ABSTRACT

This review of ideas from cognitive and educational psychology that are related to the problem of how to teach non-programmers to use computers explores two techniques. The first one discussed is the effects of concrete models on people's understanding and learning of new technical information such as computer programming. Research results provide evidence that a concrete model can have a strong effect on the encoding and use of new technical information by novices. The second technique for increasing the meaningfulness of technical information was elaboration or encouraging the learner to explain the information in his or her own words, and to relate the material to other ideas or concepts. Research findings reveal that, although there is no fool-proof way to design useful elaboration activities, learners should be able to describe the effects of each program statement in his or her own words. The issue of what to teach to enhance a novice's understanding of computer programming is also discussed in terms of knowledge for understanding a statement and a program. A bibliography of 68 items and a list of 46 titles in this technical report series are provided. (CHC)
Psychology of Computer Programming for Novices

The Psychology of Learning Computer Programming by Novices

Richard E. Mayer

Department of Psychology, University of California, Santa Barbara, California 93106

This paper examines the current state of knowledge concerning how to increase the novice's understanding of computers and computer programming. In particular, this paper reviews how advances in cognitive and educational psychology may be applied to problems in teaching non-programmers how to use computers. Two major instructional techniques are reviewed: providing a concrete model of the computer, and encouraging the learners to actively put technical information into their own words.

Keywords and Phrases: psychology, programming, novices, instruction, man-machine interface

INTRODUCTION

This article focuses on the question, "What have we learned about how to increase the novice's understanding of computers and computer programming?" In particular, this paper reviews ideas from cognitive and educational psychology that are related to the problem of how to teach non-programmers to use computers. Since people who are not professional programmers will have to learn how to interact with computers, an important issue concerns how to foster meaningful learning of computer concepts by novices.

Meaningful learning is viewed as a process in which the learner connects new material with knowledge that already exists in memory (BRAN79). The existing knowledge in memory has been called "schema" and the process of connecting new information to it has been called "assimilation." However, there is not yet agreement concerning the specific mechanisms that are involved in "assimilation to schema" (ANDE77, AUSU77, BARD32, KINT74, MING75, RUME75, SCHA77, THOR77).

Figure 1 provides a general framework for discussion the process of meaningful learning (or assimilation to schema) of technical information (MAYE75a, MAYE79a). In the figure, the human cognitive system is broken down into:

- short term memory -- a temporary and limited capacity store for holding and manipulating information, and
- long term memory -- a permanent, organized, and unlimited store of existing knowledge.

New technical information enters the human cognitive system from the outside and must go through the following steps for meaningful learning to occur:
(a) Reception. First the learner must pay attention to the incoming information so that it reaches short term memory (as indicated by arrow a).

(b) Availability. Second, the learner must possess appropriate prerequisite concepts in long term memory to use in assimilating the new information (as indicated by point b.)

(c) Activation. Finally, the learner must actively use this prerequisite knowledge during learning so that the new material may be connected with it (as indicated by arrow c from long term memory to short term memory).

Thus, in the course of meaningful learning, the learner must come into contact with the new material (by bringing it into working memory), then must search long term memory for what Ausubel (AUSU68) calls "appropriate anchoring ideas" or "ideational scaffolding," and then must transfer those ideas to working memory so they can be combined with new incoming information. If any of these conditions is not met, meaningful learning cannot occur; and the learner will be forced to rote memorize each piece of new information as a separate item to be added to memory. The techniques reviewed in this article are aimed at insuring that the availability and activation conditions are likely to be met.

The goal of this article is to explore techniques for increasing the novice's understanding of computer programming by exploring techniques that activate the "appropriate anchoring ideas." Two techniques reviewed in this paper are: (1) providing a familiar concrete model of the computer, and
(2) encouraging learners to put technical information into their own words.

Each technique is an attempt to foster the process by which familiar existing knowledge is connected with new incoming technical information. For each technique, a brief rationale is presented, examples of research are presented, and an evaluative summary is offered.

1. UNDERSTANDING OF TECHNICAL INFORMATION BY NOVICES

1.1 Definitions

For present purposes, understanding is defined as the ability to use learned information in problem-solving tasks that are different from what was explicitly taught. Thus, understanding is manifested in the user's ability to transfer learning to new situations. Novices are defined as users who have had little or no previous experience with computers and who do not intend to become professional programmers, and thus lack specific knowledge of computer programming.

1.2 Distinction Between Understanding and Rote Learning

The Gestalt psychologists (WERT59, KATO42, KOHL25) distinguished between two ways of learning how to solve problems—"rote learning" vs. "understanding." With respect to mathematics learning, for example, there is often a distinction made between "getting the right answer" and "understanding what you are doing."

In a classic example, Wertheimer suggests that there are two basic ways to teach a child how to find the area of a parallelogram (WERT59). One method involves dropping a perpendicular line, measuring the height of the perpendicular, measuring the length of the base, and calculating area by use of the formula, Area = Height x Base. Wertheimer calls this the "rote learning" or "senseless" method, because the student simply memorizes a formula and a procedure. The other method calls for the student to visually explore the parallelogram until the student sees that you could cut a triangle from one end,
put it on the other end, and form a rectangle. Since the student already knows how to find the area of a rectangle, the problem is solved. Wertheimer calls this method "structural understanding" or "meaningful apprehension of relations," since the learner has gained insight into the structure of parallelograms.

According to Wertheimer, if you give a test involving parallelograms like the one used during instruction, both groups of children will perform well. However, if you give a transfer test that involves unusual parallelograms then the rote learners will say, "We haven't had this yet," while the understanders will be able to derive answers. Thus, the payoff for understanding comes not in direct application of the newly learned material, but rather in transfer to new situations. This example suggests that when creative use of new technical information is the goal, it is important to use methods that foster understanding.

2.0 DO CONCRETE MODELS AID MEANINGFUL LEARNING OF COMPUTER PROGRAMMING?

2.1 Statement of the Problem

Since novices lack domain specific knowledge, one technique for improving their understanding of new technical information is to provide them with a framework that can be used for incorporating new information. This technique is aimed at insuring availability of knowledge in long term memory (See Figure 1). The present section explores the effects of concrete models on people's understanding and learning of new technical information such as computer programming. The major research questions concern how concrete models influence the learning process and how to choose an effective model.

2.2 Concrete Models in Mathematics Learning

One technique for providing the appropriate prerequisite knowledge is the use of familiar, concrete models. For example, Brownell & Moser (BROW49) taught third graders how to use a subtraction algorithm, using two different
methods. One group of several hundred children was taught by using concrete objects like bundles of sticks. For these children, concepts like "borrowing" and "place value" were described in terms of rearranging bundles of sticks into groups of tens. The other group was taught in a "purely mechanical rote fashion"; these children were explicitly given the rules for subtraction at the start and given plenty of "hands on" experience in executing the procedures on standard two digit subtraction problems. Although both groups of students learned to perform equally well on standard two digit subtraction problems, the students who learned with bundles of sticks performed better on tests involving transfer problems (e.g., more complicated subtraction problems).

In current instructional practice, manipulatives, such as coins or sticks or blocks, are used in mathematics teaching in order to make computational procedures more concrete (WEAV72, RESN80). In a careful set of interviews with children who were learning to subtract, Resnick & Ford (RESN80) noted that children often invented a concrete model to help them understand the procedure. Since computer programming shares many of the characteristics of computational procedures in mathematics, it seems possible that the use of manipulatives in computer programming might be as successful as in mathematics.

2.3 Models, Titles, and Advance Organizers in Text

There is also encouraging evidence that similar techniques may be used to increase the meaningfulness of technical information presented in text. For example, Bransford & Johnson (BRAN72) presented the following passage to subjects:

The procedure is actually quite simple. First you arrange items into different groups. Of course, one pile may be sufficient depending on how much there is to do. If you
have to go somewhere else due to lack of facilities that is the next step; otherwise, you are pretty well set. It is important not to overdo things. In the short run this may not seem important, but complications can easily arise. A mistake can be expensive as well. At first, the whole procedure will seem complicated. Soon, however, it will become just another facet of life. It is difficult to foresee any end to the necessity for this task in the immediate future, but then, one never can tell.

After the procedure is completed one arranges the materials into different groups again. Then they can be put into their appropriate places. Eventually they will be used once more, and the whole cycle will have to be repeated. However, this is part of life.

Subjects who read this passage, without a title, rated it low in comprehensibility (2.3 on a 7 point scale) and recalled an average of only 2.8 out of 18 ideas from the passage. However, some subjects were given a description of the topic—washing clothes—before the passage. These subjects rated the passage much higher in comprehensibility (4.5 on a 7 point scale) and recalled more than twice as much information (5.8 idea units out of 18). In addition, a third group was given the washing clothes topic after the passage was presented. However, this group performed at about the same low level as the subjects who were given no topic, (rating the passage at 2.1 in comprehension and recalled an average of 2.7 idea units). Similar studies (BRAN72, DOOL71, DOOL72) also found that students' recall of ambiguous and technical passage was enhanced when an organizing title or diagram or sentence was given prior to reading. However,
these techniques did not have the same facilitating effect when presented after the student had read the passage. These results suggest that the learner must have an appropriate assimilative set available at the time of learning. Even though the same total amount of information may be presented, the students' ability to recall and use the information in the passage is much higher when the clarifying title or picture is given before rather than after reading.

Ausubel (AUSU68) has argued that learning of new technical prose may be enhanced by providing an advance organizer—a short expository introduction, presented prior to the text, containing no specific content from the text, but providing the general concepts and ideas that can be used to subsume the information in the text. The first advance organizer studies conducted by Ausubel and his colleagues in the early 1960's (AUSU60, AUSU63, AUSU68), provided some support for this assertion. For example, in a typical study (AUSU60), 120 college students read a 2500-word text on metallurgy after reading either a 500-word advance organizer that presented the underlying framework for the information or a control 500-word historical passage. The advance organizer presented the abstract principles involved in the text. On a reading comprehension post-test covering the basic information in the passage, the advance organizer group performed significantly better than the control group, with scores of 47% correct versus 40% correct, respectively.

More recently, reviews of the advance organizer literature reveal that advance organizers tend to have their strongest effects in situations where learners are unlikely to already possess useful prerequisite concepts—namely, for technical or unfamiliar material, for "low ability" or inexperienced students, and when the test involves transfer to new situations (MAYE79a, MAYE79b). For example, to study the effects of advance organizers on different kinds of materials, Lesh (LESH76) asked 48 college students to watch a four-
hour videotape on finite geometry. An organizer that gave concrete examples and models was provided either before or after instruction. The instructional lesson was organized either in a order of increasing difficulty (hierarchical order) or in an order that repeated key concepts and related new material to previous material (spiral order). Results of a standard post-test indicated that the advance organizer group outperformed the post-organizer group for the hierarchical unit, but the difference was much less for the spiral unit.

Similar treatment x material type interactions were obtained using social studies lessons (SCHU75) and mathematics lessons (GRUT68). Similarly, Raye (RAYE73) reported that the title biasing effects obtained by Bransford & Johnson (BRAN72) with the washing clothes passage were eliminated when the passage was made more concrete and familiar. Thus, there is consistent evidence that organizers have stronger effects for unfamiliar, abstract information than for familiar, concrete information.

In a study investigating the effects of advance organizers on students with high and low ability (or knowledge), physics material was taught to high school students (WEST76). Advance organizers, consisting of concrete models, tended to improve test performance of low ability students but had a much smaller effect for high ability students. Similar group x ability interactions were obtained by several other researchers (RING71, FITZ63, AUSU62, AUSU61, AUSU63, AUSU77, SMIT69). Thus, there is evidence that advance organizers have a stronger effect on low knowledge or low ability learners as compared to high knowledge or high ability learners.

Finally, in studies involving transfer tests (i.e. problems that are different from those in instruction), there is consistent evidence that advance organizers have a stronger effect on transfer performance than on simple retention. For example, this pattern was obtained with material on mathematical
topology (SCAN67), number bases (GROT68, MAYE77), and an imaginary science (MERR66).

Many of the apparent conflicts in the advance organizer literature (BARN75, LAWT77) can be accounted for by the idea that advance organizers find a way of connecting new information with existing knowledge—organizers are not needed for familiar material, experienced learners, or when the test does not involve transfer.

While there is at present no foolproof procedure for generating useful advance organizers, a careful review of the existing literature suggests the following guidelines (MAYE79a): (1) The organizer should allow the reader to generate all or some of the logical relations in the text. (2) The organizer should provide a means of relating the information in the text with existing knowledge. (3) The organizer should be familiar to the learners. (4) The organizer encourages the learner to prerequisite knowledge that the learner would not normally have used. To date, advance organizers have been most effectively used in mathematics and science topics (MAYE79a).

Royer and his colleagues (ROYE75, ROYE76) have demonstrated that concrete models may serve as effective advance organizers in learning of new scientific information. In their studies, subjects read two passages, such as a passage on electrical conductivity followed by a passage on heat flow. For some subjects, the first passage contained several concrete analogies, such as electrical conduction being described as a chain of falling dominoes. For other subjects, the first passage presented the same information in abstract form without any concrete analogies. Reading of the second passage was facilitated if students had been given concrete models in the first passage (e.g., recall of the information in the second passage was about twice that of control groups). Apparently, the models presented in the first passage could be used
by learners during the reading of the second passage to help relate the technical terms to familiar concepts.

Similarly, White & Mayer (WHIT80) analyzed physics textbooks to determine how concrete models were used. For example, many textbooks explain Ohm's Law by describing water flowing in pipes, or a boy pushing a heavy load up an inclined street, or electron flow through a circuit. Recent results (MAYE80) show that when concrete analogies are embedded in a technical text, novices tend to perform best on recalling these familiar models and tend to recognize the information adjacent to the model in the text.

2.4 Concrete Models in Computer Programming

In previous sections, research was presented concerning the role of manipulatives in mathematics instruction, titles and pictures in remembering ambiguous passages, and advance organizers and models in science text. In each case there was evidence that these techniques serve to provide the learner with appropriate anchoring knowledge that is required for comprehension of new technical information. The present section focuses on research related specifically to computer programming.

DuBoulay and his colleagues (DUB076, DUB080) have provided a concrete model for teaching LOGO to children. The model consists of a conceptual LOGO machine with concrete memory locations, switches and work space, which allow the learner to "work" the machine.

DuBoulay and his colleagues have argued that there are two basic approaches to learning to interact with a computer. The first approach could be called the black box approach. In this approach the user develops the attitude that the computer is a black box—"you put in commands and data and out comes the answer as if by magic." The mechanisms by which the computer operates are hidden from the user, and the user is likely to assume that computers are just
not understandable. Such users are likely to memorize algorithms that "work"—i.e., that generate the desired answers. However, such users are not able to relate the commands to an understanding of what goes on inside the black box.

The second approach is what can be called the glass box approach. In this approach, the user attempts to understand what is going on inside the computer. Each command results in some change in the computer and these changes can be described and understood. The level of description need not—indeed should not—be at the "blood and guts" level. Users do not need to become electronics experts. There is an appropriate level of description that Mayer (MAYE79c) refers to as the "transaction level." Similarly, Duboulay et al. (DUBO80) offer two important properties for making hidden operations of a language more clear to a novice: (1) simplicity—there should be a "small number of parts that interact in ways that can be easily understood," and (2) visibility—novices should be able to view "selected parts and processes" of the model "in action." The LOGO model appears to fit these specifications because it is a simple, familiar model of the computer operations involved in LOGO; in short, it allows the user to develop intuitions about what goes on inside the computer for each line of code. Unfortunately, however, Duboulay and his colleagues have not provided empirical tests concerning whether the LOGO machine model actually influences the problem solving performance of new learners, as compared to "traditional" methods that emphasize only "hands on experiences."

2.5 Effects of Models on Transfer Performance

In order to provide some information concerning the effects of concrete models on learning computer programming, a series of studies was conducted (MAYE75b). In the studies, subjects were either given a concrete model of the computer or not. Then subjects read a manual on a BASIC-like language and took a transfer test on the material.
Method. Figure 2 shows the model of the computer that was used to explain elementary BASIC-like statements to novices. The model provides concrete analogies for four major functional units of the computer: (1) input is represented as a ticket window in which data is lined up waiting to be processed and is placed in the finished pile after being processed, (2) output is represented as a message note pad with one message written per line, (3) memory is represented as an eraseable scoreboard in which there is natural destructive read-in and non-destructive read-out, and (4) executive control is represented as a recipe or shopping list with a pointer arrow to indicate the line being executed. This model is similar to DuBoulay's model of the LOGO machine in the way it makes the basic operations of the computer visible to the learner. A 2 x 3 foot diagram containing these parts, and a brief one page description were provided to subjects in the "model group" (see Figure 2) but no model was given to the "control group."

All subjects then were given a 10-page manual that described seven statements modified from BASIC and FORTRAN. (see Table 1). For each statement, the manual presented the statement, provided the grammar rules for the statement (e.g., definitions of legal address names), and gave an example of the statement as it might occur in a line of a program. Subjects in both groups were given the same manual to read at their own rates, averaging 20 to 30 minutes.

Following reading, the same test was given to all subjects. The test consisted of six types of problems: (1) generate-statement problems gave a problem in English and required a one statement program as the solution,
predicts that presenting a model prior to learning will enhance learning because it provides a meaningful context, but presenting the model after the text will not enhance learning because students will have already encoded the material in a rote way. In further studies (MAYE76a) subjects read the same BASIC-like manual, but some subjects were shown a concrete model of the computer before reading while others were shown the same model after reading the manual. Thus, subjects in the before group (i.e., those who received the model first) were able to use the model while encoding the material in the text, but the after group (i.e., receiving the model last) was not.

Method. The booklet, model and test were similar to those used in the previous experiment. The before group received the model, then the booklet, then the test. The after group received the booklet, then the model, and then the test.

Results. The proportion of correct answers by type of problem for the two groups is given in Table 4. As can be seen, the after group (like the controls in the previous study) excels on retention-like problems (i.e., generation-statement and generation-nonloop), but the before subjects excel on problems requiring creative transfer to new situations (i.e., generation-loop, interpretation-statement, interpretation-nonloop). Thus, these results provide further support for the claim that subjects who use a concrete model during learning develop learning outcomes that support broader transfer. As predicted, the locus of the effect is before rather than after instruction.
(2) generate-nonloop problems gave a problem in English and required a short non-looping program for solution, (3) generate-looping problems gave a problem in English and required a looping program for solution, (4) interpret-statement problems gave a single statement program and asked the student to describe what the computer would do, (5) interpret-nonloop gave a non-looping program and asked for a description of what the computer would do (6) interpret-looping problems gave a looping program and required a description of what the computer would do. Examples of the six problems are given in Table 2.

Results. The proportion correct response by type of problem for each of the treatment groups is given in Table 3. As can be seen, the control group performs as well or better on problems that are very much like the material in the instructional manual, e.g., generate-statement and generate-nonloop. However, on problems that require moderate amounts of transfer—e.g., generate-loop and the shorter interpret problems—the model group excels. Both groups do poorly on the very complex interpret-looping programs. The difference in the pattern of performance is consistent with earlier results in other domains in which models enhance transfer performance but not simple retention of presented material. Apparently, the model provided an assimilative context in which novices could relate new technical information in the booklet to a familiar analogy. This learning process resulted in a learning outcome that supported some transfer.

Insert Tables 1, 2 and 3 about here

2.6 Locus of the Effect of Models

One problem with the above study is that the model subjects received more information than the controls. However, assimilation theory (see Introduction)
2.7 Effects of Models on Recall Performance

The above studies used transfer tests as a measure of what is learned under different instructional techniques. Another technique involves asking subjects to try to write down all they can remember about certain statements. In a follow-up study (MAYE80) subjects read the same manual and were given the model either before or after reading as in the previous study. However, as a test, subjects were asked to recall all they could about portions of the manual.

Method. The same booklet and model were used as in the previous experiment, with some minor modifications. The before group received the model, then the manual, then the recall test; the after group received the manual, then the model, and then the recall test.

Results. In order to analyze the recall protocols, the information in the manual was broken down into "idea units." Each idea unit expressed one major idea or action. There were three kinds of idea units in the manual:

1. conceptual idea units related to the internal operation of the computer,
2. technical idea units gave examples of code, and
3. format idea units gave grammar rules. Table 5 gives examples of each type of idea unit.

Table 6 shows the average number of correctly recalled idea units from each category for the two groups. As can be seen, the before group recalls more conceptual information while the after group recalls more technical and format information. This pattern is consistent with the idea that good retention requires recall of specific code, but good transfer requires understanding of conceptual ideas. Also, Table 6 shows that the before group included more intrusions about the model and about other idea units from other sections of the booklet, thus suggesting they integrated the information better. For example, an intrusion is, "An address is a slot in the memory scoreboard." The after group, however, included more vague summaries and connectives which served as "filler." For example, a connective is "And that's
how READ statements work." Thus, as with the transfer test, subjects given the
model before learning show evidence of more integrated and conceptual learning
of technical information.

Insert Tables 5 and 6 about here

2.8 Effects of Models on Transfer and Recall Using a Different Language

Although the above results are consistent and were obtained in a long
series of studies, their generality is limited by the fact that just one type
of language was used. Thus, a follow-up study (MAYE80a) was conducted using
a file management language based on SEQUEL (GOUL74; REIS77). The goal of this
study is to determine whether the results from previous studies generalize to a
new domain.

Method. Subjects read a manual that presented the file management lan-
guage. For one group of subjects, the model group, the manual began with
discussion of a concrete model and related each statement to the model (see
Figure 3), but no model was given to the control group. The manuals were
informationally equivalent. Each page of the booklet presented one of the
eight statements shown in Table 7, along with examples of how the statement fit
into a program. Figure 3 presents the concrete model that was used: long-term
memory is represented as a file cabinet; the sorting function is represented as
an in-basket, out-basket, and save basket; temporary memory is represented as
an erasable scoreboard; executive control is represented as a list and pointer
arrow; output is represented as a message pad. The entire model was presented
on a 2 x 3 foot diagram, in order to enhance the learner's ability to visualize
the system.

After reading the manual, all subjects took the same 20 item test.
Problems varied in complexity from generating or interpreting a sort-1 program
(with very few operations) to a computer program (with many different statements integrated into one large program). Table 8 lists the five different kinds of programs used.

Results. Table 9 gives the proportion of correct answers by type of problem for the two treatment groups. As can be seen, the control group performs as well as the model group on very simple problems like those in the manual, but the model group excels on longer problems that require creatively integrating all of the statements in the booklet. Thus, as in the studies with Basic-like materials, a familiar model serves to enhance performance on creative transfer when it is presented prior to technical instruction.

Insert Figure 3 and Tables 7, 8 and 9 about here

2.9 Ability

The pattern of results described above tended to be strongest for low ability subjects (MAYE75b) where ability is defined in terms of Mathematics SAT score. For example, for low ability subjects the advance organizer increased transfer test performance (55% correct) as compared to the control group (45% correct), but for high ability learners the advance organizer group performed more poorly than the control group (55% versus 62% correct, respectively). Apparently, high ability learners already possessed their own useful "models" for thinking about how a computer works, but low ability students are more likely to lack useful prerequisite knowledge.

2.10 Text Organization

The pattern of results described above also tended to be strongest when material was poorly organized (MAYE78). For example, the Basic-like manual was presented either in its original order or in a random order. In the random
order, presentation order of paragraphs was randomized. For the randomized version of the manual, the advance organizer group performed better on a transfer test than a control group (41% correct versus 31% correct, respectively); but for the logical version of the manual advance organizer group performed but did not outperform the control group (36% versus 44% correct, respectively). Apparently, the model is more useful when material is poorly structured because it helps the reader to hold the information together.

2.11 Conclusion

These results provide clear and consistent evidence that a concrete model can have a strong effect on the encoding and use of new technical information by novices. These results provide empirical support to the claims that allowing novices to "see the works" allows them to encode information in a more coherent and useful way (DUB076, DUB078). When appropriate models are used, the learner seems to be able to assimilate each new statement to his or her image of the computer system. Thus, one straightforward implication is: If your goal is to produce learners who will not need to use the language creatively, then no model is needed. If your goal is to produce learners who will be able to come up with creative solutions to novel (for them) problems, then a concrete model early in learning is quite useful. More research is needed in order to determine the specific effects of concrete models on what is learned, and to determine the characteristics of a useful model.

3.0 DOES STUDENT ELABORATION ACTIVITY AID MEANINGFUL LEARNING?

3.1 Statement of the problem

The previous section provided evidence that concrete models may influence learning of computer programming because they provide a familiar context for assimilating the new material. The second major technique for increasing
the meaningfulness of technical information is elaboration—encouraging the learner to explain the information in his or her own words and to relate the material to other ideas or concepts. Elaboration techniques may influence meaningful learning because they encourage the activation of existing knowledge that is relevant for comprehending the newly presented material, i.e., elaboration may affect the activation process (see Figure 1).

3.2 Putting It in Your Own Words

There is some evidence that asking subjects to put ideas into their own words during learning can enhance the breadth of learning. For example, Gagne & Smith (GAGN62) asked subjects to give a verbal rationalization for each step as they learned to solve a three disc version of the Tower of Hanoi problem (EWER12). These subjects took longer to learn than those who did not verbalize; however, they were able to transfer what they had learned to different problems, such as a six disc version, much more efficiently (e.g., 3.8 minutes to solution) than the non-verbalizers (e.g., 10.0 minutes to solution).

More recently, Wittrock (WITT74), has proposed the idea that "learning is a generative process"—i.e., learning occurs when the learner actively generates associations between what is presented and what he already has in memory. As an example, Wittrock (WITT74) presented a study in which elementary school children read a passage and either generated a one-sentence summary for each paragraph or did not. Recall by the students who generated summary sentences was nearly double that of the control group. Apparently, when students are actively encouraged to put information in their own words, they are able to connect the new information to existing knowledge.

Elaboration techniques have long been used by experimental psychologists to enhance the learning of paired associates (such as HOUSE-CASA). For example, when students are asked to actively form mental images or a sentence involving
word pairs, paired associate recall is greatly enhances (BOWE72, PAIV69). More recently, elaboration techniques have been used in school curricula (DANS78, WEIN78). For example, in studying human physiology, students are asked "How do arteries differ from veins?". Several researchers have argued that students should be given explicit training in "learning strategies" for actively processing new material (UNEI78).

The following is a series of studies that explore the role of elaboration techniques in learning computer programming. The main theme of this research is to determine how "putting it in your own words" influences the learning of a new computer language.

3.3 Effects of Model Elaboration on Transfer Performance

The first set of studies (MAYE80a) address the question of whether elaboration activity influences students' ability to engage in problem solving. In these studies, subjects learned a new computer programming language and either were or were not encouraged to describe what they learned in their own words by relating it to a concrete familiar situation.

Method. Subjects read an instructional manual covering an information management language similar to that described in the previous section (see Tables 7 and 8). For subjects in the model elaboration group, there was an elaboration page after each page in the manual while for subjects in the control group there was no elaboration exercise. The elaboration exercises asked the subject to describe the newly learned statement in terms of operations within a concrete model of the computer. Table 10 provides a typical exercise. Then, all subjects took the same 20 item problem solving test as described in the previous section.

Insert Table 10 and 11 about here
Results. Table 11 shows the proportion correct response by type of problem for the two groups. As can be seen, the control group performs well on simple retention-like problems, but the model elaboration group performs considerably better on problems requiring creative transfer. Thus, there is evidence that requiring the learners to put technical information in their own words though relating the material to a familiar situation, results in broader learning outcomes. The results are similar to those given in Table 9, and suggest that model advance organizers and model elaboration have similar effects.

3.4 Effects of Comparative Elaboration on Transfer Performance.

In the previous study, a concrete situation is presented and the learner is asked to relate the new information to it. However, the results are ambiguous in the sense that they may be attributed either to elaboration activity per se or to the fact that additional information (about the concrete model) was presented to the model elaboration group. The purpose of the present studies were to use a kind of elaboration activity that does not add new information. Thus, a set of studies were conducted in which some subjects were asked to compare newly learned statements in their own words.

Method. Subjects read the same manual about an information management language as in the previous study. However, some subjects were given an elaboration page after each page in the booklet (Comparative elaboration group), while, for other subjects there was no elaboration (control group). The elaboration activity asked subjects to tell how two statements were similar and different, in their own words. Table 12 provides a typical exercise. Then, all subjects took the same test as in the previous study.

Results. Table 13 shows the proportion of correct answers by type of problem for the two groups. As can be seen, the control group excels on
retention-like problems but the comparative elaboration groups excelled on the more complex transfer problems. Thus, there is evidence corresponding to that found in the model elaboration studies, that asking learners to put technical information in their own words (through making comparisons) results in broader learning which supports transfer.

Insert Tables 12 and 13 about here

3.5 Effects of Model and Comparative Elaboration on Recall

The previous studies suggest that elaboration activity can influence transfer performance. As a further test (MAYE80a) subjects were given manuals with either no elaboration questions, model elaboration questions, or comparative elaboration questions. It can be predicted that the elaboration subjects should recall more information that supports transfer—such as conceptual information—while the control group should recall more information about specific statements—such as technical information.

Method. As in the previous study, subjects read a manual explaining the information management language that contained either no questions (control group), model questions (model elaboration group), or comparative questions (comparative elaboration group). Then, subjects were asked to recall portions of the text.

Results. For purposes of scoring the recall protocols, the text was divided into idea units. Some of the idea units presented information about how the computer operated (conceptual idea units) and others emphasized the grammar and technical aspects of each statement (technical idea units). Table 14 shows the average number of idea units recalled by type for the three groups. As can be seen, the control group recalls equal amounts of both types of information,
but the elaboration groups each tend to emphasize recall of conceptual as compared to technical information. These results are consistent with the results of the transfer studies, in that conceptual information is likely to be needed to support transfer.

3.6 Effects of Note-taking on Transfer and Recall Performance

The foregoing series of studies provides some evidence that elaboration techniques influence the breadth of learning. However, the generality of the result is limited by the fact that just one type of manual was used and just two types of elaboration activity. In addition, previous studies did not control for amount of reading time. Thus, an additional series of studies (PEPE78) was conducted using a different language (a BASIC-like language) and a different elaboration activity (note-taking).

Method. Subjects watched a 20 minute videotape lecture describing seven BASIC-like statements similar to the manual described earlier. Some subjects were asked to take notes, by putting the basic information in their own words. Other subjects simply viewed the lecture without taking notes. As a test, subjects were given problems to solve or asked to recall portions of the lesson. Videotape presentations controlled for presentation time in the two groups.

Results. Table 15 gives the proportion of correct answers on generative problems (similar to those in the lesson) and on interpretation problems (which were not in the lesson). As can be seen, for low ability subjects (based on Mathematics SAT scores), there is a pattern in which note-taking helps performance on transfer but hurts performance on the retention-like problems. For high ability subjects, note-taking has no effect, presumably because high ability
learners already possess strategies for actively assimilating the new information.

Table 16 shows recall of the lecture by type of idea unit for the two groups. As can be seen, the note takers recall more conceptual information, but there is no difference between the groups in recall of technical information. Thus, the results are consistent with the model elaboration and comparative elaboration studies concerning the effects of asking subjects to put new technical information in their words during learning.

3.7 Conclusion

The goal of elaboration is to help the learner to be able to describe the key concepts in his own words, using his existing knowledge. Unfortunately, there is no fool-proof way to design useful elaboration activities. Emphasis on format or grammatical details and emphasis on errorless verbatim recall of statements will not produce the desired effects. The learner should be able to describe the effects of each program statement in his own words.

4.0 UNDERSTANDING COMPUTER PROGRAMMING

The previous sections have focused on the issue of how to teach novices. This section briefly examines the issue of what to teach. Greeno (GREE76) has argued that instruction for problem solving tasks should be based on cognitive objectives—statements of what the learner should have in his or her head at the end of instruction. Two major objectives that are relevant to enhancing a novice's understanding of computer programming are: knowledge for understanding a statement and knowledge for understanding a program.
4.1 Understanding a Statement

What does it mean to say that someone "understands" a certain statement? In a recent analysis of BASIC, each statement is described as a "transaction" (MAYE79c). A "transaction" consists of an action, an object, and a location in the computer. For example, the statement LET X = 5, consists of the following six transactions:

1. Find the number indicated on the right of the equals. (ACTION: Find; OBJECT: Number; LOCATION: Program).
2. Find the number in the memory space indicated on the left of the equals. (ACTION: Find; OBJECT: Number; LOCATION: Memory).
3. Erase the number in that memory space. (ACTION: Destroy; OBJECT: Number; LOCATION: Memory).
4. Write the new number in that memory space. (ACTION: Create; OBJECT: Number; LOCATION: Memory).
5. Go on to the next statement. (ACTION: Move; OBJECT: Pointer; LOCATION: Program).

Thus, there is a general structure for each transaction; you can expect some action to be carried out on some object in some location in the computer. The two techniques cited in previous sections can be applied to teaching a transaction-type analysis of statements. It may be noted that statements with the same name may actually consist of different actions. For example, a "Counter Set LET" such as above is different from an "Arithmetic LET" such as LET X = 5/2. Explicit naming and describing of different types of statements with the same keyword may become a part of computer instruction.
4.2 Understanding a Program

What do experts know about computer programming that beginners do not know? One answer is that experts possess much more information, and that the information is organized more efficiently. For example, a review of research on teaching people how to become better problem solvers concludes that good problem solving requires that the user has domain-specific knowledge: "All problem solving is based on knowledge" (GRE80). Similarly, Simon (SIM080) estimates that a person needs 50,000 chunks of domain-specific information to become an expert in some domain.

In a classic study, subjects were asked to view briefly presented chess board configurations and then try to reconstruct them (CHAS73). Chess masters performed much better than less experienced players on reconstructing board configurations if the board positions came from actual games; however, the advantage was lost when random board patterns were presented. This finding suggests that experts in chess do not necessarily have better memories, but rather they have a repertoire of many meaningful patterns of board positions. They can chunk several pieces together into one meaningful pattern while a less experienced player must try to remember each piece separately. In an analogous study reported by Shneiderman (SHNE80), experienced and inexperienced programmers were given programs to study. Experienced programmers were able to recall many more lines of code than inexperienced programmers when the program was a meaningful running program; however, when the program consisted of random lines of code the two groups performed at similar levels. Apparently, the experts were able to chunk lines of code together into chunks while less experienced users were less able to form such chunks.

For example, Atwood & Ramsey (ATWO78) suggest that experienced programmers encode a segment such as,
as "CALCULATE THE SUM OF ARRAY X." An experienced programmer has a "schema" for this task and is able to generate a variety of lines of code to accomplish it. In order to provide a more precise description of the "schemas" that are involved in understanding programs, Atwood & Ramsey (ATWO8O) used a modified version of Kintsch's (KINT74) propositional analysis. Each statement in the program can be written as a predicate with arguments, and a macrostructure can be constructed. Although a detailed description of Atwood & Ramsey's system is beyond the scope of this paper, their work is promising in that it suggests that knowledge can be represented precisely.

One implication of this work is that it might be possible to explicitly teach the major "chunks" or "schemas" involved in computer programming using the techniques cited in previous sections. Explicit naming and teaching of basic schemas such as these may become part of computer programming curricula.

SUMMARY

This paper is concerned with how to make computers and computer programming more understandable for novices. Two instructional techniques from educational and cognitive psychology are described—using concrete models to represent the computer system, and encouraging the learner to describe technical information in his own words. A review of the effectiveness of these techniques revealed that, under certain conditions, both may enhance the learner's understanding as measured by ability to solve transfer problems. Finally, two major objectives of computing instruction were suggested—enhancing the novice's ability to understand statements and to understand programs.
ACKNOWLEDGEMENTS

I wish to thank Tom Moran for his editorial comments. A shorter version of this paper was presented at the NSF Conference on National Computer Literacy Goals for 1985, held in Reston, Virginia on December 18-20, 1980. Preparation of this paper was supported by Grant NIE-G-0118 from the National Institute of Education, and Grant SED-80-14950 from the National Science Foundation.
FOOTNOTES

1. Transfer problems are problems that are different from those given in the text, but can be solved using information in the text. Since the text gave information about how to generate single statements and simple programs, these two kinds of problems are not transfer problems. Since the text did not explicitly mention looping, problems that require the generation of a looping program are transfer problems. Similarly, since the text did not explicitly deal with interpretation of programs, interpretation problems are transfer problems in this study. However, looping—interpretation may require much more transfer than the others, since it is most different from the text.

2. These tables are broken down by problem complexity, with more complex problems requiring transfer. The same general pattern is found for both generation and interpretation problems. Table 13 shows data for interpretation problems only, in order to avoid unnecessary complexity. However, this table cannot be directly compared with Table 11.

Figure 1. Some information processing components of meaningful learning. Condition a is transfer of new information from outside to short term memory. Condition b is availability of assimilative context in long term memory. Condition c is activation and transfer of old knowledge from long term memory to short term memory.
Figure 2. A concrete model of the computer for a BASIC-like language.
Figure 2a. Description for Model

The figure above represents a simple computer system which you will learn about in this experiment. The computer is made-up of three main parts: (1) INPUT & OUTPUT WINDOWS which allow communication between the computer's memory and the outside world, (2) MEMORY SCOREBOARD which stores information in the computer, and (3) PROGRAM LIST & POINTER ARROW which tell the computer what to do and what order to go in. Each of these three parts will now be explained.

INPUT & OUTPUT WINDOW
Notice that to the far left is an input window divided into two parts. A pile of computer cards with numbers punched into them can be put in the left part of the window; as the computer finishes processing each card it puts the card on the right side of the input window. Thus when the computer needs to find the next data card, it takes the top card on the left side of the input window; when it is done with the card, it puts it on the right side.

On the far right is the output window. This is where printed messages (in this case, only numbers can be printed) from the computer's memory to the outside world appear. Each line on the printout is a new message (i.e., a new number).

Thus the computer can store in memory a number that is on a card entered through the input window or it can print out what it has in memory onto a printout at the output window. The statements which put the input and output windows to work are READ and WRITE statements, and each will be explained later on.

MEMORY SCOREBOARD
Inside the computer is a large scoreboard called MEMORY. Notice that it is divided into eight spaces with room for one score (one number) in each space.
Also notice that each space is labeled with a name -- A1, A2, A3, A4, A5, A6, A7, A8. These labels or names for each space are called "addresses" and each of the eight addresses always has some number indicated in its space. For example, right now in our figure, A1 shows a score of 81, A2 has the number 17, etc.

It is possible to change the score in any of the eight spaces; for example, the score in box A1 can be changed to 0, and you will learn how to change scores in memory later on when we discuss EQUALS statements and CALCULATION statements.

**PROGRAM LIST & POINTER ARROW**

Inside the computer to the right of the MEMORY is a place to put a list of things to do called PROGRAM LIST and an arrow which indicates what step in the list the computer should work on.

Notice that each line in the PROGRAM LIST has a number so that the first line is called P1, the second step is P2 and so on. When a program is inserted in the step indicator arrow will point to the first line (P1); when the first step is finished the arrow will go to the next step on the list (P2), and so on down the list. You will learn how to control the order of steps later on when the IF statement, GO TO statement and STOP statement are discussed.
The computer is capable of three main functions: sorting record cards into sorting baskets, remembering numbers on its memory scoreboard, and outputting information to the world through its message pad.

To understand the sorting function of the computer you could think of an office worker sitting at a desk with three sorting baskets, a line pointer arrow, and file cabinet with many drawers. Each drawer of the file cabinet contains a different set of records; the name of the file is indicated on each drawer. If the worker needs all the records in a particular file all the worker needs to do is open that drawer and take out all the records. To avoid mix-ups the clerk can take out all the records of only one file at a time; if the clerk needs to bring records from a certain file drawer to his desk, first all the records from all other files must be put back in their proper drawers. Thus, a worker may have all the records for only one file on his desk at a time. These could be placed in the "in basket" which is on the left side of the clerk's desk—it thus contains all of the to-be-processed record cards, waiting for the office clerk to look at them. In the middle of the desk is a work area with a line pointer arrow; the clerk may place only one card in the work area at a time, and the pointer arrow points to just one line at a time. To the right are two more baskets—the "save basket" and the "discard basket." If a record card passes the clerk's inspection it is placed on top of the pile of cards in the "save basket"; but if it fails it is placed in the top of the pile of cards in the "discard basket." The procedure the office worker uses is to take the top card from the "in basket", place it in the work area with a pointer arrow aimed at one line, and based on inspection of this line to move that card to either the "save" or "discard basket." The worker continues until
all of the the records in the "in basket" have been processes so that the "in basket" is empty and the "save" and "discard baskets" contain all the records; then, sometimes the worker might be asked to take the pile in either the "save" or the "discard basket" and put them in the "in basket" for further processing.

To understand the memory function of the computer, think of a memory scoreboard. The scoreboard consists of 15 rectangular spaces like a classroom blackboard divided into 15 spaces. Each space has a label such as COUNT2, and each space has one number (of any length) in it. The office worker may count all the records that have been stored in the SAVE Basket, and this number could be stored in one of the spaces on the scoreboard. When a new number is stored in a space on the scoreboard, the old number is erased. However, when the office worker copies a number from one of the memory spaces onto the output pad the number is not erased.

To understand the output function of the computer think of a telephone message pad. To communicate with the outside world the computer can write one piece of information on each line of the pad. It fills all the lines on one page, it will just turn to the next page and begin with the top line. The office worker may write down two kinds of information on the output pad: a number may be copied from one of the spaces on the scoreboard onto the pad (but this does not alter the number on the scoreboard), or information that is on each card in the Save Basket can be copied onto the output pad.
