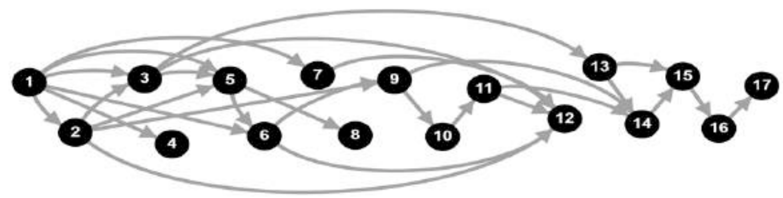

Figure 4: A Visual Model of Coherence Lesson with Brief Diversions

Strong coherence. Several lessons designed as mathematical stories displayed an incredibly high level of connection across acts with no diversions or temporary coherence gaps. The coherence map of one lesson with strong coherence is represented in Figure 5. In this lesson, students built understanding of the Rational Root Theorem by investigating potential roots. The lesson's high degree of coherence is evident in the multiple complete subgraphs (e.g., Acts 5-7). The strong coherence is due to both a set of questions from Act 1 and new questions introduced in subsequent acts that remain open for most of the lesson. The teacher permits the students to gradually explore and refine their ideas as they consider new challenges, prompting them to explore their initial questions during each subsequent task. The progressively complex nature of each new task (e.g., checking provided roots versus selecting their own potential roots) likely makes it so that students do not grow bored of their investigation.

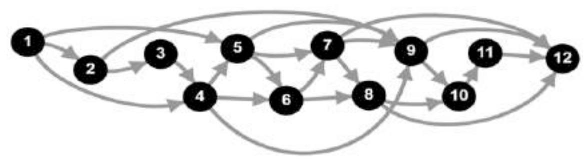

Figure 5: A Visual Model of Strong Coherence

Discussion

We do not claim that these three types of coherence are discrete. There might be additional intermediate levels, or even a continuous coherence spectrum. The presented levels are only samples of this possible spectrum; our goal is to present a way to describe the coherence of a mathematics lesson. Lesson coherence is not only a quality indicator of a mathematics curriculum but also a useful dimension for making a lesson more captivating in terms of student engagement. Increasing coherence requires purposeful design and management of mathematical inquiry. Through coherence mapping, lesson coherence that is often implicit can be visualized so that teachers will be able to see how they can make stronger connections between parts of a lesson.

AN ANALYSIS OF COORDINATE SYSTEMS PRESENTED IN GRADE 6-8 TEXTBOOKS

Hwa Young Lee
Texas State University
hylee00@txstate.edu

Lino Guajardo
Texas State University
lrg74@txstate.edu

We analyzed a total of 1129 tasks in grade 6–8 textbooks to examine the type of coordinate system presented and the associated graphing activity required in each task. We share our findings and discuss educational implications of such findings.

Keywords: Representations and Visualization, Coordinate System, Graph, Textbook Analysis

Middle school is a critical time for students to develop robust understandings of coordinate systems and graphs. In the Common Core State Standards for Mathematics (CCSSM; NGA Center & CCSSO, 2010), for example, students are first introduced to the Cartesian plane and learn to plot or interpret points in the first quadrant in 5th grade; thereafter, students are expected to use the Cartesian plane for exploring and representing other mathematical ideas including geometrical shapes, proportional relationships, number systems (6-7th grade), and graphs of linear relationships (8th grade). In this report, we share results from an analysis on the types of coordinate systems presented and associated graphing activity required in grade 6–8 textbooks and discuss educational implications of such findings.

Conceptual Framework

By coordinate system, we mean a representational space in which an individual systematically coordinates quantities (Thompson, 2011) to organize some phenomenon. We have previously distinguished between two types of coordinate systems depending on the goal they serve: spatial and quantitative coordinate systems (Lee, Hardison, & Paoletti, 2018; 2020). A spatial coordinate system is used to quantitatively organize a space in which a phenomenon is situated (Figure 1). Constructing a spatial coordinate system involves an individual organizing a space by (mentally) overlaying a coordinate system onto some physical or imagined space being represented where objects within that space are tagged with coordinates. For example, in Figure 1b a coordinate system is overlaid onto a region of a city from a bird's eye view where the *x*- and *y*-axes coincide with roads in the city.

On the other hand, a quantitative coordinate system is used to coordinate sets of quantities by constructing a geometrical representation of the product of measure spaces (Figure 2). Constructing a quantitative coordinate system involves an individual extracting quantities from the space in which a phenomenon occurs and projecting them onto a new space, different from the space in which the quantities were originally conceived. For example, in Figure 2b the coordinate system is showing the relationship between time (in minutes) and the number of boxes a machine packages over time where both quantities were taken from a space separate from the presented coordinate system.

Relatedly, graphs represented in each of these coordinate systems are fundamentally different (Lee, Hardison, & Paoletti, 2018; 2020). Graphs created on spatial coordinate systems can be viewed as projections or traces of physical objects or phenomena onto an analogous space containing the original objects or phenomena. Whereas, in a quantitative coordinate system, graphs are not projections of physical objects or phenomena from the same space containing the original objects or phenomena. Due to this distinction, different ways of reasoning could be productive when creating and interpreting spatial and quantitative coordinate systems and their associated graphs (c.f., Lee, Hardison, Paoletti, 2020).

(b) Task from Berry III et al. (2017c), p. 119.

Figure 2. Examples of tasks using a quantitative coordinate system.

Using this framework, our goal in this study was to investigate the different types of coordinate systems presented in grade 6–8 textbooks. Specifically, we examined (a) what type of coordinate systems textbooks present, (b) what type of graphing activities problem solvers are prompted to engage in, and (c) how frequently these coordinate systems and graphing activities appear in textbooks. We emphasize that the textbook analysis involved *our* interpretations of the textbook author's intended use of coordinate systems, which do not necessarily coincide with how students might perceive of the coordinate system.

Methods

We extracted and coded a total of 1129 tasks from three major textbook series (*Mathematics in Context*, *enVision Math 2.0 Common Core,* and *Texas Math TEKS*; see references) for grades 6–8 to date. The three series were selected to represent a variety of curricula. The first step in our analysis involved selecting and extracting tasks. The criterion for inclusion was that the task presented a pre-constructed two-dimensional coordinate system, either left blank or containing a graph. Relatedly, we also included tasks referring to previous tasks containing a pre-constructed coordinate system. We excluded tasks that had coordinate system-like grids but did not explicitly involve problem solvers to attend to the coordination of quantities (e.g., a grid superimposed onto a shape to find its area, box-and-whisker plots, and bar graphs with categorical data). Our unit of analysis, what we call a task, is a sequence of explanations or questions surrounding a single context or a single coordinate system. This means that explanations/questions about a single context with several coordinate systems (e.g., comparing several graphs) and explanations/questions with multiple contexts around a single coordinate system (e.g., graph several things on the same coordinate system) all counted as a single task.

After extracting tasks, we coded each task along two dimensions. The first dimension is the type of coordinate system. A task received the code *spatial* if the coordinate system is spatial; *quantitative* if the coordinate system is quantitative; *both* if the task involves both types of coordinate systems in a single task (e.g., comparison tasks with both types); and *neither* if it was difficult to discern as spatial or quantitative due to lack of context (e.g., *x-y* graph without specification of what *x* and *y* represent). When necessary, we referred back to previous or subsequent tasks in the textbook to determine the context of the task.

The second dimension was the type of graphing activity required in the task. A task received a *create* code if it requires problem solvers to create a graph by plotting a point or collection of points (e.g., tasks in Figures 1a and 2a). A task received an *interpret* code if it requires problem solvers to make sense of a pre-constructed graph, such as describing the relationship between two variables or constructing an algebraic equation that describes the graph (e.g., tasks in Figures 1b and 2b). Our distinction between create and interpret is similar to Leinhardt et al.'s (1991) distinction between construction and interpretation; however, different from Leinhardt et al., we consider building algebraic functions for a graph as interpretation and not construction. A task received a *both* code if it required the problem solver to both create and interpret a graph; a *neither* code if there were no requirement for the problem solver to create or interpret a graph.

We reiterate that codes were attributed to each task based on our interpretations of the authors' intention of the task. Once all tasks were coded, we compared our codes and when there was a disagreement, we discussed them to come to a consensus. Finally, we recorded the mathematical topic covered in each task using the topic names used in the textbook.

Findings and Discussion

The results are summarized in Table 1. Because our purpose was not to compare textbooks, we report only on the total frequencies for each code across all textbooks within each grade. As shown in Table 1, the coordinate systems were predominantly *quantitative* and most tasks required problems solvers to *interpret* a graph. There were consistently and predominantly more tasks that required students to interpret a graph rather than create a graph across all three grades. However, the trend in coordinate system type changed across grade levels. In grade 6, both types appeared close in frequency. Many grade 6 textbooks introduced the Cartesian plane, asked students to plot points or enact operations on coordinates (i.e., coordinate geometry) and then used the Cartesian plane to represent graphs of functions. As such, coordinate systems were often first introduced spatially and students were expected to transition from a spatial to quantitative coordinate system unproblematically. In grade 7, there was a stark difference in the number of quantitative coordinate systems (n=128) in comparison to those that were spatial (n=8). Relatedly, in grade 7 textbooks we coded, statistical graphs (e.g., bar graphs, histograms) and linear relationships were the main focus of content. Finally, in grade 8, there was a more balanced use of quantitative and spatial coordinate systems, with more quantitative (58%) than spatial (42%). In grade 8, textbooks covered linear relationships (functions, systems of equations) and statistical graphs in which quantitative coordinate systems prevailed; however, they also covered topics such as transformations of shapes and the distance between points, in which spatial coordinate systems were used.

Table 1. Number of Tasks by Problem Type, Coordinate System Type, and grade level.

Grade	Problem Type	Coordinate System Type				Total
		Quantitative	Spatial	Both	Neither	
6	Create	10	0	0	7	17
	Interpret	42	51	0	15	108
	Both	18	12	0	3	33
	Neither	0	0	0	1	1
	Grade Total	70	63	0	26	159
7	Create	9	0	0	15	24
	Interpret	83	3	0	19	105
	Both	35	5	0	4	44
	Neither	1	0	0	5	6
	Grade Total	128	8	0	43	179
8	Create	27	22	0	34	83
	Interpret	225	151	0	124	501
	Both	84	71	0	44	199
	Neither	0	0	0	8	8
	Grade Total	336	244	0	210	791
Grand Total		534	315	0	279	1129

Note there were no tasks that involved both types of coordinate systems but a total of 279 tasks coded neither for coordinate system type. Previously, Paoletti et al. (2016) analyzed graphs in STEM textbooks and practitioner journals at the undergraduate level and found that the majority of graphs either mathematized a spatial situation or represented two (contextual) quantities. On the other hand, they found that most graphs in commonly used precalculus and calculus mathematics textbooks represented two decontextualized quantities, finding a discrepancy between graphs students experience in their math classes and those used in other STEM fields. Looking across our *interpret* graph tasks, 22.13% of those tasks used decontextualized coordinate systems, thus received a *neither* coordinate system type code. Although not as dramatic as Paoletti et al.'s findings, the mathematics textbooks we analyzed also presented decontextualized graphs for students to interpret, which increased over time (15, 19, 124 tasks in grades 6, 7, 8, respectively).

Based on our findings, we propose the following changes in curricula (and relatedly, in teaching) on coordinate systems and associated graphs to support students' mathematical development as well as potential future STEM courses and careers: (a) tasks drawing from contexts that afford opportunities to develop a balanced understanding of both coordinate system types; (b) a more balanced graphing activity associated with coordinate systems, and hence more opportunities for students to create graphs; and (c) better support in curricula materials assisting students' transitions from spatial to quantitative coordinate systems.

In this study, we specifically focused on tasks that presented pre-constructed coordinate systems. Future research directions include identifying the different types of activities required for coordinate systems (e.g., create or interpret a coordinate system) in conjunction with the extant three dimensions (coordinate system type, graphing activity type, and mathematical topic).

TYPES OF PROBLEMS LINKED TO THE DEVELOPMENT OF ALGEBRAIC REASONING IN CHILEAN PRIMARY EDUCATION

TIPOS DE PROBLEMAS VINCULADOS AL DESARROLLO DEL RAZONAMIENTO ALGEBRAICO EN LA EDUCACIÓN BÁSICA CHILENA

The Chilean Curricular Bases of primary education (students from 6 to 12 years old), establish in the Patterns-and-algebra axis that algebraic thinking will be developed through a problem-solving approach. However, international research shows that working with the algebraic objects involved in these types of problems is not the only way of enhancing the development of such thinking; there is another type of arithmetic-nature-problem which also enhances it at proto-algebraic level. This paper aims to identify and characterize this type of problems, associated with the Numbers-and-operations axis in the official Chilean textbooks. For this, the model of Algebrization Levels is considered as a theoretical reference, which is a theoretical-methodological tool proposed by the Onto-Semiotic Approach of mathematical knowledge and instruction.

Background

There are approximately three decades in which educational authorities and researchers in the field of Mathematics Education have shown a great interest in introducing algebraic ideas to the primary education curriculum. The introduction of these ideas aims to develop algebraic reasoning in students from 6 to 12 years old. This approach is currently known as Early Algebra. There are studies at a global level (Cai, 2004; Fong, 2004; Lew, 2004; Watanabe, 2008) developed under this approach, which have identified the characteristics with which these ideas have been introduced into the curriculum.

In the Mexican context, Aké and Godino (2018) state that, although the tasks proposed in the first-grade textbook are not aimed at promoting algebraic thinking in children, since numerical register is prioritized, some implicit algebraic objects are identified in some mathematical tasks and, from the authors' perspective, those tasks guide towards proto-algebraic ways of thinking. In the case of Colombia, Castro, Martínez-Escolar, and Pino-Fan (2017) report the promotion of algebraic reasoning through mathematical tasks from first to sixth grade of primary education which, for example, at the first grade include expressing numerical sentences in an equivalent way ($42 - 9 = 43 - \square$), and solving numeral sentences ($\square + 4 = 4$). Those tasks require, for instance, solving inequalities and then graphing the solution, verifying numerical conjectures, etc. Finally, in the American context, four standards of algebraic context are established: understanding of patterns, relations and functions; representation and analysis of mathematical situations and structures using algebraic symbols; use of mathematical models to represent and understand quantitative relations; and the analysis of change in various contexts (National Council of Teachers of Mathematics, 2000).

These studies, and others, have shown that currently there is no consensus in the field on the characteristics of algebraic reasoning and, even more, on what is meant by this concept. Thus, in Blanton and Kaput (2011), they refer to it as an activity of generalization of mathematical ideas. In addition, the work with undetermined quantities, the use of variables, algebraic symbolization, relations between quantities, unknowns, equations, patterns, and the study of change, are considered as other notions related to the development of algebraic reasoning. In addition, other studies relate the development of this type of reasoning based on the work with some notions of arithmetic. These

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. results somehow support and justify the existence of the Early Algebra approach, which emerged as a counterweight to the curricular separation created between arithmetic and algebra. Molina (2009) points out that some authors suggest that this separation accentuates and prolongs the difficulties of students. This is why the work with activities that enable the transition and integration of algebra and arithmetic is proposed, with a different approach to the computational one (which predominates in the first grade) and that benefits the development of algebraic and arithmetic modes of thinking.

In the Chilean context, the few studies developed to characterize algebraic reasoning, focus on how algebraic ideas are introduced to the primary education curriculum. Mejías (2019) published a study on the presence of algebra in Chilean textbooks from first to sixth grade of primary education, and its incorporation into the national curriculum, focusing the attention on the Patterns-and-algebra axis. This axis, together with Numbers-and-operations, Geometry, Measurement, and Data-and-probability axes, are part of the curricular organization proposed in the Curricular Bases (Ministry of Education of Chile [MINEDUC], 2018) from first to sixth grade of primary education (students aged 6 to 12 years old). Particularly, with the study of concepts such as pattern, in this axis it is expected that the bases for the development of more abstract mathematical thinking at higher levels, especially algebraic reasoning, will be established (MINEDUC, 2018). However, in the Numbers-and-operations axis it is expected that some concepts that promote this type of reasoning can be identified. As a consequence of the above, in this work it is proposed to characterize a typology of problems, related to the Numbers-and-operations axis in the Chilean context, which promote algebraic reasoning.

Theoretical And Methodological Aspects

This work is based on the theoretical notions developed by the Onto-Semiotic Approach to mathematical knowledge and instruction (Godino, Batanero, & Font, 2007, 2019), specifically on the Algebrization Levels model (Godino, Aké, Gonzato, & Wilhelmi, 2014). This model is considered as a theoretical-methodological tool, which allows characterizing algebraic reasoning in terms of the representations used, the generalization processes, involved, as well as the analytical calculation that is put into play during the (personal or institutional) mathematical practice related to a type of algebraic task. It should be noted that this model has been implemented in other studies, and it has been evident that it is a good predictor of (intended or assigned) algebrization levels for mathematical tasks in textbooks collections (e.g., Aké & Godino, 2018; Castro, Martínez-Escobar, & Pino-Fan, 2017).

The levels related to Primary Education are listed below, which are of particular interest to this work.

- Level 0 (*absence of algebraic reasoning*): mathematical objects are expressed through natural, numerical, iconic, or gestural language; if symbols that refer to an unknown value intervene, the result of such value is obtained by operating on particular objects.
- Level 1 (*incipient level of algebrization*): properties, numerical equivalences, and relations from particular tasks are identified; languages are natural, numerical, iconic, or gestural.
- Level 2 (*intermediate level of algebrization*): mainly, undetermined quantities or variables expressed in symbolic or symbolic-literal language intervene, in order to refer to recognized intensives, although linked to information from the spatial-temporal context.
- Level 3 (*consolidated level of algebrization*): intensive objects, represented in a symbolic-literal way, are generated and operated on; transformations of algebraic (symbolic) expressions are performed.

It is pertinent to clarify that these levels are not established by the problem itself, but by the practice (or practices) developed to solve the problem. A mathematical practice is defined as “any action or manifestation (linguistic or otherwise) carried out by somebody to solve mathematical problems, to communicate the solution to other people, so as to validate and generalize that solution to other contexts and problems" (Godino & Batanero, 1994, p. 334).

This work has a qualitative nature (León & Montero, 2003). The research technique is content analysis (Gil-Flores, 1994), specifically focused on mathematical practices (proposed in official textbooks). The analysis is carried out following these phases: 1) preliminary study and selection of problems related to the Numbers-and-operations axis, 2) resolution of the selected problems and detailed analysis of mathematical practices, and finally 3) the categories of problems are generated. Namely, mathematics textbooks distributed by the Chilean Ministry of Education for primary education levels are analyzed. In this work, we particularly report the results obtained from the first and second grade mathematics textbooks.

Preliminary Results

The analysis evidenced that a series of institutional mathematical practices proposed in the context of the Numbers-and-operations axis, would enable the development of algebraic reasoning. Arithmetic is seen by several researchers as a key access to algebra (Warren, 2003). For example, Carpenter, Frankie and Levy (2003) state that, when studying algebra, students do not understand that the procedures they use to solve equations and simplify expressions are based on the properties of numbers. Meanwhile, Molina (2009) argues that "being able to count requires working algebraically since it is necessary to have a structured and organized way of counting" (p. 137, personal translation from Spanish). Therefore, it is considered that, despite the gap between arithmetic and algebra in the context of Chilean Primary Education, the problem situations included in the textbooks and their respective practices, would serve as promoters of algebraic reasoning at incipient levels (specifically, levels 0 and 1).

19 types of problems have been identified in the first-grade textbook (16 related to the Numbers-and-operations axis; 3 related to the Patterns-and-algebra axis), and in the second-grade textbook, 21 types of problems were characterized (18 related to the Numbers-and-operations axis; 3 related to the Patterns-and-algebra axis). The problems belonging to the Patterns-and-algebra axis are not considered in this study, because the current curricular document already established that these kinds of problems develop algebraic thinking (MINEDUC, 2018). In the case of the Numbers-and-operations axis, the entire typology of problems has been quantified, however, attention is only focused on those which promote algebraic reasoning through their mathematical practices. Among the typology of problems, related to the first and second grade of primary, the following can be found:

- Apply the algorithm of composing and decomposing numerical quantities to solve problems.
- Compare quantities (greater than, less than or equals to, it is more than, it is less than, <, >, =).
- Identify the condition to know when an element belongs to a set.
- Identify and represent the cardinality of a set by means of a number.
- Operate numerical quantities (addition or subtraction).

The practices promoted by the typologies of previous problems are related to a level 0 of algebrization (absence of algebraic reasoning), that is, mathematical objects are mainly represented in the numerical, iconic or mother language. Numerical quantities (extensive objects) are decomposed as the sum of two (or more) numerical quantities. In addition, tabular representations are used to organize the information, mainly when using algorithms for addition and subtraction. The concept-definitions are: addition, subtraction, compose, decompose, abacus, place value, additive decomposition, etc. The procedures are related to the use of algorithms, and they are also supported by the use of materials such as the abacus. Propositions and arguments are primarily related to how numbers can be decomposed or composed in accordance with the place value of their digits.

On the other hand, level 1 (*incipient level of algebrization*) has only been identified in the practices promoted in the second-grade textbook, in which the typology of problems related to them is as follows:

- Identify the additive properties of natural numbers (commutative, associative) (5 problems),
- Identify the properties of multiplication of natural numbers (existence of multiplicative neutral, zero property of multiplication) (10 problems).

Among the algebraic objects identified the following can be found: notion of an unknown value, structure properties, notion of a numerical equivalence. Practices at this level allow us to identify that extensive objects (examples) intervene that explicitly promote generalization (a rule) through mother language. Properties and relations are identified from the structural tasks.

Projections

Analogously to the analysis developed for the first and second grade textbooks, it is intended to characterize typologies of problems related with the development of algebraic reasoning for the remaining texts, from third to sixth grade of primary education, but not only for the Numbers-and-operations axis, but in Patters-and-algebra axis too. It is considered that a characterization of this nature will allow identifying the didactic-mathematical knowledge that primary teachers should have in order to develop instructional processes in accordance with curricular approaches.

En las Bases Curriculares de primaria (6 a 12 años) de Chile, se establece que con el estudio de problemas del eje de Patrones y álgebra se desarrollará el pensamiento algebraico. Sin embargo, investigaciones internacionales han demostrado que no sólo el trabajo con los objetos algebraicos involucrados en ese tipo de problemas potencia el desarrollo de dicho pensamiento, sino que existe otra tipología de problemas, de índole aritmética, que también lo promueve en niveles conocidos como proto-algebraicos. En este trabajo se pretende identificar y caracterizar esa tipología de problemas, asociados al eje de Números y operaciones, en los textos escolares oficiales de Chile. Para ello, se considera como referente teórico el modelo de Niveles de Algebrización, herramienta teórico-metodológica propuesta en el Enfoque Onto-Semiótico del conocimiento y la instrucción matemáticos.

Palabras clave: álgebra y pensamiento algebraico, análisis del currículo, educación primaria

Antecedentes

Aproximadamente son tres décadas en las que autoridades educativas e investigadores del campo de la Educación Matemática han mostrado un gran interés por introducir ideas algebraicas al currículo de educación básica. La introducción de estas ideas al currículo tiene por objetivo el desarrollo del razonamiento algebraico en estudiantes entre los 6 y 12 años. A este enfoque se le conoce actualmente como Early Algebra. Existen investigaciones a nivel mundial (Cai, 2004; Fong, 2004; Lew, 2004; Watanabe, 2008), elaboradas dentro de este enfoque, que han dado cuenta de cuáles son las características con las que dichas ideas han sido introducidas al currículo.

En el contexto mexicano, Aké y Godino (2018) declaran que, si bien las tareas propuestas en el texto de estudio de primer año de primaria no están dirigidas a promover un pensamiento algebraico en los niños, puesto que se prioriza el registro numérico, sí se identifican algunos objetos algebraicos implícitos en algunas tareas matemáticas y que, desde la perspectiva de los autores, orienta hacia formas de pensamiento proto-algebraico. En el caso de Colombia, Castro, Martínez-Escobar y Pino-Fan (2017), reportan la promoción del razonamiento algebraico a través de tareas matemáticas desde primero a sexto grado de educación primaria, las que, en el primer grado, por ejemplo, contemplan expresar sentencias numéricas de manera equivalente ($42 - 9 = 43 - \square$), resolver sentencias numéricas ($\square + 4 = 4$), que requieren, por ejemplo, resolver inecuaciones y luego graficar la solución, verificación de conjeturas numéricas, etc. Finalmente, en el contexto estadounidense, se establecen cuatro estándares de contenido algebraico: comprender patrones, relaciones y funciones; representar y analizar situaciones matemáticas y estructuras usando símbolos algebraicos; usar modelos matemáticos para representar y comprender relaciones cuantitativas y analizar el cambio en diversos contextos (National Council of Teachers of Mathematics, 2000).

Estas investigaciones, y otras más, han demostrado que actualmente no existe un consenso en el campo sobre las características del razonamiento algebraico y, más aún, qué se entiende por este concepto. Así, en Blanton y Kaput (2011), se refieren a éste como una actividad de generalización de ideas matemáticas. Además, se considera al trabajo con cantidades indeterminadas, el uso de variables, la simbolización algebraica, las relaciones entre cantidades, las incógnitas, las ecuaciones, los patrones, el estudio del cambio, como otras nociones asociadas al desarrollo del razonamiento algebraico. Otros estudios, además, relacionan el desarrollo de este tipo de razonamiento a partir del trabajo con algunas nociones de la aritmética. Estos resultados de alguna manera abonan y justifican la existencia del enfoque Early Algebra, el cual surgió como contrapeso a la separación curricular creada entre la aritmética y el álgebra. Molina (2009), señala que algunos autores sugieren que esta separación acentúa y prolonga las dificultades de los alumnos y es por ello que se propone trabajar actividades que posibiliten la transición e integración de ambas, con un enfoque diferente al computacional (el cual predomina en los primeros cursos escolares) y que beneficie el desarrollo de modos de pensamiento algebraico y aritmético.

En el contexto chileno, los pocos trabajos desarrollados para caracterizar el razonamiento algebraico se centran en cómo son introducidas las ideas algebraicas al currículo de educación básica. Mejías (2019), elabora un estudio de la presencia del álgebra en los libros de texto chilenos de primero a sexto año de enseñanza básica y su incorporación en el currículo nacional, centrando su atención en el eje Patrones y álgebra. Este eje, en conjunto con Números y operaciones, Geometría, Medición y Datos y probabilidades, forman parte de la organización curricular propuesta en las Bases Curriculares (Ministerio de Educación de Chile [MINEDUC], 2018) de primero a sexto básico (niños de 6 a 12 años). En este eje, en particular se espera que, con el estudio de conceptos como el de patrón, se establezcan las bases para el desarrollo de un pensamiento matemático más abstracto en niveles superiores, en especial el razonamiento algebraico (MINEDUC, 2018). No obstante, se considera que, en el eje Números y operaciones, además, se pueden identificar algunos conceptos que fomenten este tipo de razonamiento. Como consecuencia de lo anterior, en este trabajo se propone caracterizar una tipología de problemas, asociados al eje Números y operaciones en el contexto chileno, que fomenten el razonamiento algebraico.

Consideraciones Teóricas Y Metodológicas

Este trabajo se sustenta en nociones teóricas desarrolladas en el Enfoque Onto-Semiótico del conocimiento y la instrucción matemáticos (Godino, Batanero y Font, 2007, 2019), específicamente en el modelo de Niveles de Algebrización (Godino, Aké, Gonzato y Wilhelmi, 2014). Este modelo es considerado como herramienta teórico-metodológica, la cual permite caracterizar el razonamiento algebraico en términos de las representaciones utilizadas, los procesos de generalización implicados, así como el cálculo analítico que se pone en juego durante la práctica matemática (personal o institucional) asociada a un tipo de tareas algebraicas. Cabe señalar que este modelo ha sido implementado en otros estudios, y se ha evidenciado que es un buen predictor de los niveles de algebrización (pretendidos o asignados) para las tareas matemáticas en colecciones de libros de texto (e.g., Aké y Godino, 2018; Castro, Martínez-Escobar y Pino-Fan, 2017).

A continuación, se enuncian los niveles asociados a la Educación básica, y que son de particular interés para este trabajo.

- Nivel 0 (*ausencia de razonamiento algebraico*): los objetos matemáticos son expresados mediante lenguaje natural, numérico, icónico, o gestual; de intervenir símbolos que refieren a un valor desconocido, el resultado de dicho valor se obtiene operando sobre objetos particulares.
- Nivel 1 (*nivel incipiente de algebrización*): se identifican propiedades, equivalencias numéricas, y relaciones a partir de tareas estructurales; los lenguajes son de tipo natural, numérico, icónico, o gestual.
- Nivel 2 (*nivel intermedio de algebrización*): intervienen, principalmente, cantidades indeterminadas o variables expresadas con lenguaje simbólico, o simbólico-literal, para referir a los intensivos reconocidos, aunque ligados a la información del contexto espacial-temporal.
- Nivel 3 (*nivel consolidado de algebrización*): se generan objetos intensivos, representados de manera simbólico-literal, y se opera con ellos; se realizan transformaciones de las expresiones algebraicas (simbólicas).

Es pertinente aclarar que el nivel no se establece al problema per se, sino a la práctica (o a las prácticas) desarrollada para dar solución al problema. Se define como práctica matemática a "toda actuación o manifestación (lingüística o no) realizada por alguien para resolver problemas matemáticos, comunicar a otros la solución, validar la solución y generalizarla a otros contextos y problemas" (Godino y Batanero, 1994, p. 334).

El trabajo es de carácter cualitativo (León y Montero, 2003). La técnica de investigación es el análisis de contenido (Gil Flores, 1994), específicamente de las prácticas matemáticas institucionales (propuestas en textos oficiales). El análisis de desarrolla en las siguientes fases: 1) estudio preliminar y selección de los problemas asociados al eje Números y operaciones, 2) resolución de los problemas seleccionados y análisis pormenorizado de las prácticas matemáticas, y finalmente 3) se generan las categorías de problemas. A saber, se analizan textos de matemática, distribuidos por el Ministerio de Educación de Chile para los niveles de educación básica. En este trabajo, en particular, se reportan los resultados obtenidos del libro de matemática de primero y segundo básico.

Resultados Preliminares

El análisis desarrollado ha evidenciado que una serie de prácticas matemáticas institucionales propuestas en el contexto del eje Números y operaciones, posibilitarían el desarrollo del razonamiento algebraico. Diversos investigadores consideran a la aritmética como acceso clave al álgebra (Warren, 2003). Carpenter, Frankie y Levi (2003), por ejemplo, manifiestan que, al estudiar álgebra, los estudiantes no entienden que los procedimientos que usan para resolver ecuaciones y simplificar expresiones están basados en las propiedades de los números. Por su parte, Molina (2009), argumenta que "ser capaz de contar requiere trabajar algebraicamente ya que es necesario tener una forma, estructurada y organizada de contar" (p. 137). Por lo tanto, se considera que, a pesar de que existe una brecha entre la aritmética y el álgebra en el contexto educativo básico de Chile, los problemas y sus respectivas prácticas, fungirían como promotores del razonamiento algebraico en niveles incipientes (0 y 1 específicamente).

Se han identificado 19 tipos de problemas en el libro de texto de primero básico (16 asociados al eje de Números y operaciones, 3 a Patrones y álgebra), mientras que en el libro de texto de segundo grado se han caracterizado 21 tipos de problemas (18 en Números y operaciones, 3 en Patrones y álgebra). En este estudio no se consideran los problemas pertenecientes al eje Patrones y álgebra, ello debido a que el documento curricular vigente ya establece que éstos desarrollen el pensamiento algebraico (MINEDUC, 2018). Para el caso del eje Números y operaciones, se ha cuantificado toda la tipología de problemas, no obstante, sólo se enfoca la atención en aquellos que fomentan, a través de sus prácticas matemáticas, el razonamiento algebraico. Entre la tipología de problemas, asociada a ambos grados, se encuentran:

- Aplicar el algoritmo de componer y descomponer cantidades numéricas para resolver problemas.
- Comparar cantidades (mayor que, menor que o igual que, es más que, es menos que, <, >, =).
- Identificar la condición para saber cuándo un elemento pertenece a un conjunto.
- Identificar y representar mediante un número la cardinalidad de un conjunto.
- Operar cantidades numéricas (suma o resta).

Las prácticas promovidas por las tipologías de problemas anteriores se asocian al nivel 0 de algebrización (ausencia de razonamiento algebraico), es decir, los objetos matemáticos se representan, principalmente, en lengua materna, lenguaje numérico o icónico. Las cantidades numéricas (objetos extensivos) se descomponen como la suma de dos (o más) cantidades numéricas. Además, se hace uso de representaciones de tipo tabular para organizar la información, principalmente cuando se usan algoritmos para la suma y resta. Los conceptos-definiciones son: suma, resta, componer, descomponer, ábaco, valor posicional, descomposición aditiva, etc. Los procedimientos se asocian al uso de algoritmos, y, además, se apoyan en el uso de materiales como el ábaco. Las proposiciones y argumentos se asocian principalmente, en cómo los números se pueden descomponer o componer según el valor posicional de sus dígitos.

Por otra parte, el nivel 1 (*nivel incipiente de algebrización*) sólo se ha identificado en las prácticas promovidas en el libro de texto de segundo grado, en el cual la tipología de problemas asociada es la siguiente:

- Identificar las propiedades aditivas de los números naturales (conmutativa, asociativa) (5 problemas),
- Identificar las propiedades de la multiplicación de los números naturales (existencia del neutro multiplicativo, propiedad cero de la multiplicación) (10 problemas).

Entre los objetos algebraicos identificados se encuentra: noción de valor desconocido, propiedades de estructura, noción de equivalencia numérica. Las prácticas en este nivel permiten identificar que intervienen objetos extensivos (ejemplos) que promueven la generalización (una regla) de manera explícita mediante lengua materna. Se identifican propiedades y relaciones a partir de las tareas estructurales.

Proyecciones

Análogamente al análisis desarrollado para los libros de texto de primero y segundo básico, se pretende caracterizar tipologías de problemas asociados al desarrollo del razonamiento algebraico para los textos restantes, de tercero a sexto básico, pero no sólo en el eje de Números y operaciones, sino que además en el de Patrones y álgebra. Se considera que una caracterización de esta naturaleza permitirá identificar los conocimientos didáctico-matemáticos que los profesores de educación básica deberían poseer para desarrollar procesos instruccionales acordes a los planteamientos curriculares.

Agradecimientos

Este trabajo ha sido desarrollado en el marco del Proyecto de Investigación FONDECYT nro. 1200005, financiado por la Agencia Nacional de Investigación y Desarrollo (ANID), Chile.

In this study, we report on how slope is reviewed in a convenience sample of 28 common calculus textbooks published in English. While most calculus textbooks studied included reviews of slope, findings suggest that the reviews are written for students who already have a fairly solid understanding of slope. Slope as a ratio, whether approached visually or nonvisually, serves as a foundational notion for derivative and was the most common conceptualization used in the textbook reviews studied. However, the lack of alternative conceptualizations and connections between various conceptualizations of slope may hinder students deeply understanding other calculus topics. Future study should look at each of these in depth to determine how slope is needed and leveraged when particular calculus concepts are introduced.

Keywords: Calculus, Post-Secondary Education, University Mathematics, Curriculum Analysis

Dietiker (2013) argues that mathematics textbooks can be interpreted as narratives that present mathematical ideas in a purposeful, influential order. Mathematics textbooks create a link between natural language and symbolic mathematical language (Fang & Schleppegrell, 2010), where both languages work using nonvisual elements, such as equations, and visual elements, such as graphs (O'Halloran, 2015). Textbooks play an important role in the way professors shape and sequence their instruction (Davis, 2009) and in how students choose strategies to consider and solve problems (Massey & Riley, 2013). Love and Pimm (1996) have suggested that textbooks are primarily geared toward students. So, textbooks often impact how students learn, aiding students as they form ideas on how to solve problems (Massey & Riley, 2013). Previous calculus textbook research has focused on a) how students consider and solve textbook problems (Lithner, 2003; Lithner, 2004), b) how instructors use textbooks in their teaching (Mesa & Griffiths, 2012), c) how textbooks present and structure examples (Mesa, 2010), d) what is required of students in examples (Özgeldi & Aydın, in press), and e) how representations are coordinated in particular reform textbooks (Chang, Cromley & Tran, 2016).

Slope is a secondary mathematics topic that becomes foundational in post-secondary (i.e., university) mathematics. It plays a key role when contrasting the covariational behavior of linear and nonlinear functions in algebra (Carlson, Jacobs, Coe, Larsen & Hsu, 2002; Teuscher & Reys, 2010) and in the development of derivative in calculus (Zandieh & Knapp, 2006). Research on slope in post-secondary mathematics has increased in recent years even extending into how slope plays a role in multivariable calculus (e.g., McGee & Moore-Russo, 2015). However, examining slope and how it is presented in single variable calculus (henceforth, simply referred to as "calculus") textbooks, has not received attention. Ideally, students should follow and use relations between conceptualizations of slope at will, demonstrating a flexible, integrated understanding of this notion. However, little is known about how, or even if, calculus textbooks review slope. This study considers both calculus for science, technology, engineering, and math (STEM) majors (deemed "STEM textbooks") and applied calculus textbooks often used in classes for business majors as well as life and social science majors (deemed "non-STEM textbooks) to see which conceptualizations of slope are included and if the textbooks are capitalizing on visual approaches in addition to linguistic resources (Moore-Russo & Shanahan, 2014). More specifically, we seek to answer the following three research questions:

1. Is slope reviewed in calculus textbooks? If so, where are slope reviews located?

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

2. Which conceptualizations of slope are used in textbook reviews? Are visual or nonvisual approaches to slope taken in textbook reviews?
3. What common links, if any, exist between the conceptualizations of slope reviewed in calculus textbooks?

Literature Review

Importance of Calculus

While a calculus course is required of STEM majors (Bressoud, 2015), applied calculus, without any trigonometry, is often required of business majors as well as social and life sciences majors. Failing, or only marginally passing calculus, is one of the main reasons post-secondary students change their majors (Hensel, Sigler & Lowery, 2008; Kaabouch, Worley, Neubert & Khavanin, 2012; Bressoud, 2015). Many STEM degree programs require a grade of C or higher in calculus to count for credit, with calculus being prerequisite to other courses required in the major, and it is often recommended that students pass calculus at a high level before moving on to further courses (Koch & Herrin, 2006). Engineering students who fail calculus lack the foundation needed for required courses in their majors (Koch & Herrin, 2006; Veenstray, Dey & Herrin, 2008). Student struggles in STEM calculus are not limited to engineering students; studies have shown that calculus attrition rates (i.e., receiving a grade of D or F or withdrawing) for students in physical science or math may be as high as 40% to 50% (Pilgrim, 2010; Fayowski & MacMillan, 2008).

Slope as a Foundational Topic for Calculus

Some mathematics courses follow a vertical path in which certain concepts rely on previous concepts (Treisman, 1992). Many key concepts in calculus build on topics introduced in algebra and precalculus (Habre & Abboud, 2006). In order to develop a robust understanding of foundational ideas in calculus, such as instantaneous rates of change and derivatives, students must first understand average rates of change and the difference between linear and nonlinear functions. Yet, individuals often a) have isolated notions of slope (Dolores Flores, Rivera López & García García, 2019); b) have trouble interpreting different representations of slope (Glen, 2017; Tanışlı & Bike Kalkan, 2018); c) are only able apply slope in particular problem contexts (Byerley & Thompson, 2017); and d) have a limited understanding of linear functions in general, even when able to transition between different representations of linear functions (Adu-Gyamfi & Bossé, 2014).

As students enter post-secondary institutions, the ways they think of slope may be quite limited and different from the ways their professors think of and communicate slope (Nagle, Moore-Russo, Viglietti, & Martin, 2013). Two reasons for this may be related to the limited understanding of slope held by some high school teachers (Coe, 2007; Moore-Russo, Conner & Rugg, 2011; Nagle & Moore-Russo, 2014a; Stump, 1999) and the differences in the way state standards and textbooks address slope (Nagle & Moore-Russo, 2014b; Stanton & Moore-Russo, 2012). No matter why, a lack of prerequisite knowledge often leads to difficulty in understanding later topics, which corresponds with poor performance (Pyzdrowski et al., 2013).

Slope Understanding

Previous studies have considered how slope is characterized in the U.S. and Mexican curriculum (Stanton & Moore-Russo, 2012; Dolores Flores, Rivera López & Moore-Russo, 2020) and conceptualized by a variety of individuals (Moore-Russo, Conner & Rugg, 2011; Nagle, Martínez-Planell & Moore-Russo, 2019; Stump 1999, 2001b). The meaning that an individual makes related to slope, or any other mathematical notion, often depends on what the task at hand evokes (Tall & Vinner, 1981), the representations used to communicate ideas (De Bock, Van Dooren & Verschaffel, 2015) and the individual's prior knowledge or experiences (Vinner, 1992). In short, slope can be conceptualized in many ways, but previous research suggests that both students and teachers often fail to make connections between the various conceptualizations of slope (Coe, 2007; Hattikudur et al., 2011; Hoban, in press; Lobato & Siebert, 2002; Planinic, Milin-Sipus, Kati, Susac & Ivanjek, 2012; Styers, Nagle, & Moore-Russo, in press).

Stump's (1997, 2001a) research findings suggest that teachers rely primarily on ratios as the dominant representations of slope. Even though secondary teachers express concern for students' understanding of slope, they often reduce slope to procedural computations and neglect to regard the importance of developing a conceptual understanding of slope (Stump, 1999). Slope is often reduced to mnemonics that hinder students' understanding of slope as a rate of change (Walter & Gerson, 2007). As a result students enter calculus with isolated notions of slope and are not able to connect slope as a ratio to other ways of conceptualizing slope, such as a measure of steepness (Nagle & Moore-Russo, 2013a; Stump, 2001b). Students are not always able to work with slope in a conceptual way in application tasks (Lingefjärd & Farahani, 2017) nor are they always able to interpret slope in non-standard settings, such as when nonhomogenous coordinate systems are used (Zaslavsky, Sela & Leron, 2002).

Teuscher and Reys (2010) found that while the majority of calculus students could determine over what interval a variable changed by a certain rate, which involved slope, only half of the students were able to determine the interval with the greatest rate of change. They suggested that part of the reason for the difficulty was the vocabulary used in textbooks. Concepts such as steepness, slope, and rate of change are described in different ways among different textbooks, leading to misunderstandings of the questions for some students (Teuscher & Reys, 2010), those who lacked a deep, connected understanding of slope.

Theoretical Framing: Reader-Oriented Theory

Weinberg and Wiesner (2011) wrote that most academic research on textbooks has framed them as static collections of ideas, simply describing students' reading of the texts as extracting information. They sought to characterize the ways in which students interpret textbooks using reader-oriented theory. Reader-oriented theory centers on the idea that meaning of a text is constructed by the reader, not by the text itself. Three ideas about the readers of textbooks emerge from reader-oriented theory: the intended reader, the implied reader, and the empirical reader. The *intended reader* is "the idea of the reader that forms in the author's mind" (Wolff, 1971, p.166, as cited in Weinberg & Wiesner, 2011). The *empirical reader* is the person who actually reads the textbook. The *implied reader* is a concept used to describe the understandings an empirical reader must possess in order to make sense of a mathematics textbook (Weinberg, 2010). Authors should ensure the intended reader and implied reader coincide. This study will use these notions of different readers as a lens to interpret findings.

Methods

The data set consisted of a convenience sample 28 introductory calculus textbooks published in English between 2011 and 2019 that the research team recognized as including the calculus textbooks most commonly used in the United States. These 28 were used since they were available to the lead researcher as sample copies on an electronic book platform through her academic institution. Of the 28, 14 were non-STEM calculus textbooks and 14 were STEM calculus textbooks. In each textbook, the researchers first reviewed the index for any occurrence of the word "slope" to find all instances where slope was reviewed without any calculus content (e.g., limits, derivatives, etc.). All such review instances were included in the study.

Coding

For the current study, Nagle & Moore-Russo's (2013b) slope coding scheme was revised slightly. Five categories were used for the conceptualization of slope. Each of the five categories was divided further in two subcategories to see if the textbook relied on a *visual* or *nonvisual* approach. Table 1 displays descriptions for all of the conceptualization category-approach pairs.

Table 1: Slope Conceptualization and Approach Coding

Conceptualization	Approach	Description
Slope as a *Ratio* (RA)	Visual	rise/run or vertical change divided by the horizontal change
	Nonvisual	$(y_2 - y_1)/(x_2 - x_1)$ or change in y over change in x
Slope as a *Behavior Indicator* of a line (BI)	Visual	line increases, decreases, is horizontal, is vertical (looks like /, \, -, |) for positive, negative, zero, undefined slope respectively
	Nonvisual	line increases, decreases, is constant, or is not a function in other words (i.e., $y_2 > y_1$ for $x_2 > x_1$) for positive slope, (i.e., $y_2 < y_1$ for $x_2 > x_1$) for negative slope, (i.e., $y_2 = y_1$ for $x_2 > x_1$) for zero slope, or (i.e., $x_2 = x_1$ for $y_2 > y_1$) for undefined slope respectively
Slope as denoting *Steepness* of line's angle of inclination with respect to horizontal (ST)	Visual	relates to how inclined, tilted, slanted, or pitched a line is <u>seen</u> as being; greater value of |slope|, line is more steep (i.e., closer to vertical); closer to zero value of |slope|, line is less steep (closer to horizontal); since horizontal lines have no tilt, they have zero slope
	Nonvisual	relates to how extreme a line is <u>calculated</u> as being; the greater the value of |slope|, the more steep the line over an interval (e.g., the closer to infinity the value of $\|y_2 - y_1\|$ is); the closer to zero the value of |slope|, the less steep the line over an interval (e.g., the closer to zero the value of $\|y_2 - y_1\|$ is); horizontal lines have $\|y_2 - y_1\|= 0$ for all y values; so, slope is zero
Slope as a *Constant Parameter* (CP)	Visual	emphasis on the uniform "straightness" of the line's entire graph; no matter which segment of the line is considered, the straight slope remains the same between any two points due to similar triangles
	Nonvisual	emphasis that a single constant holds a property for the line's equation/table (not dependent on input); for any interval of a line, slope calculations remain the same between any two points
Slope as *Determining Relationships* between lines (DR)	Visual	two unique lines have the same slope if and only if they never intersect in two-dimensions (i.e., are parallel); two unique lines have different slopes if and only if they intersect at a common point; two unique, nonvertical lines have negative reciprocal slopes if and only if their intersection is at a right angle
	Nonvisual	two unique lines have the same slope if and only if a system of these two lines has no solution; two unique lines have different slopes if and only if the system of these two lines has one solution; two unique, nonvertical lines have negative reciprocal slopes if and only the product of their slopes is -1

A textbook was used as a unit of analysis and coded as an entity, meaning that if a textbook had more than one instance of one of the 10 categories (i.e., *visual* and *nonvisual* approaches to a *Ratio*, *Behavior Indicator*, *Steepness*, *Constant Parameter*, and *Determining Relationships* conceptualization), it was only marked once. To explain coding, consider this example involving two different approaches to the same conceptualization category. For example, consider the numerical computation of slope between two points (coded RA_n, for *Ratio-nonvisual*) being accompanied by a graph with labeling of Δy for the vertical displacement and Δx for the horizontal displacement (coded RA_v, for *Ratio-visual*). This graph of a line with Δy and Δx labeled and accompanied by $m = \frac{\Delta y}{\Delta x}$ would be coded as the link RA_v-RA_n. The implied reader, in this case, is meant to have an understanding of the slope computation and how it correlates with the visual markings indicated on the graph. Similar coding was used if two different conceptualization approaches were linked.

Findings and Discussion

Research Question 1: Slope Reviews in Calculus Textbooks

Since the concept of slope is an important building block for students taking calculus (Noble, Nemirovsky, Wright & Tierney, 2001), it was not surprising that all but one of the STEM textbooks in this study contained at least some review of slope. Most (22 of the 28) textbooks had the slope review at the beginning of the textbook only, while 3 had some slope review at the beginning and at the end of the textbook. This suggests that most calculus textbook authors feel that a review of slope should be available to students (or covered through instruction) prior to the introduction of derivatives and other calculus concepts. Calculus textbook authors appear to envision intended readers as students who need to have a solid base of prerequisite knowledge that includes an understanding of slope.

