A Search For Prose Features That Influence the Perception of Topical Organization

This study sought to develop a method for describing readers' perceptions of the topical organization of prose and to specify text features that determine perception of organization. A hierarchical clustering analysis was applied to high-school and college readers' judgments of the topical relatedness of sentences in two prose passages. This produced semantically similar clusters of sentences that were reliable indicators of topical organization. In searching for text features related to topicality, it was found that the perception of topicality was weakly related to the lexical similarity of sentences and that both the spatial relationship between sentences and typographical conventions influenced the perception of topicality. (Author/AA)
A Search For Prose Features That Influence the Perception of Topical Organization

Esther U. Coke and Mary E. Koether
Bell Laboratories

The writer of a reasonably long piece of expository prose usually discusses a number of topics in presenting the general subject of the passage. Part of the reader's understanding of what the writer is trying to say involves perceiving these topics. At present, little is known about the stimulus attributes of texts that readers use in detecting the topics presented by the writer. The purposes of the present study were (a) to develop a method for describing the topical organization perceived by readers and (b) to look for text features that determine the reader's perception of topical organization.

Method of Describing Topical Organization

The method for describing topical organization is based on readers' judgments of the topical relatedness of sentences, rather than on a content analysis of the meaning of sentences. Readers mapped topics onto text sentences by identifying sentences that were topically similar. Then an hierarchical clustering analysis of the matrix of reader responses was used to determine clusters of topically identical sentences. The details of the method are as follows.

1. Mapping of Topics onto Sentences.

A. Reading. A reader was given a passage and told to read
the passage carefully. The reader was told that he would be asked to summarize the topics discussed in the passage after he had finished reading it.

B. Topic generation. After reading the passage once, the reader was told to review the passage and write down from five to nine topics. A topic was defined for the reader as a general description of something the writer discussed. The reader was also given an example of a topic. To encourage the reader to describe topics clearly, he was told that another person would try to locate the topics in the passage. The reader wrote down his topics on separate 3x5 cards which were collected by the experimenter. The reader could consult the passage while generating topics.

C. Topic identification. The reader identified the sentences that discussed each of the topics he generated. The reader was given his own topic cards, one at a time, along with the passage and was told to underline all the sentences that had to do with that topic. The reader's topic cards were given to him in a haphazard order obtained by shuffling the cards. Each time the reader was given a card he was also given a fresh copy of the passage. This allowed the reader to assign a sentence to more than one topic.

2. Data analysis.

The readers' responses were entered into a matrix representing all possible sentence pairs in a passage. A cell
entry in this response matrix is the number of readers who underlined both sentences of a pair to indicate that they belonged to the same topic. The following two measures of topical similarity were then derived from this response matrix:

(1) Frequency measure of similarity. This measure is the number of readers who indicated that two sentences were topically related. This measure of similarity is simply the cell entry in the response matrix for a sentence pair.

(2) Probability measure of similarity. This measure is the cell entry in the response matrix weighted by the number of readers who assigned the two sentences to topics. This measure is the geometric mean (GM) of two contingent probabilities:

\[ GM = P(\frac{[n,m]}{m}) \times P(\frac{[n,m]}{n}) \]

where

- \( P(\frac{[n,m]}{m}) \) is the probability that sentences \( n \) and \( m \) are assigned to the same topic given that sentence \( m \) is assigned to a topic;
- \( P(\frac{[n,m]}{n}) \) is the probability that \( n \) and \( m \) are assigned to the same topic given that sentence \( n \) is assigned to a topic;
- \( [n,m] \) is the number of readers assigning \( n \) and \( m \) to the same topic;
- \( n \) is the number of readers assigning sentence \( n \) to topics;
- \( m \) is the number of readers assigning sentence \( m \) to topics.

The two similarity matrices derived from a response matrix
differ from each other in that the level of similarity between two sentences for the frequency measure is partly determined by the number of subjects who assigned the sentences to topics. This is not the case for the probability measure.

