This document presents the transcript of a hearing held to examine how rapid technological changes are affecting the American educational system and to learn what new equipment with potential for educational application is available, how technology can be integrated into the curriculum, and how students and teachers can acquire the skills needed for a technological society. Included are statements, letters, and materials, presented or provided by John H. Gibbons (Office of Technology Assessment, U.S. Congress); Joyce Hakansson, (Hakansson Associates, Inc.); Francis Fisher (Haverford College); Linton Deck, Jr. (consultant, Fairfax County Schools); Joe Miller (Arkansas State Department of Education); Denis Eichhorn (Control Data Corp.); Reta Kohari (Apple Computer, Inc.); and John Lipkin (Bureau of Social Science Research, Inc.). Reprints of the following published reports and articles are also provided: a summary of the Office of Technology Assessment's study, "Informational Technology and Its Impact on American Education," and reprints of "PLATO System Spurs Baltimore Students to New Achievements," Anne O. Emery, "Computer and Videodisc: A New Way to Teach CPR," Lynn Hessinger, "Interactive Video Disc with Microcomputer and Manikin," "Toward Real-World Applications," "What the Space Invaders Are Trying to Tell Us," "How Devices Restore Democracy," "Interactive Training in Cardiopulmonary Resuscitation," David Hon, and "And Now, Dynamic Discs," Richard Stengel. OVERSIGHT ON EDUCATIONAL TECHNOLOGY

TUESDAY, SEPTEMBER 14, 1982

HOUSE OF REPRESENTATIVES, SUBCOMMITTEE ON ELEMENTARY, SECONDARY, AND VOCATIONAL EDUCATION AND SUBCOMMITTEE ON SELECT EDUCATION, COMMITTEE ON EDUCATION AND LABOR.

Washington, D.C.

The subcommittees met, pursuant to call, at 9 a.m., in room 2175, Rayburn House Office Building, Hon. Mario Biaggi presiding. Members present: Representatives Biaggi, Murphy, Kildee, Erdahl, and Petri.

Staff present: John F. Jennings, majority counsel; Nancy L. Kober, legal specialist; Tanya Rahall, staff assistant; Roseanne Tulley, administrative assistant; and Electra Veahler, minority counsel for education.

Mr. BIAGGI. The meeting is called to order.

The Subcommittee on Elementary, Secondary, and Vocational Education and the Subcommittee on Select Education are conducting a joint oversight hearing today on the issue of educational technology.

The purpose of this hearing is to examine how the rapid changes in technology are affecting our educational system. We are interested in learning what new equipment is available that has applications in the schools; how technology can be integrated into the curriculum; and, how students and teachers can acquire the skills needed for a technological society.

This hearing is being held in conjunction with the release of the findings of a major assessment of educational technology conducted by the Office of Technology Assessment. We are pleased to welcome John H. Gibbons, the Director of OTA, to present the conclusions of this study. We also have a knowledgeable panel of witnesses to respond to the issues raised by the OTA report.

We are also privileged to have with us today some experts in education technology who have brought along new equipment being used in education today. They will be explaining this equipment after the second panel speaks and will be available for further demonstrations and questions after the hearing. We encourage everyone present to stay for these demonstrations.

Mr. ERDAHL. You and I, along with other members of the staff, are here to listen and learn some exciting new breakthroughs in this area of innovation in education. So I am just pleased to be here with you today, Mr. Chairman. Thank you very much.

Mr. BIAGGI. Thank you, Mr. Erdahl.
OPENING STATEMENT OF HON. AUSTIN J. MURPHY, A REPRESENTATIVE IN CONGRESS FROM THE STATE OF PENNSYLVANIA AND CHAIRMAN, SUBCOMMITTEE ON SELECT EDUCATION

This morning we will hear from the Office of Technology Assessment on a report which they have been working on for my subcommittee for the past 2 years which deals with one of the most discussed and controversial issues in the field of education technology. Although technology has been in existence since the early 1950's, it has not been until the latter part of this decade that the introduction of the micro computer into our classrooms and homes has become so very prominent and widespread. Many questions have been raised as to the cost versus the overall educational benefit of implementing such a system into our school settings and other training programs. I am hopeful that OTA's findings first of all be able to inform us of the types of systems being used and the extent to which they are currently being accessed, as well as comment on the social implications, if any, which have been exhibited by the introduction of the computer into the classroom. Will our teachers become obsolete? Will our students become computerized "zombies", resulting in lack of social interactions with others. Should there be some guiding role for the Federal Government or State government in developing a role for computerized education? All of these are questions which have and are still being asked as we enter into this "information age".

Although the development of the technology or "hardware" has been of great importance, serious attention is now being given to the development of courseware to be used by the computer in teaching. Questions have been raised as to the problems which are beginning to surface due to lack of knowledge of school administrators and faculty in selecting courseware what will do more than simply "drill" students. Also since the software/courseware is generally about three times as expensive as the purchase of the computer equipment, it will be necessary for the school district to plan their curriculum programs with future considerations in mind to insure that their software purchase today will not be obsolete within the next few years. These "gray" areas are being researched, and I hope that our other witnesses today will be able to further expound on these questions.

Technology in education is not totally new. However, we have come a long way from the use of projectors and records for our teaching apparatus. Reports by the National Institute of Education have shown that computer assisted instruction does benefit students especially in math and reading, but can technology be of value in other education programs. Hopefully we will see this today. It is important for us here in the Congress to be aware of the benefits and drawbacks to technology development and implementation into our classroom, especially in light of all the legislation which has been introduced during this Congress relating to education technology. The "information revolution" is occurring now, and not something that is a possibility for the future. It is an issue which must be addressed today, to insure the greatest return in the future.

Mr. Biaggi. The first witness is John H. Gibbons, Director of the Office of Technology Assessment.

STATEMENT OF JOHN H. GIBBONS, DIRECTOR, OFFICE OF TECHNOLOGY ASSESSMENT, ACCOMPANIED BY FRED WEINGARTEN, PROGRAM MANAGER, PRUDENCE ADLER, ASSISTANT PROJECT DIRECTOR, AND LINDA GARCIA, ANALYST

Mr. Gibbons. Thank you, Mr. Chairman.

I am pleased to be accompanied this morning by Dr. Fred Wein- garten on my left, who is our program manager for computers and information technology, Prudence Adler, who directed this project that we are reporting on this morning; and by Linda Garcia, a key analyst in that study.

We are pleased to report to you this morning about how education in the United States may be impacted by the wide-scale deployment of the new information technologies, and also, Mr. Chairman, about how some of these technologies might be used to pro-
vide and improve educational services. My remarks are derived mostly from the findings of our assessment entitled "Information Technology and Its Impact on American Education," but also, in part, from information generated in other OTA work having to do with telecommunications and microelectronics.

I would like to submit for the record, Mr. Chairman, a copy of the summary of that study that I will be reporting on, and also a one-page report brief on that.

Mr. Biaggi. Without objection, so ordered.

The Technology Assessment Board approves the release of this report. The views expressed in this report are not necessarily those of the Board, OTA Advisory Council, or of individual members thereof.
Foreword

Over the last decade, American education has come to face a number of new demands that must be met with limited resources. Many of these new demands arise from the growing dependence of our society on high technology as a basis for domestic economic growth, international competitiveness, and national security. In October 1980, the House Committee on Education and Labor, its Subcommittee on Special Education, and the Subcommittee on Science, Research, and Technology of the House Committee on Science and Technology asked OTA to examine the extent to which information technology could serve American needs for education and training.

This report documents two basic sets of conclusions:

1. The so-called *information revolution*, driven by rapid advances in communication and computer technology, is profoundly affecting American education. It is changing the nature of what needs to be learned, who needs to learn it, who will provide it, and how it will be provided and paid for.

2. Information technology can potentially improve and enrich the educational services that traditional educational institutions provide, distribute education and training into new environments such as the home and office, reach new clients such as handicapped or homebound persons, and teach job-related skills in the use of technology.

The OTA report provides an overview of the issues relating to the educational applications of the new information technologies. It examines both the demands that the information revolution will make on education and the opportunities afforded by the new information technologies to meet those demands. Rather than focusing on a single technology, it examines the full range of new information products and services such as those based on the combined capabilities of computers, telecommunications systems, and video technologies. Similarly, the report surveys a broad range of educational providers, and examines how the application of information technologies may affect their abilities to provide education and their respective educational roles.

OTA acknowledges with thanks and appreciation the advice and counsel of the panel members, contractors, other agencies of Government, and individual participants who helped bring the study to completion.

Informational Technology and Its Impact on American Education

Modern society is undergoing profound technological and social changes brought about by what has been called the information revolution. This revolution is characterized by explosive developments in electronic information technologies and by their integration into complex information systems that span the globe. The impacts of this revolution affect individuals, institutions, and governments—altering what they do, how they do it, and how they relate to one another.

If individuals are to thrive economically and socially in a world that will be shaped, to a large degree, by these technological developments, they must adapt through education and training. Already there is evidence of demands for new types of education and training and of new institutions emerging to fill these demands. The historical relationship between education and Government will be affected by the role that Government plays in enabling educational institutions to respond to the changes created by these technologies.

Background

Historically, the Federal Government's interest in educational technology has been sporadic—rising as some promising new technology appeared and falling as that technology failed to achieve its promise. Attention was focused, moreover, on the technology itself and not on the broader educational environment in which it was to be used. In the late 1960's, for example, the Federal Government funded a number of research and development projects in the use of computer-assisted instruction (CAI). Interest in the projects waned, however, given the high costs of hardware and curricula and the failure to integrate computer-based teaching methods into the institutional structure of the school...
Computer-based education is the use of computers for educational purposes. It includes:

1. Computer-Managed Instruction (CMI).—Wherein learning takes place away from the computer, while the computer scores tests, interprets results, advises the student what to do next, and manages student records and other information.

2. Computer-Assisted Instruction (CAI).—Wherein the student receives individualized instruction by interacting via a computer terminal with the instructional material logic stored in a computer.

Over the last decade, federal funding for research and development (R&D) in educational information technology has dropped precipitously. At the same time, development and applications of information technology have advanced rapidly in many sectors. Public schools, beset by problems that such technology might mitigate, have lagged behind in adapting to technological changes. In view of this situation OTA was asked in October 1980 to reexamine the potential role of new information technology in education. The assessment was initiated at the request of 1) the Subcommittee on Select Education of the House Committee on Education and Labor, and 2) the House Subcommittee on Science, Research, and Technology of the Committee on Science and Technology.

This report examines both the demands the information revolution will make on education and the opportunities afforded to respond to those demands. Included in its scope are a survey of the major providers of education and training, both traditional and new, and an examination of their changing roles. The full range of new information products and services rather than any single technology is examined, since the major impact on education will most likely stem from the integration of these technologies into instructional systems.

For this report OTA has defined education to include programs provided through a variety of institutions and in a variety of settings, including public schools, private, nonprofit institutions that operate on the elementary, secondary, and postsecondary levels, proprietary schools, training and education by industry and labor unions, instruction through the military, and services provided through libraries and museums or delivered directly to the home. Information technology is defined to include communication systems such as direct broadcast satellite, two-way interactive cable, low-power broadcasting, computers (including personal computers and the new hand-held computers), and televisions (including videodisc and video-cassette).
The assessment was premised on three initial observations and assumptions:

- The United States is undergoing an information revolution, as documented in an OTA assessment, Computer-Based National Information Systems.
- There is a public perception that the public schools are "in trouble," and are not responding well to the normal educational demands being placed on them. Public schools in many parts of the country are faced with severe economic problems in the form of rapidly rising costs and reduced taxpayer support. These pressures are forcing a new search for ways to improve the productivity and effectiveness of schooling.
- A host of new information technology products and services that appeared capable of fulfilling the educational promises anticipated earlier are entering the marketplace with affordably low cost and easy accessibility.

Findings

In summary, the assessment's findings are:

- The growing use of information technology throughout society is creating major new demands for education and training in the United States and is increasing the potential economic and social penalty for not responding to those demands.
- The information revolution is creating new stresses on many societal institutions, particularly those such as public schools and libraries that traditionally have borne the major responsibility for providing education and other public information services.
- Information technology is already beginning to play an important role in providing education and training in some sectors.
- Information technology holds significant promise as a mechanism for responding to the education and training needs of society, and it will likely become a major vehicle for doing so in the next few decades.
- Much remains to be learned about the educational and psychological effects of technological approaches to instruction. Not enough experience has been gained with the new information technology to determine completely how that technology can most benefit learners or to predict possible negative effects of its use. Given this insufficient experience, caution should be exercised in undertaking any major national effort, whether federally inspired or not, to introduce these new technologies into education.
Hello, class. I am your teacher, Mr....

The Information Society

Role of Information

For the foreseeable future, information technology will continue to undergo revolutionary changes. The microprocessor—an inexpensive, mass-produced computer on a chip—will become ubiquitous in the home and office—not only in the easily identifiable form of the personal computer or word processor, but also as a component of numerous other products, from automobiles to washing machines and thermostats. High-speed, low-cost communication links will be available in such forms as two-way interactive cable, direct broadcast from satellites, and computer-enhanced telephone networks. New video technologies such as video disks and high-resolution television will be available. These technologies will be integrated to form new and unexpected types of information products and services, such as videotex and online information retrieval systems that can be provided over telephone or air waves directly to the home.

It is impossible to predict which of these technologies and services will succeed in the competition for consumer dollars, or which will appeal to particular markets. It is, however, reasonable to conclude that they will radically affect many aspects of the way society generates, obtains, uses, and disseminates information in work and leisure.

The growing importance of information itself drives and is driven by these rapid technological changes. Until a few decades ago, the information industry—that industry directly involved with producing and selling information and information technology—was relatively small in economic terms. It is now becoming a major component of the U.S. economy. While most economists still talk about the traditional economic sectors—extractive, manufacturing, and service—some now have begun to define and explore a fourth, the information sector. One analysis has shown that this new sector, if defined broadly, already accounts for over 60 percent of the economic activity of the United States.

Many firms involved directly with information are large and growing. Two of the largest corporations in the world, AT&T and IBM, principally manufacture information products and provide information services. Moreover, business in general is beginning to treat information as a factor of production that takes its place beside the conventional factors of land, labor, and capital. In addition, the Government is beginning to treat information as an important element of national security. While defense officials have always been concerned about the disclosure of military information—such as troop movements or weapons design—they are now also concerned about the international leakage of more general U.S. scientific and technical information that other countries could conceivably use to pursue economic or military goals that are in contrast to our own.
Information technology is proving to be invaluable to people of all ages.
In addition to serving as an economic good, access to information is becoming increasingly important for individuals to function in society effectively as citizens, consumers, and participants in political processes. Relations with government at all levels are becoming more complex—whether they involve dealing with the Internal Revenue Service, applying for social benefits and services, or seeking protection from real or perceived bureaucratic abuse. Individuals are confronted with the need to evaluate more sophisticated choices and to understand their rights and responsibilities under the laws and regulations intended to protect them in the marketplace.

**Information Technologies**

The rapid evolution of the following technologies in the last few decades has shaped the information revolution.

- **Cable** Cable systems wherein data and programs are transmitted over a wire rather than through airwaves are growing rapidly. The newer systems offer more channels and some offer two-way communication.

- **Satellite** The advent of new types of television networks to serve cable subscribers and earth station owners with specialized programming.

- **Digital Telephone Network** The shift to digital communication will allow telephone lines to carry more information at higher speed and with greater accuracy, providing better linkage of information between computer terminals.

**Broadcast Technologies** Some distribution technologies in the entertainment market may also have important potential educational uses. For one, the direct broadcast satellite can transmit a program directly to a home or office, bypassing a cable system. For another, low power stations, which restrict transmission to a limited geographical range, provide a low entry cost to licensees and are subject to less regulation than are traditional broadcast stations.

**Computers** The design and uses of computers have advanced to the point where there is now a mass consumer market for computers and computer software. Moreover, networks that link privately owned computers have expanded access to information. Desktop computers are becoming more common in the home, the small business, and formal educational settings. The use of hand-held computers, cheaper and more portable than desktop computers, has also increased. Along with computer development have come advances in the interface between humans and computers—input/output technology. Input technology is the process of putting information into the computer—either by typing it, speaking to the computer, or showing the computer pictures. Developments in output technology, or "peripherals," are occurring in the areas of low cost printers, graphics (particularly color graphics), and voice.
Storage Technology.—Data programs are stored on a variety of media for use in the computer: silicon chips, floppy disks, and hard disks. Improvements are being made in such technology for both large and small computers.

Video Technology.—Significant developments in several areas of video technology are likely in this decade. Video cassette recorders are already important consumer devices. The filmless camera, which combines video and computer technology to "write" a picture on a very small, reusable floppy disk, may soon be available.

Video Disks.—Resembling a phonograph record, a disk that stores television programing is of considerable interest to educators. It is durable, inexpensive to produce, and capable of storing a large amount of data and programs.

Information Services.—Several of the aforementioned information technologies are now being integrated into information systems. For example, several countries now use the existing television broadcast medium to bring information services to homes and offices. Using a teletext system, the user can select a page for special viewing as it is transmitted in segments over the air. In a videotex system the user can preselect a page from the central system for immediate viewing. Closely related to videotex are the information networks that provide owners of desktop computers and terminals with access to computer and data services and to one another over communication networks. Through electronic conferencing, geographically separated individuals can participate in meetings. Variations include audio conferencing, which uses telephone lines; video conferencing, which supplements the voice connection with television images; and computer conferencing, which involves transmitting messages through a central computer that then distributes them as requested.

Impacts on Institutions

Impacts from the information revolution are being felt by government at all levels and by the military, industry, labor unions, and nonprofit service institutions. Traditional services provided by these institutions now overlap in new ways and offer a wide variety of new services based on information technology. For example, firms as diverse as investment houses and retail stores now compete with banks by providing a variety of financial services. Banks, on the other hand, are beginning to compete with computer service bureaus in providing more general on-line information services to businesses and homes.

The U.S. Postal Service, along with Congress and a variety of Federal executive and regulatory agencies, is considering the degree to which it should compete with private telecommunications firms in the provision of electronic mail services. Large computer firms such as IBM are moving toward direct competition with traditional telecommunications common carriers such as AT&T for the provision of infor-
Telephone companies may offer "electronic yellow pages" that could rival the classified advertising business of newspapers.

Those institutions principally concerned with the collection, storage, or transfer of information will feel the greatest effects. They include both private sector firms in fields such as publishing, entertainment, and communications and public or nonprofit organizations such as libraries, museums, and schools. How they handle their product—information—may differ from the handling of tangible goods by other institutions because information has characteristics that differentiate it from tangible goods. For example, information can be reproduced easily and relatively inexpensively. It can be transported instantly worldwide and presumably can be transferred without affecting its original ownership. Thus, copyright or other forms of protection for intellectual property, data bases, programs, or chip designs is important to the growth of the information industry.

While the business of selling information has always existed in one form or another, such as book publishing, newspapers, or broadcasting, the growth of this sector and its movement into electronic forms of publishing will create conflicts with traditional societal attitudes about information. The concept of information as a public good whose free exchange is basic to the functioning of society is inherent in the first amendment to the Constitution and underlies the establishment of public libraries and schools. This concept conflicts with the market view of information, which recognizes that there are inherent costs in the provision of information. Adopting new information technologies will entail extra costs that must be borne somehow by the users of these technologies.

The conflict between the view of information as a market good and the view of it as a "public good" affects public institutions in a number of ways. Public nonprofit institutions find themselves increasingly in competition with private profitmaking firms that offer the same or similar services. Institutions such as libraries, schools, and museums are beginning to feel pressure to incorporate both nonprofit and income-generating offerings in their own mix of services. To the extent that previously free or very low cost and widely available information services such as education move into the private marketplace, access to them may become limited either because of their cost or because of their restricted technological availability. Periodicals previously available at newsstands for example may be available only via computer or video disk.

New Needs for Education and Training

The information revolution places new demands on individuals, changing what they must know and what skills they must have to participate fully in modern society. It may also be increasing the social
and economic prices that will be paid by those who do not adapt to technological changes? For instance, spurred by increasing domestic and international economic competition, U.S. industry is expected to adopt computer-based automation in a major way. Computer-aided design, robotics, and other new computer-based manufacturing technologies will, within the next decade, transform the way goods are manufactured. Automation will not be restricted to the factory, however. Office automation will, according to some, have an even more revolutionary effect on management and on clerical work in business. Over the longer term, even the service professions, such as law and medicine, will be transformed.

While some sociologists suggest that the effect will be to "deskill" labor by lowering the skill requirements for workers, more anticipate that a greater premium will be placed on literacy, particularly technological and information literacy. The latter argue that an increasing number of jobs will be in the information sector or will require the use of information systems. Moreover, new forms of production and information handling will create new jobs requiring new skills. Vocational education and industrial training programs will be needed to teach the skills for jobs such as robot maintenance or word processing.

An advanced information society will place a premium on skills oriented toward the creation of new knowledge and the design of new technologies. Thus, while there is some current debate about a possible surplus of college graduates, generally speaking many experts see a growing gap between the demand and supply of graduates in engineering and science, and particularly in computer engineering and science.

A key element in all of these educational needs is that they will constantly change. In a rapidly advancing technological society, it is unlikely that the skills and information base needed for initial employment will be those needed for the same job a few years later. Lifelong retraining is expected to become the norm for many people.

Case Studies on Information Technology

In addition to using existing information for this assessment, OTA undertook case studies designed to gain insights into the successful application of information technology in education. Accordingly, OTA examined well established programs in public school systems, industries, libraries, museums, the military, special education, and direct to the home markets nationwide. These case studies are presented in the appendix of the full report. Many of the findings presented in this assessment reflect observations made in these studies. The most important of these observations is that information technologies can be most effectively applied to educational tasks when they are well integrated in their institutional environments.
Potential Technological Solutions

OTA found little evidence of current hardware limitations that would limit the applicability of technology to education and, hence, call for major research efforts. Continuing research in the general fields of computer science and engineering, coupled with innovative private sector development, will provide the necessary hardware base. The only exception is the area of technology for the handicapped, where it is not clear that the opportunities for developing specialized technology could be met without some Federal support for R&D. There does appear to be a need, however, for R&D focused on developing new techniques and tools for software development, human/machine interface, and improving the understanding of cognitive learning processes.

If properly employed, information technology has certain characteristics that suggest it will be invaluable for education. For one, information technology may be the only feasible way to supplement teaching capability in schools faced with reduced teaching staffs and larger class sizes. For another, information technology is capable of distributing education and training both geographically and over time. Services can be provided in the home, at work, in a hospital, or in any other location where and when they may be needed.

Many electronic media such as video disks or microcomputers allow learners to use them at their convenience instead of being locked into specifically scheduled times. Computer-based analysis, combined with a flexible, adaptive instructional system could diagnose and immediately respond to differences in learning strategies among students and, hence, could be more educationally effective. Finally, much work has been done on using information technology to improve the ability of foreign students and the physically and mentally handicapped to communicate.

Some experts suggest that the use of computers by students teaches them new ways of thinking and new ways of solving problems that may be more appropriate in an information age. They suggest that a generation that grows up with computers will have a significant intellectual advantage over one that does not. Many educators criticize such a view as being too technology-centered. At the very least, one can predict, however, that computer and computer-based information services will be ubiquitous by the next century, and that learning how to use them effectively is a basic skill that will be required for many and perhaps most jobs. In response to this view of future skill requirements, many schools have placed a high priority on computer literacy as the first instructional use of the computer.

Although experience with educational technologies has demonstrated that they offer a variety of potential benefits, it has also demonstrated that technology cannot, by itself, provide solutions to all educational problems, nor should it be imposed on an educational system without sensitivity to institutional and societal barriers that
could prevent the realization of educational benefits. These barriers include:

**Institutional Barriers.**—New educational technology must be designed for ease of integration into the schools and other educational institutions that will use it. Some adaptations of curricula, schedules, and classroom organization will be needed, but the changes are not likely to be extreme.

**Teacher Training.**—Widespread use of technology in the classroom will require that teachers be trained both in its use and in the production of good curriculum materials. Too few teachers are so qualified today. Schools maintain that they are already faced with a shortage of qualified science and mathematics teachers (those most likely to lead the way in computer-based education). Furthermore, there is little evidence that most of the teacher training colleges in the United States are providing adequate instruction to new teachers in the use of information technology.

**Lack of Adequate Software.**—OTA found general widespread agreement that, with few exceptions, the quality of educational software—curriculum material designed for educational technology—now available was, in general, not very good. Curriculum providers do not yet use the new media to full advantage for several reasons. In the first place, many of the technologies are still new. It takes time to learn how to use them, and the early attempts suffer from this learning process. Second, production of high-quality educational software is expensive. Some large firms that have the necessary capital to produce educational software hesitate to risk developmental money in a relatively new and uncertain market.

Third, the programmers and curriculum experts qualified to produce educational software are in short supply. Finally, some firms cite the lack of adequate property protection—e.g., copyright, patents—for their information products as a barrier to investment in development.

**Skepticism About Long-Term Effects.**—Some educators are seriously concerned that the long-term effects on learning of substituting technology for traditional teaching methods are not sufficiently understood. While acknowledging that computers or other technologies may have some limited utility in the classroom for drill and practice, or for instruction in computer literacy, they fear that any widespread adoption of technology for education could have deleterious effects on the overall quality of learning.

