This document, intended to accompany "Analytic Summaries of Specifications for Model Teacher Education Programs" (SP 003 719), provides a basic introduction to the techniques of educational planning which were used in developing the ten models. General principles of models, system analysis, and behavioral learning systems are presented in concise outline-discussion form and are then illustrated with examples drawn from the field of teacher education, in general, and the ten USOE-sponsored models, in particular. Among the subjects treated are: (1) kinds of models (symbolic, mechanical, biological, cybernetic, economic); (2) characteristics of a good model (five evaluative criteria); (3) systems theory and various approaches to it (subsystems, input-output models, and models based on the heuristic approach); (4) six steps in the process of systems analysis; (5) typical constraints on systems planning and teacher education programs; (6) the essential relationship between information and systems theory; and (7) the ways these elements were combined to develop models appropriate to teacher training programs. It is emphasized throughout the document that the models have been developed as guidelines, rather than prescriptions, for planning as institutions develop programs relevant to their particular characteristics, capabilities, and needs. PREFACE

Ten elementary teacher education models summarized in a companion report* form part of a program being sponsored by the U.S. Office of Education. The ten models, developed separately by ten research teams from educational institutions across the United States, provide total designs for programs to prepare elementary teachers for the schools of the present and the future. The charter from USOE required that the models incorporate the principles of systems analysis, behavioral learning systems, and other advanced planning techniques. Each model, to a greater or lesser degree, complied with the charter, and, as a result, education now has the first specifically planned, total programs of teacher education. In this respect, the models represent a significant advance in the field of educational planning.

This document is intended to accompany the summaries of the models and to supply a very basic introduction to these new planning techniques. The reader will find two kinds of information in this report. General principles and theoretical discussions of models, systems analysis, and learning systems are presented. This theory, however, has been simplified and kept brief. Accompanying this basic information are examples drawn from the general field of teacher education and specifically from the ten models involved in the USOE program. The reader familiar with teacher education may find these examples helpful in understanding the principles presented.

* Analytic Summaries of Specifications for Model Teacher Education Programs. Falls Church, Virginia: System Development Corporation (TM-WD-(L)-319/000/00), July 1969. The institutions providing leadership in developing the ten models have been Columbia University, Florida State University, University of Georgia, University of Massachusetts, Michigan State University, Northwest Regional Educational Laboratory, University of Pittsburgh, Syracuse University, University of Toledo, and University of Wisconsin.
It is emphasized throughout the document that each teacher education program and institution represents a unique situation and requires individual planning. The reader is urged to consider this short discussion and the summaries only as guidelines for his own efforts. No more than this was intended. Yet if discussion is provoked and insight achieved, some value can be assigned to this effort.
I. **Introduction: New Planning Techniques and Systems**

Teacher education in the United States has evolved in response to forces affecting the schools and the teacher's role. This education has been, in general, a reaction to societal forces, and only rarely has a deliberate process of planning been undertaken. The fault, however, does not necessarily rest with teacher educators. America as a nation has evidenced a distaste for deliberate planning, and until the second World War, little deliberate planning was undertaken in any social field—let alone education!

The increasing complexity of technology and expanding demands on the schools have made the deliberate planning of education a cultural necessity. To develop teachers and other educational personnel who will be responsive to the future needs of the schools requires the positive planning of preparation programs, both pre-service and in-service. This planning, in turn, introduces to education the use of many new techniques first developed in other fields. Broadly speaking, these techniques fall into three categories: *educational models*, *systems analysis*, and *learning systems*. These areas form an important background for working with the ten models involved in the USOE elementary teacher education program.
II. Educational Models

A. Types of Models

The ten elementary teacher education projects developed a group of program models but not model programs. The distinction is not merely one of playing with language. A model program suggests an ideal concept—one to serve as an example to others. Indeed, these projects may do just that, but it is not their primary intention, because a program model has as its purpose the organizing of parts, functions, and processes into a meaningful format for analysis and understanding. These ten elementary teacher education models, as their developers will be the first to admit, are hardly ideal. They are, however, important examples of how programs can be organized for effective presentation.

A model in this context is a representation of a whole, a total universe. Models resemble symbols because both are abstractions of reality. A symbol, however, represents a single idea, perhaps a very complex one, but a symbol does not represent a universe.

A model attempts to explain a complex organization or process by comparison or analogy with a commonly understood and less complex phenomenon. The earliest models compared physical objects with abstract ideas. The pyramid of Egypt resembled the ascending levels of society and became a common way of explaining one form of social organization. These early models permitted the classification and organization of reality, but they did not permit the representation of a process.
During the fifteenth and the sixteenth centuries the use of mechanical models became commonplace. Based on a fascination for the newly developed clock mechanism, these models could show both organization and process. Each part could be clearly identified and the movement of all the parts together could easily be recognized. And if the model fell apart, much as the wheels might fall off a cart, one could still pick up the pieces and start the process operating again. This condition remains an important aspect of mechanistic models. The pieces are independent, much as a school district has traditionally operated independently of the teachers college although both contribute to the same process.

Mechanistic analogies were popular until the nineteenth century when the study of evolution provoked increased interest in biological models. Like the mechanical model this form of analogy showed the organization of the parts and the processes performed, but unlike the earlier representation, the parts of a biological model cannot exist apart from the whole organism. The heart, for instance, dies without oxygen from the lungs. Biological models added the concept of interdependence to models while seeking to explain reality.

The biological analogy continues to exert a strong influence on models in the social sciences. Organizational science in particular has depended on this form of understanding. Such expressions as "the heart of the program," "the organization's lifelines" (meaning usually its resources and finances), "the guts of the organization," and "the lifetime of the corporation," all testify to the pervasiveness of biological analogies in the social sciences.
In education, such a concept as "the functional analysis of teaching" owes its origin to mechanical and biological models. While these analogies have proved useful for dealing with some problems, they have not always adequately explained the processes underlying teaching. Indeed, it has been suggested that some models of teaching work effectively against improvements in the process of education by locking-in our thinking and hence inhibiting our ability to conceptualize the complexities of the system. New forms of analogy have been required, and these are being provided by the twentieth century revolution in our thinking about information and the consequent development of cybernetic models.

The evolution of computer systems has meant that virtually limitless amounts of information can be processed rapidly and accurately. This development has motivated a revolution in thinking about effective models to describe the universe. One such model sees the process of evolution as the constantly increasing ability of the organism to communicate with its environment through continuous sophisticated systems for receiving and processing data received from the environment. A vital organ processes certain kinds of information and responds to changes in the environment.