Research Question 2: Slope Conceptualizations in Calculus Textbooks

We now consider which conceptualizations of and approaches to slope were used in the sample of textbooks used in this study focusing on the implied reader to consider how concepts emphasized in different textbooks' slope reviews involve different understandings readers must possess in order to make sense of the calculus concepts presented in the textbooks. Table 2 displays the findings from the textbooks. All five of the conceptualizations of slope were used in at least one of the textbooks.

Almost all (25 of 28) textbooks used the *Ratio* conceptualization of slope. Postsecondary instructors and calculus students have been found to respond to open-ended questions about slope with responses that included a *visual* or *nonvisual* approach to *Ratio* (Nagle et al., 2013), as have high school teachers (Stump, 1999). So, this finding suggests that the slope reviews in the textbooks might be trying to connect with how students often think of slope. Understanding slope as a *Ratio* is important in calculus, especially in the understanding of derivative, when the limit of a difference quotient ties together the concepts of slope, limit, and derivative. So, it is not surprising that *Ratio* is the most prevalent conceptualization in calculus textbooks.

For calculus, students need a solid understanding of the idea of ratio (not just in the sense of slope, but in general) that goes beyond chanting "rise over run" or plugging and chugging into a formula. This is important since research (e.g., Carlson, Madison, & West, 2015) has shown that students often do not consider slope as representing the ratio of two covarying quantities in complex problems, such as those found in calculus. Textbook authors who do not consider this may lead to a disconnection between the intended and implied readers. In calculus, readers need to understand that the visually-oriented, rise-to-run graphical comparisons of a linear segment and the corresponding algebraic formulas that represent the slopes of secant lines connecting two points on a curve approach the value of the slope of a tangent line to the point on a curve in order to understand how a derivative is defined. However, in their reviews of slope, most textbook authors did not mention that slope is a foundational topic for understanding calculus concepts, and focused solely on finding slope as a numerical value (*nonvisual*) or as a property associated with the image of a line (*visual*).

Table 2: Slope Conceptualizations and Approaches in Textbooks

Conceptualization	Approach	Textbook Type		Total
		non-STEM	STEM	
Ratio (RA)	Visual Only	0	0	0
	Nonvisual Only	0	0	0
	Both	14	11	25
Behavior Indicator (BI)	Visual Only	3	7	10
	Nonvisual Only	1	0	1

	Both	10	4	14
Determining Property (DP)	Visual Only	1	0	1
	Nonvisual Only	1	2	3
	Both	9	7	16
Constant Parameter (CP)	Visual Only	2	2	4
	Nonvisual Only	1	1	2
	Both	6	7	13
Steepness (ST)	Visual Only	2	3	5
	Nonvisual Only	0	0	0
	Both	6	2	8

Behavior Indicator tied as the most used conceptualization of slope in the reviews, present in 25 textbooks (as was the *Ratio* conceptualization). However, all *Ratio* coded textbooks used both *visual* and *nonvisual* approaches, while *Behavior Indicator* textbooks did not. STEM textbooks more often used *visual* approaches only. Slope is often associated by students visually as the way a line is displayed on a graph (Moore et al., 2013). In Nagle and colleagues' 2013 study, this was a conceptualization commonly reported by post-secondary calculus students but not by their instructors. In the cases of textbooks emphasizing *Behavior Indicator*, the implied reader should be able to build an understanding the ideas of "increasing" and "decreasing" as well as related conventions of graphing to slope. In order to understand the idea of derivative and related topics (e.g., role that a slope of zero has in identifying potential relative extrema in the first derivative test), students will need to know more than just how the slope of a tangent line behaves visually; they will need to be able to work with intervals of functions using formulas.

Determining Property was the conceptualization used third most by textbook authors. In the textbooks where this conceptualization was noted, implied readers should be able to build on an understanding of concepts such as parallel, perpendicular, reciprocal, and so on. In the case of textbooks using this conceptualization, readers are typically asked to interpret two or more lines that are being compared (either graphically or using formulas). This should help prepare readers for tasks involving identification of the equation of a normal line, which is perpendicular to the line tangent to a curve at a point. Students also need to know that parallel lines have the same slope in order to understand the Mean Value Theorem and Rolle's Theorem.

The second least used slope conceptualization was *Constant Parameter*. Textbooks which include this conceptualization require their students to understand what the word "constant" means in a mathematics context for linear functions where slope acts as a parameter that results in a constant numerical change seen in tables or in the graphical straightness noted in a *visual* display of a line. Implied readers need to leverage an understanding of the straightness of a line for approximations over sufficiently small intervals when using linearization.

Steepness was the least used conceptualization of slope used in the calculus textbooks. Students should be able to construct ideas of "steepness" in a physical sense that relates the higher the absolute value of the slope of a line is, the steeper that line is. This understanding is often needed for related rates problems involving angles of inclination and right triangles, such as tasks involving where the vertical rate of ascension for a rising balloon is given.

Research Question 3: Links between Slope Conceptualizations

To answer the third research question, we now consider common links between the slope conceptualizations in the textbooks. In order to be coded as a link, the textbook had to indicate that two conceptualization-approach pairs related to the same idea. Table 3 displays the type of links present in the textbooks, and the total number of textbooks per link type. The RA_n-RA_v link was most frequent (22), which supports that the implied reader must to be able to relate the *visual* and *nonvisual* approaches of the *Ratio* conceptualization in order to understand slope. This was frequently shown as the graph of a line with the rise and run indicated, accompanied by the corresponding numerical calculation. Table 3 displays most frequent links, those that occurred in at least 10 textbooks.

Table 3: Links between Conceptualization-Approach Pairs in Textbooks

Link	Textbook Type		Total
	non-STEM	STEM	
RA_n-RA_v	12	10	22
CP_n-RA_n	9	6	15
DP_n-DP_v	7	7	14
CP_v-RA_n	7	6	13
BI_n-BI_v	8	4	12
CP_n-CP_v	6	6	12
CP_n-RA_v	6	6	12
CP_n-RA_v	5	6	11

Links containing either the *Ratio* or *Constant Parameter* conceptualization (with either a *visual* and *nonvisual* approach) were the most frequent. Given the prevalence of the *Ratio* conceptualization in textbooks, it is not surprising that its *nonvisual* and *visual* approaches would be linked most often.

Research (e.g., Nagle & Moore-Russo, 2013b) has referred to slope as a constant ratio, whereas *Constant Parameter* and *Ratio* were defined separately in this study. As such, the links containing either the *Ratio* or *Constant Parameter* being the most common is not surprising. In other words, understanding that slope is a constant rate of change between two covarying quantities, an equivalence class of ratios appears to be considered by authors as pivotal when first learning the concept of derivative. This suggests that the implied readers typically will need to make the link that slope can be considered as both a *Ratio* and a *Constant Parameter*.

The *Behavior Indicator* conceptualization occurred just as often as the *Ratio* conceptualization in 25 of the 28 textbooks. However it was not linked to other conceptualizations of slope very frequently. It does not seem that textbook authors deemed this way of thinking about slope to need to be connected to other ways of thinking of slope. This lack of connection could lead readers to concentrate on procedures without a connected, conceptual understanding of why first derivative tests are used to determine functional behavior in calculus.

Conclusions, Instructional Implications, Further Study

Slope is not heavily reviewed in calculus textbooks. Given the importance of understanding slope for calculus and how textbooks review slope, textbook writers seem to be assuming that the intended readers of these texts have a healthy understanding of slope upon entering calculus. Some conceptualizations of slope are sparsely represented in textbooks, and many textbooks do not provide a well-rounded, connected review of slope. Instructors must be aware that they may need to provide additional review over what is offered in textbooks to ensure that students are making connections between different conceptualizations of slope so that students have the robust understanding of slope that is needed as a foundation for the topics they encounter throughout calculus. Instructors should read the slope reviews, encourage students to do the same, and then be aware of other conceptualizations of and approaches to slope that they may need to provide to their students that are not present in textbooks.

The emphasis on slope as a *Ratio* and linking this idea to slope as a *Constant Parameter* should prepare students for the limit definition of a derivative; however, the lack of connections between the various conceptualizations of slope may result in students' failure to deeply understand other calculus topics that require alternative notions of slope. The role of slope in introducing derivatives is documented, but it is important that instructors also consider how textbooks leverage slope to introduce other calculus topics, such as how students come to think about average rates of change, why a derivative of zero may yield relative extrema, how parallel lines play a role in the Mean Value Theorem, how the "straightness" of a line is leveraged in linearization, etc. Future study should look at each of these in depth to determine how slope is needed and leveraged when particular calculus concepts are introduced.

One limitation of this study is that it only considered the stand-alone reviews of slope. It is possible that textbook authors are using a just-in-time review approach and connecting different conceptualizations of slope while introducing the calculus concepts themselves. Future research should consider this possibility.

COMPUTATIONAL THINKING PRACTICES AS A FRAME FOR TEACHER ENGAGEMENT WITH MATHEMATICS CURRICULUM MATERIALS

Kathryn M. Rich
Michigan State University
richkat3@msu.edu

Teachers routinely make adaptations to their mathematics curriculum materials as they plan and enact lessons. In this paper, I explore how encouraging two elementary teachers to examine their mathematics curriculum materials through the lens of computational thinking practices – abstraction, debugging, and decomposition – supported them in adapting tasks from their curriculum materials in ways that raised the cognitive demand.

Keywords: Computational Thinking; Curriculum; Elementary School Education

Background and Purpose of the Study

Mathematics curriculum materials (CMs) can serve as supports for teachers in creating high-quality mathematics instruction (Stein & Kaufman, 2010; McGee, Wang, & Polly, 2013). One way CMs can act as a support is by providing tasks with high cognitive demand (Stein, Smith, Henningsen, & Silver, 2000) or starting points for such tasks. For the potential of this support to be realized in practice, teachers must learn ways of interacting with CMs that allow them to thoughtfully choose among tasks and adapt them in ways that support students' engagement with productive mathematics (Brown, 2009). Existing research has revealed teachers differ in the specific strategies they use to approach CMs (Remillard, 2012; Sherin & Drake, 2009), and not all such strategies result in instruction that maintains high cognitive demand for students (e.g., Amador, 2016). On the other hand, a number of studies have supported the notion that teachers can create instruction that maintains high cognitive demand when they engage with CMs through lenses related to big mathematical ideas (Stein & Kaufman, 2010), student thinking and knowledge (Choppin, 2011; Grant et al., 2009), and the connections between these two elements (Drake et al., 2015). In this paper, I present a post-hoc analysis of how two teachers adapted tasks when reviewing a lesson in their CMs through the lens of three computational thinking (CT) practices: decomposition, debugging, and abstraction. In particular, I focus on how these three CT practices supported teachers in transforming low cognitive demand tasks presented in their curriculum materials into tasks of higher cognitive demand by helping to focus teachers' attention on the big mathematical ideas of the lessons and students' potential strategies.

Conceptual Framework

This study utilized the mathematical task framework, which has two parts. First, Smith and Stein (1998) developed four cognitive demand categories for mathematics tasks. Two categories —Doing Mathematics and Procedures with Connections—are high cognitive demand because they engage students in thinking about mathematical concepts and relationships. The others—Procedures without Connections and Memorization—are low cognitive demand because they focus on use of procedures and correct answers. Second, Smith, Grover, and Henningsen (1996) argued any task passes through three phases when used in instruction: (1) the task as it appears in instructional resources, (2) the task as set up by a teacher, and (3) the task as implemented by students. In this study, I categorized the tasks in participants' CMs and the tasks they planned according to the cognitive demand categories. I focused on the transition from the first task phase to the second: the changes teachers made to CM tasks to the way they planned to set up the tasks.

Methods

Study Context and Participants

The purpose of the CT4EDU project is to support elementary teachers to incorporate CT into their mathematics and science teaching. CT is a broad set of thinking practices used by computer scientists (Yadav, Stephenson, & Hong, 2017). The CT4EDU project is focused on big ideas in CT, including *abstracting* important information from situations, *decomposition* of complex problems into simpler parts, and *debugging,* or finding and fixing errors. In a professional development workshop, participating teachers worked in groups to plan a math lesson, starting from CMs, that incorporated at least one of the CT practices ideas mentioned above. Two teachers from the project were chosen for inclusion in this study. Alice and Cindy (both pseudonyms) were using *Math Expressions* (Fuson, 2012), the CMs mandated by their district. Alice was a fourth-grade teacher with 15 years of experience. Cindy was a fifth-grade teacher with five years of experience.

Data and Analysis

I examined the *Math Expressions* lessons referenced by Alice and Cindy, as well as the tasks that were the focus of their conversations. I classified these tasks according to level of cognitive demand. Next, I used transcripts of Alice and Cindy's planning conversations to create descriptions of the tasks these teachers planned to pose to students. I classified these tasks according to cognitive demand. To understand how CT played a role in how teachers adapted the tasks, I read the transcripts of the planning conversations to identify decisions related to changes to the tasks. Next, I examined the explanations the teachers articulated for these decisions. I considered an explicit mention of a CT practice or reference to a CT handout as potential evidence of influence of CT on the teachers' reasoning. I coded the decision as influenced by CT when the teacher (1) related a decision to a CT practice's description, (2) described how a proposed change would provide opportunities for students engage in a CT practice, or (3) connected a decision to a CT practice as she reflected on the lesson-planning process.

Results

Alice

Alice was working from a *Math Expressions* lesson on estimation and mental math. Table 1 shows the initial tasks posed in the CMs and the task Alice set up in the classroom. Both tasks on the left can be classified as Procedures without Connections. Students are asked to produce an estimate and an exact total in the first task, but not to explain their reasoning. Students are asked to provide a solution method and a yes-or-no answer for the second task. The task on the right, by contrast, can be classified as Procedures with Connections. To engage with this task, students must think about the impact of estimating via rounding to the nearest hundred on the real-world context of the problem rather than merely do the rounding for themselves. Thus, the planned version of the task has a higher level of cognitive demand than the tasks as posed in the CMs.

Three of Alice's decisions were influenced by CT. First, Alice chose a task from the CMs to use as the main task in her lesson. She primarily attended to the two tasks at the left in Table 1, and decided to start with the latter because she wanted to give students an opportunity to *decompose* a problem. She felt the two-part format of the first task did the decomposition for students: "I feel like now, looking at this, this wouldn't be good because they're giving it to them. They're telling them how to break it down." Second, Alice changed the statement of the problem to prompt a discussion about different possible estimates and how those estimates differ from the exact total. Third and relatedly, Alice changed the numbers in the task. According to Alice, students always rounded to the highest place value—two-digit numbers to the nearest 10, three-digit numbers to the nearest 100, and so on. She expected students to use this rounding technique as they made estimates, and felt that changing the numbers to be in the hundreds would lead to estimates farther away from the exact total: “These numbers aren’t gonna have them overestimate. So maybe change them so that the numbers are higher?” Estimates further away from the total, reasoned Alice, could lead to a discussion of *debugging*.

Table 1: Alice’s Starting Tasks and Task as Set Up in the Classroom

Starting Tasks from *Math Expressions*	Task as Set Up by Alice
The best selling fruits at Joy’s Fruit Shack are peaches and bananas. During one month Joy sold 397 peaches and 412 bananas. a) About how many peaches and bananas did she sell in all? b) Exactly how many did she sell? Tomas has $100. He wants to buy a $38 camera, a $49 CD player, and 2 CDs that are on sale 2 for $8. How can Tomas figure out if he has enough money for all four items? Does he have enough?	My friend gave me $930 to purchase items for a trip. The exact costs are $651 for his plane ticket, $112 for clothes, and $156 for meal gift cards. I rounded the amounts and added them to get an estimate of $1000. I told my friend he did not give me enough money, but he said I was wrong. I rounded the costs to the nearest hundred and added: 700 + 100 + 200 = $1000. Can you help me figure out what I did wrong? Did he give me enough? Did I round incorrectly?

Cindy

Cindy was working from a lesson on fractions greater than 1. Table 2 shows the tasks from the CMs and the task Cindy set up. The CM tasks can be classified as Procedures without Connections. Students can complete them by following the procedures given in the examples. The task on the right can be classified as Procedures with Connections. Students must think about the whole and provide two other representations of a fraction greater than 1, given one representation. Thus the cognitive demand of this task is higher than the tasks given in the CMs.

Table 2: Cindy’s Starting Tasks and Task as Set Up in the Classroom

Starting Tasks from *Math Expressions*	Task as Set Up by Cindy
Change each mixed number to a fraction. **Example:** 2½ = 2 + ½ = 1 + 1 + ½ = 2/2 + 2/2 + ½ = 5/2 3 2/5 = ____ 2 3/8 = ____ (etc.) Change each fraction to a mixed number. **Example:** 13/4 = 4/4 + 4/4 + 4/4 + ¼ = 1 + 1 + 1 + ¼ = 3¼ 10/7 = ____ 12/5 = ____ (etc.)	Fill in the missing parts. In the unit fraction column, draw a ring around the whole. **Picture** **Sum of Unit Fractions** **Fraction** ¼ + ¼ + ¼ + ¼ + ¼  12/5 (additional rows were given)

Cindy made four decisions influenced by her attention to CT. First, Cindy decided to teach the *Math Expressions* lesson over two days to allow her to spend more time on representing fractions greater than 1. Cindy credited this decision to thinking about *decomposition*:

> The CT is helpful to me as the teacher, in a sense that I’m now looking through a finer lens at the lesson itself and thinking, gosh, the workbook does go in this order, this fast. But really breaking it down and trying to think like the students are, and really think about what challenges they have. And how I can decompose the lesson itself into smaller pieces.

Second, Cindy decided to launch the lesson by showing students one representation at a time (picture, or sum of unit fractions) and discussing how students could change one representation into the other. Third, Cindy incorporated pictures and sums of unit fractions into the student page so students' independent work would more closely mirror the class discussion. Fourth, she limited the examples to numbers less than 3, so drawing models and writing sums of unit fractions remained a viable strategy. Cindy related these three decisions to supporting students in realizing that symbolic representations of fractions are an *abstraction*:

> Yeah, that abstraction is heavy. Even having them consciously aware of what that abstraction feels like and looks like here. To talk and have that discussion when you go from the visual to the sum of unit fractions or to the mixed number and really highlighting that idea.

Discussion

Alice's attention to CT supported her in thinking deeply about how students would approach tasks. Thinking about decomposition led her to consider the impact of the CMs breaking problems into subparts for students—which is one way of lowering the cognitive demand of a task by changing a challenge into a nonproblem (Stein et al., 2000). Thinking about debugging led Alice to consider how she expected her students to approach rounding and the impact that approach may have in a real-world context. This suggests that thinking about CT practices supported Alice in making curriculum adaptations based on student thinking, which other studies have suggested leads to productive use of CMs (Choppin, 2011; Grant et al., 2009).

Cindy's attention to CT supported her in thinking about big mathematical ideas in her lesson. As she considered symbolic fractions as an abstraction, she began to consider the multiple ideas encapsulated in those representations (e.g., 7/5 is an abstraction intended to show that wholes are divided into 5 equal parts, we are considering 7 of parts, and so on). Cindy realized she did not think students would be able to "see" all this information in a symbolic fraction without more experience with other representations. This led her to decompose the lesson. Ergo, examining her CMs through the lens of CT helped Cindy unpack big mathematical ideas—another strategy research suggests leads to productive CM use (Stein & Kaufman, 2010).

This data does not allow me to empirically examine *why* the lens of CT practices led teachers to consider and adapt their CMs in this manner, but considering the conference theme suggests one possibility. While the CT practices highlighted here resemble disciplinary practices in mathematics, the import of these ideas from another disciplinary culture, computer science, may have aided teachers in engaging with them in ways that supported new kinds of pedagogical thinking. Decomposition, for example, is discussed in the Common Core State Standards (CCSSI, 2010), but only in reference to decomposing mathematical objects such as numbers or geometric shapes. Computer scientists tend to discuss decomposition of *problems* (Yadav et al., 2017). This broader nature of the object being decomposed seemed to support Alice in thinking about decomposing the steps of a problem (rather than a number) and to support Cindy in thinking about decomposing the multiple mathematical ideas in her lesson. As computer science education emerges as a unique research area, math education researchers may benefit from cross-disciplinary conversations that offer new perspectives on existing ideas.

BROADER INTENTIONS: EXPLORING THE ROLE OF AIMS FOR SCHOOL MATHEMATICS IN TEACHER CURRICULAR DECISION MAKING

Andrew Richman
Boston University Wheelock School of Education & Human Development
asrich@bu.edu

The current study develops theories about why the system of mathematics education in the United States is struggling to meet many of its beyond-the-classroom aims by exploring to what extent and how aims permeate curriculum planning and enactment systems and the role that aims play in the decision making of teachers in these systems. It examines the written, planned, and enacted curriculum of three high school algebra lessons. It finds that aims influence the decision making of all three teachers, but permeate the lessons differently in ways that are potentially explained by teacher aims, the topic taught, the types of evident aims, the number of years the teacher has been teaching, and how long they have been using their textbook.

Keywords: Curriculum, Curriculum Analysis, Curriculum Enactment

Secondary mathematics students often lament "Why do I have to learn this stuff?" There is good reason to take this question seriously. There are a number of broader goals that school mathematics is intended to support and the system of mathematics education in the United States is struggling to meet many of these aims. For example, US schools have had limited success developing students' ability to use quantitative information to make day-to-day decisions (Kastberg et al., 2016), participate in the labor market (Carnevale & Desrochers, 2003; Deloitte, 2015) and succeed in college STEM majors (Ganter & Barker, 2004).

I refer to the rationales for teaching and learning school mathematics, such as developing students' abilities to use mathematics to make day-to-day decisions or preparing students for the labor market, as *aims for school mathematics.* These are the beyond-the-classroom benefits that are attributed to the teaching and learning of mathematics in K-12 schools. The system's failure to achieve many of these aims raises an important question: Are aims considered in the curricular work of mathematics education decision makers and if so, how?

The current exploratory study adds to what is known about curricular decision-making systems by examining the curricular stages and changes that occur in three different high school algebra lessons as the teachers transform them from written textbook lessons to plans to an enacted lesson perceived by students. This examination is guided by the following research questions: 1) *To what extent and how do aims for school mathematics permeate these curriculum planning and enactment systems? 2) What role do aims for school mathematics play in the decision making of these teachers in these lessons?*

Theoretical Framework

I describe any desired ends of school mathematics as *curricular intentions*. I refer to classroom-based curricular intentions that are oriented toward improving students' mathematical proficiency (National Research Council, 2001) as *mathematical goals* and beyond-the-classroom benefits that mathematical proficiency provides as *aims for school mathematics*.

In order to understand the role that aims play in curricular decision making, different aims need to be identified and categorized because it is likely that the role of aims will differ depending on the type of aim invoked. I have compiled and categorized a list of aims mentioned in a variety of policy and research literatures and categorized them based on common characteristics (e.g., Geiger et al., 2015; González & Herbst, 2006; Gutiérrez, 2017; NCTM, 2000; Sinclair, 2001; Steen, 2001; Usiskin, 1980; Williams, 2012) (see Figure 1).

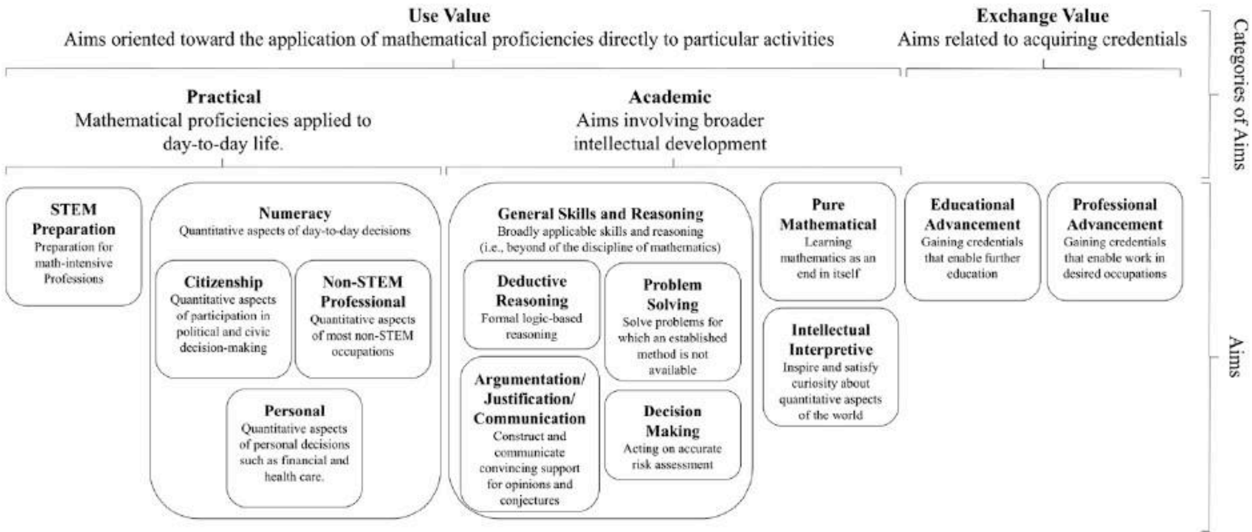

Figure 1: A Conceptual Framework for Aims for School Mathematics

Curricular decision making takes place within *curriculum policy, design, and enactment systems*. These systems include three stages: 1) the curriculum formulated before instruction (*intended)* which includes system-level expectations for student learning, textbooks, and teacher plans; 2) the curriculum that emerges as students and teachers interact (*enacted)*, and 3) the curriculum learned by students (*student learning)* (Remillard & Heck, 2014).

In planning and enacting curriculum, teachers vary widely in the extent to which they modify written materials (Remillard, 2005; Sherin & Drake, 2009). This variation can be described as a continuum in which some offload their design decisions to text, some adapt the text, and other improvise (Brown, 2009). Teachers' skill in making these decisions in order to achieve their intentions can be described as their *pedagogical design capacity* (Brown, 2009). One important element of this capacity is a teacher's developing knowledge of how their curriculum materials function in their particular context, their *curriculum context knowledge* (Choppin, 2009).

A key issue in investigating the role of aims in curriculum decision making is the extent to which aims permeate the system. At one extreme is the *low permeation* model whereby a particular set of mathematical goals, both process and content (e.g., NCTM, 2000; NGACBP/CCSSO, 2010), are established as supportive of the range of aims set for the system and teachers focus on mathematical goals without explicitly considering aims. At the other extreme is the *high permeation* model adopted by teachers who place aims at the center of their day-to-day decision making.

In investigating aims permeation, it is important to determine the types of curricular activities (what I will call *curricular structures*) in which aims are evident. This study investigates three kinds of structures, *tasks*, *discussions*, and *connectors*. I define tasks as anything students do that involves more than conversation. I define discussions as the verbal substance of the lesson. Connectors are verbal or written exposition that come before a task or discussion to frame it, after a task or discussion to summarize it, or between lesson elements as a transition. Tasks can be further categorized by their contextuality as not contextual (*mathematical)*, containing all of the complexity of a real-life problem (*authentic contextual)* somewhat simplified but still might reasonably occur outside of the classroom *(practical contextual),* or contextual but unrealistic (*prototypical)* (Csikos & Verschaffel, 2011; Palm, 2009; 2018).

Methods

The current study examines the curricular systems of three high school algebra teachers in economically and racially diverse high schools. Tobin[1] is in her seventh year of teaching, Megan in her fourth, and Rose in her third. Tobin and Megan are in their second full year using their text while Rose is in her first full year using hers (although she previously used elements of it).

For each lesson, data was collected from teacher interviews, classroom observations, student interviews, and textbooks. General interviews were conducted with teachers to learn their perspective on aims for school mathematics, the outside forces that impact their decisions, and how they use the written curriculum provided to them. Teachers were also interviewed before observed lessons, and teachers and up to four students per classroom were interviewed after each lesson. All interviews were audio recorded and transcribed. Lessons were observed and audio recorded. Additionally, Tobin and Megan's first days of school were observed and audio recorded and Rose described her first day of school in an interview. Introductory textbook materials were collected along with observed textbook lessons, relevant teacher-created materials, and pictures were taken of the classroom environment during the lesson.

Textbook overviews and general interviews for each teacher were analyzed for evident aims. A thematic analysis (Braun & Clarke, 2006) was conducted, using the previously described conceptual framework as initial codes, to create a coherent description of the textbook or teacher's perspective on aims for school mathematics. The lesson-based data was first analyzed to determine the structure of the lesson. Then the written, planned, and enacted stages were coded for stated intentions of the lesson, any other evident aims and contextual intentions, and any other mathematical goals that were connected to aims or the stated intentions of the lesson. Furthermore, any curricular decision described by the teacher was coded for any intentions cited by the teacher as justification for that decision.

Findings

The practical aim of effective financial decision making is evident in all curricular stages of Tobin's lesson as well as in her decision making. The stated intention of Tobin's textbook lesson is to use what students know about linear and exponential functions to help them understand the difference between simple and compound interest. In the lesson itself, there is considerable attention paid to developing a continuous model for calculating compounding interest. In her planning and enactment, Tobin makes significant adaptations that she describes as focusing the lesson on the value of interest in general and the power of compounding. This shift focuses the lesson more explicitly on financial decision making and less on the underlying mathematics.

In the textbook lesson, the aim of financial decision making is evident in an opening discussion, an opening written passage, and four practical contextual tasks. There is also a practical contextual task and a lesson summary in which the aim is not evident. Tobin's adaptations in her planning all relate to the aim. They include changing the framing and summaries of tasks, adding an authentic contextual task, a prototypical contextual task, and some teacher exposition, modifying tasks, and eliminating tasks. In enactment, Tobin makes further aims-related changes. She adds task framings and summaries, more teacher exposition, two personal asides, and gets four unplanned student-initiated conversations. The two students interviewed from Tobin's class cite financial decision making as evident in the lesson.

Aims are evident in all curricular stages of Rose's lesson as well as in her decision making but less so than in Tobin's lesson. Furthermore, Rose's perspective on aims differs from her text book so her adaptations change the nature of evident aims. The stated intention of Rose's textbook lesson is

[1] All names are psudonyms.

solving real world problems using systems of linear equations. In the written lesson, this practical aim is evident in two suggested class discussions and four practical contextual tasks, three of which are in a business context. Rose, however, is more focused on her students' general problem solving skills and in having them collaborate so they will enjoy the lesson and thus be more likely to consider STEM careers. As a result, her adaptations from planning to enactment end up eliminating the practical tasks. She uses prototypical tasks and modifies them to incorporate more problem solving and collaboration. Interestingly, despite these adaptations, two of the four students interviewed after this lesson identified the practical use of systems of equations as an aim for the lesson.

Unlike Tobin and Rose's lessons, aims are not evident in Megan's lesson, yet the aim of communication drives some of Megan's decisions and multiple aims are perceived by students. The stated intention of Megan's written lesson is for students to be able to add and subtract rational expressions. Megan's aim-related adaptation is to ask all of the groups to present their solutions to the first task in the lesson, a change that she explicitly ties to the aim in interviews, but not in the class. Despite this lack of evident aims in the written and enacted lesson, two the four students interviewed identify the aim of communication as evident in the lesson and one of four identifies collaboration and problem-solving. This is consistent with passages in the textbook introduction and teacher exposition on the first days of school that link mathematical goals such as communication, collaboration and problem-solving to broader aims.

Conclusions and Discussion

Thus, there are a variety of curricular structures in which aims can be evident, including a range of tasks, discussions, and connecting activities. Most notably, Rose and Tobin's textbook lessons and planning demonstrate how authentic contextual tasks can make practical aims evident in a lesson. Tobin's enactment suggests that aims-related personal asides and summaries may make aims evident in ways that register with students as they seem to inspire both student-initiated conversation and student-perceived aims. In contrast, Rose's enactment suggests that a lack of these structures may lessen the impact of evident aims. It also demonstrates the power of the teacher to eliminate aims to which she is not attending. Megan's lesson shows that intending to support mental discipline aims is not the same as making them evident in the lesson. However, it also suggests that explicit connection of mathematical practices to mental discipline aims in overview materials and general teacher exposition may have an impact on student perception of aims in later lessons even if the aims are not explicitly evident in the lessons themselves.

The differences in evident aims between these three lessons may be due, in part, to the topics. It is unsurprising that lessons on exponential functions and systems of equations would be more clearly connected to practical aims than one on simplifying rational functions. However, the finding that Tobin more effectively adapts her lessons suggests that more experience with her curriculum may have helped her develop more curriculum context knowledge (Choppin, 2009) and more years in the classroom may have allowed her to develop more pedagogical design capacity (Brown, 2009). Megan's use of overviews to link goals to aims may suggest another element of curriculum context knowledge and pedagogical design capacity.

Overall, this analysis suggests that aims can, indeed, permeate curricular processes, and provides some initial ideas for how this permeation may be indicative of teacher skill in using curriculum and how it might influence the achievement of aims. It lays the groundwork for future research to explore whether and how this kind of curricular work can, in fact, support the achievement of aims for school mathematics.

Introduction

This poster presentation focuses on the comparison of syllabi for secondary mathematics methods courses across cultures. The authors uncover similarities and differences between these documents and their relevance. According to Wikle and Fagin (2014): "Within most college or university courses the syllabus serves as the principal tool for course planning" But is this true across cultures? Similarly to Kaki (2000), the authors believe culture does play a role influencing syllabus production.

Research Question and Design

The research questions guiding this comparison study are: a) how are secondary mathematics methods courses similar and/or different across cultures? b) How are the objectives of those courses similar and/or different according to their syllabi? And c) How are the evaluation methods similar and/or different according to their syllabi?

To conduct the comparison, the authors collected secondary mathematics methods syllabi from five institutions: two United States (US) colleges of education, one public teacher preparation program in Uruguay, one college of Engineering in Colombia, and one college of education in Korea. The syllabi were review first structurally, to see what sections they included, and then the content of those sections, specially objectives and evaluation methods, similarly to what Parkes, Fix and Harris (2003) and DuBois, Burkemper (2002) did.

Summary of Findings

Structurally, the US syllabus contained the greatest number of sections, and were in general the longest documents. They had the most coincidence with Korean syllabi, even though these were the shortest along the Uruguayan one. This one also was the one with the least number of sections, notoriously not including any information about how the students would be evaluated for the course, which was also the case for Colombia. Korea and US included outlines of the content by week. Standards and accreditors information was only included in the US syllabi.

When looking at the objectives all of the syllabus mentioned planning of instruction, and classroom assessment. All of them but the Colombian one also mentioned societal issues like diversity and equity through mathematics education. And the two south American syllabi also mentioned the importance of considering mathematics methods as a scientific discipline.

Last, looking at the course evaluation methods, the authors of this poster found that only the US cases have sections explaining assignments. There were some coincidence on the topics for evaluation: readings, planning, and assessment. Korea had a very broad explanation of how students would be evaluated, mentioning lecture, discussion/presentations, xperiment/practicum, and field study.

MATHEMATICS INSTRUCTION DURING PROSPECTIVE TEACHERS' PERFORMANCE-BASED ASSESSMENT IN SPECIAL EDUCATION CLASSROOMS

Dr. Katherine Baker

Dr. Danielle Lane
Elon University
dnowosiadlo@elon.edu

Keywords: Assessment and Evaluation, Special Education, Teacher Education – Preservice

This research project examined the perceived tensions of prospective teachers' (PTs) between their university coursework centered on student-led mathematics instruction and their internship placements' scripted mathematics program for students with disabilities in special education settings. The scripted program was a mandated district initiative featuring a mathematics curriculum with set pacing, required daily lesson materials, and a teacher script. A yearlong case study followed five PTs enrolled in a dual major Elementary Education and Special Education program. All participants were completing student teaching internship requirements in K-5 special education classrooms: four traditional resource classrooms (children with disabilities received instruction in a pull-out setting), one autism spectrum disorder classroom. Participants were also completing their performance-based teaching assessment called the edTPA, which focused on the instructional needs of one student with a disability in the area of mathematics.

The edTPA is a performance-based assessment intended to determine if beginning teachers are prepared to enter the classroom. This performance-based assessment was developed by Stanford University and the Stanford Center for Assessment, Learning, and Equity (SCALE). The Special Education edTPA is evaluated across 15 scored rubrics in areas of planning, instructing, and assessing. Currently, 920 Teacher Preparation Programs in the United States complete the edTPA (SCALE, 2019). The edTPA faces critique (Behizadeh & Neely, 2018; Gitomer et al., 2019), however, specific to this case study, it required that the PTs justify how their instruction integrated the personal, cultural, and community assets of their students. This focus on students' assets was emphasized in PT coursework that urged them to follow their students' mathematical contributions rather than follow a lockstep curriculum (Carpenter et al., 2014).

The study's qualitative PT data sources included: (a) focus groups pre, during, and post completion of the edTPA, (b) interviews, (c) written responses to the edTPA prompts, (d) written reflections about the process, and (e) open-ended survey responses from the teacher preparation program's feedback survey about the edTPA. Grounded in theory and literature around teacher preparation assessments (Darling-Hammond, 2020), qualitative data was analyzed to note emergent codes which resulted in persistent themes of PTs' perceptions of math teaching and perceptions of teaching self, contextualized in the tension of their setting and the edTPA. edTPA scores were included as quantitative data sources whose analysis produced descriptive statistics of the overall case and revealed edTPA subsets of challenge or above-average performance that provided insight into why certain tensions may have been magnified. Findings indicated that the PTs expressed tension between following the scripted program versus following their learner was exacerbated by the edTPA. Although the edTPA could have been used as a PT's catalyst for rejecting the scripted program, the PTs instead settled with a disjointed compromise among their perceived demands of the edTPA, their Clinical Educators, the scripted program, and their own expressed beliefs about teaching and learning.

Instead of interventions that focus on direct instruction, number strings provide opportunities for students to engage in mathematical discourse, both in describing their strategies and connecting with the mathematical strategy of others. Research on number strings has found that students participating in number string routines can adopt new strategies (O'Loughlin, 2007) and make connections between conceptual understanding and procedures. Studies on number strings have not previously focused on students with disabilities or students who are significantly underperforming in mathematics, investigating this problem can provide information that could lead to solutions that improve computational fluency in multiplication and division. In particular, interventions for students with disabilities (Lambert, 2018; Lambert & Tan, 2020) within the Multi-Tiered System of Support (MTSS) in mathematics.

To explore student computational fluency, we designed a standard aligned number string intervention for students (N= 35) with disabilities ages 8 through 11 significantly underperforming in multiplication and division (Lambert, Mendoza, & Nguyen, 2020). A number string is a short (15–20-minute) daily instructional routine in which a teacher presents a carefully designed sequence of problems one at a time for children to solve mentally and modeling student thinking with a representation (Lambert, Imm, & Williams, 2017). Research question: What are the effects of a Tier 2 number strings intervention in multiplication and division for students needing additional support in these areas?

Findings

In order to assess whether student computational fluency improved after eight number string interventions and three iterations of the Multiplication and Division CCSS CBM Math Assessment. . Using a dependent samples t-test, students improved their scores after the 8 session intervention, $t(32) = 2.30$, p=0.028. (We used a dependent sample t-test since repeated measures were taken from the same sample). After the pre-intervention test scores (first iteration of the assessment) of ~29.10%, the post-test scores (3rd iteration of the assessment) increased to ~36.93%. This is a 26.9% multiplicative increase for all students.

TEACHER'S COLLABORATION WITH FRESHMEN UNDERGRADUATES TO IMPROVE FEEDBACK PRACTICES THROUGH COGENERATIVE DIALOGUES

Providing students with written feedback on their homework yields many benefits on their learning (Black, Harrison, Lee, Marshall & William, 2003; Fyfe, 2016; Landers & Reinholz, 2015). These benefits include providing students with information on their current levels of understanding, and in providing possible next steps for student improvement. However, in many cases, teachers take the position of "presenter of knowledge" (Black et al., 2003, p. 89), providing students with feedback that they assume the students need, and which may or may not match the actual students' needs. Students, on the other hand, rarely read and implement change on their work based on the written feedback (Black et. al., 2003), making the feedback lose its effectiveness. To improve the effectiveness of written feedback, researchers suggest that teachers seek different ways of using written feedback in mathematics classrooms (Frey & Fisher, 2011). We conjectured that using cogenerative dialogues (cogens) (Emdin, 2016; Tobin, 2006) to invite students into deciding on the nature of written feedback they would be receiving, and ways of using it efficiently, may support more student-centered forms of feedback.

We carried out a practitioner-inquiry study (Samaras & Freese, 2009) in a first year undergraduate Probability and Statistics class taught by Wambua. The class consisted of ten students at a private university in the Northeastern region of the United States. We hypothesized that we could improve the effectiveness of written feedback in classroom tasks by leveraging student autonomy to shape the nature of the feedback they received and in deciding how they use the feedback to produce new work. For six weeks, we held 15-minutes long cogens (structured teacher-student dialogues aimed at co-constructing classroom practices) after each class with all participants. For data analysis, we used constant comparison method (Savin-Baden, & Major, 2013). We coded all cogen-transcripts, students' worksheets and teacher's feedback to look for evidence of improvement in the teacher's feedback based on students' comments.

Working closely with students through weekly cogens focused on improving written feedback as a formative assessment technique generated improvements in three areas: (a) helping the teacher transition from giving general feedback to give specific feedback, (b) providing students opportunities to state how immediate feedback supported their learning and (c) in transforming the classroom culture. By listening to and learning from the students, the teacher improved her written feedback from using general statements like "Good job" and "explain more" to providing more elaborate feedback that articulated what was right or wrong in the students' work, and gave suggestions on how to correct the mistakes. The students highlighted that the cogens provided opportunities for prompt and focused feedback that helped them curtail practicing the same mistake in future. Finally, the cogens boosted students' motivation in their mathematical abilities and served as an evidence that their perspectives and experiences are valuable in co-constructing classroom practices. In future, we hope to explore how cogens could leverage feedback provision in larger class sizes and in education levels beyond undergraduate.

Mathematics educators sometimes have trouble enacting equity-based pedagogy. Part of this is due to the lack of authentic opportunities to engage in analyzing difficult scenarios involving power, identity, and access. Additionally, mathematics educators sometimes have trouble finding, sharing, and collaborating on activities and materials that interrogate these spaces. In this research report, we present how a collective of equity-oriented mathematics educators created, enacted, and studied the use of scenarios presenting difficult situations to pre- and in-service mathematics teachers. More importantly, this report shows how we, as a field of mathematics educators, can enact large-scale collaboration that disrupts the capitalistic norms of knowledge ownership and neoliberal approaches to teacher preparation. The CARDS tool was not created by an individual, but by an amorphous group aligned and committed to equity.

Keywords: Social Justice, Teacher Education – Preservice, Teacher Education – Inservice / Professional Development, Teaching Tools and Resources

The 2020 PME-NA conference theme, *Across Cultures,* promotes the exchange of ideas and collaborations across cultures in addition to thinking beyond traditional forms of educational research. This research report introduces a curricular tool, whose design, implementation and subsequent research of, directly aligns with this *Across Cultures* theme. The Critically Analyzing and Responding to Difficult Situations (CARDS) tool promotes dialogue across the many cultures and stakeholders involved in dismantling inequities embedded within mathematics education. The CARDS, intended to support each of us in rehearsing and preparing for difficult conversations associated with equity issues, aligns with the perspectives of the PME-NA Equity Statement (2019). Additionally, this research report is not just about presenting the CARDS tool, but about sharing and analyzing the process in which the CARDS were refined over several years by a collective of critical mathematics educators across institutions, generations, and geographies.

The MathEdCollective is a loosely organized and open membership group organized in the Fall of 2017 in response to attacks on mathematics educator Dr. Rochelle Gutiérrez by white supremist media (Gutiérrez 2017b, 2018). The CARDS were designed to help pre-service teachers, in-service teachers, and teacher educators develop and promote critical perspectives of mathematics as sociopolitical (Gutiérrez, 2010/2013). The CARDS ask users to image or enact difficult scenarios and practice potential responses, largely based upon Gutiérrez's (2015) "In My Shoes" activities and Crockett's (2008) case studies for mathematics educators to contemplate the intersection of culture and mathematics teaching.

Enterprise

The MathEdCollective

When mathematics education scholar Dr. Rochelle Gutiérrez (2017b, 2018) was attacked for her scholarship, white supremacist attacks on equity and justice work in mathematics education in the

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

U.S. rose to a previously unseen level of vitriol. Professional and personal attacks crossed every imaginable boundary, causing colleagues to maintain open lines of communication via email and weekly video calls to organize, provide solidarity, and support to Gutiérrez and other scholars who might be the next to come under attack. As a result, the MathEdCollective was formed to organize and exhibit solidarity with U.S. mathematics educators and organizations under attack. Quickly, the MathEdCollective defined its collective principles based on used various sources of inspiration, including U.S. Civil Rights Era activism, works by Paulo Freire and bell hooks, and the hacker-activist group Anonymous (The MathEdCollective, 2019). As the group grew in number and increased its activities, a series of implicit organizing principles began to evolve.

The MathEdCollective (2019) practices (1) shared ownership of ideas, which creates a community that can shield individuals from further harm by "anonymizing" their ideas through the MathEdCollective's voice, (2) heterarchical and open membership, which means that it is without hierarchy, "leaders", "representatives", defined membership, or email list, (3) collective action, meaning no decisions or action by the MathEdCollective reflect individuals but reflect the consensus of the moment with whoever happens to be participating at the time, and (4) taking the high road, transforming negative hate and energy into something positive and productive.

The CARDS Emerge

The previously mentioned attacks on mathematics educators and researchers underscore an ideological war present within our field, making necessary the need for preparing teachers to engage in these difficult and critical conversations. During one call with several mathematics educators and graduate students, the MathEdCollective discussed the importance of the reactive work of the collective which provided support and trauma aftercare to those attacked. But we also recognized that being reactive was not enough, we needed to move toward a more proactive, educative approach. One member of the collective suggested using a set of playing cards that could be used to help a person rehearse for difficult situations. Essentially, the idea involved supporting a broad range of stakeholders in mathematics education through helping them be ready to respond to difficult conversations by practicing in advance using real-life scenarios and simulations of politically dangerous interactions that might emerge within the work of teaching (Crockett, 2008; Kazemi et al., 2016).

Teaching rehearsals are a simulation of conversations, interactions, situations, and/or relationships that might emerge during the work of teaching (Kazemi et al., 2016). By engaging in and practicing these rehearsals, teachers can improve "routine and improvisational decisions in practice" (p. 18). Therefore, the CARDS describe scenarios rooted in the social, historical, and institutional contexts related to the work of mathematics teaching. These scenarios, similar to and inspired by "In My Shoes" activities (Gutiérrez, 2015), provide opportunities to rehearse such conversations as a means for developing preservice teachers' sociopolitical toolbox. Like the "In My Shoes" activities, the CARDS aim to develop "nuanced perspectives on situations" and to consider multiple options or a "repertoire of moves that can be used and the kind of language that would accompany those moves in challenging situations" (pp. 22–23) for mathematics educators of all levels of experience.

The CARDS reflect not only a commitment to collective enterprise and shared intellectual ownership, but also to emergent design research (Tom, 1996). All persons who were involved with the ideation, refinement, and conversation around the CARDS are recognized as equal participants in the design, feedback, piloting, and intellectual development of this work. The mathematics teacher educators, the teachers we worked with, the various members of professional organizations who attended conference sessions or engaged in conversations related to the CARDS, and the MathEdCollective are collectively always "gathering" and "generating" data and knowledge in the form of anecdotes, videos, and feedback. This collective participatory design research method (Bang & Vossoughi, 2016) means that all participants helped guide the research questions, the research design, and even the interpretation of the data. Additionally, the development of the CARDS reflects the anti-hierarchical organizing principles of the MathEdCollective that disrupts colonial ways of defining people, land, and ideas as things to be owned, taken, and sold (MathEdCollective, 2019; Patel, 2016).

Development of the CARDS

The development of the CARDS started with solicitation and creation of scenarios based upon conversation within the MathEdCollective calls. This led to the idea of engaging in mathematics teacher education that was proactive in helping mathematics teachers be prepared for difficult conversations in their careers. We briefly describe the three cycles of development of the CARDS here.