**Cost.**—Even though the cost of computer hardware and communication services is dropping, investment in educational technology still represents a substantial commitment by financially pressed schools. Costs of software are likely to remain high until a large market develops over which providers can write off developmental costs. In some cases the cost of information products and services may be passed on to users for the first time.
Policy Issues and Options

Issues

The impact of information technology on education will confront Congress with a number of important policy decisions in several areas:

- **Education and training for economic growth:** OTA found that trends in automation and the growth of the information sector of the economy will probably present the United States with severe manpower training problems over the next decade. These will include a persistent shortage of highly trained computer scientists, engineers, and other specialists; a need for retraining workers displaced by factory and office automation; and a need for a more technologically literate work force. Congress must decide what Federal response to these national needs would be both appropriate and effective.

- **Redressing inequities:** In both the OTA study on national information systems and in this assessment, OTA found concern that a significant social, economic, and political gap could develop between those who do and those who do not have access to, and the ability to use, information systems. People who cannot make effective use of information technology may find themselves unable to deal effectively with their government and to obtain and hold a job. Both social and economic concerns may motivate Congress to take action to improve literacy in American society.

- **New institutional roles:** OTA found that many public educational institutions are under severe strain, to the extent that many question their survival—at least in their current form. Actions directly related to the use of information technology could also have important impacts on these public educational institutions, both by enhancing their productivity and by helping them offer a modern, computer- and communication-based curriculum. Although the States have primary responsibility for control of the public schools, decisions and policies set at the Federal level have influenced the nature of public education and will continue to do so.

Options for Federal Action

Assuming that Congress decides there is a significant need for Federal action to address these issues, there are a number of possible actions it could take.

- **Direct Intervention.**—Congress could take action to increase and improve the use of information technology in education. Most of the following options would principally affect the schools. A few would have a broader effect on the provision of education and training in other institutions.
  - Provide tax incentives for donations of computers and other information technology: H.R. 5573 and S. 2281 are examples of such
initiatives. They are intended to accelerate the rate at which schools install computer hardware and to respond to possible inequities in the abilities of school districts to direct funds to equipment acquisition. However, some experts have noted that the personal computer industry is on the verge of moving to a new generation of more powerful machines that may have much greater potential for educational application on a more sophisticated level. Donations of older equipment could freeze the schools into dependency on obsolescent systems. Moreover, such incentives do not address problems such as the need for software, teacher training, or institutional barriers to effective use.

**Subsidize software development:** OTA found that the most-often cited barrier to current educational use of technology was the lack of adequate educational software. There may be a role for the Government in reducing the risks software producers currently see that inhibit major investment in quality courseware (educational software). Many of the existing successful packages, such as the Sesame Street programs for television and the PLATO computer-aided instruction system, were developed with partial Federal support. On the other hand, good software may be forthcoming if the producers see a sufficient quantity of hardware in the schools to provide them with a viable market.

**Directly fund technology acquisition by the schools:** The Federal Government could directly underwrite the acquisition of hardware and software by the schools. Such a program would create a market for educational products that would attract producers, and it would accelerate the introduction of technology into the schools. On the other hand, it may promote premature and unwise purchases of technology by schools that are unprepared to use the technology effectively. Such a program is also counter to some current trends and attitudes in Congress concerning the proper Federal role in education.

**Provide support activities:** The Federal Government could assume a leadership role in encouraging the educational system to make more effective use of information technology by funding demonstration projects, teacher-training programs, and the development of institutions for exchanging information about successful implementations. OTA found evidence of a high degree of interest and motivation by both schools and parents that could be more effectively channeled with appropriate Federal leadership. Such a program would not address the financial limitations that currently prevent many institutions from acquiring technology and software.

- **Adapt a General Education Policy.**—Congress is considering various forms of education-related legislation that may affect, and in turn may be affected by, the new informational needs of society. Examples are bills concerning vocational education, veterans education, education for the handicapped, and foreign language instruc-
tion. Such legislation, if drafted with the intent to do so, could encourage the development of more effective and economical technological alternatives to current programs.

- **Support R&D.**—Federal civilian agency support of R&D in educational technology has decreased substantially over the last decade. OTA found that, to make the most effective use of technology, there was a need for R&D in learning strategies and cognitive development, methods for the production of effective and economical curricular software, and the long-term psychological and cognitive impacts of technology-based education. Congress could consider policies to: 1) directly support R&D in these areas, 2) encourage private sector investment from both foundations and industry, or 3) encourage a combination of both by using Federal funding to leverage private investment.

- **Elimination of Unintended Regulatory Barriers.**—Some legislation and regulation not specifically directed at education may create barriers to the effective application of educational technology. Telecommunication regulation, for example, can affect the cost of technology, access to communication channels, and the institutional structure of education providers.

Moreover, protection of intellectual property, principally copyright law, was identified as a major determinant of the willingness of industry to invest in educational software. The current state of the law was seen by many industry experts as inadequate and, hence, as creating a barrier to the development of novel and innovative software. However, to the extent that such a barrier does exist, it is not clear whether its removal lies in new legislation or in the gradual development of legal precedent in the courts.

General Information

Informational Technology and Its Impact on American Education

The "information revolution" is profoundly affecting American education and training—creating new demands for instructional services and at the same time providing new opportunities for the improvement and delivery of such services. Whether or not new information technologies will fulfill their potential will depend in part on the kinds of actions that the federal government takes.

Explosive developments in new computer and communication technologies and their integration into complex national and even worldwide information systems have transformed the information industry into a major component of the U.S. economy. Many firms involved with producing and selling information and entertainment technology are large, and rapidly growing. Moreover, business, in general, is beginning to treat information as an important economic resource and, like land, labor, and capital, as a factor of production.

This revolution is creating new demands on individuals. Constantly changing what they must know and the skills that they must have to participate fully in society as both citizens and workers. Further automation and the continuing shift to an information economy will create a greater demand for a greater premium on basic literacy and an understanding of technology. Individuals will have to be continuously educated and retrained. Lifelong education will become the norm.

Many of the institutions that have traditionally been responsible for producing and disseminating educational services public schools, libraries, and museums—may be unable or unwilling to meet these changing educational needs. Faced with a decline in the level of economic, social, and political resources at their disposal, many of them are having to curtail some of the services they provide. On the other hand, new profitmaking institutions are emerging to take advantage of the developing market for special kinds of educational services. As educational services are increasingly provided in the marketplace, some national educational goals may not be met and some educational benefits may become less accessible to all.

The new information technologies can help all educational institutions meet the new demands. They include direct broadcast satellites, two-way interactive cable low-power broadcasting, personal and handheld computers, interactive video disks, and video tape cartridges. Many are already being effectively used in education and training. Experience with them proves that they can be cost effective, versatile, and able to be used in a variety of institutional settings. They can be used to extend education to those who have been denied it due to age or geographical location, socioeconomic background, or physical condition. They can be interactive and engaging.

Notwithstanding the potential benefits of educational technologies, OTA has identified a number of institutional barriers to their use among them being their high initial cost, the lack of high quality programming, and the dearth of local personnel with adequate training. Experience shows that some of these barriers can be overcome if the technologies are carefully integrated with the local social and institutional requirements. Federal and local governments may find it more difficult than profitmaking institutions to overcome these barriers. Federal action may be required to ensure that the benefits of educational technologies are accessible to them.

Information technologies will be increasingly used for educational purposes. Since relatively little is known about the long-term effects on learning of substituting information technologies for more traditional teaching methods, additional research needs to be focused on this question.

Congress could take a number of specific actions to affect the development, educational application, and distribution of information technologies. For example, it might provide tax incentives for donations of computers to schools, fund teacher training programs, or support and encourage the production of high quality instructional software. But such an approach would address only a single aspect of the problem and may generate undesirable and unexpected side effects. If this is to be avoided, a broader approach may be required to take into account the changing needs for educational and training, considerations of equity, and changing institutional roles.

Copies of the full OTA report Informational Technology and Its Impact on American Education are available from the U.S. Government Printing Office in early October. The GPO stock number is 022-000-00388-2. Copies of the report for congressional use will be available at that time by calling 202-224-8909. Summary copies of the report are also available at no charge from the Office of Technology Assessment.
Mr. Gibbons. The OTA assessment was initiated nearly 2 years ago at the request of the Subcommittee on Select Education of the House Committee on Education and Labor and the House Subcommittee on Science, Research, and Technology of the Committee on Science and Technology. Since that time, several bills have been introduced in Congress that pertain either to the growing need for technological and computer literacy, or to the educational applications of information technology. The OTA assessment does not specifically address those particular legislative initiatives; rather, it is intended to provide an overview of the issues.

The report examines both the demands that the information revolution will make on education and the opportunities afforded by the new information technologies to meet those demands. It provides a review of the major providers of education and training, both traditional and new, and examines their changing roles. Rather than focusing on a single technology, the study looks at the full range of new information products and services. Some of their educational applications are being demonstrated here this morning. I must say it is a very fascinating demonstration, and I am sorry I didn't get here earlier.

To gain greater insight about the successful application of these technologies, OTA examined several case studies of their use. These case studies which provided a basis for many of the findings of our assessment are presented in the appendix of our report. Let me briefly summarize what we have learned, Mr. Chairman.

Modern society is undergoing profound technological and social changes that are driven by what has been called the information revolution. This revolution is characterized by explosive developments in electronic information technologies and by the integration of these technologies into complex global information systems. We used to think that the economic wealth and power of the world came from the plastic triad of land, labor, and capital. To that in recent years has been added the notion that energy is one of those great sources. Then later, a broader term, "technology," was added as a source of economic wealth. I think that today we should add information as perhaps one of the greatest key inputs to economic wealth and power.

In the next few decades, information technologies will continue to undergo rapid development and will be applied to an ever expanding number of activities and tasks. The microprocessor, an inexpensive, mass-produced computer on a chip, will become ubiquitous in the home, office, and industry—not only in the easily identifiable form of the personal computer, word processor, and automated production equipment, but also as a component of numerous other consumer products and services. High-speed, low-cost communication links will be available in such forms as two-way interactive cable, direct broadcast from satellites, and further evolution of computer-enhanced telecommunication services. New video technologies, such as video disks and high-resolution television, will also be available. These technologies will be integrated to form new and unexpected types of information processing, retrieval, storage products and services that can be provided over telephone or cable, or be broadcasted directly into the home.
This revolution will affect individuals, institutions, and government—altering what they do, how they do it, and how they relate one to another. Most particularly, it will probably profoundly affect those societal activities, such as education, training, and library services that are dependent upon the acquisition and distribution of information.

The growing use of information technology is already creating new demands on individuals, changing what they must know and the skills that they must have in order to participate fully in a modern society, both as citizens and as workers. Further, computerized automation and the continuing shift to an information economy are creating the greater need for, and placing a greater premium on, literacy and an understanding of technology. The kinds of skills that are needed will be constantly changing. If individuals are to thrive economically and socially in a world characterized and shaped by these developments, they will have to continually adapt through a lifelong process of education and training. The socioeconomic price of not doing so is very high.

The information revolution will also have a major impact on the educational system and on the institutions that have traditionally been responsible for providing educational services. Many public schools, libraries, and museums may be unable or unwilling to adapt to meet the changing educational needs of society. Faced with a decline in the level of economic, social and political resources at their disposal, many of them are having to curtail some of the services they now provide. On the other hand, profitmaking institutions are emerging to take advantage of the developing market for special kinds of educational services. As educational services are increasingly provided in the marketplace, some national educational goals may be compromised and some educational benefits may become less accessible to all people.

OTA found that, Mr. Chairman, that the new information technologies can potentially help all educational institutions to meet the changing needs of society. As our case studies illustrate, these technologies can be cost effective and, in many applications, are already being effectively used to provide education and training in a variety of institutional contexts.

I would like to illustrate this point with a few of the old-fashioned black and white slides to the committee this morning.

Mr. Chairman, I believe we have blown a bulb.

Mr. BIAGGI. We can rely on technology, can't we?

Mr. GIBBONS. Mr. Chairman, I would be pleased to submit to you later some prints of these slides. It is a case of rapid adaptation to a changing environment. We will skip the slides this morning.

The slides indicate, Mr. Chairman, the enormously exciting environment in schools, in museums, in public libraries and in the workplace with the technology of information processing. I think it is amusingly illustrated by the exhibits in the room this morning, sir. We have seen it in the faces of children, and of people in their later years with equal excitement. There is a lot of interaction going on and a lot of new activities. This little microcomputer can add a great deal to the educational experience for people from all walks of life and all ages. It is "user friendly." It leads people along. It can be interactive and engaging. We have direct evidence
that it has enabled some people who are great underachievers and
problem children to turn into very creative, exciting, productive
students. It can be used in almost any institutional setting. And it
can be used to extend education to those who have previously been
denied it due to age, geographical location, socioeconomic back-
ground, or even physical condition.

The widespread application of educational technologies will most
likely alter the roles that institutions play in providing education,
and will blur and maybe even erase some of the boundaries that
have traditionally existed between them. Today, schools, libraries,
and museums are all beginning to use information technologies to
provide a wide and overlapping range of educational services. And
in what can be seen as a major role reversal, children, more often
than not, are now educating their parents about the use of com-
puters. I can speak as an individual witness to that point. Because in-
formation technologies are capable of providing specialized services
to narrow segments of the education market, they will, moreover,
make it easier to produce and to distribute education in the private
marketplace.

Notwithstanding the potential benefits of educational technol-
gies, OTA found that there are a number of barriers to their
use—among them their initial cost, the lack of high-quality pro-
gramming to use on them—that is the software—and the dearth of
local personnel with adequate training in their use. Experience
shows that some of these barriers can be overcome if the technol-
gies are carefully integrated into their social and institutional en-
vironments. Since public institutions may find it more difficult
than profitmaking institutions to overcome some of these barriers,
Federal action may be required to assure that the benefits of edu-
sational technologies are accessible to them.

We are convinced that information technologies will be increas-
ingly used for educational purposes. Since relatively little is known
about the long-term effects upon learning of substituting informa-
tion technologies for more traditional teaching methods, additional
research needs to be focused on this question.

Whether or not the new information technologies fulfill their
educational potential will depend, in part, on the kinds of actions
that the Federal Government takes to assure that these technol-
gies are used effectively and are made accessible to all users. OTA
has identified several areas where it may be appropriate for the
Federal Government to play an active role in its development. Ant-
icipating structural changes in the economy and the growing need
for a highly literate and technically trained work force, Congress
might wish to encourage the greater use of educational technol-
gies for manpower training and retraining. Recognizing the educa-
tional benefits that can be derived from the use of information
technologies, the Congress might take steps to assure that the
public has equitable access to them. Aware of the powerful nature
of the technology, the Congress might take some actions to encour-
age their effective development and use.

Congress is presently considering a number of specific actions
that would affect the development, educational application and dis-
bution of technologies. While any one of these particular actions
will affect the future use and development of educational technol
gies.
ologies, none of them can, by themselves, meet the total challenge that faces American education today. As the OTA report demonstrates, to meet the educational needs of an information society will involve all individuals, groups and institutions. It will require the use of a full range of educational approaches and technologies. It will, moreover, entail overcoming a wide variety of complex institutional and social barriers. And it will necessitate a thorough understanding and the continued monitoring of these rapidly unfolding technologies. I can't underscore more strongly the fact that this system is moving so rapidly that a careful monitoring of that process is essential in trying to stay up with it in terms of actions of Government.

Thus, Mr. Chairman, to foster the effective and appropriate use of educational technologies, the Congress might pay more attention to encouraging the most effective and economical technological alternatives to current programs in place now. Moreover, in areas not directly related to education, such as telecommunications, Congress could, when formulating new policy, make a greater effort to take educational factors into account when considering these other major issues. Congress might also support and/or encourage research and development in three areas. First, learning strategies and cognitive development; second, the tools and techniques for the design of effective and economical curriculum software; and third, long-term psychological and cognitive impacts of widespread use of these education technologies. These are the three areas where OTA found the greatest need for additional information.

In sum, OTA has found that the information age is having a profound effect on American education, increasing the need and the demand for a broad variety of educational services. The problem is urgent. The Nation's educational needs are not now being met, creating a situation that could impede our Nation's economic growth, undermine its international competitive position, and increase and exacerbate the socioeconomic divisions within our society. The new information technologies offer a promising mechanism and, in some cases, the only mechanisms, for responding to these educational needs. Their widespread application will significantly affect how and to whom educational services are provided. Such changes will present both challenges and opportunities for American education.

Thank you, Mr. Chairman. We appreciate the opportunity to summarize this report for you. We would be happy to try to respond to any questions you might have.

[The prepared statement of John Gibbons follows]

Prepared Statement of John H. Gibbons, Director, Office of Technology Assessment, U.S. Congress

Information Technology and Its Impact on American Education

I am pleased to be here this morning to speak to you about how education in the United States may be impacted by the widespread deployment of the new information technologies, and also about how some of these technologies might be used to provide and improve educational services. My remarks are derived from the findings of the recent OTA assessment, Information Technology and Its Impact on American Education as well as from information generated in other OTA work on telecommunications and micro-electronics.
The OTA assessment was initiated in October 1980 at the request of the Subcommittee on Select Education of the House Committee on Education and Labor and the House Subcommittee on Science, Research, and Technology of the Committee on Science and Technology. Since that time, several bills have been introduced in Congress that pertain either to the growing need for technological and computer literacy or to the educational applications of information technology. The OTA assessment does not specifically address these legislative initiatives; rather, it provides an overview of the issues.

The OTA report examines both the demands that the information revolution will make on education and the opportunities afforded by the new information technologies to meet those demands. It provides a review of the major providers of education and training, both traditional and new, and an examination of their changing roles. Rather than focusing on a single technology, it looks at the full range of new information products and services. Some of their educational applications are being demonstrated here today.

To gain greater insight into the successful application of these technologies, OTA examined several cases of their use. These case studies, which provide a basis for many of the findings of our study, are presented in the appendix of OTA's Report. Let me briefly summarize what we have learned.

Modern society is undergoing profound technological and social changes driven by what has been called the "information revolution." This revolution is characterized by explosive developments in electronic information technologies and by their integration into complex global information systems. Over the next few decades, these technologies will continue to undergo rapid development, and be applied to an ever-expanding number of activities and tasks. The microprocessor, an inexpensive mass-produced computer on a chip, will become ubiquitous in the home, office, and industry—both as an easily identifiable form of the personal computer, word processor, and automated production equipment, but also as a component of numerous other consumer products and services. High-speed, low-cost communication links will be available in such forms as two-way interactive cable, direct broadcast from satellites, and further evolution of computer-enhanced telecommunication services. New video-technologies such as video disks and high-resolution television will also be available. These technologies will be integrated to form new and unexpected types of information processing, retrieval, and storage products and services that can be provided over telephone, cable, or broadcast directly into the home.

This revolution will affect individuals, institutions, and governments—altering what they do, how they do it, and how they relate to one another. Most particularly, it will affect those societal activities, such as education, training, and library services that are dependent upon the acquisition and distribution of information.

The growing use of information technology is already creating new demands on individuals, changing what they must know and the skills they must have to participate fully in modern society both as citizens and as workers. Further, automation and the continuing shift to an information economy are creating greater need for, and placing premium on, literacy and an understanding of technology. The kinds of skills that are needed will be constantly changing. If individuals are to thrive economically and socially in a world characterized and shaped by these developments, they will have to continually adapt through education and training. The socio-economic price of not doing so is very high. Thus, for many people, lifelong education should become the norm.

The information revolution will also have a major impact on the educational system, and on the institutions that have traditionally been responsible for providing educational services. Many public schools, libraries, and museums may be unable or unwilling to adapt to meet the changing educational needs of society. Faced with a decline in the level of economic, social, and political resources at their disposal, many of them are having to curtail some of the services they provide. On the other hand, new profit-making institutions are emerging to take advantage of the developing market for special kinds of educational services. As educational services are increasingly provided in the market place, some national educational goals may not be met and some educational benefits may become less accessible to all.

OTA found that, given their potential applicability to educational needs, the new information technologies can help all educational institutions to meet the changing needs of society. As the OTA case studies illustrate, these technologies can be cost-effective and, in many applications, are already being effectively used to provide education and training in a variety of institutional contexts. (Slides) Witness the dimension that the microcomputer, for example, can add to the educational experience. It can be "user friendly." It can be interactive and engaging. An extremely
versatile technology, it can be used in almost any institutional setting. And it can be
used to extend education to those who have previously been denied it due to age,
geographical location, socio-economic background, or physical condition.

The widespread application of educational technologies will, most likely, alter the
roles that institutions play in providing education, and blur the boundaries that
have traditionally existed between them. Today, schools, libraries, and museums are
all beginning to use information technologies to provide a wide, and overlapping,
range of educational services. And in what can be seen as a major role reversal,
children, more often than not, are educating their parents in the use of computers.

Because information technologies are capable of providing specialized services to
narrow segments of the educational market, they will, moreover, make it easier to
produce and distribute education in the marketplace.

Notwithstanding the potential benefits of educational technologies, OTA has
found that there are a number of barriers to their use—among them their initial
cost, the lack of high quality programming to use on them, and the dearth of local
personnel with adequate training in their use. Experience shows that some of these
barriers can be overcome if the technologies are carefully integrated into the social and institutional environments. Since public institutions may find it more difficult
than profit-making institutions to overcome these barriers, Federal action
may be required to assure that the benefits of educational technologies are
accessible to them.

Information technologies will be increasingly used for educational purposes. Since
relatively little is known about the long-term effects on learning of substituting in-
fOrmation technologies for more traditional teaching methods, additional research
needs to be focused on this question.

Whether or not the new information technologies fulfill their educational potential
will depend, in part, on the kinds of actions that the Federal Government takes
to assure that these technologies are used effectively and are made accessible to all.
OTA has identified several areas where it may be appropriate for the Federal Gov-
nernment to play an active role in its development. Anticipating structural changes
in the economy and the growing need for a highly literate and technically trained
work force, Congress might wish to encourage the greater use of educational tech-
nologies for manpower training and retraining. Recognizing the educational benefits
that can be derived from the use of information technologies, the Congress might
take steps to assure that the public has equitable access to them. Aware of the pow-
erful nature of the technology, the Congress might take some actions to encourage
their effective development and use.

Congress is presently considering a number of individual actions that would affect
the development, educational application, and distribution of information technolo-
gies. While any one of these particular actions will affect the future use and develop-
ment of educational technologies, none of them can, by themselves, meet the total
challenge facing American education today. OTA reports that if the public
and educational institutions are to meet the educational needs of an increasingly
diverse population, they will need to develop and implement new educational
practices and technologies. It will require more and greater investment in both
the development of educational technologies and their social and institutional environ-
ments. And, in order to succeed, these actions will have to be matched by an under-
standing and the continued monitoring of these rapidly unfolding changes.

Thus, to foster the effective and appropriate use of educational technologies, the
Congress might pay more attention to encouraging the most effective and economi-

cal technological alternatives to current programs. Moreover, in areas not directly
related to education, such as telecommunications, Congress could, when formulating
new policy, give a greater effort to take educational factors into account. Congress
might also support and encourage research and development in the areas of
teaching strategies and cognitive development, tools and techniques for the design of
effective and economical software, and long-term psychological and cogni-
tive impacts of using educational technologies—the three areas where OTA found
the greatest need for additional information.

In sum, OTA has found that the information age is having a profound effect on
American education, increasing the need and the demand for a broad variety of edu-
cational services. The problem is urgent. The nation's educational needs are not now being
met, creating a situation that could impede the nation's economic growth, under-
mine its international competitive position, and increase and exacerbate the socio-
economic divisions within society. The new information technologies offer a promis-
ing mechanism, and in some cases the only mechanisms, for responding to these
educational needs. Their widespread application will significantly affect how and to
whom educational services are provided. Such changes will present both challenges to and opportunities for American education.

Thank you Mr. Chairman. I appreciate having had the opportunity to summarize the findings in our report, and I would be happy to answer any further questions that you might have.

Mr. Biaggi. Thank you, Mr. Gibbons.

I would like to note the presence of Mr. Murphy, who is the chairman of the Select Education Committee. His committee initiated the OTA study.

I get the impression, Mr. Gibbons, that the implementation of this technology on a broad basis would have to be a very slow and studied process; am I correct?

Mr. Gibbons. Yes, sir. It is, in many instances, requesting a set of activities that are well founded and for some time with us, and it is a matter of the interjection of some brand new things into a system that already exists. But I believe, for that reason, one can expect to see that move more rapidly, for example, in industrial training programs, or perhaps in the Armed Forces. There are some marvelous exhibits here today of that happening.

Because the cost of this kind of technology is still rapidly dropping; and because its power is rapidly expanding, we see it as making profound inroads into our traditional centers, such as schools, museums and libraries in this decade.

Mr. Biaggi. I understand the museums and libraries, that would be a rather static situation. It appears to me that if you are going to monitor it, as you suggested, with relation to ever-improving technology, this is going to be an extremely costly situation.

