James T. Lynn, Under Secretary
Harold C. Passer, Assistant Secretary for Economic Affairs

BUREAU OF THE CENSUS
George Hay Brown, Director
ACKNOWLEDGMENTS

This report was prepared by David C. Shaw and Dorothy M. Johnson of the International Demographic Statistics Center, Population Division, under the general direction of Samuel Baum, Assistant Chief, International Demographic Statistics, and Leo Solomon, Chief, Research and Analysis Branch.

The centerpiece of the Demographic Computer Library (DCL) is a computer program which generates a specified Regional Model Life Table (subroutine MLTX). Since all of the other parts of the DCL can be looked upon as appendages of MLTX, the authors are indebted especially to Dr. Ansley Coale and Dr. Paul Demeny, who developed the model life table methodology.

The authors wish to express their thanks to Dr. Richard Hornseth and Chris Jorgenson for programming MLTX, to Reginald Masano for valuable programming support, and to Mildred Goff, Naomi Donovan, and Dolores Adams for their typing and proofreading assistance.

This technical paper was prepared under a participating agency service agreement with the Office of Population, Agency for International Development, Dr. R.T. Ravenholt, Director, Thomas W. Merrick, Project Manager.

I. Introduction

This paper requires a firm grasp of both mathematical demography and FORTRAN programming for complete comprehension. Subsequent papers can aim at developing one or another of the seminal capabilities presented here or at minimizing the programming or demographic skill requirements for effective use. This paper aims at the establishment of a language with which complex demographic manipulations can be briefly expressed in a form intelligible both to demographic analysts and to computers.

The Demographic Computer Library (DCL) has been structured around three interrelated operations: Life table construction, stable population generation, and population projection. Life table construction is fundamental to the other two operations. A stable population cannot be generated without a life table nor can a population distribution be projected.

The subroutines of the DCL have been written as parts of a system. The output of one subroutine is available for immediate use by any of a number of other subroutines. Once a life table has been constructed, for example, several avenues are open to the programmer with a single CALL statement. He can print the life table (CALL LSR (NSEX)), generate a stable population (CALL SPP (R)), or load the survival ratios of the life table into the projection table (CALL LSR (NSEX)). Other examples of DCL flexibility will be given in part IV.

At present, the inclusion of computer programs with the documentation of a scientific publication is generally not tenable due to the length of the programs and the difficulty of reading unfamiliar programs. If a library came into general use, both of these obstacles would be overcome. A short main program could easily communicate a complex sequence of computations to those familiar with the library. The DCL is an early attempt at a small but fundamental system of computer programs to use the system more effectively and to communicate a complex sequence of computations to those familiar with the library. The DCL should be evaluated from this point of view.

The case studies in part IV illustrate the amount of computational work achieved in relation to the number of program instructions. Note that FORTRAN instructions other than the CALL statements to DCL subroutines can be combined as desired with these CALL statements. The system has "canned" program features but remains open for modification by the programmer. Although the fundamental operations of the DCL can be programmed with almost no knowledge of FORTRAN, the firmer the programer's grasp of FORTRAN the more varied will be the results obtainable with the DCL.

The nonprogramer who wishes to understand the DCL as a system of computer programs to use the system more effectively should obtain information about the following programming concepts:

1. Program
2. Main program
3. Subprogram
4. Subroutine
5. SUBROUTINE statement
6. CALL statement
7. RETURN statement
8. Calling program and called program
9. The communication of information between calling program and called program by means of either:
   A. The arguments of the CALL and SUBROUTINE statements
   B. The COMMON statement

If these concepts are understood, intelligent application of the DCL should be possible even for a demographer who lacks understanding of other fundamental programming concepts and is, therefore, unable to program. The program listings (part V) will remain intelligible only to the programmer.

The nonprogramer who wishes to understand the DCL as a demographic computer system to use the system more effectively should obtain information about the following demographic concepts and associated methodologies: Life table, stable population, quasi-stable population, and component population projection. The contribution of the DCL to demographic analysis consists of reducing the drudgery and delays required by the multitude of mathematical computations. The DCL cannot, however, claim to endow the nondemographer with the ability to produce high quality demographic analysis.

The DCL is presently operative on the following computers: Univac 1107, IBM 360/40, and GE 635 (time sharing). Copies of the DCL source programs (IBM 360 version) can be obtained on magnetic tape. For further information write to:

Attn: DCL

ii. Subroutine Linkage

There are two ways to communicate between a calling program (a main program or a subroutine) and a called program (always a subroutine). The first way is through a COMMON statement. Most of the subroutines of the DCL are linked together primarily by means of a standard COMMON statement which has the form COMMON A(21,9), B(21,8), C(51), where A represents the life table array, B represents the projection table array, and C represents the array containing the parameters of a stable population. These names need correspond only with the name used for the array in question in the program in which the COMMON statement appears. The order of the arrays, however, must be that indicated in the standard COMMON above. For example, one subroutine may contain one of the following standard COMMON statements and another subroutine the other statement without mishap:

COMMON A(21,9), B(21,8), C(51)
COMMON C(21,9), Z(21,8), A(51)

as long as the first array name in each COMMON statement corresponds to the array name for the life table array in the program in which the COMMON statement appears. One of the following COMMON statements appearing in one subroutine and the second COMMON statement in another subroutine would cause a communication breakdown:

COMMON A(21,9), B(21,8), C(51)
COMMON B(21,8), C(51), A(21,9)

The second way to communicate between a calling program and a called program is through the arguments of a CALL statement. Although a called program can be linked to a calling program both by a COMMON statement and by the arguments of a CALL statement, communication of the same information by both methods is not permitted. It is important to note that in the DCL, the standard life table, stable population, and projection arrays are always communicated by means of the COMMON statement and these arrays are, therefore, never communicated through the arguments of a CALL statement.
Examples of the information usually communicated through the arguments of a CALL statement in the DCL are the life expectancy at birth, the sex code, and the region code for the model life tables (CALL MLTX (EX, NSEX, NREG)), or the rate of increase to be used in generating a stable population (CALL SPP (R)).

When writing main programs that use the DCL, the programmer should include the standard COMMON statement and be sure that the arguments (if any) of the CALL statements of the main program correspond to those of the DCL SUBROUTINE statements. A description of each subroutine in the DCL including the required form of the CALL statement in the calling program is presented in part III. A firm comprehension of these descriptions is necessary for the effective use of the DCL. Part IV will illustrate some frequent DCL applications.

III. Subroutine Descriptions

This part is divided into three sections which correspond to the three principal DCL operations. Each of these sections begins with a description and discussion of the principal array for the corresponding operation.

Note that throughout the DCL, birth rates, fertility rates, death rates, rates of natural increase, and sex ratios are expressed not per 100 or 1,000 population but on a unit basis (per person). For example, a 1 percent rate of natural increase is expressed .010.

A. Life Table Related Subroutines

In order to achieve a mastery in the use of the DCL, the user should be aware of the contents of the arrays being manipulated, otherwise much of the flexibility of the system will be lost. Although many of the operations of the DCL take place without requiring the user to discriminate among the elements of the principal arrays, several additional important capabilities are also the command of the user who takes some care in noting these details.

The first array of the standard COMMON statement (with dimensions 21 by 9) represents the DCL life table array. Whether the life table is a model or an empirical one, not only the dimensions but also the column definitions (excluding column 9) of the table are identical. The column definitions of all life tables constructed by the DCL will always be as shown in diagram 1. All age groups except the first two and the last (N+) represent consecutive 5-year intervals. The final age group of the table is determined by the number of input qx values. The final age group represents an open ended interval with a maximum lower boundary of 95. That is, the open interval 95+ would fall in row 21, the last possible row of the table as dimensioned. The model life tables use 18 rows of the table with N equal to 80.

It is assumed that the user understands that certain of the life table columns are defined in relation to the lower boundary of the interval (1xT, eX) rather than in terms of the interval itself. This understood, the only exception to the row definitions as presented is column 6, the survival ratios. These represent 5-year groups throughout the column. The first ratio represents survival from birth, the second survival from the 0-4 interval, etc. Beginning with row 3, the denominators of the ratios correspond to the row definitions of the other columns. The last row of the life table has a survival ratio of zero.

Much further use can be made of life table columns Lx (for generating stable populations) and Px (for projecting population distributions).

1. Subroutine MLTX. An understanding of this complex subroutine is essential for all users. It is recommended that the beginner proceed to subroutine MLT after scanning this description.

</table>

MLTX computes a regional model life table1 for the level, sex, and region specified in the CALL statement. The required form of the CALL statement is:

CALL MLTX (ET, NSEX, NREG)

CALL statement arguments (all inputs):

ET. The life expectancy at birth of the life table constructed will rise and fall together with this independent variable. No fixed relationship has been found, however, between this control variable and the life expectancy at birth of the resulting life table. A life table of desired life expectancy at birth can be obtained by successive iterations. (See description of Subroutine MLT below.)

NSEX, NREG. There is a series of model life tables for each sex and each of four regions as described in the text cited. The codes for sex (NSEX) and region (NREG) are recognized throughout the DCL as follows: NSEX: 1 = female, 2 = male. NREG: 1 = West, 2 = North, 3 = East, 4 = South.

The output of MLTX (a model life table) is placed in the standard life table array of the standard COMMON statement (last age group is 80+, in row 18). In addition to the life table, MLTX places the value of the associated control variable, ET, in position 1, 9 of the standard life table array, and the control variable that will produce the life table of the opposite sex of the same region, according to the relationship of the model life tables, in position 2, 9 of the standard life table array. 2

The methodology for obtaining the Qx values of the model life tables is complex. No explanation is attempted here. The reader is referred to chapter 2 of the Coale-Demeny volume, and also to the MLTX program listing in part V of this paper.

From a given set of qx values, MLTX computes dx and lx values as follows:

\[ d_x = q_x + 1, \quad 0 = 100,000, \quad x = 0, 1, 5, 10, \ldots, 80 \]

\[ l_x = l_{x+1} - n d_x, \quad x = 0, 1, 5, 10, \ldots, 75 \]

1 See text for explanation of N+.
2 See part III, A1 for explanation of positions 3, 4, 5, 9. See part III, C1 for an explanation of positions 4, 9 and 50. Note that in the subroutines of the DCL, subscripts representing rows always precede subscripts representing columns in accordance with statistical convention.