This first cycle of the CARDS development consisted of soliciting and creating scenarios and possible responses to the scenarios, sharing those scenarios and responses with the MathEdCollective, and then creating a public, online space in which various individuals could add comments or questions about the scenarios and responses. The scenarios and responses were formatted to be able to be printed as physical cards that are approximately four inches by four inches each. The CARDS and pilot data based on small enactments within our mathematics methods courses were shared at the Association of Mathematics Teacher Educators (AMTE) conference in 2019. After that presentation, several members of the MathEdCollective immediately used these cards in their own teaching and reported back about issues they encountered through emails to the CARDS development team or directly on the CARDS google document itself.

Once a set of pilot cards had been developed, using the process and resulting in the materials as described above, we set forth on a second cycle to implement and, this time more intentionally, study the sorts of learning that the CARDS seemed to support. We decided to each use the cards in ways that made sense in our particular mathematics teacher education contexts: some of us work with pre-service teachers, some with in-service teachers; some of us with work with elementary teachers, some with middle or high school mathematics teachers. Some of us were most interested in using the CARDS as an in-class activity, others assigned them as outside-of-class work to be completed individually; some incorporated them with reflective writing, others used them as prompts for discussion, and others had teachers interact with the cards over innovative, virtual spaces for communication. Some of us were additionally interested in having a graduate student or a "more junior" mathematics teacher educator lead others in the use of the cards, so that we could study how the cards were taken-up and implemented by a mathematics teacher educator who was NOT involved in their development.

The second cycle involved refining and printing out eight physical cards for distribution to the MathEdCollective for use in their practice. The authors used these cards in their own mathematics methods courses in various ways. The authors then came together to engage in constant comparative analysis (Dye et al., 2000) through reading transcripts, listening to audio interviews, and watching video responses that the pre-service teachers generated when encountering the scenarios to create a list of themes. We then engaged in conversation to collapse these themes to those that seemed most important, and then re-analyzed specific points of data with this collapsed list of themes in mind.

A third cycle followed, involving the creation and solicitation of eight additional scenarios and then sharing them in three more situations: the 2020 AMTE conference, an elementary mathematics methods course with 25 pre-service teachers, and a professional development course with 20 practicing elementary teachers and assistant teachers in a public elementary school.

Through these cycles of analysis, multiple questions arose, such as: How are people using these cards? How do people respond to the cards? How are the enactments mitigating the historical violence that might be triggered through some of these scenarios? What are potentially dangerous assumptions that we and the MathEdCollective have made in the creation and implementation of these scenarios? While we collected a large amount of data that can be analyzed in multiple ways, we focus this paper on unpacking the critical conversations that the authorship team engaged in after these three cycles. We feel this analysis best serves the goal of the PMENA conference, engaging in our own difficult conversations about and across cultures.

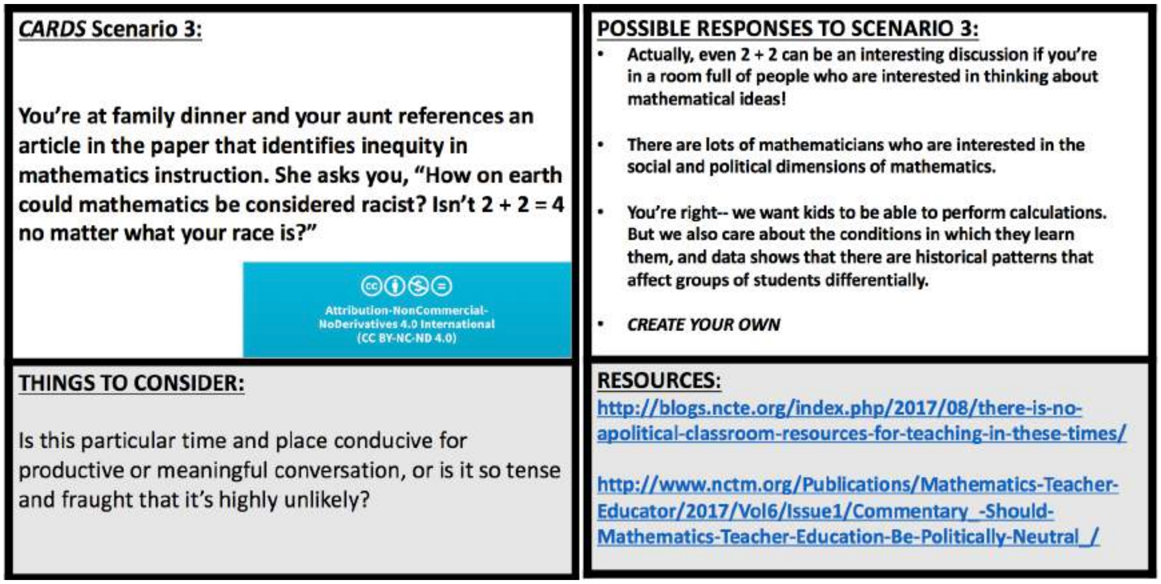
These various solicitation and collaborative cycles informed the design and content of the cards in several ways. We regard everyone who has been engaged with the CARDS as co-authors/designers. These individuals provided feedback on current scenarios and responses and made suggestions for new scenarios, things to consider, example responses, and resources. In addition, the co-authors/designers offered suggestions for a user guide. These suggestions were often a result of their own local contexts and connected to their own experiences, allowing the CARDS to involve scenarios that moved across cultures. These interactions and reflections provided valuable data on how the CARDS were taken up, both in their purpose and structure. Co-authors/designers also provided key reminders of how critical tools such as the CARDS could potentially cause harm, discomfort, or trauma for people using the cards. The feedback also included ways to think carefully about various audiences, how to scaffold the CARDS, and the necessary pre-work in building a community of trust.

Design of the CARDS

The CARDS are the result of an on-going collaborative effort involving a broad community of mathematics teacher educators, teachers, coaches, pre-service students, etc. Many voices contributed to the content and design considerations of the evolving tool. The CARDS (see Figure 1) were designed to be a tool intended to both 1) serve as a catalyst to open up dialogue between us about a variety of situations related to equity in mathematics teaching/education; and 2) support the development of our preparedness to engage in difficult conversations with others.

The front of each CARD includes a short scenario related to a topic in mathematics education. The scenarios are deliberately short, often with a variety of details omitted. This is purposeful. The vagueness of some of the scenarios provide an opportunity for further conversations and things to consider. Below the scenario, a list of “Things to Consider” are included. These are meant to be used to help the user think about external issues that might impact one’s response to the scenario.

The back of the CARD includes a range of possible responses as well as a list of resources that may support the topic or issue raised in the scenario. The possible responses are NOT intended to be used as actual statements to be used as response to but rather to further open up conversations among us as we engage with the CARD. The range of possible responses also aims to further promote dialogue about the topic and how the response contributes to a productive conversation or not. For example, some provided responses could be taken up as inviting others into a conversation versus some that intentionally shut people out.



CARDS Scenario 3:

You're at family dinner and your aunt references an article in the paper that identifies inequity in mathematics instruction. She asks you, "How on earth could mathematics be considered racist? Isn't 2 + 2 = 4 no matter what your race is?"

POSSIBLE RESPONSES TO SCENARIO 3:

- **Actually, even 2 + 2 can be an interesting discussion if you're in a room full of people who are interested in thinking about mathematical ideas!**
- **There are lots of mathematicians who are interested in the social and political dimensions of mathematics.**
- **You're right-- we want kids to be able to perform calculations. But we also care about the conditions in which they learn them, and data shows that there are historical patterns that affect groups of students differentially.**
- ***CREATE YOUR OWN***

THINGS TO CONSIDER:

Is this particular time and place conducive for productive or meaningful conversation, or is it so tense and fraught that it's highly unlikely?

Figure 1: Front and Back of Scenario 3 CARD

Findings: Impact of the CARDS

We present three of the main impacts that we found as a result of our initial implementations with the cards. We refer to these as impacts in the sense that these are three ways in which the cards seem to provoke moments of learning for us mathematics teacher educators: about the cards themselves as curricular materials, about our preservice teachers' experiences in teacher preparation programs; and about our own orientations toward our work as mathematics teacher educators working with teachers. Below we briefly present three initial findings about these impacts, sharing illustrative examples from the interview transcriptions; the video responses, and written assignments. As a reminder of our data analysis process: we reviewed selections the data together (we watched videos, listened to interviews, read transcripts and submitted assignments) and engaged in consensus-building discussion about what themes seemed to emerge in multiple instances (i.e., in more than one preservice teachers' response) and what themes seemed most compelling to us and most immediately informative to our work as mathematics teacher educators.

The Importance of Place and Space

As preservice teachers reacted to the scenarios on the cards, they considered both the individual scenarios and the possible responses. In doing this, we noticed that the specificity of place (i.e., the grocery store or a family dinner) was a significant detail in how several participants responded to scenarios, particularly as they thought about the ideas of the "appropriateness" of having "sensitive" conversations in those places. Several preservice teachers said they would want to talk about things in a different place or at a different time. For example, as she was interacting with the cards, Marta was also influenced by the setting of the scenario. She mentioned that if she were at the grocery store, the scene of Scenario 1, she would probably be "in a rush" and "not be in the right mindset to have that kind of serious conversation." Other preservice teachers told us that they would want additional information about the topic before they would feel comfortable responding if they were in similar situations. We reflected on the ways that the preservice teachers' responses may have been affected. That is, we see the consideration of place as very understandable and relatable, but realize that the content on the cards may have influenced responses of this nature. As retreating is a frame of whiteness, in how white-identified peoples hold the privilege to be able to retreat from difficult situations (Picower, 2009), we realize the need to have preservice teachers, and ourselves, explore the different possibilities for responding to issues of power, identity, and access given the different settings, times, and people involved in our interactions.

Considerations of Our Teachers

Students of color or from marginalized identities bear some emotional weight related to personal experiences with the content of the cards. In Kat's interview, she expressed how a recent experience in her university courses influenced whether or not she was comfortable with certain responses to the Columbus Day scenario (Scenario 2). For example, she recalled the racial tension in her class after speaking up about an issue. She said: I was in a class, and me being the only, well, one out of two black students that were in the class. I spoke up and said something about, something relating to social studies and Columbus Day and things like that, where I felt like people in the class weren't taking seriously… And I received a lot of backlash...it was hard for weeks...now things are getting a lot better. But it was just hard because you can feel the racial tension and just the divide. The weight of that experience influenced which possible responses to the scenarios she saw as acceptable and which felt like "an attack to somebody".

As Abdulah worked with the cards, he specifically connected with Scenario 5, where the scenario is related to a teacher who is unable and unwilling to learn the correct pronunciation of his students' names. Abdulah shared personal experience of how his name was very often mispronounced. In sharing his experience, Abdulah discusses the need for teachers to learn the correct pronunciations of students' names from the start, but he also mentioned that his name is never pronounced correctly due to differences in language. Although Abdulah said that he took no offense when people mispronounced his name, another preservice teacher reacted differently this saying, "My name has always been mispronounced which makes me feel uneasy." The situations on the cards brought out the emotional weight these preservice teachers have experienced throughout their schooling in a range of different experiences, and we want to acknowledge concerns we have heard from MTEs about using these cards framed as worry for upsetting or triggering their students of color.

Moving from Deficit to Asset Perspectives of our Teachers

The data were a reminder that all of our students have backgrounds, knowledge, and experiences that they can draw on in meaningful ways during activities with the cards. As the preservice teachers worked with the cards, they referenced what they knew based on their experiences in schools. For example, Norah mentioned experience from her field placement school where students were making predictions based on the cover of a book. On the cover, a group of children were standing around another child holding a cap. As the students in the field placement classroom made predictions, one of the students predicted that the two Black children on the cover were brother and sister because they had the same skin tone. Norah used this as an opportunity to begin a conversation in the classroom. Several other preservice teachers related the scenarios on the cards to concepts they had discussed and explored in other coursework, such as their social studies methods course, educational policy courses, literacy course, among others. They weren't required to make connections to what they knew or had learned in their teacher preparation courses but many of them did.

Discussion and Next Steps

Working Groups and professional conference sessions extended our methodology, in which participants learned about, received, and were challenged to use an early iteration of the CARDS. These opportunities to work across cultures (mathematics educators, teachers, parents, other stakeholders) served as an impetus for multiple MTEs to implement the cards in their own institutions. The feedback received has helped make improvements related to content, context, form, and delivery. Content and context details have been added along with the addition of new scenarios. Variations of the cards are being developed to be used with different audiences (teacher candidates, teachers, administrators, etc.) The form of the cards is being modified to become more user-friendly and incorporate additional resources and technology. Different delivery options (online, game formats, etc.) are also being explored and will be included in a user guide. We did not "construct" the cards and then evaluate them, rather they were a result of emergent design research (Tom, 1996). In other words, and an ongoing effort of collectively collaborating to create/design tools that come out from the larger community.

As a next step, we reiterate our invitation and our plea that our colleagues (and by that we mean anyone who plays a role in mathematics teacher education) continue to join in the shared creation and improvement of the cards. We will continue to share the cards, user guide, and other relevant materials freely- not only to download, but to add to and to suggest revisions. These materials are licensed under creative commons copyright law, so as long as users are doing so with attribution and for educational, non-commercial purposes, they are free to do so. This is what we mean by collective ownership.

In fact, we consider the collective ownership of the cards to be one of, if not the, most significant findings of this project thus far. Our field is dominated by scholars who work in higher education institutions, which are organized by a capitalist framing of knowledge creation and ownership. We recognize that we ourselves are a part of this problematic structure which inhibits true collaboration or idea sharing, in which individual knowledge creation and selfish ways of thinking are rewarded and incentivized. We seek to enact a decolonizing stance to educational research (Patel, 2015) to think about ways to create true collaboration in our field and to enact research designs that honor all voices. In this project, we have offered a glimpse of what this might look like, through the ideation, creation, enactment, and study of a tool for mathematics teacher education that has been completely collaborative from start to finish. Even now, we do not present the CARDS project as a finished project, but as an evolving tool that will grow through collective action.

Turning our attention to use of the cards: there are many concepts and frameworks regarding equitable mathematics teaching practices from which mathematics teachers can base their work with these CARDS. Paradigms and frameworks such as Guitierrez's *Four dimensions of equity,* Tuner, Drake, McDuffie, Aguirre, Bartell, and Foote's (2012) *learning trajectory for building on children's multiple mathematical knowledge bases* (Project TEACH MATH), and the *antiracist tool for mathematics teacher educators* (A3IMS Project) all offer foundations from which MTEs might regard the cards as resources. We do not intend to homogenize differences between these approaches, thereby trivializing the significance of theoretical framework and the intellectual work involved in articulating the affordances of any one perspective. We ourselves have been intrigued by Love's description of abolitionist teaching (2019), and the statements in our data expressed by Abdullah and Kat echo Love's call that students of color--in our case: our preservice and inservice teachers of color--need to know that they *matter*. They need to be repeatedly and resolutely assured that their communities, their families, their neighborhoods, their stories, their bodies, their hopes and their dreams *matter.* The Cards provide one mechanism to support our practice of inviting, eliciting, and honoring these multiple dimensions of our students' and teachers' lives into our interactions with them.

For our colleagues in mathematics teacher education who share our interest in developing deep, theoretical understanding alongside a skillful, practical usage of the cards, we invite researchers to develop and apply their various conceptual and analytic frameworks. As we have analyzed the data together, we have begun to wonder in what ways interactions with the cards reveal whiteness within our teachers, ourselves, and our systems and institutions, our practices and policies. Battey and Leyva's (2016) *framework for understanding whiteness in mathematics educatio*n offers one tool for this.

Interestingly, and perhaps counterintuitively: as a result of the efforts described here, we are learning more and more about what might be the most appropriate intentions for using these cards. When we began developing these resources, we admittedly did not have a clear objective. We were guided by curiosity, a sense that these would be useful, and a lot of encouragement and expressions of interest from colleagues. In some ways, these cards were developed antithetically to the "design" approach so ubiquitous in education research wherein problems of practice are identified and then answers are proposed, studied, and refined. Our process was more akin to an "undesign" approach (Leander & Boldt, 2018), wherein we were motivated by a "What can we do with these?" wondering about a curricular resource that we found ourselves compelled by. The "What can we do with this?" curricular approach has been adopted by mathematics teachers in productive and interesting ways for posing rich mathematical tasks and we are intrigued by what this stance could bring to mathematics teacher education.

Fundamentally, we do not view equity, diversity, and inclusion as "problems of practice" that need to be "solved:" rather we view them as the existential commitment most relevant and animating to our work as mathematics teacher educators--individually and collectively. We will never be finished, we will never get to cease remaining vigilant in our commitment to remaining watchful and attentive to harm that arises in mathematics teaching and learning as a result of abuses of power. Contributing toward more equitable mathematics classrooms is a practice: we will need to hold ourselves accountable and reaffirm our commitments again and again. These cards-and this approach to collaboratively developing and owning them--are one way to do this. They do not "hold" or "convey" the right answers because there are no such things, but a commitment to return to them again and again, always adding to our collective understanding, is a stance worth taking.

BETWEEN THE BOUNDARIES OF KNOWLEDGE: THEORIZING AN ETIC-EMIC APPROACH TO MATHEMATICS EDUCATION

Lee Melvin Peralta
Michigan State University
peralt11@msu.edu

Researchers and reformers across multiple areas of scholarship have challenged the idea of mathematics as fixed, politically neutral, and value-free. Ethnomathematics has brought attention to the mathematical practices of particular cultural groups that differ from Western ways of mathematical understanding. These practices raise the following question for mathematics education, especially within Indigenous communities: whose knowledge should be taught and from whose perspective? One response to this question is to teach both dominant and non-dominant perspectives on mathematics, which can be considered an "etic-emic" approach to mathematics education. Drawing on the literature on decolonizing studies in education, I offer a theorization of this etic-emic approach in terms of re-mythologizing mathematics, pursuing recognition and reconciliation, and refusing colonization.

Keywords: Ethnomathematics

The sociopolitical turn in mathematics education calls for an examination of the ways mathematics is framed, conceptualized, and presented in the curriculum (Gutiérrez, 2013a). For instance, ethnomathematics researchers have brought attention to the mathematical practices of particular cultural groups that differ from Western ways of understanding mathematics (D'Ambrosio, 1985; Barton, 1996). These mathematical practices, even when they are not explicitly labeled as ethnomathematical, can serve as important resources for mathematics educators seeking to draw connections between dominant and non-dominant forms of knowledge and challenge the notion that there is only one way to learn, understand, and do mathematics.

Ethnomathematics seeks to promote expanded views of what counts as mathematical activity. This raises the question for mathematics education, especially within Indigenous communities, of how to balance the perspectives created by and enacted through dominant and non-dominant mathematical practices. One response is for teachers to teach both dominant and non-dominant perspectives on mathematics, a practice that I will refer to as an etic-emic approach to mathematics education. In this paper, I seek to theorize this etic-emic approach and, in doing so, to highlight how historicized and ongoing effects of colonization make it difficult, if not impossible, to reconcile dominant and non-dominant ways of knowing. I begin with existing conceptions of and approaches to ethnomathematics in order to provide background on the various ways in which researchers have brought attention to and grappled with multiple systems of mathematical knowledge, particularly as the existence of these multiple systems implicate approaches to mathematics education. I proceed by reviewing the work of scholars who have proposed an etic-emic approach to mathematics education. Drawing on the literature on decolonizing studies in education, I conclude by theorizing this etic-emic approach in terms of re-mythologizing mathematics, pursuing recognition and reconciliation by Indigenous communities, and refusing colonization.

Ethnomathematics

Ethnomathematics began as an endeavor to identify and elaborate on the practices of cultural groups, particularly from the point of view of one immersed in scholarly mathematics (D'Ambrosio, 1985). Over the past four decades, ethnomathematics has branched out in several directions. Barton (1996) identifies a few of these directions, including an interest in the ways mathematics is culturally

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

based, the nature of mathematical thought and activities across cultures, the evolution of mathematics from a socio-anthropological perspective, the politics of mathematics, the use of culturally specific contexts in schools, and the relationship between mathematics education and society. He proposes the following definition for ethnomathematics:

> “a research program of the way in which cultural groups understand, articulate and use the concepts and practices which we describe as mathematical, whether or not the cultural group has a concept of mathematics” (Barton, 1996, p. 214).

The term *mathematics* refers to the work of school and scholarly mathematics (e.g. algebra) and the term *mathematical* refers to concepts and practices identified as somehow related to mathematics (e.g. kinship systems that can be interpreted in terms of algebraic structures) (Barton, 1996). Barton (1996) points out that this definition of ethnomathematics is not absolute or definitive. The meanings of the terms are culturally situated and depend on the person or group using them. Ethnomathematics is a culturally specific practice performed by one cultural group seeking to make sense of another, often by reference to a specific conceptualization of mathematics (Barton, 1996).

Barton’s approach to define and frame ethnomathematics is joined by other perspectives. D’Ambrosio (2006) argues that ethnomathematics concerns the history and philosophy of mathematics with pedagogical implications, the goal of which is to develop a broader vision of knowledge by making cross-cultural comparisons of the ethnomathematics of different groups. Borba (1990), Gerdes (2005), and Powell and Frankenstein (1994) emphasize the importance of ethnomathematics for education, pointing out the ways mathematical practices of cultural groups can be brought into the classroom. Pais (2013) suggests a path for ethnomathematics that critiques its own directions and purposes, particularly those that would render ethnomathematics a mere pedagogical tool for importing cultural contexts into schools.

Pais (2011, 2013) and Vithal and Skovsmose (1997) raise concerns regarding ethnomathematics. When a mathematical lens is applied to a cultural practice, there is a risk this lens becomes a “gaze” that suggests a group’s cultural activity is valuable only because one can see mathematics in it (Pais, 2013, p. 3). This gaze also highlights the unidirectional nature of ethnomathematics, the alternative being that ethnomathematics can and should be directed back toward dominant mathematics through a critical examination of how mathematics has taken its current form and how it powerfully formats reality in ways that are often unjust (Pais, 2013).

In the context of mathematics education, a mathematics gaze focuses on bringing local knowledge into mathematics classrooms in the name of promoting diversity and highlighting that mathematics appears everywhere in the world (Pais, 2013). Although this is often accompanied by good intentions and the promises of multicultural education, there is a risk that an essentialist view of culture will be promoted that positions communities and peoples as foreign Others and ignores the tensions inherent in cultural approaches to education in multicultural contexts (Pais, 2011, 2013; Vithal & Skovsmose, 1997). For instance, in South Africa the meaning of *ethno* in *ethnomathematics* was used by policymakers to separate individuals into supposed cultural groups organized by race, wherein white students were provided a higher quality mathematics education (Vithal & Skovsmose, 1997). Ethnomathematics thus became associated with the racism of apartheid. Vithal and Skovsmose (1997) point out that in using ethnomathematics to structure the learning experiences of students in South Africa, there was a failure to specify the relationship between culture and power and a failure to recognize the formatting power of dominant mathematics and to teach toward cultural competence and self-empowerment.

Etic and Emic Perspectives

Albanese, Adamuz-Povedano, and Bracho-López (2017) propose two distinct approaches to incorporating ethnomathematics into mathematics education. Under the first approach, the mathematics of cultural groups are studied, understood, and taught from the point of view of dominant mathematics. The researcher, teacher educator, or teacher identifies and chooses cultural material to translate into the formal language of mathematics, even if this formal language does not exist within the studied community (Albanese et al., 2017). For example, Ascher and Ascher (1986) analyzed kin relationships found among the Aranda of Australia using diagrams and group theoretical terms. Borrowing terminology from anthropology (Rosa & Orey, 2012, 2013), Albanese et al. (2017) call this an *etic* perspective. In short, the etic approach is "the *recognition* of *mathematics in cultural practices*" (Albanese et al., 2017, p. 324). The goal of the etic approach is to build bridges between dominant mathematics and the mathematical practices of other cultures and to establish communication between them (Albanese et al., 2017). It suggests that dominant mathematics is a universal system that can be found everywhere, including within the cultural practices of communities that would not necessarily characterize these practices as mathematical (Pais, 2013). The pedagogical implication is that teachers ought to bring cultural contexts into the classroom under the assumption that students have experiences with or interests in out-of-school mathematical practices and that relating school mathematics to students' life experiences will lead to better learning (Pais, 2013).

The second approach is *emic*, which takes into account the categories and schemes of thinking of the community or cultural group of interest (Albanese et al., 2017). This leads to "the *discovery* of different *ways of thinking*" (Albanese et al., 2017, p. 324). For instance, bricklayers in some rural areas of Mozambique build houses with rectangular floors but do not have tools for designing right angles (Albanese et al., 2017). They use sticks and ropes of equal measure to find the vertices of a rectangle. This practice may be identified as deploying the property of rectangles that diagonals are equal and bisect each other (i.e. an etic perspective) or may be identified as a practice-embedded, operational definition for these bricklayers (i.e. an emic perspective). Barton (1999) explains that this approach to ethnomathematics rejects the idea of a universal mathematical or logical system to which both scholarly and cultural mathematics are a mere approximation. Mathematics in its most general form is instead a system for dealing with quantitative, relational, and spatial aspects of human experience, which Barton (1999) calls a "QRS system" (p. 56). Certain cultural groups have their own QRS systems. Dominant mathematics is one QRS system, and the purpose of ethnomathematics is to explore how different QRS systems relate to one another. Rather than being used to locate cultural contexts to import into classrooms, the emic approach suggests that ethnomathematics should be incorporated into a larger project of critiquing schooling and the curriculum (Knijnik, 2012; Pais, 2011, 2013).

Albanese et al. (2017) argue that both etic and emic approaches should be considered in every ethnomathematics project, including the use of ethnomathematics for teaching and learning mathematics. For instance, artisan-architects on an Indonesian island use a stick and pencil to find the midpoint of a segment based on a sequence of moves that yield a better approximation with each iteration (Albanese et al., 2017). An emic perspective would acknowledge the situatedness of this practice while an etic perspective would view the practice in mathematical terms, observing the ways the practice resembles error reducing algorithms (Albanese et al., 2017). Problems arise when both perspectives are not brought into dialogue. Merely contextualizing mathematical tasks without reflecting on the nuances between dominant and non-dominant forms of mathematics misses out on the opportunity to think about different ways of knowing (Albanese et al., 2017). Focusing exclusively on cultural ways of knowing misses out on the opportunity to seek correspondences between dominant mathematics and the cultural practices of other communities (Albanese et al., 2017).

Theorizing an Etic-Emic Approach to Mathematics Education

The previous discussion highlights the diversity in how one might approach the study, understanding, framing, and teaching of mathematics, particularly in light of the findings of ethnomathematics researchers that multiple mathematical systems exist. This motivates a framework for making sense of how an understanding of multiple mathematics might impact ones approach to mathematics education. For Albanese et al. (2017), a reasonable response is to seek dialogue between etic and emic perspectives on mathematics knowledge. In doing so, they acknowledge the significant formatting power of dominant mathematics and its role in modern society while still embracing different ways of knowing mathematics. However, if we are to take this suggestion seriously, there is a need to theorize what exactly such an etic-emic approach would entail. The next section proposes three dimensions to this theorization: re-mythologizing mathematics, pursuing recognition and reconciliation for Indigenous communities, and refusing colonization. Through these dimensions, a theorization would propose to do three things—deepen our understandings of ethnomathematics and its role in mathematics education, emphasize the relevance of decolonizing studies to mathematics education research, and speak to broader conversations about balancing dominant and non-dominant perspectives on knowledge within school curricula and teachers' instructional practices.

Re-Mythologizing Mathematics

Scholars in fields as diverse as anthropology, sociology, and education have shown the many ways in which mathematics is neither universal nor politically neutral (Appelbaum, 1995; Borba, 1990; D'Ambrosio, 2006; Eglash, 1997; Ernest, 1998; Gerdes, 1998; Gutiérrez, 2013a; Hersh, 1999; Iseke-Barnes, 2000; Knijnik, 2012; Skovsmose, 2011). Modern conceptions of mathematics have been shown to be rooted in mathematics' alleged purity and close connections to technology and the natural sciences (Skovsmose, 2011). The theorems and objects of mathematics have been shown to be cultural products created through human activity (Ernest, 1998; Hersh, 1999). Bishop (1990) challenges the idea that dominant mathematics is value-free, pointing out that such mathematics is grounded in four values: rationalism, objectism, power and control, and progress and change. Related to this conception of mathematics is a Western-based hierarchy of rationality that privileges abstract thought as the highest form of intellect (Gutiérrez, 2013b). Drawing on Foucault and Wittgenstein, Knijnik (2012) argues that dominant mathematics "expels 'out of its margins'" different kinds of mathematics by constraining the circulation of divergent mathematical discourses (p. 97). In each case, a critique is made that not only seeks to challenge mathematics education but also seeks to challenge the status of mathematics itself.

An etic-emic approach to mathematics education can be seen as part of this larger project to re-right views of mathematics that perpetuate myths about its universality and political neutrality. Wagner and Herbel-Eisenmann (2009) call on scholars to "re-mythologize" mathematics by reconceptualizing it with human stories that are not traditionally part of dominant mathematics discourses. The purpose is not to discredit dominant mathematics nor is it to "de-mythologize" dominant mathematics in an attempt to render it powerless. It must be acknowledged that the "myth of mathematics" continues to powerfully position students, teachers, and practitioners (Wagner & Herbel-Eisenmann, 2009) and that dominant conceptions of mathematics inevitably impose themselves on interactions among doers of mathematics. Ethnomathematics has and can continue to be used as a counter-narrative and engine for re-storying a plural understanding of mathematics. By balancing etic and emic perspectives on mathematics knowledge, reformers can continue to dismantle notions that Western mathematics is the only legitimate mathematical system. The ability to shift from one mathematical system to another promotes the view that Western mathematics is simply one of a multitude of culturally based mathematical systems, where each system is grounded in human activity and a particular set of values. In teacher education contexts, this approach can be used to support mathematics teachers in undergoing the epistemological shifts that Knijnik (2012) and Pais (2011, 2013) say are necessary for widespread mathematics education reform.

Pursuing Recognition and Reconciliation

An etic-emic approach to mathematics education can also be seen in relation to broader politics of recognition and reconciliation for Indigenous peoples. The dominant status of Western mathematics means that throughout history, alternative conceptions of mathematics among Indigenous peoples have been, and continue to be, marginalized or subject to erasure. Bishop (1990), for instance, shows how through dominant conceptions of mathematics, Western explorers sought to replace Indigenous mathematics through regimes of trade, administration, and education, which mediated a process of cultural invasion by dominant methods of measurement and numerical procedures and by a value system grounded in rationalism. Takeuchi (2018) finds that hierarchies created by dominant conceptions of mathematics led Filipina mothers to undervalue their mathematics knowledge—particularly with respect to calculating international currency conversions—and involvement in school education for their children. As Takeuchi (2018) explains, "[P]arents' funds of knowledge...can be masked through school practices if only certain ways of knowing are treated as legitimate and valued" (p. 139).

This process of erasure of Indigenous ways of knowing is not a mere accident of history but rather one of historicized and ongoing colonization (Bernales & Powell, 2018; Iseke-Barnes, 2000; Stathopoulou & Appelbaum, 2016). Bernales & Powell (2018) point to the Programme for International Student Assessment (PISA) and the tendency to "unreflectively copy the developed countries curricula, reinforcing power structures in the societies" (p. 566) as well as the "hominization of curricula that OECD's PISA causes on national curricula" (p. 566). An etic-emic approach can be seen as serving the project of reversing erasure and pursuing recognition and dignity in the face of dispossession of land and knowledge (Stathopoulou & Appelbaum, 2016). In schools, this would mean modifying curricula and pedagogical practices so that instruction begins with students' out-of-school knowledge and worldview of local culture while still giving students access to dominant mathematical discourses. Doing so provides recognition and dignity to students whose contemporary and heritage practices are delegitimated and displaced by Western mathematical values and practices (Stathopoulou & Appelbaum, 2016), and it can promote social justice through the fundamental values of ethnomathematics, which include respect, solidarity, and cooperation with other cultural groups (D'Ambrosio, 2007). Developing fluency around both dominant and non-dominant mathematical forms confronts what Battiste (1998) calls the educational model of "cognitive imperialism" (p. 17), which comprises of "Eurocentric strategies that maintain their knowledge is universal, that it derives from standards of good that are universally appropriate, that the idea and ideals are so familiar they need not be questioned, and that all questions can be posed and resolved within it" (Stathopoulou & Appelbaum, 2016, p. 38). This approach not only gives students access to mathematical practices necessary for social mobility but it also aids toward a process of "reconciling [the] dignity of each person" in light of "legacies of centuries of privilege and power, cultural authority and school-based deligitimation practices" (Stathopoulou & Appelbaum, 2016, pp. 39-40).

This approach of balancing "insider" and "outsider" views of mathematics must be seen as part of a larger movement in education to provide marginalized and minoritized youth with both dominant and non-dominant knowledge. Ladson-Billings (1995), for instance, puts forth a framework of culturally relevant pedagogy (CRP), which calls for academic excellence, cultural competence, and sociopolitical consciousness for students. CRP entails the development of "literacy, numeracy, and technological, social, and political skills in order to be active participants in a democracy" (p. 160). Paris and Alim (2006) extend CRP by proposing culturally *sustaining* pedagogy as a way to emphasize the preservation of students' heritage and contemporary practices and to foreground the way students often enact their cultural identities in novel ways. Stathopoulou & Appelbaum (2016) call for a similarly expansive view of culture within ethnomathematics, which have historically been based on static colonialist categories of culture. In contrast to these static colonialist categories, an etic-emic approach emphasizes a *fluidity* not just in how mathematics can be viewed but also how people and knowledge can be granted dignity and recognition.

Refusing Colonization

In contrast to the politics of recognition, an etic-emic approach can be theorized in terms of a *politic of refusal* (Coulthard, 2014; Grande, 2018; McGranahan, 2016; Mignolo, 2011; Simpson, 2007; Tuck, 2009; Tuck & Yang, 2014). Grande (2018) describes this politic of refusal in terms of Indigenous sovereignty, noting that refusal is not about attaining recognition but rather about reconstructing culture and tradition in a way that "positively asserts Indigenous sovereignty and peoplehood" (p. 59). Drawing on scholars such as Glen Coulthard, Audra Simpson, Walter D. Mignolo, and Anibal Quijano, Grande (2018) theorizes refusal as "a stance or space for Indigenous subjects to limit access to what is knowable and to being known" (p. 59) and a form of "epistemic disobedience" (p. 59) that severs the link between Indigenous and Western understandings of knowledge. Two important points must be made about refusal. First, refusal is an alternative to recognition, which seeks reconciliation with the state—an idea that several critical Indigenous scholars criticize "as a technology of the state by which it maintains its power (as sole arbiter of recognition) and thus settler colonial relations" (Grande, 2018, pp. 49-50). Second, refusal is connected to settler colonialism, which refers to colonialism premised on the removal of Indigenous peoples from land followed by the creation of labor and knowledge systems and infrastructures to make the land productive for settlers (Bonds & Inwood, 2016; Grande, 2018). In this light, refusal is premised on the idea that decolonization "is a political project that begins and ends with land and its return", and thus "the very nature of settler colonialism precludes reconciliation" (Grande, 2018, p. 53).

A politics of refusal troubles the possibility of taking an etic-emic approach to mathematics education. By seeking to recognize and reconcile both insider and outsider perspectives of Indigenous mathematical practices, one continues to legitimate the Western "gaze" as the arbiter of recognition. That is, attempts to reconcile dominant and non-dominant perspectives on mathematics reproduce configurations of colonial power that have and continue to deprive Indigenous people of knowledge. Raising the issue of *psycho-affective attachment* to colonialist forms of recognition, Grande (2018) discusses the "unequal exchange of institutionalized and interpersonal patterns of recognition between the colonial society and the marginalized" (p. 54). By seeking recognition and reconciliation, one may not be able to avoid the feelings of attachment to dominant knowledge forms felt among the colonized, as such feelings often stem from "inducements" (Wolfe, 2013), which manifest as the material and psychological rewards often associated with success in dominant mathematics.

This is not to say that Indigenous communities should not be taught dominant forms of mathematics knowledge, which can be instrumental for social and economic mobility. Rather, a politics of refusal highlights the competing impulses that can arise when one attempts to take an etic-emic approach to mathematics education—on one hand, a yearning to reconcile dominant and non-dominant ways of knowing but, on the other hand, a refusal of Western mathematics premised on Indigenous sovereignty and the delegitimization of the settler colonial state. For instance, Stanton (1994) describes a "both ways" mathematics curriculum for aboriginal teacher education, pointing out the extent to which dominant conceptions of mathematics were entrenched within the beliefs and attitudes of participants. He further describes the tensions created when teachers expressed the need for Aboriginal children to become prepared for key positions within their community through the mastery of dominant mathematical techniques. Stanton (1994) is ultimately optimistic about cross-cultural attempts to bridge dominant and non-dominant forms of mathematics, though his concerns highlight the difficulty that historicized and ongoing effects of colonization create with respect to reconciling etic and emic perspectives on mathematics.

Concluding Remarks

There has been a significant increase in attention toward concerns for equity and social justice within mathematics education, and yet ethnomathematics and decolonizing studies in mathematics education remain niche areas of research. This is despite the fact that dominant mathematical activity is a form of ethnomathematics. I discuss the project of balancing etic and emic perspectives on mathematics not only because it represents a key tension within ethnomathematics and decolonizing studies in mathematics education but also because it highlights how these research areas can speak to larger conversations about the role of dominant and non-dominant ways of knowing in curriculum and instruction. In this paper, I have raised the question of whose knowledge should be taught and from whose perspective. Although a reasonable response to this question might be to say, "everyone's knowledge and everybody's perspective", I have sought to nuance and problematize such an attempt at an etic-emic approach to education. The historicized context of math-making cannot be separated from the mathematical practices we seek to teach in classrooms. We cannot avoid the fact that much of the mathematics knowledge we seek to teach youth is laden with histories of settler colonialism, racial violence, and white supremacy. How, then, do we move forward? This paper's theorization does not offer a definitive resolution. At best, I offer this theorization to highlight the relevance of ethnomathematics and decolonizing studies for mathematics education research and to urge researchers to continue to critique dominant and oppressive forms of knowledge as part of a larger project of individual and collective empowerment.

MEASURING HIGH SCHOOL STUDENTS' FUNDS OF KNOWLEDGE FOR LEARNING MATHEMATICS

MEDICIÓN DE LOS FONDOS DE CONOCIMIENTO DE LOS ESTUDIANTES DE SECUNDARIA AL APRENDER MATEMÁTICAS

Tiffini Pruitt-Britton
Southern Methodist University

cwalkington@smu.edu

Mathematics experienced by students can be derived from the contextually situated "real world" experiences of the educator, which is typically White and middle class and not a reflection of the demographics of many classrooms in the United States. Activities where students find connections to their lives and interests have shown promise in enhancing student performance and experiences in mathematics classrooms. In this study, mathematics funds of knowledge are assessed in a novel survey instrument, reinforcing the salience of relating math experiences to students' lives and acknowledging skills and knowledge originating from experiences outside of the math classroom.

Keywords: Culturally Relevant Pedagogy, Equity and Diversity, High School Education

Many believe that there is no culture in mathematics. This would mean that arithmetic is the same no matter who a person is or where a person is physically in the world. However, the "real" in "real world" problems being solved is different for each student. Developers pull from their personal world but may not consider the perspective of their audiences. As such, many math word problems tend to be written from a white, middle class perspective (e.g., see Gerofsky, 2009; Frankenstein, 2009).

Expectations and decision-making of teachers are grounded in their cultural systems that may not align with those of their students. As teacher cultural expression is displayed and enacted through classroom practices, the lack of acknowledgement of those expressions and how they affect students can be problematic. The knowledge and awareness of how one's beliefs, experiences, values, and expectations are linked to their cultural identity is a major tenet of culturally responsive teaching (Griner & Stewart, 2013).

The racial gap between teachers and students in the United States continues to widen as the rate of diversity in teachers is declining more slowly than the rate of enrollment of students of color (NCES, 2017). According to NCES, White teachers make up 80% of teachers while over half of US students are Black, Latinx, Asian, Pacific Islander, Native American/Alaska Native or other races/ethnicities. This disparity in teacher-student ethnic demographics, structural barriers in advanced mathematics courses (U.S. Department of Education, 2018), lower expectations for African-American students (Gershenson & Papageorge, 2016), and racist policies for students being recommended for gifted courses (Ford, 1998), perpetuates the idea that there is no place for Students of Color in these classrooms.

Because of the opportunity gap that exists for students of color, math performance and preparation for college pathways in STEM for these students have become a matter of high interest and importance to teachers, schools and leaders in education policy and reform (Contreras, 2011; Gullatt, 2003; Noble, 2013; Marzocchi, 2016; Balfanz, 2006; Kotok, 2017). In this paper, we describe a research study conducted with high school students who were predominantly Latinx and African-American and were poised to become first-generation college students. Using a survey instrument we developed, we assessed students' everyday funds of knowledge for learning mathematics. The purpose of developing this assessment was to drive further instruction and enrichment in mathematics for these students. Here we report on the properties of the survey instrument, in the

hopes that it could be used by teachers and researchers to assess their students' funds of knowledge and enact culturally responsive teaching.

Theoretical Framework

Culturally Responsive Teaching

According to Ladson-Billings (1995), Culturally Responsive Teaching (CRT) includes (a) students having the opportunity for collective success, (b) students developing or maintaining cultural competence, and (c) students developing a critical consciousness through which they challenge the status quo of the current social order. These things are not typically found in everyday lesson plans and many teachers require assistance to include these characteristics of CRT into their pedagogy. CRT involves teachers maintaining a high level of "cultural competence" in their pedagogy (Lindsey, 2009). These teachers are able to gather from the cultural experiences brought into their classroom via their students in their learning environment. CRT not only requires acknowledgement of student culture, but also the use of student culture as a learning tool in the classroom. The culture of the classroom transcends ethnic backgrounds, but also includes sexual orientation, disabilities, religion and language (Rogers, 2016), among other identifications and groups. Culture also includes the community inside and outside of school.

Funds of Knowledge

Funds of Knowledge (FoK) are the everyday knowledge bases from which students experience and learn within their homes and communities (Gonzalez, et al., 2005). Posited from the works of Velez-Ibanez and Greenberg (1992), the concept of FoK conveyed the notion of the existence of skills, talents, aptitudes, and inter-cultural exchange within Mexican-American homes. Moll et all. (1990b) focused on FoK originating solely from the household, but updated this opinion later (2005) crediting that FoK must incorporate information accumulated outside of the household in varied settings and activities. Moje et al. (2004) found that students' FoK derived from a combination of the home, peers and other networks. Andrews and Yee (2006) concurred that FoK stems from students' lived lives including their personal interests and influences. These personal interests serve as a source of knowledge not only useful for the wellbeing of the household, but of the student as well. Barton and Tan (2009) actually describe FoK as deriving from students' interests and talents.

Although it has been shown that Latinx households demonstrate strength in the complexities associated with sharing recourses and social networks within their community (Velez-Ibanez, 1988), educators have historically not used these FoK as a resource inside the classroom. Taking educators out of the classroom and into the homes and communities of their students has been highlighted in the works of Gonzalez, Moll, and Amanti (2005). In this study, teachers became researchers seeking and discovering the household knowledge of students developing rich relationships which set the stage for transactions of knowledge between teacher and student targeting student interest. FoK were found to focus on activities and tactical knowledge deriving out of culture (i.e., social, economic, political) essential to household functioning and progression. The involvement of student background into daily lessons and teacher pedagogy requires teachers to take an authentic inventory of their students and those students' cultural experiences to truly direct their pedagogy with a culturally responsive lens.

FoK emphasizes the salience of both academic and personal background knowledge of students. A culturally responsive educator focuses and utilizes this accumulated lived experience and knowledge to build upon it, increasing student learning. The FoK used to navigate social contexts are affirmed in culturally responsive lessons when properly addressed and utilized. As educators facilitate culturally responsive opportunities for students to broaden their FoK including their world views shaped by cultural, historical and political events, students' sociopolitical and critical consciousness are influenced to critique the inequities in their own educational and societal establishments.

Funds of Knowledge for Mathematics

Funds of Knowledge in mathematics and connections between home and community involvement has been the subject of considerable research (Civil, 2007; Gonzalez, Andrade, Civil & Moll, 2001; Civil & Andrade, 2002; Nasir, 2002; Nasir, et al., 2008). The work of Civil (2007) on mathematical FoK focused on everyday life activities and how they connect to mathematics. Civil's work highlighted success in using FoK in the development of mathematics learning objectives through an educator's authentic desire to learn about their students' community, and to understand and leverage the community's resources and the knowledge originating from students' households. As opposed to making cultural generalizations about the community, teachers took invested interest in learning about their students' home and community lived experiences. Certain dilemmas are addressed in Civil's work, such as the tension between authentic problem-solving opportunities that relate to home and community experiences and dealing with socio-mathematical norms in the classroom where students are conditioned that mathematics "work" involves worksheets inside the classroom.

Work on FoK in mathematics has also been connected to research on personalizing instruction. Personalizing students' mathematics learning by drawing upon their FoK can affect student interest and performance in mathematics, as demonstrated in Walkington and Bernacki (2015). In their article, Walkington and Bernacki had students pose mathematical problems based upon their out-of-school interests in areas like sports or video games, harnessing their FoK to develop more meaningful connections to mathematical concepts. Walkington and Hayata (2017) also describe a series of teaching experiments where students posed, solved, and shared algebra problems related to their out-of-school interests.

Algebraic story problems can be presented to students as a method of contextualizing life experience to confront inequalities. In Turner, et. al., (2016), using students' FoK, an educator gave students opportunities to discuss mathematical situations where injustices they have experienced in their lives that could be represented as inequalities. Prompting students within the context of injustices with inequalities, students gained deeper understanding of constructing these types of equations and contrasting them against others.

While there is a large body of work that support the use of FoK within an educational context, there are also critiques of this practice. Zipin (2009) notes the absence of what he calls "dark" or negative pedagogies including abuse of others and substances, mental health issues and alcoholism. Here, the idea is presented that educators wish to only focus on "light" or positive FoK as opposed to the whole lived experience of students, light and dark, which may seem troubling for educators to consider in the classroom (Zipin, 2009). Although dark FoK may challenge traditional approaches by educators, it provides a rich and authentic source of knowledge from which students could draw. In addition, knowledge as metaphorical capital has been criticized for being incomparable to financial capital and has been framed as an inappropriate connection to the negative economic and political dominance of capitalism (Hinton, 2015). Oughton (2010) also points out the theory of funds of knowledge literature has morphed from deriving from household knowledge into various sources of knowledge which may be influenced by what the researcher has determined to be FOK. However, the power of individual, parental and educator agency as potential propelling forces behind the acquisition of knowledge and increases of performance in students is highlighted in by Rodriguez (2013).

Research Purpose

Very few prior studies have focused on quantifying FoK. In one such study (Rios-Aguilar, 2010), 212 K-12 Latinx students took the Latino/Hispanic Household Survey where connections to FOK were made to both academic and non-academic outcomes focused in reading and literacy. Rios-Aguilar (2010) found that activities and experiences in Latinx households contributed to both academic and non-academic outcomes for these students.

Here, our purpose was to expand this work and consider specifically what knowledge bases students might have that are relevant to learning mathematics. Our first research questions is: (1) How are different areas of FOK in mathematics related to each other? Our remaining research questions are: How do measures of students' FOK for mathematics (both overall and in individual areas) predict: (2) Student interest in mathematics? (3) Math grades? (4) AP math course-taking? (5) Dual Credit math course-taking? (6) Desire to pursue a career in STEM?

Method

Participants

This study included students participating in an educational program outside of school hours. These students are from various high schools in a large, urban, US Southwestern school district. Students' ages ranged from 14 to 17 years old. All students are low socioeconomic status and most are Black and Latinx. Similar to other US urban school districts, the one the students from this study come from serves over 150,000 students where 87% of the community is economically disadvantaged and 44% are limited in English proficiency. Students in the district were 69.6% Latinx, 22.5% African-American, 5.4% White, 1.4% Asian-American, 0.3% Native American, and 0.7% two or more races.