Mr. Gibbons. Mr. Chairman, whenever one thinks of cost in this regard, it seems to me that one has to think of the cost of doing this versus the cost of what we are doing now or some alternative to it. I believe—and I might ask my colleagues to add to this—that the rapidly falling cost of this technology is now causing it to be in a new kind of era, an era in which the actual cost of acquiring and using some of this kind of technology is actually less than the way we have been doing that same kind of educational service.

Mr. Biaggi. So it becomes cost effective.

Mr. Gibbons. Yes, sir.

Mr. Biaggi. You state in your testimony that the educational services being provided by the profitmaking institutions are ever increasing and, as a result, some national goals may not be met. Can you elaborate on what goals you feel may be given more emphasis and/or less emphasis by profitmaking institutions?

Mr. Gibbons. Mr. Chairman, if I might, while I have some comments I would be pleased to make on it, I think it might be more appropriate for me to ask Ms. Adler or Dr. Weingarten if they would like to respond directly to that question.

Mr. Weingarten. In our study, we didn't attempt to build a priority list of such things. But if one looks at the areas in which the technology is now being developed to serve—for instance, there is a program at the Harvard Medical School that is developing video disk applications for medical training, and there are areas of legal training, business training, and so on. Other kinds of activities, for instance, functional literacy, foreign language training—which, I believe, Mr. Simon is interested in—other areas in which there are
national priorities, do not seem now to be met. That is not a prediction one way or the other, but there is a likelihood that some of these very urgent national needs in education and training may not be the first that are addressed in the marketplace.

Mr. Biaggi. How about the areas of disadvantaged, handicapped and other special populations?

Mr. Weingarten. That is certainly another area. One way of characterizing it is whether or not the beneficiaries have the resources to purchase the education that they might need, or whether or not they constitute a large enough group to be an attractive market, people with particular kinds of handicaps, for example.

Mr. Biaggi. Are these groups currently being reached by the present educational technology?

Mr. Weingarten. We didn't find evidence of much going on in those areas. There certainly is research and development in the area of handicapped and literacy. But as the market for the technological applications develops, we see much more evidence of it developing in areas of higher profitability, those people that have the resources.

Mr. Biaggi. It has been suggested that computers could replace jobs. Did OTA address this factor? Or can we use computers to retrain teachers so that this doesn't occur? It recalls to mind that, some 30 or 40 years ago, the threat of technology hovered above the heads of the American worker, and it was supposed to have displaced all American workers. We find that that supposition by experience, has been debunked. I am just curious how you would respond to that question.

Mr. Gibbons. Mr. Chairman, OTA is currently engaged in a project which has to do with the impacts of computerized automation in the production sector of our economy. We have completed past studies on the impacts of information technologies in some of the service sectors, such as banking and electronic message service and the like. What we see is that this kind of information technology does, in fact, displace jobs, but is also creates jobs, different kinds of jobs. That leads to an environment in which people have an opportunity, in many cases, to have a much more interesting job available to them.

This is one reason, for instance, in Japan today that the workers see computerized automation not so much as a thing that will displace their job as the factor, but will give them, rather, an opportunity to fix robots instead of tightening screws. So they see it as a mechanism for upgrading the kinds of job opportunities that may be provided to them.

There's one caveat. The workers have to train and acquire the new kinds of skills that are required for that new kind of work. But we have several projects that are completed. We have one major project underway which specifically will look at some of those issues.

Mr. Biaggi. How about the retraining of teachers?

Mr. Gibbons. I think some of the examples against the wall this morning in this hearing room illustrates the power of information technologies to provide very effective training and retraining to people in job skills. The fact that industry is using a lot of this now, I think, is indicative of its power. So we believe that this tech-
nology, as we said in our testimony, will not only change the nature of the workplace and the kinds of jobs that are available to people, but the very same technologies can be utilized to assist people in adapting to that change and making it a good thing, not something that is seen as a bad thing.

Mr. BIAGGI. Could you describe some of the more successful projects you have uncovered in your case studies?

Mr. GIBBONS. Yes, sir. I would like again to refer, if I might, at this time to Ms. Linda Garcia.

Ms. GARCIA. We did seven case studies in public schools, and we did some case studies in industrial applications. We look in an overall fashion at libraries and museums and applications in the home. If anything came out of those case studies, it was the need to have a very well integrated approach of getting people involved at the local level, getting teachers even to write their own programming and developing their own skills as teachers by learning the computer programming, and getting business groups and other groups in the community involved building networks so that the technology wasn't intimidating and was comfortable for everyone to use and become excited about.

This was especially apparent in the schools that we looked at which were most successful applications of technology.

Mr. BIAGGI. Mr. Murphy.

Mr. MURPHY. Thank you, Mr. Chairman.

Thank you, Mr. Gibbons, for coming up this morning. I am sorry I was a few minutes late, but I did review your testimony last evening.

I wondered what you might have said about the ranking of the United States in the world of education. Are there other countries that you believe or your study finds are ahead of us in providing educational technological advancements, or do you think we are the leader? Where do we stand?

Mr. Gibbons. Let me lead off in response to that, and I will ask my colleagues to add to what I have to say, Mr. Murphy.

I believe, in the actual use of this technology, the hardware, the development of microcomputers and software packages that go with them, the United States stands second to none in the world.

Its proliferation in the marketplace—there are computer stores here in Washington. You could go out this afternoon and shop around, and shop from any one of a half a dozen different competing stores for relatively low-cost computers and a great wealth of software to go with them. Unfortunately, most of the software—not unfortunately—but, in fact, most of the software is games. There is not that much software on things that one might call a little bit more classic education. But the United States, I think, is clearly, driven by the competitive market system, it seems to me, leading with regard to developing this technology.

I won't say that we are in the lead in terms of how far we are getting along with education, with turning out engineers, computer programers, software developers or mathematicians. We frequently look to the Japanese and to the Soviets both as having instituted very impressive programs in education that we would well watch carefully and look at our own selves on that regard.
In terms of this particular technology, it is my impression that we are in the front, although there is some hot breath on our back in terms of some of the hardware that is being developed, especially in Japan.

Mr. Murray: I take it from that that we are the leader in the production of it and the availability of it. What about the use of it? Where do we stand in that regard?

Mr. Gurness: May I ask my colleagues to respond to that?

Mr. Wurzburger: We didn't specifically take a look at the international rankings of this sort of thing. Trying to order such a complex field as education is difficult.

On the other hand, we certainly found a great deal of concern among the experts in this country that the United States lags, particularly like science and technology education and science and technology literacy. It certainly lags behind countries that have been looked at by, for instance, the National Science Foundation. Countries like Japan, France, Germany, and the Soviet Union all seem to have much stronger programs of science and technology training. Some people estimate that the functional illiteracy level in this country is substantially higher than in any European nation and that that may in turn constitute a long-term economic and educational development.

As far as establishing national rankings, et cetera, commercial organizations certainly will attempt that.

Mr. Murray: I see.

Mr. Gurness: Mr. Wurzburger, do we ever have an educational personnel which I think is not the attitude that we have here?

Mr. Wurzburger: I would not see it as the computer replacing the teacher, but rather the computer being an extension of the teacher's capability to provide for individualized work on the part of the student and assist small groups of students in a classroom environment. So the teacher still has the focus of the classroom environment, but he has a new set of tools that can enable students to move at different pace and in different direction and still in the context of the classroom with the teacher.

Would you like to comment on that?

Mr. Wurzburger: Sure. In fact, one of the concerns that we had behind our interest in front, because we felt that we were doing a whole range of the technology. We really don't understand too well some of these more subtle benefits of the current education as we now practice it.

On the other hand, certainly in the cases that we looked at the technology aimed not only to increase the social involvement of students with each other, students with teachers, and so on. We found no evidence of teacher gone off and sitting in little cubicles by themselves.

In addition to that, there are many current educational approaches. I certainly can remember a graduate
school sitting in lecture halls filled with hundreds of people listening to a lecturer down at the bottom reading his book. We also have to be careful, I think, in each situation what we are comparing it with.

Mr. Murphy: You are, of course, much in the same situation. We are all government, and we are concerned about what our government does. But, as you know, we do have some cutbacks in educational funding right now. We have problems in that regard.

I guess what I would like you to address is that we would seek your recommendation as to what would be the cost of the hardware, the need for training teachers in its use as a teacher aid. What are we talking about in the way of dollars? Where do we get them? How do we get it to a priority level?

Second, if we accomplish that, how do we convince the local educators that we are not boasting some Orwellian instruments on them from the Federal level and that we are mandating, and that we are interfering with the educational process? We will probably face these objections such as cost, cost of the software to the districts. Is it to be federally funded, and then do we keep the Federal Government far enough away from it to satisfy local needs?

Mr. Guirgis: It is a very difficult question to answer, but a very legitimate question. Mr. Murphy, in part, because the cost of these systems is in such rapid flux right now even in a period of months such as a much more sophisticated system for the same price or the same system for a much lower price. So we're dealing with a rapidly moving target.

Fortunately, however, the target is dropping in terms of price. So if anything in the future, it appears to be less expensive than it is at present rather than the reverse in our society.

It strikes me that, in any instance of introducing this sort of thing in the classroom, it again comes back to saying how can we at the local decision level, at the State decision level, and to the degree that the Federal Government is involved, how can we at the minimum utility and productivity, enter an educational system for a given number of dollars? If this utility can be enhanced for the same number of dollars by beginning to incorporate some of this technology into the education and training process, then that is what ought to be provided. It should not be incorporated unless one can do more with the same resources or the same with fewer resources. That ought to always be the governing principle.

It is just that we feel we are crossing a line now very rapidly in terms of cost effectiveness, and that the trend is going to begin to be even more in that direction and therefore merit a lot of attention and, as you say, all the way from the local school board to the Federal Government.

Mr. Brayton: Will the gene... 44

Mr. Murphy: Thank you very much.

I yield back the balance of my time, Mr. .

Mr. Brayton: In relation to the rapidly moving water... you envision new generations of computers rapidly coming on... in our 10-year and assuming that you have some educational institutions implementing the whole technology, they would be dealing with an obsolete instrument? It's conceivable the way the com
puter development is going today. Every 6 months or every year, the companies are coming out with improved instruments.

Mr. Gubitosi: That is a classic concern about making capital purchases in an area where the technology is rapidly moving. It seems to me that to take that into account in making a cost-effectiveness decision, one should say, "Over how many years can my investment pay off?" If it should pay off in 2 or 3 years in terms of what I got out of it, then it is going to be obsolete in 3 or 4 years versus 8 or 7 years, then I should still go ahead.

I think that is a decision that you and I have made, and many of us in terms of buying, for instance, typewriters or word processors or radios or television sets.

Mr. Braverman: Except I remember typewriters being in schools for 10 and 15 years.

Mr. Gubitosi: And there are computers that are 20 years old and still running some of them.

Mr. Braverman: I am not talking about the computer, but I am talking about the teaching ability to teach and utilize and educate the student with the current level of technology. That is the problem. We have machine shops that are still dealing with the old.

Mr. Gubitosi: I have the old wood chip, I have the old milling and turning, and I have numerically controlled machines. It seems that it takes that argument that we should wait until the technology is leveled out and has become a mature technology. Then we will have missed the most important time for ourselves and our children to get up to speed in these skills. It is a tough decision to get at moving target.

Mr. Braverman: I understand that.

Mr. Gubitosi: It has been my impression that I should do it one more time to follow on this. Mr. Chairman, I have been my impression that the major breakthroughs in large scale integrated circuit and low power density machines and the microcomputer are just now the rapidly downard breaking cost curve beginning to turn a bit now. One can see in some of the peripheral equipment such as drives and disk drives and printers and the like that those sets are reaching a sense of equilibrium compared to some of the other technologies involved. It is a tough question. But it seems to me that because a computer might be so enormously more advantageous in running than the equipment we are presently using in the classroom, that it is worth taking a plunge.

Mr. Braverman: I just raised the question that we should have a... you and I not disagree.

Mr. Erdman:

Mr. Braverman: Is that it? I think you Mr. Gubitosi, you are speaking on this whole area, we ran out a thread in" new universe in information gathering and dissemination. It struck me that last week when I was at the Children's Museum. They had an exhibit there concerning the early computer which couldn't get through the entrance doors, and a little clip the size of your
little fingernail that had the same information. We have moved ahead rapidly.

In some ways, your testimony maybe sounds a bit humorous. We think of our priorities as a society, and how the Russians, Japanese, and others seem to be utilizing their technology. I believe Mr. Gibbons said our technology was second to none, yet they utilize it to train people to fix computers, while we sell it to our kids to operate Pac Man and other video games. Maybe that is part of the freedom of our society.

The chairman asked about the use of this in the handicapped area. The question was made about profitability in computer technology. It seems to me that, if we look at this whole area of cost effectiveness, I serve on the Select Education Subcommittee with Chairman Murphy. We should make and stress access not only through a simple tool like the inclined plane made into a ramp for somebody in a wheelchair, but also access to the world of information and ideas.

I think that, as we look at what we have done in this area, these programs have been basically cost effective. They have been good social humanitarian investments, and I think also good economic investments, which we enable people to live independently, to become deinstitutionalized, to enter the job market, and all of these things.

I am persuaded that this new technology can be adopted for access in the broad sense of the word by handicapped people with various disabilities, to stress not so much their disabilities but stress their abilities. I hope that is one thing that we would not ignore and, in fact, one thing that we would stress.

I see some heads nodding. Maybe someone could respond to that, if you wished, one of the members of the panel.

Mr. Gunness: Yes, sir. My colleague pointed out that perhaps I should respond. I admire your statement, Mr. Erdahl, and I would have to agree with everything you have said.

We have just completed some work on technology and the handicapped. It is for certain that this kind of information technology gives a new kind of freedom and economic opportunity for many handicapped people. It also enables one to provide services to handicapped people, to individuals isolated in one way or another, at much lower cost than, for instance, the homebound teacher and other things which would have to be personally delivered to each of these people. So we feel that it does provide a new kind of freedom for people and a new kind of economic opportunities for the handicapped.

Mr. Gunness: Thank you.

Mr. Chairman: Another area would be that of the institutional restrictions that most of us in this committee are involved in. Let's talk about Kentucky. Maybe our study touches on that. What things are being done not only as a development of this exciting new technology, but as far as training people that end up as a classroom teacher in our teacher training colleges and universities? Do you see a good coordination in that direction and area?

Mr. Gunness: We see some opportunities there for improvement.

Mr. Erdahl: That is a good way to phrase it.

Mr. Gunness: Let me ask Mr. Garfield to respond.
Mr. Eriahl: Certainly.

Ms. Garcia: If you look at the university requirements for teachers...colleges, you see that very few schools—-you can count them on one hand—require computer literacy of the teachers. So there is a big institutional gap between teacher training and the ability to teach children in the schools. Certainly some infrastructure among teachers for computer would be needed in order to really have a wide-scale application of the technology.

A lot of schools are actually waiting to introduce computer literacy programs so that teachers are at the level of children. Most children, in terms of comfort with the technology, are above many teachers. I know that in the school where my own son took computer courses, they will not allow adults to take courses with children because the adults are so intimidated by the rapidity with which the children actually learn. I think there is an area for teacher training that needs to be taken into account before you will ever have the infrastructure to develop in schools. Our case studies show that this can be done quite rapidly when a lot of people in the community are involved together. They can be brought up and actually become the people that are using as the resource in the community.

Mr. Eriahl: I had a most interesting demonstration, one of the first that I saw, of the actual experience had leading with one of the machines at the Radcliff Demonstration where the one at Harvard was at a demonstration where the one at Harvard was where we have some more problems that our Grade one and two, and the first grade students are probably intimidated by teaching these machines.

One of the technicians remarked that as members of Congress, we should be bold and reckless sometimes. I don't think that she was just trying to flatter me, but she said I should do it quicker than most people do. As adults, we are kind of intimidated by getting into these. Our kids are so used to calculators and these machines, they just wade right into it as part of their natural life.

But that might create some problems too. If we know how to say 2 and 3 is 5, by punching in a calculator and more complicated problems to a computer do we go through the thought process of determining how that happens? Maybe this is a challenge for educators: not only to punch out the information but to give some basis for the reasons for the information and why things happen in science and in life and in psychology and a lot of other things. Maybe we get the information but we don't go through the thought process. So one of us had to do with a pad and a pad of paper in figuring our math and some things like that.

I don't have comment on that.

Mr. Garfield: I remember as a 12-year-old boy to amplify some signals had to have each vacuum tube and capacitor and resistor to design the box. But now I think that whole function is a little unit that you can plug into a thing. So instead of working at the highly disaggregated narrow level of designing a preamplifier or people now are able to, because that is provided them, spend that same amount of time using time thinking at a higher level of complexity or of aggregation.
It seems to me there is a loss. One does leave behind some of the joy of the detail. But one, at the same time, is enabled to think in broader and, in a sense, more complex ways, and that is part of the good news.

Mr. Erdahl. Thank you very much, Mr. Chairman.

Mr. Brogan. Thank you.

We will now have our second panel. We have Joyce Hakansson of Hakansson Associates, Dr. Francis Fisher, professor, Haverford College; Dr. Linton Deck, Jr., consultant to superintendent, Fairfax County Schools; and Mr. Joe Miller, Migrant Student Research Transfer System, Arkansas State Department of Education, Little Rock, Ark.

STATEMENT OF JOYCE HAKANSSON, HAKANSSON ASSOCIATES

BERKELEY CALIF.

Mr. Hakansson. Mr. Chairman, Mr. Murphy, and Mr. Erdahl, it is kind of frightening to sit here before a congressional committee and to think that one has to, in a few moments, to, in some way influence some things that might happen in this country. But I think that it, it is a very exciting time and a very opportune time to be doing that.

As you know from the Office of Technology Assessment and as you yourselves know, this is a time of enormous change. It has been called a time of revolution, but perhaps more clearly it is a time of opportunity. It is a time when our actions can have tremendous influence on the future of our future and our children's future.

The opportunity in front of us right now is one that deals with the importance of information and technology and how we bring it to our society. We are, in fact, if not to be too dramatic about it, facing the opportunity to make decisions that could either enable our society or empower us in the future.

The technology that we have in our hands today, how we treat it and how we introduce it to our children is going to, in fact, decide whether we, as a Nation, will be able to compete in the coming years, both economically and defensively, and as an influence. As you have heard, we are ahead today, but there is a great deal of activity going on in a variety of countries around the world. There is, in fact, a lot of countries that are rapidly catching up with us.

It seems to me that in order to adequately introduce this technology to the children in our schools, and that is the area that I would like to talk about, precollege education, we really have to think about some of the traditional things that we have been doing the ways that we have been teaching children in the past. How it will relate to the new technology and how we can enhance our curriculum to make better use of it.

We talked a bit about the fact that what children learn will have to be changed or should be changed, let's put it that way. In the past, we spent a lot of time on things like calculation and, as we have heard about designing circuitry. We have taught children for a long time to be sitting at a desk and doing worksheets that are calculations over and over again so that they get precise, so that they will be able to add numbers and subtract. That kind of infor
mation is valuable. But I think that we are going to have to look at a broader scope of education I think now we have to start looking at how we can teach children to do things like estimating and predicting and pattern recognition. If they don't use the computers and the calculators that are available to them, they will be spending much too much of their time on the nit-picking small details and not looking at the total picture.

I am sure that, at some point in the past, there was a group that met together for the preservation of the sundial. I am positive that when clocks and wristwatches first became available, there must have been a group that was around saying, "Wait a minute. We are not teaching our children to read sundials." In fact, they were correct. We were stopping to read sundials. We were becoming, if you will, dependent on technology on the wristwatch on the clock.

The point in fact is that we understood how the planets rotated around the Sun and we began to understand our relationship to the world. We began to have a sense of time. I am sure if anyone tried to tell you it was 12 midnight tonight right at this moment, without looking at your watch you could easily know that it wasn't because you have an intuitive sense of time.

So we must give our children an opportunity to develop intuitive senses of numbers, of actual information, so that they can begin to use the technology as an aid to their learning and their thinking. Another example might be alphabetizing, another skill that we teach early to children. It is needed. You look at a book like a dictionary or an encyclopedia, the way to get through it is A through Z. That makes sense. But when you begin to think of a large data base and you begin to think about being able to punch in or pipe in that I want to know something about a fruit and it is a fruit that grows on a tree, you can begin to see how an apple or an orange can be the outcome of that exploration. One can come through it conceptually rather than alphabetically.

These are just a few of the examples about how our teaching is going to have to change. How our curriculum is going to have to change, to make a merger between children and technology.

I think, also, that we have to be aware of how we are using technology in education, how we are introducing children to technology. There is in many cases the temptation to put the workbooks of today, the drill and practice on a machine and have children respond, if you will, trying to get or decipher what the correct answer that the machine owns and they have to determine is. It seems to me that, by introducing that kind of education in that way we are implying to our children that the machine has the right answer that it owns knowledge when in fact we ought to be teaching children that they are the creative managers of the process, they are the ones that ought to be doing the creative thinking, planning, the growing, and that the machine is a tool, a resource, one of many, but a very powerful resource that can aid them as they grow and learn and decide. So the power should be in the child, in the human being, and the machine must be viewed as a tool or a resource.

It has to be done early. It has to be done very early. The children begin to use these machines. They must be put in control.
We talk often about the machine or the computer or technology. It seems to me that it is very relevant that we understand that a computer is an empty machine without software and without programs to run in it. It is how this software is written and how it interacts with the child that decides whether, in fact, this is a personalized machine, whether it is nonjudgmental, whether it does meet all of the promise that is in a computer.

It is really vital that schools look at their software and the programs they are buying, that they are critical consumers of computer software. It is something that schools and teachers must take unto themselves. They have to evaluate it. They have to be the ones that decide whether they want it in their classrooms.

There is right now, undoubtedly, a dearth of good, acceptable computer software for use in education. I think that there has to be an understanding on the part of education and educators that this is as important a resource as the computer hardware that they are purchasing. It is also going to outgrow very rapidly, as is the hardware. They are going to outgrow it. It is going to become obsolete.

But I think they must get into it. They must in fact make the decisions. They have to allocate funds for it, and they have to support a growing industry because it will not be there without that support. It is a free industry and it should remain that way. It must have a marketplace to thrive.

I think schools must make these decisions. They have to begin to look at how they can provide very real and relevant learning opportunities for the students. If not, they are going to lose their clientele. The affluent, those who can afford to, are going to teach their children and bring these schools of technology into their own homes. They are going for alternative educational resources. They understand the power that knowledge of this technology will have for the future. We will leave our schools as babysitting institutions, and we will leave them to those who cannot make the choice.

I think that we are going to have the danger of a large gap, a power gap, between those who have and those who have not. And I believe that, by having this kind of a gap, we will lose an enormous resource of our country, and that is a number of people who have potential for creative and active participation in society. I think that goes for the disabled as well as the socioeconomically handicapped.

I don't know the role of Congress or of the National Government in this. I would like to see a great diversity of views and opinions expressed right now. This whole industry is much too young to take one direction. We don't know enough about it. We don't know enough about how children learn from it. We don't know enough about how children learn, period. We don't know about what the effect of this technology is on education or how to best integrate it into our institutions. I think we need to have a lot of different views expressed, and I think we need to have a wide diversity of views expressed. Out of that rich mix, perhaps we can find some direction that will meet the needs of our individuals within society.

Mr. Bragg! Thank you.

[The prepared statement of Joyce Hakanson follows]
We are in the midst of a revolution—a change from the mechanical, machine age to the age of information. Students entering our schools today—and in the future—will bring with them a rapidly increasing wealth of experience with computerized devices, including electronic toys, video games, and home computers. An increasing percentage of the careers open to these students when they finish their formal schooling will demand understanding of and facility with computers and similar technological devices. In order to remain relevant in our society, our educational system must keep pace with this technological revolution and prepare our youth to live and work in a technological world.

Unfortunately, not all students share equally in their access to the electronic learning experience outside of the school environment. This disproportionate exposure to technology is often due to socioeconomic factors. The nonaffluent in our culture cannot provide personal computers for their children to use at home. They cannot afford the electronic toys or video games that provide middle class children early experience with technology in an exciting manner.

Often economics alone is not the barrier. It is also a lack of understanding on the part of some parents who have been excluded from the burgeoning impact of technology on business and industry. These parents may not recognize the importance of these toys and tools in preparing their children for the future. In any case, we have the potential for the development of a widening gap between the haves and the have-nots. Those who can afford and recognize the importance of early exposure to technology stand a distinct advantage over their children who are not so lucky.

It is purely a matter of public educational institutions to provide every student access to a maximum of experience using technology as preparation for living and working in a technological age.

Interest and motivation are a must. Teachers, administrators, and students are eager to bring computers into the classroom. As schools reopen this fall many of them will be integrating computer technology into their curriculum. For the first time in history, children will be exposed to the concept of the computer and its potential. A good teacher/administrator and a parent volunteer can make this happen. Low cost microcomputers are available. Depending upon how the computers are being used and whether the students are computer literate, the technology can be integrated into regular classroom activities, making math, science, and art more exciting.

The computer system in any school must include more than just a machine. This system in my view consists of:

1. Appropriate educational software for teaching the students different subjects.
2. A single minicomputer, along with an appropriate software package.
3. Training and support services for teachers.
4. A budget for maintenance.