2 See Coale-Demeny, op. cit., p. 23. See also below part IV, case 2.
The formulas for the remaining life table columns taken directly from the Coale-Demeny volume are as follows:

\[ L_0 = k_0 l_0 + (1 - k_0) l_1 \]
\[ 4_1 = k_1 l_1 + (4 - k_1) l_5 \]
\[ 5_l = 2.5(l_x + 1_x + 5_l), x = 5, 10, ..., 75 \]
\[ e_{80}^o = 3.725 + (0.0000625) (150) \]
\[ T_{80} = e_{80}^o / e_{80} \]
\[ L_{80} = T_{80} \]
\[ T_x = \sum L_x / T_{80} \]
\[ e_x^o = T_x / L_x \]

The values of \( k_0 \) were as follows, when \( 1q_0 > 0.100 \):

<table>
<thead>
<tr>
<th>Region</th>
<th>Females</th>
<th>Males</th>
</tr>
</thead>
<tbody>
<tr>
<td>West, North, South “Regions”</td>
<td>0.35</td>
<td>0.33</td>
</tr>
<tr>
<td>East “Region”</td>
<td>0.31</td>
<td>0.29</td>
</tr>
</tbody>
</table>

The values of \( k_0 \), \( 1q_0 < 0.100 \), were given by the following expressions:

For females:
- West, North, South
  - \( k_0 = 0.050 + 3.00 \times 1q_0 \)
- East
  - \( k_0 = 0.010 + 3.00 \times 1q_0 \)

For males:
- West, North, South
  - \( k_0 = 0.0025 + 2.875 \times 1q_0 \)
- East
  - \( k_0 = 0.0425 + 2.875 \times 1q_0 \)

The values of \( k_1 \) were as follows, when \( 1q_0 > 0.100 \):

<table>
<thead>
<tr>
<th>Region</th>
<th>West</th>
<th>North</th>
<th>East</th>
<th>South</th>
</tr>
</thead>
<tbody>
<tr>
<td>For females</td>
<td>1.361</td>
<td>1.570</td>
<td>1.324</td>
<td>1.239</td>
</tr>
<tr>
<td>For males</td>
<td>1.352</td>
<td>1.558</td>
<td>1.313</td>
<td>1.240</td>
</tr>
</tbody>
</table>

The values of \( k_1 \), \( 1q_0 < 0.100 \), were given by the following expressions:

For females:
- West
  - \( 1q_0 = 5.046 \times 10^{-1} \times \log(10) \times 1q_0 \)
- North
  - \( 1q_0 = 4.604 \times 10^{-1} \times \log(10) \times 1q_0 \)
- East
  - \( 1q_0 = 4.871 \times 10^{-1} \times \log(10) \times 1q_0 \)
- South
  - \( 1q_0 = 5.046 \times 10^{-1} \times \log(10) \times 1q_0 \)

Age-specific mortality rates \( m_x \) were calculated from the formula

\[ m_x = n_x / n_{-x} \]

Five-year survival rates for projecting 5-year age groups \((S_{5x})\) were calculated by the formula

\[ S_{5x} = S_{x+5} / S_{x}, x = 0, 5, ..., 70 \]

The first survival rate is the proportion surviving to the end of a 5-year time interval of persons born during the interval, estimated as \( S_{50} T_{75} \). The last survival rate is of persons over 75 at the beginning of an interval (and over 80 at the end), estimated as \( T_{80} T_{75} \).

The control variable for the opposite sex associated with the CALL statement argument ET is obtained by solving the following equation for ETM or ETF as required:

\[ ETM - EXM = (SM/SF) (ETF - EXF) \]

where ETM and ETF are the control variables for males and females respectively, one of which is given and the other is unknown. The value of the other factors for each region are presented below.

<table>
<thead>
<tr>
<th>Region</th>
<th>West</th>
<th>North</th>
<th>East</th>
<th>South</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXM</td>
<td>55.749</td>
<td>53.922</td>
<td>54.064</td>
<td>53.054</td>
</tr>
<tr>
<td>EXF</td>
<td>58.540</td>
<td>56.622</td>
<td>56.664</td>
<td>55.290</td>
</tr>
<tr>

</tr>
<tr>
<td>SF</td>
<td>5.046</td>
<td>6.112</td>
<td>5.683</td>
<td>5.601</td>
</tr>
</tbody>
</table>

For an explanation of the formula, consult page 23 of the Coale-Demeny volume. These factors which do not appear in the text were obtained directly from the authors.

Although the user will seldom make a call to MLTX directly (it is generally called indirectly through MLT), it is clearly the foundation of the entire system.

2. Subroutine MLT. MLT places in the standard life table array a model life table of the life expectancy at birth, the sex, and the model life table region indicated in the CALL statement. The required form of the CALL statement is:

\[ \text{CALL MLT (EX, NSEX, NREG)} \]

where EX indicates life expectancy at birth, NSEX is the sex code (1 = females, 2 = males), and NREG is the region code (1 = West, 2 = North, 3 = East, 4 = South).