Cybernetics is a new field concerned with models based on information flow. Unlike the biological model which was limited to dealing with parts and wholes, cybernetic models permit a concentration on processes through an examination of the information flow in a given system. In brief: the system receives data, the data causes some action (or process) to occur, and this action results in some output. If the model is complete, information
about the output, called feedback, is returned to the system as a basis for changes and adjustments. This very basic cybernetic, or information flow, model can be used to effectively describe very complex realities including school systems, manpower programs, and teacher education programs. The University of Wisconsin teacher education model includes a detailed example of an emphasis on the cybernetic approach.

The concept of an input-output model, however, first became popular in the field of economic planning. By comparing the input of resources—men, money, expertise, and technologies—to the resultant output of products, the effectiveness and efficiency of a system could be determined. By altering the combinations of resources the effects of alternative procedures for achieving the same ends could be measured and compared. Rather sophisticated mathematical processes have been developed to deal with these questions, although their applicability to education has been limited by disagreements about the purposes of an educational system.

As input-output models have been applied to educational problems, one conclusion always emerges: only very inadequate data exist about the nature of the inputs (time, money, expertise, etc.), about the effects of the educational processes upon students, or about the ability of these processes to produce the desired outputs. In other words, very little information has been developed as a basis for the construction of adequate models of the educational system or its subsystems.
B. Characteristics of a Good Model

So far, we have mentioned five kinds of models in their historical order. They are:

1. Symbolic analogies
2. Mechanical models
3. Biological models
4. Cybernetic models
5. Economic models

All these kinds of models attempt to describe a complex and usually non-physical reality by analogy with a simple and familiar set of concepts. All such models try to show the parts, the functions, and the relationships among parts of the reality they are describing. Each offers certain advantages depending on the purposes for which the model was intended. In any event, once models are constructed, they tend to become prescriptive as well as descriptive. People come to accept the model as the true description of how things are. In this case, it becomes necessary to reexamine the assumptions underlying the model and to redefine the significant factors in the description attempted by the model. Awareness of these needs for reexamination and redefinition is a characteristic of the ten elementary teacher education models.

What makes a good model? It has already been suggested that in this day and age there is a strong preference for models which describe the information processes within a universe of concern, but some other forms of modeling are useful depending on the
purpose. All types of models, however, have certain characteristics by which their value can be judged. The following discussion enumerates a few of these.

The Model Should Be Complete

Most models fail to be useful because they do not explain the whole system, or, if they describe only part of a system, they cannot be related to the rest of the system. Educational planning has been particularly guilty in this respect. School operating units are sometimes totally separated from the designers and producers of materials, and both remain apart from the colleges and universities producing the teachers: Small wonder then that many new teachers are unprepared to cope with the realities of the classroom.

To be complete, a model for teacher education would trace the process from the student's entry through his initial years of teaching. In other words, it would include both pre-service and in-service components in a common structure. The model would also describe the linkages between the college of education or teacher education program, as a system, and other parts of the total system of education. The flow of information and resources among these systems would be described, and the areas of independent and cooperative action would be indicated.

When six blind men described the whole elephant in terms of their experience with a part, they were reacting in much the same way most persons describe the field of education. It is, of course, only human nature to reflect a personal bias based on experience and learning, but sometimes this range of perception prevents a necessary reconceptualization of problem areas--changes in behavior to meet changes in conditions.
The Model Should Reflect an Operational Reality

Some conceptions of teaching prevent a confrontation with operational reality. It has been suggested, for example, that by viewing the teacher both as an idealistic hero figure and as a person trapped in a predetermined system of values, a productive description of teaching is blocked. No hero can operate in a carefully circumscribed environment. Another block to effectively viewing the teacher's role has been the concept of the "teacher as generalist," an omniscient renaissance man surviving in an age of overspecialization. The tenacity with which this view of teaching is upheld has prevented necessary attention to describing the tasks and activities of teaching, hence to limiting the kind of information so necessary for the construction of adequate teacher education models. A third inadequacy may be represented by an insistence that teaching can be learned by imitation. Student teaching remains essentially a form of apprenticeship in which the neophyte is introduced to the craft by the master teacher. This craft orientation prevents the development of teaching as an intellectually conscious task.

Perhaps no single model, or set of models, can achieve a completely adequate description of teaching. The important concern, however, should be that any model permits a realistic confrontation with reality, which, in turn, imposes the requirement that viewpoints be made explicit and attitudes be challenged.

The Model Should Be Understandable

A model will be understandable if it describes a universe in a straightforward manner and if it can show a relation between its concerns and the next larger universe. A teacher education
model, for instance, would be related to both a model of the total university and the educational system which consumes its products.

The amount of detail in a model frequently causes a problem. People tend to overdescribe those parts of a process with which they are most familiar and to overlook components which are beyond their field of concern. To guard against this tendency, a general model of the major parts should be constructed first. Each part can then be detailed, and in this manner sub-parts to any degree of refinement can be related to the whole.

The Model Should Encourage Analysis

The primary weakness in the research techniques of single variable analysis and controlled sampling has been their inability to encourage further analyses within the area of interest. Indeed, they limit inquiry and narrow the problem to a point which makes the results of such research of limited value for a field so complex as teaching. A recognition of this condition does not detract from the use of these techniques under appropriate conditions; rather, it requires that specific research be related to a pre-conceived general model.

Until recently, education has lacked these general models, and educators have been locked-in by buildings, content organization, and a confusion about aims and goals. To a large extent we have lost sight of the process of education because we have replaced it with a concern for the institution. Education models have become descriptions of structures rather than operations. These kinds of models fail to encourage the kind of analyses which facilitate basic understanding. Indeed, they tend to become
circular: they seek for self-improvement based on traditional assumptions instead of questioning basic purposes.

The Model Should Encourage Feedback

As change and development become increasingly important, effective models must be responsive to the information from their operation and from their environment. This process is called feedback. The term is useful because it is more general than evaluation or assessment. Feedback implies that information collected is used in some way to affect the operation of the system. In other words, information from the operation is returned to the system to adjust it in order to better achieve its goals.