There were 72 students participating in the study with 49 (68%) female students and 23 (32%) male students. Students' self-reported grades in their prior math class were 24 (33%) with As, 41 (57%) with Bs, 6 (8%) with Cs, and 1 (1%) Ds. Seniors made up 14% (10) of total students while 44% (32) were Juniors, 24% (17) were Sophomores and 18% (13) were Freshman. Students' current high school math class included 10 (14%) in Algebra 1, 22 (30%) in Algebra 2, 3 (4%) in AP Calculus, 4 (6%) in College Algebra, 4 (6%) in AP Statistics, 12 (17%) in Geometry, 1 (1%) in Math Models, 13 (18%) in Precalculus, 1 (1%) in Trigonometry and 2 (3%) students that did not answer. Sixty-five percent of students indicated interest in pursuing STEM major in college and 68% of students were interested in STEM careers.

Students completed the survey on their phones. There were no incentives for the students to complete the survey. All included participants gave assent along with having parental consent.

Measures

This study used the researcher-created Mathematics Funds of Knowledge Survey (MFoKS) to assess students' level of FOK. The MFoKS is used to quantify students' level of Funds of Knowledge in 9 "bins" including: Money, Travel, Sports/Fitness, Social Media, Video Games, Cooking, Health, Art, and Directions. The survey is a 70 item mixed-model of qualitative (9) and quantitative questions (61). Each bin had 3-11 items. The survey includes a 5-point Likert scale including 1 for "almost never," 2 for "at least once a year," 3 for "at least once a month," 4 for "at least once a week," and 5 for "almost daily." The survey calculates FoK as a frequency of usage in each of the bin which will generate a score for each bin. Some examples of items from the MFoKS include: "How often do you check how many retweets or shares a post [on social media] has gotten?" and "How often do you pay attention to how many plays, spins or streams a song has?" and "How often do you consider different shipping rates when shopping online?"

The overarching survey that students in the educational program took also included questions about students' interest in mathematics using a scale from Renninger and Schofield (2014) with 24 Likert questions ranging from 1 to 5. Students had an average score of 2.89 in math interest.

Data Analysis

To answer the first research question, a correlation matrix was generated to determine which categories were highly correlated or not correlated. The remaining research questions were answered using regression models. The *lm()* command was used in RStudio. The outcomes were average math interest (rated on a 1-5 scale), grade in their last math course (4=A, 3=B, 2=C, 1=D), AP Track (i.e., a 0/1 variable denoting whether the student was in AP math classes), Dual Credit (i.e., a 0/1 variable denoting whether the student was in Dual Credit classes) and STEM Major interest (i.e., a 0/1 variable denoting whether the student was interested in majoring in STEM). Math interest and last math grade were fit as linear outcomes. The *glm()* command was used for AP Track, Dual Credit, and STEM Major Interest, as these were 0/1 variables - we used the binomial family and logistic regression. Predictors in the models were average 1 – 5 Likert scale ratings of the 9 areas in funds of knowledge. Control variables (not shown in table for brevity) were what math course the student was currently enrolled in and their gender. The Dual Credit model also included an additional control for what year in high school the student was currently enrolled, as dual credit opportunities are usually for older students.

Results

Students rated their FOK for mathematics highest for cooking, with an average rating of 3.56. The lowest FOK rating across student was for Money with an average rating of 2.46.

With respect to our first research question, when examining how students' ratings of the 9 different areas of FOK were related (Table 1), none of the correlations were over 0.6, which suggests that all 9 of the areas of funds of knowledge surveyed may be distinct from one another. It was also found that there were higher correlations between money and travel, health and art, and cooking with travel, sports, health, and art. FOK areas found to have low correlations with each other were money and art, and video games with travel, sports, social media, health, cooking and distance, with the lowest correlation found between video games and travel.

For the second research question, we found that in the regression models (Table 2) math interest was significantly positively predicted by certain areas of FOK. The FOK areas showing significance include money (p = .004), travel, (p < .0001), cooking (p = .019), distance, (p = .034), and, overall mathematics FOK (i.e., a composite average from the 9 areas; p = .005). For the third research question, it was found in the regression models that travel showed significance in positively predicting math grade (p = .04). The fourth research question addressed predicting the AP Track of students, and it was found that travel (e.g., recognizing the use of numbers and distances while using various modes of transportation) showed significance as a negative predictor (p = .023). For the fifth research question, it was found in the regression models that social media showed significance in negatively predicting Dual Credit enrollment (p = 0.035). The sixth research question addressed STEM Career interest which was significantly and positively predicted by travel (p = .008), social media (p = .046), and overall mathematics funds of knowledge (p = .034).

Table 1: Means, standard deviations, and correlation matrix

FOK Variable	M	SD	1	2	3	4	5	6	7	8	9
1. Money	2.46	.726	--								
2. Travel	2.55	1.080	.45	--							
3. Sports	3.16	1.216	.28	.35	--						
4. Social Media	2.92	1.212	.39	.26	.40	--					
5. Video Games	2.86	1.557	.30	.00	.02	.15	--				
6. Health	3.1	1.219	.23	.29	.43	.37	.18	--

Distances	.21(.08)*	.07(.06)	-.11(.22)	.28(.24)	.31(.21)

Discussion and Conclusion

In the present study, we developed a quantitative measure of students' FOK for learning mathematics, and discussed the results of administering this measure to a sample of high school students. Our measure covered 9 facets of everyday funds of knowledge, which correlational results suggest were distinct areas – with some facets of FOK being more highly related to each other than others. Our next step will be to conduct a factor analysis and calculate internal consistency values for the survey instrument. We also found that students' FOK for mathematics were predictors of mathematics outcomes that we would care about for students – particularly interest in learning mathematics and their interest in careers in STEM related fields. This suggests potential directions for future work – leveraging students FOK in the classroom could enhance students' interest in learning mathematics, as could asking students to increasingly apply a mathematical lens to their everyday activity. Cultivating students' mathematics FOK could also influence career interest in STEM fields, an area underrepresented by Latinx and African-Americans (Funk & Parker, 2018). A well-designed survey instrument could help teachers assess their students' FOK to be used in targeting instruction; this paper represents the first step towards creating such an instrument.

The purpose of the MFoKS is to collect and quantify students' levels of FoK focused in mathematics for daily living. When teachers and administrators have access to student math FOK, they are able to utilize student interests in personalized lesson plans and identify strengths of their students for participation and opportunities. Students' FoK data counters the narrative about deficits students have with experience with mathematics and numbers outside of the classroom. Lastly, the MFoKS can provide administrators and community leaders with the blueprints for establishing programs to build math FoK in the community.

PREDICTING THE MATHEMATICS PATHWAYS OF ENGLISH LANGUAGE LEARNERS: A MULTILEVEL ANALYSIS

Cristina Runnalls
California State Polytechnic University, Pomona
ccrunnalls@cpp.edu

This study employed hierarchical linear modeling to investigate the student- and school-level factors associated with the secondary mathematics achievement of English language learners (ELLs) and non-ELL students among a nationally representative sample of ninth graders in the United States. While certain characteristics, such as socioeconomic status, attitudes and interest in mathematics, and school engagement and belonging were predictive of access to and achievement in mathematics for both student groups, the direction and relative magnitude of the predictors differed. School-level variables, such as whether the school was public or private and administrator perceptions of school climate, were only predictive of mathematics grade point average (GPA) for non-ELLs. Implications of the findings are discussed.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Equity and Diversity; High School Education

English language learners (ELLs) are among one of the fastest growing groups of students in the United States. This group of students vary considerably in terms of English language proficiency, educational experiences, and many other factors (National Center for Education Statistics, 2004; Ryan, 2013). Adapting to these shifting demographics has proven challenging for educators, who must contend with difficulties in the fair identification of ELLs (Carlson & Knowles, 2016), simultaneous attention to language and content (Janzen, 2008), and development of appropriate assessments (Abedi et al., 2005; Bailey & Carroll, 2015).

These issues become increasingly urgent in the face of evidence that ELLs continue to face limitations in access to multiple educational outcomes. ELLs are less likely to graduate high school (National Center for Education Statistics, 2004) and some researchers have found that ELLs encountered more restricted access to college preparatory courses and postsecondary planning (Callahan & Shifrer, 2016; Kanno & Cromley, 2013, 2015). The lack of access to resources may lead ELL students to conclude that academic success is not be for them (Kanno & Kangas, 2014; Menken & Kleyn, 2010). Such beliefs are not reflective of the possibilities of public education, and as educators it remains our duty to address these discrepancies in opportunities to learn.

Note that the term "English language learner" or "ELL student" is used throughout the text to align with the phrasing used by the federal data analyzed in the study, and the language that continues to be used across many policy documents. The author more strongly recommends use of the term "emergent bilingual" to refer to linguistically diverse students, as it demonstrates a greater respect for the student, their existing knowledge of a home language, and their emergent language skills in other languages.

Purpose of the Study

Much past research has focused on general educational outcomes of ELL students, with more attention paid recently to ELL students' progress through secondary mathematics course-taking (e.g. Thompson, 2017). Special attention to ELL students progression through secondary mathematics is key for several reasons. Mathematics courses are required for graduation, and almost always serve as gatekeepers for postsecondary access (Adelman, 2006). While there remains a significant language factor involved in the study of mathematics (Schleppegrell, 2007), these courses retain an important

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. place in the majority of students' access to postsecondary access, secondary graduation, and future access to a wide range of STEM fields.

Given the disadvantages facing ELL students, as well as the importance of mathematics for future academic success and attainment, it is critical to understand how the mathematical progress of ELLs in high school differs from that of their English-proficient peers, and whether factors predictive of success differ between the two. The primary research question was the following: What student- and school-level factors are significantly related to the secondary mathematics attainment of ELL and non-ELL students, and to what extent do key factors differ between the two groups?

Theoretical Framework

The present study was framed using Bronfenbrenner's ecological model of human development (Bronfenbrenner, 1976, 1977). Bronfenbrenner proposed that human development evolved through increasingly complex interactions between the organism and its ecological environment. The environment was conceptualized as multiple nested levels of influence, where levels ranged from the environment surrounding the individual (microsystem), up to relationships with others inside and outside the environment (mesosystem, exosystem), and expanded to include how society impacts the individual (macrosystem) and how influences change over time (chronosystem). In education, this model posits that students' learning is closely connected to the learning environment (classroom,) and shaped by interactions with actors in the environment, such as students, teachers, and administrators (Bronfenbrenner, 1976).

The microsystem was of primary interest to the present research, defined as "the complex of relations between the developing person and environment in an immediate setting containing that person" (Bronfenbrenner, 1977, p. 514). This level reflects the initial point of interaction between the individual and the environment. Variables at this level include perceptions of the environment and roles adopted within that environment, as well as relationships between student, teachers, and peers. Bronfenbrenner's model was used to select variables likely to affect mathematics outcomes in secondary school. Students' development in the mathematics classroom may be impacted by factors at multiple levels, ranging from psychological or cognitive factors to social or cultural. The present research drew on the ecological model to select variables that may impact students' mathematics attainment primarily in the microsystem.

Method

This study used two-level hierarchical linear modeling (HLM) to analyze restricted-use from the High School Longitudinal Study of 2009 (HSLS: 09). The HSLS: 09 consisted of data from a nationally representative group of approximately 24,000 students from over 900 schools. The study collected data beginning in 2009, with follow-ups in 2011, 2012, 2013, and remains ongoing. Analyses in this study were restricted to students with data regarding their status as an ELL student prior to 9^{th} grade, and weighted using NCES-provided weights to account for non-response bias in the sample from 2009 through 2013. This restriction resulted in an analytic weighted sample of 3,220,965 students, with 124,042 ELLs prior to 9^{th} grade nested within 91 schools and 2,930,349 non-ELLs nested within 920 schools.

Variables

A total of 13 student-level variables and 9 school-level variables were selected for study. Student-level variables included factors such as socioeconomic status (SES), race/ethnicity, affective characteristics, and school engagement and belonging. School-level variables included factors such as whether the school was public or private, school climate, and percentage of ELL students enrolled. The outcomes of interest were the number of mathematics credits earned and mathematics grade point average (GPA). These two measures were chosen as a proxy for the number of mathematics courses completed, as well as an average success in those courses.

Data Analysis

Analysis began with the unconditional model containing only one outcome variable and no independent variables. The unconditional model allows for examination of whether the school grouping variable has a significant impact on student-level scores. Next, full models were developed that introduced both student- and school-level variables to the unconditional model. First, to examine the absolute effects of the independent variables, each student- and school-level variable was tested individually. Statistically significant variables ($p < 0.01$) were then introduced together to examine relative effects. To achieve parsimony, variables that were no longer statistically significant were removed one by one, beginning with the variable with the largest p value and proceeding until all remaining variables were statistically significant. The resulting models reduced the overall complexity of the final model, and allowed us to focus only on those variables that had both absolute and relative effects on the outcomes of interest. The same procedures were carried out separately for both ELL and non-ELL students.

Results

Descriptive Statistics

Examination of the descriptive statistics in Table 1 indicated that students who had been previously classified as ELL demonstrated lower number of mathematics credits earned and lower mathematics GPA. There was a significant difference in scores for both mathematics credits earned and mathematics GPA ($p<0.001$). Previously ELL students also had significantly lower SES and standardized mathematics assessment scores.

Table 1: Descriptive Statistics for the HSLS Student Sample

	ELL Previously		Never ELL	
	M	SD	M	SD
Mathematics credits earned	3.50	1.26	3.64	1.16
Mathematics GPA	2.12	0.92	2.38	0.94
Socioeconomic status	-0.58	0.73	0.03	0.79
9^{th} grade standardized score	-0.23	1.33	0.06	1.08

City	0.46	--	0.30	--
Suburb	0.33	--	0.34	--

Town	0.06	--	0.12	--
Rural	0.15	--	0.24	--

[a] Native Hawaiian/Pacific Islander, American Indian/Alaska Native, and More than one race categories are excluded due to low proportions relative to the entire sample size (<0.01)

Unconditional Models

Table 2 presents the unconditional models for both mathematics credits and mathematics GPA models for ELL and non-ELL students. Calculation of the ICC of each model proceeded by dividing the between-school variance by the total variance. The ICC ranged between 28% and 55%, suggesting that a significant proportion of variance of the outcome measure was at the school-level. This implied a multilevel nature of the data and justified further use of HLM.

Predictors for ELL Students

Table 3 presents the final models for ELL students. At the student-level, 10 out of the 12 variables were significant. SES, mathematics utility, and school engagement were all strong predictors of increases in credits earned. Mathematics assessment score and school belonging were also positively related, although smaller in magnitude. Alternatively, both self-efficacy and interest in 2009 mathematics course were negatively related to credits earned.

Regarding mathematics GPA, 10 out of the 12 student-level variables were significant. Mathematics assessment score, SES, mathematics identity, self-efficacy, and school engagement were all positively related, while interest and school belonging were negatively related.

Of the 7 school-level variables examined, none were statistically significant predictors of either credits earned or GPA for ELL students.

Predictors for Non-ELL Students

Table 4 presents the final models for non-ELL students. At the student-level, 10 out of the 12 variables were statistically significant. Specifically, increases in SES, assessment score, identity, self-efficacy, belonging, engagement, and interest were all significantly and positively related to mathematics credits earned.

Regarding mathematics GPA, 11 out of the 12 student-level variables were significant. Increases in SES, assessment score, identity, self-efficacy, engagement, interest, and belonging were positively related to GPA, while mathematical utility was negatively related.

Of the 7 school-level variables examined, none were significant predictors of credits earned for non-ELL students. However, 2 of the 7 school-level variables were significant for non-ELL students, with private schools and positive school climates related to increases in GPA.

Discussion and Significance of the Study

The present study explored the associations between mathematics credits earned in high school, mathematics GPA, and student- and school-level factors for ELL and non-ELL students. While many variables were predictive of both outcomes for ELL and non-ELL students, effects differed between the two groups. Such differences highlight the need for educators to approach students who are or have been classified as ELL in ways that specifically target these differences, acknowledging that assistance which may be beneficial to non-ELL students may not be as effective or necessary for ELLs. Key differences are discussed below.

Perhaps one of the most concerning findings is that of the statistically significant negative relationship between interest in 9th grade mathematics and both access and achievement in mathematics outcomes for ELL students. “Interest” in this survey was operationalized as a composite of students’ responses to six survey questions, all of which addressed the extent to which the student enjoyed mathematics and spoke of it as a preferred subject. In both final models, interest was related to decreases in the outcome measure, indicating that ELLs who began with higher levels of interest were more likely to experience worse access and achievement. Such findings indicate the need for investigation into the experiences of ELL students who exhibit mathematics interest early on, but perhaps then struggle to pursue that interest. Early interest in mathematics is vital in encouraging future growth, and efforts must be made to turn ELLs’ interest in 9th grade mathematics into a positive predictor of future success.

While many of the relationships between attitudes, school perceptions, and the outcomes were significant, the effects of variables such mathematics identity, efficacy, and engagement were inconsistent between the two groups. For example, belonging was positively related to GPA for non-ELLs, but negatively related for ELLs. Mathematics identity was a significant positive predictor for non-ELLs’ credits earned, but insignificant for ELLs. One potential reason for these contradictory findings is that while mathematics identity and sense of belonging in the classroom are representative of the role the student adopts in their learning environment, this role may not necessarily be recognized by others in that environment (e.g. teachers, administrators, counselors). ELL students may find themselves fighting inaccurate academic placements or reduced opportunities to learn, despite their own beliefs and self-perceptions. These findings indicate also that the relationships between student attitudes and feelings of belonging and engagement differ for ELLs compared to their English proficient peers, and these details are difficult to identify. As educators, it remains critical to attend to all students’ feelings of belonging and engagement, self-efficacy, and views of mathematics. However, it is necessary to keep in mind that such efforts may not have the same effects on all students, and students who were previously classified as ELLs may require more positive focus on mathematics utility, self-efficacy, and feelings of school belonging.

Finally, the final models for both ELL and non-ELL students included few school-level variables, with many significant predictors entered at the student-level and much variance unaccounted for at the school-level. Such findings indicate that there are other unaccounted for school-level variables which contribute to the school-level variance, likely related to aspects of institutional climate or environmental issues beyond the control of the student. Further investigations should include other more school-level variables to account for these differences.

The mathematics pathways of ELLs and non-ELLs differed significantly. Students previously classified as ELL were significantly more likely to earn fewer mathematics credits and a lower mathematics GPA. Some factors, such as SES and mathematics assessment score, exhibited similar positive relationships with the outcomes for both groups. In these cases, educators may continue to address both student groups in similar ways. For other factors, such as a student's interest in their 9th grade mathematics course, school belonging and engagement, and other attitudes, it is necessary to proceed with caution. A student's linguistic background and prior classification may have long-lasting effects on their mathematics success, and it is critical to acknowledge the ways their school experiences differ. Careful attention should be paid to fostering and maintaining early interest in mathematics, as well as developing mathematics self-efficacy and utility for ELL students. While school-level factors did not appear as often as student-level factors, the two are often intertwined, and educators should seek to positively impact ELL students' experiences throughout their school experience.

WHY THEORIZING AFFECT MATTERS FOR MATHEMATICS EDUCATION RESEARCH

Ryan Ziols
Georgia State University
rziols@gsu.edu

This paper briefly examines theories of affect and some of its possibilities and limits for mathematics education research. First, psychological, socio-cultural, embodied, and new materialist perspectives are considered. The paper juxtaposes emerging and older theories of affect in mathematics education with alternative approaches in the humanities and social sciences. Then, the paper briefly historicizes some of the changing and enduring economies for affect in mathematics education across three historicized "moments" of U.S. mathematics education reform circa the 1830s, 1890s, and 1930s. This section aims to consider some of the ways 'bodies' have become differently legible for theorizing affect in problematic ways with potential implications for future research.

Keywords: Affect, Equity, Body Studies, Emotions, Inclusive Materialism, Reform, History

What is affect and why might its theorizations matter for mathematics education research? To start, affect, however conceptualized, is widely considered to be important to learning school mathematics. Most commonly, affect has been defined as a complex psychologized construct located in individual minds, distinct from cognition, and bundled with some amalgam of emotions, attitudes, moods, feelings, beliefs, and/or values (de Freitas & Sinclair, 2019; Hannula, 2012; McLeod, 1994). Somewhat less frequently, affect in mathematics education has also been theorized to include physiological effects, such as changes in neuronal firing patterns, pulse rates, skin sensations, and other changes – sometimes at levels considered outside the range of conscious awareness (de Freitas & Sinclair, 2019; cf. Dowker, Sarkar, & Looi, 2016). More recently, socio-cultural and -historical perspectives have begun to (re)consider affect as something that may also exceed analysis at the level of the individual, such as by theorizing its emergence through practices, activity, and/or norms (Hannula, 2012; Roth, 2012).

The latter focus on practices, norms, and activity have also intersected with a recent proliferation of "body studies" (de Freitas & Sincliar, 2019; Roth, 2012). Here, perspectives tend to eschew long-standing dualisms familiar to mathematics education research (e.g., cognition/emotion, mind/body, abstract/concrete). For example, a "mathematical concept" conceptualized with a Deleuzean-Spinozan perspective, may be approached as a kind of 'body' that affects (and is affected by) classroom atmospheres, teacher-student conversations, and corporeal body movements (de Freitas & Sinclair, 2014). This notion of affect need not privilege human agency or center the human as 'in control' of the 'bodies' that are made through shifting material-discursive practices and/or "affective networks" (de Freitas, Ferrara, & Ferrari, 2019; see also, Barad, 2007).

At the same time, despite considerable social and political shifts occurring through the COVID-19 pandemic, a 'mathematical concept' may at once circulate as a 'new' amalgam of messy and dynamic 'bodies' that, without alternative possibilities for thinking-doing, tend nonetheless to stabilize what (school) mathematics may be, become, and/or do. Put another way, while 'bodies' may produce complex and emergent amalgams of *affectivity*, much not only necessarily escapes capture by the research apparatus - (school) mathematics is also stabilized by grids of capture that treat affect as a knowable 'object' or 'objects' that take school mathematics as a more or less neutral site for producing affect based on various pedagogies (see also, Popkewitz, 2008). Indeed, mathematics education research has little theory to engage research questions that attend to such (always partial and incomplete) complexity, messiness, and multiplicity. Yet, theories of affect in the humanities and

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

social sciences have for several decades offered possible entry points that do not seek to foreclose (school) mathematics or the 'bodies' with potential for affectivity as stable or necessary objects of inquiry (see also, Sinclair & de Freitas, 2019).

Of course, opening to new possibilities may also invite old dangers. For example, and as discussed briefly below, the emergence of efforts to theorize the mind as something interdependent with the corporeal body and, at times, as intimately linked with emotionality and materiality have historical antecedents that were also problematic. For example, Herbartian efforts to mathematize and study 'correct' sensation as the basis of truth claims were carried forward through social control projects and scientific racisms in the late nineteenth century in ways that continue to haunt contemporary education (see, e.g., Crary, 1988).

This theoretical paper, then, aims to provide a brief introduction to theories of affect in mathematics education research and consider both possibilities and limits for mathematics education research. In the first section, the paper provides a brief overview of research on how affect has been conceptualized in mathematics education research. In the second section, examples of three well-circulated perspectives on affect theory from the humanities and social sciences that are largely absent in mathematics education are considered. Finally, the focus shifts to three sketches of "moments" in U.S. discourses taken from a larger study investigating how objects of inquiry (or, 'bodies') in psychologized and socio-cultural approaches to research have shifted with respect to changing economies for affect in U.S. mathematics education. Because an in-depth discussion is not possible in this space, the "moments" selected are not intended as comprehensive 'histories.' Rather, they are intended as entry points for further discussion about how affect has become differently available with shifting notions of 'bodies' and their presumed relations. Finally, the approach to the three "moments" also seeks to draw attention to how emphasis on 'affect' may inadvertently stabilize the 'bodies' it purports to investigate in ways that obscure their historical traces in making the present appear thinkable and actionable (see Popkewitz, 2008; Yolcu & Popkewitz, 2019).

Theorizing Affect

Affect in Mathematics Education Research. There has been wide agreement across many fields in the social and mind sciences that affect is messy at best. As noted above, affect has been operationalized and defined in mathematics education research as something primarily bio-psychological, and, with less frequency, as something socio-culturally and historically contingent. As a psychological construct, affect has typically been considered something available to self-report in the form of emotions, beliefs, attitudes, values, and moods; where each category is presumed to differ primarily with respect to duration and/or intensity, and, at times, with respect to relation with (but distinct from) cognition and sometimes behavior (Hannula, 2012, 2019; McLeod, 1994). For example, a belief may seem more durable over time when compared with an emotion, mood, or feeling and have different 'effects' on cognition (McLeod, 1994). In studies prior to those considered explicitly as part of what became considered domain-specific studies of "affect" in the late 1980s, attention to 'affect' tended to center on constructs of anxiety and attitudes (see, e.g., McLeod, 1989; Zan, Brown, Evans, & Hannula, 2006). More recently, psychologizing approaches have also begun to include notions of identity and motivation among the collection of psychologized constructs (Hannula, 2012).

Socio-cultural perspectives on identity formation have also circulated widely in 'equity'-oriented literature. However, such scholarship rarely attend explicitly to theories of affect. This is particularly of note given the prominent role given to theories of affect once had on formulating theories of identity formation (e.g., that school mathematics appears to *affect* identity formation differently across racialized, gendered, and abilized categoriess) (see, e.g., d' Ambrosio, 1987; Fennema, 1979). More recently, theories of affect in 'equity'-oriented scholarship may be implicit in concerns with identity formation in multiple ways. For example, calls for improving "engagement" with school mathematics often require assumptions that something beside 'cognition' matters for learning, such as with what appears to constitute a "racialized narrative", grids of "positionality", an activity, or an artifact (e.g., Nasir & Shah, 2011).

In more recent socio-cultural approaches dealing explicitly with theories of affect, some scholars have claimed that intellect and thought are fundamentally inseparable from emotion (and/or affect) in ways that are culturally and historically specific (e.g., Radford, 2015; Roth & Walshaw, 2019). Additionally, Hannula (2012) has argued that affect understood through "situatedness" or "enactivism" may be understood as a social as well as mental process. Related scholarship has argued that recruiting the corporeal body and/or social groups to make generalizations based on movements and/or practices as adaptation to situations and environments also work to erode long-standing emotion/thought and mind/body binaries (Hannula, 2012). However, the majority of scholarship from socio-cultural and -historical perspectives has not engaged in substantive historicizing or moved much away from emphasizing that 'emotions' and 'bodies' are cultural and historical productions (see, for examples, Radford, 2015; Roth, 2012; cf. Yolcu & Popkewitz, 2019).

Biological and/or physiological theories of "affect" are often located somewhere between the confluence of second-order cybernetics and new materialisms, neuroscience, and physiology. At one pole, for example, transcranial electrical stimulation (tES) has been offered as a potential hope for treating "mathematics anxiety" (Dowker et al., 2016), reducing affect to something solely in the brain. At another pole, theories of embodiment that avoid brain-based reducationisms abound. Examples include perspectives linking gestures to semiotic constructions (e.g., Abrahamson, 2009), embodiment as generative of metaphorical worlds-forming (Lakoff & Nuñez, 2000), or relational embodiment as immanent to what it means to be and become a mathematical 'body' (de Freitas & Sinclair, 2014). While the former two perspectives on embodiment have been discussed at length (see, e.g., Hannula, 2012; de Freitas & Sinclair, 2013; Radford, 2009), inclusive materialisms are more recent arrivals to the literature. In brief, and often drawing from feminist and post-structural perspectives, inclusive materialisms assume relationality as an *ontological* commitment, where matter and mathematical concepts, diagrams, or other objects, much like corporeal bodies and feelings, are not bracketed out as something independent of language or thought. Matter, like subjectivity, from this perspective, is thus necessarily ongoing, immanent, unfinished, agential, and perspectival (de Freitas & Sinclair, 2013). In other words, 'bodies' are *made* mathematical by a "dance of agency" that does not start or finish as a property of or in people or things (p. 454). Rather, "agency" is understood as emerging through the complex and ephemeral ways human-nonhuman assemblages become differently intelligible for thought and action, such as through tools, symbols, pedagogies, curricular texts, corporeal body gestures, and research.

In some ways, new materialisms also invite comparisons with second-order cybernetics and enactivisms that themselves recall lines of research drawing from American cybernetics-inspired radical and social constructivisms (de Freitas et al., 2019; Hannula, 2012; see also, Eisenhart, 1988; von Glasersfeld, 1995). For instance, relational and systems-oriented ways of knowing do not presume or center an observer that is independent from complex social and material fluxes that are always partial and emergent. However, inclusive materialisms differ in important ways. For one, material (or the 'environment') is not a neutral space devoid of its own agency. Rather, matter is both produced through discourse *and* produces discourse. Put another way, 'maps' of minds, groups, flows, and/or practices are only possible because the various objects bracketed through apparatuses of observation also 'map back' in ways that 'cut' and make 'bodies' differently legible, invisible, and/or 'able' (Barad, 2007; Yolcu & Popkewitz, 2019). For instance, 'mapping' the purported cognition of a child also participates in *making* the child's cognition as something available for new strategies of intervention through pedagogy, policy, and research (see also, Popkewitz, 2008). In the next subsection, additional alternative approaches to theorizing affect in the social sciences and humanities are considered as potential supplements to existing scholarship in mathematics education.

Affect Theory. In one reading of affect theory, Sara Ahmed (2010) defines affect in part with the term "affective economy" as "what sticks, or what sustains or preserves the connection between ideas, values, and objects" (p. 29). Here, affect is not understood as an emotion or feeling *per se* (though whatever may be understood as an emotion or feeling are not excluded from participating in affective economies). Rather, affect is considered to be *circulated* as a kind of *economy* in the sense that objects become affective and "sticky" through their circulations. In other words, affective economies circulate in ways that may recruit notions of the cultural, psychological, and the political, but they also exceed capture as something *primarily* psychological and cultural that can be located as something 'in' individuals or 'in' social groups. Rather, affective economies gesture to how different notions of interiority and exteriority are produced through material-discursive practices. For one example, by thinking of "growth mindset" as something that may produce neuronal growth (and thus rebiologized notions of "intelligence") in the brain (Boaler, 2015), the brain (and neuronal growth) also becomes exteriorized and mappable as a site appearing to justify new forms of intervention (e.g., those that may promote "mindset" changes) and create new notions of interiors that can be divided and sorted in ways that perpetuate exclusionary practices (e.g., those that 'have' growth mindset and those that do not). Yet, whether or not "growth mindset" is considered in this way or otherwise, the notion of "mindset" has also become "sticky" and circulated in 'other' economies of affect concerned with enhancing and optimizing bodies and selves assigned various degrees of risk. A possible critique of perspectives of affect for Ahmed include the potential 're-centering' of affect as something involving emotions, feelings, and/or something of the psyche, however deconstructed.

From another perspective, affect theory is concerned with how bodies are 'affected' and 'affect' each other *prior* to and/or between 'capture' and labeling as emotions, feelings, etc. (Massumi, 1995; de Freitas et al., 2019). Here, affect is *not* emotion, feeling, attitude, belief, etc. – it is potentiality. This analytic shift involves theorizing both the messiness and the incompleteness of the assemblage of 'bodies' that appear to make emotions and feelings possible for capture and 'self' through processes that exceed human control and/or agency. By 'decentering' the human, some analyses have emphasized studying physiological and neuronal changes that seem to anticipate *and* exceed conscious 'capture' in the messiness of the everyday (Massumi, 1995). If, for example, mathematics anxiety (or joy) is approached not as a state or dynamic construct but as something necessarily partial, emergent, and messy, what assemblages of 'bodies' (e.g., tools, symbols, spaces, temperatures, political 'moods' and 'atmospheres', texts, etc.) may be virtually affective *before* it it put into feelings labeled as 'anxiety'? Or, how do not-quite-yet sensations and changes in 'bodies' become differently available for capture in research apparatuses when viewed as potential pathologies (e.g., as anxiety) through cultural theses about which "mathematical bodies" are desirable (and having 'health') and which are not (and thus needing 'intervention')? Despite the promise of new lines of inquiry that take seriously health discourses in relation to school mathematics in such ways, it is also of note that critics have argued that this approach may invite new and problematic universalisms and reductionisms, especially when affect appears to be something relocated in neurons and/or physiological responses in ways that recall various forms of humanism (see, e.g., Rutherford, 2016).

Additional perspectives in affect theory have built on the work of Sedgwick and Frank (1995) and suggested that even more familiar constructs such as 'emotions' like *shame* can be quickly denaturalized by attending to its complex, contingent, and multifaceted messiness that exceeds capture as a clear construct. For instance, shame as an amalgam of "interest-excitement" and "surprise-startle" and "contempt-disgust" *at the same time* invite a kind of messiness and incompleteness less familiar to more orthodox psychological renderings that have since been circulated as entry points into rich description in gender and sexuality studies. Turning to mathematics education, the always already excess of categories may provide entry points into studies that question either/or paradigms that often assign affect constructs along continua of duration, intensity, and absence/presence. Further, they may invite new renderings that open discussions about identity that exceed efforts to generalize and reduce identity to debates between essence and/or environment. Such perspectives may also open new lines of inquiry into 'old' problems, in part by noting how questions of knowledge-power in mathematics education-related spaces are not simply matters that can be hashed out on an 'empowerment-oppression' continuum. Critiques may question the extent to which complicating existing constructs move away from centering the 'self' and experience as the primary focus of theories of change.

Finally, affect theory also may have something to say about how research is presented, as the *approach* to writing also matters in much contemporary affect theory (Massumi, 2015; Seigworth & Gregg, 2010). It is not enough, for example, to address racializations/racisms in mathematics education through counter-narratives, histories, quantitative studies, or meta-analyses without *also* attending to the (political) aesthetics of presentation and the circulations of affective 'bodies' that are differently "sticky", such as via terms like equity, urban, or diverse. Additionally, if the human is not centered as the primary agent or subject-object of analysis, how might affect theory at once contribute to analyses of a broad field of possible considerations involved in the makings of what produces possibilities for feeling, action, and/or thought while not collapsing the potential for 'strategic essentialisms' that may offer new points of resisting oppression? This may not be an either/or – perhaps by explicitly attending to the messiness of how geographies of social categories (e.g., race, gender, class, ability) become configured through the messy and ongoing emergence of new 'body' assemblages that exceed the possibilities of capture, research may open to generative spaces that do not require school mathematics as a kind of "slow emergency" that doubles as a 'necessary' condition for mattering in the world (Anderson, Groves, Rickard, & Kearns, 2020; Sinclair & de Freitas, 2019).

In short, affect theory, at least via some perspectives, may offer one set of possibilities for attending to the messiness and spillage of the 'everyday' that may trouble (while not necessarily jettisoning) assumed categories, boundaries, representations, states, rules, modes of capture, etc.; if research is less concerned with making definitive statements or claims about what 'happened' and more concerned with how different 'bodies' come to matter in ways such that their incompleteness and messiness are no longer pathologized but offer springboards into the necessarily unknowable (de Freitas & Sinclair, 2019). In this sense, rather than seeking to define "affect" *as* 'this' and *not* 'that', many approaches seek to explore affect as something *necessarily* processual, messy, as multiplicity, 'not yet' and thick (Seigworth & Gregg, 2010).

In the next and final section, I pivot to attend to some of the limits of affect theory as a strategy for research that do not attend meaningfully to how 'bodies' are themselves historically and culturally contingent. To do so, I shift to provide a brief sketch of the additional need to historicize how some of the objects of inquiry of mathematics education research and affect theory (minds, bodies, emotions, and their presumed relations) have become differently circulated and made intelligible through different 'economies' for producing affect (see also, Baker, 2013). Brief engagements from 3 "moments" of considerable ontological and epistemological change in ways of thinking about 'bodies' and school mathematics reform discourses were selected that continue to resonate with some of the social, cultural, and political themes that continue to move with mathematics education (research).

3 "Moments"

Circa 1830s. Schooling and society in the post-revolutionary United States saw many changes that directly affected how school mathematics was to be learned and taught. In addition to the emergence of publicly-funded school systems, educational journals, and a proliferation of organizations and institutions, the first quarter of the nineteenth century also saw a marked increase in circulation of mathematics textbooks and materials intended specifically for children (P. Cohen, 1999; Monroe, 1917). On the one hand, such changes were not surprising, given the perceived stability of the Republic and the increasing efforts to link mathematics education (mainly as arithmetic and cyphering) with managing commercial and industrial affairs and promoting mental cultivation for the presumed rigors of democratic (and 'white male') citizehnship (P. Cohen, 1999).

Within this milieu, the concept of "mental discipline" – a term widely circulated as marking aspects of nineteenth century theories of mathematics – emerged as a central hope for what school mathematics could provide beyond applications to practical affairs (e.g., Stanic, 1986). Briefly, mental discipline has typically been described as a doctrine suggesting the mind was like a muscle composed of separate but interdependent faculties, where 'exercise' of any of the faculties (such as via arithmetic) offered routes to strengthening the mind and, by extention, the intellect (e.g., Clason, 1970; Stanic, 1986). However, such a perspective may obscure the nuances and traces of how mental discipline and faculty psychology were also circulated in their historical present through a wide array of new theories of minds and bodies. For example, faculty psychology accompanied new theories such as phrenology that began to consider capacities for mathematics as something at once 'in' the brain, correlated with head shape and character, and, at times, differently modifiable through physical exercise (Tomlinson, 2005). [1]

Further, mental discipline was also understood in part through new medical discourses. For example, from the perspective of the influential U.S. physician Benjamin Rush, bodies could now be conceptualized as systems of "oscillatory matter", where mental "laws" were equated with physical "laws" (Altschuler, 2012). Further, for Rush, mind was understood as influenced by diverse and distributed social and material systems, including blood circulation, political affiliation, occupation, commercial trade, and perceived racialized/racist effects of institutional slavery on health and physiognomy (Herschthal, 2017). And, with phrenology, the faculties of mind that appeared to be exercised through school mathematics also circulated with new theories of associations between physiognomy and intellectual capacity. The corporeal body and the emotions/passions were considered interdependent with 'healthy' mental cultivation and theories linking heredity to dispositions toward mind-body-spirit im/balance and the future of the Republic (Ziols, 2019).

Finally, new theories of childhood also emerged that located children as ontologically distinct from immature adults. As such, children were considered particularly vulnerable to too early or too intense exposure to mathematics (though they were also felt to be especially sensitive to Lockean sense impressions and capacity for cultivation) (Ziols, 2019). Within this milieu, it is perhaps not surprising that school mathematics became a subject that was increasingly to be designed specifically for children in ways that included new hopes and fears about the potential effects of school mathematics in new economies for affect. For example, Samuel Goodrich (1818) was among the first arithmetic textbook authors who argued that arithmetic should be "attractive" to children and "divest[ed]" of "all that is not necessarily difficult or disagreeable" (p. iii). Goodrich's hopes also included making arithmetic more "inviting", satisfying, and pleasurable. Although Goodrich's textbook is among the more explicit in this way, subsequent textbooks across a range of "systems" for teachers also began

---

[1] Tomlinson (2005) has argued that phrenology discourses *a la* George Combe and Horace Mann were woven into the inception of U.S. public schooling as a "moral technology" linking the "exercise" of minds-bodies with racist, sexist, and abilist efforts to eliminate the "abnormal" as routes to 'improving' humanity.

to include appeals to securing interest and preventing injury. For example, in addition to advocating arithmetic as a site for “mental discipline”, Colburn felt that using fingers and objects had made arithmetic learning more appealing for younger children in “both sexes and among all classes” (Colburn, 1830, as quoted in Monroe, 1912, p. 465). At the same time, with an arithmetic textbook intended for children as would-be missionaries, school mathematics was less about learning to ‘reason’ per se and more about converting ‘heathens’ through “Christian benevolence” and by “training a rising generation to esteem the privilege, and the practice of doing good” (Weeks, 1822, p. iv).

In short, school arithmetic had now become available through changing notions of children, mental cultivation, schooling, and their presumed relations with new theories of minds, bodies, and groups (e.g., by sex, race, age, nation, language, profession, brain size, blood circulation, physiognomy, ability, class) (Ziols, 2019). In this economy for ‘affect’, the arrival of mental discipline was not simply about ‘beliefs’ or ‘ideas’ that mathematics could cultivate the mind and/or affect the emotions – it also required complex changes and new amalgams that included colonizing logics, racialized and newly ‘bodied’ notions of mathematics learning, and theories of reasoning that recruited the corporeal body in different ways (Ziols, 2019). It is perhaps no surprise, then, that school mathematics also began to emerge as a school subject that could potentially injure children by ‘unbalancing’ mind-body-spirit amalgams in ways that reinforced exclusionary discourses (Ziols, 2019; see also, Jenkins, 2010).

Circa 1890s. By the 1890s, what might have seemed “difficult or disagreeable” in Goodrich’s historical present shifted to new ways of thinking. Some texts lamented old fears of arithmetic study in new ways. For example, an article in *The Journal of Education* claimed a “juggernaut Arithmetic” was “grinding” children into “physical and nervous wrecks” and making “a sound body, steady nerves, and a clear brain impossible” (Arent, 1896, p. 77). (Such “grinding” pain was also described as the mental equivalent of a man being hung by his thumbs as punishment for committing a crime). Those at risk for becoming “wrecks” retained earlier nineteenth century fears that pathologized the ‘precocious’ child as those considered to be “ambitious for high scholarship” (Arent, p. 77; Ziols, 2019). However, the risks of too much study were now put in the language of experimental physiology and the “new” psychology (Popkewitz, 2008; Stanic, 1986). In short, new amalgams of ‘danger’ accompanied a (partial) erosion of mental discipline logics, as mathematics education became increasingly visible as a topic of concern in a growing number of “attacks” on U.S. school mathematics (Stanic, 1986). Importantly, responses to such “attacks” also recruited new assemblages of ‘bodies’ for reform-oriented justifications for the ‘why’ of school mathematics.

For instance, the “new” psychology sought to map the child’s mind as a scientific object for study and planning the future through the mind and social sciences in response to fears of (im)migrant populations moving to the cities (Popkewitz, 2008; Ziols, 2019). Also, as learning school mathematics became largely domain specific and less tethered from its value for ‘mental discipline,’ it paradoxically became increasingly relied upon as a standard for mental testing, partly linking scientific racism and eugenics through new bio-psychologized notions of intelligence, character, and individual difference (Danziger, 1997; see for an example, Thorndike, 1922).

Importantly, though, mapping the child’s mind was not simply a project related to studying the child’s mind as a psychologized object. It also appeared to require the study of children *in situ*, a perspective informed in part by the study of ‘othered’ cultures such as through ethnology, folklore studies, and history (see, e.g., Dewey, 1884, 1886). In brief, by providing a sense of teleological progress as the inevitable directionality necessary for a desired moral order, a technoscientific future could be secured through application of scientific ‘expertise’ to pedagogy (Popkewitz, 2008; Yolcu & Popkewtiz, 2019). Progress had also become entangled with Spencerian notions of human agency and cultural ‘development’, secured in part through efforts to predict and control behavior by studying the duration and intensity of various senses (Crary, 1988). In short, as the mind-body-spirit became set in linear notions of technoscientific progress, it also became increasingly available (along with disciplinary mathematics) as a social and cultural construct that both required and exceeded notions of human agency to secure 'advancement' along rank-ordered developmental continua on a 'great chain of being' (Baker, 2013; Crary, 1988).

Within this milieu, James McClellan and John Dewey (1895) in the *Psychology of Number* argued that scientific principles would provide a plan for the "natural" alignment of children's mathematical activity with "civilization." Culturally-mediated activity would foster discernment and reason in ways that would move 'inward' to the corporeal body and 'outward' to secure the mind (and civilization) from ethical and psychological "destruction" (McClellan & Dewey, 1895, see pp. 4-5). The avoidance of 'destruction' also entailed efforts to tie activity to the production of quantity through accurate measurement, discernment, and relation as strategies to predict, control, and direct the future. For example, McClellan and Dewey argued: "The child and the savage have very imperfect ideas of number, because they are taken up with the things of the present moment. There is no imperative demand for the economical adjustment of means to end; living only in and for the present, they have no plans and no distant end requiring such an adjustment" (p. 38). By moving 'out' of the present moment, the 'child' and the 'savage' required developing an "idea of quantity" through "arrang[ing]… acts in a certain order, to prescribe for himself a certain course of conduct so as to accomplish something remote" (p. 38). In one section, the racializing/racist psychologizing of number was also one that could be summarized by "embodying the idea that number is to be traced to measurement, and measurement back to adjustment of activity" (p. 52).

Also, with this 'new' onto-epistemological framing, the psychologizing of number accompanied new claims that *all* humans and some animals had mathematical 'capacities.' Cultural 'activity' then, was, what explained purported differences in the power and rigor of 'culturally'-specific mathematical practices and distinctions made between humans and animals (Ziols, 2019; see for different examples, Dewey & McClellan, 1895; McGee, 1898). Further, 'access' into 'civilization' was explained not only by converting and/or assimilating the activities of the child-as-savage into 'civilization' but also as a political project that located 'access' based on theories of cultural tool use. For example, ethnologists, working in part to establish anthropology as the pinnacle of the sciences, argued that cultural tools (e.g., the hand, objects, and written signs) provided the levers that would 'liberate' the 'primitive' mind from its 'mystical' past (see, e.g., Conant, 1896, McGee, 1898). From one perspective, by directing one's goals toward an imagined future through targeting cultural group "leaders" (as the 'strong'), educators-as-scientists could offer the most direct routes for 'racial' uplift and desired social change (Haller, 1971; Ziols, 2019). Such notions not only exacerbated racist and ethno-centric discourses centered around 'Western' concepts of mathematics – they linked static notions of the environment and climate with the 'extranatural' (or socio-cultural), unconscious, kinetic, and linguistic as sites for securing imperial notions of Spencerian 'progress' in social groups defined as on separate developmental trajectories (see, e.g., Haller, 1971).

Finally, although the modern psychologized notion of the personality (and the person) as a set of discrete constructs was not yet thinkable (Danziger, 2012), character-building and habit-forming discourses also permeated journals and books related to mathematics education. For an example distinct from *The Psychology of Number*, an article in the *Journal of Education* suggested that "reasoning about things" in early school mathematics was subsidiary to learning to "use the signs and symbols" of arithmetic and "by every ingenious contrivance" to "cultivate habits, habits, HABITS, of accuracy, rapidity, and neatness, both in mental and manual activity, and of speech as well" (emphasis original, Allyn, 1892, p. 281). However, it was not 'enough' to simply cultivate 'mathematical' practices believed to align the mental and the manual through activity and speech. A teacher was also to cultivate "above all… truthfulness and honest sincerity" in ways that avoided "making dunces who hate math" (p. 281).

However partial the above account, the intention here has been to note that although the mind may have been conceptualized as distinct from the body, mind-body amalgams were not eschewed with the arrival of new theories about how 'mental' processes were produced through social and cultural practices, the corporeal body, the senses, language, and notions of character and conduct. Similarly, though reworkings of a mind/body split were certainly present in such discourses, new notions of materialisms and efforts to mathematize sensation also undergirded them (Crary, 1988). In the next subsection, a third shift in economies for affect are considered, where new notions of character and individual difference were increasingly scientized through hopes and fears about securing democracy, promoting the 'adjustment' of the modern personality, and impressing the 'cultural value' of mathematics.

Circa 1930s. Around the 1930s, the institution of mandatory secondary schooling in the United States accompanied efforts to address new fears, particularly those involving the inclusion of the "other 50%" now required to attend secondary school (see Lagemann, 2000). One primary site for addressing 'new' hopes and fears of a mathematics education under "attack" was via the insertion of mental hygiene and cultural value-creation into policy documents and pedagogies (Ziols, 2019). On the one hand, reform discourses sought to reconceptualize the "un-emotional subject *par excellence*" of mathematics education as one intimately requiring both emotion *and* intellect as essential and interdependent for meangingful learning (Progressive Education Association [PEA], 1940). By "understanding the student", mathematics educators would avoid the potential dangers of psychological, social, and physiological 'maladjustment' (PEA, 1940). Or, from the joint Yearbook published by the Mathematics Association of America and the National Council of Teachers of Mathematics (1940), educators were to focus on the "problem of the dull normal" who differed in "degree" from the "gifted" (p. 133). And, though the "[t]he data" appeared to show the "fact that the slow group grows in the same proportion as the fast group though on lower levels of development" (MAA & NCTM, 1940, p. 134), the 'problem' was considered in part to be one of "implanting the cultural value of mathematics" such that students would "comprehend certain essential elements of the civilization they are to share" (NCTM & MAA, 1940, p. 48).