MLT calls MLTX repeatedly until a model life table is obtained whose life expectancy at birth differs by not more than .001 of one year from the life expectancy indicated by the CALL statement. If greater precision is desired, subroutine MLT can easily be modified to achieve this. The number of iterations required to satisfy the specified level of precision is placed in position 3,9 of the standard life table array. For the .001 level of precision, the number of iterations is generally between 3 and 5.

3. Subroutine ELT. ELT constructs a life table using a series of \( q_x \) values entered in column 1 of the standard life table array prior to a call to ELT. The CALL statement must be of the form:

\[ \text{CALL ELT (NSEX)} \]

where NSEX is the sex code: 1 = females, 2 = males.

The life table is placed in the standard life table array. Apart from the exceptions noted below, the special problems in life table construction are resolved by ELT in the same manner as stated in the description of subroutine MLTX above. In computing \( 1L_0 \) and \( 4L_4 \), the \( K_0 \) and \( K_1 \) factors of the West region are always used. The following ELT formulas are somewhat different from those of MLTX:

\[ L_n = L_0 log_10 T_n \]
\[ T_x = \sum L_x \]
\[ e_n = T_n / L_n \]

where \( n \) is the lower boundary of the final, open-ended age group. The last \( Q_x \) value should be \( 1.0 \). If it is not, ELT will change the last nonzero cell in column 1 of the standard life table array to 1.0 before proceeding. The final age group of the life table is implicit in the length of the list of \( Q_x \) values entered.
4. Subroutine MXOX. MXOX converts a series of empirical \( M_x \) values to \( Q_x \) estimates by means of the Reed-Merrell method. The CALL statement must be of the form:

\[
\text{CALL MXOX (EMX, NSEX)}
\]

where EMX is an array containing the \( M_x \) values (unit basis) and NSEX is the sex code: 1 = females, 2 = males.

EMX must be dimensioned EMX (21) in the calling program regardless of the actual number of \( M_x \) values entered. The set of \( M_x \) values must represent in succession the standard 5-year life table age groups; i.e., 0-1, 1-4, 5-9, 10-14, etc. The Reed-Merrell method is not used for the first two \( Q_x \) estimates. The value entered in the first position of array EMX is assumed to represent total deaths below age one (male or female) divided by total births for the same 12-month period as the \( M_x \) values. This value is directly accepted as the \( Q_0 \) estimate without change. The estimate for \( Q_{10} \) is obtained by resolving the formula:

\[
4 Q_{10} = \frac{1}{1 + (4 - k_1)} M_4
\]

where \( k_1 \) is the same as West region \( k_1 \) as presented in the description of subroutine MLTX. The \( Q_x \) value for the position following the final \( M_x \) input is set to 1.0. For the remaining 5-year age groups, \( Q_x \) values are computed from the given \( M_x \) values by means of the following Reed-Merrell formula:

\[
5 Q_x = 1 - e^{5 M_x}
\]

where \( e \) is the base of the natural logarithms. The \( Q_x \) estimates (unit basis) are placed in column 1 of the standard life table array in order that a call to ELT can follow immediately if desired. See part IV, case 3.

---

B. Stable Population Related Subroutines

Once a life table (model or empirical) is present in the standard life table array, an age structure and many other parameters of a stable population can be easily generated simply by specifying a rate of natural increase. A call to the DCL stable population generating subroutine (SPP) results in a large selection of stable population parameters being placed in the standard stable population array. For a detailed list of the contents of the 51 positions of this array, see part III, B.2. The proportions in various age groups of a stable population are computed by means of the formula:

\[
C(x) = e^{lx} L_x / \sum e^{l X} L_x
\]

where \( C(x) \) is the proportion of total population in the age group whose midpoint is \( x \); \( e \) is the base of the natural logarithms; \( r \) is the rate of natural increase; \( L \) is the life years column of a life table for that age group whose midpoint is \( x \); and \( a \) is simply a variable expression for \( x \).

This formula and the formulas for the computation of other stable population parameters found in the standard stable population array are adequately explained in the demographic literature. A painstaking presentation is not attempted here.

</table>

1 This sample is the result of a CALL PLT(18) instruction following a CALL MLT(8,0,1,1) instruction.
1. Subroutine SPP. Using the \( L_k \) column of the life table present (by means of a previous call to MLTX, MLT, or ELT) in the standard life table array, SPP generates the selected list of stable population parameters (see part III, B2). The results are placed in the standard stable population array. The CALL statement must be of the form:

\[
\text{CALL SPP (R)}
\]

where \( R \) represents the rate of natural increase (unit basis).

2. Subroutine PSPP. PSPP prints the selected stable population parameters together with labels. The CALL statement must be of the form:

\[
\text{CALL PSPP}
\]

A sample of PSPP output is shown in table 2. The numbers to the left of the line indicate the address of the standard stable population array position containing the parameter. These numbers are not part of PSPP output but will be necessary if the programmer wishes to manipulate the contents of the array directly (that is, without using the DCL subroutines). See part IV, case 4.

C. Projection Related Subroutines

Projection, the third principal operation of the DCL, is more complex, has more related subroutines, and demands closer attention than the first two principal operations. The subroutines connected with the projection operation can most easily be described in relation to the standard projection table. Each of these subroutines either loads data into the projection table prior to projection or carries out the computations of the projection process (that is, manipulates the data within the projection table) or prints the contents of the projection table. Before describing the individual projection related subroutines, therefore, attention must be directed to the standard projection table and its position definitions which are presented in diagram 2.

Note that the formal inputs required for a projection are found in the five first columns of the projection table. These formal inputs are: population distributions (male and female), survival ratios (male and female), fertility rates, and sex ratio at birth. There can be no guarantee that the data selected to satisfy these formal input requirements for projection will constitute a set of reconciled parameters. The selection of the proper data to satisfy these formal input requirements requires a great deal of demographic understanding, which this paper does not attempt to provide.

As a general rule each row of the projection table represents information for a 5-year age group except the last which represents an open-ended interval. The survival ratios (columns 3 and 4) have the same row positions as they had in the life table (see part III, A). That is, they occupy the row corresponding to the age group of the survival ratio numerator. Thus, the survival ratios of the incoming birth cohort occupy the first row position. The sex ratio at birth (unit basis, males/females) is found in row 1, column 5. Fertility rates (unit basis) are found in rows 4 to 10, column 5.

Columns 6 and 7 contain the projected age distributions. Column 8 contains a selection of statistics summarizing the contents of the projecting table. These statistics as well as the projected age distributions are computed in connection with the projection process.

Before projection can take place, the required inputs listed above must be loaded into the first five columns of the standard population table. Six simple subroutines are available to assist the user in this loading operation. (All of these subroutines begin with the letter "L").

Definition of Symbols:

SRB: sex ratio at birth, unit basis
Total Births (Deaths): 5-year period.
Midyear Total: that is, middle of 5-year period. (one-half of the sum of columns 1, 2, 5, 7)
CBR: crude birth rate, midyear, unit basis. One-fifth of total births divided by total midyear population.
CDR: crude death rate, midyear, unit basis. One-fifth of total deaths divided by total midyear population.
RNI: rate of natural increase. (CBR - CDR)
---: blank

1. Subroutine LSP. LSP loads a stable population percent age distribution (5-year groups to 80+) into the first or second column of the projection table depending on the definition of the sex code. The stable population must be available in the standard stable population array (through a previous call to SPP). The CALL statement must be of the form:

CALL LSP (NSEX)

where NSEX represents the sex code (1 = female, 2 = male).

Before returning to the calling program, LSP places the birth rates into column 9 of the standard life table array. The birth rate is placed in row 4 if the sex is male; in row 5 if the sex is female. This feature makes possible the calculation of a weighted birth rate (see subroutine LMFPX) once the male and female population totals have been assigned (see subroutine PART). Case study number 8 (part IV) illustrates how this feature can be exploited.

2. Subroutine LSR. LSR loads the survival ratios present in the standard life table array into the third or fourth column of the projection table depending on the definition of the sex code. The CALL statement must be of the form:

CALL LSR (NSEX)

where NSEX is the sex code (1 = female, 2 = male).

3. Subroutine LPOP. LPOP loads a population distribution (5-year groups) present in a 21-word array (floating point) into column 1 or 2 depending on the definition of the sex code. The CALL statement must be of the form:

CALL LPOP (ARRAY, NSEX)

where ARRAY is the name of a previously dimensioned floating point array containing a male or female population distribution and NSEX is the sex code (1 = female, 2 = male).

4. Subroutine LPT. LPT is a meta-subroutine. It contributes nothing but a higher level organization of other subroutines. LPT obtains and loads not only male and female stable population percent age distributions into the first two columns of the projection table but also the sets of survival ratios (corresponding to the average life expectancy of the 5-year projection interval) into the third and fourth columns. The CALL statement must be of the form:

CALL LPT (EM, EF, R, NREGM, NREGF, STEP)

CALL statement arguments (all are inputs):

EM, EF. Life expectancies at birth at the starting point of the projection for males and females, respectively. The values of EM and EF are returned to the calling program with an increment of STEP multiplied by 2.5.

R. Rate of natural increase for both sexes at the starting point of the projection. R is expressed of unit basis (1% = .010).

NREGM, NREGF. Model life table regions for males and females, respectively.

STEP. Average annual increment to life expectancy for the 5-year interval.

Note that the floating point variables EM, EF, R, and STEP when entered as constants must have a decimal point. A glance at the listing of LPT in part V should remove any confusion about what LPT does and how. LPT will be useful in the preparation of quasi-stable projections. To convert percent distributions in columns 1 and 2 to absolute distributions, see part III, C7. Note that LPT calls LSP and, therefore, male and female birth rates are placed in rows 4 and 5 of column 9 (life table array) respectively.

5. Subroutine LMFP. LMFP loads fertility schedules based on any one of eight model fertility patterns into rows 4 to 10 of column 5 of the standard projection table. These fertility patterns are taken from U.N. Population Bulletin No. 7.6 The reader is referred to this source for a complete explanation of the model fertility patterns. The fertility patterns are expressed as percentages summing to 100 across the 5-year age groups between 15 and 48. By converting the percentages to proportions and multiplying each by a predetermined total fertility rate (divided by five) a fertility schedule is obtained. The CALL statement must be of the form:

CALL LMFP (N, TFR)

where TFR is the desired total fertility rate (TFR must have a decimal point if entered as a constant) and N is a code (1 to 8) indicating one of the eight model fertility patterns. The codes are as follows:

Low fertility patterns

Early peak........... 1
Broad peak........... 2
Late peak........... 3

High fertility patterns

Early peak

(type A)........... 4
(type B)........... 5

Late peak

(type A)........... 6
(type B)........... 7

6. Subroutine LMFPX. Subroutine LMFPX is similar to subroutine LMPF. LMFPX uses LMPF to load a model fertility schedule into rows 4 through 10 of column 5 of the projection table. The fertility schedule loaded will be reconciled with a specified crude birth rate representing the midpoint of the 5-year projection cycle. All of the other projection table inputs required for projection must be present in the projection table before LMFPX is called. The required form of the CALL statement is:

`CALL LMFPX (N, CBR)`

where N is a model fertility pattern code (see part II, C5), and CBR is a crude birth rate (unit basis). CBR must have a decimal point if entered as a constant. Note the utility of entering a weighted average of male and female stable population birth rates as CBR in a call to LMFPX. This will establish a fertility schedule reconciled with these stable populations. See part III, C1 and part IV, case 6, line 12.

7. Subroutine CPT. When percent distributions are present in columns one and two of the standard projection table, they can be converted to numerical distributions with a call to CPT. The CALL statement must be of the form:

`CALL CPT (TM, TF)`

where TM is the total population for males and TF is the total for females. If entered as constants, TM and TF must have decimal points. An overall sex ratio of TM/TF is, of course, implied. The resulting age distributions in absolute form associated with sets of survival ratios in turn imply a sex ratio at birth which may not be tenable if CPT is used carelessly. Subroutines PART and SR have been designed to assist the user with these problems.

8. Subroutine PART. PART partitions a given population total into a male and a female component in accord with a given sex ratio. The required form of the CALL statement is:

`CALL PART (OSR, T, TM, TF)`

where the call statement arguments are as follows:

- **OSR**: Overall sex ratio, unit basis (input)
- **T**: Population total (input)
- **TM**: Total male population (output)
- **TF**: Total female population (output)

9. Subroutine SR. SR can be used only if the projection table is loaded as follows:

- **Columns 1 and 2**: Age distributions, percent form.
- **Columns 3 and 4**: Survival ratios corresponding to the same point in time as the age distribution in columns 1 and 2.

If these conditions are met and the sex ratio at birth is known, SR will calculate the overall sex ratio (which can be used when calling PART). The required form of the CALL statement is:

`CALL SR (SRB, OSR)`

where SRB is the sex ratio at birth, unit basis (input) and OSR is the overall sex ratio, unit basis (output).

For stable populations, subroutine LVT (with STEP set to zero) can be used to load the first four columns of the projection table prior to calling SR. For an example of the use of CPT, PART, and SR, see part IV, case 6.

10. Subroutine PROJ. Once the required inputs have been loaded into the standard projection table, a call to PROJ will project the population distributions present in columns 1 and 2 for 5 years. The results will be placed in the appropriate row positions of columns 6 and 7 respectively. PROJ then applies the annual fertility rates for each 5-year age group between 15 and 49 (present in columns 1 and 2 of the projection table) to the average number of women in each age group during the 5-year interval. The cumulated results (which represent an average annual cohort of births for the 5-year period) are multiplied by five, partitioned with the sex ratio at birth (present in row 1, column 5), and survived. If no sex ratio at birth is specified, a ratio of 1.05 will be used. The survivors of the 5-year male and female birth cohort are placed in row 1 of columns 6 and 7 respectively. PROJ also places a selection of summary statistics of the 5-year projection interval in column 8. See diagram 2 for the positions and descriptions of these statistics. The CALL statement must be of the form:

`CALL PROJ`

IV. Case Studies

CASE 1. Construct and print a model, west, male life table with a life expectancy at birth of 50.0 years.

Line Instruction
1 CALL MLT(50.0,2,1)
2 CALL PLT(18)
3 STOP
4 END

Line Comments
1 Places the specified life table in the standard life table array.
2 Prints 18 rows of the standard life table array. Column 9 is not printed.
3 The standard COMMON statement is not required in the main program because no manipulations of the standard arrays are carried out within the main program.

DCL subroutines which must be included: MLT, MLTX, PLT.
Output: one life table.

CASE 2. Construct and print a model, south, male life table corresponding to the female, model, south life table with life expectancy at birth of 50.0 years.