Feedback systems impose several requirements on the design and execution of a model. As has already been suggested, the importance of data (information) is basic to the concept of feedback. An effective feedback system is designed and implemented at the beginning of a process. Information about the inputs and the environment is collected, and statements of goals and purposes are formulated. At critical points throughout the operation of the system, and at designated concluding points, output information is collected for comparison with the original data. In this way, the effectiveness and the efficiency of the system can be measured. Appropriate adjustments can be made in the system's operation based on this information or in conformance with changing goals or standards.
Traditional teacher education programs have been especially weak in this kind of feedback system. Lacking a clear-cut purpose, programs have generally produced young teachers who are liberally educated and who have been exposed to some aspects of teaching—usually from a distance. The relation of these training experiences to the real world of teaching remains unclear, but adjustments are difficult because no feedback system—in this case, data from the teacher (and the school district) to the institution preparing the teachers, in a form encouraging program adjustment—exists to control the system.

One important contribution of the ten elementary teacher education models is their direct involvement of local districts as feedback mechanisms. Several of these models (Syracuse, Toledo, Wisconsin, and others) call for the inclusion of local school districts working directly with the teacher education program. For example, Florida State University proposes a "portal" school which not only gives the student ample opportunity for observation and student teaching, but also provides his first paid employment as a teacher. In this way the college can offer support to its graduates, can observe and evaluate their performance, and can make needed revisions in its own education program. At the same time, implications for the educational programs of the participating school districts will become apparent.
III. Systems Analysis of Teacher Education Programs

A. A Brief Description of Systems Theory

"Systems Analysis" has become a popular catchword indicating a process for the application of scientific thinking to large problems. The phrase is used indiscriminately to mean the analysis of information for computer programming, the development of planned management activities, or, on other occasions, simply the orderly relationship between any two or more things or ideas. These uses, at least in the popular sense, seem to convey some special magic of science.

There has never been one system methodology; indeed, the tradition of systematic analysis in one sense is as old as Aristotle. What is new, though, is the concentration on quantifiable aspects of analysis (to the extent that this is possible), and on the isolation and control of the numerous factors and variables made possible through the power of the computer. This, in turn, has led to a revolution in our thinking about the nature, organization, and use of information, so that at the heart of systems procedures there exists a philosophy of information.

The word system is used to communicate many different ideas, but in this paper it should be thought of as indicating a process. In briefest form, "systems analysis" is an orderly process for, first, defining and describing a universe of interest (and the significant factors and their interrelationships within the universe); and, second, determining what changes in the universe will cause a desired effect. Systems analysis generally begins with the broadest statement of the
universe, proceeds to isolate and define parts of the system according to their functions, and then notes the interrelationships among these functions.

There are different approaches to the description of systems. The following, among many, will be appropriate for the present review:

1. **Subsystem Description.** A subsystem is an operational entity within a system capable of functioning independently or of permitting independent design and analysis. Critical factors in the selection of subsystems include, first, the explication of a major process within the system, and, second, a clearly understood relationship between the operation of the subsystem and the goals of the system.

Each subsystem description would contain information on the men, materials, etc., required for its operation, because the subsystem is an operating entity contributing to the goals of the system. Most significantly each subsystem would be described in terms of its goals and the process for achieving these goals. The resources required by each subsystem could be determined in relation to its goals.

In the field of education it is possible to suggest a number of viewpoints for the selection of subsystems. If the school is considered as the universe (the total system), the following subsystems might be considered:

- **Hardware subsystems** including production, transmission, reception and related equipments, software, and service.
- **Specific curriculum areas** (subject matter, but longitudinally, throughout the school experience).

- **Grade-level programs** (e.g., the total program for the kindergarten).

- "**Package procurements**" (perhaps a major unit of study organized around a major theme).

- One or more specific and persistent **educational problems** (good health, physical handicap, reading difficulties, etc.).

- Specific and persistent **problems unique to the environment** (poverty, isolation, teacher shortage, etc.).

- **Assumed needs** (based on present inadequacies, conjecture that the present will not prepare for the future, "band-wagon applications," "equal education" themes, etc.).

Compatibility of system description is maintained when subsystems are selected according to a common viewpoint. The selection of a particular viewpoint represents an important decision for the systems analyst and is governed by a number of significant considerations aimed at permitting ease of analysis and design. Among these considerations may be the availability and form of required information, avoidance of "sensitive spots," conformity to administrative decree, or the ability to operationally define the span of control. An effective viewpoint will avoid areas which cannot be changed or in which resistance to analysis is predictable. State-of-the-art information and prior experience with the system provide useful guidelines. The critical factor in the selection of subsystems is the clear-cut and simple explanation of the important factors in the situation.
Each of the ten elementary models organized a unique set of subsystems for developing a program of teacher education, but several major elements are common to all of them. Clearly the process of curriculum planning and development received considerable emphasis. In most instances management subsystems were developed. These included both the management of the process and the management of the student (e.g., entry profiles, achievement information, and proficiency standards). Separate subsystems for the production of materials, the procurement of professional staff, and the provision of buildings and equipment were not usually developed. This is justified because these areas, while important to the larger universe of the school of education (or other unit), are not major emphases in the development of an elementary teacher education program. This program uses the end-product of these other subsystems, and, by specifying its requirements, it can then request these other subsystems to produce the desired products. This distinction in locus of control is extremely important. No one model can encompass the whole universe, and choosing a viewpoint which provokes concentration on the major program functions requires considerable care.

2. Input-Output Models. Input-output models for educational planning have received considerable attention since the advent of PPBS (Planning-Programming-Budget Systems). Such models begin by describing the desired outcomes of the system and then determine the changes necessary to achieve these outputs. For instance, in planning a program of teacher education, one would first describe the profile of the finished product, i.e., the trained teacher, and then determine what changes would be required in program entrants to achieve this end-product.
Inputs to the system would also include the necessary staff and other resources required to operate the program.

There is, of course, an inherent dilemma in this kind of planning. No adequate, or relatively homogeneous description of the product (the teacher) can be postulated, and, therefore, any satisfactory program model would have to begin at this point. An input-output model in teacher education would be useful only to the degree that a relationship between this "picture" of the teacher and the program of preparation could be shown and that feedback procedures could be implemented to govern the process. This, in turn, implies that knowledge of the objectives is the first requirement of system design and evaluation.

3. The "Heuristic" Approach. This third aspect of system theory is more complicated than the preceding two, but it is most useful when the specific nature of the product cannot be clearly stated. In this approach, there are no binding preconceptions about the situations the system will encounter. The aim is to provide action guides even in the face of completely unanticipated situations and in situations for which no formal model or analytic solution is available.