3. Hierarchical Clustering Analysis.

An hierarchical clustering analysis was used to determine the topical organization of a passage. This analysis finds the sentences that are closest together at each level of topical similarity in a similarity matrix. The analysis results in a tree structure. At the top of the tree are clusters of sentences that are highly similar to each other. Clusters at lower levels of the tree represent decreasing levels of similarity between sentences. The tree structure is hierarchical. Sentences that form a cluster towards the top of the tree are all members of the same cluster at lower levels of the tree. Also, a sentence cannot be a member of more than one cluster.

Often data that are being analyzed are not truly hierarchically organized. Johnson (1967) has developed algorithms for retrieving underlying hierarchical structures. Johnson's maximum method was chosen for the present analysis of topical organization. The maximum method is an iterative procedure for joining clusters together until only one cluster remains. This method only forms a new cluster when all the similarities between cluster sentences are at or above a minimum value.
This minimum value defines a cluster level of a tree. All clusters forming at a cluster level have the same minimum similarity value.

Any similarity matrix can be analyzed with the maximum method. Therefore, a scheme is needed for evaluating the goodness-of-fit of the tree structure to the data being analyzed. Halff (1975) has suggested a graphical evaluation technique. Halff proposed that an index of goodness-of-fit be calculated for each cluster level of a tree. This index is the proportion of unclustered sentence pairings that should have been clustered at a given cluster level. This index would be zero at all cluster levels if the data were truly hierarchically structured. Therefore, goodness-of-fit can be evaluated by looking at the deviation of the index from zero at each cluster level. Halff also proposed that a value of the index can be calculated that represents the worst fit for each cluster level. This is the expected value of the index if sentences were clustered together at random.

Halff's evaluation procedure was used in the present study to decide how well the readers' perceptions of topical relatedness were described by the hierarchical clustering analysis. Using this procedure, it was also possible to decide which of the two measures of similarity produced the better tree structure for a passage.
Application of the Clustering Technique

The clustering technique was used to determine the topical organization of two prose passages. Two tree structures were derived for each passage. One was based on the frequency measure of similarity and the other, on the probability measure of similarity.

Method

Material. Two passages were taken from a publication containing technical articles of general interest. One passage (GOP) discussed gopher damage to telephone cables; the other passage (NOD) discussed pay telephone service. Each passage was approximately 2000 words long. There were 97 sentences in GOP divided into 24 paragraphs; there were 99 sentences in NOD also divided into 24 paragraphs. Both passages were fairly difficult (Flesch Reading Ease Score was 50.7 and 50.8 for GOP and NOD, respectively).

Subjects. Judgments of topical relatedness were made by two groups of readers.

(1) Twenty-eight paid, volunteer high school students. Each student only saw one of the passages.

(2) Thirty-two paid, volunteer college undergraduates. These readers also served in Experiment 1, to be reported. They read the published version of one passage and an altered version of the other passage. Only judgments for the published
versions of a passage were used. Sixteen students generated topics for GOP and 16 generated topics for NOD.

Results

The response matrices produced by the two groups of readers were compared with each other. The Pearson product-moment correlation between the matrices indicates that the two groups of readers were in general agreement about the topical relatedness of the sentences (r = .82 and .93 for GOP and NOD, respectively). This result suggests that the method for describing topical relatedness yields reliable results.

The response matrices of the two groups were combined into a single matrix for each passage. These combined matrices were used to derive the frequency and probability measures of inter-sentence similarity. Each similarity matrix was then subject to an hierarchical clustering analysis.

The tree structures representing the topical organization of a passage are shown in Fig. 1-4. Figures 1 and 3 are the tree structures for GOP and NOD derived from the probability measures of similarity. Figures 2 and 4 are the tree structures for GOP and NOD derived from the frequency measure of similarity. The cluster levels and their similarity values are shown in the left-hand column of each figure. Sentence numbers are listed along the top of the figure. The formation of a new
sentence cluster from an old cluster is indicated by a horizontal dashed line connecting the new sentences entering a cluster with the vertical line coming down from the old cluster.

In order to demonstrate how these tree structures relate to the content of a passage, Tables 1 and 2 give verbal descriptions of the content of the clusters for GOP and NOD, respectively.

Insert Tables 1 and 2 about here.