To achieve a sense of cultural value, the 'why' of mathematics education also appeared to need justification. On the one hand, justification was now expressed in new (eugenic) theories of health that included not only concerns with 'intelligence' but also with attention to emotion and conduct, attitudes, and "traits" (MAA & NCTM, 1940; PEA, 1940; Zachry & Lighty, 1940). On another hand, approaches such as those in the *Mathematics Teacher* included efforts to link the "mathematic of a culture" to that culture's purported "soul" or "spirit" (Schaff, 1930). Such a perspective was not unique. Schaff drew in large part from Oswald Spengler's (1965) widely circulated book, *Decline of the West,* that argued every culture was defined by its "mathematic", where developments in mathematics marked a 'culture' as either ascendant or in decline. Schaff, however, argued for a more optimistic interpretation: Mathematics as a human and cultural product suggested that humans were the "the law givers of the universe" and that it was "possible… that the greatest of our material creations is the material universe itself" (Sullivan, as quoted in Schaff, pp. 502-503).

Additionally, creating a shared sense of a cultural value for regulating emotion and conduct involved another object of inquiry: the "modern" personality (Danziger, 1997). As an amalgam of "traits", the "modern" personality emerged through efforts to measure a person's character – a perspective drawing heavily from Galtonian-inspired eugenics (see Danziger, 2012). In related U.S. mathematics education journal articles and policy documents, some authors explicitly argued for "reform" as a "concern with the effect of arithmetic on personality" that required "a major reorganization of subject matter and methods" (Buswell, 1941, p. 10). Further, in the same chapter, such "reorganization" involved engineering "an organized body of number experiences from which both mathematical insight and social significance may be derived" (p. 10), where a "number experience" was what might offer "positive contributions to the development of desirable personality traits" (p. 10).

Lastly, shifts in the 1930s could also be summarized in part by the PEA's (1940) companion report to *Mathematics in General Education* titled *Emotion and Conduct in the Adolescent* (Zachry & Lighty, 1940), where what constituted the "un-emotional subject" of school mathematics was now juxtaposed with perspectives on how emotion and conduct were to be reconceptualized by bucking the purported status quo. Namely, it was argued that the "Puritan tradition" believed "responsible [for]… the tendency in all Anglo-Saxon cultures paradoxically both to discount emotion and to counsel its mastery" was to be challenged (Zachry & Lighty, 1940, p. 5). "Emotion thus broadly conceived" was to be "fused with thinking - for the most part harmoniously - in the healthy, competent individual" (Zachry & Lighty, 1940, p. 5).

In short, school mathematics had become in part a translation device for addressing fears of "maladjustment" in adolescents and children through reforms centered on "understanding the student" to regulate emotion and conduct, establish and secure social cohesion, cultural unity, and "democratic order," and strengthen and/or muting un/desirable personality and character "traits" during times of perceived crisis in school and society (see also, Yolcu & Popkewitz, 2019).

Concluding Remarks

This paper has had two aims. First, it has made an argument that mathematics education research may broaden its scope by engaging with theories of affect that eschew analysis of the individual or group. Second, it has argued that affect theory is also limited with respect to what it may take as assumptions of ahistorical continuity across different material-discursive assemblages and space-times. While neither argument is entirely new to mathematics education research (see, e.g., de Freitas & Sinclair, 2019; Popkewitz, 2008), little research has addressed how and why mathematics education research continues to locate desirable 'affect' as something messy and seeming to be a problem of largely ahistorical approaches to methodology *despite* rather dramatic onto-epistemological shifts in how affect (and mathematics education) has become intelligible. Engaging with affect as historically and culturally contingent assemblages of 'bodies' requiring further scrutiny and historicizing may thus provide important new entry points for future research.

STUDENT ENGAGEMENT AND GENDER IDENTITY IN UNDERGRADUATE INTRODUCTION TO PROOF

Emmanuel Barton Odro
Montana State University
emmanuelbartonodro@montana.edu

I examined how gender identity shapes engagement experiences in undergraduate mathematics classrooms through a mixed methods study. Data collected from 12 classroom observations, stimulated recall interviews, and student-reported data on engagement were used to answer the question, "How does gender identity shape students' engagement experiences in undergraduate mathematics classroom?" The findings indicate that students' in-the-moment engagement is characterized by classroom environments that foster collective mathematical discussions and group work.

Keywords: Equity and Diversity, Gender and Sexuality, Inclusive education

Introductions

Student engagement is a strong predictor of achievement and behavior in school irrespective of students' socioeconomic situation (Klem & Connell, 2004), making it a powerful factor in education. Additionally, in the social sciences, women earned a majority of bachelor's degrees (55%) and master's degrees (57%) from 1993 to 2015 (NSF, NCSES 2019). On the other hand, of all STEM degrees awarded in 2016, women earned about half of bachelor's degrees, 44% of master's degrees, and 41% of doctorate degrees, about the same as in 2006 (NSF, NCSES 2019). Based on these data, it is possible that gender identity plays a role in the field(s) one chooses to pursue. At the classroom level, gender identity and participation in mathematics are related in that students' gender identity can influence their decision to continue studying mathematics (Boaler, 2002a; Boaler & Greeno, 2000). To better understand how students learn mathematics, there is potential in better studying connections between students' engagement and gender identity in mathematics learning environments.

Student Engagement in Mathematics Education

Engagement manifests itself in activity, including observable behavior and mental activity involving attention, effort, cognition, and emotion (Middleton et al., 2017). Engagement is thus a complex meta-construct consisting of cognitive, affective, and behavioral dimensions (Fredricks et al., 2004). For students to learn mathematics, they must be engaged. For instance, Bodovski & Farkas, (2007) found that student engagement is a significant contributor to students' mathematical growth in early elementary school. At the middle and high school level, researchers found that higher cognitive, behavioral, and emotional engagement predicted students' academic achievement (Wang et al., 2016). However, the literature lacks studies of student engagement in mathematics classrooms at the undergraduate level (cf. Williams, 2017).

Gender Identity

In the early 1900s, researchers used sex hormones to explain masculinity and femininity (Bell, 1916; Lillie, 1939), replacing religious justifications with scientific ones for restricting women's roles (Risman et al., 2017). In the latter part of the century, social scientists began to push back against using scientific justification to explain gender and viewed masculinity and femininity through the lens of roles that were assigned to men and women by society. In the 21st century, sociologists including gender research expert Risman (2017), argue that gender identity is a socially constructed

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

component of one's identity built as a result of internal and societal interactions. For the purpose of this study, gender identity is comprised of personal identity made up of psychological characteristics and a social identity encompassing salient group classifications which differs across cultures and can change.

Gender Identity and Student Engagement

At the college level, most studies regarding student engagement and gender identity strive to either explain the growing disparity between degrees awarded to men and women or differences in undergraduate enrollment at baccalaureate-granting institutions between women and men. Thus, at the college level, most studies on student engagement and gender focus solely on how many males and females either graduate or drop out from degree programs. However, such conceptualization of student engagement is different from student engagement as defined in this study nor are the labels "male" and "female" sufficiently capturing what is meant by gender identity (Risman, 2017). Engagement goes beyond enrolling or graduating from a degree program. Additionally, of the literature reviewed, most work on gender differences in student engagement tend to generalize across content areas that is not math focused. This study is unique in its focus on student engagement (as defined by Fredricks et al., 2004) and gender identity(as a social structure) in the mathematics classroom at the college level.

Theory

Flow theory offers an effective lens for interpreting student engagement in that both flow and engagement describe states of total involvement in a task and involve internal motivation (Steel & Fullagar, 2009). From flow theory, student engagement is made up of interest, enjoyment (emotional & behavioral), and concentration (cognitive) (Shernoff, et al., 2003). Thus, the extent of students' engagement is based on these factors.

To understand gender identity as a social structure (Risman, 2017), this study adopts the stance that gender identity is a person's own sense of self by virtue of being part of a society. Gender is socially constructed in that societies have a set of gender categories that usually serve as a basis for the formation of gender identity. This perspective emanates from Tajfel and Turner's social identity theory (1986), which assumes individuals define their own identities as a result of societal norms. Gender as a social structure has psychological and social characteristics.

Methods

I addressed the research questions: (a) What characterizes student's engagement in an undergraduate introduction to proof course? (b) What are the different ways in which gender identity shape students' engagement experiences in this setting? To address these questions, I observed an introduction to proof class for five consecutive weeks. The participants in this study are students enrolled in the course. Fifteen undergraduate students: three of those who identify as women and twelve of those who identify as men volunteered for the study. The sessions I observed focused on the teaching of combinatorics. All students are assigned pseudonyms.

Sessions were video recorded. A demographic survey was administered to students, which asked questions such as "Please describe your gender identity?", "Do you believe that how you identify (gender) affects your experiences during classroom interactions? If so, please explain?". In-the-moment student engagement was captured through the experience sampling method (ESM) (e.g., Shernoff, et al., 2003). ESM data took student-reports of interest, enjoyment, concentrate (i.e. engagement), perceived skill and challenge.

Lastly, ESM responses and video data were used to develop protocols for stimulated recall interviews. Using thematic coding, data from this study were analyzed to understand the nature of student engagement and how gender identity shapes student engagement experiences.

Results and Discussions

I present themes associated with students' engagement that emerged from the stimulated recall interviews as students described both their personal high/low engagement moments. Finally, I focus on how gender identity influences these students' engagement.

Student Engagement

A theme associated with students' engagement from the stimulated recall interviews was the social norms of the classroom. The instructor presented the content with a very nontraditional approach. For instance, almost every single day, students presented their mathematical ideas on the board. Furthermore, students' ideas were valued in the classroom and were encouraged to initiate mathematical discussions. Students asserted that the nature of the classroom influenced their engagement. For instance, Bridget, who identifies as a woman, asserted that "seeing how they (students) thought to solve mathematical problems in different ways influenced my concentration positively." Being able to see the multiple ways to solve mathematical problems influenced her engagement. Nat, who identifies as a man, explained that "the fact that I was given an opportunity to describe the mathematics to my peers increased my interest." On the other hand, Ian, who identifies as a man, explained that since the nature of the class was not lecture based, his engagement was on the low side. As Bridget, explains seeing multiple ways of doing math influenced her concentration, her cognitive engagement is increasing. Nat's interest about verbalizing his mathematical reasoning positively influenced his emotional engagement. However, Ian's emotional engagement is on the low side as he does not enjoy the mathematical content being covered. Although Ian's emotional engagement was low, two of his peers explained how this student-centered environment fosters their emotional and cognitive engagement.

Group work was instrumental, in that all participants who volunteered for the stimulated recall interviews asserted that working with peers influenced their engagement positively. Bridget asserted that "I don't know, just working with my peers increased my interest and concentration." Nat explained that working with his classmates served as a competition for him to be cognitively engaged. During the stimulated recall interview, he explained,

> with the partners I have its kind of a motivation thing kind of use this as a competition type deal like to try match my partners' skills. if I was working individually, I don't think my concentration would be high for this mathematics class.

Ian explained that being a "privileged" male, he speaks less in group work when working with those women to enable them to express their ideas. He explained that working with his classmates positively influenced his cognitive and emotional engagement. He also explains that, "when working with classmates even though no one is an expert, they can still point that why did he (emphasis added) did that in this proof, so I think working with my classmates helps to concentrate."

Thus, from this study, there is a positive association between group work and their engagement. It is interesting to note how Ian did not wish to be the only speaker during a mixed gender group interaction to allow those he perceives as women to talk. Furthermore, it is more fascinating how he used a "male pronoun" for a hypothetical student, when describing his experiences working with classmates. This points out some connections between one's gender identity and engagement experiences.

The Role of Gender Identity in Student engagement

ESM data show that overall those identifying as women reported higher levels of engagement than those identifying as men. Aaron, who identifies as a man, reported being less engaged than his peers; whereas, Janet, who identifies as a cis woman, reported being most engaged. Aaron did not volunteer for the stimulated recall interview hence much cannot be inferred on the low engagement reported by him. Observations suggest his behavioral engagement aligned with his self-reported levels of engagement from the ESM survey. During the analysis of the initial demographic survey, Janet explained,

> I have a distinct memory of trying to take Calc 1 in summer and being the only woman in the room, and it being my first class not taught by a woman and feeling anxious about it. I don't think it was a very fair feeling, but I did feel it.

She did not volunteer for the stimulated recall interview, which might be explained by prior experience in her calculus 1 summer class and that possibly because I identify as a black man.

Five participants asserted that their gender identity influenced engagement. Ian, who identifies as a man, explains,

> If I am in a group interaction made up of different genders, the same actions done by a man and a woman will be definitely be viewed differently so I definitely think gender has an impact on how students engage with mathematics.

Edwin, who identifies as a man, explained how he thinks gender influences engagement in the mathematics classroom by indicating that being male has not "negatively affected" him as a learner of mathematics. Some students identifying as men said they did not think one's gender identity influenced experiences in mathematics courses; however, they would also say something to suggest otherwise. Although Nat explicitly acknowledged that gender did not influence one's engagement, his explanation indicated that gender actually influenced how he approaches group work, "when working with women I allowed them to express their mathematical ideas to get them involved in the discussion." Thus, we do see that those perceived to be women are on the disadvantage. For instance, Mike thinks men contribute more in the mathematics classroom. On the other hand, Bridget asserted one's gender did not influence their engagement while studying mathematics. In conclusion, some students indicated that their gender did influence how they engaged in the mathematics classroom.

Conclusion

This study investigated the nature of students' engagement in mathematics and how their gender identity shapes engagement experiences in the mathematics classroom at the college level. Some students indicated that their gender identity did influence how they engaged in the mathematics classroom, with those who identified as women more likely to be negatively affected. However, this perception was not borne out by the observation and ESM data. In the observation and ESM data, those who identified as women reported higher levels of engagement than those who identified as men. There is room for further exploration and research on gender as a social structure rather than biological, and much remains to be learned about the different ways in which gender identity shapes student engagement in mathematics.

End Notes

Students' gender identities were reported exactly as identified in the demographic survey.

RECONCILING TENSIONS IN EQUITY DISCOURSE THROUGH AN ANTI-HIERARCHICAL (ANARCHIST) THEORY OF ACTION

CONCILIANDO LAS TENSIONES DEL DISCURSO DE EQUIDAD A TRAVÉS DE TEORÍA DE ACCIÓN ANTI-JERÁRQUICA (ANARQUISTA)

David M. Bowers
Michigan State University
bowersd2@msu.edu

Brian R. Lawler
Kennesaw State University
brian.lawler@kennesaw.edu

In this text, we invite others into a different paradigm of thought and action than what has been historically represented at PME-NA. We surface anti-hierarchical theory of action as a macro-theory implicitly present across substantial discourse in equity in mathematics education, then explore some of the affordances and challenges to be considered in adopting anarchism as a theory of action for research and practice. Findings relate to (1) the (de)colonizing tension between focus/specificity and the reification of compartmentalization, (2) the concomitant tension of constructed (in)visibility, and (3) the pursuit of solidarity in the disruption of a violent status-quo. Implications for ongoing research and pedagogic praxis are shared.

Keywords: Equity and Justice, Systemic Change

The 42nd annual conference of the North American Chapter of Psychology in Mathematics Education invites us to "promote the exchange and enrichment of mathematics education research" by looking to its manifestation across "different cultures, places, and contexts" (PME-NA, 2020). The goal of this article is to outline and trace the value an anti-hierarchical (anarchist) theory might hold as a macro-theory undergirding and providing definition (and direction) to equity-oriented research. We aim, in short, to invite others into a different paradigm of thought and action than what has been historically represented at PME-NA. Our goal for each section of this text is not to be exhaustive, but to be illustrative of a different way of being and living. (Restivo, 1998)

What is Anarchism?

For the purposes of this paper, we place emphasis on anarchism as an articulation of ethics, as a mode of human organization with social self-determination, rooted in the experiencing of daily life (Suissa, 2010). Anarchism aims to maximize both individual autonomy and collectivist freedom, leading to the reduction of fixed hierarchies that systematically privilege some people over others. Individual autonomy is, perhaps, self-explanatory as a principle; it is a self-determination, the freedom of choice in one's own acts, with no form of external compulsion. Collectivist freedom is one in which the individual finds their freedom through voluntary association with other members of society, not isolation from them. Bakunin (1971) argued that man is only truly free when among equally free men; "the freedom of each is therefore realizable in the equality of all" (p. 76). Concisely, to embrace any form of anarchism is to express profound skepticism toward skewed, coercive, and exploitative power relations, and to reject all forms of oppression, including those of class, race, gender identity, religion, etc. (Lawler, 2019).

In short, anarchism is the absence of hierarchy. It imagines a relationship among people that minimizes if not eliminates coercive structures and interactions, taking seriously the possibility of an equal and free society, organized on core values of *cooperation*, *mutual aid*, and *freedom from hierarchy*.

How is Anarchism Currently Alive and Well in Mathematics Education and How Might Anarchism Resolve or Inform Tensions in Mathematics Education and Equity?

The proliferation and diversity of ways anarchism manifests in equity discourse may, at first, seem surprising, given the small number of publications that explicitly draw connections between anarchism and mathematics education (e.g. Lawler, 2019; Restivo, 1998, 2011; Wolfmeyer, 2012, 2017a, 2017b). However, the undergirding tenets of anarchism (e.g. cooperation, mutual aid, and freedom from hierarchy) exist as a common thread within mathematics education equity discourse, conceptually stitching a wide array of professional and political efforts. Here we foreground this thread, offering a silhouette or sketch of anarchism as a potentially valuable macro-theory in mathematics education equity research and practice.

Relations between people – absence of hierarchy. Education as a social activity is a widely held stance; many scholars argue that the field now understands the perspective that mathematical activity and learning is fundamentally social (Lerman, 2000). But the social is necessarily political, and thus the social contexts of mathematical knowledge construction, identity development, and of our work as researchers is best understood through examination of power differentials or hierarchies of this sociopolitical context (Gutiérrez, 2010/2013). Freire (1970/2000) provided useful models to reimagine the hierarchical relationship between the teacher and student so as to disrupt the perpetuation of oppression. These models defined a heterarchical relationship between teachers and students.

Through dialogue, the teacher-of-the-students and the students-of-the-teacher cease to exist and a new term emerges: teacher-student with students-teachers. The teacher is no longer merely the one-who-teaches, but one who is himself taught in dialogue with the students, who in turn while being taught also teach. They become jointly responsible for a process in which all grow. In this process, arguments based on "authority" are no longer valid (Freire, 1970/2000, p. 80)

Steffe and Thompson (2000) identified the problematic nature of the researcher-student relationship in any effort to make a claim about what the other knows. Steffe's Radical Constructivism took seriously the notion that knowledge is constructed, and thus ways of knowing are unique to each knower, viable in their experiential reality. It follows that the researcher must acknowledge their role as observer and work to create second-order models of the child's knowing—fully realizing this second-order model is merely one's own knowing, not a claim of truth about the child. Gutiérrez (2017) similarly disrupts hierarchies of knowing by demonstrating how indigenous ontologies see mathematics as a quality of all living beings. We have methodologies in mathematics education that have potential to disrupt the violence of uninterrogated hierarchies of knowing in our relationships with others (Lawler, 2012).

Disruption of (M)athematics. In the course of engaging in research or praxis in the area of mathematics education, one inevitably encounters a certain narrative of worship around the discipline, a mythology Lakoff and Núñez (2000) refer to as the *Romance of Mathematics*. In broad terms, the *Romance of Mathematics* is a mythology that perceives mathematics as objective, acultural, and beyond the vagaries of the human. The *Romance of Mathematics* constructs and propagates "...the mystique of the Mathematician with a capital M as someone who is more than mere mortal—more intelligent, more rational, more probing, deeper, visionary" (p. 340).

This mythology presents an immediate barrier to equity work. "If mathematics is objective, it makes no sense to be concerned with learners' cultures and lived experiences. If mathematical achievement can be accurately and fairly measured with standardized tests of routinized items, it makes no sense to develop more "subjective" assessments of mathematical understanding. And if mathematics is inherently too difficult for many to master, it makes no sense to try to teach all students rigorous aspects of the discipline" (Ellis & Berry III, 2005, p. 13). In response to this barrier, substantial research has sought, either directly or indirectly, to reveal the illusory nature of the myth (e.g.

Bowers, 2018, pp. 290–291). Some (e.g. Burton, 1999; Sinclair, 2009; Wells, 1990) have observed the powerful and subjective role aesthetic plays throughout the discipline, some (e.g. D'Ambrosio, 1985; Lipka et al., 2012; Meaney et al., 2013; Thomas, 1996) have observed the ways mathematical meaning-making have varied from culture to culture, and some (Burton, 1999; Joseph, 1987; Lakatos, 1976) have observed the ways (culturally localized) human interdiscursivity acts as the force by which mathematics is constructed, to name but a few directions researchers have taken in this vein.

Thus, we see again in this context that equity work is anarchic at its foundation—it opposes the socially constructed hierarchy of discipline. In foregrounding this anarchic thread, we see a means of tying these superficially disparate efforts together. Several of the above cited works (e.g. Lakatos, 1976; Wells, 1990) would not even typically be identified as works of equity, but in their valuing of the human and cooperative aspects of mathematics they nonetheless find a place in the greater social project of social justice. Through the paradigm of anarchism, we highlight a broad array of work that stands in opposition to the hierarchy of discipline.

Disruption of white supremacy. Public education within and beyond North America, in both theory and practice, is grounded in whiteness, (re)producing hegemonic social norms such as cultural deficit perspectives, colorblind racism, race neutrality, and meritocracy (Nicholson, 1998; Ladson-Billings, 2000; Sleeter, 2001). The problems here are not so superficial as simply having teacher education programs or rosters of practicing teachers that are predominantly white (though in some places this is a keenly felt tension); rather, the crux of the problem lies in the ways whiteness is normalized across these spaces. Subscribing to whiteness inherently supports institutionalized white supremacy because it tacitly (or overtly) reifies a system that has historically disadvantaged minoritized groups (Matias et al., 2016).

Equity work in mathematics education has tackled this ever-looming problem from a number of directions. Some work has focused on how positioning and identity manifest in the context of small-group interactions (Bishop, 2012; Langer-Osuna, 2011; Wager, 2014), while other work has focused on broader macro-narratives and bias (LópezLeiva & Khisty, 2014; Martin, 2011; Shah, 2017; Tiedemann, 2002). Some work has tackled the topic of power and domination (Battey & Leyva, 2016; Martin, 2009; Setati, 2008), while other work has interrogated cultural practices and pedagogy in mathematics education (Dominguez, 2011; Gutstein, 2012; Leonard, 2008; Lipka et al., 2005). Some work has considered the insular nature of mathematical language (Halliday, 1978; Herbel-Eisenmann, 2002; Pimm, 1987; Schleppegrell, 2007), while other work has broken tackled white supremacy from an intersectional lens (Bullock, 2017; Civil, 2002; Esmonde et al., 2009; Gholson & Martin, 2014). All this is to say that disrupting white supremacy has been one of the core social projects of equity in mathematics education, and though it has been tackled from many perspectives, they share at their foundation an anarchic valuing of the human's right to self determination and opposition to hierarchy.

The above equity projects share, at their core, opposition to racial hierarchy. In foregrounding the anarchic thread connecting these and other seemingly disparate spaces, we see opportunity. For, though we speak here of race in particular, it is difficult nigh impossible to extricate racial power structures from those power structures that are expressed in terms of gender, sexuality, ability, or socioeconomic status. As Roibeard (2015) said of feminism, "Feminism and anarchism are kissing cousins; feminism aims to abolish patriarchy, yet patriarchy does not stand alone and its abolition is intertwined with the abolition of all oppression. We cannot pick and choose which power structures we like and which ones we don't like; they are all connected, for patriarchy to truly be dismantled they all must be." In foregrounding the anarchic thread undergirding equity work, we see the potential to push back against compartmentalization and the interrelated hierarchies imposed thereon.

In foregrounding the anarchic thread, we see the opportunity to make visible the multiply marginalized (e.g. Crenshaw, 1991; Gholson, 2016), and to proceed in solidarity.

What Dangers and Limitations Must We Consider?

It is important at this juncture that we acknowledge and draw attention to potential dangers and limitations in operationalizing anarchism as a macro-theory. The vision of anarchism expressed throughout this text is a broad one, and there are many interpretations of anarchism which entail different assumptions and values, each having very real consequences in their adoption and use. An exhaustive overview of all of the potential risks of particular instantiations of anarchism would lead us far astray from our central goal of introducing and inviting others into a new paradigm of thought that has not seen explicit representation at PME-NA, so here we must satisfy ourselves with something smaller but more intentional—a scalpel rather than a sledgehammer. We draw particular attention to two substantial and complex areas of risk: Recolonization (e.g. Patel, 2016) and constructed (in)visibility (e.g. Crenshaw, 1991; Gholson, 2016). We do not select these risks for further conversation because they are more important than other risks, but simply because their risk is substantial and because they serve the purpose of suggesting the ways these dangers are deeply and complexly interwoven with the very affordances we spoke about above. Indeed, these two risks are complexly interwoven with each other and will consequently be treated in concert below. After all, one of the tools of colonization is compartmentalization (Patel, 2016), and it is precisely compartmentalization that gives rise to constructed invisibility, that trick of (social) cognition wherein the multiply minoritized are only "seen" in terms of one minoritized identity at a time.

We begin with the perennial tug-of-war between the inertias of *colonization and white supremacy* and conscious efforts of *decolonization and antiracism*. The ways humans continuously come into being, the ways we carry and perform ourselves, are living and breathing mixtures of affordances shaped and informed by the echoes of long-standing yet not sealed histories (Baldwin, 1963; Gordon, 1997). Phrased differently, subjectivities are inextricably entangled with material conditions, and social becomings enact and exact material consequences (Barad, 2007). Given these deep trajectories and the role of educational research in perpetuating settler-slave-Indigenous relationships, educational researchers are answerable to working to dismantle those structures (Patel, 2016).

Like all things, the common image of anarchism summoned by the public imagination is a Eurocentric and white image, commonly conjuring white (cis-male, heterosexual, …) European visages such as Max Stirner, Peter Kropotkin, or Henry David Thoreau. Restricting oneself to these visions of anarchism recolonizes, and (re)constructs many voices and bodies as invisible, hypocritically reifying hierarchy while nominally standing in opposition to it. A decolonizing and antiracist vision of anarchism must think outside these frameworks that mask white Western parochialism as universal and eternal verity (Grovogui, 2006). A decolonizing and antiracist vision of anarchism must expand beyond perspectives that recognize and respond to only one hierarchy—the hierarchy of class and capital. Thus, whatsoever vision of anarchism we might choose in any given moment or context should be grounded in visions constructed and expressed by diverse groups of thinkers and activists (Alston, 2003; Grovogui, 2006; Roibeaird, 2015).

BEARING WITNESS TO MATHEMATICAL GHOSTS: THE ETHICS OF TEACHERS SEEKING JUSTICE

Grace A. Chen
Vanderbilt University
grace.a.chen@vanderbilt.edu

Common mathematics education practices such as valuing speed and accuracy over creativity and reflection often cause mathematical trauma. Once established, this trauma haunts students, their teachers, and even a researcher in future mathematical experiences, calling for recognition and for a justice that can only be found through transformative engagement. This study integrates sociological theory, poststructural methods, and empirical data from an ethnographic study of veteran mathematics teachers to explore how teachers enact ethical relations by bearing witness to students' mathematical ghosts and, in doing so, make possible a more just future.

Keywords: social justice; marginalized communities; affect, emotion, beliefs, and attitudes

Common mathematics education practices such as tracking, valuing speed over reflection, and assigning repetitive procedural homework constitute a "slow violence" (Gutiérrez, 2018, p. 3) that (re)marginalizes students who have historically been marginalized in mathematics education due to racism and other forms of oppression, in part by denying students' agency (Lange & Meaney, 2011). Students who have been repeatedly subject to such mathematical violence carry trauma resulting from their prior experiences and also from the "ongoing, accruing impact and consequences of social malignancies such as racism" (Dutro & Bien, 2014, p. 23). In mathematics classrooms, then, "the past haunts the present" (Gordon, 2008, p. viii). If this is the case, how can mathematics teachers engage in ethical response? In other words, how ought they attend to the lasting impact of traumas perpetuated on students by hegemonic forms of mathematics teaching and learning within an already oppressive society?

Conceptual Framework: Haunting

In this paper, I view haunting as an apparition of students' mathematical trauma. Many scholars have probed the presence of ghosts in public schooling (e.g., Ewing, 2018; Lawrence-Lightfoot, 2003); here, I follow Gordon's (2008) framing of ghosts as "one way in which abusive systems of power make themselves known and their impacts felt in daily life, especially when they are supposedly over and done with" (p. xvi). In Gordon's conceptualization, ghosts call out for justice: for the damage that has been done by abusive systems of power to be addressed, not because it can be undone, but in order to "en[d] this history and se[t] in place a different future" (p. 66). In mathematics, then, ghosts might call out for transformative ways of teaching and learning that are no longer traumatizing, violent, or marginalizing.

Methods: Greeting the Ghost

The data for this study were collected ethnographically in a high school serving almost exclusively Latinx students eligible for free-and-reduced-price lunch. I followed two veteran mathematics teachers, Franck and Clark (all names are pseudonyms), in their Algebra 1 classes for one week each month across a full school year, taking extensive descriptive fieldnotes and writing in-process memos (Emerson et al., 2011). Since subjectivity is inevitable in qualitative research, I positioned myself as a partner for brainstorming and reflecting rather than minimizing my role, and was welcomed "as an outsider and as an insider" (email from Clark, 2/2019).

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

As I observed, I was struck by the frequency and force with which Franck and Clark named a teacher who had taught many of their students the previous year: Mr. Montoya. Mr. Montoya's ghost first appeared to me in October, when, in an interview about building relationships with students, Franck repeatedly cursed Mr. Montoya for "the damage that he did to these kids." According to students, Mr. Montoya's pedagogy included requiring them to memorize conventions of mathematical notation regardless of whether they made sense, randomly calling on students, and shaming them for not having immediate correct answers; in an interview, a student explained to me that "he kept on trying to make us better each time but in a way that would make us feel like we weren't good." Mr. Montoya may have intended tough love but nevertheless created a mathematical culture of exclusion (Louie, 2017) through hegemonic practices that are especially routine in classrooms with marginalized youth (Gutiérrez, 2018).

Mr. Montoya's ghost provoked strong affects throughout the school year, illustrating the "living effects, seething and lingering, of what seems over and done with" (Gordon, 2008, p. 195). Despite no longer being in his class, students brought him up unsolicited when I asked them about their *current* mathematics classes, saying he was "rude," "really bad," and "he would pick on me." He haunted teachers' interviews and collaborative meetings: Franck called his methods "public abuse," Clark mentioned "kids that hate him," and another teacher, Abigail, said that hearing them talk about him made her both "want to cry" and "fight." As a researcher, I felt constantly alert to his name or the mere possibility that someone might be referring to him. As an instantiation of both the individualized and structural trauma carried in mathematics classrooms, Mr. Montoya's ghost offers an analytic opportunity to examine 1) how students, teachers, and researchers are haunted by histories of oppressive mathematics education, and 2) how we can reckon with ghosts as "pregnant with unfulfilled possibility" for change (Gordon, 2008, p. 183).

To greet the ghost of Mr. Montoya, I engaged in Jackson and Mazzei's (2012) "thinking with theory," reading theoretical perspectives and empirical data through analytic questions derived from and tied to both. The entangled nature of this method presses against forms of research that seek to classify and determine truths after data collection is "complete," instead honoring the ambiguous and emergent nature of any possible "truth." To do so, I attended to the "*flow* and *arrest* of thoughts" (Gordon, 2008, p. 65, italics original) in students' and teachers' talk to identify Mr. Montoya's presence, looking for "how a person translates his or her experience of historical trauma across time and space" (Zembylas, 2006, p. 315). I sought moments of wonder and surprise (MacLure, 2013) experienced by those haunted—students, teachers, and myself as researcher—rather than moments of clarity. I used these moments to examine what is known and what counts as reality, thus allowing ghosts to speak.

Preliminary Findings: Bearing Witness to Mathematical Ghosts

How does one listen when ghosts speak? Gordon (2008) suggests that by haunting, ghosts are "leading us somewhere… [calling for] something to be done" (p. 205), and that exorcising ghosts requires attending to their insistence on a future that is more just than the past (Yoon, 2019). Those who see hegemonic practices of teaching and learning mathematics as violent, then, are called by mathematical ghosts to *do* something. Zembylas' (2006) draws on Kelly Oliver and others to articulate "witnessing as an affective practice [and] an ethical and political project" (p. 316); I use this theorization to describe the somethings that Franck and Clark *do*. First, I present how Franck and Clark bear witness to mathematical ghosts by "see[ing] Others with loving eyes that invite loving response" (Oliver, 2001, p. 19). Then, I illustrate how they "wor[k] through rather than merely repeating the blind spots of domination" (Oliver, 2001, p. 218), being vigilant against the injustices that cause mathematical ghosts to appear (Zembylas, 2006).

Seeing Others with Loving Eyes. In the "state-sanctioned violence" (Yoon, 2019, p. 421) of public schooling, students who do not meet participation expectations are typically viewed as off task, disengaged, or noncompliant; as a researcher who has observed in hundreds of mathematics classrooms, I have seen many teachers react to students this way, and many students accustomed to this treatment. Both I and students, haunted by these assumptions, were consequently *arrested* when these assumptions were subverted. For the sake of space, I offer two brief examples from my data. First, when a student was unprepared to answer a question that Franck had given students ample time to answer independently and also discuss in their groups, Franck responded: "Oh you didn't have enough time. My bad." Similarly, when Clark noticed that several students had left blank his request for comments on a homework assignment, he said to the class, "I don't think you were being lazy. Maybe you just forgot and that's fine… it would be great if you left me two comments today but you don't have to." Mathematics classrooms are haunted by the assumption that students who do not participate how teachers expect them to are deficient. Franck and Clark challenged this so-called reality by offering generous interpretations that saw students with loving eyes instead of recycling damaging assumptions about them. In doing so, they opened up opportunities for future connection and reciprocity (Dutro & Bien, 2014).

Working Through Rather Than Repeating Domination. Franck and Clark, respectively, wanted students to have "an enjoyable five hours [each week]" and to "be at ease in my class." As a result, they grappled with whether particular pedagogical practices would contribute to or undermine this desire, even and especially those taken for granted as commonsense (Kumashiro, 2014) in other mathematics classrooms. Although they discussed many practices, here I share how they considered their participation expectations for students in light of mathematical ghosts summoned both in the guise of Mr. Montoya and by contemporary equity discourse.

Calling randomly on students to answer questions has long been commonsense practice in mathematics classrooms. Like many of their predecessors across decades and classrooms, several of the students I interviewed were haunted by memories of Mr. Montoya requiring that they stand at the whiteboard, in front of waiting classmates, until they could produce a correct answer. Clark bore witness to these mathematical ghosts, accounting for students' experiences and affects—what he called their "anxiety"—by offering ways for students to demonstrate their interest and ideas without repeating this exercise of teacher power:

> If you don't want to share [with the whole class], you can raise your hand and share with me as I'm walking around… you don't have to share in front of the class to get points… I don't want you to share for points; I want you to share for love. (classroom observation, 8/2018)

Ethics, however, demands engagement with the uncertainties and complexities in teaching. Upon hearing that one of their students associated being "randomly pick[ed] on" with "the way [my teacher] trusts me" in an interview that I conducted, Franck and Clark negotiated their surprise around how students interpret their actions (collaborative meeting, 2/2019):

Clark: This is interesting: 'because he really trusts you.' That's interesting. I would hesitate to pick students because I think they would feel—that's an interesting correlation, right?

[*Clark asks if I've seen comments like this before; I say I found it interesting too.*]

Franck: When you are doing the task, you are not particularly looking to solicit an answer, you're soliciting their thinking. 'Whatever you say is correct, even if it's wrong. It's okay, just tell me what you're thinking. You can't think wrong, even if the answer is wrong.' If we didn't do those things and if the problem has one answer and the kid says the wrong answer then they'll feel bad for being wrong…

Clark: I don't call on them randomly.

Franck: But you don't particularly call them for the ANSwer

Clark: No, I avoid that.

Franck: ‘Cause there's no point.
Clark: I would rather not you contribute to the result. Maybe, the process, or something, contribute to the process. Is just as important as contributing the result. So you trust them to contribute is maybe the way it could be seen. You're basically saying, like, the kids feel like you trust them to contribute something to the class. That feels like agency to me.

Asking students to publicly share answers is a common ritual in mathematics classes (Mehan, 1979) and a traumatizing one in classrooms like Mr. Montoya’s, but structured groupwork can also provide equitable access to mathematical learning opportunities (Cohen & Lotan, 1997). Even so, Franck wondered if insisting that students perform in specific ways repeats domination:

> I’m not sure if I’m sold on the fact that we need to make all the students in our class talk to each other… I’ll listen to the kids but I know like [student name] or certain kids in my class they don’t want to talk out loud and I don’t want to force them to. The philosophical questions I’m trying to reconcile are: what people are doing in their classrooms that’s deemed as equity and access [e.g. making students talk], to me it just seems annoying and you’re forcing it upon the kids… I’m still reconciling a lot of things. (interview, 2/2019)

Mathematical ghosts summoned by pedagogical practices taken for granted in both hegemonic and equity-oriented mathematics classrooms make students feel (uncomfortable, trusted, coerced) when teachers require them to speak in front of their classmates. Franck and Clark heed the affective hauntings of these ghosts and the power dynamics that they signal by contending with what forms of student participation they value and why, thereby starting to build towards a less traumatic, more transformative version of mathematics education.

Discussion: Stretching Toward the Horizon

Mr. Montoya is a named ghost who haunted Franck’s and Clark’s Algebra 1 classrooms during the school year I observed. He is also a stand-in for unnamed mathematical ghosts across contexts whereby students and teachers are haunted by histories of racialized oppression in public schooling, histories of hegemonic mathematics education, and their own personal histories of traumatizing mathematics experiences. I have begun to illustrate how Franck and Clark bear witness to mathematical ghosts by seeing their students with loving eyes and by working through rather than repeating domination. What happens when teachers bear witness to mathematical ghosts, rather than perpetuating the “abusive systems of power” that give rise to ghosts in the first place? I suggest that Franck and Clark are adopting an ethical stance in seeking to remedy past injustices by negotiating an alternative vision of mathematics education. The presence of mathematical ghosts attunes them to the violence done to students by hegemonic forms of mathematics education, and by transgressing—by attending to ghosts that might otherwise be ignored—they make possible a future that is different from the past.

RURAL PARENTS' VIEWS ON THEIR INVOLVEMENT IN THEIR CHILDREN'S MATHEMATICS EDUCATION

Daniel L. Clark
Western Kentucky University
daniel.clark@wku.edu

As rural parents can face barriers that are different from those encountered by suburban and urban parents, this study sought to assess the level of rural parents' satisfaction with their level of involvement in their children's mathematics education in a rural location in the Midwestern United States. Semi-structured interviews were conducted with seven parents from one rural school district. Parents' satisfaction with their level of involvement in their children's mathematics education correlated highly with their children's success in school mathematics. Another result found that often at least one of the rural parents in each household commuted a great distance each day from where their children attended school, but that the commuting parent was the parent most likely to help children with mathematics homework. Implications of this finding are discussed.

Keywords: Rural Education, Marginalized Communities, Communication

Purpose

Parental involvement has been shown to positively influence children's education (Sheldon & Epstein, 2005; Liu, Wu, & Zumbo, 2006). Rural parents can face barriers to involvement in their children's mathematics education that other parents do not. Therefore, the purpose of this study was to research the involvement of rural parents in their children's mathematics education. In particular, this study sought answers to the following research questions:

1. How satisfied are rural parents with their involvement in their children's mathematics education?
2. What level of involvement do they desire to have in it?
3. If they want more involvement, what hinders their involvement? On the other hand, if they want less involvement, in what ways would they like to be less involved?

Perspectives

This study was grounded in the previous work of Lareau, Civil, and Remillard and Jackson. First, Lareau (2000) discussed the idea of social capital. Essentially, some parents are able to interact more fluidly with mathematics teachers and the entire school setting than other parents are based on their previous experiences, perceptions of school mathematics and its purpose, and other related cultural values and norms. Indeed, some parents place themselves in perceived positions of authority over math teachers while others would never think of questioning a math teacher.

Next, Civil worked to help parents view themselves as funds of mathematical knowledge (Civil, Bratton, & Quintos, 2005; Civil & Bernier, 2006). Many parents have the knowledge to assist their children with school mathematics but simply are not confident in doing so. Regardless of their current mathematical knowledge, Civil et al. helped their participants see that they could both learn mathematics and facilitate mathematical learning at the same time.

Finally, Remillard and Jackson considered parents' involvement in their children's learning and schooling, both in terms of what the school could and could not see (2006). They considered a parent-centric view of parental involvement that consisted of three things: involvement in the

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

children's learning, involvement in the children's schooling, and involvement in the children's school. While all three are important, only the last of the three is directly observable by the school.

Methods

Context

Rural places and people are not homogeneous. There is variety among rural people both in different localities and within the same locality. This study focused on rural people who live within a 45-minute drive of an urban center in the Midwestern United States. Originally, families were sought for this study that both a) lived outside the city limits of the town or towns in which the children attended school and b) lived at least five miles from all schools attended by the children at the time of the study. Selecting parents to interview in this manner would have eliminated both those who live in towns and near schools. It was hoped that what remained would constitute a population from which a characteristically rural sample may be have been drawn.

Participants

Parents were recruited with the assistance of principals and mathematics supervisors. The principals and mathematics supervisors were sent a letter detailing the project and asking for help to identify potential participants.

Two principals recommended thirteen people who agreed to give their contact information to me. After being contacted, seven parents eventually participated in the interview process. After the interviews began, it became clear that the principals recommended some people who did not satisfy the original participant criteria of living outside of town and at least five miles away from the schools. Upon analysis, the comments of the parents who lived closer to the schools than originally desired were quite similar to those of the parents who did satisfy the original criteria. Therefore, the inclusion criteria were relaxed.

One *severe* limitation of this study, though, is that many of the people recommended by the principals were employed somehow either with the school district in which their children lived or another school district in the area (see the table below). When studying parental involvement in children's mathematics education, this clearly produces an unwanted bias in the participant sample; however, on one hand, because of this it could be argued that we should expect to see the best parental involvement results possible with this sample. In a more unbiased sample, we would expect to see less involvement and more frustration among parents than in this sample of school-affiliated parents. Therefore, the results below may well indicate a best-case scenario for rural parental involvement, while the reality is likely worse. On the other hand, it could be argued that a more representative sample of rural parents may well be nothing like this sample of mostly school-affiliated parents. Problems like this are typical of parental involvement studies. For example, Civil and Bernier's (2006) study of 15 mothers contained several who were teacher's aids, some who were members of the local parent teacher organization, and some who were already regularly volunteering in the schools. Similarly, nearly half of Jackson and Remillard's (2005) sample of mothers were highly involved in their children's schools before the study. While this study's sample is somewhat flawed and non-representative, the results below could still inform our ideas of rural parental involvement in mathematics education. Below is a table profiling the participants.

Table 1: Participants

Name	Children's Age, Grade, Gender	Education	Occupation	Spouse Education	Spouse Occupation
Amanda	23 21, F 15, 9th, F 12, 7th, M	Bachelor's degree	Nurse		

Brad	15, 10th, F 12, 7th, M 9, 4th, M 8, 2nd, M 3, F	Bachelor's degree	Youth minister in town of children's school	Bachelor's degree	Stay at home mother
Chad	15, 10th, F 12, 7th, F 8, 3rd, M	Master's degree	Middle school teacher 31 miles away	Associates degree	Childcare professional at children's school
Denise	12, 7th, F	One year of college	Lunch lady at school in child's district	High school diploma	Retail manager 25 miles away
Elizabeth	19, M 17, 11th, M 14, 9th, M	Master's degree	Elementary resource room teacher in children's district	Bachelor's degree	Administrator 17 miles away
Fallyn	17, 11th, F 13, 8th, M	High school graduate	Secretary in children's school	Two years of college	Construction foreman 24 miles away
Gabby	19, F 17, 11th, F 14, 8th, F	Master's degree	Kindergarten teacher 8 miles away	Bachelor's degree	Computer specialist 58 miles away

Data Collection and Analysis

Semi-structured interviews were conducted with the seven parents. With permission, the interviews were audio recorded and transcribed. Direct and indirect questions were asked to assess the participants' thoughts with respect to the research questions. Responses were probed to make sure respondents were being understood as fully and correctly as possible. The researcher also attempted to ask follow up questions that enhanced the narratives being given by the interviewees. As the interviews were semi-structured, a few standard questions were asked, but the flow of the interview and the information gathered were largely left to the interviewees.

In conducting these interviews, I was thinking of parental involvement in the terms of Lareau, Civil, and Remillard and Jackson. From Lareau (2000), I considered whether parents were as involved as they would like to be and maintaining communication about mathematics education with the schools in a way with which they felt comfortable. From Civil, I wanted to assess whether parents viewed themselves as funds of knowledge (Civil & Bernier, 2006). Furthermore, from an ethnomathematics perspective, I wanted to know how well they felt their knowledge and use of mathematics aligned with their experiences of helping their children with schoolwork. Finally, from Remillard and Jackson (2006), I wanted to ask about the parents' involvement in their children's learning and schooling, both in terms of what the school could and could not see.

After the interviews were collected and transcribed, an open coding process began. The interviews were listened to in their entirety as notes were affixed to the transcripts summarizing what points were being made. Then, the transcripts and notes were inspected for common themes. When a theme was found, all instances of that theme were highlighted in all transcripts.

Results

The first two research questions were: How satisfied are rural parents with their involvement in their children's mathematics education, and what level of involvement do they desire to have in it? During data analysis, it became apparent that these two research questions could not be answered separately. When asked the first question, five of the seven parents interviewed said that they were satisfied with their level of involvement. For many of them, though, it appeared that they were satisfied with their level of involvement because between them and their spouses they were doing what needed to be done for their children to succeed. So, the apparent answer to the second research question seemed to be that they desired whatever level of involvement was necessary for the success of the children at school mathematics.

One parent who stated at the beginning of the interview that she was "absolutely not" as involved as she would like to be was Gabby. She said she wished she could be more directly involved, but was happy that her husband and a hired tutor were helping her daughters get what they needed:

> Gabby: My husband does a little more, but if we really get in trouble, we hire a tutor.
> Interviewer: How has the experience been so far with hiring the tutor? Was that pretty easy to do, to find somebody?
> Gabby: It was wonderful. Because I'm a teacher, it was pretty easy. I think it's probably more difficult for other people. I think it was wonderful if you can afford to do it. Especially being a teacher, I'm kind of done with that when I get home, and I don't really want to deal with it any more. So, it's really nice. I happily would pay somebody to do that for me.

The other parent who wanted more direct involvement was Elizabeth, a kindergarten teacher in the district where her children attend school. She said all of her children have struggled with math and that she probably should have been more involved. She cited concerns of both her perceived lack of mathematical ability beyond the elementary level and the time commitment it would take to be on top of communicating with mathematics teachers in a meaningful way as keeping her from being more involved.

Even among the five parents who said they were satisfied with their level of involvement in their children's mathematics education when directly asked, sometimes the interviews indicated that they would be happy to be less involved if they thought their children could succeed in class with less involvement on their part. Denise was one such parent:

> Interviewer: When you say you're really involved in your daughter's math education and working with her on the advanced math stuff, what does that mean? What does that take the form of?
> Denise: It means I have an A in math right now. <*laughs*> Just kidding. It means that, basically, she'll come home with her math book and a sheet of questions, and she'll say, "I don't know how to do any of these. <*laughs*> And I'll have to read over the book and the first few pages of the chapter, and do the examples, and then teach her the math…I feel like I'm in class every time she has homework, and I have to relearn seventh grade algebra piece by piece, and then teach it to her, and then do the problems together.