The critical aspect of this heuristic concept is the use of principles to guide inventive action; again, the process is central to the analysis, governed by a statement of direction or goals. In other words, the set of principles should permit the establishment of a program to achieve specified ends regardless of the conditions under which the program might operate. In planning teacher education programs, principles
concerning the nature of the teacher's role, the conditions of operating, the functions of teaching, and the personal characteristics of the teacher would be explicaded as a basis for program design.

Our present knowledge of the teaching process suggests the following heuristic approach to the development of teacher education programs. Generally, this approach was followed by the developers of the ten elementary teacher education models. The Columbia Teachers College Model, for example, is explicitly put forward as a set of guidelines rather than as detailed specifications. As the program is put into action, it will be expected to change.

Basically this approach provides for the step-by-step analysis of teaching in the following manner:

a. The behavior of all teaching personnel, i.e., individuals relating to children in the learning environment, should be related to its contribution to effecting desired changes in children.

```
Specify Desired Changes in Children
Specify Teaching Tasks
Specify Complexity of Teaching Task
Assign Tasks to Appropriate Level
```
b. Other tasks of educational personnel, i.e., those who while still performing as teaching personnel, are also concerned with tasks not directly related to interacting with children, can be described as they relate to the teaching function.

\[
\text{Specify Desired Changes in Children} \rightarrow \text{Specify Teaching Tasks} \rightarrow \text{Specify Support Tasks} \rightarrow \text{Specify Type and Complexity of Support Tasks} \rightarrow \text{Assign Tasks to Appropriate Level}
\]

c. The primary concentration of analysis should be an effective interaction of a teacher-person with a learner. Other tasks could be organized as: (1) concomitant activities coterminous with the teaching task; (2) independent activities in support of the teaching task. The following organization is suggested by this distinction:
### Tasks Concomitant with Teaching

<table>
<thead>
<tr>

</table>

Needless to say, this approach is highly theoretical, but it is useful for understanding the relationship of various kinds of inputs to the processes of teaching. At the present state-of-the-art, much of the specific information for designing programs based on this kind of analysis is unavailable. Research has not been concerned with this kind of paradigm. The challenge, however, should be obvious. If programs of teacher education (including the provision of other educational personnel) can be related to the effects these teachers will have on children, exciting and productive program planning will result.

**B. A Step-by-Step Systems Analysis Procedure**

There are six steps in the process of systems analysis. Each step requires its own group of techniques and suggests a different set of problems and limitations. Systems analysis has perhaps been viewed with greatest alarm through pre-occupation with these limitations.
STEP ONE: CONCEPTUALIZING THE SYSTEM OR THE "PROBLEM UNIVERSE"

The first step develops a clear statement of the system of concern. This definition includes all those elements which are a part of the problem universe. The analysis also sets limits to the problem by separating the system from its environment and by relating it to other distinct systems.

Every system is a subsystem of some larger system and is composed of a hierarchy of subsystems, sub-subsystems, etc., each of which is a system in its own right. The systems analyst, therefore, must select a universe which is consistent with the purposes of his analysis. A useful and productive analysis is distinguished by the formulation or design of the problem, the selection of appropriate objectives, the definition of the relevant and important environment or situation in which to test alternatives, and the provision of reliable cost data and other pertinent information.

STEP TWO: DEFINING THE "SUBSYSTEMS"

A subsystem is an operational entity within a system, capable of functioning independently or of permitting independent design and analysis. Subsystems are defined according to sets of common properties. In the design of educational systems, the major subsystems are facilities, training (or personnel), and administration. Subsystems interact at the system level through a process called "systems integration."

STEP THREE: STATING THE OBJECTIVES OF THE SYSTEM

Systems procedures have sometimes been defined in terms of two basic operations; first, state the goals for the resolution of a problem; and, second, organize the means to achieve these
goals. The critical point in understanding or using system procedures rests on the importance of clearly explicating the objectives of the system. Indeed, every element within a system is evaluated in terms of one basic question: Does it contribute effectively to the achievement of system goals? A mechanism, therefore, for determining the objectives of the system, for ranking multiple objectives, and for choosing between incompatible objectives is a first requisite for effective systems planning.

STEP FOUR: DEVELOPING ALTERNATIVE PROCEDURES

Once the goals for the system have been established, the system designers will explore the various alternatives available to them for the accomplishment of the goals. Alternatives may be designed to utilize various uses of resources (especially cost levels) to indicate different learning paths based on variations in entry profiles, and to develop operating relationships which are necessary for implementing new technologies. Since so much educational research has remained inconclusive, it can offer little of value for reaching firm decisions. Nevertheless, research and practice are excellent sources for determining worthwhile alternatives to be explored.

Too frequently in educational planning we begin by explaining why something can't be done, what resources are unavailable, or which regulation prevents trying out an idea. Such attitudes effectively prevent the serious design and consideration of alternatives. What is first required is a great deal of thinking about ideal programs and resources. One can always cut back as reality demands, but if we never design an ideal program, or think about using new techniques, we will never have a basis for growth and change.
As alternative procedures are designed, it is important to predict the consequences of selecting one alternative over another insofar as this is possible. For instance, what are the implications for the total system on a program based on considering the student's time as the critical resource? Or, what will be the differences in appreciation for a subject if it is learned through a series of programmed instructional units rather than in a group situation? Each program designer should conjecture both the positive and negative consequences of decisions about alternatives.

STEP FIVE: SELECTING THE BEST ALTERNATIVE

The selection of the best alternative depends upon inherent values of the community, the school, and the future. It is at this point that the philosophical orientation of the decision-maker becomes relevant. Having determined that the objectives can be accomplished, and that an effective system can be implemented, careful consideration should be given to the extent to which the job is worth doing, and then whether it is worth doing through the use of the most effective or most efficient system.

Teacher education is faced with some real dilemmas. We conjecture that an academic major-minor provides the appropriate "general education" program for an elementary teacher. In fact, we assume that a college of education is the best place to train teachers! And we structure programs based on these assumptions. It is not the present intention to question the value of these assumptions; rather, by pointing to them, we may simply recognize that our assumptions govern our planning and selecting of programs.
Among the assumptions underlying the construction of the ten elementary teacher education models are positive attitudes towards the use of systems analysis, positive planning for the future, and the value of behaviorism. On a broad level, it is also assumed that teaching, as a process, can be understood (at least in part) and trained for by each of the model programs. In addition, the models assume the necessity for total program designs (rather than further changes in the parts) if an adequate view of the future is to be achieved. In short, the ten models project an inherent faith in the use of rational processes for the promotion of the humanistic and scientific goals of education. These assumptions appear valid, but the results of their application to operational programs will be the true measure of their value.