A brief summary of each sentence in a passage is shown. The sentences are organized as they are in the tree structures derived from the probability measures (Fig. 1 and 3). Sentence numbers are shown in the left margin of the page. The lines connecting sentences correspond to clusterings at different levels of the tree. The letter labels correspond to the letters labeling each major branch of the trees in Fig. 1 and 3. The sentence numbers and brackets in the right margins of the two tables represent the tree structures derived from the frequency measures of similarity (Fig. 2 and 4). This information was included in the tables to help in comparing the two tree structures for a single passage.

The two different measures of similarity produced slightly different tree structures for each passage. Clusters differed primarily in the clustering levels at which specific sentences joined clusters, rather than in which sentences formed clusters. This is illustrated by the letter labels on the figures. Each major branch of the probability-measure trees for GOP and NOD has been assigned a letter. These letters were
then used to label corresponding parts of the frequency-measure trees. For GOP, four of the five major branches in Fig. 1 correspond to major branches in Fig. 2. One major branch (E) in Fig. 1 split into two branches in Fig. 2. For NOD, four of the six major branches in Fig. 3 correspond to major branches in Fig. 4. Parts of two branches (C and D) in Fig. 3 form a single branch in Fig. 4.

Evaluation of Goodness-of-fit. Halff's goodness-of-fit indices were calculated for all trees and used to determine which measure of similarity produced the better tree structure for a passage. The indices and the estimates of the worst fit are plotted in Fig. 5-8. These plots correspond to the

Insert Fig. 5-8 about here.

tree structures in Fig. 1-4. Halff's index remains reasonably near zero for all tree structures except at low levels of similarity. This finding suggests that the topical organization retrieved by the clustering technique describes the similarity data reasonably well.

Specific comparisons between similarity measures for both passages indicate that the tree structure derived from a probability measure matrix provides a better description of the readers' perception of the topical organization of a passage than the tree structure derived from a frequency measure matrix.
For both GOP and NOD, the deviations of the goodness-of-fit indices from zero appear to be less for the probability measure data (Fig. 5 and 7) than for the frequency measure data (Fig. 6 and 8).

Discussion

The hierarchical clustering analysis generated clusters of semantically related sentences. These clusters appeared to be related to the subjects discussed in the passages. In addition, the clustering analysis produced tree structures that described the similarity data for sentences reasonably well. These findings indicate that the clustering method is a valid method for describing the readers' perception of topical organization. Thus, clusters of topically similar sentences can be retrieved without evaluating the verbal labels that readers use to describe topics.

Exploration of Text Features that Determine Topical Organization

Experiment 1

The topical organizations for GOP and NOD (Fig. 1 and 3) were compared with clusters of sentences that had been formed from sentences that shared content words. This comparison was part of an effort to find text features that would predict topical organization. The co-occurrence of content words in sentences was analyzed because it was thought that writers might tend to use the same words when discussing a topic. If so, sentences
that were similar in their use of content words should be topically related.

The comparison revealed little relationship between clusters based on topical similarity and clusters based on lexical similarity. One reason for this lack of correspondence was that topically similar sentences tended to be near each other in the text while lexically similar sentences could be located anywhere in the text. It was hypothesized that spatial proximity might have an influence on the reader's perception of topical relatedness. In that case, lexically similar sentences would be perceived as topically similar if these sentences were near each other. To test this hypothesis, the GOP and NOD passages were rewritten. A few lexically similar sentences that were far apart in the original texts were moved so that they were adjacent to each other in the rewritten texts. Each pair was chosen so that the sentences of a pair were lexically highly similar and topically very dissimilar. It was predicted that the sentences would become topically similar in the rewritten passages.

Method

Material. Both the original and rewritten versions of the GOP and NOD texts were used. The texts were rewritten so that nine sentences were moved in each passage. A moved sentence was placed next to the sentence with which it was lexically similar, but topically dissimilar. Topical dissimilarity
was insured by picking sentence pairs that came together in a
cluster at low levels of the tree representing the topical
organization of a passage. Lexical similarity was insured by
picking sentences that clustered together at high levels of the
tree representing the lexical organization of a passage. The
lexical organization of a passage was determined from a measure
of lexical similarity. This measure was based on both the
number of content words shared by two sentences and the number
of content words in the two sentences that co-occurred in other
sentences. The index of commonality (Deese, 1965) was used to
determine the degree of lexical similarity.

When a sentence was moved, all anaphoral words were
replaced with their referents. In addition, the tense of the
moved sentence's verb was changed if it conflicted with the verbs
in the sentences adjacent to the moved sentence.

Procedure. The versions of a passage seen by a reader
during the topic generation and topic identification phases of
the mapping procedure were varied. Some readers saw the same
version of the text in both phases (00 - original version of
text during both phases; RR - rewritten version during both
phases). Other readers saw one version of the text while
generating topics and the other version while identifying topic
sentences (OR - original version during generation and rewritten
version during identification; RO - rewritten version during
generation and original version during identification).

The design for the experiment is shown in Table 3.

---

Insert Table 3 about here.

---
Each reader mapped topics onto sentences for both passages. After mapping topics for one passage, the reader was given a short rest before mapping the topics for the other passage.

Subjects. Sixty-four paid, volunteer college undergraduates were assigned at random to one of the conditions shown in Table 3.

Results

The mean similarity measures for the nine lexically similar sentences are shown in Table 4. To determine whether

 Insert Table 4 about here.

these sentences became topically similar when the sentences were adjacent to each other, the means for conditions OR, RR and RO were compared with the means for condition OO. A t-test for correlated means was used.

The lexically similar sentences became topically similar when moved next to each other during the topic identification phase of the mapping procedure. For both passages, topical similarity was significantly greater when the sentences were adjacent (t = 8.91 and 9.76, df = 8, p < .05 for the OR and RR conditions of GOP; t = 5.82 and 5.84, df = 8, p < .05 for the OR and RR conditions of NOD).

The topical similarity between pairs did not increase when readers saw the rewritten texts only during topic generation (condition RO). For GOP, sentences actually became less topically similar (t = 2.96, df = 8, p < .05) while for
NOD, there was virtually no change in topical similarity ($t<1$).

Discussion

The finding that use of the rewritten text during topic generation had little effect on topical similarity is not surprising. During the generation phase of the mapping procedure, readers were only concerned with summarizing the subjects discussed by the writer. Apparently, the displacement of a very few sentences (less than 10%) did not disrupt the reader's ability to understand what the writer discussed.

It was during topic identification that sentence proximity had its effect on topical similarity. During this phase of the mapping procedure, readers have to make judgments about each sentence. In keeping with the findings of Dooling and Lachman (1971) among others, the results of this study show that the topical context of a sentence played an important role in the reader's interpretation of the sentence's meaning.

Experiment 2

While spatial proximity and the perception of topical relatedness are strongly related, this is not invariably the case. Detailed examination of the tree structures for both passages indicated that the first sentence of a new paragraph and the last sentence of the previous paragraph were often in different clusters. This was especially so for clusters with high levels of similarity. These sentences at paragraph boundaries seemed to be perceived as topically less similar.
to each other than sentences within a paragraph.

This observation suggested that the perception of topical organization was influenced by the typographical convention of dividing a passage into paragraphs. This experiment evaluated the influence of paragraph structure on topical organization by comparing passages with and without paragraph indentation. Readers appear to use paragraph indentation as one cue that a new topic has begun. It was hypothesized that sentences at paragraph boundaries (i.e., the first sentence of a paragraph and the last sentence of the previous paragraph) would be perceived as more topically similar when the indentation cue to topic change was removed.

Method

Material. The original, indented GOP and NOD passages and versions of these passages without paragraph indentation were used. Each original passage was divided into 24 paragraphs. Thus, 24 of the 97 sentences in GOP were indented in the original version, and 24 of the 99 sentences in NOD were indented in the original version.

Procedure. Readers mapped topics to sentences for both the GOP and NOD texts. Half of the readers saw the GOP text first while half saw the NOD text first. After mapping topics for one passage, the reader was given a short rest before mapping the topics for the other passage.

Readers used the indented versions of the texts during the topic generation phase of the mapping procedure. The unindented
version was used during the topic identification phase. This was done because we wanted readers to generate topics under optimal conditions for perceiving topic boundaries. In this way we could better assess the effect of removing a cue to these boundaries on the perception of topical relatedness. Also, the topical similarity data from the first study reported in this paper were used to evaluate changes in similarity due to the removal of indentation. Therefore, it was desirable for readers in this experiment to generate topics under the same conditions as readers in the first study.

Subjects. Eighteen paid, volunteer high school students participated in the experiment.

Results

The response matrix produced by the readers in the present experiment was compared with the response matrix for the 30 readers in the first study. The Pearson product-moment correlations indicated that there was general agreement between the two groups of readers ($r = .90$ and $.80$ for GOP and NOD, respectively). Also, the tree structures resulting from a clustering analysis of the probability measure matrices for this experiment closely resembled the tree structures for the first study shown in Fig. 1 and 3.

The finding of little difference between the topical organization perceived by the two groups could be expected. Readers in both groups generated topics under identical conditions, and removal of indentation during topic identification only
affected 24 sentences. The general agreement of the groups confirms the conclusion that the present technique for studying topical organization produced reliable results.

The effect of removing paragraph indentation on the similarity of sentences at paragraph boundaries is shown in Table 5. This table shows the mean probability measure of

similarly (a) for the adjacent sentences at paragraph boundaries (i.e., the sentences at the end of one paragraph and the beginning of the next) and (b) for the adjacent sentences within paragraph boundaries.

When readers used the indented versions of texts, adjacent sentences at paragraph boundaries were less similar than adjacent sentences within paragraphs ($t = 11.06, df = 94, p < .05$ for GOP; $t = 12.10, df = 96, p < .05$ for NOD). When paragraph indentation was removed, readers still perceived the adjacent sentences at paragraph boundaries to be less similar than adjacent sentences within paragraphs ($t = 4.63, df = 94, p < .05$ for GOP; $t = 6.77, df = 96, p < .05$ for NOD). However, there was a tendency for paragraph-boundary sentences to be perceived as more similar when paragraph indentation was removed than when indentation was present. This increase in similarity was statistically significant for both passages when evaluated with $t$-tests for correlated means ($t = 2.58$ and $2.78$ for GOP and NOD, $df = 22, p < .05$). This increase in similarity for
the sentences at paragraph boundaries contrasts with a decrease in the similarity between adjacent sentences within paragraphs.

Discussion

The results of this experiment suggest that paragraph indentation is only one cue that readers use in determining topical boundaries. Even when paragraph indentation was removed, readers still found adjacent sentences at paragraph boundaries less similar than adjacent sentences within paragraphs. This result is consistent with the finding of Koen et al. (1969) that readers can identify the first sentence of a paragraph with greater-than-chance accuracy when paragraph indentation has been removed. The results of the present study suggest that paragraph indentation acts to enhance the effects of the syntactic and semantic cues to topical boundaries.

General Discussion

The study presented a method for determining the reader's perception of the topical organization of a passage. The hierarchical clustering analysis produces clusters of semantically related sentences that seem to reflect the subjects discussed by the writer. In addition, the method yields reproducible results.

This clustering method of retrieving topical organization was devised to help in the search for text features that readers use to understand what they read. The results of Experiment 1
showed that the lexical similarity of sentences may lead readers to perceive that two sentences are topically similar if the sentences are close together. This finding suggests that the spatial relationship of sentences is an important determinant of the perception of topicality. Perhaps one of the reading strategies used by readers is to assume that spatially adjacent sentences belong to the same topic unless the writer signals the reader that a new topic has begun. Experiment 2 presented evidence that one such signal may be the typographical convention of paragraph indentation.

The hierarchical clustering method provides a reliable way of characterizing the organization perceived in a passage. Having a metric to describe organization can be valuable to both writers and researchers. This clustering method provides a way to map topical organization on texts and to detect the sequencing of topics in a passage. Using this method it should be possible to evaluate how alternative ways of organizing passages affect readers from both a practical and theoretical point of view.
