This evaluation briefly considers the numbers of women faculty at higher educational institutions, their status or rank, their distribution in various academic fields, and their salaries. The availability of women for faculty positions and the process by which they are selected are discussed. Among the processes that can limit the hiring of women for academic positions are: the use of sex-biased criteria; institutional rules and regulations that disproportionally affect women; biased or unfair application of neutral criteria, such as differential expectations for and evaluations of men and women; and women's own self-concept and expectations for success. Even when young women are hired as faculty members, they are more likely to hold positions in the lower academic ranks than are men and they do not advance as rapidly up the career ladder. Women are often excluded from many of the opportunities that are available to men. Women faculty continue to be affected by the same myths and differential evaluation problems which may have limited their employment opportunities. Factors that account for women faculty earning less than do comparable male faculty are discussed. (SW)
RESEARCH MEMORANDUM

ISSUES IN THE RECRUITMENT, PROFESSIONAL DEVELOPMENT, PROMOTION, AND REMUNERATION OF WOMEN FACULTY

Issues in the Recruitment, Professional Development, Promotion, and Remuneration of Women Faculty

Ruth B. Ekstrom

I. Introduction - Current Status of Women Faculty

According to recent data (U.S. Office of Education, 1976), women comprise about 24% of the full-time instructional faculty in institutions of higher education. While the proportion of women faculty has increased slightly in recent years (up from 19% in 1962), most of this growth has occurred as individuals under the age of 30 enter the untenured academic ranks (instructor and assistant professor). The 1975 Ladd-Lipset survey found that, among academic men and women under the age of 35, 15% of the men and 41% of the women held the rank of instructor while only 8% of the women, as compared to 21% of the men, had reached the tenured rank of associate or full professor. The status of women faculty in private universities is especially discouraging; women comprise only about 5% of all the full professors in these institutions while they constitute nearly 10% of all the full professors in all types of public institutions (junior colleges, colleges, and universities) and in private two- and four-year colleges.

There are also tremendous differences in the percentage of women faculty in various academic fields within the faculties of major universities. Women comprise about 5% of the university natural science faculty and 18% of the social sciences faculty, as compared to 43% of the faculty in the more applied fields which have traditionally attracted women (education, library science, nursing, child development, and home economics).
Moreover, despite laws which require equal pay for equal work, women faculty still tend to receive lower pay than do men faculty; this is true even when the type of higher educational institution where they are employed and the rank which they hold are taken into consideration. For example, among university faculty the average salary for male full professors is $24,485 while for female full professors it is only $21,582. While the salary difference is less at the lower ranks, for example $14,638 for male assistant professors in universities and $13,919 for female assistant professors in these institutions, there is no type of institution or rank where the average salaries for male and female faculty are equal.

II. Faculty Recruitment

In discussing the problem of recruitment, it is important to consider the availability of women for faculty positions and the process by which they are selected.

A. Availability of Women Doctorates

Among the basic questions raised by these data on the status of academic women are "Are there enough qualified women available to increase the proportion of women on college and university faculties?" and "What is the relationship between current and future demands for doctoral degree holders and the fields in which women have obtained doctorates?" Women were approximately 10% of the total doctoral degree recipients during the 1950's and 1960's although the proportion of doctorates awarded to women has increased sharply during the 1970's.

Moreover, in recent years, doctorates awarded to white men have decreased by 9% while those awarded to white women have increased by 34% and to minority women by 133% (McCarthy and Wolfle, 1975). Interestingly, the increases in the doctorates awarded to women are even more pronounced in graduate departments which are rated as distinguished or strong.
However, there are considerable differences across academic fields as to the proportion of women; 45% of all doctorates awarded to women are in anthropology, biology, education, the health sciences, psychology and the Romance languages. Women also receive more than 25% of all doctorates awarded in home economics, art history, Germanic languages, comparative literature, social work, English, speech, library sciences, linguistics, classics, microbiology and sociology. In other fields, however, such as engineering and the physical sciences, it is still difficult to find a substantial number of women doctorates. The evidence suggests that, in most academic fields, there are proportionately more women who receive the doctorate than there are women who receive regular faculty appointments. However, the supply of women doctorates appears to be greatest in fields which are traditionally feminine and/or which already have an oversupply of doctorates; there is still a lack of women doctorates in nontraditional and/or rapidly growing academic fields.

B. Barriers to the Recruitment of Women Faculty

Even if there were an adequate pool of women in every field to be recruited for available faculty positions, the recruitment process itself combines elements which can act as barriers to the employment of women.

Among the processes which can limit the hiring of women for academic positions are: 1) the use of sex-biased criteria; 2) institutional rules and regulations which disproportionately affect women; 3) biased or unfair application of neutral criteria, such as differential expectations for and evaluation of men and women; and 4) women's own self-concept and expectations for success.
1. Sex Biased Criteria.

One problem in the selection of women for any academic position is the nature of the job criteria. Often these criteria, because they are based on certain assumptions about lifestyles, needs and career ladders which are more typical among and suitable for men than for women, inadvertently discriminate against many women. A first step in attempts to increase the number of women faculty might involve a review of job criteria prior to the advertising of the position so that requirements relating to age, full-time employment, extent of previous experience, etc., which may not be really relevant to job competency, can be revised or omitted.

2. Institutional Policies.

Among the institutional rules and regulations which may operate as barriers to the recruitment of women faculty are those which limit part-time employment, nepotism rules, and inadequate provisions for maternity leave and for child care.

Because many young women faculty have family responsibilities in addition to their academic jobs, they may prefer to work part-time during some portion of their careers, such as when their children are young. Not only do many colleges and universities not allow for temporary, part-time faculty appointments but, in addition, those institutions which do have such appointments often consider them to be outside of the tenure track. Thus, women faculty who are able to obtain part-time positions are permanently relegated to the lower academic ranks and may be able to obtain only year-to-year appointments. In addition, part-time faculty are much more vulnerable to the effects of faculty reduction than are full-time, tenure track faculty.
One possible solution is to allow faculty to switch from full-time to part-time appointments for a limited number of years but to continue on the tenure track by requiring the part-time years to correspond to the full-time equivalents typically involved in reaching tenure. This would free the part-time faculty from having to meet criteria regarding the amount of teaching and number of publications prior to tenure which are realistic only when a faculty member works full-time. Of course, improved maternity benefits and child care facilities could do much to remove the necessity for part-time appointments for women faculty with young children.

Formal nepotism rules, which in the past prevented many academic women from obtaining employment in the same institution or in the same department as their husbands, are now rapidly disappearing. However, informal policies regarding nepotism still exist and limit employment opportunities for many women.

A review of institutional policies to determine their impact on the recruitment, retention, and promotion of women faculty is an important step and is, also, in keeping with Title IX regulations.

3. Different Expectations for and Evaluation of Women and Men

In addition to these more obvious barriers to the recruitment of women faculty, these are the more subtle obstacles to the employment of academic women created by the sex-role stereotyping which society holds for all women and by society's attitudes about and expectations for women.

Certain beliefs, although false, greatly restrict the opportunities available to women. These include such myths as:
Women are less intelligent than men.

Women do not have a real commitment to a career.

Married women are more interested in their families than in their jobs.

Women are irresponsible and emotionally unstable.

Thus, when a group holding these views interviews both male and female job applicants, their evaluation of equally able candidates may reflect these beliefs and result in the male being perceived as the "better" candidate. Experimental studies in a number of academic fields have confirmed the widespread prevalence of this process. In addition, female job applicants are frequently evaluated both in terms of how well they meet the cultural standards of femininity and how well they meet the job competency standards by which both men and women are evaluated. This type of differential evaluation of males and females is not, of course, limited to individuals being recruited for faculty positions but continues throughout every phase of faculty evaluation for salary, promotion and tenure. This same process also affects other women, such as those being selected for positions as administrators and trustees.

Women who serve on committees where other women are evaluated and selected, whether for faculty, administration, or trustee positions, should be sensitive to this problem of differential evaluation and take whatever steps to remedy it as will be most appropriate with that group. Constructive efforts to make male colleagues aware of these different views for males and females may gradually modify the extent of this process. There is a need for training materials which could help sensitize faculty,
administrators, and trustees to the problem of differential evaluation of men and women.

It may be helpful for a woman senior administrator to review the recommendations which faculty members write for men and women graduate students who will be seeking teaching positions. For example, if a male faculty member comments on the physical attractiveness of all of his female graduate students but for none of the males and/or on the career promise of all-male students but none of the females, then a discussion with this faculty member might help him to structure parallel types of letters for both sexes and to omit an area only when it is one on which the recommender prefers not to comment.

4. Women's Own Expectations

Women, themselves, often are affected by the societal expectations for them and, as a result, may undervalue themselves and their own abilities. For women doctorates, this may result in their seeking jobs at a lower academic rank or in a less prestigious institution than do equally able men.

Women may also feel that their own careers are secondary to their husbands' career development. For academic women, this may lead to taking a number of low-level or temporary positions in different colleges rather than making normal progress up the tenure ladder. It may also mean that these women are not employed at or have the opportunity to move to institutions which could best advance their professional and career development.

Despite the above problems in the hiring of women faculty, there has apparently been a sincere effort in recent years at affirmative action in their recruitment. Thus, both Bayer and Astin (1975) and Cartter
and Ruhter (1975) have reported that by the mid-1970's evidence of discrimination in first job placement and initial salary seemed to have disappeared. The next question is whether "women with the same qualifications and accomplishments as men are advanced and remunerated in equitable fashion throughout their professional careers."

III. Faculty Development and Promotion

Even when young women are hired as faculty members, they are more likely to hold positions in the lower academic ranks than are men and they do not advance as rapidly up the career ladder. Moreover, these women are often excluded from many of the opportunities which are available to their male counterparts. Women faculty continue to be affected by the same myths and differential evaluation problems which may have already limited their employment opportunities.

A. Evidence about the Appointment and Promotion of Women Faculty

Women faculty are more likely to receive initial appointments to the lower academic levels than are men; they are also more likely to receive marginal appointments which are not a part of the career ladder (Robinson, 1973). Both of these tend to limit the subsequent advancement and promotion of these women.

In addition, a number of studies show that, once appointed, women advance more slowly through the academic ranks than do men. For example, in studies for the National Academy of Sciences, Harmon (1965, 1968) found that, although the women doctorates in the sample had somewhat greater academic ability than the men, they achieved the status of full professor more slowly than did men. The lag varied somewhat with field, being from 2 to 5 years in the social sciences and up to 10 years
in the physical sciences. Single women were usually advanced up the career ladder more rapidly than married women. Women who have been fellowship recipients have been found to advance more slowly than men even though their publication rates and teaching loads are comparable.

Similar evidence is available for a wide variety of academic fields as well as for many colleges and universities (Robinson, 1973). In every case, women faculty progress through the ranks at a slower rate than do men.

B. Barriers to the Promotion and Professional Development of Women Faculty

Many of the same processes which affect the recruitment of women faculty also affect the advancement of women in the academic ranks and in their professional fields. Thus, the criteria for advancement may be sex-biased, institutional policies may differentially affect men and women, women and men may be evaluated differently on supposedly neutral criteria, and the woman's own role expectations and conflicts may limit her advancement. An additional barrier to the advancement of academic women is the lack of those experiences which are important for advancement. Moreover, the experience of being in a minority status may have a psychological impact on some women's working behavior.

1. Sex-Biased Criteria

When women faculty are evaluated for promotion, the criteria may reflect male biases about what constitutes relevant experiences for achieving a higher ranked position. Additionally, the "significance" of an activity or of an area of specialization, for research and scholarship, is defined in terms of what the male-dominated educational community has, in the past, defined as important and "legitimate." Rarely are the
different values held by women academicians taken into consideration and, as a consequence, new types of scholarly work by women may be depreciated by men when they review women faculty for promotion or for professional honors. Brown (1976) states that exclusion of women from the research and decision-making areas of intellectual life has affected quality because of the united views of areas and priorities. "Without a healthy mix of women and minorities in the academic world," she says, "many values and assumptions will remain unchallenged."

Women faculty are described as being and report themselves as more interested in teaching than in research. Some studies suggest that this is a consequence of a higher proportion of women faculty compared to men being in colleges and junior colleges which emphasize teaching rather than in the research universities; others suggest that it is a result of the male-female differences in fields of specialization.

Tidball (1976 a, b) has described how male faculty subscribe to the research image of an institution, as contrasted with a teaching emphasis, to define institutional quality and to be an important part of the image of academic success. Each college and university needs to decide for itself the relative importance of research and teaching in relation to its institutional image and, then, to see that the criteria by which its faculty are evaluated reflects these values.

In institutions where "publish or perish" is the byword, considerable emphasis is placed on the research done by faculty members and on the resulting publications. While some studies have found women faculty to have lower publication rates than do men (Centra, 1974), there is evidence that, in mathematics, political science, and chemistry, sex accounts for less than one percent of the variance in academic productivity (Hargens, 1971). Simon and her colleagues (1966, 1967) found that the sex differences in
productivity may be related to marital status; married female faculty were more likely to have published at least one article and had a higher mean number of articles published than either married men on the faculty or unmarried women faculty. (But a considerably higher proportion of women faculty than faculty men are unmarried.) However, Centra (1974) implies that marriage is one reason for women's lower publication rate.

When faculty members who are to be reviewed have been involved in research or other work in areas which are not those which the members of the department have studied in the past, it would be wise to bring in evaluations from outside experts rather than assuming that failure to repave the same academic furrows indicates a lack of an appropriate choice for scholarly enterprise. This is especially important when reviewing faculty who have worked in fields like women's studies or who have developed new teaching programs to meet the needs of women entering traditionally masculine fields.

2. Institutional Policies

As was discussed earlier, institutional policies which do not allow faculty to hold part-time positions tend to differentially affect academic women. This is especially true for younger women who face heavy expectations for teaching, research, and publishing during their first few working years which are, for many women, also the childbearing years. Allowing the option for faculty to hold part-time appointments during some of these years and to use full-time equivalent years in setting dates for promotion and tenure review will provide more flexibility for those women who need it.

Institutional policies regarding support for faculty research, attendance at professional meetings, and other professional development
activities also need to be reviewed to see if funds are to be allocated over the entire faculty rather than simply to the tenured faculty. Additionally, trustees and/or administrators may wish to encourage the acquisition of special funds to support the professional development of junior faculty by offering stipends to support small research projects, participation in professional organizations, and other activities which will enhance the continued intellectual growth and professional visibility of nontenured faculty.

Of course, the availability of any such funds or other opportunities for faculty development should be announced publicly and the announcement should be repeated on a regular basis. Often, although faculty development opportunities exist, their availability is communicated by word-of-mouth; in predominately male faculties, this can result in this information being passed on by the "old boys network" only and, hence, not being known to women faculty.

3. Differential Evaluation

When women faculty are reviewed for promotion, they must often carry the burden of many of the sex-role stereotypes which we discussed earlier. Among these and other additional stereotypes which are frequently voiced in the evaluation of women are:

- Women faculty lack career commitment.
- Women faculty don't do research.
- Academic women are ambivalent about success.
- Married women will not undertake really demanding jobs.
- Married women don't want to be promoted to jobs which would give them higher status than their husbands.
Even when these erroneous beliefs are not voiced, the same skills and competencies which are considered assets for men may be described as liabilities for women and used as obstacles to their promotion. For example, individuals in leadership positions are expected to be independent and assertive. These are positive characteristics for a man in our society but are less acceptable for women. Men are praised and promoted for being "clear headed and attentive to detail" but women exhibiting the same behaviors are often described as "tough and bitchy."

4. Women's Expectations

The lack of women in senior faculty and administrative positions may act as a signal to younger women faculty that the institution is not likely to promote women or to encourage their professional advancement. This, of course, can produce a self-fulfilling prophecy with younger faculty seeking to move to institutions where women are more visibly successful.

In order to break this cycle, it is necessary for colleges and universities to recruit women at every level, not only for entry-level, junior faculty positions. Even in the current period of very limited appointments to tenure positions, such appointments are made and there are women available to fill these senior positions. However, an extensive search may be necessary to find these well-qualified senior faculty women. To facilitate such searches, some institutions have set aside special funds to help underwrite the costs of these wider, and consequently more expensive, searches to find women to fill these role-model positions.
5. Lack of Relevant Experiences

It has been well documented that women and men being appointed to junior faculty positions are often not treated by their senior colleagues in a comparable manner and that, as a consequence, young academic women may not have the opportunity to have the same experiences as do their male counterparts. These differences in experience may then limit the women's promotional opportunities.

Part of this difference in treatment may be related to the expectation that women will be more interested in teaching and less interested in research. As a consequence, women faculty may be more frequently asked to teach an extra class and less frequently asked to participate in a research project with more senior faculty. A review of teaching loads and research participation for men and women junior faculty would be in keeping with Title IX and would serve as a means of alerting administrators to possible inequitable treatment.

Moreover, young women faculty members often lack the kind of interaction with colleagues which is so important in the professional development of a scholar. Research evidence points to the importance of a male mentor in the advancement of many prominent women academicians and administrators. This is partly because senior men are in a stronger position of power and influence in most organizations, whether colleges or businesses, than are women and, as a consequence, these men can better facilitate the advancement of younger proteges. Additionally, there is the lack of senior women to serve as role-models and mentors. Moreover, some of these potential mentors may not be willing to work for the advancement of younger women either because of their own insecurity and lack of power or because they have succumbed to the "queen bee" syndrome.
However, senior men or college faculties are often considerably more reluctant to take on young women as protegées than to have young men in the same role. This may be because the older man still holds many of the erroneous stereotypes about women faculty, because he feels that his colleagues may insinuate that the relationship has sexual overtones, or because he simply is more accustomed to and comfortable in working with members of his own sex. As a consequence, many formal and informal professional development opportunities are communicated only from man to man. Tenured faculty should be made more aware of this and asked, when they are selecting junior faculty to assist in research and other scholarly work, if the opportunity has been communicated to all junior faculty members in that department or division.

Still another factor which affects the promotion of women faculty is the number and type of committee assignments which they receive. In many institutions, service on committees is a factor weighed in decisions about promotion and tenure. Often such service is viewed as an indicator that the faculty member is concerned about the problems of the college or university, as well as being a scholar and a teacher, and that the individual might have the potential to move into an administrative position. Such committee service also provides the faculty member with an opportunity to "play campus politics" and to become better acquainted with department chairmen and administrators. Evidence from the early 1970's (Robinson, 1973) suggests that women faculty are not only given fewer committee assignments than are men but that those assignments which they receive are to less prestigious committees. More recent anecdotal reports suggest that faculty women may now be dealing with heavy overloads of committee assignments as institutions frantically search for a "token female" for every committee.
Brown (1976) points out the importance of helping women faculty to develop their administrative skills by expanding "opportunities for them" to attend professional meetings, serve on committees, work on budgets, learn computer programming, write books, or take part in bargaining sessions. Through such experiences, women can gain not only skill and knowledge, but the exposure, contacts, and references necessary for mobility and survival.

6. Minority Status of Women Faculty

Often an academic woman finds herself as the only female in her department. This affects both how she is treated by her colleagues and her own work performance.

The lone woman is often subject to "statistical discrimination," that is, treated as though she resembles women on the average. Additionally, the lone female in male-dominated groups is often cast in one of several stereotype roles: "mother," "seductress," "pet" (group mascot), or "iron maiden" (militant and unapproachable) according to Kanter (1975). These women then tend to behave in ways which are reactions to the stereotypes. When a person is a statistical rarity, s/he must spend more time establishing a competency-based working relationship. For women faculty, this additional time may be a significant element in slowing their professional advancement.

Some women, finding themselves in the position of being the deviant member of a group, will react by exhibiting that phenomenon which has been described by Horner as "fear of success." Recent reanalysis of Horner's work suggests that what women fear in these circumstances is not success but being deviant (Lockheed, 1975) or conspicuously visible. This fear is one reason why women's groups are so important for faculty women (Blaska, 1976). Groups of women holding similar positions can be particularly helpful in dispelling the "fear of success." Groups which give women
faculty, administrators, graduate students, undergraduates, and trustees; an opportunity to meet together from time to time will help to encourage women to make status transitions.

IV. Faculty Salaries

One study of faculty salaries (Gordon, Morton, and Braden, 1974) found that women earn approximately 10% less than do comparable men. One reason for this, they found, was that women's salaries peaked earlier than did those of men. Centra (1974) reports relatively small income differences between men and women in the early postdoctoral years but larger increases with time.

One factor which accounts for these salary differences, on a gross level, is the difference in types of institutions where women and men are employed. As mentioned earlier, proportionally more women faculty are in junior colleges (which have relatively lower salaries) and proportionally fewer women faculty are in universities (where the highest salaries are found). Another element in the female-male salary differences is the academic discipline difference. Thus, we find that fields like medicine, which are heavily male dominated, also have the highest salaries.

Data from the U.S. Office of Education's National Center for Educational Statistics (1976) show that the average salary for men who are members of university faculties is $18,946 while women on university faculties have an average salary of $14,660. The discrepancy between the remuneration of women and men is much more pronounced at the upper ranks and less in the untenured positions. These data suggest that the salary differences, in part, may reflect the processes already discussed which account for women's slower promotion in academe.

A study at the University of Illinois (Loeb and Ferber, 1971) found that sex added significantly to the predictability of faculty salary but it did not
predict rank or speed of advancement through the ranks. These authors hypothesized that salary may be related to outside offers which are, in turn, influenced by the faculty member's visibility outside of the institution.

Sandler (1973) has described some of the myths which may lead to academic women being given lower salaries. These include:

- Married women faculty members don't need as much money, so it's all right to pay them less.
- Unmarried women faculty members don't need as much money, so it's all right to pay them less.
- Academic women earn less than academic men because they aren't as well qualified.

The studies cited by Sandler to refute this last myth indicate that an academic woman's sex costs her approximately $1,000 a year as compared to equally qualified men. Centra (1974) cites data that, as of 1973, faculty women were earning about 2.5% less than men (after equating the sexes on relevant background characteristics).

Conclusion

One recent study (Liss, 1975) has suggested that because of their ignorance of the facts, concentration in the lowest ranks, acceptance of merit myths, and cooptation, women faculty fail to perceive that they are the victims of sex discrimination. As a consequence these women "are not able to help well-intentioned administrators to understand the incremental decisions that tend to exclude or discriminate against women." Strong social networks among women aware of the affirmative action requirements for training, upgrading, and promoting underutilized women were recommended as one solution.
We must also take other actions which will reduce the role conflict for women faculty, provide them with the same kinds of external support (such as role-models and mentors) which men have available, and provide them with the same rewards (both in terms of salary and career opportunity) as men if we are, indeed, serious in our commitment to improving the status of women faculty.