Line Instruction
1 COMMON D(21,9), TM:1(21,8), E(51)
2 CALL MLT(150.0,1,4,1)
3 CALL MLTX(D(21),9,24)
4 CALL PLT(18)
5 STOP
6 END

Line Comments
1 Standard COMMON statement must be present whenever the main program makes direct use of any of the standard arrays. Note the call to MLTX, line 3.
2 Places male life table in the standard life table array.
3 Eighteen rows (excluding column 9) of the current contents of the standard life table array (in this case, the male life table) are printed.

DCL subroutines which must be included: MLT, MLTX, PLT.
Output: one life table.

CASE 3. Print a male life table constructed from a given set of Mx values using the Reed-Merrell method for Mx to Qx conversion.

Line Instruction
1 DIMENSION EMX(21)
2 DATA EMX/.18933,.02838,.00381,.00372,.00693,.00903,.00928,.00964,.01037,.01154,.01275,.01609,.02255,.02949,.04712,.06388,.5*0.0/
3 CALL MXOX(EMX),
4 CALL ELT(2)
5 CALL PLT(17)
6 STOP
7 END

Line Comments
1 It is necessary that the array containing the Mx values be dimensioned 21 regardless of the actual number of Mx values in the set concerned.
2 A set of Mx values are entered into array EMX with this DATA statement.
3 This call converts the Mx values to Qx values. The Qx values are placed in column 1 of the life table array.
4 With Qx values already in place, this call to ELT will complete the life table.
5 Sixteen Mx values were entered and subroutine MXOX adds another Qx value (set to 1.0).

DCL subroutines which must be included: MXOX, ELT, PLT.
Output: one life table.
CASE 4. Generate a stable population with a model, east, male life table with a life expectancy at birth of 37.2 years and a rate of natural increase of .020. Print the stable population parameters with labels.

Line Instruction
1 CALL MLT(37.2,2,3)
2 CALL SPP(.020)
3 CALL PSPP
4 STOP
5 END

Line Comments
1-3 See subroutine descriptions for details.

DCL subroutines which must be included: MLT, MLTX, SPP, PSPP.
Output: a selection of stable population parameters. See description of subroutine PSPP.
Output can be checked with Coale-Demeny volume 9, p. 574.

CASE 5. Project male and female stable population structures (life expectancies at birth: male = 50.0, female = 52.0; region is south and rate of natural increase = .010 for both sexes) 25 years into the future using constant mortality and fertility (model fertility pattern 6, total fertility rate = 6.4). Sex ratio at birth is 1.05 and constant. No migration. Print percent age distributions for the starting points of each 5-year projection cycle.

Line Instruction
1 COMMON A(21,9),B(21,8),C(51)
2 CALL LPT(50.0,52.0,.010,4,4,0.)
3 CALL LMFP(6,6.4)
4 DO 1311,51=1.05
5 DO 21=1,5
6 CALL PROJ
7 CALL PP
8 2 CALL T67
9 STOP
10 END

Line Comments
2 This CALL causes the first four columns of the standard projection array (in this case, array B) to be loaded.
3-4 These CALLs cause column 5 of the standard projection array to be loaded. (Note that the use of the total fertility rate does not guarantee a birth rate reconciled with the birth rates of the stable populations. See case 6.)
6 This CALL: (1) projects columns 1 and 2 for 5 years, (2) computes, partitions, and survives a 5-year birth cohort, and (3) calculates the selected statistics of column 8. The results are placed in the positions of the standard projection array indicated in diagram 2.
8 After each 5-year projection cycle, the new population distributions (columns 6 and 7) are placed in the source population columns (1 and 2) in preparation for the next projection cycle.

DCL subroutines which must be included: LPT, MLTX, SPP, PSPP, LMFP, PROJ, T67.
Output: five sets of percent age distributions. See sample output for subroutine PP above.

CASE 6. Project male and female model stable populations (e_m = 50.0, e_f = 52.0, South region for both sexes, rate of natural increase = .010 25 years into the future using constant fertility (model fertility pattern 6). Reconcile birth rate with those of the stable populations. Mortality is declining at the rate of .75 years increment to life expectancy per year. Initial total population is 15,000. Sex ratio at birth is 1.05 and constant. No migration. Print the age distributions (totals and percent) for the starting points of each 5-year projection cycle.

Line Instruction
1 COMMON A(21,9),B(21,8),C(51)
2 EM=50.0
3 EF=52.0
4 STEP=.75
5 B(1,5)=1.05
6 CALL LPT(EM,EF,.010,4,4,0.)
7 CALL SR(B(1,5),OSR)
8 CALL PART(OSR,TM,TF)
9 CALL LPT(EM,EF,.010,4,4,STEP)
10 CALL CPT(TM,TF)
11 CALL LMFPX(6,C811)
12 DO 21=1,5
13 CALL PROJ
14 CALL T67
15 STOP
16 END

Line Comments
8 With the first four columns of the projection array loaded, SR calculates the overall sex ratio implied by the sex ratio at birth.
9 PART partitions the given population total by means of the overall sex ratio obtained from SR.
10 LPT must be called again here to load the survival ratios appropriate for projection.
12 A weighted average of the stable population birth rates is obtained here to be used as input to the following instruction. (See part III C1 and C6.)
17-22 Male and female life expectancies at birth are incremented, new life tables generated, and the new survival ratios loaded into columns 3 and 4 of the standard projection array prior to a call to T67 and the next call to PROJ.