**STEP SIX: IMPLEMENTING THE SYSTEM**

Assuming that sufficient resources are available, systems implementation should be relatively automatic if the system has been carefully designed and tested, but systems procedures include several important aspects of implementation. One is feedback. This effort continues throughout the operation of the system in order to assist three purposes:

1. The continuing effectiveness of the system or the requirement for changes.

2. The continuing relevance of the system in terms of its objectives.

3. The need for the creation of new systems as a result of changing objectives, new developments, or new criteria for selecting alternatives.
Another important aspect of implementation concerns the ability of the institutions to accept new systems. Some universities and colleges of education are unable to make the necessary adjustments; others, seeing the need for change, have undertaken programs to examine the ways and means. The ten models in this study faced the problem in different ways. Florida confined its model to the sphere of control exercised by the school of education. This decision was based on the realities of the campus, and from this base it will be possible to increase involvement. Michigan State, on the other hand, incorporated all the college experiences of its teacher candidates, including academic and general course work. Each model copes with the present situation and points to steps necessary for involving the remainder of the university.

Phase II of the USOE model project will indicate the feasibility of implementing selected models under various conditions, including available resources, needed personnel and facilities, and requirements for the design and production of new materials. In this respect, the present models are incomplete system descriptions until implementation procedures have been completed. The models, designed under ideal conditions, will require some redesign to meet the realities of each operational situation. Phase III, the establishment and operation phase of the USOE project, will supplement the two preceding phases to represent a complete system design and implementation cycle. Only by uniting these aspects can the requisite processes of constant reiteration and adjustments through feedback be adequately fulfilled.
C. Constraints on Systems Planning

The design of any system is constrained by many factors, some of them negotiable, but many of them beyond the control of the systems designer. Deciding which factors fit which category becomes an important aspect of the process. In a sense, systems designers are fortunate; they can design ideal systems, without consideration of the day-to-day real world operations which can clog the best of designs. The difficulty with this stance is that it has frequently caused the creation of beautifully engineered systems which are perfectly incompatible with their environment. On the other hand, unless designers consider carefully just how realistic some assumed barriers are, their field of vision will be limited, and the system will fail to cope with the true problems. In the planning of programs of teacher education, the following constraints are significant:

1. **Time**: The first constraint is time. We are required to educate a teacher in four years or less, or perhaps five, if the masters program is included. It is easy to conjecture programs which take less time, either because of a reevaluation of educational requirements or through increased efficiencies in the training processes. The models have contributed greatly to this discussion. They have also considered the apportioning of time among required areas of study, experience, and on-the-job practice. In a similar manner the close relationship between pre-service and in-service training has contributed to an understanding of the time factor in teacher training.

2. **Data**: Perhaps the most important constraint on the design of elementary teacher education programs is data. We simply don't possess adequate information in a number of areas,
especially the relationship between a teacher's behavior and a student's learning, to adequately design programs. Using present information in the designing of the ten models has pinpointed many of these gaps and suggested new and significant areas of research in teacher education.

3. The Scope of the System: The broader the initial conception of the system, the stronger will be the design of any sub-universe. For example, a major weakness of teaching has been the inability (through time and press of responsibilities) for the classroom teacher to get beyond the four walls of the room and to interact with other colleagues. This condition contributes to a narrowing of vision and an inability to view the process of education as continuous. The relationship between first grade and sixth grade is often blurred; subjects are repeated, and students are confined to a limited curriculum. At a larger level of analogy than the classroom in the school, education in general operates on three distinct subsystems: the operating district, the university which produces teachers, and the "industry" which produces materials. Little direct communication and even less joint planning has existed among these groups. Indeed, interaction has often been considered undesirable. The ten models have carefully examined some of these relationships and are moving to increase both the scope of the system—the broad view—and the potential interactions among the constituent parts. The Syracuse model, in particular, has emphasized cooperation with school districts, industry, and other organizations.

4. Communications: Any system is constrained by the ability of the parts to communicate with each other and by its ability to communicate with other systems. For instance, the
relationships between teacher education programs and the other parts of the university are sometimes counterproductive. The staffs of several modeling projects found that while they were trying to make their course work more individualized and based on proficiency rather than time and letter grades, their students still had to meet university requirements in order to graduate. On the other hand, some school systems have developed operational linkages with many universities, industries, educational organizations, and other groups. Through this process of extending communications channels, the concept of the system and the program of education are extended beyond the limits of the school. The desirability of these linkages has been emphasized throughout by the U.S. Office of Education in its statements regarding the overall teacher education program concept.

5. **System Integration:** It is often possible to design a beautiful system, one which is consonant with our view of reality, but then have it fail because it does not resemble the real world of other system designers. If the system of educating elementary teachers results in a product which is unable to function in harmony with teachers trained through other systems, communication will be limited and friction will result. The process of obviating this difficulty is called integration. It requires that the designers of a system, regardless of how complete that system may be, must be aware of that system's ability to mesh with other systems. An educational program which does not produce the kind of labor force required in the future will not serve the needs of the economic system; similarly, a school system which cannot educate a large percentage of its students cannot claim absolute control over the process of education. The models have
been aware of these difficulties, especially in relating the program of teacher preparation to the realities of the changing school and culture. Since this process is evolutionary, it is more difficult than in some other kinds of design. Its importance, however, cannot be urged strongly enough.

6. **Facilities:** Too rarely is heard "Design the program, then build the building." What usually happens is that the program is constrained by the pre-existing building. Facilities too frequently control the potential decisions. New techniques such as modular walls, inside-outside rooms, and heat, light, and sound controls (for example, the multi-media rooms with student response systems) offer fewer constraints on program planning than do the older buildings, but they are still constraints. Sometimes a pre-existing building makes little real difference, but on occasion, it can determine the success of the program. On the other hand, the location of activities can play an important part in the nature and quality of an experience. Watching pupils in a classroom--actually taking part in the activities--can result in perceptions quite different from observing a movie in a college lecture hall. Since it is particularly difficult to change extant facilities, careful planning must precede their development, but careful planning can also obviate many of the apparent restrictions on present facilities.

7. **Resources:** To a systems analyst, resources are of many types. The most obvious one, of course, is money. Others might include: teacher time, student time, equipment, space, expertise, information, and other institutions. The list of potential resources can be quite long. Frequently, systems operate without considering the broad number of resources
available to it. Recognizing these resources forms bases for designing alternative systems so as to conserve the use of the critical resources. Generally, in education, we have assumed that the student's time was the least valuable resource, but if we plan programs to make effective use of this time, it becomes a critical resource itself.