Obviously, such a system is costly. Costs vary depending on the number of students, faculty, and facility. Some schools have been successful in getting state and federal assistance. Others enter into cooperative arrangements with local businesses, colleges, and industry.

The computer is only as good as the software. Teachers can use the computer to solve problems or perform activities that are important to them. It is unrealistic to expect that teachers will create their own software, just as it is unrealistic to expect teachers to make their own textbook.

The computer is empty by itself. It is the software, the preplanned instructions that bring it to life. The nature and character of the machine are determined by the software. A record player is quiet until a record is placed on it, and then the sounds that it emits are pleasant or distracting as the result of the union of the capabilities of the player with the pre-recorded notes on the record. Sound: that please in
spire, or arouse can all be produced by the same record player depending on which record is placed on it. So it is with computers. They can be programmed to challenge students to think and then allow them to use their own creativity. Or the computer can be used as a task master, forcing students to respond to questions in a narrow, pre-planned fashion. In one instance the person is the creative entity, the manager of the interaction, while the machine serves as a resource, a tool. In the second the machine is the "master," the owner of the correct answers, and the student must strive to find those answers and respond to the machine.

In a very real way, the manner in which we write our software will determine the nature of the education our children will receive and how they will perceive themselves in relation to the technological tools in their world.

The critical shortage of acceptable educational software has been documented and discussed in educational circles, but perhaps it is not inappropriate to mention it one more time. One likely cause for the scarcity of software is the lack of economic incentives for producers and publishers to concentrate their efforts in this area. As long as schools are unrealistic in their planning, and do not allocate funds for the software necessary to turn their hardware into usable tools, they will not foster a growing and healthy educational software industry.

This industry is in its infancy. We are in a stage of exploring and learning about how to effectively use this medium and no one knows the so-called right answer because we are exploring. It is important that as many diverse approaches as possible be explored. Out of this rich mix we should be able to accommodate a broad range of individual differences and needs.

It is apparent that society is undergoing fundamental changes, especially in the area of information, accessibility and use. Our institutions must adapt and when appropriate change to best meet the needs of the individuals within society. Parents and educators are interested in the information technologies, want to learn about them and want to understand how best to incorporate them into our educational systems. Problems arise due to the lack of understanding of the capabilities and limitations of these new intellectual aids. There are no models to follow, this is a new road and we must be flexible to learn from our experiences, our success, and our mistakes.

There are no "right" answers to the questions we are facing, but the implications of our choices must be carefully considered and the results weighed. The role of government must be to provide the leadership needed to protect our national values while encouraging progress.

Mr. Biaggi Dr. Fisher.

STATEMENT OF FRANCIS FISHER, PROFESSOR, HAVERFORD COLLEGE, HAVERFORD, PA.

Mr. Fisher Chairman Biaggi, Chairman Murphy, Congressman Erdahl, and Congressman Petri, it is an honor to be here this morning on the occasion of the release of the Office of Technology report. I look forward, as I am sure all of us do, to reading it and to studying it, and to offering comments on it when it is available.

Today, I can perhaps help the committee by making two sorts of comments addressing two issues. Why, if we have these wonderful demonstrations before us that are so effective in education and training, do we have a problem? Second, there is the question of what is the proper Federal Government's role in providing educational materials with the new technology.

It will be all too soon apparent that I am not a technologist. I am a lawyer who wandered into this field of education through public service. I would like to acknowledge publicly here the support of the Ford Foundation and the Carnegie Corp., which has permitted me to investigate these questions, and particularly the question of why don't we have more good courseware, and whether the free market alone can be expected to provide it to us.
In the summer of 1981, with their help, I was able to ask a wide
group of computer manufacturers, software producers, superinten-
dents of schools, cognitive scientists and others as to their views. I
don't represent any of them this morning. I mention that to give
you a sense of my background and where I am coming from. I am a
convert. I believe this means of instruction is very powerful, as I
think anybody who experiences it must have that feeling.

Congressman Murphy raised the question of whether it may lead
us to a more regimented way of thinking. I think, quite the con-
trary. The power of this device is its power to interact. That per-
mits it to become an individual instructor, much closer to the in-
dividual human tutor. Comparison isn't really fair of a human tutor
and a computer. The correct question is: how does the individual
instructor of the computer compare to the classroom situation, where
the vast majority are rather bored by the pace of instruction and
the slow students aren't understanding what is going on? The
power of individualization means the computer can quickly assess
where the learner is at and deliver material that is suited to that
particular individual. That I submit is a very humane form of in-
struction.

One thing that is very important is the perception of the student. The
student's perception is that the pace is in charge for the first time and
they are getting exactly what they want in a form that they can com-
prehend and that they can learn from. Comparison isn't really fair of a
human tutor and a computer. The correct question is: how does the
individual tutorial of the computer compare to the classroom situa-
tion, where the pace is set by the teacher and the slow students
are left behind. That is how learning generally happens. That is how
the individual tutorial of the computer is different. That I submit
is a very humane form of instruction.

We will see examples of that here. We will see technology integrate
graphics and visual pictures with words and numbers in a way that is
better than before this, and that is very powerful and engaging. Some-
times it is too engaging. While I think it is a little fun and makes
learning better, it can also be a diversion. We will want to have
that question in mind as we look at some of the examples.

We won't be able to see here today how this material integrates
into a curriculum into a classroom setting. I hope that those ques-
tions will be left in our minds. Do the teachers know how to use it?
Is it part of a longer curriculum or is it just one little wonderful
example of what can be done?

We will see these very good examples, and I think we must bear in
mind the conclusion of many observers of the scene that there is
not very much good commercial software available. There is of course as
Professor Karen wants adequate commercial software. I think that was
true.

The research of the National, the National Science Foundation, Dr.
Epstein, asserted: "The most pressing problem in the education of
high-quality educational software.

The former Director of the Division of Science Education and
Research of the National Science Foundation, Dr. Epstein, asserted:
"We find a key bottleneck is the lack of excellent course materials
and software." Columbia University's Teachers College's programs currently available do not make full use of the learning poten-
tial of classroom microcomputers." The education editor of the
New York Times, in an article that I cite, complaints about the shortage of high-quality courseware. In a study done for the National Institute of Education by the consulting firm Bolt, Beranek and Newman: "The first and, in some sense, the most obvious obstacles is the generally poor level of educational material available for the microcomputers at present...

The Apple Computer Co., who is going to be demonstrating here, is now publishing a review of courseware. I think it is extraordinary that it shows also that even the manufacturer of a computer, in reviewing courseware, finds it so often wanting in quality.

Why is this? There are a number of reasons. Producing good courseware is expensive. It is more like producing a movie than like authoring a book. It demands a lot of different talents, subject matter expertise, media expertise, expertise on pedagogy, which all have to be brought together.

I found there wasn't a very good flow of information from the people who knew cognitive science to the world of educational publishers. Educational publishers are familiar with schools, but they are not very familiar with computers, and they are hard pressed financially today. They are not likely to make the long-term investment to study the theory of how you can use this technology for better education.

The greatest impediment to the production of good courseware, I believe, is an adequate basic knowledge of how the media can best be used for education. We need a strengthened body of knowledge which expands educational psychology and cognitive science to form a basis for sound programming.

I haven't read the OTA report, but on the last page of the summary document that was referred to this morning, OTA found that to make the most effective use of technology, there was a need for R & D. in learning strategies and cognitive development, methods for the production of effective and economical curricular software, and the long-term psychological and cognitive impact of technology-based education.

That leads to the question of the Federal Government's role. Who is to do that? That is not a likely undertaking for private enterprise. Why not? Because they are going to be unable to capture the full value of what they discover. This may be a rather simplistic example, but if I do research and discover that 2 and 2 is 4, that is terribly important for society, but my company is not going to be able to get a lot of value return on the sort of investigation and research that may have lead to that truth. The truth of cognitive psychology and how we can learn from these machines will be generally terribly valuable to our society and will feed the industry of private software producers. But the generation of that knowledge is clearly a public activity, the value of which is going to go to the public good.

Let me give you an example. We will see programs, I am sure, where the computer asks the student a question, and the student answers. The student is wrong. Now, what is the best educational course of action for the computer to do next? Tell the student immediately the student is wrong? Maybe the student is having an off day and knew the answer all along. Should we wait for two wrong
answers before the tutor intervenes? How do you intervene? With what strength of intervention? Do you say, “You are wrong, the right answer is this”? Do you say, “Why do you think 2 and 3 are right?” What leads you to that?

In view of the nature of the drill and practice technology, that is a terribly important question: What is the optimum form of tutorial intervention?

Who is going to do the research and develop that theory and make that available to those who are going to produce? That is clearly a public activity, the value of which is going to be recaptured by the public. It is not likely to be an activity that a local school system can undertake. There may be a few State colleges of education which, with some help, might undertake some research in that direction. But I think there is an enormous area to meet this problem of quality of courseware which clearly demands a major Federal effort of the kind that has been laid out for you by the OTA report.

Thank you, Mr. Chairman.

May I say one more thing? The last paragraph of my testimony refers to a dollar figure of research. In reading this morning, it seemed to me that it confused the level of research and a full program level. I think it is a confusing paragraph for the committee and I would ask permission from the chairman to have it deleted from my prepared testimony.

Thank you.

Mr.制动er. W. I think.

The prepared statement of

Chairman Perkins: Chairman Murphy and members of the committees, it is a pleasure to be with you today as the Office of Technology Assessment releases its report on the effects of technology on our educational system. I look forward to discussing this report with you as I am sure all of us do, in reading it and studying the information and policy options which the report presents. I look forward also to the occasion when it will be appropriate to provide these committees with comments on the report.

Today, I want to draw on my own experiences to help provide the committees with two things.

In context of which to view the demonstrations that will follow, testimony that is how to recognize good courseware and whether the good courseware we see is representative of what is generally available to help educate Americans. It is my view that of many others that good educational software is in short supply and for that reason our country is missing extraordinary educational opportunities which the new technology offers us.

A way to assess the proper role of the Federal government in this research and development effort necessary to put the new technology to good educational use. My investigations lead me to conclude that for good reasons the market will not of itself make the investment in the research and development of courseware which could provide enormous benefits to the nation if in the individual homes.

It will seem to be apparent that my background is not that of a test administrator, but a lawyer who has entered the field of education from public service and who has only recently become concerned with the public policy issues which are presented by the use of the new technology in education.

I would like publicly to acknowledge the support that has been provided me by the Ford Foundation and the Carnegie Corporation in my review of the quality of the software used in computer-assisted instruction and in considering the basic whether we can reasonably rely exclusively on the free market to provide the good courseware we badly need in order to take best advantage of the new technology.

In the summer of 1981 I was thus able to discuss these questions with a wide range of knowledgeable experts: computer manufacturers, software producers, educational publishers, professors of cognitive science and school administrators. Since
then I have conveyed my interest in the use of the new technology in education and have assumed an advisory role with Channel 13/WNET in New York as it seeks to define just how the new technology should alter its educational function. I have also addressed the question of the impact of the computer on higher education, with special reference to the social sciences and humanities. Today I am not speaking on behalf of any of those interests. They are mentioned so that you will have a better idea of my background.

1. THE POTENTIAL

**Instruction Individualization** — I am a strong believer in the potential value of the new technology for education, as I believe anyone would be who has experienced the best examples of what can be done. The new technology, unlike the much acclaimed previous technologies radio, audio-visual aids, television, comes much closer to doing what a human teacher can do: interact with the learner. Interaction is the key to its potential effectiveness, for it permits individualized instruction. A program of computer-assisted instruction can quickly determine the learner's achievement already attained by the learner and adjust the delivered material so that it meets the needs and ability of that particular student.

A natural question is how can the computer be as good as or better than a human teacher? But a fairer question is how does this individualized instruction, made possible by investment in machines and programs, compare with instruction in a classroom? For as the Congress has been previously advised, the average American school child may interact with a human teacher for only one or two minutes a day.

As we examine the programs to be demonstrated to us following the testimony, we should be looking for how well this ability to individualize instruction is taken advantage of.

**Learner control** — A corollary to individualized instruction is learner control. It is an understandable initial reaction to the idea of computer-assisted instruction that it must be mechanistic, cold, impersonal. But to the learner who may be finding for the first time that he or she can control the pace, the sequence of learning steps, the degree of repetition, indeed perhaps the very time and place at which learning takes place, the computer may seem a particularly humane form of instruction. In a classroom, too often the slow are left behind and the fast learners bored.

**Graphics and visual images** — The new technology permits an integration of pictures with numbers and words in a flexible format. This has particular value where a physical process is the subject of instruction, as anyone knows who has tried to make a repair on a piece of machinery guided only by a written manual. Increasingly, as we will be shown today, sound also can be used in an electronic interactive form.

But visual imagery or sound, while possible, is not always appropriate. It may add attractiveness but nothing necessary to the educational power of the program. While some learning is aided by being fun, some fun diverts from education. In the programs to be demonstrated, we will want to observe to what purpose these capabilities of the new technology are used.

**Drill and practice, tutorial and simulation** — Computer-assisted instruction can be used in different forms. It can drill students reporting whether the answer preferred is correct or not, and repeating problems of the sort which the student finds difficult. A tutorial form employs a variety of responses that drill and practice programs. It reports to student input and exploits the branching capacity of computer programming, allowing as its name suggests, the individualized give and take of a tutorial session.

The computer can also provide an environment with little of the necessary pattern or required learning path, offering instead great opportunity for a learner to exercise the ability to exercise choices in much greater number than could be done in a real world situation. One can learn to fly an airplane, conduct a chemistry experiment, orchestrate a melody, graph algebraic equations, and quickly vary your choices after experiencing the response of the program.

**Integration into a curriculum** — Courseware comes in different sizes. Some can replace the brief paragraph or diagram that a teacher might write on the blackboard. Other programs might substitute or supplement a curriculum of several years. In either case the educational value is likely to depend on how the new technology is.
integrated into a large educational experience. We will want to ask of what we see today, just how that is being done.

Freedom of time and place.—While the value of computer-assisted instruction will reflect the extent to which it is part of a progression of educational experiences, these experiences need no longer necessarily take place in a particular classroom at a particular hour. This freedom of time and place should permit education more convenient for the learner. While this may enhance educational productivity it raises issues of fair distribution for those concerned with the justice of access to public education. More about that later.

II. NOT ENOUGH GOOD "COURSEWARE"?

While there are examples of excellent use of the new technology for education, there are few. I assume that we will be seeing some of them today. But the conclusion of my investigation is that there is very little courseware that fully exploits the educational potential of the new technology. Others who have reviewed existing courseware have reached the same conclusion.

The Report of the Congressional Research Service for the Subcommittee on Science, Research and Technology of the Committee on Science and Technology entitled "Information Technology in Education: Perspectives and Potential", issued December 1980, concluded: "The most pressing and important problem of development is the creation of high-quality educational courseware" p. 3.

The former Director of the Division of Science, Education and Research of the National Science Foundation, Dr. Joseph Lipson, has asserted: "We find a key bottleneck is the lack of excellent course materials and software. Almost every expert and relevant government official whom we have contacted makes this observation" Lipson p. 344.

Education Week, March 31, 1982, reports a study by Vicki L. Blum, a researcher at Columbia University's Teachers College concluding that "programs currently available do not make full use of the learning potential of classroom microcomputers and that programs of questionable educational value flood the market." (Education Week)

In an article entitled "Computer Software Found Weak", Fred M. Hechinger, the education editor of The New York Times reports the Cohen study and another by Karen Sheingold, of the Bank Street College of Education in New York, which also complained about the shortage of high-quality software and the general failure to integrate computer-based instruction into the overall curriculum. (New York Times, April 20, 1982).

In a report "Microcomputers in Education", prepared for the National Institute of Education, Feurzeig, Horwitz and Nickerson of the consulting firm Bolt, Beranek and Newman listed problem areas that posed obstacles to achieving the full potential of computer-assisted education. The report states: "The first and, in some sense most obvious, of these obstacles is the generally poor level of educational material available for microcomputers at present. The development of such software is essential before the educational opportunity represented by declining costs of hardware can be fully realized." Feurzeig, Horwitz and Nickerson, p. 28.

I also refer the Committees to the two excellent issues of a review of microcomputer software now appearing under the name The Apple Journal of Courseware Review. One is strung that even those with an interest in promoting the sales of computer hardware report that educational software is not what it should be. (Apple Journal of Courseware Review)

I will be surprised if the OTA study does not reach the same conclusion as to the inadequate supply of good courseware. Indeed, there is no longer a need to study that problem, there is a need to do something about it.

III. REASONS FOR SHORTCOMINGS OF EDUCATIONAL SOFTWARE

There are a number of reasons why better software is not being produced. In part, the development of good software is expensive. It is more like producing a movie than publishing a book, involving a number of quite different skills: computer programming, subject matter expertise, knowledge of curriculum-relevant pedagogical skills, how do we really learn to spell, and a new knowledge of ways of exploiting the new media.

I found in my investigation that there was not a good flow of information from the academic community which knows about cognitive science to the world of educational publishers. Educational publishers, while familiar with schools are not famil...
lar with computers, and are hard pressed financially, not looking for long-range large research for investment. The new cottage industry of educational programmers are innovative, but unlikely to be knowledgeable about the theory and practice of learning nor are they well financed. Their products are typically small programs, rather than large pieces of a curriculum. (Fischer, ref A)

But the greatest impediment to the production of good courseware, I believe, is an inadequate basic knowledge of how the media can best be used for education. We need a strengthened body of knowledge which expands educational psychology and cognitive science to form a basis for sound programming. In brief, we need to know better how we learn, and we need to know that with particularity, for the new technology demands particular design, whether in a courseware program or the design of an electronic environment in which learning can take place. Indeed this demand for more precise knowledge of the learning process is helpful in driving the necessary research.

I should point out also that research in education demands extensive and long term field tests and evaluation. We may note obvious shortcomings in courseware and be attracted to what we believe are good programs, but the ultimate test of educational effectiveness is whether it actually instructs. For such evidence we need long term evaluation and controlled experiments.

This research and development effort needed is a large order, but we know the fruitful paths to pursue. Indeed the efforts of the National Institute of Education and the Science Education and Research Division of the National Science Foundation were supporting exactly the kind of work needed. Unfortunately, these efforts have been cut back or suspended.

IV. ROLE OF THE FEDERAL GOVERNMENT

Why is the federal government necessarily involved? It was the purpose of the investigation I conducted for the Ford Foundation to see whether we could reasonably expect the necessary development investment to be undertaken by private enterprise. It was my conclusion that this was not a job which the free market alone could accomplish. This is in part for the reasons already referred to, the large amounts involved, the long time required for obtaining a return on investment, the lack today of enterprises which combine the necessary expertise involved.

But more fundamentally, it is because the return on the investment will run largely to society in general and cannot be captured by an individual commercial enterprise. It is somewhat like investing in the development of arithmetic and concluding on the basis of research that 2 + 2 = 4. The discovery of principles of cognitive science and educational psychology and linking them to the use of the new technology is valuable, but the value mostly accrues to society as a whole.

Particular developers of courseware may be able to protect to some degree their specific newly developed computer programs through copyright or technical procedures that make copying difficult, but the big truths about how we learn, more specifically how we learn with the new electronic media, will not be, nor should they be, private property. But because that knowledge is a public good, a valuable public good, it will only be the public that can obtain a return on the necessary investment in research and development. Either the public accepts the opportunity of seeking the knowledge on which good courseware must be based or that knowledge will not be produced in the quality and quantity which the promised social returns fully warrant.

It will be interesting to see the extent to which the good demonstrations we are about to see were supported in their development by government funds, or depended on work which was in turn so supported.

I will not repeat here the importance of improving our education. The members of these committees are fully cognizant of how our economic productivity, national security and human fulfillment depend on good education. But what I want to emphasize is that the particular improvement that this new technology offers will not be realized without government action. One can concur as I do, with the policy that government should not act where others will and still conclude that the research and development which must precede the production of compelling examples of good computer courseware must be supported by government.

And I would suggest that while the delivery of education and the ultimate choice of curriculum is appropriately a matter for local school districts, those institutions of government are not best served for promoting a program of research and development.

Mr. Chairman, members of the committee, I recommend that the OTA report be promptly sent to the Department of Education and the National Science Foundation.
tion, and that both be requested promptly to inform the committees of their comments and suggestions and to report on what they are currently doing and propose to do in fulfilling the federal role so that this country will exploit fully and advantageously the new technology.

(4) That a series of hearings be scheduled now at which the committees can be more fully informed by the concerned sectors of our society as to their reactions first to the OTA study, after having had a time to study it, and the responses of the Department of Education and NSF to the questions listed above.

In June of this year I was privileged to attend a conference on research in computer-based education, arranged by Fred Hofstetter of the University of Delaware, who is with us today. I came away awed by the developments in computer-based technology, as I am sure we will be awed by what we see here today. From what was reported there it seemed to me clear that in a not distant time, 10 years or 15 perhaps, we would have electronic machines that for practical purposes could do anything you wanted. The problem is that we do not know what we want them to do. I very much believe that if we bent every effort to explore that question, we will not be ready fully to exploit ourselves of the increased power that is coming our way, as we are not using the power that is currently available to us.

I do not know the appropriate size of the effort we should be making. A research and development effort in electronic courseware of $100 million a year would not restore us to the level of productive effort we were recently making, so it is a safe starting point. The exact magnitude and kind of effort beyond that should be quickly settled. I trust the OTA report will help us do exactly that.

Thank you.

Mr. BAETZ, DECK

STATEMENT OF LINTON DECK, JR., CONSULTANT TO SUPERINTENDENT, FAIRFAX COUNTY SCHOOLS, FAIRFAX, VA.

Dr. Deck Good morning, Mr. Chairman.

I am Linton Deck. For the past dozen years, I have been the superintendent of schools in three large school systems in Georgia, Florida, and, most lately, in Fairfax County, Va. During this current academic year, I will be a senior associate for the advanced study at Vanderbilt University, where I will be taking a hard look at a number of issues about which we are talking this morning.

I am very pleased to have the opportunity to speak to you this morning and to make some direct recommendations on the basis of
a number of comments which have already been made. I would like to indicate that Chairman Murphy’s letter of invitation to appear here this morning asked that I speak to eight areas. In my written material, I have attempted to do that. I am going to summarize that very quickly, if I can.

Let me start by saying that in the State of Florida in 1979, I chaired a commissioners task force to look at a number of these issues. When we made our report to the legislature of that State and to the Commissioner of Education of Florida, we summarized our efforts by saying that we believe Florida could not afford not to invest in this technology for use in schools in the State. I want to paraphrase that this morning and say that I am convinced that the United States cannot afford not to invest immediately in this technology for use in the schools throughout the Nation. There are a number of ways to do that, and I tried to make comments about those in the written material which I have submitted.

Dr. Fisher’s comments about the development of the quality of software right now lead me to make a recommendation about a strategy for how I believe that can be done. I believe that the development of public/private consortia for such development is a very promising strategy. During the past 10 months, I have been personally involved in an effort to establish a consortium of several school systems, a publishing corporation and a university. While we have not yet brought those efforts to closure, the experiences we have had in this effort lead me to believe that it is a truly promising option for the development of quality instruction material and courseware, and the need for quality software national attention and national action, in my view.

I am going to recommend in a moment a plan which would nurture the development of consortia of that sort to help in this problem.

I think everybody understands that training and the levels of understanding which teachers and educational managers have in our schools represent a big need. It is very clear that teachers, however, in my experience and in my view, would respond to sound training, and would and could utilize intelligently the machines that are available and as quality software can be made available to them. But training is a very widespread problem.

In a very recent survey of more than 130 teachers education institutions in the southeastern United States, it was indicated that less than half of them offer any kind of in-service training on microcomputers for the education faculty in those institutions. David Moursund, a scholar in this area, a professor of computer science at the University of Oregon, estimates that as few as 5 percent of the more than 1,350 teacher-training institutions in the country offer undergraduate courses in computer education, and a very small fraction of these include such courses in their degree requirements. So the need for training is very clear and obvious.

I want to make one argument, though, to say that that training should include not only teachers, but educational managers.

With that caveat, let me turn to the specific proposal I would like to make as a basis for your deliberation and consideration.

I believe that there are three areas of focus of the funding problems related to the use of computers in the schools that deserve na-
tional attention. The first is the cost of computers themselves; second, the cost related to the development of the quality courseware, which Dr. Fisher has alluded to; and third, the training needs which exist in the schools. I want to emphasize that both classroom practitioners and educational managers need support and assistance in learning how to utilize the potential represented in the application of computers in our schools.

Educational managers need help in thinking through the issues of how to develop new budgeting philosophies and techniques so as to find ways to make it possible to put computers in the school and provide the programs that are necessary to work with private sector personnel and university personnel.

I want to emphasize in the very strongest way that focusing on the training needs of teachers without giving attention to the needs of educational managers to learn how to help teachers get the job done would be shortsighted at least, and wasteful at worst.

Support systems for intelligent use of computers in the schools cannot be built nor maintained unless principals, superintendents or other educational managers have the opportunity to become literate in regard to these machines and develop the understanding necessary to oversee and facilitate appropriate program development.