DCL subroutines which must be included: LPT, MLTX, SPP, LSR, WSPP, LMFP, PROJ, T67, LMFPX, T67, SR, PART.
Output: five tables. See sample output of T67 for format.

VI. Miscellaneous Information

A. Subroutine Name Mnemonics

- **CPT**: convert percents to totals
- **ELT**: empirical life table
- **LPT**: load projection table
- **LMFP**: load model fertility pattern
- **LMFPX**: load model fertility pattern
- **LPOP**: load population
- **LSP**: load stable population
- **LSR**: load survival ratios
- **MLT**: model life table
- **MLTX**: model life table
- **MXQX**: converts $M_x$ values to $Q_x$ values
- **PART**: partition total population into male and female totals
- **PLT**: print life table
- **PROJ**: project
- **PP**: print percents
- **PSPP**: print stable population parameters
- **PT**: print totals
- **PTAB**: print (projection) table
- **PTP**: print totals and percents
- **SPP**: stable population parameters
- **SR**: sex ratio
- **T67**: transfer columns 6 and 7

B. Summary of the Required Form of DCL

CALL Statements

- **CALL CPT (TM,TF)**
- **CALL ELT (NSEX)**
- **CALL LPT (EM,EF,R,NREGM,NREGF,STEP)**
- **CALL LMFP (N,TFR)**
- **CALL LMFPX (N,CBR)**
- **CALL LPOP (ARRAY,NSEX)**
- **CALL LSP (NSEX)**
- **CALL LSR (NSEX)**
- **CALL MLT (EX,NSF.X,NREG)**
- **CALL MLTX (ET,NSEX,NREG)**
- **CALL MXQX (EMX,NSEX)**
- **CALL PART (OSR,T,TM,TF)**
- **CALL PLT (NROW)**
- **CALL PROJ**
- **CALL PSPP**
- **CALL PT**
- **CALL PTAB (NROW)**
- **CALL PTP**
- **CALL SPP (R)**
- **CALL SR (SRB,OSR)**
- **CALL T67**

Definition of symbolic names used as arguments:

- **ARRAY**: the name of the 21 word array containing the population distribution of the sex indicated by NSEX
- **CBR**: crude birth rate, unit basis
- **EF**: female life expectancy at birth
- **EM**: male life expectancy at birth
- **EMX**: the name of the 21 word array containing the set of $M_x$ values
- **ET**: control variable (see description of MLTX.)
- **EX**: life expectancy at birth
- **N**: model fertility pattern code (see description of subroutine LMFP)
- **NREG**: model life table region code (1 = West, 2 = North, 3 = East, 4 = South)
- **NREGF**: NREG for females
- **NREGM**: NREG for males
- **NRROW**: number of rows to be printed
- **NSEX**: sex code (1 = females, 2 = males)
- **OSR**: overall sex ratio, unit basis
- **R**: rate of natural increase, unit basis
- **SRB**: sex ratio at birth, unit basis
- **STEP**: average annual increment to life expectancy at birth for the 5-year projection interval
- **T**: total population, both sexes
- **TF**: total female population
- **TFR**: total fertility rate
- **TM**: total male population

C. Schema of DCL Relationships

Diagram 3 presents a schema that reveals at a glance the network of DCL relationships. The symbols on the margin of the diagram represent data inputs, the boxes represent the three principal arrays, and the circles represent DCL subroutines. Wherever it could be done easily, the locations of subroutine inputs and outputs are indicated by directed lines. Output external to the computer is indicated by the three curved boxes.

The 1970 Census Users' Guide is a two-part publication designed to furnish most of the information data users will need for effective access and use of 1970 census data products.

Part 1 of the Guide (standard, paper-bound publication) includes the text and three appendices. The text covers such subjects as the collection and processing of 1970 data, data delivery media (computer tapes, microfilm, and printed materials), maps and information on how to obtain census materials. The appendices are:

- 1970 Census Users' Dictionary - defines concepts associated with population and housing tabulations and geographic areas relevant to the collection and publication of data.
- Comparison of Printed Reports and Summary Tapes summarizes and compares the contents of the reports and tapes.
- Glossary - defines many terms used in connection with collecting, processing, and publishing census data, and lists many abbreviations relevant to the census.

Part 2 of the Guide (prepunched for 3-ring binder) contains appendixes specifically related to the use of census summary tapes and the Address Coding Guide.

- Technical Conventions and Character Set - present information on the physical characteristics, format, and languages associated with tapes released by the Bureau.
- 1st-4th Count Technical Documentation - describes the arrangement of geographic codes and census data on the first four series of summary tapes.
- Address Coding Guide Technical Documentation - furnishes information on the format and content of ACG's.

Many data users will find both Parts 1 and 2 of great value. Part 1, with its comprehensive coverage of the decennial census program, data products, and related services, is an important instructional and reference tool. Part 2, concerned exclusively with computer tape products, is designed particularly for those who plan to obtain tapes or who want complete information on the data content of the summary tapes.