D. Constraints on Teacher Education Programs

The above list of constraints can apply to the design of any program, and each planner must apply these principles to his work. In the field of teacher education, several specific constraints can be mentioned. Some of these define the limits of potential programs, because they can be modified only within fixed limits. Indeed, changing them requires changing our perceptions of teachers in rather radical ways. This may be a necessary concomitant to the improvement of teacher education, but it is a slow process. The following are examples of constraints which may affect program planning in some form or other:

1. Certification Requirements: Each state establishes minimum requirements for the certification of professional personnel. In the field of teaching much progress has been made towards establishing uniform certification and towards focusing the proficiency measures on the teacher education institution. The state still sets the standards, but the college certifies that graduates of its programs have met these standards. Any program of teacher education, including those of the ten models, must be consonant with present standards. In one sense, this implies a hardship because the granting of a degree is universally accepted as evidence of qualification to teach. It
may be conjectured that other avenues of entrance, among them
the new careers profiles, offer viable alternatives to the four
year undergraduate program.

2. **Local and State Personnel Policies:** Personnel policies
are established to govern the behavior of individuals within
complex organizations. Usually, these large institutions re-
quire some form of structure to promote their purposes. On
the other hand, personnel policies sometimes work against the
kinds of individuals who can make a positive contribution.
For instance, how many persons choose not to teach because of
policies against beards, certain codes of behavior, or various
ethnic costumes? Again, the schools have become increasingly
liberal, or at least sensitive to individual differences, but
these policies still exert a strong pressure on the acculturation
aspects of teacher education programs. "Adjusting to the
realities of teaching" rather than "developing the person as a
teacher" too frequently governs the design of programs. The
ten models have done much to examine these problems and to
resolve this inherent conflict through providing a number of
experiences and career lines.

3. **Individual School Administrators:** The building
administrator is usually free to rule within his four walls and
football field much as he sees fit. His style of leadership
will determine both the tone of the school and the quality of
the education. He usually selects teachers with whom he can
get along. While this management technique appears reasonable,
it can serve to prevent diversity and to limit the kinds of
experiences available to students. It can also mean that some
schools will not find the teachers produced by innovative
programs acceptable. For this kind of reason, no doubt, we
find several of the ten models advancing the concept of the "portal school," a specific school within a district which will serve as a bridge between the college of education and the world of teaching.

4. **The Profession:** The teaching profession, often conservative and inbred, tends to fear radical departures from present practices. Professionally acceptable teacher activism most notably concerns itself with pay and prestige rather than with problems of change and education. In this situation, a new breed of teacher, militant, liberal, and action oriented, will often be defeated by outdated colleagues and unresponsive school systems and communities. It remains true, however, that little progress could have been made in American education without an organized profession of teachers.

Regardless of the stance, and there are many to choose from, the profession, through its several agencies and organizations advises, directs, and censures many practices in teacher education. In one respect, a profession is, by definition, an inhibitor of change. Those who are "in" will keep others out, until the "outs" come to look like the "ins." This professionalism is as much an unconscious phenomenon as a direct threat to programs of preparation. The ten models, having sensed these problems, have worked with professional organizations and with teachers associations in local districts. The stance accepted by the professional groups interacting with a program of teacher preparation will in large part affect the ability of that program to achieve its goals.
5. The Teacher Candidates: Teacher education programs must be responsive to the persons who apply for admittance. During the past two decades numerous authors have pointed out that the lowest calibre of university student enters the field of education, and, consequently, quality programs must be "watered down." Other writers have suggested with equal force that good programs will attract strong candidates. There is virtue in both positions. Yet other studies indicate that even graduates of strong programs leave teaching after three or five years unless they have "acculturated" to the existing limitations of the school. At best the very conditions of teaching seem to limit the effectiveness of strong college programs. The ten models have set reasonable admittance standards, and they have envisioned attractive programs. It seems reasonable to expect that they will attract desirable candidates. Working with local districts should do much to improve the retention of graduates. These are encouraging signs.

E. Information and Systems

1. The Importance of Information. Systems analysis is based on information. Systems theory evolved as an information-oriented decision-making process. In this respect systems designs are based on the requirements for getting and organizing information. Four kinds of information are usually specified: input, output, process, and environment. To express this concept in basic terms, we want to know what the student looks like when he enters the program and how he is different when he leaves. What knowledge and skills does he possess as a result of the program? Again, we want to know if the program was effective and/or efficient? Did it achieve its aims and
goals, that is, did it change the student in the way we desired him changed? All of these questions in the last analysis are "situation specific," that is, they operate within a definable environment. Our fourth form of information then requires that we understand the relation of the process to the environment. Was the process an acceptable system within the operating environment? Did it change the environment? Did the environment change the system? What adjustments were required because of constraints imposed upon the program?

A feedback system is explicitly developed as a part of the design of several of the ten models to provide these kinds of information at appropriate operational points. Changes in the system can be made as a result of the information received through operating the system, or as a result of changes in the environment. Similarly, the environment provides information on needs, and this information affects the priorities assigned to various processes. If it is more important to produce teachers strong in arithmetic and science skills, the program can be adjusted accordingly. The particular information requirements of an elementary teacher education model will vary according to the conception of the system, its definition of the teacher, and its relationship to the environment; therefore, it is difficult to do more than suggest the importance of designing a system based on information rather than on traditional guesswork, clairvoyance, or luck. In this respect systems analysis provides a realistic framework for applying the results of research and other feedback activities to the improvement of the process.
2. Some Fundamental Kinds of Information. The systems analyst, as he looks at the process of teacher education, would be concerned with selecting an approach and explicating the constraints. To aid him in this process, he might ask himself the following questions:

1. What are the functions and tasks of teachers in the context of the school environment?
2. What do we want the teacher to do in the learning environment?
3. What knowledge and skills are required in order to perform these functions and tasks?
4. What experiences would reinforce that knowledge and give the prospective teacher the chance to practice the tasks?
5. How can this analysis of functions and concomitant knowledge and experiences be stated in terms of program goals?
6. How could a program of teacher preparation be organized to achieve these goals?