So, in this case, Denise expressed before the above excerpt that she was as involved as she wanted to be, but it might be more accurate to say that she was as involved as she thought she needed to be for her daughter to succeed. At several points in her interview, she expressed frustration that her daughter seemingly always came home not knowing how to do the problems on the homework, which often made her question what went on during her daughter's math class. Denise's willingness to be involved in the process of doing the homework at this high of a level could also have contributed negatively to her daughter's education by allowing her daughter to pay less attention in class. Still, she was doing what she thought she needed to do in order for her daughter to be successful.

This brings us to the third research question regarding what causes unwanted parental involvement and what hinders desired parental involvement from happening. While Denise's comments best illustrate the only type of desire for less involvement found during the interviews, several common themes emerged from the majority of the interviewees' comments about what hindered their involvement. First, most of the parents that were interviewed said either they or their spouse had already reached a point where they did not feel confident helping with or doing the mathematics that their children were doing in school, or that they anticipated reaching that point in the future.

Whether the parents had already felt like they could no longer help their children with mathematics homework depended chiefly on the age of their oldest child. Those parents with at least one child in or beyond high school spoke of it as something that had happened already, as Amanda, Fallyn, and Gabby did. Those parents whose oldest child was only in middle school anticipated it, though. Denise, whose only daughter is in seventh grade, said:

There seemed to be two potential causes for this split. First, the parent most likely to be interacting with the school either worked in the school or at least in the town where the school was located. The other parent generally did not work in the same town where the school was located, and often worked in another town some considerable distance away. This sort of long distance commuting is common in rural areas; however, given these commuting distances, it makes sense why the one parent would be communicating with the school more regularly than the other because of proximity. Elizabeth, who works in the local school but whose husband works nearly twenty miles away, was one example of this phenomenon:

Second, however, where this parent split existed, it fell directly on gender lines. The mothers were more likely to be working at the school or in the town of the school, and the fathers tended to work in another town. Also, among the parents interviewed, the two men were helping their children with mathematics homework. One of them noted that his wife wasn't comfortable doing so, or would often ask him questions afterward on the occasion that she did assist her children with math. The majority of the five women interviewed said that their husband was the primary mathematics homework helper in the home, particularly once the children were beyond elementary school. Chad, who is a certified mathematics teacher in another district over thirty miles away, but whose wife works in the local schools, was in this situation:

Conclusions

This study also attempted to determine what hinders and what facilitates rural parental involvement in mathematics education. One main finding was that while the geographically closer mothers were often the parents engaging in the most communication with the children's teachers, the fathers who were more confident in their mathematics ability but worked farther away were most often the parents assisting the children with their mathematics homework. Clearly this disconnect is not ideal. Having teacher communication with the parent most likely to help the children with the mathematics would be more helpful.

It would appear that there are two potential ways to close this disconnect. First, as Civil et al. (2002) and Jackson and Remillard (2005) have done, the mothers can be engaged in a way that results in them feeling more confident with their mathematics ability. In turn, they might be more likely to help their children with their mathematics homework. Recall Gabby, who helped her children with homework in other areas, but said she "must" stay away from helping her children in mathematics because of her lack of confidence at doing mathematics.

Second, perhaps more could be done to facilitate more communication between the fathers and the schools. Granted, the fathers tended to work farther away. This largely caused the lower level of communication with the schools and lower attendance at parent conferences. One tool that could potentially help this situation is the Internet. While work locations may well interfere with a rural father's ability to attend parent-teacher conferences held during the school day or shortly thereafter, the Internet is available at any time. Perhaps mathematics curricula authors and mathematics teachers could work together with rural fathers to find ways to engage with each other meaningfully using the Internet. This could be as simple as sending out a daily email as some of the interviewed parents said some teachers did. It could also be more broad-based in scope, with curricula authors developing modules for teachers to display on their websites for parents not familiar with the type of mathematics being taught or the way it is being taught. Also, while it is closing, the digital divide is still a matter to contend with for many rural families. While this is still the case, perhaps more low bandwidth Internet solutions should be studied.

AN ETHNOGRAPHY OF RE/HUMANIZING (MATH) PEDAGOGIES AT A PREDOMINANTLY LATINX CALIFORNIA HIGH SCHOOL

Emma C. Gargroetzi
Stanford University
egroetzi@alumni.stanford.edu

This ethnographic study of one predominantly Latinx-serving high school in California theorizes around the functioning of re/humanizing pedagogies layered through the school and the mathematics department as they challenged flattened social, academic, and mathematical identities. Findings revealed that math department practiced built from school-wide commitments, offering students de-flattened identities. However, challenges remained specifically related to the availability of advanced mathematics courses.

Keywords: culturally relevant pedagogy, equity and diversity, high school education, marginalized communities

Colonial projects flatten the histories and lived experiences of minoritized communities, presenting homogenized narratives that label, compare, and sort people into groups for the sake of resource extraction and economic gain (Mignolo, 2003; Said, 2012). Schools are critical sites for the reproduction of these flattened social categories, (Eckert, 1989; Willis, 1977). Mathematics education participates in this project by providing fodder for categories of intelligence through the political legitimacy of mathematics (Apple, 1993) and the proliferation of tracking available in K-12 mathematics education that consistently relegates minoritized students to lower tracks where they are denied quality learning opportunities (Oakes, 1990).

The persistent reproduction of inequitable mathematical learning experiences and outcomes for minoritized students is well documented (Martin 2013; Tate, 1994). Yet, calls for change most often center mathematics pedagogy and programming as sites for intervention without attention to school-wide culture and organization beyond mathematics itself (NCTM, 2018).

This paper presents findings from a school-based ethnography that examined the production and negotiation of identities of mathematical competence across one predominantly Latinx-serving high school in California. The study uses re/humanizing pedagogies as a lens for asking how identities of mathematical competence were produced and negotiated. The dual focus on both whole school and math department commitments and practices revealed both resonance and tensions. Findings demonstrate that school and math department commitments challenged the flattening of social, academic, and mathematical identities to varying degrees of success.

Humanizing Pedagogies and Rehumanizing Mathematics

I use humanizing pedagogies (Bartolome, 1994) as an umbrella term inclusive of those pedagogies that challenge the colonial flattening of minoritized students. Under this umbrella, and specific to this study I focus on pedagogies that center care and relationship (Noddings, 1988; Valenzuela, 2005), and those that embrace responsibility for providing opportunities for academic excellence and supports, especially attending to the most vulnerable or traditionally excluded (Ladson-Billings, 1995; Duncan-Andrade, 2005). Care and responsibility were central commitments of Sierra High School (SHS), the site of the study. Relations of care and deep responsibility for students were understood by SHS staff as challenges to the exclusion and neglect common to experiences of schooling for minoritized students.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Specific to mathematics education, Gutiérrez (2018) poses eight dimensions of rehumanizing practice. SHS math department commitments closely resonated with two: participation/positioning and the broadening of mathematics. Rehumanizing mathematics practices position students as valued participants in mathematics itself, not simply as consumers. A broadening of mathematics includes understanding mathematics as a living practice that entails communication, reflection, visual approaches, and collaboration.

The dual frameworks of re/humanizing pedagogies and practices provided a lens through which to conceptualize the relationship between the school and math department in disrupting flattened social, academic, and mathematical identities to varied degrees of success.

Methods

Ethnography is an anthropological method for tracing cultural production and involving participant observation in the community of study over an extended period of time (Geertz, 1973). Ethnography was chosen for this study to enable mapping production and negotiation of intersecting social and mathematical identities at multiple layers.

Sierra High School, the site of the study was a predominantly Latinx-serving public high school in a small urban district in California. The school faced a history of racialized stigma as the only predominantly low-income and predominantly Latinx school in a highly segregated district. In the years immediately preceding and including the study, the school community was conscientiously working to provide a counter-narrative to this entrenched negative reputation.

Over two school years, the author acted as a participant observer across multiple school contexts including academic and non-academic spaces, with a focus on mathematics teaching and learning. All math teachers were observed and interviewed. Formal and informal interviews were conducted with students and either audio-recorded or captured in fieldnotes. Detailed fieldnotes were produced daily. Artifacts were collected including lesson plans, student work, school brochures, and math course enrollment data by student.

Analysis entailed bi-weekly review of field notes and artifacts and the production of an analytic memo (Emerson, Fretz & Shah, 2011). Analytic memos captured new and recurring themes and critical incidents that illuminated or contradicted details of a developing theme (Creswell & Poth, 2016). The themes of care, responsibility, and de-flattening were identified and elaborated through this process.

Findings

I use two metaphors from SHS – the Energy Bus and the sheep – to illustrate the SHS staff's commitments to care and responsibility. These school-level commitments permeated the mathematics department as well. A commitment to responsibility was expressed through the providing students an abundance of opportunities for both academic excellence and academic support. These opportunities also provided opportunities for relationships of care between teachers and students. Together, forms of responsibility and care functioned to challenge the flattening of social and academic identity categories, including but not limited to those of mathematical competence. However, challenges remained. Specifically, the availability of categories related to advanced math courses reproduced flattened math identities and racialized the distribution of these positions.

Sierra High School Commitments: The Energy Bus and the Sheep

When I initially approached the SHS math department about research I was enthusiastically welcomed to the "Energy Bus." The Energy Bus was a metaphor used by the staff to describe the dramatic commitment of energy to students that SHS staff undertook together. This metaphor permeated staff communication. The Google Drive that hosted teacher resources was named "The

Energy Bus." At the opening staff meeting of school year 2018-2019, new staff were introduced and enthusiastically commanded to "Hop on the Bus!" (Fieldnote 8.10.18).

At the same opening staff meeting the Principal shared a video from her summer trip to Ireland, where she visited a sheep farm. Staff knew that she was raised on a sheep farm, and the use of sheep as a metaphor was familiar. The video showed a tractor and a sheepdog working together to maneuver a herd of sheep across a road into pasture. The sheepdog was seen gently pursuing one sheep who had strayed from the group. After sharing the clip, Principal James asked, "Did anyone think of any likenesses?" Staff called out, "kindness," "patience," "encouragement" comparing the role of the sheepdog's to theirs as teachers. One staff member commented, "You gotta get them all, we're not going to leave any one on the side of the road." The principal concluded, "Love always goes way farther with our kids. They need clear boundaries and some sternness, but there has to be love in there." (Fieldnote, 8.10.18).

The Energy Bus and the sheep metaphors were lived in tandem at SHS, through the provision of a multitude of opportunities for academic and extra-curricular excellence as well as academic and social supports. Centrally organizing the joint commitment to academic rigor and academic support was the combination of two programs: Advancement Via Individual Determination (AVID) and the International Baccalaureate (IB) program. These two programs traditionally have distinct target audiences. An AVID teacher described AVID as supporting "students who could go to college but just didn't have the things they needed to get there" (Interview, 1.11.19). In contrast, IB coursework and the IB Diploma program provide an elite international certificate of advanced standing.

Students, while enthusiastic about the plethora of high quality academic and extra-curricular opportunities offered, consistently cited their teachers as the best thing about SHS. Students described teachers using words such as "supportive," "friendly," "nice," and "helpful." One student explained, "All the teachers I've had - they were always there when I needed help, so I think teachers are pretty amazing here" (Interview, 10.24.18, 11th grader). Another student said the best thing about SHS was "the connections I feel with my teachers. The more you build connections with them the more confident you feel to ask a question or share during class" (Fieldnote, 9.11.18, 12th grader).

The SHS Math Department: We Keep it Rollin'

SHS math teachers in particular were recognized by students and staff as providing multiple layers of support and care, making themselves available during lunch and after school, and providing opportunities for re-takes of assessments and submission of late assignments. As one guidance counselor said, "Our teachers are here, especially in the math department, all the time. They're here all the time working with kids that come to see them" (Interview, 10.12.18). Classroom observations captured interactions across all ten math teachers that reflected rapport with students – examples of evidence included the use of humor and making connections to students' lives within and beyond instructional contexts.

In accordance with NCTM's articulation of the tenets of high quality mathematics instruction (NCTM, 2014), the SHS math department was committed to student-centered and discourse-oriented approaches to teaching and learning mathematics. These approaches centered student participation and positioned students as authors of mathematical ideas, with students relying on each other for evaluation and revision of those ideas through peer conversation. These practices were in line with Gutiérrez's (2018) "participation/positioning" dimension of rehumanizing mathematics. Observations of all teachers evidenced that students worked in collaborative groups and engaged in rich mathematical tasks. The department used a set of curricular materials reflecting discourse and sense-making approaches to mathematics. The department collaborated to revise and extend the materials to support and challenge their own students where they saw the need, providing expanded notions of the discipline of mathematics, Gutiérrez's sixth principle.

De-Flattening: Successes and Challenges

The wide range opportunities available and the commitments of adults to building connections with students provided students multiple access points to into the school community and relatedly multiple opportunities for complex identities. For example, in a space with a majority Latinx student-body this meant that understandings of what it meant to be Latinx were taken for granted as multiple and complex - drum major, IB student, lead actor in the school play, football player, valedictorian, or community service club president.

The particular combination of opportunities and supports combined with the caring teacher relationships also served to broaden notions of academic excellence. For example, students at times were jointly enrolled in IB courses and in AVID. AVID, a symbol of extra support for reaching college, was widely respected at the SHS suggesting a de-flattening of notions of excellence in which making use of a wide range of academic supports was not equated with being a low-achiever or being unsuccessful.

In the context of mathematics, students also articulated complex ideas about mathematical competence where students consistently referenced participation, perseverance, and being able to explain to others as indicators of mathematical competence. While many students also shared notions of mathematical competence that included accuracy and speed, in line with the dominant narratives of success in math (Franks, 1990), the de-flattening of mathematical competence itself provided expanded opportunities for students to identify as people with mathematical competence.

One significant challenge to the de-flattening of identities through re/humanizing pedagogies at SHS was the fact that the multitude of programs made available a multitude of categories related to these courses and programs. While the aspirational vision of the school was one where every student benefited from both IB-level rigor and AVID-informed supports, the particular prestige of IB courses was recognized by students as a marker of comparative intelligence and status. In the math department specifically, Latinx students were underrepresented in IB courses and in their advanced prerequisites.

Discussion and Implications

School-wide commitments to care and an outpouring of energy through academic and extra-curricular programming was reflected in the mathematics department through student-teacher relationships and was extended through pedagogical commitments to student-centered, sense-making pedagogies that offered expanded views of mathematics and therefore more expansive and inclusive opportunities for students to identify people with mathematical competence.

Careful attention to the school context revealed the ways in which school level commitments shaped the aspects of rehumanizing mathematics practices taken up in the math department. Findings suggest that the rehumanizing math practices that math teachers develop will draw from whole-school commitments. At the same time, there may be tensions between the school-level conceptualization of humanizing pedagogies and enactment in the mathematics context. For example, mathematics education is one of the disciplines most susceptible to notions of comparative categories, including both advancement and remediation, such that the multitude of high quality opportunities at SHS, while largely celebrated by students and families, played into the reproduction of widely available of narrow, comparative, and racialized categories of math student.

SUPPORTING THE WHOLE STUDENT: BLENDING THE MATHEMATICAL AND THE SOCIAL EMOTIONAL

Sara Gartland
University of Delaware
sgart@udel.edu

This case-study sought to describe instruction that supported students' mathematical learning (ML) and social-emotional learning (SEL). Transcripts from audio-recorded lesson observations and teacher interviews, field notes, and written teacher reflections were collected to answer two research questions: (1) In what ways does a high school mathematics teacher support ML and SEL during instruction? (2) How does the teacher characterize her attempts to provide social-emotional and mathematical supports during instruction? Preliminary findings suggest that strategies for revising ideas and handling errors support students ML and SEL.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Classroom Discourse; Equity and Diversity; High School Education

Traditionally, research in mathematics education has focused much of its attention on achievement. However, a growing body of research suggests that maintaining a focus on achievement ignores other key factors in understanding students' learning of mathematics, especially in discussion- and collaboration-oriented classrooms of the reform era (Bargagliotti, Gottfried, & Guarino, 2017; Battey & Levya, 2016; Horn, 2008). More specifically, researchers have highlighted the importance of understanding the social and relational aspects of particular learning contexts (Battey, 2013; Battey & Levya, 2013; 2016; Hackenberg, 2005; 2010; Moschkovich, 2002).

Across a variety of contexts, researchers have noted the importance of teacher-student relationships (Allexsaht-Snider & Hart, 2001; Averill, Anderson, Easton, Smith, & Hynds, 2009; Delpit, 2012; Hackenberg, 2005). These relationships are especially important – and complex – when students and teachers from different cultural backgrounds come together to pursue the learning of mathematics (Battey, 2013; Delpit, 2012; Hackenberg, 2010). Therefore, the primary goal of this study is to describe mathematics instruction that fosters students' development of positive relationships with individuals and mathematics within the classroom.

Theoretical Framework

Seeking to understand the social and relational elements of instruction is a complex undertaking (Battey, 2013; Hackenberg, 2010; Horn, 2008). A previous study (Gartland, 2019) identified instructional moves made by a third-grade mathematics teacher that supported students' mathematical learning (ML) *and* their social-emotional learning (SEL). Additionally, Bargagliotti, et.al. (2017) linked instructional choices made in kindergarten mathematics to students' learning *and* social-emotional development. However, I have yet to locate literature on supports for ML and SEL at the high school level. This study addresses that gap.

Supporting Mathematical Learning

Positive social interactions and relationships within the classroom are a necessary element of instruction. Thus, Battey's (2013) framework for *relational interactions* to help define what I consider to be instruction that supports ML. A relational interaction is "a communicative action or episode of moment-to-moment interaction between teachers and students, occurring through verbal and nonverbal behavior that conveys meaning and can mediate student learning" (Battey & Levya,

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

2013, p. 981). A relational interaction can be categorized as: addressing behavior, framing mathematics ability, acknowledging student contributions, attending to culture and language, or setting the emotional tone (Battey, 2013). These categories take into consideration a teacher's Mathematical Knowledge for Teaching (Loewenberg Ball, Thames, & Phelps, 2008) and other instructional practices for focusing students on mathematical ideas (Battey, 2013). Thus, I consider instruction that supports ML to be the observable relational interactions and instructional decisions associated with meeting a particular mathematics learning goal.

Supporting Social-Emotional Learning

Instruction that supports students' SEL has been most systematically researched in the K-6 context (Weissberg & O'Brien, 2004). However, with increasing numbers of districts adopting SEL initiatives, the Collaborative for Academic, Social, and Emotional Learning (CASEL) has taken a leading role in working with schools to research and promote SEL best practices (Blad, 2015) at all levels of schooling. Across SEL curricula and policy documents, several key features emerged. Instruction that supports SEL in students can be defined as what a teacher does to promote self-awareness and self-management of feelings, positive identity development, and decision-making skills among students (CASEL, 2019; Elias & Moceri, 2012).

Blending Mathematical and Social-Emotional Supports

More research shows the benefits of SEL-focused interventions than on intentional blending of academic *and* social-emotional supports (CASEL, 2019; Weissberg & O'Brien, 2004). Even fewer studies directly link ML and SEL. In one such study, Bargagliotti, et.al. (2017) highlighted relationships between kindergarten mathematics instruction and academic and social-emotional outcomes. Although they noted several positive associations between mathematics instruction and *both* academic and social-emotional outcomes, they warned "readers against generalizing these findings to grade levels beyond kindergarten" (p. 27). In response to their concern, this study aims to explore similar phenomena at other grade levels.

Since little research exists that explicitly describes instruction that supports both ML and SEL, other literature informs potential areas of overlap. Real-time reports of academic-SEL integration in school districts (CASEL, 2018) as well as research on learning from errors in mathematics (Steuer, Rosentritt-Brunn, & Dresel, 2013; Zander, Kruetzman, & Wolter, 2014) point to instruction on the handling of errors as a means for improving discussion and collaboration. Futhermore, instructional strategies such as *rough-draft talk* (Jansen, Cooper, Vascarello, & Wandless, 2017) can provide students with opportunities to discuss not only errors but also incomplete mathematical thoughts in ways that enhance the learning experience. These findings highlight a space for potentially observing instruction that supports both ML and SEL.

Guided by these ideas, this study explored two research questions: (1) In what ways does a high-school mathematics teacher support ML and SEL during instruction? (2) How does the teacher characterize her attempts to provide social-emotional and mathematical supports during instruction?

Methods

Participant

This paper presents the preliminary findings from a case-study (Hatch, 2002) of one high-school mathematics teacher, Ms. Yang. She has 5 years of experience teaching at a large suburban high school, and she has taught versions of Geometry, Algebra, Pre-Calculus, and Calculus. Ms. Yang actively participates in professional development and continuing education focused on improving students' discussion of mathematics.

Data Collection

A variety of data was collected over the course of a high-school semester. Four audio-recorded observations of an 80-minute, semester-long, college-preparatory, integrated mathematics course were conducted. In addition to the audio-recordings, each observation also generated field notes, a transcript, and a written teacher reflection. Finally, following the final observation, Ms. Yang participated in a half-hour semi-structured interview (Strauss & Corbin, 1994).

Data Analysis

Data analysis is currently ongoing. Thus, data has been, and will continue to be, coded using multiple approaches. First, a priori codes informed by the literature were applied to the data. More specifically, data was coded for observed relational interactions (Battey, 2013), which constitute ML supports, and observed SEL supports (CASEL, 2019). Next, an open coding process was used to reveal any unanticipated themes or patterns (Hatch, 2002). Codes have been compared and grouped using a constant comparison approach (Strauss & Corbin, 1994). Observation data has been more thoroughly analyzed than the interview data at this point.

Preliminary Findings

The following sections present two emerging themes. First, rough-draft talk frequently stood out as an instructional practice that supported ML and SEL in Ms. Yang's class. Second, while reflecting on and discussing her own teaching, Ms. Yang consistently linked student feelings of comfort and confidence with high quality mathematics.

"I'm Not Looking for a Final Answer."

To the left of Ms. Yang's Smart Board was a section of decorated space dedicated to "Rough Draft Talk," in which paper cut-outs of hands giving a "rock-on" gesture contain examples of what constitutes rough-draft talk. On another wall, the "Rights of Learners" (Kalinec-Craig, 2017) were listed: students in this classroom always have the right to be confused, to make a mistake, to say what makes sense to them, to share unfinished thinking and not be judged, and to revise their thinking. These displays and the consistency with which she referred to aspects of rough-draft talk as conceptualized by Jansen, et. al. (2017) and the rights of the learner showed that they were an integral part of her teaching practice. Most importantly, instructional practices involving rough-draft talk emerged as the ones most frequently supporting both ML and SEL.

While coding the data for relational interactions and SEL supports, references to and the use of rough-draft talk appeared often. To investigate relationships between the three constructs further, excerpts that illustrated the principles for supporting rough-draft talk (Jansen, et.al., 2017) were selected. Then, any codes for ML supports (i.e. relational interactions) *and* SEL supports associated with the excerpts were noted. This process allowed connections to be drawn between key features of each construct. Table 1 summarizes the relationships between the principles for supporting rough-draft talk and observed instruction that was coded as a relational interaction *and* a support for SEL. Also included in the table is an excerpt illustrating each principle.

Table 1: Rough-Draft Talk as a Support for Mathematical and Social-Emotional Learning

Principles for Supporting Rough-Draft Talk	Corresponding ML Categories	Corresponding SEL Supports
1) Foster a culture supportive of intellectual risk taking	Framing mathematics ability; setting the emotional tone	Promoting decision-making skills

Example: "Can I see your graph? Would you be willing to share it on any of these boards? No pressure, no pressure…Oh! Snaps! Snaps! Hey, and that's your right, right? Share unfinished thinking. No one's judging you. Thank you for even starting this off."		
2) Promote the belief that learning mathematics involves revising understanding over time	Acknowledging student contributions; addressing behavior	Promoting self-awareness and self-management of feelings; promoting positive identity development
Example: "Do you know all the words for the different transformations? Can you rattle them all off? …How about this, if you don't know them just say left/right, up/down, big/small. Okay? Mirror. Whatever it is. Then we'll refine those words together."		
3) Raise students' statuses by expanding on what counts as a valuable contribution	Acknowledging student contributions; framing mathematics ability	Promoting positive identity development
Example: "Thank you! For being honest about that! How many of us felt that way? Like, 'the three minutes lapsed and I don't have any idea what is happening.' Hey! Look around the room. Everybody's in the same boat as you. You're good. Alright, so help each other out."		

"Be Brave. Be Kind"

A second finding is that when discussing her own instruction Ms. Yang tends to focus on decisions related to student discussions of mathematics. In describing those decisions, she almost invariably links the decisions to perceived student comfort and confidence. For example, Ms. Yang explained that "the students shared how it's not so much what their teachers say that makes them feel devalued, but it's what [their teachers] don't say when they present an answer that makes them feel like there was something inherently wrong with their response." In working to avoid those types of interactions, Ms. Yang expects herself and her students to live by the class motto: "Be brave. Be kind." She believes that deeper and higher quality mathematics discussion, and therefore learning, will take place only after students feel comfortable and confident in the classroom. This finding will likely be expanded as the analysis of the interview data is completed.

Discussion and Conclusion

Individually, these findings identify a particular instructional strategy that supports both ML and SEL and highlight the ways in which a high-school teacher characterizes her own attempts to provide such supports. Taken together, these findings suggest that teachers who attend to student comfort and confidence within the classroom are likely to be implementing instructional strategies that support both ML and SEL. This is significant because such limited research exists beyond the K-6 grade bands related to the integration of ML and SEL. More specifically, it provides a viable starting point for future research.

Limitations associated with the single-participant case-study design prevent generalization and establishment of any links between the support of ML and SEL and student learning outcomes. Additionally, this study excludes the student perspective. Thus, immediate future research will focus on collecting and analyzing student data to continue gaining a deeper understanding of instruction of this type.

NON-BINARY PEOPLE'S VIEWS OF GENDER AND MATHEMATICS

Jennifer Hall — Monash University — jennifer.hall@monash.edu

Travis Robinson — Monash University — travis.robinson@monash.edu

Limin Jao — McGill University — limin.jao@mcgill.ca

A considerable corpus of research exists about people's views of gender and mathematics. As this research is nearly always reported by binary participant groups (e.g., women/men), there is a gap in the research about the views of people with non-binary genders. We conducted a study in Canada and Australia about the general public's views of gender and mathematics. Here, we report on the findings specific to the non-binary participants in the study (n = 7). Participants generally were quite gender-egalitarian in their responses, demonstrated sound understanding of gender as a social construct, and avoided the use of "sex" language and binary language. We conclude by discussing considerations for conducting research with non-binary participants.

Keywords: LGBTQ; Gender and Sexuality; Affect, Emotion, Beliefs, and Attitudes

A great deal of research has been conducted about people's views of gender and mathematics, the vast majority of which has been undertaken with students, teachers, and parents (e.g., Denner, Laursen, Dickson, & Hartl, 2018; Moè, 2018; Nürnberger, Nerb, Schmitz, Keller, & Sütterlin, 2016). Although parents and teachers certainly play a substantial role in students' developing conceptions of gender and mathematics, it is also important to understand the broader context in which these conceptions form. Therefore, investigating the general public's views of mathematics provides crucial information about other views to which students are exposed.

There is a paucity of research about the general public's views of mathematics, and even less regarding the general public's views of gender and mathematics. One notable study about the latter topic was conducted by Forgasz and Leder in Australia, working with international collaborators in Canada, South Korea, Spain, and the United Kingdom (e.g., Hall, 2018; Forgasz, Leder, & Gómez-Chacón, 2012; Forgasz, Leder, & Tan, 2014). Participants were asked about their views of gender and mathematics, as well as related topics (e.g., science). All of the gender-related questions used in this study were worded in a binary manner (e.g., "Who are better at mathematics, girls or boys?"), and participants' genders were assumed, based on appearance, by interviewers.

Although the findings of this study are informative, we were concerned about the binary wording of the questions, as well as the gender attributions (Ryle, 2019) made by the interviewers. Therefore, we adapted Forgasz and Leder's instrument so that the questions were written in a non-binary manner, and participants were explicitly asked to identify their genders. We trialled this instrument in Canada and Australia with approximately 400 members of the general public.

Here, we report on findings specific to a participant group that is vastly under-represented in research: non-binary people. In studies regarding people's views of gender and mathematics of which we are aware, findings are presented by binary participant groups (e.g., girls/boys). Such groupings are indicative of binary conceptions of gender and therefore marginalize an entire gendered participant group and overlook their views and experiences.

Theoretical Perspectives

Working from a feminist and social constructivist stance, we view gender as a performative social construct that occurs on a spectrum, rather than in a binary (Butler, 1999; Ho & Mussap, 2019). Specifically, we conceive of gender as the "behavioral, social, and psychological characteristics"

(Pryzgoda & Chrisler, 2000, p. 554) of women, men, and non-binary individuals. The broader category of non-binary genders comprises several variants, such as pangender and genderqueer. Here, for simplicity and to reflect our participants' terminology, we use the term "non-binary" to refer to participants with genders outside the woman/man binary.

Since gender is a social construction, what is considered appropriate for each gender is subject to the specificities of time, place, and culture. Mathematics is a field that was historically and continues to be conceptualized as masculine in Western culture (Ernest, 1998; Leyva, 2017). Hence, exploring views of gender and mathematics remains a worthy research goal.

Research Design

The study was conducted in two large, comparable cities: one in Canada and one in Australia. People in four 'matched' public places (e.g., shopping mall in each city) were approached and asked to orally complete a brief questionnaire about their views of gender and mathematics. In the following sections, we describe the data collection instrument, participants, and analysis methods.

Data Collection Instrument

Our data collection involved the replication of some questions from the questionnaire used in the aforementioned study led by Forgasz and Leder, but we altered the gender-related questions to make them non-binary. For instance, instead of asking "Is it more important for girls or boys to study mathematics?", we asked "For which gender is it most important to study mathematics?" The purpose of changing the wording was twofold: 1) We did not want to provide binary gender options and 2) We wanted to make the wording sufficiently open-ended so that participants would use their own wording in their responses. As such, we were able to analyze the linguistic choices that the participants made in their responses, as we will later discuss.

The questionnaire had three sections. In the first section, participants provided demographic information (e.g., gender, age). Participants' genders were not assumed based on appearance; rather, participants were asked, "What is your gender?" In the second section, participants were asked five questions about their views of gender and mathematics (e.g., ability, importance) and prompted to explain their responses. In the third section, participants were asked three questions about their views of gender and related constructs (e.g., sex) and again prompted to explain their responses. Finally, participants were given the chance to provide any additional comments about gender and mathematics. Here, we report on findings from the second section of the questionnaire.

Participants

In total, 405 adult participants took part in the study: 195 from Australia and 210 from Canada. Due to the participants' inconsistent use of gender terminology (e.g., woman, man, genderqueer) and sex terminology (e.g., female, male), responses to the gender demographic question were combined into the following categories: women/females/etc., men/males/etc., and non-binary. Examples of 'etc.' responses were "girl" for the first category and "bloke" for the second category. Information about the participants is shown in Table 1, with percentages applying to columns.

Table 1: Australian and Canadian Participants, by Gender Group

Gender Group	Australian Participants	Canadian Participants
Women/Females/etc.	88 (45.1%)	109 (51.9%)
Men/Males/etc.	105 (53.8%)	96 (45.7%)
Non-Binary	2 (1.0%)	5 (2.4%)

There was a higher proportion of non-binary participants in Canada than in Australia. In total, seven (1.7%) of the participants across the sample were non-binary. This percentage is slightly higher than estimates (less than 1%) from larger questionnaires conducted with the general public in Australia and Canada (Australian Bureau of Statistics, 2018; Waite & Denier, 2019). Additional details about the non-binary participants are shown in Table 2.

Table 2: Demographic Information about Non-Binary Participants

Participant	Gender Response	Age Category	Language(s) Spoken at Home	Highest Level of Education Completed
AusNB1	"genderqueer… non-binary"	18–39	English	High school
AusNB2	"non-binary"	18–39	English	College*
CanNB1	"non-binary"	40–59	French	College
CanNB2	"other or third"	18–39	English	High school
CanNB3	"non-binary"	18–39	English	High school
CanNB4	"non-binary"	18–39	English	Undergraduate
CanNB5	"non-binary"	18–39	English/French	Undergraduate

**Note: In Australia and Canada, college is a post-secondary institution that typically offers career-focused programs.*

Data Analysis

The participants' responses to the open-ended questions were analyzed using emergent coding (Creswell, 2014). That is, all responses to a question (from the entire dataset) were read multiple times to get a sense of the data. Then, codes were created and applied to the responses. Participants' responses were also allocated a "sex/gender language" code (SGL code; e.g., sex, gender, mixed) and a "binary/non-binary language" code (BNBL code; e.g., binary, non-binary, no indication). For instance, if a participant responded, "It's equally important for boys and girls to study math," the response would be coded with a "gender" SGL code and a "binary" BNBL code. In contrast, a response of "Males, females, and people of mixed genders can do math equally well" would be given a "sex" SGL code and a "non-binary" BNBL code. Due to the small number of non-binary participants, only descriptive statistics (e.g., counts) could be calculated.

Findings

In the following sections, we provide details about the non-binary participants' views on gender and mathematics, based on their responses to five open-ended questions on these topics. Unless otherwise mentioned, no SGL or BNBL was used in the vast majority of responses.

Relationship Between Mathematics Ability and Gender

Participants were asked whether they believed that mathematics ability was related to gender, and, encouragingly, most (n = 5) did not. Participants cited that individual variability precluded this kind of relationship, as characterized by a comment that any observed ability difference "is due to socialization and it's not actually due to their innate abilities" (CanNB5). Of the participants with other viewpoints, one argued that there was "a very strong emphasis in males, especially to perform in mathematics" (CanNB2) and the other explained that "girls are better at maths because they…are raised to have more patience, are not expected to just be good at things automatically" (AusNB1). Interestingly, these participants also justified their positions using arguments about social practices, rather than inherent differences.

Change Over Time in this Relationship

Next, participants were asked if they believed that there had been a change over time in the relationship between mathematics ability and gender. Most (n = 5) expressed a belief that there had been a change over time, but that this change related to outcomes rather than actual ability. Participants noted that there has been increased opportunity in recent times for people with marginalized genders to access mathematics. AusNB1 explained that "education and employment in maths and sciences hasn't been accessible to women and people of other genders historically until very recently." The remaining participants indicated that they did not think there had been a change over time but did not elaborate on their reasoning. In terms of the use of SGL, the bimodal responses ($n = 3$ for each category) were gender language or no indication of SGL.

Perceptions of Parents' Views of this Relationship

Participants were asked if they believed that parents thought that mathematics ability was related to gender. The responses to this question were bimodal ($n = 3$ for each category): that it depended on the parents or that parents favoured boys. For example, CanNB1 suggested that parents' views depended on their cultural backgrounds, whereas AusNB1 argued that "obviously parents have gendered expectations of the vocations that their children will choose and I think they probably are more likely to expect boys to become engineers." While responding, some participants referenced their own parents' views, while other participants answered generally.

Perceptions of Teachers' Views of this Relationship

Participants were also asked if they believed that teachers thought that mathematics ability was related to gender. There was little consistency in the responses: three participants said that such views depended on the teacher, one thought that teachers favoured boys, one thought that teachers viewed all children equally, and two provided unclear responses. Some participants responded generally, while others extrapolated from their own experiences. For example, AusNB2 reported, "I just feel like they would always put the people that were males ahead of the class or think that they would do better" and shared a story of a teacher thinking that they cheated on a test because they earned 100%, while no boys did (AusNB2 identified as a girl at this point).

Gender and the Importance of Studying Mathematics

In the final question, participants were asked, "For which gender is it most important to study mathematics?" The modal response ($n = 5$) was that it was important for people of all genders to study mathematics. For instance, CanNB2 stated, "I believe all of them are equally important. I don't think that professions should be limited by gender." The other two participants 1) provided an unclear response and 2) stated that it was more important for women to study mathematics. While responding, four participants used non-binary language while one used binary language.

Concluding Remarks

In this report, we described the findings pertaining to the non-binary participants in our study of the general public's views of gender and mathematics. Generally, these participants held gender-egalitarian views and mixed perceptions of others' views (i.e., teachers, parents). With regards to language use, use of any SGL or BNBL by the participants was limited. However, when used, sex language was rare, and only one instance of binary language occurred. Although we cannot know for certain, it is reasonable to assume that as a result of their personal experiences exploring gender, these participants are more knowledgeable and understanding that gender is social construct. Indeed, non-binary people tend to use gender-related language that is more sophisticated than that used in general society, and they are more likely to use gender language and non-binary language than are people with binary genders (Hall & Jao, 2018a, 2018b; Matsuno & Budge, 2017).

Pervasive binary perspectives and structures of gender in society continue to marginalize non-binary people. We, in the mathematics education community, are not immune to such marginalizing practices. In the vast majority of mathematics education studies that include gender (either as a focus or simply as one of many demographic "variables"), researchers strictly involve binary gender groups. We hope that our study may serve as an example of a way to frame research, and collect and analyze data in a more inclusive way. In so doing, we hope to encourage other researchers to reflect on their own practices. It is only with our ongoing collective efforts that all members of our society will be included and represented in research.

AN HISTORICAL EXPLORATION OF ACHIEVEMENT GAP RHETORIC: A CRITICAL DISCOURSE ANALYSIS OF FEDERAL EDUCATION LEGISLATION

Michelle Hawks
Independent Researcher
hawks@ualberta.ca

This article presents initial findings of how the ideas of achievement and the achievement gap are presenting throughout U.S. federal education legislation. Through the lens of Critical Race Theory and governmentality, I highlight the ways in which achievement is used in legislation as well as how that connects to discussions of race and equity in mathematics education. The discussion links to research on how current trends in language use perpetuate policy as performance as well as anti-Black sentiments within U.S. mathematics education. In conclusion, I join the calls for altering conceptions of what achievement means beyond the performance on assessments.

Keywords: equity & diversity; marginalized communities; policy matters; social justice

Mathematics education holds a unique position within the curriculum of K-12 education in the United States (U.S.) given that the National Assessment of Educational Progress (NAEP) has legislated periodic testing since 1969. This assessment requirement, together with legislated concern about the existence of achievement gaps in education, focuses attention on the disaggregated data of student test scores broken up by race. More specifically, the continued existence of a test score gap between Black and white students raises questions about how racism plays a role in legislation and what the focus of that legislation should be if not the gap between test scores.

The continued inability for Black students to obtain a proficient status on mathematics assessments (U.S. Department of Education, 2019) is manifested in mathematics classrooms through the master-narrative that racialized students, and Black students in particular, are unable to achieve in mathematics (Martin, 2009; Nasir, Atukpawu, O'Conner, Davis, Wischnia, & Tsang; 2009). This narrative exists within ideologies such as the myth that "mathematics is a white male subject" (Gutiérrez, 2008; Stinson, 2013) that lead to students having racialized experiences, where "the socially constructed meaning for race comes to be a deciding factor in who gets to do mathematics and who does not" (Martin, 2006, p. 223).

As a way to illuminate the entrenchment of racism within mathematics education teaching and practice, I focus on how the messages of the master-narrative and racialized experiences exist within legislation in the U.S. To that end, this paper aims to explore the beginnings of the achievement gap conversation through an historical exploration of U.S. federal education legislation in an attempt to question if a focus on the achievement gap actually maintains ideas of racial neutrality within policy, when really there should be a more pointed focus on race as it impacts education (Bonilla-Silva, 2014; Martin, 2003). In the end, this research shows that the continued removal of references to race, racism, and racialization as they relate to achievement is a continuation of an unequal and highly stratified education system based on race.

Theoretical Framework

There are two theories that I rely on to provide grounding for my research; they are Critical Race Theory (CRT) and governmentality. The importance of CRT stems from the ultimate goal to eliminate racial oppression while simultaneously working to rid society of all forms of subordination (Gutiérrez, 2013; Ladson-Billings & Tate, 1995; Solórzano, 1997, 1998; Tate, 1997; Yosso, Parker, Solórzano, & Lynn, 2004). CRT research in mathematics education uses the five elements of CRT to

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

acknowledge how practices such as tracking and intelligence testing actively work against students of color (Berry, 2008). The second part of my theoretical framework is governmentality, which works with CRT to engage with policy documents and to uncover how the discourses of race have, in Foucault's (1991) terminology, disciplined our way of thinking about particular topics. In essence CRT and governmentality together seek to find, acknowledge, and name the ways in which power functions within the actions of mathematics classes in relation to education legislation.

Methodology

The methodology that I rely on to guide my analysis is historical ontology which allows for both a historical and philosophical analysis simultaneously. Essentially, historical ontology uses history, temporally, in an effort to understand how particular vocabulary can be used to limit how an idea is understood in the present (Hacking, 2002). Thus, looking at how a specific word is used in a particular time and place, and following its trajectory through time, it is possible to see how present ideas around that same word are constrained by the ways in which the word was used in the past. In this way, historical ontology works together with both CRT and governmentality to address issues of power through the use of vocabulary within legislation.

Results

In order to historically analyze vocabulary around achievement and the achievement gap, I used the historical record of U.S. federal education legislation starting with the Elementary and Secondary Education Act of 1965 (ESEA) including all of the subsequent reauthorizations of that Act. This includes the well-known reauthorizations such as No Child Left Behind (NCLB), as well as the Reagan era reauthorization which occurred within the Omnibus Budget Reconciliation Act of 1981. The method used to conduct this research is Critical Discourse Analysis (CDA) which provides a way to both search for and analyze underlying ideologies present within educational discourse (Fairclough, 2010). CDA allows for policy analysis to look beyond explicit rhetoric that exists within the policy documents to determine if present legislation is maintaining previous trends (Atkins & Wallace, 2012).

Achievement in the Legislation

As a way of exploring how achievement appears within the legislation, I searched through all of the reauthorizations for the words achievement and achievement gap. Table 3 presents the breakdown of those searches, together with a representation of how many sections address both the achievement gap and contain racial terminology to see if and where these ideas appear together.

Table 1: Individual Uses and Section References to Achievement and the Achievement Gap

	1965	1966	1968	1970	1972	1974		1976	1978	1981	1983	1988	1994	2002	2015	Total
Achievement (all uses)	3	1	1	5	9	10		1	33	1	0	65	110	535	215	989
Achievement gap, phrase	0	0	0	0	0	0		0	0	0	0	0	4	6	2	12
Achievement gap, sections incl. racial terminology	0	0	0	0	0	0		0	0	0	0	0	2+1	4+1	0	6+2

Note. Full sections that include racial terminology relating to one theme are counted as "1" and sections that include racial terminology relating to more than one theme are counted as "+1" to indicate any partial sections referring to a particular theme.

The word achievement on its own becomes more common in recent legislation, although it is present throughout most of the reauthorizations. A notable shift seems to have occurred with the 1978 reauthorization, likely due to the introduction of the NAEP examination to the legislation. Clearly with language referencing student test scores and discussing the level of achievement of students, the introduction of a new federal testing regime would account for the increased use of the word achievement in the 1978 reauthorization. The other interesting shift to note is the almost quintupling of the use of the word achievement from 1994 to 2002. Arguably, this increase could be largely due to the stated purpose of NCLB as desiring to pay closer attention to the achievement gap. However, this does not explain why there is such a drastic decrease immediately following NCLB where the legislation maintains a similar stated purpose.

Despite a proliferation of research after NCLB extremely concerned about testing requirements and achievement gaps, the phrase achievement gap originates legislatively in 1994.

Thus, according to historical ontology, the idea of the achievement gap presented in IASA feeds into the understanding of the achievement gap presented in NCLB. In addition, it is interesting to note how the use of achievement gap follows a pattern similar to the term achievement, in that the peak usage is in the 2002 reauthorization, followed by a drastic decrease in 2015.

The third and final line of Table 3 represents a thematic analysis of sections within the legislation that contain racial terminology pulled from my dissertation (Hawks, 2019). This data was created by first searching for racial terminology, then thematically analyzing each section. For this data the theme of achievement gap was used for all sections of the legislation that indicated that a funded program was meant to focus on either eliminating the achievement gap or increasing minority student achievement. One of my assumptions when I created this category was that testing requirements and achievement gap sections would have a significant correlation with racial terminology given concerns about racial testing disparities in research (Meier & Wood; 2004; Rothestein, 2004). However, as Table 3 shows, there are very few connections between the use of racial terminology and references to achievement within the legislation. In fact, comparing the 6+2 sections that use both racial and achievement gap terminology with the instances of the phrase achievement gap shows a lot of overlap between the two measures. This trend is especially true for NCLB where the only mentions of the achievement gap that are not also linked with racial terminology are two sections which set aside funding to present recognition and awards to schools that have made substantial gains in closing the achievement gap between student test scores. The overlap lends credence to Hilliard's (2003) conclusion that references to the achievement gap are implicitly referencing the *racial* achievement gap.

Discussion

One of the most intriguing elements of the achievement gap rhetoric is the simultaneous focus, and yet complete ignorance, of how race plays a factor in gauging achievement. For example, in a section of NCLB a definition of the achievement gap is proffered which identifies that one of the gaps of interest is the one between racial and nonracial students (P.L. 107-110, sec. 1503(d)(3)). This specific use of the term nonracial in relation to a definition of the achievement gap actually seems to suggest a self-correction within the legislation, simultaneously acknowledging how race plays a factor in the creation of the achievement gap while also indicating that there are those who do not fit within a "race" per se. The self-corrective nature of this turn of phrase and use of the term nonracial could be a further indicator of the anti-Black nature of U.S. education as theorized by Danny Martin (2019).

The biggest problem with race falling to the background of the overall legislation is that when we begin to talk about the achievement gap and how that impacts racialized students, we are unable to engage with how racism, and racialization play roles in how those scores have come into being. Essentially, highlighting the racial achievement gap puts a spot light on disaggregated student test scores which then reifies the master-narrative around which students are able, or capable, of achieving well in mathematics. Thus as mathematics educators responsible for student performance in the subject most often tested and highlighted in achievement gap rhetoric, by avoiding race in our research and teaching we inadvertently, or intentionally, are complicit in maintaining the structures that uphold racist ideologies. In a similar vein, Schick (2011) argues that moving from specific language around ensuring that racialized students do well to language around all students doing well, shifts the focus of policy away from the importance of considering how racialization impacts racialized students.

In the end, mathematics education and the achievement gap are inextricably linked through both rhetoric and practice and what this analysis shows is that attempts to understand discrepancies in educational attainment and achievement is completely without a race analysis of any kind. This is partially because the ways in which race and achievement are used together, or linked, in the legislation are so limited as to be almost meaningless. For example, the main stream mathematics education literature that strives to discuss student test scores, merely uses race as a category to assist in the disaggregation of data as a comparative measure (Harwell et al., 2007; Post et al., 2008; Price, 2010; Stiefle, Schwartz, & Chellman, 2007; Wei, 2012). This practice is also used in the presentation of scores for *The Nation's Report Card*, which is also the basis for claims of the existence of an achievement gap between Black and White student test scores in mathematics. At a very basic level, these practices ignore, or attempt to simplify, the extremely complex nature of the idea of "race" to a categorical comparison between groups of students. What occurs because of this ignorance or inability to engage with the realities of racism and racialization in K-12 schooling, is that the master-narrative is reified into existence and pseudo-scientific claims of hierarchies of intelligence are able to flourish unacknowledged in the background. Therefore, the danger of mathematics education policies and federal education legislation systematically removing references to race as they relate to achievement is the continuation of an unequal K-12 education system that is highly stratified based on race.

Conclusion

This conclusion suggests that if future legislation maintains the goal of eliminating the achievement gap(s) then it must be reframed to not only focus on the children of low-income families, but also the children of racialized families. Thus, if the goal of federal education legislation is actually to reduce or eliminate the achievement gap(s) there needs to be a stronger and more purposeful focus on issues that are impacting racialized students. Including the ways in which the legislation and policies have a tendency to refer to achievement as an individual characteristic rather than acknowledging the system of policies and assessments that define how achievement is to be understood. This includes, but is not limited to, acknowledging the historical ways in which racialized people have been systematically devalued, how that process continues in K-12 schooling today through tracking and testing requirements, and the importance of noting how the process of racialization treats students differently on both an individual and systemic level. Without these, and other measures to actively engage with how race impacts schooling, the systems that maintain the existence of the achievement gap(s) will continue unfettered. In conclusion, as Spencer (2009) suggests, a way forward is for legislation to redefine what it means to achieve, by renegotiating the focus from achievement to success, which includes the role of resistance as a response to the limitations of schooling.

Abstract: This research report explores the ways in which the Community Mathematics Project (CMP) supports underserved populations to learn mathematics in a large urban area. This project seeks for parents to have tools to teach their children mathematics at home. As part of a longitudinal study, in this report we explore the experiences of a student-parent when learning and re-learning mathematics with the supports of a researcher and a teacher-parent. Findings suggest that sense-making strategies supported the student-parent to make connections with prior knowledge to figure out new mathematical concepts. Further, the student-parent leveraged from this mathematical knowledge to use it in her daily life and to support her son learn mathematics at home.

Keywords: equity and diversity, social justice, culturally relevant pedagogy.

Objectives of the Study

Family and parent engagement in mathematics is a crucial practice that facilitates and enhances deep mathematical learning (Turner et al., 2012), yet many parents feel disconnected from schools and from their child's education in mathematics (Civil & Berneir, 2006; Mistretta, 2013). Thus, it is essential that teachers learn to leverage children's funds of knowledge (Moll et al., 1992) in mathematics instruction (Turner et al., 2016) to engage families and communities, but it is also imperative that parents feel connected to their child's learning. Indeed, parent participation in the early years of math education of children can increase academic development and math achievement (Cho, 2017).

When parents and families become a part of the goal-setting and deep learning, children benefit. This research report will describe preliminary findings from the *Community Mathematics Project* (CMP)[1], a collaborative endeavor that aims to address mathematics opportunity and achievement gaps that exist, especially as they relate to Hispanic and low-income students in the urban center of San Antonio, Texas. The project supports prospective elementary school teachers to attend to both in school (pedagogy that is centered on the use of student funds of knowledge) and out of school (to connect parents and communities to school/mathematics) opportunities through partnerships between a community college, a four-year institution of higher education, and community centers based in low-income neighborhoods, with a goal of sustainability through the identification of parent experts. This study focuses on a one-on-one tutoring program between a parent educator and a parent tutee.

The CMP is multi-faceted and includes various mechanisms for facilitating partnership between these entities. The community college and four-year institution work to align curricula to improve prospective teacher pedagogical content knowledge and theoretical foundations. Moreover, prospective teachers are provided with bridging opportunities as they matriculate to the four-year institution's teacher preparation program. In this program, students who have been identified work with faculty in a community center to provide mathematics tutoring to parents in low-income communities. This allows the prospective teacher to gain knowledge about community members and parents while engaging them in culturally relevant mathematics activities. Further, parents are

[1] Project funded by the Department of Education (Title V)

empowered to connect everyday practices to the school mathematics that they will be learning, and can engage more readily with their student who is learning similar concepts. After one semester of this program in a community center, we envision identifying a "parent scholar" who can assist in sustaining the program once our prospective teachers move on. In subsequent semesters, then, we will work with additional community centers. This one-on-one tutoring aspect of the project will be the focus of this presentation, which will present data related to the following guiding question: What are the experiences of a parent tutee who participated in the CMP tutoring center?

Theoretical Framework

To answer the aforementioned research questions of CMP, there are two main theoretical frameworks that undergird our work. The first framework draws from the immense research that foregrounds the mathematical knowledge and expertise of parents and families. The research in the literature review is situated in frameworks that resist the deficit notion that parents, families, and young children do not engage in practices that connect to mathematical ideas and skills. Rooted within seminal work of Moll et al. (1992) and the research of Funds of Knowledge perspective, when mathematics teachers value the experiences and practices of parents and families, they can make more connections to authentic ways that children use mathematics at home and in their communities.

The second framework continues to dispel the myth that young children only learn mathematics in traditional classroom or pre-school settings—parents and families can play a role in how and in what contexts young children develop their mathematical knowledge and experiences (Berkowitz et al., 2015; Cho, 2017). That is, through collaborations with researchers and mathematics teachers, parents and families can have more opportunities to learn mathematics, which may be shared with their children at home. The work of Marta Civil (Civil, 2007; Civil, Bratton, & Quintos, 2005) and colleagues (Rodriguez, 2013; Téllez, Moschkovich, & Civil, 2011; Willey, 2008) offer examples of how parents and families can engage in learning new mathematics based on their existing experiences. When parents and families have more opportunities to strengthen their own mathematical knowledge by making more connections to new ideas and skills, they can also have more opportunities to engage in similar discussions with their young children; thereby further pushing back on the notion of learning only occurring in the classroom. As a result, a broader outcome of this project is to support more families, parents, and young children to build upon their existing knowledge while seeking new connections to more knowledge. The following sections will briefly discuss the existing literature and seminal scholars who have explored the notion of families of young children in the field of mathematics education. Given these frameworks, it is important to continue to study the integral role that parents and families play on how young children learn mathematics (Berkowitz et al., 2015; Civil, Díez-Palomar, Menéndez, & Acosta-Iriqui, 2008; Jackson & Remillard, 2005; Sheldon & Epstein, 2008) and their background knowledge that can be used as foundation for learning more mathematics.

Methods

Context. In an eight-week course, the researchers and a parent-tutor used aligned curricula to provide mathematics tutoring to parents and care givers seeking for them to have the tools to teach mathematics to their children at home. On this phase of this longitudinal study, the researchers worked with a Latino community in which parents spoke Spanish as first language (L1), they had limited knowledge of English, and in most cases parents held a high school diploma or less. The researchers provided supports in the form of co-teaching and content knowledge to a mother-tutor—Isabel [all names are pseudonyms]—who taught mathematics to parents in her community. Isabel's role was to promote sustainability of the program. From the twenty parents who started the program, we chose one of them—Ofelia—as a case study. We sought to understand teaching moves that could support Ofelia make sense of mathematics, and understand additional supports that Ofelia can benefit from to learn and to teach mathematics to her child.

Participants. Ofelia participated in an eight-week course in which the parent worked in a triad with the researcher and the parent expert Isabel. One of the researchers observed Ofelia at the community center as she received tutoring classes from Isabel. We sought to observe a parent whose educational background and characteristics represents the average parent of the Latino community.

At the time of the study, Ofelia was 44 years-old. She arrived to the USA 12 years ago by crossing the border. Ofelia has been married for 20 years and has 2 children—the oldest was 19 (attended a local community college), and the youngest was 10 (5^{th} grade). Ofelia went to school in Mexico and studied until 9^{th} grade. Ofelia's main job was cleaning house, however, at the time of the study, she was unemployed. Ofelia shared that she enrolled in the "*Latino Math*" program to support her youngest child to learn mathematics at home. Ofelia expressed that her youngest struggled with mathematics, and prior participating in the program, Ofelia did not have the mathematical knowledge to support him increase his mathematical achievement (Cho, 2015). Ofelia expressed that the differences between the way she learned mathematics in Mexico, and the way mathematics is taught in the USA presented challenges to support her child at home.

Data collection. Data collection took place throughout eight weeks, which was the duration of the course. For one hour each week, one of the researchers went to the community center and supported Ofelia in developing understanding of mathematical concepts along with the parent-instructor—Isabel. In class, the researcher used sense-making moves to support Ofelia relearn mathematical concepts, and also understand and figure out new ones.

Data sources include: 420 minutes of transcripts from classroom observations, 99 minutes of transcript from two interviews to Ofelia and Isabel, detailed field notes from 7 classroom observations, and artifacts such as pictures from Ofelia's work in her mathematics book.

Analysis. Data collection and analysis were iterative processes (Yin, 2014). Coding took place in four cycles. Before coding we adopted an interpretivist approach (Miles & Huberman, 1994) to capture the essence of the participant's sense-making process. Specifically, we coded the different ways in which the participant made sense of mathematics. We also coded on how the participant figured out content by building on prior knowledge. Because we acknowledged the participant's educational background, we coded for her studying strategies to support her in developing new ones.

Initial coding started by re-reading the data, but this time we looked for provisional themes and highlighted relevant quotes. Next, we used a descriptive coding process (Saldaña, 2013) which enabled us to analyze participant's sense-making and figuring out over time. A provisional list of codes emerged and we organized these codes into a "meta-matrix" (Miles & Huberman, 1994, p. 178). In other words, we assembled the descriptive data on a spreadsheet in chronological order. We used short phrases to find basic topics across the different data sources, and labeled each data source with codes. For instance, we focused on how different sense-making moves systematically supported Ofelia to learn the mathematics content and to figure out content without receiving explanations but from building on prior knowledge. Examples of these codes are: patterns, association, logical reasoning, look backwards, negotiate, think out loud, talk at every stage of problem solving, think of alternative ways to perform a task, and so on. To organize and refine the codes and themes we used "code mapping" (Saldaña, 2013, p. 194). In other words, we went through three iterations of analysis to reorganize the full set of codes into a list of 17 categories, to later condense those into 3 central themes: sense-making, figuring out, and studying strategies. These themes are unpacked in the following section.

Results

Working with Ofelia one-on-one for eight weeks enabled us to explore in-depth the supports that she needed to make sense of mathematics. Analysis of the data suggests that sense-making moves supported Ofelia in developing understanding of mathematical concepts to systematically figure out new ones. At the same time, learning about mathematics provided Ofelia with tools to support her 10-year-old son learn math at home, and to be confident to use math in her daily life.

Sense-making and figuring out. One of the challenges to support the development of *sense-making* was to bridge the disconnect between the way Ofelia was taught in Mexico and the way that mathematics is taught in the USA— "apprenticeship of observation" (Lortie, 1975, p. 61). In multiple opportunities Ofelia expressed the need to memorize mathematical procedures and time tables, and to be given answers away as opposed to making sense and finding answers for the mathematical problems. During our first sessions, Ofelia explicitly asked to be explained procedures and to be a passive listener. Ofelia would often give up when working on tasks and asked to be given answers. To move away from top-down learning, the researchers relied on sense-making moves such as building on prior knowledge and using logical reasoning. For example, Ofelia was working on factorization and the number she had was 75. Ofelia's first attempt was to factorize by 2, "¿Se le hace? 75 entre… Y es 5, entre 2 (giggle), 35. [Is this? 75 divided by… And it is 5, divided by, 35.]" In the previous lesson, I explained that numbers that end in 5 or 0 are multiple of 5. The researcher encouraged Ofelia to make connections with the prior lesson and to reflect on how to solve the problem. Ofelia revisited the previous lesson and reflected, "Ay, a ver (erase). ¿Entonces voy a dividir entre qué? Entre 5, a ver (thinking out loud and working). 5x5=25. ¿Entonces divide entre 5? Y luego me da 15. Y 3x5, pienso. [Oh, let's see. Then, I divide it between what? Between 5, let's see. 5x5=25. Then, divide it by 5? And I get 15. And 3x5, I think.]" As part of teaching Ofelia studying strategies, the researcher encouraged her to check her answers. She shared, "A ver, entonces pongo 5x3=15. A ver. Es 75. Let's see, then I write 5x3=15. Let's see. It is 75.]" In this example, we share one way in which we supported sense making by building on prior knowledge and reasoning, and avoided giving answers away and memorization.

Another sense-making move used was thinking out-loud. Thinking out-loud supported Ofelia to self-correct, negotiate, reflect, build from prior knowledge, and to think of multiple ways to perform a task. For instance, Ofelia worked on another factorization problem,

> Ofelia: 7x5=35 estoy repitiendo las tablas (giggle). 7x5=35; 7x6=42. Ah entonces es 42. Entonces me dijo según yo, aquí pongo el 42, lo resto. Serían 2 y aquí sería cero. Entonces bajo el 7, verdad? O ya voy mal? Ahora, 7x3=21; 7x4=28; sería 3. 7x3=21. Hago una restita, y luego son 6 y aquí son cero. Y el último lo bajo. ¡Yo ya no sabía que hacer con este híjole! (giggle). Okay, serían hay ya yai. 7x9=63. 9x7=63. ¿Será? Ya ya recordé (giggle).
>
> [*7x5=35 I am repeating timetables. 7x5=35; 7x6=42. Then, it is 42. Then according to me, here I write the 42, I subtract it. It would be 2 and here it would be zero. Then, I bring down the 7, right? Or am I wrong? Now, 7x3=21; 7x4=28; it is 3. 7x3=21. I subtract, and then here is 6 and here 0. And the last one I bring down. I didn't know what to do! Okay, it will be… hay ya yai.7x9=63. 9x7=63. Would that be? I I remembered*.]

In this example, Ofelia said timetables out loud as she looked to the answers. Then, she walked us through the procedure and because she was talking, she self-corrected, and she revisited previous exercises to solve this problem.

Changes in terms of sense-making were more evident by the fourth learning session. By then, Ofelia asked *not* to be told the answers to the problems and she started looking for alternative ways to solve them—*figure out*.

Mathematics in Ofelia's daily life. The learning sessions supported Ofelia not only to make sense of mathematics and to figure out. The learning sessions also supported Ofelia in developing confidence about using math in her daily life, and bonding with her son more as they studied mathematics together. By the end of the program, Ofelia shared how she started using mathematics outside the learning sessions,

Another important aspect of learning mathematics was that Ofelia could develop a better relationship with her son. Ofelia expressed, that learning mathematics allowed her to teach her son content related to his grade level and spend more time together,

Discussion and Conclusions

Secondly because Ofelia comes with an immense amount of mathematical experiences that she can draw from (as is what we posit is true for all parents, families, and young children who do mathematics) we bore witness to Ofelia actively leveraging her existing knowledge with her new knowledge and sense-making practices to advocate for herself during a purchase at a garage sale. Ofelia shows how when parents and families engage in mathematical sense-making while accessing connections to new mathematical knowledge, they also identify moments in which they can access and use this knowledge and practices in their daily lives. Moreover, Ofelia inspires us to help more parents and families to seek a wide number of opportunities for them to use their mathematical knowledge and sense-making practices to enact a sense of agency for fairness for themselves, their families, and communities (McGee & Spencer, 2015). The practice of engaging in sense-making while advocating for fairness and social justice is a line of research that can help the field to know more about the role of parents and families in the broader field of mathematics education (e.g., Mistretta, 2013; Rodriguez, 2013).

GENDER DIFFERENCES IN NUMBER STRATEGY USE FOR STUDENTS SOLVING FRACTION STORY PROBLEMS

Cassandra Quinn
University of Missouri
cdquinn@mail.missouri.edu

Susan B. Empson
University of Missouri
empsons@missouri.edu

Victoria R. Jacobs
University of North Carolina at Greensboro
vrjacobs@uncg.edu

Gender differences in fourth and fifth grade students' strategy use for a fraction story problem were investigated using multinomial logistic regression on a sample of 193 written student strategies. Gender was not a significant predictor of type of strategy used, in contrast to earlier studies finding that boys tended to use more abstract strategies whereas girls tended to use more concrete strategies or the standard algorithm.

Keywords: Gender and Sexuality; Elementary School Education; Number, Concepts, and Operations

Gender differences in mathematics have long been a topic of study in mathematics education (Fennema, 1974; Leyva, 2017). One particular focus of interest has been gender differences in strategy use, inspired in part by research in which Fennema, Carpenter, Jacobs, Franke, and Levi (Fennema, et al., 1998a, 1998b) found gender differences in students' strategies for story problems. In a longitudinal study with 38 girls and 44 boys in grades 1-3, they found no gender difference in the ability to solve addition and subtraction story problems and multidigit computations, yet significant difference in type of strategy used to solve these problems. Girls tended to use concrete solution strategies. Boys tended to use abstract solution strategies that "reflected conceptual understanding" (p. 11). The researchers argued these results indicated differences in the degree to which girls and boys had developed mathematics understanding.

Fennema et al. (1998a) invited interpretations of the results from four scholars: mathematics educator Judith Sowder; social psychologists Janet Hyde and Sara Jaffee; and feminist philosopher Nel Noddings. Sowder (1998) suggested these gender differences could reflect differences in preferences for explaining one's strategy (e.g., girls prefer to give explanations that are clear for others) and worried that students who use more abstract strategies are more likely to make sense in mathematics and have a better chance at succeeding mathematically. Hyde and Jaffee (1998) cautioned against interpreting female deficits based on findings. They suggested teachers could hold gender stereotypes (e.g., girls are compliant, boys are independent) and that those stereotypes were activated in teachers' interactions with students. Noddings (1998) suggested girls could be less interested in mathematics and noted that society does not show the same concern when boys demonstrate less interest than girls in other activities (such as early childhood education or nursing), which led to a critique of the social structure: "Do we approve of a social structure that values competence in mathematics over competence in child care?" (p. 18).

Other education researchers have also studied gender differences in strategy use (Carr & Davis, 2001; Carr, Jessup, & Fuller, 1997; Carr, Steiner, Kyser, & Biddlecomb, 2008) and framed their findings in a variety of ways. For example, Carr and Davis (2001) examined 84 students' use of strategy under both free and constrained choice. Under free choice, girls chose manipulative strategies while boys chose retrieval strategies, consistent with findings by Fennema and colleagues. Under constrained choice, they found that boys were able to use manipulative strategies, but girls were "not as capable" as boys in using retrieval. In their study, manipulative strategies were considered more concrete and retrieval strategies more abstract. In a cross national study, Shen, Vasilyeva, and Laski (2016) found gender differences in strategy use that mediated accuracy for

students in the United States and Russia but not Taiwan, suggesting that differences could be attributed to instructional contexts, rather than inherent to girls and boys.

If gender differences in strategy use exist, they might reflect important differences in students' conceptual understanding (Fennema et al., 1996; Sowder, 1998), the enactment of gender stereotypes by teachers (Hyde & Jafeee, 1998), or simply differences in students' interests (Noddings, 1998). Whatever the source, attending to differences in strategy use is important, as they could reflect differences in opportunities to develop conceptual understanding. Further, because potential disparities in strategy use are not visible in standardized tests that do not differentiate between types of strategies used, investigating strategy use on a large scale requires analyses that account for the types of strategies girls and boys use to solve problems.

Building on the early study on gender differences in mathematics (Fennema et al., 1998a), this study investigates gender and strategy use in fraction story problems. Our study is different in important ways. (1) Our analysis is over 20 years after the publication of the study by Fennema and colleagues, and thus provides a glimpse of current gender dynamics in mathematics teaching and learning. (2) Our study is comprised of fourth and fifth grade students solving a fraction story problem, compared to the first, second, and third grade students and a focus on whole-number addition and subtraction in the original study. Like Fennema and colleagues (1998a) and the invited interpretations (Hyde & Jafeee, 1998; Noddings, 1998; Sowder, 1998), we are careful to consider the importance of strategy use and avoid framing these differences as reflective of inherent differences in ability. We investigated these differences for 193 fourth and fifth grade students by asking the following: Are there significant gender differences in strategy use for fourth and fifth grade students solving fraction story problems?

Methods

Sampling and Participants

Data for this analysis came from a larger professional development design study, focused on documenting and supporting the development of teachers' responsiveness to students' fraction thinking during instruction (Jacobs, et al., 2019). As part of this larger study, students from 50 different classrooms were administered a paper and pencil assessment at the beginning and end of the school year, to measure fraction problem solving and conceptual understanding. Items were open response. A rubric for scoring and coding student responses was developed, and for each item, all responses were triple coded until 85% (or higher) agreement was reached among coders, at which point, responses were single coded.

Data Sources and Analysis

For the current study, we focus on one item on the assessment administered at the end of the school year to 562 students, in grades 4 and 5. Of these, 244 student responses were coded as having a valid strategy, which means the student started with the given quantities and operated on those quantities in some justifiable way to reach an answer, and they could include small mistakes. The item consisted of the following story problem: *Allie has 1 6/8 sticks of butter. She needs a total of 5 1/8 sticks of butter to make cookies. How much more butter does Allie need so she can make cookies?*

Each of the responses was coded individually for type of strategy used. For this analysis, we focused on valid strategies (n = 193), including concrete strategies (n = 19), invented algorithms (n = 90), and the standard algorithm (n = 84). Strategies labeled as "other" (n = 24) or "none" (n = 27) were not included because they were not interpretable with respect to the research question. The final sample included 101 girls and 92 boys. These strategy codes and their frequencies in the sample are described and illustrated in Figure 1. Type of strategy served as our dependent variable.

Type of Strategy		Example
Concrete Strategies Girls (n = 10) Boys (n = 9)	*Direct modeling:* strategies that represented all sticks and fractional sticks of butter individually. Usually these were notated with drawings. *Counting up/down by unit fraction*: Strategies that represented each individual group of 1/8 in the count in some way.	 Counting strategy
Invented Algorithms Girls (n = 45) Boys (n = 45)	Computation strategies that decompose the mixed numbers and/or fractions in some way and/or increment or decrement in "hops" (larger than a unit fraction) in some way.	Standard Algorithm Girls (n = 46) Boys (n = 38)	Standard algorithms for subtraction in which a child uses knowledge of the standard algorithm procedure to determine the missing addend.	
Figure 1: Types of Valid Strategies and Examples Used in the Analysis

Because the dependent variable is categorical, we used multinomial logistic analysis. Concrete strategies and the standard algorithm were separately predicted against the reference category of invented algorithms. We chose invented algorithms as the reference category because if gender differences reflecting conceptual understanding were significant, we would expect to see an over representation of girls in either concrete strategies or the standard algorithm. Using invented algorithms as the reference category allowed comparison of both concrete strategies and the standard algorithm to invented algorithms.

We used three models to analyze students' strategy choice and gender. The first model was used to detect if gender significantly predicted strategy use across grade levels. The second model was used to detect if gender predicted strategy use in fourth or fifth grade. In the third, we added the interaction of grade and gender to the second model.

Results

Results from the statistical models are listed in Table 1. Odds ratios (and standard errors) of the three models show that gender was not a significant predictor of concrete strategy use or standard algorithm use. In the first model, there was some significance in the intercept, meaning students were less likely to use concrete strategies than invented algorithms ($p < 0.001$), but these differences were not based on gender. In the second model, the significance in the intercept remained, and there was some significance in grade level ($p < .05$), meaning fifth grade students were less likely to use concrete strategies compared to invented algorithms. Again, these differences were not based on gender. We included the interaction of gender and grade in the third model and did not detect significance in the interaction.

Table 1: Results of Statistical Models

	Odds ratio (and standard errors)		
Variable	1	2	3
Concrete strategy compared to invented algorithm			
Intercept	0.20 (0.37)***	0.33 (0.40)**	0.36 (0.41)*
Female (compared to M)	1.11 (0.51)	0.99 (0.51)	0.81 (0.58)
Fifth (compared to fourth)		0.22 (0.67)*	0.12 (1.10)
Gender X Grade			3.14 (1.39)
Standard algorithm compared to invented algorithm			
Intercept	0.84 (0.22)	0.64 (0.28)	0.64 (0.34)
Female (compared to M)	1.21 (0.30)	1.27 (0.31)	1.28 (0.45)
Fifth (compared to fourth)		1.63 (0.31)	1.64 (0.45)
Gender X Grade			1.00 (0.62)
	R^2= .00 χ^2 = 0.40, p > .05	R^2= .03 χ^2 = 12.43, p < .05	R^2= .04 χ^2 = 13.18, p < .05

N = 709; *p < 0.05; **p < 0.01; ***p < 0.001

Discussion and Conclusion

The implications of these findings are in the statistical insignificance of the dependent variable. We tested three models related to the research question: Are there significant gender differences in number strategy use for fourth and fifth grade students solving a fraction story problem? Because gender was not significant in any of the models tested, gender-based differences in strategy use were not indicated, a finding that is in opposition to previous findings. However, we focused only on a single item and two grade levels, which limits the scope of our findings. Further, our study was not longitudinal and cannot speculate on trends in development of strategy use and conceptual understanding. Research across multiple assessment items and grades is needed for a more complete examination of students' gender and strategy use in the domain of fractions. Finally, we noted that only 193 of the 562 students used a valid strategy, roughly a third of all students, which suggests that this was a difficult problem for the sample. Research on an item in which a greater proportion of students used a valid strategy is necessary to examine if and for what items the finding holds.

Gender-based inequities can arise within inquiry-oriented (IO) classes, affecting women's participation and achievement. Given that social norms can enable/constrain students' participation, it is pertinent for researchers to study social norms that are conducive to women's learning and how they can be fostered. In this paper, we explore social norms present in two IO abstract algebra classes with positive learning outcomes for women students. We found social norms related to working on tasks, giving contributions, and responding to others' contributions. We provide examples of these normative behaviors, discuss the instructors' roles in fostering these norms, and examine how these norms could promote gender-based equity in IO instruction.

Keywords: Gender, Inclusive Education, Classroom Discourse, Post-Secondary Education

Prior research has shown that active learning approaches to instruction lead to improved student achievement (e.g., Freeman et al., 2014). However, Eddy and Hogan (2014) argued that any instructional intervention will affect different student groups in varying ways. Johnson et al. (in press) found men and women had differential learning outcomes in an inquiry-oriented (IO) setting; men experienced greater achievement gains than women in IO abstract algebra classes. This gap was not present in the non-IO classes that served as the comparison group for Johnson et al.'s study. In this study, we selected two divergent cases from the Johnson et al. data base. In these two classes, women students had positive learning outcomes. We analyzed the social norms in each class, identified the instructors' roles in fostering these norms, and hypothesized ways in which these social norms may be conducive to women's learning.

Background

Given the interactive nature of Inquiry-Oriented Instruction (IOI), it is pertinent to consider how IOI settings align with aspects of equity. Gutiérrez (2002) outlined four dimensions of equity as access, achievement, identity, and power. These dimensions align with Cook et al.'s (2016) characteristics of inquiry-based classes, for access is given to students through inquiry pedagogies that encourage participation and peer involvement (Tang et al., 2017). Participation gives the opportunity to build knowledge, which can foster achievement and confidence in mathematics. Peer involvement may lead to a shift in a student's mathematical identity (Boaler & Greeno, 2000; Hassi & Laursen, 2015). There is also a shift of power from teachers to students in inquiry pedagogies. However, inequities may emerge with peer involvement. Group work may support privileged groups over marginalized groups by placing value on input given by students who are more likely to participate (Esmonde et al., 2009; Esmonde & Langer-Osuna, 2013). Smith et al. (2019) found evidence of instructors' gender bias, with men disproportionately contributing to class discussions and women disproportionately being asked to contribute in less sophisticated ways. Since women have been

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. marginalized in mathematics classes, we investigate the social norms present in mathematics classes that may be conducive to women's learning.

Social norms describe the general rules and expectations for the teacher and students' roles within any classroom. They "characterize regularities in communal or collective classroom activity and are considered to be jointly established by the teacher and student as members of the classroom community" (Cobb & Yackel, 1996, p. 178). Norms are a person's "beliefs about [his/her] own role, others' roles, and the general nature" of classroom activity (Cobb & Yackel, 1996, p. 177). Social norms within a classroom can support or constrain students' participation, which can potentially impact equity in students' participation and achievement. We posit that certain social norms may provide students with access and opportunities for mathematical identity development. We believe this warrants research on the social norms present in IOI classes and the role of instructors in fostering these norms. We address the following questions: What social norms were present in two IO abstract algebra classes that had positive achievement outcomes for women students? What is the instructor's role in fostering these social norms?

Methods

We analyzed social norms present in two IO abstract algebra classes, taught by Dr. Carter and Dr. Ryan. Dr. Carter is a White man who taught at a large doctoral-granting institution in the Midwest US. Dr. Ryan is a White man who taught at a midsize masters-granting institution in the Northern US. Both instructors participated in a semester-long professional development focused on implementing IOI. Their women students had positive learning outcomes; their average scores on the Group Theory Content Assessment (Melhuish, 2015) were higher than the comparison sample of women. The same instructional unit involving the reinvention of definitions of isomorphism from the Inquiry Oriented Abstract Algebra curriculum (Larsen et al., 2016) was recorded for both instructors during weeks 4–6 in a 15-week semester.

We analyzed two 50-minute subsequent class periods for each instructor. We identified episodes of behavior that conveyed students' roles during class. We focused on how participants reacted to those behaviors. We wrote descriptions of these episodes, as well as memos (Maxwell, 2013) reflecting on how the behaviors in each episode seemed normative. We inferred a certain behavior was normative if it was common, classroom participants did not challenge one enacting that behavior, and/or class participants challenged a class participant when they did not comply with that behavior. These criteria were based on Clark et al.'s (2008) conditions for documenting the development of norms. We open coded these episodes (Miles et al., 2013), naming the norms present in these episodes. We also analyzed how the instructors fostered these class social norms.

Results

Norms for Students Working on Tasks

Working on new tasks individually. Dr. Carter explicitly stated his expectation for students to work on tasks individually, saying phrases such as, "I want you to do this on your own" and "Paper. Pencil. Human. Solo." Students behaved this way for the rest of the class. Each time they started a new task later in the class period, they worked on it individually before they talked to other members of their groups, without being prompted to do so. The commonality of this behavior was evidence of this being a social norm in Dr. Carter's class. He fostered this social norm by setting expectations for students' behavior.

Discussing tasks with group members. After students in both classes worked on tasks individually for a few minutes, the students commonly started discussing the tasks with other group members, often without prompting. After some students began discussing the task, Dr. Ryan reinforced this behavior by telling the class to "convene in our groups and discuss what you've done so far and any progress you've made." The entire class began to discuss their ideas within their groups. This behavior seemed normative, for once students had ideas from their work, they began talking. Dr. Ryan fostered this social norm by reinforcing his expectations for students' behavior, particularly when students did not yet comply with the expected behavior.

Norms for Students Providing Contributions

Sharing contributions. Dr. Carter and Dr. Ryan fostered this norm of students sharing contributions by explicitly leveraging students' contributions to inform the lesson. For instance, Dr. Carter's student, Jessica, shared a conjecture regarding necessary conditions for the correspondence between the elements in D_6 and elements in the group represented by the mystery Cayley table. Dr. Carter assigned a follow-up task to Jessica's conjecture, asking why a specific correspondence, which met the conditions Jessica specified, would not work for showing the mystery group was D_6. Dr. Carter said, "So Jessica, I am challenging your conjecture. I'm gonna put it up here [on the board] as well. It has merits! It has good merit." Dr. Carter reinforced his expectation that students should share their conjectures by giving the opportunity to share contributions, writing Jessica's conjecture on the board, assigning a follow-up task that leveraged her conjecture, and saying that her conjecture had "good merits."

Explaining their reasoning. Another social norm present in these classes involved students explaining their reasoning. Dr. Ryan demonstrated his expectation for this behavior by calling on a student, Matt, and telling him to "explain your reasoning, tell us about the mappings you found, how you found them." The instructor reinforced the social norm of explaining reasoning by stating his expectations for the student's response. Matt then complied with this social norm and was not challenged because he did not violate the norm. If students violated this social norm by giving contributions without explaining their reasoning, the instructors challenged them for doing so by asking questions. For instance, as Dr. Carter's class discussed a student's definition of isomorphic groups, which said "$a, b \in G.\ c, d \in H.\ a \cdot b = c * d$," Becky claimed, "I'm a smidge bothered by the equal sign...so I think that we need to define some kind of function that maps one to the other." Dr. Carter responded, "Wait, hold on, why are you a smidge bothered? I don't understand. What's wrong with the equal sign?" Dr. Carter fostered this norm of explaining reasoning by challenging students when they did not comply with it.

Explaining difficulties they experienced. Students were expected to share the difficulties they experienced with mathematical tasks. For example, a student, Mallory, volunteered to share what Dr. Carter called a "productive failure." Mallory shared her initial failed attempts for a homework problem. She explained how she got stuck on the problem, took a break from it, and later tried a new strategy. Dr. Carter asked, "your productivity in the failure is?" Mallory replied, "Well I learned about that strategy…I feel a little bit more resilient now 'cause I just learned to like try stuff… not be afraid to try new different things." Mallory's experience in sharing her productive failure could have been an instance in which she developed her identity as a mathematician. This showed her confidence in her problem-solving ability, despite her previous failed attempts. By having Mallory present her productive failure, Dr. Carter reinforced the idea that it is okay to fail because something productive might come from it, which fostered the norm.

Norms for Students Responding to Others' Contributions

We identified social norms of responding to other students' contributions, giving productive feedback, and being non-judgmental. Dr. Carter explicitly stated his expectation for this behavior at the beginning of class, saying "remember that we are in a non-judgmental phase in our lives right now, so keep your comments very productive." To demonstrate these social norms, consider the following episode of Dr. Carter's class where each small group presented their definition of isomorphic groups on whiteboards, displayed at the front of the class.

Dr. Carter: "$a, b \in G, \phi(a \cdot b) = \phi(a * b)$." What is going on here?
Madison: We would have to split up the phi. (This means $\phi(a \cdot b) = \phi(a) * \phi(b)$)
Dr. Carter: This is another operation, right? [pointing to $*$]….so G is defined as G and dot, right?….But I think there is something going on here as well. Right? There's this phi. Not sure what it is yet, but there's this kind of correspondence as well.
Dr. Carter then directed the students' attention to another definition on the whiteboard.
Dr. Carter: What's going on over here? "G is isomorphic to H if and only if there exists a homomorphism."
John: I think that it is relevant to mention the homomorphisms. I think to add to that, you have to say that there exists a homomorphism G to H and there also exists a homomorphism H to G.

Responding to other's contributions. In this episode, both students, Madison and John, responded to other students' definitions of isomorphic groups. This behavior was common throughout the class discussions. Dr. Carter gave students an opportunity to respond to a group's contributed definition by asking "what's going on over here?" This reinforced the social norm.

Providing productive feedback to contributions. Both students then responded by giving productive feedback to make the contributed definitions more precise. Dr. Carter fostered this norm by providing productive feedback, thereby modeling the behavior in his own response.

Being non-judgmental of contributions. These students responded in a non-judgmental way, by not commenting on the imprecision or the incompleteness of the contributed definitions; rather, they validated and elaborated on the other students' contributions. Dr. Carter fostered this norm of being non-judgmental of contributions by modeling that behavior in his responses.

Discussion

We explored the social norms present in two IOI classes that had positive learning outcomes for women. We hypothesize these norms may be conducive to women's learning and promote the equity dimensions of access and identity (Gutiérrez, 2002). Working on a task individually gives access to the opportunity of engaging in meaningful mathematics tasks. Discussing tasks with group members, sharing contributions, explaining reasoning, and responding to others' contributions gives women opportunities to develop their mathematical identity as they present and evaluate each other's ideas (Hassi & Laursen, 2015). Having students explain the difficulties they experienced and normalizing productive failure can promote women's confidence. Norms of being non-judgmental and giving productive feedback to peers' contributions can promote a positive learning environment where students can contribute without fear of judgment. Although researchers have documented deficiencies in women's mathematical confidence (e.g., Lubienski & Ganley, 2017), these social norms can foster women's confidence and give opportunities for access and identity development, which can lead to achievement and power (Gutiérrez, 2002).

We aimed to explicate the instructor's role in fostering positive social norms. Instructors in our study fostered social norms by establishing expectations for students' behavior, modeling the expected behavior, challenging students when they do not comply with those expectations, and reinforcing those behaviors by showing they are valued. Our study contributes to research on social norms by further explicating the instructor's role in fostering norms. Instructors can use these strategies to foster positive social norms in their own classes.

DIFFERENCES IN MATHEMATICAL ABILITY BELIEFS BETWEEN TEACHERS AND MATHEMATICIANS IN HIGHER EDUCATION

Yasemin Copur-Gencturk	Han Du	Ian Thacker
Univ. of Southern California	Univ. California, Los Angeles	Univ. of Texas, San Antonio
copurgen@usc.edu	hdu@psych.ucla.edu	ian.thacker@utsa.edu

Existing stereotypical beliefs regarding mathematical ability as being innate and being associated with men more have severe consequences for female students' perceptions of their mathematical ability, their course-taking decisions, and eventually, their decision to enter and stay in STEM fields. Yet how such beliefs compare among educators at different educational stages needs more attention. In this study, we analyzed the beliefs held by K-8 teachers and mathematicians who had or were pursuing a doctoral degree in mathematics regarding whether mathematical ability is innate. We found significant differences between mathematics teachers and mathematicians in their beliefs about mathematical ability and in the underlying structure of their responses.

Keywords: teacher beliefs, mathematics ability beliefs, gender-specific ability beliefs

Gender disparities persist in the representation of women in mathematically intense STEM fields (National Center for Education Statistics, 2013; National Science Foundation [NSF], 2015). Some research has explored the extent to which these gender differences can be explained by widely held stereotypical beliefs and biases that are communicated to girls at an early age in social environments, harming their self-perceptions and academic performance (e.g., Rosenthal & Jacobson, 1968; Steele & Aronson, 1995; also see Ceci, Williams, & Barnett, 2009 and Wang & Degol, 2017, for reviews). Exposure to gender-specific beliefs and implicit biases is hypothesized to reinforce stereotypes that affect women's feelings of competency (or self-concept) in a specific domain (Correll, 2001; Greenwald et al., 2002), potentially dissuading them from pursuing careers in that domain. Thus, it is important to explore potential implicit and explicit messages students receive throughout their academic lives, especially from their teachers during elementary and secondary education as well as their instructors in postsecondary education, given that teachers' and instructors' opinions can have a substantial impact on their self-concept. As such, the objective of this study was to measure and compare teachers' and mathematicians' beliefs about mathematical ability.

To date, little research has compared stereotypical beliefs held by instructors at different stages of education. Prior studies have found that K-12 teachers' conceptions play a role in shaping their actions (for foundational studies, see Cooney, 1985; Ernest 1989; Thompson, 1984; 1992), that elementary and middle-school teachers sometimes believe that mathematical ability is fixed and innate (Copur-Gencturk, Thacker, & Quinn, in press; Chrysostomou & Philippou, 2010), they associate innate mathematical talent with boys more often than girls (Authors, 2019; Fennema, Peterson, Carpenter, & Lubinski, 1990; Tiedemann, 2000, 2002), and they stereotype mathematics as a male domain (see Li, 1999, for a review)—stereotypes that are also associated with those held by their students (Keller, 2001). As students transition from secondary to postsecondary education, young women aspiring to pursue STEM careers continue to be exposed to messages conveying that mathematical ability is innate (e.g., Leslie, Cimpian, Meyer, & Freeland, 2015; Meyer, Cimpian, & Leslie, 2015). Women also receive overtly gender-biased messages from their professors about their mathematical ability (Robnet, 2016) that may lead to gender differences in STEM self-concept (Boysen, 2009; Sax, 1994), suggesting that stereotypical messages might be passed on from professors and internalized by students through personal interaction. However, based on the existing evidence, it is difficult to assess how professors' beliefs compare with those of elementary and

middle-school teachers given that few studies have directly measured professors' beliefs about mathematics, and those that do use scales that differ from the ones used at the elementary and middle-school levels.

Current Study

In the present study, we used the same set of questions with two different populations—K-8 mathematics teachers and mathematicians at universities—to investigate what beliefs these two groups held about mathematical ability and how their beliefs compared with one another. To our knowledge, no studies have compared whether the beliefs held by teachers at these different grade levels are different. We aimed to answer the following two research questions:

1. What are mathematics teachers' and mathematicians' beliefs regarding the role of raw ability, hard work, and gender in students' mathematical success?
2. How similar are the constructs underlying the responses of K-8 teachers and mathematicians to these questions about mathematical ability?

We leveraged the existing data gathered by Leslie and colleagues (2015) and then adapted the items used in their study to capture K-8 teachers' beliefs on the same issues. We argue that knowing the kinds of messages students receive across their academic lives has important implications for recognizing female students' perceptions of their ability and their available career trajectories.

Methods

We used existing data from the study by Leslie and colleagues (2015) along with a new data set we created from the survey responses of K-8 teachers. Leslie and colleagues distributed an online survey to experts across 30 disciplines from nine universities in the USA. Of this wider sample, 1,427 mathematicians were contacted, and 133 of them provided usable data (9.3%). Mathematicians were graduate students (45%), postdoctoral researchers (12%), and faculty members (43%) who were mostly female (83%. With regards to K-8 teachers, we collaborated with the Consortium for Policy Research in Education (CPRE) to send out our survey items to elementary and middle school teachers in a large school district in the USA. We restricted our analytical sample to those teachers who reported teaching mathematics and who answered all the survey items, which resulted in 412 teachers. Teachers were mostly female (89%), and taught grades K-2 (45%), grades 3-5 (38%) and grades 6-8 (17%).To make the comparison meaningful between the two groups, we revised the wording of the items used by Leslie and colleagues (2015) to make them relevant to elementary and middle school contexts (see Table 1 for original and updated items).

Analytical Approach

To answer the first research question, we examined descriptive statistics for each group separately and then ran independent *t*-tests for each item to investigate whether the differences in mean scores for these two groups were statistically significant. To answer our second research question, we explored and tested several factor model structures separately for each group to identify which structure fit the data better.

Results

We began by summarizing teachers' and mathematicians' responses to the survey items. As shown in Table 1, the survey responses indicated significant differences between mathematics teachers and mathematicians in their agreement with the statements that (a) being a top student in mathematics requires innate ability that cannot be taught, (b) innate ability is needed to be successful in mathematics, (c) that anyone can become a top student or scholar in mathematics with the right amount of effort and dedication, and (d) that males are more better at/more suited for mathematics than girls. Significance was Bonferroni corrected ($\alpha = .05/5$).

Table 1: Descriptive Statistics for the Item Responses of Mathematics Teachers and Mathematicians

	Mathematicians			Mathematics teachers				
Individual items	Mean (SD)	Min	Max	Mean (SD)	Min	Max	*t*	*p*
V1. Being a top student (scholar) of mathematics requires a special aptitude that just can't be taught	4.84 (1.78)	1	7	2.41 (1.40)	1	7	16.3	**<.0001**
V2. If you want to succeed in mathematics, hard work alone just won't cut it; you need to have an innate gift or talent	4.52 (1.74)	1	7	2.14 (1.18)	1	7	17.9	**<.0001**
V3. With the right amount of effort and dedication, anyone can become a top student (scholar) in mathematics	3.15 (1.88)	1	7	5.56 (1.50)	1	7	15.1	**<.0001**
V4. When it comes to mathematics, the most important factors for success are motivation and sustained effort; raw ability is secondary	4.44 (1.82)	1	7	4.81 (1.61)	1	7	2.22	.033
V5. Even though it's not politically correct to say it, boys are often better at mathematics than girls (men are often more suited than women to do high-level work in mathematics).	2.23 (1.69)	1	7	1.84 (1.22)	1	7	2.92	**.004**

Note. N = 133 for mathematicians, and N = 413 for mathematics teachers. To account for multiple tests, significance was Bonferroni corrected at α = .05/5. Item text that appears in parentheses indicates the version given to mathematicians.

To answer our second research question regarding the factors underlying these two groups' responses, we explored the same two-factor model for these five items in both mathematician group and mathematics teacher group, given that beliefs about innate mathematical ability and gender ability seemed to be two theoretically different constructs. Thus, we expected that in the two-factor model, the first four items (V1–V4) would load onto the first factor because they were designed to capture mathematics as a discipline that requires raw aptitude, and we expected the fifth item (V5) to load onto the second factor because it was designed to measure beliefs about gender-specific mathematical ability. An exploratory factor analysis (EFA) for the mathematicians' data supported the two-factor model structure. Conducting the EFA with two factors and a promax rotation (i.e., the factors were allowed to correlate), the factor loadings of the five items (V1–V5) on the first factor were 0.726, 0.765, 0.709, 0.746, and 0.014, and the factor loadings of the five items on the second factor were 0.032, 0.081, −0.031, −0.084, and 0.994. On the basis of the results of the EFA, we performed a confirmatory factor analysis (CFA) with the data from mathematicians, in which V1–V4 loaded onto the first factor and V5 loaded onto the second factor. The two-factor model fit was good for the mathematicians' data (CFI = .996; RMSEA = .033; SRMR = 0.032). The factor loadings on V2–V4 were 1.050, 1.000, and 0.987 (Bentler, 1990; Hu & Bentler, 1999).

We attempted to fit the same two-factor model to the mathematics teachers' data, but the model fit was poor (CFI = .692; RMSEA = .213; SRMR = 0.109). Because the same structure was not valid in both groups, the configural invariance test failed. This result implies that the mathematics teachers' data had a different structure. We then conducted an EFA of the mathematics teachers' data to explore the structure of the data. Only the first two eigenvalues were larger than 1 (i.e., 1.99 and 1.28), and a relatively large drop occurred after the first two factors. Therefore, with an EFA of two factors and a promax rotation, the factor loadings of the five items (V1–V5) on the first factor were 0.743, 0.652, 0.008, 0.043, and 0.493, and the factor loadings of the five items on the second factor were 0.021, 0.006, 0.995, 0.468, and −0.071. According to the results of the EFA, V1, V2, and V5 should load onto the first factor, and V3 and V4 should load onto the second factor. To confirm this structure, a CFA was conducted, and the model fit was good (CFI = .994; RMSEA = .034; SRMR = 0.021). The factor loadings of V2 and V5 onto the first factor were 0.710 and 0.525, and the factor loading of V4 onto the second factor was 0.650 (for model identification, the factor loadings of V1 and V3 were constrained to 1). Thus, the two items emphasizing the raw talent needed for success in mathematics and the item associating boys with higher mathematical ability formed one construct, whereas the two items emphasizing the role of hard work and dedication in mathematical success formed another scale for mathematics teachers.

Discussion and Conclusions

These results show that mathematics teachers and mathematicians seemed to hold different sets of beliefs regarding mathematics requiring innate ability, the role of hard work in success in mathematics, and female students' mathematical ability. Furthermore, the underlying structure for these two groups was not identical. The mathematicians seemed to think that mathematics required ability and hard work and that dedication would not lead to success; however, they also did not consider this ability as belonging only to men. In contrast, teachers seemed to differentiate effort and dedication as constructs separate from innate ability. Unlike mathematicians, K-8 teachers did not agree that mathematics was a subject requiring innate ability. Rather, they seem to think that hard work and dedication could lead to success in mathematics.

As mentioned, students' academic self-concept is shaped by the messages they receive from their social environment. Thus, our study suggests that students may be receiving mixed messages from their environments, which could contribute to changes in their self-concept at different stages of their education (e.g., Robnett, 2016; Sax, 2008; Wigfield et al., 1997). The elementary and middle school teachers seemed more likely to agree that mathematical ability is a malleable construct and that effort and hard work could lead to success in mathematics, whereas the mathematicians seemed to believe ability played a key role in success in mathematics. This finding, showing that elementary teachers' and mathematicians' beliefs were different, might explain why gender differences in self-concept shift and expand after elementary school and into postsecondary education, although causal evidence of this link is still needed. Additionally, such potentially drastically different messages between these two groups might severely affect students' self-concept in college, which could explain their shifting majors (e.g., Seymour & Hewitt, 1997). However, more research is needed on the impact of these different and contrasting messages on students' self-concept at different stages of their education. Our study suggests that close attention needs to be paid to the messages teachers and college instructors send so that female students avoid entering or have difficulty staying in STEM-related fields because of stereotypical beliefs their educators may have held.

PRODUCTS OF WHITE INSTITUTIONAL SPACE: AN ANALYSIS OF WHITENESS IN ONLINE MATHEMATICS TASKS

Blake O'Neal Turner
University of Maryland
BClark37@umd.edu

Research has shown that mathematics education is a white institutional space. Utilizing two frameworks, I interrogate an online mathematics curriculum for tenets of neutrality, impartiality, and color blindness. While several themes emerged from this analysis, for the sake of this paper, I highlight three themes: mathematics is portrayed as neutral, real-world scenarios are readily manipulated with data, and lack of cultural sensitivity. There is a value in dismantling mathematics education as a white institutional space because it broadens the opportunities for students to engage with mathematics in more authentic ways. I encourage other scholars to join in interrogating whiteness in mathematics education.

Keywords: Curriculum Analysis, Equity and Diversity, Teaching Tools and Resources

Purpose of the Study

In recent years, scholars have started to problematize how we research, teach, and learn mathematics to dismantle systems, pedagogies, and practices that privilege whiteness while oppressing minoritized students. Using Martin's (2013) framework of mathematics as a white institutional space, I analyze six lessons from the *Mathalicious*[1] curriculum to examine the extent to which the curriculum perpetuates white institutional spaces. Martin (2013) argues that mathematics education and its products (e.g., curricular materials) operate as a white institutional space that produce racial/ethnic educational inequities. White institutional spaces are characterized by

> (1) The numerical domination by whites and the exclusion of people of color from positions of power in institutional contexts, (2) the development of a White frame that organizes the logic of the institution or discipline (3) the historical construction of curricular models based upon the thinking of white elites, and (4) the assertion of knowledge production as neutral and impartial, unconnected to power relations," (Martin, 2013, p. 323).

As such, mathematical curricula are not neutral and often have connections to politics and inequities (Lesser and Blake, 2006).

While mathematics is often conceptualized as universal, culture-free, and based on a system of meritocracy, anthropologists have shown that mathematics is a product of the social, cultural, and economic needs, values, and norms of societies and cultures (Powell and Frankenstein, 1997). Simply put, mathematics is not neutral or objective (Battey, 2013; Gutierrez, 2013; Bishop, 1994). The research questions elucidated in this paper are the following:1) Does *Mathalicious*, treat mathematical knowledge as neutral and impartial, if so, how do we identify neutrality and impartiality? And 2) do mathematics tasks or lessons, such as *Mathalicious*, discuss societal phenomena unconnected from power relations, if so, how do we identify this discontinuity?

Theoretical Frameworks

For this study, I integrate two complementary theoretical frameworks: Martin's (2013) work on mathematics education as a white institutional space and Battey and Leyva's (2016), framework for understanding whiteness in mathematics education. Divided into three dimensions, Battey and Leyva's (2016) framework serves as a lens that functions to, "(a) systematically document how

[1] www.Mathalicious.com

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

whiteness subjugates historically marginalized students of color and their agency in resisting this oppression, and (b) make visible the ways in which whiteness impacts White students to reproduce racial privilege," (Battey & Levya, 2016, p. 49). The dimensions of whiteness (institutional, labor, and identity) are divided into corresponding elements. The elements encompassed in institutional whiteness are ideological discourses, history, organizational logic, and physical space. The labor dimension includes cognition, emotion, and behavior. The final dimension, identity, encompasses academic (de)legitimization, co-construction of meaning, and agency and resistance.

Methodology

I choose to investigate *Mathalicious* because the mathematics lessons integrate Common Core State Standards (CCSS) and Standards for Mathematical Practices (SMP) as its foundation and use real-world contexts to help students build conceptual understanding in mathematics. Several prominent researchers frame mathematics education as an example of white institutional spaces due to the historical construction of curricular models based upon the thinking of white elites. CCSS serves as a racial project in that it "presents itself as a colorblind and universal effort with equity and social justice ends" (Martin, 2013, p. 326). Moreover, CCSS serves as a product of white institutional spaces, because the curriculum encourages assimilation, and is organized by a white frame of logic that is also inherent in the discipline (Martin, 2013).

Statistical literacy is an essential skill. Individuals need to be able to interpret, produce, and be critical consumers of data-based arguments. Thus, as statistical literacy, "is rooted in practices for participating in, critiquing, and (re)shaping structures and discourses in society that are crucial for critical citizenship in society," (Weiland, 2016, p. 988), educational stakeholders must critically investigate how we teach statistics. For the purposes of this paper, I examined six lessons in *Mathalicious* that dealt with statistics. Three of the lessons were from the One Variable Statistics unit, and the remaining three lessons were from the Bivariate Statistics unit. The One Variable Statistics lessons were "Good Cop, Bad Cop," "Police Academy," and "Distributive Properties." The Bivariate Statistics lessons were "Joy to The World," "Pic Me," and "Win At Any Cost."

As part of my analysis, I mapped the lessons from *Mathalicious* onto Battey and Leyva's (2016) framework. There are three dimensions in the conceptual framework: institutional, labor, and identity.

Results

While several themes emerged from this analysis, for the sake of this paper, I am highlighting those that specifically addressed the research questions presented above: mathematics is portrayed as neutral, real-world scenarios are readily manipulated with data, and lack of cultural sensitivity.

Results from the analysis indicate that, in some cases, mathematics was conceptualized and depicted as unconnected to power relations. For example, in the "Distributive Property" lesson, students examine income inequities in the United States. Educators utilizing the lessons are advised to stick to math and not be swayed by the nuances or real-world consequences connected to the data: "They are evaluating which subgroup made the most improvement in their income distribution, rather than trying to determine if the distributions are more equitable. As long as students flesh out their argument and support it with evidence from the data, there is no right or wrong answer" (p. 6). While students can address the problem in several ways, there is no discussion of how the income disparities have real consequences for communities. If students approach the problem in one direction, they will learn that white women had the most significant change in income distribution. If students examine percentage change, then they will conclude that Hispanic women are making the most progress. Students leave with the message that progress can be quantified with numbers. A second instance can be found r in "Good Cop, Bad Cop," where teachers are cautioned against allowing the conversation to deviate from the math (analyzing and interpreting graphical displays). The lesson notes state "While the discussion provides important context for the problem, it could also make it difficult to redirect the conversation back to the math," (p. 5). The message is clear: the data can be separated from the contexts in which they are collected.

In conjunction with the theme that mathematics is neutral, the *Mathalicious* lessons under analysis present conflicting messages about the ease with which real world data can be manipulated and modeled. In each of the lessons, the real-world data presented by *Mathalicious* is devoid of the mathematical complexities that exist in the real world. In the lesson, "Joy to the World," students learn that the data are not as perfect as the linear regressions suggest. Students are cautioned against making definitive conclusions about what increases happiness. Moreover, students learn that while mathematical models can be applied to data, the resulting models do not always tell the complete picture. However, in "Good Cop, Bad Cop" and "Police Academy," students are encouraged to use data to draw conclusions about policies. The data is presented as an easy model and complete enough to make, "decisions about the appropriateness and effectiveness of a policy meant to change that data," (Good Cop, Bad Cop Exemplar Response, p. 1). Thus, while it is important for students to understand that data and subsequent analyses may have limitations, there is a difference in messaging between these three lessons.

These lessons in *Mathalicious* demonstrate that real-world relevance does not equate to cultural relevance or sensitivity. Some fail to consider issues of race, gender, or how communities are impacted by structural or institutional racism. In "Good Cop, Bad Cop," the curriculum guide suggests that some instances of excessive force by police are understandable given that officers, "deal with people in public as well as prisoners in jail, and some officers do this often." Implicit in this message is that some people and communities need excessive policing. The message normalizes or justifies some instances of excessive force. Additionally, there is a disproportionate number of People of Color in jails. By justifying the use of excessive force in prisons, the curriculum also perpetuates that violence against Black and Brown bodies is sometimes necessary. In "Distributive Property," students make comparisons between different subgroups of the population. The comparisons are between white men and women and their "non-white" counterparts. Hispanic and Black men and women are collapsed into two categories (men and women) that imply their lack of whiteness.

Discussion

Of the six lessons examined for this project, five had indicators of or were related to whiteness. The lesson, "Win at Any Cost," did not have any direct connections to whiteness, although it could be argued that the lesson topic is tangential to whiteness. "Win at Any Cost," requires students to use data to make judgments about whether professional sports organizations (Major League Baseball, National Basketball Association, National Football League, and National Hockey League) are spending their money well when they secure talent. For the lessons that had connections to whiteness, the indicator that was observed the most amongst the lessons was, "Mathematics as neutral." This is directly related to the fourth tenet of Martin's framework, "the assertion that knowledge production as neutral and impartial, unconnected to power relations" (p. 323). The second most frequently occurring indicator was "Distribution of classroom and mathematical authority." I contend that this indicator is related to Martin's (2013) second and third tenet: The development of a white frame that organizes the logic of the institution or discipline and the historical construction of curricular models based upon the thinking of white elites. Mathematics curriculums position students differently in relation to mathematics, their peers, their teachers, other people, and their own experiences (Herbel-Eisenmann & Wagner, 2007). The *Mathalicious* curriculum is positioned as the mathematical authority. Additionally, the curricular model encompassed in *Mathalicious* is like other contemporary mathematics lessons and tasks.

It is troubling that a majority of the lessons had instances of whiteness for many reasons. This analysis reveals the pervasive nature of whiteness in contemporary mathematics curriculum materials and the potential for its use in the continued marginalization and exclusion of the experiences of children of Color. Second, there were many messages of mathematics being neutral. Mathematics as neutral and relationship with deficit discourses students in terms of their racial, gender, and cultural identities are two indicators of whiteness in mathematics education (Battey & Leyva, 2016). While *Mathalicious* does not broadcast the number of teachers or districts that utilize their curriculums, it has been featured in The Washington Post, Education Weekly, and at several mathematics education conferences, including National Council of Teachers of Mathematics and National Council of Supervisors of Mathematics. With such a broad publicity base and open access to their lesson, it is likely that *Mathalicious* has a broad reach.

To begin to dismantle systems of oppression in mathematics education, we must publicly interrogate the policies and practices that perpetuate inequities. This project is essential because, "An ideology of whiteness would then serve to position white people, white ideas, and white behaviors as more valued institutionally and in classrooms, which may not always be visible in terms of curriculum designers and policy developers," (Battey and Leyva, 2016, p. 55). This project provided an example of whiteness in mathematics lessons. More research is needed to examine how mathematics curriculum perpetuates and reinforces whiteness. To facilitate more research on mathematics lessons or tasks as a product of or connected to whiteness, analytic frameworks are needed.

TENSIONS OF RESPONSIBILITY IN CRITICAL MATHEMATICS: DEFINING TEACHER RESPONSIBILITY AND STUDENT AGENCY

Trevor T. Warburton
Assistant Professor, Utah Valley University
trevor.warburton@uvu.edu

Often even teachers who are committed to and plan to teach critical mathematics struggle to do so. To understand this struggle I studied discussions between seven preservice secondary mathematics teachers and myself. From these discussions I identified a key theme of responsibility for teaching CM. I argue that our understanding of responsibility was shaped by dominant discourses in ways that were incompatible with the goals of CM.

Keywords: Teacher Education-Preservice, Social Justice, Equity and Diversity

Since its introduction, critical mathematics[1] (Frankenstein, 1990; Gutstein, 2006) has gained interest. However, teachers often struggle to effectively teach CM (Bartell, 2013; Brantlinger, 2004; Rubel, 2017). Preparing teachers for social justice is a challenge of teacher education (Galman, Pica-Smith, & Rosenberger, 2010; Sleeter, 2001), especially mathematics education (de Freitas, 2008; Gutiérrez, 2009; Gutstein, 2006). This may stem from the difficulty of developing a critical understanding of “teacher” and “student.” Dominant discourses cast teachers as authoritative and students as passive.

Resistance to social justice in education, especially from White teacher candidates, has been linked to Whiteness (Aveling, 2002; Sleeter, 2001). This resistance is manifest even as teacher candidates disrupt Whiteness (Applebaum, 2010; Aveling, 2006; Hytten & Warren, 2003; McIntyre, 1997). Here I am concerned with how teachers who support CM struggle to understand a teacher role that is socially just. To this end, I present selections from discussions with a class of pre-service mathematics teachers. While dominant views bounded our discussions, there were moments when we began working towards discourses that reflected responsibility to students.

Theoretical Framework

The theorizing of CM has drawn on critical pedagogy (Frankenstein, 1990; Gustein, 2006). This perspective emphasizes the use of mathematics for social critique. Expanding this view, Gutiérrez (2012) describes four dimensions of equity in mathematics education: access, achievement, identity, and power. *Access* views the resources that students have available, including technology and quality instruction. *Achievement* is measured with grades and test scores. Both access and achievement generally leave the content unchanged. *Identity* means providing opportunities for students to draw on their linguistic and cultural resources, meeting their own standards, and understanding themselves and their world mathematically. *Power* addresses voice in the classroom (authority), mathematics for social critique, nature of mathematics, mathematical ways of knowing, and humanizing mathematics.

Discourse, Whiteness, & Responsibility

In focusing on discourse I draw from Gee (2005) and Fairclough (2001). Discourse includes how we speak and the things that accompany speech. While discourses do not create the physical being of a mathematics teacher, they define the categories of mathematics teacher, mathematics student, and mathematics. Discourses enable and constrain, particularly dominant discourses (Fairclough, 2001).

[1] I use CM broadly to include much of what is referred to as social justice and/or equity in mathematics.

The pressure felt to conform to discourses maintains power structures. In the United States dominant discourses are discourses of Whiteness. Whiteness Theory uncovers how discourses maintain and promote White power structures. Whiteness Theory operates on the assumption that the lives of all people in the U.S., in particular, are racially structured (Frankenberg, 1993; Frye, 1992). Dominant discourses of responsibility (and Whiteness) center around *individual* responsibility. For students, these discourses are used to justify the inequities in schools by suggesting that students or their families are responsible for their own failures (Gutiérrez, 2015). A key aspect of the dominant discourses of mathematics and Whiteness is the need to portray school mathematics as neutral. Thus mathematical achievement is constructed as individual skill and effort. Individual responsibility helps support the view of mathematics as neutral by justifying blaming students.

Methods

In this study I focus on the discourses seven pre-service secondary mathematics teachers and I used during their final course. The participants included four White males (Pseudonyms: Jeff, Karl, Gavin, and myself), two White females (Stella and Lisa), one Latina (Esperanza), and one Japanese-American female (Jane). All of our classes were recorded and transcribed. I then selected those transcripts when we discussed mathematics and social justice. In my analysis I used Critical Discourse Analysis (CDA) as defined by Fairclough (2001). I combine this approach to CDA with Walshaw's (2013) recognition that teachers as well as students are caught in dominant discourses, and Thompson's (2003) explanation of how White anti-racist educators can reinscribe Whiteness. As I analyzed our discussions on the roles of teachers, students, and their relationships I found us repeatedly circling around ideas of responsibility and blame.

Results and Discussion

Taking Responsibility

For progressive educators one logical response to dominant discourses would be to accept responsibility. However, accepting responsibility may become a means of taking power in the classroom and reinscribing Whiteness. These problems with taking responsibility were illustrated in Lisa's narrative. She carefully links her struggles to her choices, rather than to her students.

> Lisa: ok so . . . I had no idea what my students were learning at all ((Lisa explains some of what led up to this project)) and then I started having problems so I realized I didn't know what they knew and then I started to plan lessons anyway and this like divide grew in my class and you should see the scores for their final it's like half As half failing they're like there's like nobody in the middle it's like crazy so I think like people were getting it and I didn't really pay attention to them because I knew that people were struggling and we kept like repeating stuff and people got bored and then I realized that that was happening so I switched my focus and started paying attention to them but by that point people had given up on trigonometry in general and the kids that were sort of lost like still were and it just became like this huge thing.

Notice throughout how frequently "I" is used as the subject of the sentence. This positions Lisa as agent and powerful, even though most of these statements refer to her mistakes. The power of her decisions can create major problems. When students are brought up they are passive ("divide grew in my class", "people were getting it", or "people got bored"). There is little student agency shown, which positions them as powerless and blameless. Students are left out of their education and teachers are problematically positioned as solely responsible the class. Lisa has taken all authority and left none for students. While Lisa does not appear to do so, this could be consistent with a "lone-hero" (White) teacher who tries to "save" her students through social justice (Thompson, 2008). Not blaming students and taking responsibility feel like necessary steps towards social justice. It could meet Gutiérrez's (2009) call to mathematics teachers to "be in charge" in their classroom. However, Gutiérrez links this teacher-in-charge with the tension to "not be in charge" to balance classroom power. Lisa does not avoid responsibility, instead she takes all of the responsibility onto herself. This is one of the few instances where the discourse of responsibility was used to place responsibility on the teacher. However, this combination does not leave room for active student roles. The problem with this combination of discourses is that recognition of structural and historical factors is disallowed while students are denied participation.

Hinting at an Alternative: Responsibility to Students

Margonis (2015) suggests that teachers can opt out of dominant discourses of responsibility through responsiveness. Through responsiveness, instead of blaming students (as dominant discourses would have us do), we are open to the messages students send, and we have an ethical responsibility to be responsive to those messages. Responsiveness requires that we view our students as worth hearing *and meaningfully responding to*. There were times when, in our discussions, we proposed a different kind of responsibility.

Considering negative effects of CM. Towards the end of the semester we again had a class devoted to what it means to teach CM. This is one of the first times in this discussion that a student perspective is taken up and students are positioned as intelligent and capable. This change in perspective shifts how we position students and teachers.

> Lisa: I feel like we need to talk about some potentially negative consequences that could happen.
> Teacher: Ok. Good.
> Lisa: Because all I want to say when you ask that question is well they'll probably think that we understand them better and that we're on their side and all these positive things but there has to be a negative side
> Teacher: Is there risk in doing that
> Lisa: Yeah and maybe they're if they don't trust they're right to so definitely negative feelings to be had ((we discuss laws regarding undocumented students and in-state tuition))
> Jane: . . . so it was kind of like depressing I feel like when they said like well hey you have to pay way more to go to school in this state because you're undocumented but then I feel like it's kind of like all those all the other students who are like legal or whatever their tax dollars are going towards the state and that's the reason they get in-state tuition or whatever I don't know I feel like that that thought would be absolutely depressing . . .
> Lisa: Oh yeah
> Jane: like $60,000 more when you already don't have very much money and like with that one especially I couldn't see any solution or any benefit of telling it . . .

Lisa flips the perspective to say "if they [students] don't trust they're right". This positions students as intelligent and selective in whom they choose to trust. This also suggests that teachers may not always be worthy of their trust. These are both important in how we position teachers and students and momentarily disrupt the dominant discourse of teacher authority. Within the context of the discussion these are students of color and White teachers. Positioning students as intelligent and careful navigators of a racist school system is necessary to work *with* students. In response to Lisa's comments Jane brings up an example from our readings. Jane characterizes this lesson as "depressing". She implies that teachers may be unaware of what students think and feel. As a daughter of immigrants Jane may feel a particular connection to this example. She does not specify a subject position for undocumented students. However, she references the argument about "legal" students whose "tax dollars" *earn* them "in-state tuition". She implies that teachers need to judge what information to share with students. This manifestation of authority is an authority to judge what is needed by others, a key aspect of Whiteness (Frye, 1992), based on the implied lack of (racial) bias that Whites possess. Despite Jane's return to dominant discourses other students address the cost of college for undocumented students.

Karl: Yeah or yeah it was really discouraging um I guess in a way it could be in a way motivating to think about or at least at least they realize how much it would cost and it would be tough but that there are probably things they could do I guess.
Jane: Mhmmm
Esperanza: A way to follow up would be like as a teacher investigate scholarships . . .
Karl: Right
Jane: But I feel like that's another problem is that they don't usually offer that many scholarships to undocumented students.

Karl suggests that knowing could be "motivating". This suggests that students have resilience. He then adds that "they realize", positioning students as capable. Esperanza then points out that teachers could "follow up". Following up assumes that the teacher has taught the lesson. For her teaching the lesson is an assumed part of being a teacher. This framing of responsibility comes as we position students as capable. This suggests a balanced responsibility where teachers share and support and where students are capable of understanding and utilizing information. Esperanza suggests that "a teacher investigate scholarships" and so positions teachers as responsible *to* their students to do this work; work that may typically be framed as outside the role of a teacher. This is also part of teacher authority, however, in this case instead of judging, the teacher uses authority to provide information and resources. Positioning teachers as responsible-to is facilitated by positioning students as capable. Jane then points out the relative lack of scholarships for undocumented students. Her she characterizes lack of scholarships as a "problem", critiquing the system and repositioning undocumented students as innocent.

Conclusion

Dominant discourses are used to portray teachers as solely responsible for what happens in their classroom. As a result in our discussions of CM we often used these discourses to position individual teachers as *not* responsible to teach for social justice. However, taking responsibility for CM is also problematic. Instead I propose responsibility *to* students. This kind of responsibility requires that students be positioned as intelligent and capable and an understanding of shared authority. Positioning students and teachers in these ways can disrupt dominant discourses.

Studies on culture, equity, and social justice issues in mathematics teacher preparation have called for preparing teachers to build on students' mathematical and cultural backgrounds. Yet few studies have examined the preparation of preservice teachers of color (PSTCs), especially those attending Historically Black Colleges and Universities (HBCUs) or Hispanic Serving Institutions (HSIs). We present preliminary findings from a cross-site research project documenting PSTCs' perspectives on culture in mathematics education. We analyzed PSTCs' engagement in a culture unit during their mathematics methods course and their expressed views on cultures other than their own. Our findings reveal that these PSTCs often defined culture based on nationality and would repeat dominant deficit discourses about minoritized students. We provide insights for the importance of culture discussions in mathematics.

Keywords: Equity and Culture, Teacher Education - Preservice, Elementary

Introduction

Mathematics education research has acknowledged the role of culture in teaching and learning, and specifically how mathematics classrooms create a context that legitimizes or invalidates various forms of knowledge (Nasir et al., 2008). Mathematics teacher educators (MTEs) have the opportunity to expose preservice teachers (PSTs) to the different ways students reason about and learn mathematics and teach them how to build on students' mathematical and cultural backgrounds. MTEs have incorporated into their courses culture activities such as classroom observations and lesson planning (Koestler, 2012), field placements and student interviews in diverse settings (Fernandes, 2012), storytelling to challenge PSTs'color blindness (Ullucci & Battey, 2011), and family and community exploration projects (Bartell et al., 2019; Zavala & Stoehr, 2019). These activities are designed to help PSTs become "culturally conscious" (Gay, 2010) by recognizing their own cultural socialization and understanding how this affects their attitudes and behaviors toward other ethnic group cultures in mathematics education.

Although previous literature on MTEs has explored opportunities in which PSTs engage in deeper discussions and reflections on the role of culture in their teaching and learning, most studies have reported on the experiences of White PSTs only. Few studies have examined the ways in which PSTs from culturally diverse backgrounds engage in and respond to similar activities. As Montecinos (2004) cautions, assumptions based on the experiences of White monolingual teachers do not translate to the experiences of all PSTs. There remains a need to understand how PSTs of Color (PSTCs) navigate their teacher education programs. MTEs would also benefit from learning about PSTCs' views on teaching mathematics and culture, enabling them to prepare all future teachers to teach equitably. Our work sought to answer the following research question: *What are PSTCs' perceptions of other cultures in the teaching and learning of mathematics?*

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Conceptual Framework

A discussion of the role of racism in mathematics education and its implications for teacher education programs is beyond the scope of this paper (Martin, 2009, 2019; Rousseau Anderson, 2019). However, highlighting the "structural phenomenon" of racism in education (Rousseau Anderson, 2019) affords us the opportunity to examine how messages about certain groups of students and their mathematical identities continue to permeate mathematics classrooms. Recent research on the mathematics learning experiences of minoritized students has found that students have had racialized experiences in which "socially and personally constructed meanings of race emerge as salient in interactional experiences related to mathematics" (Martin, 2019, p. 461). Thus, PSTCs are likely to have experienced mathematics classrooms as White institutional spaces in which non-white cultural knowledge may be positioned as inferior or lacking. This recognition highlights the need for all PSTs to learn to question and understand issues of power, race, culture, and identity in mathematics classrooms (Gutiérrez, 2015; Rubel, 2017).

In discussing how to prepare PSTs to enter culturally diverse communities, Bartell and Aguirre (2019) warn MTEs about the deficit perspectives some PSTs hold about children and their communities and their potential resistance to engaging with families and communities that are different from their own. Thus, preparing PSTCs must include recognizing and creatively responding to discourse that positions minoritized students as incapable and developing the PSTC's role as an advocate (Gutiérrez, 2015). This is especially important because when PSTCs become teachers, they may "carry problematic beliefs into the classroom and replicate the cultural alienation students of color experience in schools" (Kohli, 2014, p. 371). Unless PSTCs have been required to reflect on their own racialized schooling experiences and engage in conversations and activities focused on creating rehumanizing mathematics classrooms that counter deficit views of minoritized students, they may unintentionally perpetuate structural inequities in their mathematics classrooms (Chao et al., 2019; Zavala, 2017).

Methods and Data Sources

CAM Up! (Cultural Awareness in Mathematics Unit Project) is a cross-site research study that seeks to illuminate PSTs' interests, perspectives, and dispositions toward teaching mathematics to culturally diverse student populations. Three institutions serve as research sites: one Historically Black College and University (HBCU), one Hispanic-serving institution (HSI), and one Predominantly White institution (PWI). We purposefully selected these sites to include PSTs who are culturally diverse across racial, ethnic, language, socioeconomic, and geographical backgrounds.

We used a modified version of a cultural awareness unit (White et al., 2016) to explore the PSTCs' perspectives. The unit included three components: (1) an article critique paper; (2) audiotaped class discussions in which PSTCs share their article critiques, describe their own culture, examine stereotypes in mathematics education, and discuss culturally relevant math teaching strategies; and (3) a post-discussion reflection paper. Project data include recorded class observations, unit artifacts, and researchers' field notes.

In this paper, we present preliminary findings for 10 female PSTCs (HBCU=3, HSI=4, PWI=3) to convey key themes on culture that emerged across the three sites. These PSTCs were randomly selected from a larger group of 52 PSTCs. Four of the PSTCs self-identified as African American/Black, one as Asian, and five as Hispanic/Latina.

The findings presented here focus solely on our analysis of the article critique assignment. This assignment required PSTs to find, read, and write a critique of an article that focused on teaching mathematics to students from a cultural group other than their own. We intentionally did not define culture prior to the assignment so as not to influence their perspectives on culture.

For the first cycle of coding/data analysis, all authors read the PSTCs' article critiques, met, and created a list of holistic codes, keeping the research question in mind (Saldaña, 2016). These holistic codes captured the overall ways PSTCs positioned themselves in relation to the culture discussed in their selected article. For the second cycle, each author re-coded holistic categories individually using values coding to arrive at more precise categories that captured the values, attitudes, and beliefs represented in the data. This cycle uncovered how PSTCs perceived the culture of others with regard to teaching and learning math. Analyzing the critiques and unit artifacts allowed us to triangulate the data, yielding two emergent themes that identified the common mathematics discourses we discuss in our findings.

Findings

A preliminary analysis of the article critiques revealed that PSTCs have complex views of culture, as evidenced by which cultures they selected and why they made that choice. Several insights emerged into how PSTCs view the intersection of culture and mathematics teaching and learning. In this section, we describe the PSTCs' views on culture and their acceptance or rejection of dominant cultural views about minoritized students in mathematics education.

Views of Culture

Understanding and unpacking the participants' descriptions of culture shed light on how they view their own culture in the context of teaching and learning mathematics. The PSTCs described culture in three ways: *culture as nationality, culture as language acquisition*, and *culture as socioeconomic status (SES)*. Six PSTCs ascribed to *culture as nationality*, comparing the way mathematics was taught in their "American culture" to the way it was taught in the cultures of other countries. In their article critiques, the PSTCs identified cultural nuances that emerged in the descriptions of the mathematical teaching strategies. For example, one PSTC noted, "One way the Chinese culture is different from my American culture is based on differences in language structure."

Three PSTCs noted that language plays an important role in learning mathematics. PSTCs who ascribed to *culture as language acquisition* contrasted their use of "standard academic English" with the language of non-native English speakers. Moreover, some PSTCs discussed the role that language played in their own identity. For example, one PSTC stated, "The primary culture described in the article is that of English language learners (ELL) . . . growing up, I could not define myself as an ELL."

Several PSTCs also viewed *culture as SES*, suggesting in their critiques that students' socioeconomic status represented an aspect of culture that influenced their mathematics learning. One PSTC wrote, "I grew up in a middle- to upper-middle-class area, therefore I don't share the low-income aspect of the students' culture either." None of the10 PSTCs saw culture as the shared norms among a group of people.

Views of Mathematics and Culture

The PSTCs expressed interest in learning about various cultures because they recognized both the changing demographics in schools and the achievement gaps that persist. Although they wanted to learn about other cultures, however, the PSTCs were often unaware of asset-based teaching strategies. Many PSTCs expressed agreement with or repeated dominant deficit mathematics discourses about minoritized students in the article critiques. These discourses included: *language is a barrier, caring parents are involved in their child's education*, and *Asian teaching methods are better in math*.

Some PSTCs viewed speaking a primary language other than standard English as a barrier to learning mathematics in the U.S. One PSTC wrote, "Although I am Asian and grew up in a bilingual household, I was never classified as an ELL nor did I need any type of additional academic instruction due to language barriers." Another PSTC wrote, "English Language Learners (ELL) and African American English (AAE) speakers are groups who suffer greatly from culturally skewed word problems . . . [M]y family always spoke Standard English. Therefore, I never faced the barrier of making sense of the Standard Academic English that is used in schools." These PSTCs viewed language as a barrier to rather than a resource for mathematics teaching and learning. In describing strategies for teaching mathematics to English language learners, the PSTCs recommended removing the complex language from word problems instead of incorporating words from the students' cultures.

Some PSTCs accepted the deficit discourse that certain cultures value parental involvement and that without it, learning mathematics is more difficult. Moreover, these PSTCs suggested that parents who care will be actively engaged in their child's education. One PSTC identified parent support as a family value, noting, "Asians are more likely to listen to their parents in regard to educational and vocational decisions, due to an innate need to not disappoint or bring shame to the family. Family is at the center of their culture, something that was once essential to the African-American community and their survival but is sadly no longer valuable."

While the critiques of eight PSTCs reflected dominant narratives, two resisted stereotypes such as, "All Asians are good at math." These participants perceived culture as learned and adaptable. One PSTC expressed a desire to examine the Asian model minority stereotype more closely, stating,

> This theory jeopardizes the students who actually need help in academics . . . I particularly like that the author says students can respond using their 'own mathematical power.' I truly believe that everyone can achieve mathematics, but we just have our own 'super power' that we cannot project.

Discussion

This study's preliminary findings uncovered three views of culture expressed by PSTCs—culture as *nationality*, *language acquisition*, and *socioeconomic status*—that reflect the dominant narratives of culture in the contemporary U.S. We also uncovered two themes related to how PSTCs perceived math and culture: agreement with deficit narratives/stereotypes about how mathematics is taught and learned, and rejection of these narratives/stereotypes.

These findings suggest several implications for methods courses and the faculty who teach them. As MTEs, we are aware of the racialized mathematical experiences of PSTCs (Martin et al., 2019), and we believe it is incumbent upon us to guide PSTCs to reflect on the cultural footprint they bring to the mathematics classroom. Moreover, we must push back against narratives that assume PSTCs will automatically make cultural connections with students of color in their classrooms. We concur with Gist (2017) that teacher educators need to "value teacher candidates' cultural and linguistic diversity and understand how to draw on and develop their multicultural capital" (p. 930). Only then will we develop PSTCs' cultural consciousness, enabling them to dismantle deficit narratives in mathematics teaching by honoring and incorporating their students' assets and strengths.

TRANSLANGUAGING TO ENSURE LATINX MATHEMATICS LEARNERS THRIVE

Craig Willey
Indiana University - Indianapolis
cjwilley@iupui.edu

Hector Morales, Jr.
Northeastern Illinois University
h-morales3@neiu.edu

This paper reports on a study designed to showcase Latinx bilingual children's linguistic and cultural resources for learning mathematics in an after-school mathematics club. Specifically, we examine the design of the activity system (Engström, 1999) and social interactions therein through a translanguaging perspective in which students leverage their language and culture to engage in mathematical learning. Our primary objective is to highlight some to the triumphs and struggles of bilingual children as they expand communicative practices and mathematical resources via interactions with bilingual facilitators and electronic communication with a math wizard, El Maga.

Keywords: Communication, Instructional activities and practices, Equity and diversity, Informal education

This paper presents a translanguaging perspective in which students use their agency to develop and affirm their Latinx bilingual mathematical identities in the context of an afterschool math club. Although research has disproven deficit-oriented beliefs that using native language during mathematics learning is unnecessary or harmful (e.g., Khisty & Chval, 2002; Moschkovich, 2007), there is still much to understand about the intricate processes by which Latinx bilingual students use their language and culture to engage in mathematical learning (Razfar, 2013). Therefore, our aim is to highlight how Latinx bilinguals leveraged their communicative practices and mathematical resources while communicating electronically with a math wizard. Specifically, we highlight critical features of a mathematics teaching and learning environment that supports Latinx bilinguals' translanguaging and what translanguaging affords learners. We use the term "bilingual" or "bilinguals" to center the reality that these students are multilingual, even if only emerging multilinguals. Additionally, we use the term "leverage" to reflect students' agency to capitalize on their communicative and linguistic repertoires (see Martinez, Morales, & Aldana, 2017, for a review of how this term is used by scholars).

Latinx Students and Mathematics

Latinx students are one of the fastest growing school age populations in the U.S. (NCES, 2016). Yet, Moll (2001) posits that classroom practices have continued to create a distance between Latinx students' language, cultural knowledge, and what they know academically. These systems persist in marginalizing, and thus not privileging linguistic, social, and cultural capital to help create dehumanizing school practices (Langer-Osuna, Moschkovich, Norén, Powell & Vazquez, 2016). Moreover, guiding texts like Principles to Actions: Ensuring Mathematical Success for All (NCTM, 2014) asserts that all students must have access and opportunity to study mathematics. As such, math classrooms have been encouraged to move from isolated seatwork to more social and verbal activities that require students and teachers to engage in more substantive mathematical discussions and collective practice (Bass & Ball, 2015). However, there is a concern that mathematics reforms may be in danger of ignoring the needs of Latinx students unless their needs are re-examined in light of the new demands of the mathematics classroom with its increased emphasis on communication and collaboration (Moschkovich, 2000). While this is a generalized perspective of classrooms with Latinx students, it nevertheless raises questions about marginalization and undervaluing Latinx students' learning resources in mathematics.

In: Sacristán, A.I., Cortés-Zavala, J.C. & Ruiz-Arias, P.M. (Eds.). (2020). *Mathematics Education Across Cultures: Proceedings of the 42nd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*, Mexico. Cinvestav / AMIUTEM / PME-NA. https:/doi.org/10.51272/pmena.42.2020

Garcia, Ibarra Johnson, and Seltzer (2017) reminds us that all good education must begin with recognizing students' strengths that come from their own community's linguistic and cultural repertoire. Much of the research with Latinx students has focused on bilingual language learners. The research is often framed from a deficit perspective focusing on the relationship between students' proficiency in their first language and learning mathematics (e.g., Mestre & Gerace, 1986) or the obstacles faced by Latinx bilinguals learning mathematics across languages (English and Spanish) (e.g., Khisty, 1995). Deficit perspectives emerge when bilinguals' linguistic resources are ignored or forbidden in the classroom while only privileging the dominant school language (Langer-Osuna et al. 2016). These are de-humanizing practices with the sole purpose of controlling and dominating students' cultural identity and excluding it from the classroom and school (Gutierrez, 2017). Garcia (2017) argues that this view of language and academic discourse in schools acts as a barrier to knowledge (in our case, mathematical knowledge), only privileging those students whose linguistic repertoire mirrors the dominant school language.

Other studies have also shown that Latinx students use a wide variety of cultural resources to construct, negotiate, and communicate (spoken or written) about mathematics (Chval & Khisty, 2009; Varley Gutiérrez, Willey & Khisty, 2011). These resources include cultural knowledge (Gutiérrez, 2002), linguistic resources (e.g. mathematics register, mathematical discourse) (Celedon-Pattichis, 2003; Moschkovich, 2000), everyday experiences, life histories, and community funds of knowledge (Moll, 2001). Moreover, Razfar, Khisty and Chval (2011) advocates for a social-cultural model for language development in mathematics classrooms. They juxtapose social-cultural theory (SCT) against second language acquisition (SLA) models. In the SLA model, learners are perceived as passive recipients of mathematical knowledge proceeding in a linear developmental path and language is seen as an external tool. In contrast, SCT positions bilingual students as active agents in their language use, capable of working collaboratively, interacting, and communicating while grappling with challenging mathematical tasks. Given this disparity, a counter-narrative to common deficit perspectives, will allow us to illuminate the ways in which Latinx bilinguals encouragingly use their linguistic and other funds of knowledge while engaging their individual and collective agency to assert their identities as mathematics learners. Gutiérrez (2017) discusses such a rehumanizing perspective as one that positions the student as central to the meaning-making process while engaging in the practice of doing mathematics. This perspective refutes the imposing of standardized or normalized practices onto students, such as the routine expectation of students reproducing the teachers' idea of productive mathematical activity. Instead, a rehumanizing perspective fosters respect and dignity through privileging the viewpoint and experiences of the student, and the ways in which they develop personal understandings through their own disciplinary perspective on mathematics.

Translanguaging

We draw on translanguaging to reconceptualize bilingualism as a liberating and empowering communicative practice and resource capable of transforming learning the goes beyond students' transition to the dominate school language (MacSwan, 2017). Translanguaging is more than just a simple shift between two languages (i.e., English and Spanish). It is a complex and interrelated communicative practice that make up bilinguals' linguistic repertoire (Cenoz, 2017). Garcia (2017) posits, "…speakers use their languaging, bodies, multimodal resources, tools and artifacts in dynamically entangled, interconnected and coordinated ways to make meaning" (p. 258). Translanguaging classrooms are powerful spaces that take full advantage of and leverage students' linguistic repertoire to engage with complex content and texts, strengthen students' linguistic repertoire in academic contexts, draw on students' bilingualism for the purpose of expanding their ways of knowing, and support students' bilingual identities that counter English only ideologies (Garcia, Johnson, & Seltzer, 2017).

Given the paucity of studies that use a translanguaging framework to understand language practices of multilingual persons in mathematics classrooms, we argue that translanguaging re-conceptualizes the mathematics learning and language practices of Latinx bilinguals. Mazzanti and Allexsaht-Snider (2018) report on a study in a kindergarten classroom with a large Latinx population. They find that their use of English and Spanish occurred simultaneously as a way to make mathematical meanings. These meanings were not limited to just linguistic accomplishments, but also used symbolic representation of numbers and visual models of the number problems to leverage these students' communicative resources. Other studies have focused on spontaneous translanguaging of 12th grade Latinx bilinguals in an upper level math classroom. Morales (2004) used a translanguaging and perseverance framework to compare the collaborative efforts of two groups of students solving a challenging mathematical task. Results show that when students are given the freedom to explore mathematics via their dynamic bilingualism they are able to spontaneously and dialogically leverage communicative resources to help them persevere and overcome in-the-moment obstacles. Morales & DiNapoli (2019) further ague that these students' translanguaging practices reposition students as competent problem solvers and agents of their own learning while leveraging bilingual identities as learners of mathematics reflecting a rehumanizing perspective for all students in the group.

Maldonado, Krause, and Adams (2018) also believe that emergent bilinguals could participate in mathematics teaching and learning in ways that are rehumanizing to all participants in the classroom. They explore ways in which a 2nd grade dual language mathematics classroom built a translanguaging stance where teachers made choices to build on children's thinking while engaged in mathematics instruction that develops knowledge, dispositions, and builds on students' cultural, linguistic, and community funds of knowledge. They argue that mathematics teachers must nurture a translanguaging stance by (1) Respecting others ideas. (2) Committing to caring for others and bringing the community together. (3) Collectively working together for the good of the individual and group. And (4) engaging in a mathematical practice together.

Research Design, Context, and Methods

Our research was conducted in a large, urban school district in a very large Midwestern city in the United States where 85.6% of the students are classified as coming from low-income families, and 13.7% are categorized as "English learners". Our research site was James Dual Language School. James was made up of approximately 425 students from Pre-Kindergarten through the 6th grade. The school population consisted demographically of 99.4% Latino/a. Additionally, 98.3% of the students were eligible for the government's free or reduced lunch program, and 68% of the students were categorized as English language learners (ELLs) (School District Data, 2007).

The research reported here is based on data gathered in an after-school project called "Los Rayos de CEMELA" adapted after the work of The Fifth Dimension (Cole, 2006) and La Clase Mágica (Vásquez, 2003). The after-school project was designed to give Latinos/as experiences doing non-remedial mathematical activities including problem solving and playing mathematics games that were intended to enhance students' knowledge of probability and algebraic concepts. Students were encouraged to be self-directed, to work collaboratively, to verbalize their thinking, and to ask questions. One of the goals of the after-school project was to promote mathematical bi-literacy. All participants were encouraged to speak Spanish. Playfulness between the adults and children was a critical part of the interactions in the after-school project. In addition, students communicated electronically with a mathematics wizard, El Maga, who engaged students in bilingual conversations about their mathematical experiences.

Findings

Despite our original efforts to privilege Spanish in the after-school, social forces prevented participants from fully realizing the potential and capital of Spanish. We highlight these challenges and discuss adjustments made to the after-school club to more authentically draw on children's, and families', funds of knowledge, including their linguistic resources.

The children's gravitation towards English – but also El Maga's persistence using Spanish and commitment to supporting language growth – was also documented in children's correspondence with El Maga (an undergraduate student facilitator).

As we mentioned earlier, we were particularly interested in creating a space that privileged communication in Spanish, so we purposely wanted to include the parents during the second session. We considered that including the parents would naturally encourage the students to speak in Spanish. We asked the students to explain the rules of the game and to demonstrate how to play the game to the parents. When Rodrigo played the Counters Game during the second session, he worked with a group that was more Spanish dominant. He played with two other students, Margarita and Rafael, his mother Olga, two more mothers, and an undergraduate facilitator, Carlo. All three mothers were Spanish language dominant, and their command of English was limited. When Rodrigo played the Counters Game again, he was more confident and even took on the role as sort of a referee making sure everyone including the parents played by the rules.

The after-school club got a critical boost from the parent-participants. Parents served multiple roles, one of those being a bridge where Spanish moved from its familiar place in family and community spaces into the academic space where children frequently preferred to speak English. Parents, through their presence and eagerness to participate alongside children, established new norms where mathematical conversations were in Spanish. Furthermore, parents embraced their role as collaborators in the design of the community mathematics projects. Their insights contributed to mathematical activity where problem solving was done within and through rich community and cultural contexts, rather than trying to bring cultural contexts into pre-fabricated mathematical activities. The evidence suggests that this collaboration allowed children and parents to draw on meaningful – although subjugated and grossly under-acknowledged and under-utilized – forms of funds of knowledge.

Conclusions and Implications

It turned out that parents, because of their language backgrounds, are natural examples of translanguaging. Mathematics learning environments are well-served by the involvement of multilingual parents and community members because they re-shape the linguistic lanscape in a way that elevates language use and development, and likely meta-linguistic awareness, too. Palmer et al. (2014) argues further that much of the work involving bilingual students is framed around an ideology and policies of language separation that encourage teachers to create separate instructional spaces (physical and other) for bilingual students to communicate in either the dominant or minority language. These ideologies and school policies also contribute to separating parents and other community members from the teaching and learning context and, moreover, do not take into consideration the power of communicating across multiple languages to adequately support the learning of mathematics among bilingual Latinxs. We are only in the beginning phases of understanding the intersection of language ideologies, mathematics learning environments and language practices. This data implies that further research should examine the role of various multilingual actors and the context of the mathematical activity in order to determine the myriad ways they support Latinx learners to thrive mathematically where traditional classroom practices and schooling structures have largely failed.

Keywords: Classroom Discourse, Cross-cultural Studies, Culturally Relevant Pedagogy, Equity and Diversity

MIM aims to promote education responsive to diversity through participatory research by developing and evaluating strengthening pedagogies. These are research based pedagogies building upon individuals' strengths and assets identified by examining past positive experiences; encouragement of hope and optimism and development of emotional satisfaction with the present (Seligman, 2002) hence moves away from cultural-deficit orientations and instead promotes achievement for all students.

Linguistic and cultural challenges are not new. Indigenous communities have experienced them for decades as a result of colonisation, as have children from non-dominant communities in other contexts. Tensions in education are intensified by language and cultural differences in times of large migration (Cenoz & Gorter, 2010). Classrooms with a high number of students from different migration waves, historically homogeneous communities with newcomers in their schools for the first time, and Indigenous schools with endangered languages are contexts that have been described in research, society and media as problematic due to race, gender, culture and religion, hence impacting *all* students.

The main objective is *to develop new scientific knowledge about how mathematics education may contribute to equity and social justice - and vice versa. At the heart of the research are students' and teachers' storylines.* Through juxtaposing Indigenous and migration contexts, we will further understand students' experiences and hence pedagogical possibilities, within Norway, Canada and the USA. We apply positioning theory (e.g., Harré & van Langenhove, 1999) to understand students' and teachers' experiences as it provides the required tools to understand *how* the people in an interaction may have different understandings both of the interaction and of the opportunities available to them within it. The storylines used by migrated and Indigenous students to interpret their mathematics classroom interactions and the role of mathematics in their life trajectories will be juxtaposed with the storylines used by the others in their classrooms and community. We have recently begun extending the field's understanding of the availability of storylines and identities in mathematics classrooms (Andersson & Wagner, 2019; Wagner, Andersson & Herbel-Eisenmann, 2019).

MIM is to be situated historically and culturally draw on and further examine research-based work that has shown to have a positive impact on groups who have been marginalized by policies and practices in educational contexts; and will be done, reflexively, in partnership with the peoples and communities who the work is supposed to benefit. MIM has all of these characteristics and will contribute to mathematics education work empirically, theoretically, methodologically, and practically.

PROSPECTIVE MATHEMATICS TEACHERS' CONCEPTUALIZATIONS OF EQUITY

Kanita K. DuCloux
Western Kentucky University

Corey M. Wadlington
West Kentucky Community and Tech College
corey.wadlington@kctcs.edu

Keywords: Equity and Diversity, Teacher Education - Preservice

Prospective mathematics teachers (PMTs) may have early and frequent opportunities to observe and teach in mathematics classrooms. What is often lacking, however, are their opportunities to examine and discuss inequities that exist in the classroom. This paper explores 30 PMTs' (19 from a university (U) and 11 from a community college (CC)) conceptions of equity, utilizing two of Gutiérrez's (2012) four dimensions of equity, namely access and power. Specifically, we investigated and compared their proposed responses to two hypothetical vignettes (Max, 2017) from mathematics department conversations regarding calculator usage and mathematical discourse.

Vignette 1-Ms. Lopez: I encourage some, but not all, of my students to use calculators in class. If I don't let these students use calculators, they can't contribute to the problem solving we're doing. Mr. Parker: I too have students who benefit from the use of calculators, but I think fairness is really important. Depending on the lesson, I either let all of my students use calculators of none of my students. This way no one ever feels cheated.

Vignette 2 -Ms. Booth: Because I know more mathematics than my students and they look to me as the expert, I do most of the talking. It's important for students to hear the correct uses of mathematical language so I model that as much as possible. Ms. Sutherby: Students will learn mathematics by using the language themselves, even if imperfectly, so I let them talk as much as possible.

Preliminary analysis revealed that the majority of the PMTs explicitly agreed with one teacher's approach (U = 84% and CC = 64% for access and U = 63% and CC = 45% for power). PMTs considered equality, creating more interactive learning environments, and classroom resources with respect to calculator usage. Most of the PMTs viewed fairness as equality and expressed a desire to create an interactive learning environment (U = 79% and CC = 55%) while less than 10% of the PMTs from each group favored only encouraging some students to use calculators. More PMTs from the community college (36%) preferred a balance of both approaches than those from the university (11%). The equality responses included: "I agree with Mr. Parker and think if I do allow students to use their calculators it should be everyone, so no one feels left out or as Mr. Parker said cheated out of the test" (CC). Modeling correct language and allowing the students to talk during class were both important factors in PMTs' views on mathematical discourse. In the discourse vignette, 63% and 45%, respectively of the PMTs supported having students do most of the talking, none of the PMTs encouraged the teacher-majority approach, and 37% and 55% of the PMTs preferred a balance of the two approaches. The student majority approach responses included: "Classroom conversation should be about creating new knowledge. … I want my students to feel comfortable about sharing their thinking, therefore, I want them to do most of the talking…" (U). Additionally, the elementary PMTs from CC were less likely to relinquish power regarding whose voice dominates in the mathematics classroom, however, all PMTs were aware of and thinking about some equitable issues.

Keywords: Equity and Diversity, Marginalized communities, Rural education, Social Justice

The inequitable experiences and outcomes for Black learners of mathematics is well documented in urban areas (Martin, 2012). There is less work on the construction of race in education in rural areas, specifically Appalachia. Because race intersects with multiple economic and social structures, it is necessary to attend to context when studying race in mathematics education (Ladson-Billings, 2005; Patel, 2016). This poster makes the case for a study of learning mathematics while Black in Appalachia and provides initial findings of research on Black students and White teachers of mathematics in West Virginia.