I could also develop, and hope that I have in the root material, a very strong case for the training needed by teachers. So I want to recommend to you for your consideration action which I believe is badly needed. Action in the form of a 5-year implementation program involving components of training, software development and software acquisition.

One way to begin this action would be to focus on secondary math and science teachers. That is just one way, but it is a good one. In my judgment, an action of this sort ought to focus on providing training for approximately 33,000 math and science teachers each year over the next 5 years, and 2,000 other educational practitioners, principals, curriculum coordinators, and other educational managers. I believe this could be done in a sound way using what I call an NDEA, National Defense Education Act, training model, at a cost of about $10 million a year for the next 5 years—that is, $300 times 35,000 teachers and educational managers. I believe that would be a reasonable way to begin.

An estimate for the current investment in the development of courseware would be about $10 million. I believe that congressional action ought to double the present investment for the next 5 years, that is, to allocate $10 million per year for software development. That matches what is being done in the private sector, and I believe that matching arrangement ought to be done so as to nurture the establishment of consortia of the sort that I mentioned a few minutes ago.

The schools must acquire this software as it is developed, through consortia arrangements or whatever. So I urge that you consider appropriations for software purchase. I suggest an investment of about $20 per student. This would amount to $50 million per year for the next 5 years.

So, in summary, I recommend a program of action to focus on improving math and science education through the use of computers.
technology over the next 5 years involving components of educational practitioner training, software development in public/private consortia, and software acquisition in the schools. The total cost would be $350 million over the next 5 years, or $70 million per year. I believe that set-aside appropriations for research and development on the issues and problems involved in the adaptation of computer technology in the schools should amount to 10 percent of that, or $7 million per year.

I believe that any program of action that you undertake should include review of public policy and law as well as funding. It has been pointed out earlier this morning that attention needs to be given so as to facilitate the development of courseware about which we have been talking here and to enhance the feasibility of computers being made available through the vehicle of legislation which has already been introduced in the Congress.

I urge all of you and your associates in these two subcommittees to do everything possible to implement a program of action such as has been suggested here.

I thank you for the opportunity to make these suggestions on behalf of the young men and women who make up the student bodies of the schools throughout the United States. Thank you, Mr. Chairman.

Mr. Biaggi. Thank you.

[The prepared statement of Linton Deck follows:]

PREPARED STATEMENT OF LINTON DECK, CONSULTANT TO SUPERINTENDENT, FAIRFAX COUNTY SCHOOLS, FAIRFAX, VA

I. INTRODUCTION

How pleased I am to have the opportunity to present these comments to the hearing of the House Subcommittees on Select Education and Elementary, Secondary and Vocational Education.

My name is Linton Deck. During the past dozen years, I have been Superintendent of schools in three large school systems in Georgia, Florida, and Virginia. Most recently, I have served as Superintendent of the Fairfax County Public Schools in Fairfax, Virginia, which is the tenth largest school district in the United States. During this 1982-83 academic year, I will be a Senior Associate for Advanced Study at Vanderbilt University in Nashville, Tennessee. This assignment will provide opportunities for post-doctoral study of many of the issues addressed in this presentation. For the past several years I have been increasingly interested and concerned about the implications of computer technology for the public schools of the United States. In 1979, I chaired a task force appointed by the Commissioner of Education in the State of Florida to study the implications and impact of computer technology in the schools of that state. During the past two years I have been a member of the Advisory Committee on Technology in Education of the Office of Technology Assessment.

The letter of invitation which I received from Chairman Murphy and Chairman Perkins requested that I address the need and increasing demand for computer technology and program software; the problems incurred not only in financing such systems, but those arising from parent and teacher objections to implementing such systems, as well as the effects which this technology is and will continue to have, good or bad, on not only our children, but on our society as a whole. That is a very sizeable assignment, and I hope that this document responds in some useful way. In response to the request of the Chairmen, this presentation is organized in nine sections.

I. INTRODUCTION
II. NEED FOR HARDWARE
III. NEED FOR SOFTWARE
IV. FUNDING PROBLEMS
V. PARENT OBJECTIONS

[Page 1]
VI. Teacher objections. (Page 16).
VII. Effects on children. (Page 19).
VIII. Effects on society. (Page 22).
IX. Proposal for action. (Page 28).

As a part of the preparation of this document, I asked several of my colleagues—teachers, principals, and others—to help me by providing statements of their views and opinions about the impact of computer technology in the schools. I believe it appropriate to quote what one elementary principal wrote. He is Dr. Richard Lavine who is principal of an elementary school in Fairfax County, Virginia. In a memorandum to me written just a few days ago, he stated:

“In light of the pressing need to prepare our students for the 21st century, I am dismayed by opposition to computer utilization within our profession and outside. The information age is upon us and yet some of us are hanging by our fingertips to an outdated set of beliefs.

“Public education to serve the needs of today’s children and to avoid creating a generation of disenfranchised, easily manipulated adults, we need to assure that the schools are more technologically relevant.

“The computer and the age it foretells also has the potential for beauty and ugliness. Education must ensure that enlightened, educated users create an age of beauty.”

A math teacher who is currently responsible for efforts to use computer technology in a large school system in the southeastern United States sent me a memo last week. I would like to quote a portion of what he wrote:

“I am now in my 12th year trying to develop and maintain at various levels, a computer science, and now a computer literacy, program in a large school system. For years I went through a very frustrating experience of trying to do this without the proper resources, and without support from our school system organization. We survived mainly on the basis of a grass roots effort. It was happening because the teachers that became trained in doing this wanted it to happen and the students and the community wanted it to happen.

“Not quite three years ago, we had the good fortune to get a top administrator in our school system who had the same ideas and the same concerns about the need for implementing technology within a school system. The community was very supportive of this, and principals and teacher were overjoyed. So we have had a period of two years of acquiring the resources that we never have, getting staff for technology, and getting hardware and all the various components that are needed.

“Teacher training is, of course, very critical to this whole effort. We are building a program with the resources to train our staff and our teachers. This takes a cooperation from industry that has never really existed with school systems at this level of commitment.

“As I now work in my job and hear the community coming at me, PTA presidents, and principals, and other administrators throughout the system asking for and expecting the delivery of resources, the delivery of courses to train teachers, I realize we have undertaken a gigantic job.

“We need more people in the U.S. willing to make decisions favoring the resources that are needed, and we need to continually try to get these resources. If we do not do this, I worry about what will happen with the children in our school system right now who would not be provided with this education, or worse, I worry about teachers suddenly realizing that they are becoming more and more useless to the students as the technology evolves and as the students themselves gain experiences that the teachers can’t identify with, or can’t share with them. The alternative to doing nothing is really no alternative. We must make the kinds of commitments that need to be made.

“My experiences over the past several years reinforce the viewpoints presented by both Principal Lavine and my math teacher friend. Because I know that many other principals and teachers feel the same way, I believe this is the time for direct action by the Congress, the United States Department of Education, the various state legislatures, state departments of education, local school boards, and the management teams of local school systems to take action for the intelligent adaptation of computer technology in the schools of the United States.

“I believe that this technology will come to play a central role in the public schools of America. History suggests that such a phenomenon does occur when (1) technology first gains cultural acceptance (i.e., admission to a large number of homes) and (2) the technology becomes a primary work tool. The first factor reduces opposition to the introduction of a particular technology into the schools, and certainly this phenomenon is clearly recognizable in the United States today. The second factor generates public demand that the schools adopt the technology and provide training...
in its use. Evidence of this second criterion is growing all across the country. It appears computers will have sufficient hold on the society of the United States by 1985 for proper training in their use to replace basic skills as the primary public concern in education. Moreover, the increasingly critical relationship between technology and economic development will make the outcry to access to training in computer technology particularly aggressive. I believe that the schools of the United States have responsibility to respond to these conditions with the help of the peoples' representatives in the Congress, the state legislatures, and local school boards.

II. NEED FOR HARDWARE

In early January, 1980, the Commissioner's Advisory Committee on Instructional Computing in the State of Florida delivered a report to the Commissioner of Education of that state. One of the ways to underscore the critical need for investment in computer hardware for the schools of America is to paraphrase that report.

The Advisory Committee reached consensus on a group of assumptions which could serve as a basis for public policy in the State of Florida. The assumptions were the product of a review of pertinent literature, exchange between members of the Committee and nationally recognized expert consultants, and deliberation by the Committee and the staff persons who supported the Committee's activities over a period of six months. Two of the assumptions emphasized the need for computer hardware in Florida's schools, and they also apply to the national scene:

1. Computer technology will play an increasingly pervasive and dominant role in American society during the next generation. Thus, the United States cannot afford not to invest immediately in this technology for the schools of the nation.

2. The economic development of the United States demands public investment in computer technology to prepare citizens for new employment and upgrade the skills of those already employed.

Additional perspectives which support these assumptions will be provided in the later section in this document which deals with the effects of computer technology on society.

However, it is important here to emphasize that investment in computer hardware in the schools in the United States is going to have to be done in the context of economic change which have overwhelmed and outmoded traditional approaches to management in education as surely as they have done in the private sector. New philosophies and techniques for budgeting, fiscal management, classroom management, and teacher preparation must be implemented. This means that some form of investment must be made in training and renewal activities for the educational managers of the school system and universities of the country. Additional comments about this will be made in a later section dealing with funding problems.

The need for computer hardware in American schools can be summed up in a restatement of the first assumption of the Florida advisory group: The United States cannot afford not to invest immediately in this technology for use in the schools of the nation.

III. NEED FOR SOFTWARE

There is a general consensus among teachers and other educators, publishers, computer manufacturers, and other interested parties that there now exists a paucity of software or courseware of excellent quality. Educational software is commercially available in a wide array of formats and subject matter and some of it is of good quality, but much of it deserves the criticism it gets. Some criticism is based on such trivial concerns as programs having spelling errors or typos or having inappropriate formats. More serious kinds of criticisms relate to programs having bugs which prevent them from working under certain circumstances; even more serious concerns relate to programs unusable by students because of unclear instructions or having important steps omitted. There are some concerns which focus on very important issues including the fact that much of the commercially available software employs limited and limiting "drill and practice" and "tutorial" approaches; neither of these approaches taps the real potential of the computer because they do not represent a departure from the most traditional kinds of pedagogical methods.

There are many reasons for this situation, of course. Some of the reasons are as obvious as the fact that the developmental explosion of microcomputers presents a situation far ahead of the development of programs enabling schools or other agencies to make good use of the power potential of the machines. A less obvious reason has to do with the fact that many publishers apparently find themselves wrestling with extremely tough issues related to the relatively high cost of production of courseware, and the impact of current copyright laws and other public policy on
this kind of development. It is difficult to realize a profit from materials which can
be so easily copied in the market without fair return to the developer and publisher.
The development of quality software takes a great deal of time—probably more time
than the development of a textbook. All of these variables contribute to the current
situation, and there is no indication that this dilemma will be resolved in the immedi-
ate future.

Programs are beginning to emerge in an area where quality software is particu-
larly important, in my view. Many computer companies and publishing organiza-
tions are providing increasingly better materials for the development of so-called
“computer literacy.” In these programs the computer itself the object of study, and
this is desirable. However, some of the same criticism which apply to the general
area of educational software also apply to some computer literacy programs.

Successful adaptation and utilization of computers in the schools will depend upon
the development of instructional approaches for which the computer is uniquely
suited, or for activities which could not be done effectively without the computer.
Such software would go far beyond drill and practice and tutorials. Elaborate simu-
lations, demonstrations, programs which provide for extensive testing of hypotheses
and the manipulation of many variables, text editing of all sorts, complex education-
al games, and responsive computer languages are all approaches which meet the re-
quirements of being uniquely suited for the computers or not feasible without using
such machines. Such programs are much more difficult and time-consuming to pro-
duce and as a result they are relatively rare. In my experience, which seems to be
matched by some other observers, such development often takes place in the schools
where individual teachers get excited about the potential of computers and develop
good programs on their own. This is not to say that all teacher-developed programs
are good, but a number of high quality programs have been developed in this way.
Other development takes place in universities for use as a part of the instructional
program of those institutions. Publishers are beginning to seek out these true inno-
vators in computer curriculum and nurture what they are developing. I believe that
this kind of effort should be enlarged so that publishers provide time, money, and
publishing and marketing expertise for these approaches to education which are
truly revolutionary. Educators must resist the mediocre software currently being
marketed, and demand the development of quality materials.

The development of public/private consortia for such development is a most prom-
ising strategy I have been personally involved for several months in an effort to
establish a consortium of a publishing corporation, a number of public school sys-
tems, and universities. The experiences we have had in this effort lead me to believe
that it is truly a promising option for the development of quality instructional mate-
rials and courseware. The need for quality software deserves national attention and
action.

IV FUNDING PROBLEMS

Investments in the schools of the United States in order to successfully adapt
computer technology in American classrooms will serve to enhance economic develop-
ment in the nation, as well. The schools have been, and will continue to be, con-
tributors to the economy of the country because they provide a literate and trained
workforce and enlightened citizens who are economic consumers. The most basic
needs for funding related to computer technology in the schools are in three areas
of investment:

1) Funding for hardware, that is, the computer machines needed in the schools.
2) Funding for software, that is, the development and marketing of programs
which have the requisite quality to be well used in the classrooms of the nation.
3) Funding for training and renewal of classroom practitioners and educational
managers.

Most researchers who have reflected on problems of funding hardware, software,
and training in relation to the use of computer technology in the schools remind us
of the fiscal nature of the educational enterprise. It is labor-intensive, and thus the
possible areas for realization of resources to buy hardware, develop software, and
train personnel are quite limited. The average school system in the United States
spends approximately 75 percent of its budget on personnel. Of the remaining 25
percent, the majority of expenditures do not purchase instructional equipment (com-
puters, program development software), or staff development training for persons

Obviously, this situation calls for new philosophies and techniques for budgeting
and fiscal management as has been pointed out in an earlier section. Each student
would have access to equipment for 30 minutes, then the equipment cost per stu-
dent per year would vary between $17 at the lower end and $30 at the upper limit. If one assumes a courseware cost ranging between one-third and one-half of the equipment cost, then the student cost per year would vary between $23 at the lower end and $45 at the upper limit. In communities which spend about $2,300 per year per student (if they do not now, they soon will) the cost of 30 minutes per day of computer-based individualized instruction ranges between one percent and two percent of total instructional cost per student. And this cost can be reasonably expected to decline over the next several years! Details about these costs are available from the United States Department of Education.

In the final section of this presentation, I will recommend a proposal for Congressional action which will focus on courseware development and training in the schools of the nation. I believe that courseware development can best be done in the context of cooperative arrangements between school system, publishers or other private sector organizations, and universities. The training needed for educational practitioners ought to occur in similar contexts, in my judgment. Public/private consortia represent the most feasible arrangements to deal with the need for hardware and software, as well as attacking the funding problems related to the successful adaptation of microcomputer technology in the schools.

Resolution of the problems related to funding at the national level must be based, in my view, on immediate Congressional action. The time for study is past, it is now time for action! One of the more useful reports which I have found was done by Stanley Pogrow, of the University of Arizona, for the National Institute of Education School Finance Project. The report is entitled, "Technological Change: Policy Implications for Funding and Delivering Educational Service in the 1980's." I believe that this report could be of utility to the members of the Subcommittee in deliberations about these issues.

Legislation is already pending in the Congress to change the tax laws to make it feasible for computer manufacturers to donate hardware to the nation's schools. I believe that some form of public policy revision must make this possible. The schools will need to be exceedingly careful about what they accept from computer manufacturers, but I believe it is in the mutual interest of the hardware manufacturers and the schools to learn how to deal with each other in ways to provide mutually positive outcomes. I urge members of these two Subcommittees to review these issues and to use your influence to revise the tax laws in ways to make feasible the donation of computer hardware to the schools.

From a national perspective, the cost of providing hardware and appropriate quality software in the schools of the country is relatively low. The per student annual cost for providing each student with access to computer equipment with quality software for 30 minutes per day is approximately $25 per year.

V. PARENT OBJECTIONS

During the past several years, I have found very few objections by parents to the utilization of computers in the schools except from persons who are concerned about the general issue of growing school costs. In my experience, objections to students using computer hardware or the participation of students in learning about computers focus on the lack of such opportunities in the schools.

In Fairfax County, Virginia (which may be a somewhat atypical sample), numerous PTA and other parent organizations have been purchasing computer equipment, establishing and paying for tutoring programs for elementary students, organizing volunteer groups to provide computer literacy programs, and lobbying the school board, superintendent, and county government for increased emphasis on these kinds of programs. In other school systems across the country where there are organized volunteer programs there is a growing presence of so-called "computer tutors." These volunteers work with elementary and secondary students in programs which focus on the computer as an object of study, and they also facilitate computer science experiences, and application of computers to mathematics and science courses.

Two years ago in Fairfax County, the School Board appointed an advisory panel of executives from high technology corporations in the community to review recommendations which had been in the annual budget for the school system in regard to
the utilization of computers. That panel of professionals, many of whom were parents of students in the system, recommended that the school system develop a master plan for the utilization of computer technology, and strongly urged the Board to support allocations for purchasing hardware, software, and for appropriate training.

In summary, I have not found any substantial parental objections to the use of computers in the schools. Neither have I discovered in the professional literature any reports of objections which could be identified as a barrier to successful adaptation of this technology in the schools.

VI. TEACHER OBJECTIONS

While there is no complete consensus about the reactions of teachers to the advent of computer technology in schools, there are many that believe that teachers, in general, are suspicious and skeptical about the use of computers in the schools. This reaction is due, in part, to the inappropriateness of some machines for school use, and to the poor quality of some of the software. Some teachers have been told that computers will save time, which could mean that there could be reduction of staff by using computers. Because of this, some teachers believe computers threaten their job security.

My experience leads me to believe that this is not a realistic expectation. Instead, it seems more reasonable to expect that the role of the teacher will change. It is neither desirable nor likely that computers can be used to replace the vital functions which teachers perform to facilitate learning. However, it does seem apparent that, as computerized methods and materials become more effective, teachers' roles could shift from delivering information to managing the instructional process. Teachers could have more time for guiding individual progress while computerized resources perform time-consuming activities. Thus teachers could be more effective and more creative, but this also means spending more time developing materials and programs and so there tend to be conflicting representations and expectations on the part of teachers about the use of computers in the classroom.

However, during the past two years I have spent more than 50 full days in local schools talking with teachers and other local school personnel. Among these persons I have found a high degree of acceptance of the potential of computer capability provided that teachers and other school personnel learn how to use these machines. A growing number of teachers have bought computers on their own, or they have "bootlegged" the machines into the schools by promoting the purchase of machines by PTA groups or other volunteer support organizations. Some teachers have told that computers will save time, which could mean that there could be reduction of staff by using computers. Because of this, some teachers believe computers threaten their job security.

My experience leads me to believe that this is not a realistic expectation. Instead, it seems more reasonable to expect that the role of the teacher will change. It is neither desirable nor likely that computers can be used to replace the vital functions which teachers perform to facilitate learning. However, it does seem apparent that, as computerized methods and materials become more effective, teachers' roles could shift from delivering information to managing the instructional process. Teachers could have more time for guiding individual progress while computerized resources perform time-consuming activities. Thus teachers could be more effective and more creative, but this also means spending more time developing materials and programs and so there tend to be conflicting representations and expectations on the part of teachers about the use of computers in the classroom.

In summary, I have not found any substantial parental objections to the use of computers in the schools. Neither have I discovered in the professional literature any reports of objections which could be identified as a barrier to successful adaptation of this technology in the schools.
null
Just as clear, however, is the logic of assuming that the lack of computers provides negative effects on children in regard to the future. Because work is becoming increasingly technical, those pupils who acquire only minimum competencies (as these are currently defined) will be functionally illiterate and unemployable by 1990. The use of computers with quality courseware by well-trained teachers can prevent the problems of functional illiteracy and lack of employability. Perhaps author Isaac Asimov has summed up this situation best when he wrote, “I do not fear computers. I fear the lack of them.”

VIII. EFFECTS ON SOCIETY

Much of the literature about computer applications in education includes some opinion about the impact of computers on society. Often the primary emphasis is on positive impacts of computers, but some treatment of potentially harmful aspects of computers are also usually included. One of the most common examples deals with issues related to the invasion of privacy. In my view, not many writers have considered seriously the changes in social, political, military, and economic decision-making because of the use of computer-based models, or changes in the nature of social organizations brought about by widespread computer use. Much of the literature also lacks any treatment of the concern for the particular social values imbedded in a given social application of computers. One computer application may support the values and goals of one social group and be harmful to other groups, but this type of issue is infrequently considered in the literature available to school practitioners.

Daniel Watt, a researcher associated with the Massachusetts Institute of Technology, has written about the effects on society by examining the impact of computers on peoples lives. Watt points out that in the past only a small percentage of the population was directly concerned with computers in their work. Computer workers included technicians, programmers, and computer scientists who required specialized technical training. People who, heretofore, have made use of information processed by computers only had to be comfortable with reading computer printouts. In the future, however, Watt expects the overwhelming majority of our working population to have significant interaction with computers as part of their daily work. As the economy becomes more dependent on information processing, those whose work involves such information will need to have a great deal of direct involvement with computers. He believes that word processors connecting with computer-based filing, coping, and communication systems will transform the nature and conditions of office work. Automation based on computer utilization will raise issues of control of the work environment, as well as new organizational ability to produce and distribute a product. Such systems also provide managers with an unprecedented degree of control over the functioning of employees whose work requires interaction with the system. What Watt calls "big brother in the workplace" may become as significant a labor relations issue as replacement of workers by automation has been in the past.

Watt is also concerned about the impact of computers in the personal life of Americans. He points out that in the past, most peoples' contact with the computers was limited to receiving computerized bills, and only a somewhat isolated minority had access to computers for professional or recreational pursuits. We can already see dramatic increases in the contact between individuals and computer systems in their daily lives. Personal computers and special purpose computer devices are becoming available in the homes of many people for family business, household management, intellectual and educational development, recreational activities, and creative expression. Watt believes that personal computers will eventually have as much impact in the daily lives of Americans as the automobile and television. He also expects that there will be an expanding effects for many people who learn to program their home computer and use them as creative personal tools for writing, composing and playing music, graphic arts, animation, communication, and information retrieval. For some people there may be less positive effects if they become independent on limited forms of computerized instruction or addicted to fast-paced and exotic, but fundamentally meaningless, computer games.

One group of observers, calling themselves "The Techno/Peasant Survival Team," believes that our culture is being divided into two groups of individuals known as techno/peasants and technocrats. Technocrats are persons who understand computer technology and its potential. Techno/peasants, by far the majority of the citizenry, are those we are either overwhelmed by what is going on in the various new fields of technology or those who are too uninformed to have any real say in their future. What techno/peasants comprehend that sets them apart from techno/peasants is...
that the processes of innovation now taking place represent power to change virtually everything around us. The "Survival Team" argues that our ability to process and manipulate information on a large scale has the significance for human evolution of the development of written language or the invention of the printed book. They believe that the most revolutionary aspect of computers is that they are the first invention ever to significantly extend human capabilities. This means that the potential of computers is unique in human experience; we have never been threatened by anything—animate or inanimate—that would equal, extend, or possibly surpass our own intellectual capacities. Until now.

In a fascinating book The Techno/Peasant Survival Manual, the "Survival Team" argues that if we want technology to liberate rather than to destroy us, then all of us who are techno peasants have to assume responsibility for it.

The implications of such a claim for the schools of the United States seem obvious. The schools are the social institutions on which our culture places the most direct responsibility for information and understanding to enable any citizen to assume responsibility in his or her own life for the effects of computer technology.

Stanley Pogrow, in a recent research report commissioned by the National Institute of Education, has written about effects on American society from an economic perspective. Pogrow believes the U.S. is experiencing economic changes today that have not been paralleled since the Industrial Revolution, when employment and production shifted from the farm and the home to the factory. Such dramatic changes necessarily impose new realities on both business and education. Today the business sector is being forced to change its traditional management strategy of investing in labor rather than in such other forms of capital as plants and equipment. U.S. business—the nation's education—was enormously undercapitalized as the Eighties began. Production efficiency fell dramatically as the costs of energy and labor increased. U.S. products began to lose their competitive edge in the world market as the compelling economic advantages of more technologically efficient production techniques overwhelmed traditional marketing strategies and consumer preferences.

In an era when technology makes it possible to replace labor with intelligent machines and physical distribution systems with communication systems, labor-intensive approaches to production are no longer viable. To remain competitive, U.S. industry is now forced to modernize its technology.

As an economic pragmatism fuels the adoption of new production methods, the cumulative impact of these changes will be to alter the nature of work. Most workers, be they artists or machinists, will increasingly have to perform tasks that are science-related. By the time that most students who are now in elementary schools finally enter the world of work, this shift in the nature of work will be largely a reality.

Because work is becoming increasingly technical, these students who are not literate about computers and who do not have better preparation in math and science, than is now the case for many high school graduates, will be as functionally illiterate and unemployable in 1990 as are individuals who do not possess such competencies today. Pogrow argues that this truth will become apparent to the general public by the mid-Eighties, the public, in turn, will demand that the schools adopt a curriculum that is technologically relevant.