These questions then suggest a number of program construction guidelines—heuristics—which can be applied with greater or less reasonableness to the design procedure. Although all ten of the models have undergone similar development sequences, each has focused in its own unique fashion on the area of elementary teacher preparation. The following generalizations from the ten models, therefore, are merely guidelines. Each person designing a model would need to restate the question in terms of his operating environment and program goals:
All program experiences should come from statements of goals and should be related to these goals.

All program experiences should provide a thoroughness and understanding of the basic concepts of the subject under consideration, including the ability to discover and to apply this knowledge.

All program experiences should be designed for effective presentation, including the maximum of student activity, utilizing the modes known or rationally assumed to be most effective for presentation.

All program experiences should be designed for maximum efficiency in presentation, based upon preservation of the critical resource, which, in this case, is assumed to be student time.

All program experiences should utilize measures of cost effectiveness in development and presentation, insofar as cost effectiveness does not require sacrifice of the critical resource, student time.

All programs should be organized sequentially, insofar as this is possible, to include attention to individual cognitive styles, prior background and experience, and special learning difficulties.

All programs should be designed to provide a constant system of feedback, first to the student on his progress and standing, second to the teacher on the success of the particular program, and third to the institution on the relation of the particular program to the total program of teacher preparation.
F. **System Objectives in Teacher Education**

The preceding discussion has provided a process for determining the objectives of a teacher education program and has indicated some of the difficulties in achieving adequate statements of aims and goals. Two guidelines, however, remain to be mentioned:

1. **State alternative series of objectives based on the profiles of individual students.**

Since the programs will service quite disparate varieties of students, objectives should be stated which are compatible with these profiles. Each student's program will, in some manner, be unique, but all will contribute to achieving the general goals and objectives of teacher education. In a sense, each student could be thought of as a subsystem, representing a unique input and output, and presenting a unique confrontation of process and environment. In this respect it is possible to establish the basis for individualized programs of instruction. The ten present models have been especially responsive to this aim. Much of their information handling problem has been solved through the design and implementation of computer information and guidance systems. Most of their instructional modules provide for individual pretest and post-test and remediation based on individual needs. The statements of objectives for each individual should be directly related to the broad objectives for the program, however, and this can be achieved through developing a careful control and evaluation process.

2. **The process of explicating objectives should remain flexible and responsive to changing patterns of teaching and learning.**
This consideration is really a reminder that the systems procedures are a constantly reiterative process. One does not state objectives and then pass on to the next steps in the process. Both changes in the environment and measurements from the operation of the process will affect the statement and ordering of objectives. It appears highly desirable that a continuing review process be established for determining the value of the objectives and the ability of the processes to meet them. Otherwise, even a carefully designed program will atrophy.

A second form of goal setting focuses on the operation of the system. These goals concentrate first on how the system is intended to affect groups of students and then on the effective management of the system. Programming, Planning, and Budgeting Systems (PPBS) and other cost-effectiveness techniques are designed to help assess the operation of systems in relation to previously stated goals. The establishment of system-level goals is important because it permits the efficient and effective selection of alternatives. For educational planning, however, a concentration on the system level may omit an adequate view of the final product, the student.

The system procedures techniques, developed for the design and delivery of hardware systems and their required support systems, tend to concentrate on aspects other than the individual. They are appropriate to the design of such technological systems as educational television, mobile facilities, or a computer system, but once these systems are designed, they must be seen as means for the achievement of goals relating to the individual. This consideration suggests that a dynamic interaction between
these two design levels should be maintained to insure a fit of the system with the essential purposes.

The question of an appropriate statement of objectives within the framework of systems procedures has received considerable attention, especially since these techniques have begun to move into the social sphere. There is no doubt that to the degree objectives can be made explicit and goals objectified, the deliberate design and analysis of systems is enhanced. Some writers have gone so far as to suggest that systems analysis represents a viable approach only in situations where the goals permit quantifiable measurement, but this position remains extreme.

If the whole of teacher education cannot be explicated and quantified, because the whole of teaching (as an art) somehow defies analysis, the systematic planning of many experiences can still be undertaken. The physical properties of color have been explicated and can be known by every budding artist. This knowledge, however, will not guarantee a Picasso, but it is highly unlikely that Picasso could paint without such basic information. In exactly the same sense, the teacher will operate as an individual person with his pupils, but he can be trained in many of the skills and techniques which will facilitate that performance.

G. The Total Design Process

The design of an operational system represents only one aspect of a total design process. Frequently, however, systems analysts and educators alike assume that they have dealt with the whole process when the design is completed. The result
has been many magnificently engineered systems which fail to achieve their goals.

There are three elements in a total design process. The first is the conceptualization and design of the operating system which we have discussed. The second is a careful analysis of the environment in which that system is going to operate. The third element is a change and implementation process which will prepare the environment to accept the new system. Each of these three elements has been discussed at great length over the past years, but only infrequently are relationships among them considered.

The ten elementary teacher education models have variously sought to achieve total design processes by involving local school districts, industrial groups, and teacher organizations. They have also carefully studied the future roles of the teacher in the schools of tomorrow, and they have stated their concern for educating a teacher who can work in the present and the evolving institution. These elements are extremely important for the success of the models, along with an implementation process which finds acceptability in the embedding university or college. In this respect, implied in systems design is a concern for the specific situation, and each school of education considering adopting a version of one of the models, therefore, will need to consider all the elements in the design process.
IV. Learning Systems for Teacher Education

A. The Design of Learning Systems

An important application of systems analysis to education has been the design of learning systems. This process is somewhat more limited than the design of a total program and all its elements, but it has helped produce some significant improvements in curriculum and teaching. In the ten models, the concept most frequently used in constructing a basic learning system is that of the learning module. Learning modules include, along with objectives and criterion measures, information on necessary resources, experiences, and prerequisites. The following example, from the University of Toledo model, indicates the general format of the learning module:

Context: Educational Technology

Major Subject Area: Programmed Instruction

Topic: Student Performance Data

Target Population: Elementary, In-Service, College-University, Administrative, Support.

Behavioral Objectives:

The student will define the following types of pupil performance data that he might obtain when his elementary pupils use an instructional program:

a. frame error rate
b. post-test item error rates
c. pretest and post-test scores and gains;

and he will indicate the significance of each type of data in:

a. evaluating pupil performance
b. evaluating programmed instruction materials.
Treatment:
The student will participate in a lecture-discussion on the topic and then read in depth in resource materials on an individual study basis until familiar with the topic.

Materials:
Glaser, R. (Ed.) Teaching Machines and Programmed Instruction.
Lecture notes, textbooks, reference books and supplementary source materials.