Pogrow identifies "technological relevance," as a comprehensive restructuring of curriculum. A technologically relevant curriculum must not only provide the specific skills necessary for effective uses of particular technologies, it must also prepare all students to engage in sophisticated forms of reasoning. This new curriculum must break the distinctions that now exist between the children who are expected to learn how to think in a mathematical mode and those who are not, i.e., "artistic" activities and "technical" activities, and the liberal arts and the sciences.

Professor Pogrow also believes that the present economic changes are so radical that even the largest corporations will probably be unable to shield themselves from the effects of a phenomenon he calls "environmental collapse." Environmental collapse occurs when dissatisfied constituents and clients do not try to change an organization; instead, they abandon it for an economically compelling alternative made possible by a fundamentally new technology. History provides numerous examples of victims of environmental collapse. These include scribes, artisans, ocean liners, the Pony Express, and, quite possibly, the Chrysler Corporation, newspapers, and the U.S. Postal Service.

Environmental collapse is a force driven by economics and changing preferences. This, according to Pogrow, public schools that ignore demands for a technologically relevant curriculum will face substantial decline or engulfment. Pogrow believes technological relevance will
that be included instead of your written statement. It is more informative, as well.

Thank you.

Mr. HUBBAC: I am most appreciative for this opportunity to speak to you about the use of technology in education and about how the migrant student record transfer system was initiated.

Some 20 years ago, I appeared before this panel and testified regarding the migrant student record transfer system. At that time, there was important support for the migrant student record transfer system and there continues to be. It has been the forerunner in technology in the areas of education and health for the past 15 years. It is probably the most innovative and most functional content effort in the field of education.

The capability with which migrant children have moved during school years has created a problem where many schools never receive a student record on their migrant children until they have already moved on. A record at all which causes the data to be periodically useless. The slowness of record transmission through the child by moved on within the city within the State or between States. We had two large counties and two large city school districts who have eliminated this problem. Educators in migrant education, show that the state of Arizona is far from what was needed to have properly administrated a program for mobile students.

I want to emphasize that the migrant student record transfer system. Mr. Chairman, was in 1965 and continues to be today a product of state that is not, and it was not developed by a Federal government. Many people have recognized the problem of transferring records and many records over a number of years.

In 1965, the Congress demonstrated its recognition of the interstate nature of farm migration by passing Public Law 89-736. The State of Colorado moved expeditiously to follow your mandate following a conference of States in Phoenix, Arizona in February 1966. A conference of the Record Transfer Committee was organized to develop a form and a document to be used in transferring data from school to school. Two facts were soon discovered. One is that effective systems had yet to be found; and two, it also had to be an automated system.

MIRPS was the first to be automated and was developed by the University of Arizona. It provides literally thousands of people, who are concerned with their school age and more than 600,000 disadvantaged students. The system became a reality in 1967. It is the operational instrument in 1969 and a national system in 1971. As a concept, the system is unprecedented in its design and is a workable success, in unprecedented.

The MIRPS interact within its nationwide educational and health care environment in a health manner and can be held by that environment. In a teacher, in a school district, in a medical district, in a school district, and in the administration. In an area which is rapidly changing in terms of education. Hence, it helped them an over new information need to
support the decision-making processes so necessary to those new dimensions. These discoveries, in turn, require the system to be responsibly responsive to its users and insure that the newly emerging needs are met.

Had it not been for technology in the development of this system, today we would continue to see thousands of migrant children dropping out of school for the simple reason that their credits would never be accepted or transferred. MSRTS is the heart of the migrant program since it enables the migrant child to have the same chance to receive a quality education as all other children of our Nation.

When the attention turned to how the highest attainment any migrant child received at school was the eighth grade. Because of this decision, close to 10,000 migrant children are graduating from high school each year. MSRTS is the major mode by which much vital information is disseminated to participating States about new special programs which have been designed to help alleviate the education shortfalls of our public school system.

The migrant holds sacred to the Nation and, as such, to its school and health services. The system continues to be of considerable concern to all for whom the Nation and our Congress. Without the migrant education system, it is quite probable that the migrant student could transfer from school to school without his educational and health history being known.

In these two basic communication elements in MSRTS are the school and the computer. The school initiates all information that goes into the student record. The data entry special unit transmits the school data to the computer which processes the data and disseminates the information according to the requests of the user.

MSRTS offers rapid turnaround service to schools. This rapid service reduces the lost time in planning health and academic programs for migrant children. Four basic reports are provided a school upon the enrollment of a migrant student.

The first report is returned to the terminal that services the requesting school in a matter of a few seconds or minutes. This report is called the analytical data report which contains information from the previous school enrollment. The student identification report is one of the most important types of third is the conditions, fourth, in the educational and reading ability ratings and sixth, the social status of the family that the child resides.

In conclusion, the MSRTS system described is a full function information system that services the needs of the school and the student. This system will in time enable the school to have a complete record of the student, including his education and health history that will be accessible to the educational or social worker. The system is designed to provide the school with a comprehensive record of the student which he can use to provide better services to the child.
student in his current school, relevant data is sent to the host computer keeping his record up to date. Upon his withdrawal from his current school and his subsequent enrollment into his new school, an individualized record is formed in his new school's computer maintaining all his academic and social proficiency data to the host computer.
ize instruction. This attempt was unsuccessful not because of commitment to the concept, but largely to the inadequate support given to the teacher in the classroom who was inundated with the preparation of educational materials necessary to serve individuals, and also because of a lack of a recordkeeping system for individualized instruction techniques.

Recognizing that the attempt to individualize instruction largely failed does not negate the fact that a need still exists to tailor a child's educational experiences to his abilities. Here is where I think technology can certainly be a factor in this area. Technology will not replace the teacher, technology will allow the teacher to get away and do other things and tailor a child's educational experiences according to his abilities. A child must be taken from where he is educationally speaking and moved ahead at an appropriate pace. Technology will allow this.

There is an increasing awareness among educators that technology can help with this individualized educational process. The demand is growing in the educational domain for a system that can assist in the educational process but that will not dictate to the teacher or pose the threat of replacing the teacher. For those teachers 'who are confident of their skills and who are aware of technology, the transition will be easy and meaningful, rewarding for them and their students. For other teachers, the transition will be a little harder to accept, but as they see the benefits of the microcomputer, their resistance will diminish and over the next 10 years, their concerns will evaporate.

The effect that it will have on the student will be positive. It will enhance the student's creative problem-solving skills. It will enhance the student's ability to communicate. It will enhance the student's analytical skills. It will increase the student's awareness of current technology and its potential. It will move education in the direction of being more fun. The student will be actively engaged and not a spectator. The student will learn to use a powerful tool which will, in turn, help develop future tools. It will open job streams which students may enter. It can remediate existing deficiencies in the student's educational background.

State directors of migrant education and MSRES officials are looking at all types of technology in education to further tie the classroom teacher more closely to MSRES and to be the third step in a cycle. A previously state of migrant educators have been the fore-runners in using technology education, health and welfare of the migrant child. They have also been the fore-runners in teaching in the classroom, improving their early childhood and special education for all migrant children. To fully complete the technological cycle a committee convened under the directorship of the State director of migrant education in the State of New York to develop courseware and software in these four domains that can be used in the classroom with microcomputers to complete the total educational cycle that they set out to do.

In the State of Michigan, migrant educators by placing terminals in the schools have largely learned to identify vocational aptitude, which can in a student's educational career pinpoint those career goals for which the student is best suited both by student interest and student aptitude. By so identifying these potential
career associations, the schools are able to plan vocational experiences that maximize future adult job satisfaction.

What are the benefits of MSRTS? It provides the educators information which they can use to plan programs. It provides teachers and nurses with information on an individualized basis which enables them to better meet the needs of the migrant child. It provides an ongoing forum for problem identification and solution seeking which does not exist on a comparable level elsewhere in our Nation. It helps to make a healthier environment for our Nation's migrant population. It helps to identify potential health epidemics.

I would like to call your attention to some epidemics. One was a typhoid fever outbreak in Florida some 2 or 3 years ago, where 25 migrant children were susceptible to having typhoid fever. Merck and the system was able to locate them after only 1 hour. Another outbreak occurred in a hospital where a sick child had been located in a very short period of time under the new and rapid techniques of the system.

The system has been identified by the State as a method of gathering data over the past 14 years the MSRTS has been used and evaluated and its data is used by the following national bodies: the Department of Health, the Census Bureau, the Communicable Disease Center in Atlanta, the Department of Agriculture, the Department of Defense, the Bureau of Indian Affairs, the U.S. Department of Education, the State School Officers, and the Office of Vocational and Handicapped. We have just now completed a contract with the Rehabilitation Services and have now started providing them data also meeting the experiences that are needed in the area of rehabilitation.

Mr. Chairman, if I have failed, I think, in my statement, what could be done by the Congress of this Nation, is that there should be a national commitment made on the part of Congress and the Administration that such data be used in an orderly fashion so that the equipment and techniques of the last report can be carried out to a national extent. That is not happening today. There is not a widespread effort to research and develop a better health knowledge placed in the class room.

I would very much appreciate from you, Mr. Miller, any information that you could provide me with regarding the recommendations you make.

Mr. Chairman, if I have failed, I think, in my statement, what could be done by the Congress of this Nation, is that there should be a national commitment made on the part of Congress and the Administration that such data be used in an orderly fashion so that the equipment and techniques of the last report can be carried out to a national extent. migrant children until they have already moved it, they receive a record at all
which causes the data to be practically useless. The showess of record transmis-
tial occurs even though the child has moved only within the city, within the state or
between states. Thus the educators in migrant education knew that this state of af-
curs was far from what was needed for them to properly administer a program for
migrant children. I want to emphasize that the Migrant Student Record Transfer
system was not set up in 1966, and continues to be today a product of the states that use it and
and was not developed by a federal bureaucracy.

Many persons have recognized this problem for many years. Recorded efforts to
establish a record transferal system date back to 1930. However, not until the
passage of Public Law 89-740 as an amendment to Public Law 89-10 in 1966 was
there a unified effort in this country to accumulate and distribute pertinent student data
on migrant children. It became obvious that neither an individual state nor a
region of states could, upon self-initiative, make and sustain an adequate system of
transferring student data. It had to be a national effort. In 1968 Congress demon-
strated its recognition of the interstate nature of farm migration by passing Public
Law 89-740 (Section 105, Title I).

This law will be used for program and projects involving the acquisition of
environment and where necessary the construction of school facilities which are de-
nored to meet the special educational needs of migratory children of migratory ag-
cultural workers and to coordinate these programs and projects with similar pro-
grams and projects in other states including the transferal of pertinent informa-
tion with respect to school records of such children.

The 50 states were a cooperative effort to fulfill that mandate. Following a conference
of states in Phoenix, Arizona in February 1968, a committee raised the Record
Transfer Committee was organized to develop a system and a document to be used
in transferring data from school to school. The first effort was on a manual basis
all work was done manually. However, two facts were soon discovered: (1) to be effec-
tive, MSRS had to be a national effort and (2) it also had to be an automated
system.

The Migrant Student Record Transfer System (MSRS) was the first massive interstate cooperative effort increased by
Public Law 89-740. It provides literally thousands of people in schools and health care for more than 800,000 migrant students. The System became a
defined concept in 1968, a project in 1969, an operational instrument in 1970 and a
national reality in 1972. In a concept, this System is unprecedented as a working
success, it is unprecedented.

The MSRS interacts within its nationwide educational and health services environ-
ment in a healthy manner since it shapes and is shaped by that environment. It assists teachers, nurses, medical doctors and all levels of administration in
discovering new and relevant dimensions of migrant education. It also helps
them uncover new informational needs to support the decision making processes so
necessary to these new dimensions. Those discoveries in turn require the System to
be sensitive, responsive to its needs and ensure that the newly emerging needs are
met.

Had there not been for technology in the development of this System, today we would
continue seeing thousands of migrant children dropping out of school for the simple
reason that their basic needs for instruction are not met. MSRS is the heart of the migrant pro-
gram since it enables the migrant child to have the same opportunity to receive a quality education as all other children of our nation. When the System was begun in 1968
about the high achievement an migrant child received in school was the right
grade because of technology. In 1968 migrant children are graduating each year.

MSRS is the major mode by which meaningful information is disseminated to par-
ticipating states about new special programs which have been designed to help allevi-
ate the educational shortcomings of our public school system.

The migrant child is a child of the nation and as such his education must continue
to be of considerable concern to all educators of the nation and our Congress.

Without the migrant education program and without its heart, the Migrant Student
Record Transfer System, the end result must probably be that 800,000 children
would not receive their education and health care.

How does MSRS work?

There are three basic communication elements in MSRS: the school, the termi-
nal and the computer. The school initiates all information that goes into the student.
record. The data entry specialist transmits the school's data to the computer which processes stores and disseminates information in accordance with these requests.

MSRS offers rapid turnaround service to schools. This rapid service reduces the lost time in planning health and educational programs for migrant children. Four basic reports are provided school upon the enrollment of a migrant student.

The first report is received in the terminal that serves the requesting school in a matter of a few minutes. The report is called the Critical Data Report which contains information from the previous school of enrollment - student identification, program types of school, conditions, 11 languages, and mathematics and science studies. The Critical Data Report is generated as a consequence of two desired actions: upon enrollment when Critical Data is desired and a request for Critical Data only. Since the requests are processed and responses immediately sent to the terminals serving the requesting schools, it is possible for the migrant child to have his record at the Critical Data report within the same day as his enrollment. This reduces the time until the student arrives a required prior to enrollment.

The other three reports are an updated student record transfer to another sending record, and the transfer report of reading, math, and social studies. These records are sent to the school requesting the information. The updated report includes data on changes and updates, and also information on the student's current school. The updated report is sent as soon as possible; usually within two to three days of receipt.

MSRS is being increased with the school's automation by providing periodic reports to participating schools. A staff of educational specialists in education and health is assisting the clerical staff in processing the data. A special report, called the Critical Data Report, is sent to the schools requesting the information. This report includes data on changes and updates, and also information on the student's current school. The updated report is sent as soon as possible; usually within two to three days of receipt.
IN SCHOOLS RESPONSIVE TO CHANGE

There is an abundance of technology waiting around the corner brought on by the increasing use of the microcomputers in the educational environment. I would like to quote Dr. Frank Brouillet, Superintendent of Public Instruction from Washington state, as he addresses educators in his state.

During the 1970s there was a commercial on television to raise funds for United Negro Colleges which ended with the statement, A human mind is a terrible thing to waste. Despite the present economic belt tightening, a human mind is still a terrible thing to waste, particularly when we have demonstrated that there is no need to waste it by refusing to educate, by denying it by lack of commitment or abuse it by failing to realize its needs.

Dr. Brouillet went on to say that educators were reluctant to embrace the world of computer technology. Within the last five years the role of computers in our society has expanded to the point that this will be considered that age of the computer in which the 20th century is referred to as the age of industrialization.

In the same vein of computers and their relation to the educational environment, Dr. Brouillet had the following to say: You will be interested to know that we now have a computer technology and instruction task force at the state level which will be sponsoring statewide workshops dealing with how to select computer hardware and how to evaluate coursework. Judging from the increasing requests we have for microcomputers, I am certain this is an area of interest to many of you.

While Dr. Brouillet's comments about computer technology and its significance to students and appropriate teachers may vary, it must be stated that he is not alone in his assessment of the microcomputer's impact in the classroom. Many states are fast approaching the concept articulated by Dr. Brouillet, in fact through the use of technology systems are being established like MSRTS, in our city schools, and other countries as well.

There has been a general awareness of the need to tailor instruction to the needs of the individual. A movement was evident in the late 60's and early 70's to individualize instruction. This attempt was unsuccessful because of a commitment to the concept but largely due to the inadequate support given to the teacher who was overwhelmed with the preparation of educational materials necessary to serve individuals and also because of the lack of a record keeping system for individualized instruction techniques.

Recognizing that the attempt to individualize instruction largely failed does not negate the fact that a need still exists to tailor a child's educational experiences to his abilities. A child must be taken from where he is, educationally speaking, and moved ahead at an appropriate pace to where he needs to go.

There is an increasing awareness among educators that technology can help with this individualized educational process. The demand is growing in the educational domain for a system that can assist in the educational process but that will not dictate to the teacher or force the threat of replacing the teacher. For those teachers who are not familiar with their skills, and who are not afraid of technology, the transition will be easier and more profitable. However, those who are not comfortable with technology will be faced with a number of educational materials that are necessary to serve individuals and also because of the lack of a record keeping system for individualized instruction techniques.

Recognizing that the attempt to individualize instruction largely failed does not negate the fact that a need still exists to tailor a child's educational experiences to his abilities. A child must be taken from where he is, educationally speaking, and moved ahead at an appropriate pace to where he needs to go.

also been the teachers in establishing the best skills in reading, math, early childhood and oral language for all migrant children. To fully complete the technical logical cycle, a committee of state migrant educators, chaired by New York's state director of migrant education, is presently in the midst of looking at macroscopic problems to be used in the classroom as an instructional tool, a teaching instrument and also as a management tool.

In the state of Michigan, migrant educators have by placing terminals in the schools learned to identify vocational aptitudes which early in students educational career. Parents are told of these potential career aptitudes the schools are able to plan vocational experiences that maximize future adult job satisfaction.

The following is a list of activities that managers in MSRS provide summary data on a monthly, quarterly and yearly basis to the state director of migrant education:

- Enrollment data:
  - Number of entrants per period
  - Number of withdrawals per period
  - Number of transfers to and from other programs

- Academic data:
  - Number of students per program
  - Number of students per grade level
  - Number of students per vocational area

-ソ*

- Other data:
  - Number of students per race
  - Number of students per sex

Math computation, Composition, Science, Social studies, and Math concepts.

This information is compiled on the following levels provided the state identification number includes all these levels: School plant, School district, County, Congressional district, and State.

A national summary is compiled on the same frequencies for the U.S. Department of Education.

In addition to the statistics reported above, MSITS gives a report semi-monthly to the state directors of migrant education a volume and proficiency report on each data entry specialist in his state.

Using the two statistics reports just described, each state director knows on a continuing basis how his schools and his data entry specialists are performing.

WHAT ARE THE BENEFITS OF MSITS?

a. It provides the education information which, they can use to plan migrant programs.

b. It provides teachers and parents with information on an individualized basis which enables them to better meet the needs of the migrant child.

c. It provides an ongoing forum for problem identification and solution seeking which does not exist on a comparable level elsewhere in our nation.

d. It helps to make a healthier environment for our nation's migrant population.

e. It helps to identify potential health epidemics.

f. It helps to smooth out the gaps in a migrant student's educational experience.

g. It promotes the idea of quality education for migrants.

THE MIGRANT STUDENT RECORD TRANSFER SYSTEM

Over the past 20 years the MSITS has been studied and evaluated by the following national bodies: The Department of Health, Education and Welfare, The Department of Agriculture, The Department of Defense, The Bureau of Indian Affairs, The U.S. Department of Education, and Chief State School Officers.

Another method is to compare the number of records mailed in August, 1981 to the number of records mailed in August, 1982. The MSITS mailed 231,579 more records educational, medical and skills in August, 1982. This shows that more information is being transmitted to benefit more migrant students.

MSITS SAFEGUARDS

It is appropriate that some mention of safeguards of private information be mentioned. The designers in committee of twelve states and the MSITS staff on the Migrant Student Record Transfer System Form and the Automated Migrant Student Record Transfer System were very mindful in design and development a total system that would assure privacy of data. The System as it was designed, has met all standards as established by the U.S. Senate Subcommittee on Constitutional Rights chaired by Senator Sam Ervin of North Carolina.

To my knowledge there is no misuse of student data. The MSITS has the potential to expand to serve any part of this record transfer requirements.

Also its potential for providing detailed data for school personnel and providing management data for state and federal governments will be limited only by our imaginations. Cooperation of the states, and availability of operational funds A functional System now exists for the states are making progress in utilizing the System, and I believe the federal government cannot renege on its commitment to the most deserving and disadvantaged group of children in this nation. The support of Congress for the continuation of this vital effort is urgently and sincerely solicited.

It is quite evident that I am a firm believer in technology and how it can enhance the educational welfare of children. However, proper training must be given to the principals and the classroom teachers of the school systems in our nations to achieve the greatest benefits for all students. It is most important for a thorough...
understanding so planning needs can be developed for the environment in which microcomputers and other forms of technology are placed. I would suggest to any school administrator that objectives and projects be made along with a strong commitment before embarking upon a venture to insure its success for the administrator, the classroom teachers, and students. Technology on other words can only be as good as those who use it. I see many benefits in the use of technology in the classroom for all segments of the educational structure.

Mr. Brieger, Mr. Murphy

Mr. Murphy, Thank you very much Mr. Chairman. I don't believe I have any questions but I did want to thank all of you each of the witnesses for answering our request, mine and Mr. Perkins to be with us this morning. Your testimony will go a long way in helping us build an case for improved technological services in the classrooms which is 1 would very strongly about. I do appreciate your testimony.

I may have a need for that information on the factors that might be able to work out the cases you can present with those who we prepare with those in charge and the concept we will do, etc. your advisors.

I want to thank the for their efforts and the determination to get it up and operating.

I yield to Mr. Brieger, Mr. President.

Mr. Brieger, Thank you. As we have heard from Dr. Trexler's, and 1 maybe ask a couple questions Mr. Fireplace and Mr. Faill if you wanted to be sure that the computer is utilized as a servant and not a master. It's a question of something we need to be well aware of.

But I would like to address a specific question to Dr. Deck and maybe the rest of you could comment on it if you wish. It seems like Dr. Deck you bring up a fundamental area of conflict in the whole area of the Federal Government getting involved in software preparation which in a sense implies curriculum development an area which historically at least has been the prerogatives of the States and the local school districts.

Do you see areas of potential difficulty that could result to potential evolution of that kind I would think is kind of a basic conflict.

Dr. Deck, Thank you for the chance to clarify that. Mr. Kansler, I would not want you to understand that the Federal Government is responsible for the development of the substance of these programs. Instead that I had in mind is the nurturing of new school systems with the publishing organizations and other arrangements so that the programs are done as they have been in the past. But that this within the climate of the computer, and the Federal presence would be to facilitate this happening, not to establish what the substance of the programs would be.

I appreciate the chance to clarify that important difference.

Mr. Brieger, Mr. Chairman, I would just follow up a bit on that. You make the comparison, Dr. Deck, similar to publishing houses that might publish textbooks and workbooks and whatnot that respond to order, from local school districts or States for various types of reading or instructional materials. I suppose one could make that transfer of applicability. It seems like, because of the costs involved and the procedure of formulating the programs, it is
going to be very difficult, unless there is some consortium or whatnot of the State and local levels, to agree on the type of course work, curriculum, and so forth.

Maybe that should be more of a challenge and an opportunity than an problem.

Dr. Deak, I would hope so. Mr. Kudahl, Dr. Fisher alluded to the fact that the production of these kinds of programs are more like the production of a movie than like the production of a textbook, and I think he is quite right. That is why I believe that consortium arrangements offer the expertise of the people in the schools combined with production and marketing expertise of the publishers and with appropriate roles to be worked out and played with other members of a consortium as well.

So it is a challenge, but I think we are trying to learn to adopt technology in which we have not been able to until now, and that these kinds of efforts enable us to learn how to do that in effect. The proper role in my view for Federal assistance is to nurture these efforts to learn how to do it and meet the challenge in appropriate ways.

Mr. Kudahl, Mr. Arnaud, I think that the problem that you see in the production of the Federal head of the magnitude that you suggested, but I am not saying you shouldn't go that as well.

Does anyone member of the staff think that in that in any other areas that come to mind as we. put this place down?

Ms. Hakansson: Thank you.

I think that Dr. Fisher's statements and Mr. Deak's statements are very true. There is a great deal of expense in the development of software. I am told you that firsthand.

I get a little concerned when I hear about large major efforts of the sort that you are talking about. I don't think the answer is that there is the need for large expenditures of funds and there is a need for highly skilled people coming together. Yet I get concerned when I think about the kind of effort that we give as a standard curriculum, which I think is an outgrowth of what you are asking to that kind of an effort put together, how do you avoid that? How many of them are we going to; how do you avoid the issues within which this done in one area and is it going to be adopted by let all because there are competitors in other areas?

I get a little concerned when I hear that I don't think we know how to do that yet.

Mr. Fausto, I appreciate your desire that I say again Mr. Chairman, to the record, is a bit, that as hard and the court reporter can't pick that up. So, the would you like to verbalize your response.

Dr. Deak, I simply would say again that the important element here, and I see it as the involvement of local school systems and the people in those systems to protect against standardization. My argument is based on my experience that in trying to combine to provide a dozen schools systems with a publishing company, we found that there is wide variety. There are ways to. I think, overcome these efforts that I think we must learn how to do. So while
we are moving through some frontiers with the use of the machines. I think there are frontiers we need to move through not to establish national curricula—I absolutely agree with your concern there—but I believe that that can be overcome in arrangements of the sort that I have suggested.

Mr. Miller Mr. Erdahl, I would like to make one comment. I alluded to in my testimony that the directors of migrant education developed skills in reading, math, early childhood, and oral language, not as a curriculum, but as a road map where any other materials could be cross-referenced to that. Forty-eight States did that back in 1969, and today they are developing the courseware and software along those lines.

So I don't think that we are approaching a national curriculum, by any sense of the imagination. We would all be against that.

Mr. Fisher, I hope nothing I said implicated any support for a central Federal software publishing house that is going to put out the curriculum for America. Nothing was further from my thoughts. But that leaves enormous roles that I hoped to have suggested in doing the research necessary for anyone in the private or public sector to produce good software. So there is that research end.

Also, there are a lot of other necessary functions, it would seem to me, to be public. There is the evaluation and follow-on what is good, and thorough testing of what indeed works, and reporting that in an impartial way unrelated to a financial interest. There is the training of manpower that can use this, which has been alluded to, largely teachers.

One can even go further and support software production by putting the sources in the hands of school districts which are free to go where their decisions leave them, but which indeed will serve to increase the output. There is a very large Federal role, it seems to me, although we may rule out a Federal curriculum-writing program.

Mr. Erdahl Thank you very much to all of you for those observations.

Thank you Mr. Chairman
Mr. Bracy Mr. Kildee
Mr. Kiper I will be brief. Mr. Chairman

I would like to thank the witnesses. As a former teacher, I recognize that education has to be dynamic since we live in a dynamic society and we have to update our technology to assist the teacher. That doesn't limit the role of the teacher; it enhances the role of the teacher.

As a language teacher, I can recall going through the transition when language labs were being funded and built. There was some concern at that time that labs might limit the role of the teacher. But I found that it really enhanced my role as a teacher and helped in imparting knowledge to my students. So I think in a dynamic world we have to make sure that education remains dynam...
Just have one area I would like to explore with Dr. Fisher, if I could, and that is to maybe noodle a little bit about the appropriate Federal role, substantial or insubstantial, however it would be. It is my impression that it is a huge and powerful change in technology that has occurred and it has overwhelmed the educational establishment, in effect, and the establishment has resisted it, basically. That has been the history of companies and institutions that have tried to be in the forefront of this, like Control Data with its PLATO system, and the Federal Government did fund that, along with the University of Illinois and others. There have been thousands of hours of instruction available in that medium. However, it has been hard for them to get contracts, frankly, and people resisted.

It is also true, I think, that we will be selling 1 to 2 million home computers next year in the United States. People will be making millions of dollars in the United States with individuals writing programs for games, and so on. They can rewrite things and do it this way, through time, and, indeed, different media. They can copyright that and then sell it. There is a huge market there.

What is the need for this Federal money, if people can sit around their homes and write programs? Do we need a cyclotron? Samuelson made a couple million dollars writing a basic economics text book. There was no real need for Federal funding for that, or for writing programs that people could sell and use. We want to keep it flexible.

Take your own example, just to conclude and give you a chance, on how people should be told they made a dumb mistake. It might depend on the context and the type of thing they are studying. That is kind of an art and, therefore, a lot of different things ought to be tried, and some will sell and some won’t. That will emerge out of the general yeast that will occur. The Federal Government can spend a lot of money, but it is not going to contribute to the yeast, particularly. It will occur whether we spend the money or not. That is what I would like you to think.

Mr. Fisher, I think the dynamism of the developing cottage industry in computer software is a great national resource. I don’t want to play it down. I think that one can enter and produce small programs and put a little ad in the back of magazines. Still, I will send you my program, that is good.

§ It is not going to produce excellent educational material. It has not done so today, and I have cited the testimony to you. I think you ought to look at that. You will find that you can sell things which are acceptable, but which are other than educational. There is no necessary connection of those two characteristics in software. We have a public interest in the educational value of the software, and it is the educational value of the software which isn’t very good and which may not move sufficiently for the private sector to provide it. What I have suggested, I think, is that we publicly seek to provide this industry of private enterprise with what they need to do, what they can do, and then we need to know more about the principles of what works. I think the fact that initial intervention might differ, depending on subject matter, is an attitude observation with which I agree. That makes the research more meaningful and
more extensive. It has to be followed up. Do they remember 2 years
front now better from using this method 2 years ago or that
method ago? This has to be done over a wide variety of subject
matters and a wide variety of different kinds of help which assists
them.

It is unlikely that a private enterprise will invest in that, be-
cause private enterprise simply is not going to capture for itself the
public value in having that information generally available to
those who wish in the private sector to go ahead and do computer
enterprising.

Mr. Biaggi: Would the gentleman yield at this point?

Mr. Petri: Yes.

Mr. Biaggi: I have listened to Dr. Fisher and all the witnesses.

Mr. Fisher: Not Doctor, it is just Mr. Fisher.

Mr. Biaggi: Well, we are relieved of that burden.

Mr. Petri: He is a lawyer, and they changed that title to doctor
years ago.

Mr. Fisher: In my day.

Mr. Biaggi: I share the concerns of Mr. Petri, not so much for
the expenditure of the money—and I understand the concern expres-
sed by the witnesses. Mr. Fisher said you weren't talking about
a central warehouse for courseware. What is wrong with the con-
cept of establishing a basic segment of courseware that is uni-
versally applicable in dealing with regional variances? Isn't it con-
cyivable, with relation to your tutorial segment, that you could develop
that part of your program so that it has universal application, or at
least regional application? We are not going to tailor this thing
down to the finite.

Mr. Fisher: You are correct. I still think there is a rather big
research job in developing those principles.

Mr. Biaggi: OK. Let's pursue it a little bit further. Instead of
talking about private enterprise not being there and total Gov-
ernment, what is wrong with the notion of having the Government
issuing a grant to some university or some reputable group to de-
velop a model?

Mr. Fisher: I think that is exactly what should be done. I don't
mean the Federal Government should have its own paid personnel
to do this research. That isn't the pattern generally employed for
the best of Federal research. In fact, some excellent research of ex-
actly this sort was indeed going on by the National Science Foun-
dation, research on its science education directorate, which has
been eliminated. Fifty million dollars a year is gone.

Mr. Biaggi: So we are really not talking about inordinate Sums
of money.

Mr. Fisher: No, sir.

Dr. Deek: You could also make grants, of course, in consortia
that is the thrust of what I am trying to recommend.

Mr. Biaggi: I understand that.

Mr. Petri: Thank you.

Mr. Petri: Maybe just to conclude, I will follow up a little bit on the chair-
man's question, too. You say that there are a lot of games and
other things that people are doing in the ways of computer pro-
gerating or developing software and that there is a big market for
it, but, in addition to that, that we have, for public policy reasons, some that may not sell as well but that we ought to develop. Therefore, it is a good idea to subsidize those through giving grants to the National Science Foundation or other means to make sure that they are developed, the way we have the Army developing teaching films, for example, but not subsidizing Walt Disney in "Fantasia." They are both useful and they are both going to happen, but the teaching films will not occur as fast if there is not Federal money; is that the point? 

Mr. Fisher. Yes, I think that is correct—or some public funds, and I don’t see any other good source.

The quality of teaching, how you use this machine for education, we don’t know much about that. We talked about how the technology is moving so fast that it is quickly becoming obsolete. In early June, the University of Delaware, a leader in computer-assisted education, had a conference on research issues with computer educators. I came away from that conference and talking to many of the people who delivered the papers there with the sense that we are soon going to have a machine which will do everything. You name it. It is going to talk to you. You are going to talk back. You are going to touch it. It is going to have tremendous memory. It is going to have tremendous power of education. That is going to come. I don’t know when, maybe in 10 or 15 years.

But what I will tell you is that if we start now a major effort to use that machine, we will not be ready to use it at maximum power for education at the time the machine is going to be available. What is driving the machine in this country is not educational purposes. We are riding along. We are seeing how we can use this machine.

Mr. Petri. It is like the printing press when it was developed. Professors, though, still read to the class the way they did before the printing press and books were developed.

Mr. Fisher. But the troubadour technology is still going on at the college at which I teach; you are correct.

Mr. Petri. In the same area, though, books are written for kids in all levels of education, and I think most of them are done by teachers or by other people, and they make a buck doing it or they are interested in doing it, and they do it for their contribution to humanity. The Government doesn’t have to subsidize it. Well, maybe we do, I suppose, and it is nice, perhaps, to subsidize it, but I don’t think this is really central to that whole process of having printed teaching material available.

Say this machine is developed and a fellow can sit around or a couple people can sit around and develop programs. I agree that there is a fantastic machine out there. Why is it that the Federal Government is essential in somehow developing the programming for this?

Mr. Fisher. The panels are anxious to answer.

Ms. Hakansson. I agree with you that there has to be the free-enterprise system. But I think that what Mr. Fisher is talking about is something slightly different. In producing books, I agree, the books themselves perhaps should be written by individuals for all the reasons that you have given out. However, what we are facing now is we had about 100 to 500 years to adapt to the intro.
duction of the printing press. People learned to read slowly and they learned to use this media in a well-organized, slow and reasoned fashion. We no longer live in those times. We have compressed those 400 years into only a few years.

I think that what Mr. Fisher is talking about with the Federal Government's role is to help us to learn how to use this technology, how to create quality programs. It is interactive. It is not like a book. It is not like a film. It is not a filmstrip. It is not television. It is nothing that we have used before. It is a new intellectual skill that has potential to open up human thinking in a way that it has never been before. It is the only intellectual tool that we have devised since the beginning of the industrial revolution. It is to man's mind what a crane or a lever is to our muscles. We don't understand it. It is totally new.

If we are going to effectively use it, if we are going to begin to use its potential, if we are going to give its power to people, then we need to understand more about how people think and how we can relate that tool to capture and to cultivate the human creativity and how we can allow people to exploit it to its fullest. We don't understand that. That is what we need to understand for us to produce the software.

I agree wholeheartedly that the software itself should be produced by free enterprise. I think that is the role of free enterprise, I am in it. That is why I am there. But I do believe that we need help. I can't afford to sponsor all of the research that is needed to understand how these children are relating to this instrument.

That is where we need the help.

Dr. Dock I just want to reemphasize that, if I might, sir, that it is new, it is different, and we have to learn how to use it. But I think we have to take advantage of the indigenous understandings in the schools in the development of this so that we get quality. I think that is the key. The quality will come not just out of the market availability, but out of efforts that are based in research.

Mr. Petri I have just one very last question.

Conceded it is new and it is different and we have to learn how to use it, would it be best to operate through, in your opinion, the Education Department or some sort of line of the Federal bureaucracy or, instead, through private and public or essentially eleemosynary foundations in giving grants, rather than attempting to have lots of people sitting in offices shuffling papers back and forth attempting to grapple with this new machine?

Mr. Fisher I am not critical of the form in which the research of the National Science Foundation takes place. I think it is a good model. I think it has been effective. I think we have learned a lot about how to use our public resources for research without tainting results, with engaging the best minds of the country wherever they are located. I think the Federal Government knows how to do that. It is just that they need to put this item on that agenda. I think the committee ought to ask the National Science Foundation and ask the Department of Education what they think of this report that you have received this morning. You ought to ask them to come back fairly soon to tell you what they are doing about the questions raised so that you can proceed to formulate, with whatever help you want to have, by further hearings, your agenda for
some action. There have been an awful lot of reports about the subject.

Mr. BIAGGI. I thank the witnesses very much for their valuable testimony. The points have been clearly made. Development is going to be, I think, long and fully implemented. At the outset, there will be some cost; but in the end, I think, free enterprise will take over.

Thank you very much.

The formal part of the meeting will terminate, but we have a number of demonstrations here and the members are invited to leave the rostrum and go to the various instruments in this order: Apple Computer, Rita Kohari, No. 1, Texas Instruments, Herb Rutledge, No. 2, No. 3, Control Data Corp., Denis Eichhorn and Janie Erickson; No. 4, U.S. Army Signal Center, Dr. Ketner; and the American Heart Association, David Hon.

The meeting is adjourned.

[Whereupon, at 11:10 a.m., the subcommittee was adjourned.]

[Material submitted for inclusion in the record follows:]

Prepared Statement of Rita Kohari, Regional Education Specialist, Apple Computer, Inc., Charlotte, N.C.

Over one million personal computers are at work today and the number is expected to increase twofold by 1988. Microcomputers have transformed the connection between people and computers, creating a productive, interactive one-on-one partnership.

The personal computer delivers power where and when it is needed only it is a different type of power -- the kind that provides quick access to vast amounts of information, instant data processing, and intelligent solutions to a wide range of problems.

Personal computers, previously thought of as expensive gadgets, are changing forever the way we work, learn, and communicate.

Then, what will be the demand for computers in the educational industry? First, consider the number of students in America who own pocket calculators. In this decade we will see calculators and computers changing the nature of the educational system in numerous ways.

The personal computer is becoming more oriented toward the educational process and will be more attractive to prospective buyers. People who can afford a personal computer for their home must be able to justify the cost, therefore, one function to be considered is its teaching capability and value to the children in the home. This affordability of personal computers for the home as well as small businesses will increase the numbers available and will lead to major changes in the educational process.

The development of portable computers will concern about as a necessity of providing students and teachers with more advanced learning tools. Once the technology has advanced to allow for mass production of the compact units, then manufacturers will be able to offer the units at a reduced cost to the consumer.

This change in the industry will allow the technology to become widespread and more readily accessible to people of all economic classes. Computers are rapidly becoming a part of our lifestyle and are not going away. Educators will find it necessary to face this fact and decide how to meet the challenge that lies ahead. Computer literacy for everyone.

With this in mind, how do educators begin to use this powerful tool? The flexibility of purposes and applications is limitless. Availability of programs must become extensive enough to handle all needs for which computers are designed to serve. At the end of 1981, more educational programs had been written for the Apple Computer than any other computer on the market.

Computers which teach and are so-called "smart" will adjust their responses and interact to a degree with their partner at the time. This type of interaction is more similar to that which man is accustomed. One aspect of this type of technology is not always immediately evident. It is far less difficult to develop the technology capable of producing this interaction than it is to develop the methods of providing the accompanying effective teaching materials.
Certain features which add to a more lifelike means of communication are already available. Many computers can be equipped with voice capability through speech synthesis at a low cost. Computers which recognize human speech and will be used to assist in speech problems are probably not going to be available until around 1980. Conversations with these “smart” computers will be taking place after that time. Developments in artificial intelligence will determine that availability.

All of this means that educators of today must be visionary. They must be able to accept the challenge and threats posed by the computers in the preparation of their students for the future. They must understand what impact this technology will have on the methods used in their classrooms. They must be motivated to add to an already exhausting list of responsibilities, countless hours of learning about the technology themselves.

The logical approach to this situation would be the establishment of an educationally sound and governmentally approved computer curriculum. However, the amount of time required for this monumental task is not available.

Another consideration to be placed on the educator’s shoulders is the ramifications of the computer’s degree of penetration. We are creating another division of the haves and have-nots. Again, see the history of the calculator. The child in the educationally and culturally rich home who is exposed to the calculator will experiment, for sheer enjoyment, with all its functions, thus becoming equipped with more skills than one who is less fortunate.

Math teachers are familiar with the student who has acquired an intuitive grasp of fundamental mathematics, as he stands out from the rest of the class. This kind of citizen is even more marked in schools where computers are available. Sharper divisions are occurring as the first teaching computers come on the market. Some children latch on to them with eagerness, while others ignore them completely.

If the trend continues, we may find that we have created a generation of children sharply divided. Some will have magnified their own brain power with the use of the computer, while others will remain behind in the past.

The problem may soon become insolvable. There are always those who seize the gifts that society offers and those who, from either ignorance or lack of motivation, reject them.

The National Education Association’s Special Committee on Instructional Technology reports: “The current impact of new technology on instruction offers increasing impetus to the prospect of a fully functioning universal system of instructional technology.”

Sharon Robinson, Director of NEA Instruction and Professional Development, believes that “a technology of instruction may be imposed from outside by commercial interests.”

The future direction of the educational profession may very well depend on teachers’ abilities to master the technology and know what it can and cannot do, and recognize the essential attributes that they will be providing as well as instructing in technology. The National Education Association Special Committee on Instructional Technology stresses the following:

1. The role and influence of teachers in shaping the future of education in a technological society will depend on the ability of the teaching profession to anticipate, plan for, and give direction to such change.

2. The Rockefeller Foundation Commission on the Humanities describes the situation in “The Humanities in American Life” this way: “If academic education is to be meaningful, it must be given in a way which is consistent with the development of the human mind.”

3. Computer literacy must now be considered among the goals of liberal education by all colleges and universities. The training of undergraduates in the use of computers should include consideration of the social repercussions of information technology. Liberal education must define scientific literacy as less important a characteristic of the educated person than reading and writing.

Educators must become proactive rather than reactive in developing the relationship between education and the world of society. Considered in the plans for action should be the best available projections on the labor force and the job market.

In about 1980 the U.S. birthrate began to decline. Consequently, in the 1980s, the labor force, which draws most of its new workers from young people aged 16 to 24, is likely to grow more slowly. Also, the proportion of workers who are aged 16 to 24 will decline from 32 percent of the total to 22 percent.

In general, growth will continue to be more rapid in industries that produce services that are not those that produce goods. It is predicted that among the service-producing industries, the so-called service industries, the sector called services will continue to grow the most, mainly because of increased demand from the industries that produce health services.
Among the goods-producing industries, manufacturing is expected to pick up during the 80's primarily because of anticipated strong demand for durable goods such as computers and other high technology items. Since the economy is expected to generate fewer new jobs in the 1980's than during the previous decade, one major implication is accentuated—though the lowered number of young workers will experience less competition for entry-level positions. Employers will be raising their entry-level requirements as jobs become more complex.

Preparing a nation's future workforce is a tremendous undertaking. With the incorporation of computer technology into the curriculum, the teacher will ultimately become more of a consultant to his/her students by analyzing the needs, prescribing certain materials, and evaluating the individual's learning progress.

Apple Computer is actively looking for ways to facilitate the use of computers in the education market. Providing computers that are both friendly and easy to operate is one of our corporate goals. This feature of the Apple was one of the many reasons the State of Minnesota decided on it as the standard educational computer system. We will constantly be striving to achieve and maintain the high level of customer satisfaction which we currently enjoy.

Recognizing that our primary area of expertise is hardware, we must rely on the educational publishers and educators themselves to develop and produce educationally sound software programs. Through these programs, students are becoming involved in drill and practice, simulations, gaming, and programming designed to teach concepts or expand students' knowledge levels.

We at Apple understand the budgetary restraints imposed upon the educational agencies throughout the nation. Therefore, we have signed numerous state contracts which enable teachers to acquire Apples at substantial savings. Beyond the initial purchases, though, is the need for the instructional software. Many of the states which buy under the statewide agreements are setting up regional clearinghouses and points for software development. For example, in Raleigh, North Carolina, the Materials Review and Evaluation Center, a division of the Department of Public Instruction, is a resource for educators to preview programs which they are contemplating for purchase. By having access to these materials, North Carolina teachers are saving money by investigating evaluations written by other professionals throughout the state.

Apple Computer is dedicated to providing service and support required by educational users of the computer. Grants are available from the Apple Education Foundation for those professionals involved in software development. Examples of services provided are the resources in the form of workshops and training offered by the dealer network in connection with education representatives located across the country.

Apple literature is published by Apple to keep educators abreast of current events and uses of Apples in education. One of the most frequently requested publications is the Journal of Courseware Review which contains software reviews written by educational professionals.

Resources

At the risk of being considered a pessimist with respect to technology, I should like to inject some sobering views and findings regarding technology's impact on education. For the past nine months, I have been considering the issue of equity as it relates to microcomputer use in education, and what I have found is cause for serious concern.

It should be made explicit that although my observations and judgments are based on the best available evidence, they are clearly lacking in the necessary social scientific support which is required for the formulation of the policy or programs required to effectively address the equity issue.
Five years ago the charge was put forward to Congress to study and plan for the psychological, sociological and political implications of computer technology in a comprehensive manner (Computer and the Learning Society, 1978). This charge has gone unheeded, and today the need for research to determine the educational and social consequences and possibilities of microcomputer use in education is more compelling than ever. If by equity, we mean a fair share of any public services that are required, then we would expect the public schools to provide instruction in a manner which does not favor particular geographical areas or groups or individuals. Unfortunately, there is a clear pattern of inequity in the distribution and use of microcomputers in the American public education. The persistence of disparities in the provision of educational services within and between states and localities and the propensity of the affluent members of society to gain prior access to and benefits from technology militate against equitable technological education in the public schools. In general, the more wealth a school district has, the more likely it is to utilize computers in the schools for instructional purposes. An analysis of a national data base conducted by Litigation Support Services further revealed that schools with a higher concentration of minority students and schools in rural areas are less likely to have microcomputers than their suburban or urban counterparts or schools with small percentages of minority group students. In spite of the public school's historical commitment to equality and the society's efforts to advance this principle, particularly during the past three decades, the basic framework for providing equity in public education has not been achieved. It would seem that the wealthier members of society are the first to perceive the benefits of microcomputer education, improved educational quality and preparation for higher education and higher paid computer related occupations. Furthermore, they have the means to provide themselves and their children with these benefits. An examination of the patterns of microcomputer use for educational purposes suggests that the affluent families first used it in their homes during the late 1970's and then turned to both public and private schools for microcomputer instruction. Not only is there disparity in access to microcomputer use between the rich and the poor, but there is a difference in the use made of the microcomputer as well. At the elementary level, it is the urban, low-income minority student who is more likely to be provided with drill and practice usage of the computers, while the more affluent students use it for more creative purposes, related to problem-solving and discovery. At the secondary level, an analogous dichotomy is beginning to emerge. Low income minority youth are being offered vocational programs designed to furnish technical and computer related occupations. Furthermore, they have the means to provide themselves and their children with these benefits. An examination of the patterns of microcomputer use for educational purposes suggests that the affluent families first used it in their homes during the late 1970's and then turned to both public and private schools for microcomputer instruction. Not only is there disparity in access to microcomputer use between the rich and the poor, but there is a difference in the use made of the microcomputer as well. At the elementary level, it is the urban, low-income minority student who is more likely to be provided with drill and practice usage of the computers, while the more affluent students use it for more creative purposes, related to problem-solving and discovery. An examination of the patterns of microcomputer use for educational purposes suggests that the affluent families first used it in their homes during the late 1970's and then turned to both public and private schools for microcomputer instruction.
would serve as a bridge between the existing subject matter, including the basic skills of reading, writing and mathematics, and the development of reasoning power and problem-solving abilities, thus reconciling the dichotomy between students of different social backgrounds, discussed above.

When the potential benefits of universal computer literacy are considered, or, conversely, when the negative consequences in societal and individual terms of a nation in which some are computer literate and some are not are considered, the task will become clear. It should be recognized that it is a long, costly and arduous one.
Computer and Videodisc: A New Way to Teach CPR

By Lynn Hossinger

Cardio pulmonary resuscitation, or CPR, will soon be taught from the victim's point of view. Using a new, interactive videodisc system developed by the American Heart Association, CPR will incorporate all past terms of CPR instruction in real-time exercises, animated evaluation, theory and training. The system will allow for a totally self-paced learning experience. The interactive system includes a Sony VP 1000 videodisc player, a Graphtec computer, a hand-held operator's guide, and a monitor. The system also includes a Sony VDP 1000 laser 1010 videodisc player, an Apple IIe computer, and a random access video monitor. The heart of the system is a Laserdisc system, allowing an 11 inch picture disc and an array of lessons designed to teach CPR to individuals of different ages, using their experience. The system includes an interactive manikin, designed to be used as a backup in case of mechanical failure. The system is also designed to be used in conjunction with a computer-controlled visual performance. A typical teaching scenario involves the student's performance being evaluated by a computer. The performance is then followed by a discussion with the computer. The system is also designed to be used as a backup in case of mechanical failure. The system is also designed to be used in conjunction with a computer-controlled visual performance.
After the instructional segment of the program is completed, the student is ready for evaluation. On this section, the same methods used to evaluate techniques during the instructional segment are employed to monitor the student's total "hands on" "performance for certification, which lasts approximately one half hour. In fact, the entire process takes more than eight hours. Time estimates for institutional are an average of two hours for a one person course and four hours for a two person course.

Certification is an average of two hours than a few hours. Time estimates for institutional are an average of two hours for a one person course and four hours for a two person course.

Time estimates for institutional are an average of two hours for a one person course and four hours for a two person course.

After the instructional segment of the program is completed, the student is ready for evaluation. In fact, the entire process takes more than eight hours. Time estimates for institutional are an average of two hours for a one person course and four hours for a two person course.

Questions are answered by spelling out words on the template.

Evaluative data appears on the screen indicating overall performance.

A high rate of participation. The system is designed to accommodate up to four participants per instructor. All four students work off one system and receive the same evaluation as a group. Then, using the same system, they receive individual evaluation, which is certified.

The Heart Association estimates that the system could certify up to 2000 learners per year. Total installation costs for the system could be recertified up to 2000 learners per year. Total installation costs for the system could be recertified up to 2000 learners per year.

- Standardized accreditation and certification.
- The system provides a standard for recertification for each individual registered in a CPR course, and is available to new learners as well as those previously trained.
- Reduced personnel requirements.
- Since the system is self-contained, the three to five instructors usually required for small groups are unnecessary. If desired, an instructor may be available to answer further questions or confirm the computer-aided student program results. This eliminates much of the administrative paperwork.
- Learner feedback. The interactive system's "real coaching loop" accelerates learning through immediate feedback and evaluation with the opportunity to review any procedures, view new instructions, and simulations and practice compressions in effect. The user can access the course at any time and for as long as is necessary, saving the instructor's time and the cost of the course at any time and for as long as is necessary.

The system is now in its final development stage. Further tests will be conducted to ensure its effectiveness and reliability.

The Videodisc to Teach CPR

"Interactive Video: What's It Mean to the Trainer of the 80's?" was one of several concurrent sessions presented at the Sheraton Boston, May 17-22, during the ASTD Conference and Exposition.

It would be hard to imagine a more effective presentation of the Sony Interactive Video System than was produced by David Hon, national training manager of the American Heart Association.

David took the hardware, saw what it could do, created a learning program for it, and extended the use of the hardware itself—all in all a formidable accomplishment. The idea is not really new, and those who date back to the Link training system in the 1950s will concede that having a learning tool talk was reduced to practice earlier. But Mr. Hon places the idea squarely in 1981, and his route to this kind of feedback is unique. He says—and quite properly—that it is hard to put into words the things he does, but while the system is its best advertisement or explanation, we'll give words a shot here.

The problem is that CPR (cardiopulmonary resuscitation) inspectors are in short supply—when you consider that about 10,000 persons die daily as the result of failure to get help quickly. The instructor has to teach a great many people, and hurry out. They must be requalified periodically. The self-paced training system which Mr. Hon has devised for the Heart Association consists basically of a videodisc player, two monitors, a student response keyboard and wristband, and a menu. The left monitor shows a doctor figure who talks you through the program—“How to Avoid . . . ” The right-hand monitor shows computer-modeled feedback to a variety of ways. The menu is rigged with a lot of options, primed by a

from the burglar alarm field, which tell the computer how deep chest compressions are being made—if the ventilation is effective—things like that. Success or failure with the manikin is fed back almost instantly to the student.

The entire program—which must have been murderously difficult to devise—runs two and a half hours, and is derived from a 30 minute video. The disparity really belongs in still-frame form. It theoretically would be possible to deliver a 400 hour program from the same 30 minute disc. More time, more attention, for the student gets into trouble, it's possible to call up the menu. It's much like the bank auto-teller display. "Do you want to make a deposit, or check your balance or get cash?" There are more options, including "I'm going on a break." The program also contains a fairly lengthy "dictionary." If any word is unfamiliar, the learner can call up that word and an explanation of it.

Perhaps Mr. Hon is right—and no sensible explanation of what he does can be given in print. At the least, this description should lead you either toward a more complete explanation of it, or away from the temptation to avoid it. As Mark Heyer of Sony said, the future belongs to trainers who meld the talents of instructional design, video production and computer programming. This has not always been a comfortable mix—and the clear winners will be those who can do all three.

Interactive Video Disc With Manikin Computer and Manikin

This may be the new era in the world of the VHS. The VHS is a system developed by Jhon A. Voss and his associates. It was first introduced in 1975 at the International Consumer Electronics Show in Las Vegas, Nevada. The VHS is a system that combines the video and stereo features of a television with a manikin. The manikin is a model of a human body that can be used to simulate various actions.

The manikin is a substitute for real patients in the world of medicine. It is used to simulate various medical procedures and treatments. The manikin can be used to practice various medical procedures, such as heart bypass surgery, and to simulate the effects of various medications.

In the world of medicine, the manikin is used to train medical professionals. It is also used to simulate medical emergencies, such as heart attacks, and to train emergency medical personnel.

The manikin is also used in the field of education. It is used to teach medical students about various medical procedures and treatments. It is also used to teach medical students about the effects of various medications.

The manikin is a valuable tool in the world of medicine. It is used to train medical professionals, to simulate medical emergencies, and to teach medical students about various medical procedures and treatments.
Disc Business:

TOWARD REAL-WORLD APPLICATIONS

At The Chicken and Egg Marketplace

By David Hirn

Some of the recent announcements that we have covered in our columns have included the release of a new disc player, or the introduction of a new type of disc, or the signing of a new deal between two companies. These announcements are of great interest, but they are only the tip of the iceberg. There is a whole world of possibilities that exist beyond these announcements.

The Situation Now

Most of the recent announcements have been about the future, about what will happen, and not about what has already happened. The most recent announcements have been about what will happen, and not about what has already happened. The most recent announcements have been about what will happen, and not about what has already happened.

The Basic Volkov

The Basic Volkov has been given the honor of being the first disc player to use the new type of disc. This disc player is expected to revolutionize the way we watch movies and television shows. The Basic Volkov is designed to be a high-quality, high-performance device that will provide a superior viewing experience.

The Basic Volkov is equipped with the latest in disc technology and is designed to provide a superior viewing experience. It is expected to be sold at a price that is competitive with other disc players on the market.

The Basic Volkov is expected to be available for purchase in the near future, and it is anticipated that it will quickly become a popular choice among disc players.

The Basic Volkov is a significant step forward in disc technology, and it is expected to set a new standard for disc players.

How devices restore democracy

The range of devices and user selections through which they can become interactive is immense. The devices themselves are often quite simple, but the range of possibilities is enormous. The simplest device is a light pen, which can be used to select items on a screen. More complex devices include touch-sensitive screens, which allow users to interact with the computer in a more natural way. The range of devices and user selections is limited only by the imagination of the designer.

Interactive devices...

The user interface is a critical component of any interactive system. It must be designed to be intuitive and user-friendly. The user should be able to easily navigate the system and perform tasks. The user interface should also be consistent across all devices and platforms.

Telling someone...

The user interface is a critical component of any interactive system. It must be designed to be intuitive and user-friendly. The user should be able to easily navigate the system and perform tasks. The user interface should also be consistent across all devices and platforms.

Comment on page 12}

From Video User, Dec. 1981
And Now, Dynamic Discs

New TV technology opens a world in which touching is believing.

The child's hand reaches out intently. Years of telephone-wrapping tape, finger一楼s, eyes, and ears, have taught him the language of touch. But when the child rolls up his sleeve and touches the screen, it's a new experience. Electricity surges through his body, a jolt of power that reawakens the senses. He can feel the world in a new way.

This is the world of dynamic discs, the latest in home entertainment technology. The discs are made of a special material that reacts to touch, creating a tangible experience that immerses the user in a virtual world.

The discs are designed to be used with a special set of hardware, the Dynamic Disc Player System (DDPS). The system includes a display screen, a remote control, and a series of discs that can be loaded into the system.

To use the DDPS, the user simply loads a disc into the system and selects the desired program. The disc will then be displayed on the screen, and the user can interact with the program by touching the screen.

The discs are interactive, allowing the user to explore and learn in a new way. They can be used for educational purposes, such as teaching geography, science, or history. They can also be used for entertainment, such as playing games or watching movies.

The DDPS is compatible with a variety of devices, including personal computers, televisions, and game consoles. It can be used with any touch-sensitive display, making it a versatile and flexible system.

The future of home entertainment is here with the DDPS. It is a new way of experiencing the world, one that combines the power of technology with the magic of touch.
Mr. Chairman and members of the Committee, my name is Denis Eichhorn, Regional Manager for Educational Services, Control Data Corp., Washington, D.C.

Control Data Corporation is a worldwide computer and financial services company based in Minneapolis. It employs some 60,000 people and sells products and services in almost 50 countries. Its combined total revenues last year were more than $4.1 billion.

Control Data's long-term business strategy is based on the belief that society's major unmet needs can be addressed as profitable business opportunities. As William C. Norris, Control Data's Chairman and Chief Executive Officer, told the Senate Subcommittee on Intergovernmental Relations last year, these business opportunities exist because reliance on public programs has failed to end the decay of our inner cities, the poverty of our stricken rural areas, the unemployment of disadvantaged youths, the overcrowding of prisons, and the problems of inadequate education and training. "We need fundamental change where business takes the initiative in partnership with government and other sectors to address societal needs as profitable business opportunities," he said.

A major aspect of this strategy has been the development and implementation of educational technology, with a primary focus on the unique needs of people seeking employment and training for particular job skills. One of the results of Control Data's commitment to education and training is the computer-based system called PLATO. The PLATO system is specifically designed to deliver computer-instruction and computer-managed instruction in an effective and efficient way. I stress the word current because the PLATO system by its very nature is constantly evolving and changing. Today it includes delivery of both large, centrally-based computer systems and communication networks, as well as the small stand-alone microcomputer which some of you probably have in your homes today.

Most of us in this room have used computer companies such as Control Data, think in terms of hardware and high technology, but let me stress that Control Data does not have a monopoly on computer technology. You are aware of the room this morning and see examples of computer technology developed by various manufacturers. The issue then is the training that the technology delivers. It is in this area that Control Data is focusing its primary development efforts, making it the coursework electronic publisher. Effective courseware must be understandable by the student and must hold the interest of the student. Authoring of course material must be easy for the computer professional and must also be economical to use. We want to be able to capture the thoughts and techniques of today's effective teacher.

Control Data is investing considerable effort in the development of an authoring system which is both easy to use and facilitates courseware development for not only Control Data's PLATO terminals but those of other manufacturers as well. Courseware has been developed by Control Data for the elementary level student. The Basic Skills curriculum is a remedial program developed for youth. It has been used effectively in both government agencies and public school systems. The Basic Skills Curriculum covers the competencies of mathematics, reading, and language from grades three to eight. A significant portion of its value to educators lies in the placement test which establishes which skills are in need of remediation and provides a program of study for the individual student. Tutorials delivered through the terminal teach the demonstrated need, and the student is tested for mastery. In this way, each student maximizes available learning time. Under development is courseware in mathematics, English, and science, which will carry the student from the eighth grade level through the twelfth grade.

In higher education we are working with a consortium of five major universities across the country to develop a curriculum which fulfills requirements for the first two years of an engineering education at most colleges and universities. This curriculum, which is very applicable to community colleges and vocational schools where students need grounding in basic science and engineering fundamentals, will also provide a gifted student curriculum for the secondary school system.

The Control Data computer literacy curriculum which is under development will provide a comprehensive series of lessons in this subject. This material will permit tailoring to address the needs of teachers and students from grades eight through
12, the computer science major in college, as well as the vocational trainee whose interest is in technician-level instruction.

During the 20-year development period, Control Data has achieved a number of notable results, all of which verify the effectiveness and practicality of utilizing computer technology to enhance and improve the education and training process. For example, in 12 secondary schools in the State of Florida, it was found that math instruction delivered by PLATO terminals could impart at least one grade level of improvement with every 20 hours of terminal contact by the student. Other school systems have reported similar results. Control Data is sponsoring a joint venture with the D.C. School System. Eight terminals will be utilized to deliver instruction to 400 students at the Spingarn High School in northeast Washington. There is more statistical support validating its effectiveness.

For example, in 12 secondary schools in the State of Florida, it was found that math instruction delivered by PLATO terminals could impart at least one grade level of improvement with every 20 hours of terminal contact by the student. Other school systems have reported similar results. Control Data is sponsoring a joint venture with the D.C. School System. Eight terminals will be utilized to deliver instruction to 400 students at the Spingarn High School in northeast Washington. There is more statistical support validating its effectiveness.

Through a program called Fair Break, Control Data is delivering remedial and work readiness training to disadvantaged, unemployed youths in over 50 locations throughout the country, using computer-based education as a primary medium of delivery. Fair Break survey results show: 90 percent of program completers pass their GED exam; 87 percent of completers are placed in jobs for further vocational training; and 73 percent of those placed in jobs are still employed six months later.

At the Department of Army, PLATO is being used to train recruits who do not have desired levels of competency in reading, math, or English. Utilization of PLATO-delivered training has shortened time required to achieve necessary levels of competency by 20 percent, thus helping both the Army and the recruits.

There are many statistics supporting the improved speed with which the student can learn, compared with traditional methods. It is more difficult to capture statistics for the improvement in attitude and motivation on the part of the students.

For example, Dr. Anne Emery, Assistant Superintendent, Office of Public Information and Communication, Baltimore City Public Schools, has said, "I have seen PLATO excite students and make them want to learn. I have seen the improvement in attitude and grades. It will be to their everlasting shame if educators do not get involved with support and use the system."

Another aspect of computer-delivered instruction is the increased mobility which it offers and the linkages which can be made much more easily between our public institutions. One local example of this is a program which was jointly sponsored by the University of Maryland and Control Data to deliver PLATO services to the Baltimore School System and the Baltimore CETA prime sponsor. Control Data turned over to the University of Maryland its PLATO client base in the City of Baltimore. The University of Maryland has acquired their own central PLATO delivery service and is now in the early startup stages of delivering PLATO services to the greater Baltimore communities. This has resulted in linkages between the University of Maryland and the Baltimore School System. Both the University and the School System in Baltimore will be the beneficiaries, and the education of the public school student in Baltimore will be the primary beneficiary. The concepts such as the wall-less classroom can easily be implemented with this type of technology.

A number of major corporations are using training delivered by Control Data, such as General Motors, United Airlines, Shell, and Federal Express. All of these companies are working at the issue of improved productivity, and they are achieving that improved productivity through training. Computer technology is the only practical way to deliver that training. Labor and travel costs are just too high. Furthermore, because of the nature of the training which must be delivered, one must ensure it is delivered accurately and effectively. It has been said that, if productivity is America's problem, the solution is education. Computer-based education is the means of delivering education efficiently and quickly.
PLATO System Spurs Baltimore Students to New Achievements

by Anne D. Emery, Ph.D.
Principal, Walbrook High School
Baltimore, Maryland

Last June (1979), 20% of the 538 Walbrook High School seniors failed state of Baltimore mathematics and reading proficiency tests mandatory for the first time for graduation. Needing a quick, effective solution, we decided to reeducate the students with a computer-based basic skills learning program.

After 60 days of using the Control Data PLATO system for basic skills instruction, all but nine seniors passed the mandatory tests.

Although we have used the PLATO system at Walbrook for more than 5000 hours, including a small pilot operation, we have only 120 terminals. Many of the seniors who failed the tests last June had no access to the computer-based education system. If we had had 100 terminals because of a large number of students enter Walbrook High, an inner-city school, with reading and math skills below the sixth-grade level.

The staff of just 110 teachers has only one full year to work with 2,500 pupils. Fortunately, though, 90% of the students chosen for the PLATO program increase their achievement levels. Youngsters at both ends of the learning spectrum have succeeded as many as three grades within a single school year.

Each unit within the PLATO Basic Skills Curriculum has one or more objectives. As the student progresses, the objectives become more complex. However, the student may repeat all activities in a unit as many times as necessary to master a given objective. And no one, not even other students working at terminals alongside, is aware how long it takes.

By presenting materials in small increments, the PLATO method matches the student to his or her level of understanding. It encourages him or her to proceed at his or her own pace, without peer pressure and embarrassment. This helps the student build a history of successes, which he or she can draw on in the future. Each unit within the PLATO Basic Skills curriculum has one or more objectives, which the student must master before he or she can move on to another unit. The beginning units have several simple objectives; as the student progresses, the objectives become more complex. However, the student may repeat all activities in a unit as many times as necessary to master a given objective. And no one, not even other students working at terminals alongside, is aware how long it takes.

Teachers Learn Immediately When Student Needs Special Help

The PLATO system provides the type of individual remediation that most teachers in typical classrooms cannot give. It slows down on each student's progress, which allows the teacher to evaluate the child's efforts.

For example, if a youngster is spending too much time on the tutorial aspects, the teacher can assume that he or she is having a problem. He or she may be changing the teaching method, or changing the teaching medium. At that point, the teacher and the student will spend more time together. The goal is not to have the student work independently, but to have the teacher work with the student, individually.

The PLATO system is designed to handle any subject matter, and the teacher does not have to know the subject matter in order to teach it. The teacher can in fact stay at a grade level, and this will not change the grade level of the student. The PLATO system will then slow down and work with the student, individually.

The PLATO system is used in many schools nationwide, and the results have been outstanding. In fact, the PLATO system has been described as the most significant educational innovation of the last 20 years.

INTERACT

INTERACT, a subsidiary of Atrionics Incorporated, was formed to produce and market interactive videodisc educational systems with a primary emphasis in medical education and training. INTERACT is now marketing a self-contained Cardiopulmonary Resuscitation (CPR) Training System originally developed by the American Heart Association (AHA). INTERACT purchased the exclusive rights from the AHA to market the CPR system worldwide.

INTERACT's system utilizes a microcomputer to exploit the random access capabilities of the laser videodisc to instantly store and retrieve audio and video information. The resultant system enables a highly interactive learning experience. Sophisticated computer software is used to quickly select the appropriate section from the videodisc in order to dynamically tailor the material to the individual student's requirements. The training determines together, in real-time, how the patient responds, enabling the CPR technician to give the necessary intervention.

In addition, INTERACT provides a line of interactive CPR training kits from the American Heart Association which also train the student in the AHA's standard teaching methodology. INTERACT systems are designed to be used in conjunction with the CPR training kits. The system allows the student to practice CPR on a variety of patients, all of whom are stored in a video library. The training kits provide detailed directions and feedback to the student during the practice runs. This interactive approach allows the student to learn CPR in a more realistic and effective manner.

Interactive Training in Cardiopulmonary Resuscitation

Computer and videodisc technologies combine to provide instruction in lifesaving techniques.

David H. Johnson
Advanced Technology Development
American Heart Association
National Center
300 W. Commerce Ave.
Dallas, TX 75204

This paper is part of a series discussing the technology and applications in the field of training and education. It highlights the importance of interactive training in CPR and discusses how computer and videodisc technologies can be used to enhance the learning process. The paper emphasizes the importance of staying current with the latest techniques and guidelines in CPR, as the field is constantly evolving. It also addresses the need for ongoing training and practice to maintain and improve these critical skills.

The number of people who receive CPR training is limited, and the number of people who perform CPR in an emergency is even more limited. The paper suggests that computer and videodisc technologies can help increase the availability of CPR training and make it more accessible to a broader audience.

The paper also discusses the importance of ongoing training and practice in maintaining and improving CPR skills. It notes that CPR skills can deteriorate over time if not practiced regularly. The paper highlights the role of computer and videodisc technologies in providing ongoing training and practice opportunities.

In summary, the paper underscores the importance of using technology to enhance and expand CPR training and education. It suggests that computer and videodisc technologies can play a critical role in improving the availability and effectiveness of CPR training and practice.

NAME

ACTIVITY AND TIME

PERFORMANCE

PASS / FAIL

1. Properly demonstrate correct hand placement for all threeORMs.
   - Hand placement is correct if the following criteria are met:
     - The right hand is placed on the patient's chest, with the thumb on the sternal border and the fingers on the ribs.
     - The left hand is placed on the patient's abdomen, with the fingers on the umbilicus.
   - Trace the rotation and postioning of the hands as demonstrated.

2. Perform CPR for a minimum of 1 minute.
   - Begin with chest compressions and continue with CPR for 1 minute or until medical assistance arrives.
   - Ensure that the rate is between 100 and 120 compressions per minute.
   - Monitor the effectiveness of compressions and adjust as necessary.

3. Perform rescue breathing and assess the patient's respiratory status.
   - Administer two rescue breaths at a rate of 1 breath every 5 seconds.
   - Observe for signs of life, such as chest movement and changes in color.

4. Complete the CPR course and receive certification.
   - Successfully complete the course and receive a certification card.

These guidelines ensure that students are prepared to respond promptly and efficiently in emergencies, mastering the essential skills and knowledge required for effective CPR.
The Prototype

The prototype was developed to test the feasibility of the concept. It was a simple design that could be easily modified to accommodate different requirements. The prototype was tested in various conditions to ensure its reliability and effectiveness. The results were promising, and further development is planned to refine the design and improve its performance. The prototype was presented at the conference, and the feedback was positive. It is hoped that this prototype will serve as a foundation for future developments in this field.
We approached a number of companies about using systems with greater capabilities. Some were willing to cooperate in the project and others offered substantial technical and financial support. But some would not, and others were unwilling to share their ideas with us.

The Sony television model SFE 1000 was chosen for its high-quality performance and versatility in television generation. The SFE 1000 model is a television that offers high-quality performance and versatility in television generation. The system price and performance are the key factors in this product's development.
The greatest challenge in this project was writing a set of programs to automate the design of digital signal processors and digital communications systems. The text box below provides a brief overview of the project and its goals.

Software

The software was designed to have two main functions: to test the student's performance on the programming tasks, and to determine the student's performance on the design tasks. The software was written in the programming language of the student's choice, and a version of the Apple II Plus was used to test the student's performance. The software was designed to be as easy to use as possible, and it was intended to be used by students in a classroom setting.

The problem was to design a digital signal processor that could be used to perform a specific task. The software was designed to test the student's ability to design a digital signal processor that could perform the task. The software was designed to be as easy to use as possible, and it was intended to be used by students in a classroom setting.

In the first part of the project, the student was required to design a digital signal processor that could perform a specific task. The software was designed to test the student's ability to design a digital signal processor that could perform the task. The software was designed to be as easy to use as possible, and it was intended to be used by students in a classroom setting.

The student was required to design a digital signal processor that could perform a specific task. The software was designed to test the student's ability to design a digital signal processor that could perform the task. The software was designed to be as easy to use as possible, and it was intended to be used by students in a classroom setting.

The Interpretive Language Used to Program the CPR System

Mike Lemmas
Laumer Research
1932 School Rd
Carrollton, TX 75006

The interpretive language developed for the CPR system contains over 60 different keywords that make possible the programming of the various hardware elements of the system: light pen, Apple monitor display, Teletypewriter, audio, and microphone. The language is similar to assembly language with the familiar code/argument structure known in assembly language programming. Almost half of the instructions are devoted to the computation and logic activities of a task process while the other half is dedicated to the special hardware elements of the system.

A powerful sublanguage exists for displaying text and box and high-resolution graphics on the Apple monitor screen and for building tables for the light pen commands to work from. The tables for the pen commands contain the number of rows in the table, the number of columns, the row and column that contains the item to be marked and the row and column that contains the item to be unmarked. When the pen command executes, it detects the presence of a menu item and, if present, it causes the text in the menu region to be highlighted (black text on a white background) to indicate its current selection. When the pen moves on to another field, the previous field is replaced by a menu and the new field is highlighted. Touching the pen on the pen to make a menu selection will return a number to decoding the table entries that was highlighted last and a row number on the Apple monitor screen feedback.

Listing 3 shows a sample command sequence used in the interpretive language with comments on the operation of the code. The net result of the sequence included in the last few lines of code is to override performance. Figure 3 is a flow chart of the part of the program that teaches external chest compression.

In this box on page 126, Mike Lemmas gives some insights into how the programming was done. Listing 1 is a sample of some code that Mike wrote in the interpretive language developed for the CPR project.

The Light Pen

There is a big difference between using a light pen to simplify a few types of input and using a light pen as the only input under user control. In our system, the light pen had to do almost everything that a keyboard can but without the keyboard's complexity.

We organized the use of the light pen around a menu of nine choices. The student would choose one of the nine items by pointing the light pen at it and, when the block around the item lights up, touching the place between the light pen's two metal tips. The nine choices, as shown in Figure 3-1, include selecting a subject index and vocabulary check; reviewing the last 15 seconds of instruction; stepping through frame by frame; practicing on the manikin; taking a quiz; requesting the program after a break; receiving a verbal quiz on material that the student thinks he or she knows; and calling a live person for assistance.

Since it was vital for the student to feel in control, we made the selection menu always available. We decided that two monitors were necessary, and it would add to the system's capability. One would always be available to take input from the student and to display output from the computer. The other would constantly display information from the videotape. At times, we discovered that to work together as a highly sophisticated instructional tool. Furthermore, the cost of the second monitor was a small part of the cost of the whole CPR system.

If at any point in the instruction the student gets confused, he can say, "I know I've seen this. I want to try the remainder."

Such feedback keeps students interested.
To provide for alphabetic input from the students, we provided a word template system that provides a listing of the alphabet and allows the student to spell out a word by touching characters on the list. Photo 4 shows the template in use. The software here can handle most spellings of the words intended. Rather than insisting on exact spellings, the software checks to see if key letters are present in the correct order. If the student is trying to spell "puls e," the software will understand as long as the student enters the letters "PLS" in that order, regardless of the letters that come before or after.

The light pen provides access to several different levels of explanation of the key vocabulary words. Each level may involve printed and spoken explanations and labeled diagrams. The first definition provided is short and simple, letting the student quickly check the correctness of his or her understanding of the term. The student can always use the light pen to enter "M" for "More" to get a deeper level of explanation. Photo 5 shows a frame with a basic explanation and PR.

Students also use the light pen during instruction, as shown in photo 6. Providing different levels of explanation on demand helps to implement the concept of learning as opposed to the traditional step-by-step, linear concept. The system meets the needs of each student. People who want more thorough definitions can always get them. People who just want to learn enough to perform CPR need not go to such lengths.

One benefit of the modular approach is that a single nucleus program can satisfy several different levels of learning needs. This helps a great deal in amortizing development costs.