Evaluation:
* Competence will be assessed by teacher-made examination.

The modules, of course, represent partial experiences within a general framework of curricular requirements. Once established, modules can then be clustered into groups of experiences to meet the needs of a particular program. In this respect an ascending ladder is created so that basic experiences can be related to the general goals of the teacher education program. The following hierarchy, from the University of Wisconsin, shows one form of interrelating learning experiences:

1. **Overall system** -- e.g., a total teacher education system.
2. **Component** -- a major set of system objectives and operations.
3. **Element** -- a subset of a component.
4. **Subelement** -- a subset of an element dealing with a specific set of closely interrelated objectives-- e.g., learning to teach reading.
5. **Module** -- subset of a subelement, e.g., units of instruction devoted to learning how to construct and administer achievement tests.
Level -- subset of a module where an objective is stated in most specific and final terms.

The learning system, therefore, may be thought of as an integrated set of media, equipment, methods, and personnel performing efficiently the functions required to accomplish one or more specific objectives. Seven steps in the process of designing learning systems are frequently acknowledged:

1. Preparing the training objectives.
2. Sequencing the objectives of the system.
3. Identifying required functions.
4. Selecting components and procedures.
6. Coordinating components and procedures.
7. Evaluating the system.

There is a certain familiar ring about this orderly curriculum design process, but one aspect of it requires comment. Instructional systems, as they have been developed as parts of total system design, have been based on an analysis of the required performance or activity needed by the student after training. The presentation and practice of knowledge in the system are governed by these performance requirements. Such a systematic analysis of present teacher education practices would reveal serious disparities between what is going on in the classroom and what is expected of teachers thereafter.

B. The Use of Behavioral Objectives

The ten teacher education models rely heavily on the specification of behavioral objectives as a basis for the selection of appropriate knowledge and experiences. Each model includes a
description of the teacher's anticipated roles and functions in the changing school. This analysis of the teaching task into more or less specific groups of behaviors forms a basis for selecting both the academic and pedagogical content and the methods of practicing its application. Using behavioral methods in effect forces the question of relevance by showing direct relationships between the teacher education program and the teacher's classroom performance.

A behavioral objective states the specific actions, or uses of knowledge, which the student will be expected to perform as a result of a training experience. A list of significant behaviors is first derived from an analysis of the teaching process. The more specific this description, resulting from increasingly intensive analyses, the more specific the statement of behavioral objectives. When the behavioral objective has been stated, criterion measures are explicated to specify the kinds of tasks and information which the student will possess as evidence of mastering the objective. When a behavior can be easily analyzed, a behavioral objective and the relevant criterion measures are readily specified. The ten models indicate that most single teaching behaviors can be described in this manner. The example below represents the ten models' general approach to behavioral objectives.

**BEHAVIORAL OBJECTIVE:** KNOWLEDGE OF OBJECTIVE TEST CONSTRUCTION

**ACTION:** The student will prepare a single page example of an objective test in a convenient subject matter.
CONDITIONS: The student will be directed to design an appropriate format and to include at least three different types of objective items.

CRITERION MEASURE: An acceptable test example will:

(1) contain a title and specify the placement of the pupil's name and the date;

(2) specify clear and complete directions to the pupil;

(3) include at least three test-item examples such as true-false, completion, short answer, matching item lists, statements for correction, multiple choice, or problems;

(4) contain no misspelled words and no incorrect grammar.

As behaviors become complex, the statement of behavioral objectives and criterion measures becomes difficult. The analyses of behaviors presented in the ten models clearly indicate the difficulties encountered in trying to understand teaching processes. Some broad areas of teacher behavior can be analyzed, objectified, and described, so that criterion levels of acceptable performance can be stated. On the other hand, the models show that very little research evidence substantiates direct relationships between teacher training activities and role performance. Teaching remains an exceedingly
complex activity, and a clear explication of some of the parts should not be taken to imply an understanding of the whole. Nevertheless, the models reflect the present state-of-the-art—in itself a valuable service—while they suggest important frameworks for further research and development.

If the whole of teaching cannot presently be derived from this behavioral analysis of its parts, important directions are nevertheless established for a process of increased control. For instance, if it can be demonstrated that teachers trained in the use of many audio-visual devices and their effective classroom applications are better able to select appropriate individualized learning experiences (presumably because they are aware of more alternatives), then this evidence recommends significant behavioral objectives for the teacher education program. Again, while the coping skills for dealing with some problem children in the classroom are not fully understood, certain teacher reactions (cynicism, ridicule, severe punishment) have been accepted as counter-productive. In this case, behavioral objectives might specify the elimination of these reactions (and their concomitant attitude structure) from the teacher's repertoire of classroom behaviors. This continuing process of analysis and conscious understanding of teaching behaviors forms a basis for training a teacher who will respond creatively to the teaching situation.
V. Conclusion

As these elementary teacher education models make clear, there is no magic process involved in the use of systems analysis in education. What is required is a hard-headed confrontation with reality—the necessity for producing highly qualified teachers within a framework of scarce resources. Too frequently the use of models, systems analysis, and behavioral objectives seems unwarranted because the processes are too complex, the problems too great, or the money too short. In point of fact, however, if we cannot understand a system, including the system of teacher education and its relation to the whole of education, we are in no position to justify present practices or to recommend changes. Again, if we confine our understandings to parts of the system, rather than to the largest universe of concern, we shall lose the sense of the whole.

An important lesson from the recent legislation for education is becoming apparent: if one part of the system is changed, the whole system must be considered. It is simply not possible to equip a school with audio-visual aids and expect that teachers untrained in their use will adopt them because they are there. An exceptionally well-trained elementary teacher, the product of one of these ten models, will not be able to use her skill unless the system—her classroom and school—are prepared to cope with and encourage the use of her expertise. These models have pointed to important directions for planning—difficult ones, at best—but directions worth the attention of educators. Each reader of the models will find fault with some part of them, but that is to be expected. And each institution will find that they make excellent guides for planning and for understanding the implications of plans. They are not, however, prescriptions which can be adopted automatically. The challenge, nevertheless, seems clear.
APPENDIX: LIST OF PUBLICATIONS

National Center for Educational Research and Development
Elementary Teacher Education Project

Copies of various project reports are now available from the Government Printing Office (The Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402) and from EDRS (ERIC Document Reproduction Service, 4936 Fairmont Avenue, Bethesda, Maryland 20014). These reports are available at the following prices:
