This training manual, the third volume in a four-volume series of curriculum guides for use in training Peace Corps agricultural development workers, deals with crops. The first chapter provides suggested guidelines for setting up and carrying out the crops component of the agricultural development worker training series. Included in the second chapter are lesson plans covering the following skill areas: the agricultural environment, crop production management principles, units of measure, soil management and fertilizer use, water management, insect control, disease and nematode control, weed control, vegetable production, and traditional field crops. The third chapter consists of a series of technical resources covering basic vegetable production practices from garden planning through harvest. Provided in the appendix are skill goals and objectives, a supply and equipment list, sample planting instructions, a sample field notebook page, and an exam. (MN)
THIS VOLUME IS ONE OF FOUR IN THE AGRICULTURAL DEVELOPMENT WORKER'S TRAINING MANUAL. EACH OF THE VOLUMES IN THE MANUAL AND A SUMMARY OF ITS TABLE OF CONTENTS IS PRESENTED BELOW:

VOLUME I: ORIENTATION FOR TRAINERS

Chapter 1: Orientation for Trainers
Chapter 2: Training Design

VOLUME II: EXTENSION SKILLS

Chapter 1: Orientation to the Extension Component of Agriculture Training
Chapter 2: Curriculum of the Extension Component
Chapter 3: Extension Resources (Handouts and Reprints)

VOLUME III: CROPS

Chapter 1: Orientation for the Crops Training Component
Chapter 2: Curriculum of the Crops Training Component
Chapter 3: Technical Guidelines and Reference for the Crops Training Component

VOLUME IV: LIVESTOCK

Chapter 1: Orientation for the Livestock Training Component
Chapter 2: Curriculum of the Livestock Training Component
Chapter 3: Technical Guidelines and Reference for the Livestock Training Component
PREFACE AND ACKNOWLEDGEMENTS

Volume III of the Agricultural Development Worker's Training Manual has been developed for Peace Corps by A. L. Nellum and Associates, Inc. (ALNA) at PENN Center in Frogmore, South Carolina in 1982.

The principal author of Volume III is David Leonard, Senior Crops Trainer. Assisting him were these training staff members: David Peters, Donna Ruscavage, Freddie Smith, Alethea Rudd, Valerie Stetson and Karen Leban. Julia Simmons, Barbara White, Kim Thorne and Ronnie Gold prepared the text. Martin J. Blank supported the development of this volume in the ALNA headquarters office, while Michael Gibbons directed the overall project in Frogmore.

Appreciation is extended to Peace Corps staff who assisted in the task of preparing this volume: Calvina Dupre and Franklin Moore. We wish to thank Emory Campbell, Executive Director of PENN Center, the St. Helena Island community and those trainees who participated in the training programs which gave life to this volume.

A. L. Nellum and Associates, Inc.

INTRODUCTION TO VOLUME III

Purpose of this Volume

This volume is designed to serve as a resource, not a blueprint, for trainers involved in Peace Corps ag training programs that have a crops technical training component.

Intended Audience

Technical Crops Trainers
Technical Ag Education Trainers
Technical Ag Community Development Trainers
Technical Ag Rural Extension Trainers

These trainers are most likely crops specialists, host country ag instructors, or ag or community development Volunteers who have done crops work. They might work with an experienced lead crops trainer in planning and carrying out sessions on soil management, insect control, and other crop production areas.

How to Use this Volume

This volume is designed to aid crops trainers in planning and carrying out the crops portion of a training program. While the training design is primarily intended for pre-service trainings, much of it would be useful for in-service workshops. Here is a usage guide to Volume III:

Chapter I provides suggested guidelines for setting up and carrying out the crops training component.

Chapter II contains the suggested crops training curriculum which includes a sessions list and a lesson plan for each session. The lesson plans are not meant to be a rigid "script" but rather a convenient starting point for session planning. Crops trainers will likely find themselves modifying the plans to suit variations in programs and training sites.

Chapter III is the crops technical resource section. It contains the Crops Guidelines package that covers basic vegetable production practices from garden planning through harvest. It was developed and written by Peace Corps crops trainers for use both in training and on the job. In addition, a detailed crops reference bibliography is included.

The Appendix contains lists and other handouts pertinent to Chapters I and II such as a supplies list, sample exams, and planting instructions.
CHAPTER I: ORIENTATION TO THE CROPS COMPONENT OF AG TRAINING

A. OVERVIEW OF THE CROPS TRAINING COMPONENT

While short term ag training cannot produce fully qualified extension workers, it can provide entry level competence and credibility and make trainees aware that crop production is a very complex endeavor with few "cookbook" recipes. This manual is primarily concerned with pre-service training which is meant to be only the first phase of an on-going skill building process that should continue throughout a Volunteer's service in the form of on-the-job experience and in-service workshops.

Because of the very practical nature of crop production and the average trainee's lack of experience, the crops training component has a definite field bias that emphasizes hands-on learning. The curriculum consists of about 65-70% field sessions and 30-35% classroom sessions. Each trainee prepares, plants, and manages his/her own individual plots and also assumes care of advance plantings. Crops production is treated as an integrated system made up of the following interrelated management areas: planning, land preparation, planting, soil management and fertilizer use, water management, weed control, pest and disease control, and harvesting, drying, and storage.

The crops training curriculum consists of the following ten Skill Groups:

I. The Agricultural Environment
II. Crops Production Management Principles
III. Units of Measure
IV. Soil Management & Fertilizer Use
V. Water Management
VI. Insect Control
VII. Disease and Nematode Control
VIII. Weed Control
IX. Vegetable Production
X. Traditional Field Crops Overview

Aside from crop production, the crops training component also attempts to foster a balanced outlook on the chemical vs. "organic" issue and an awareness of conservation, ecological, and social issues relating to small farmer agriculture. In addition, a special effort is made to reinforce and illustrate many of the ag extension principles covered in the extension component—most importantly the principle that "improved" agricultural practices require adequate testing in a local environment before being promoted.
B. PREPARING THE CROPS TRAINING COMPONENT

Preparing the crops training component involves the following tasks:

1. Assemble and review host country program and ag information.
2. Agree on crops staff roles.
3. Design the crops training and make a rough schedule.
4. Design the training plots.
5. Assemble written materials.
6. Assemble supplies.
7. Prepare the site.

1. ASSEMBLE AND REVIEW HOST COUNTRY PROGRAM AND AG INFORMATION

Program information: The host country program's goals and activities are usually covered during the all-component staff training sessions. However, the crops staff must also gain a clear understanding of the specific entry level ag skills needed by the program's Volunteers. For a checklist of specific skills, refer to the crops training objectives in the Appendix of this volume.

Ag Information: It is essential that the crops staff have adequate host country ag information available so that technical training does not become overly generic. (For a list of needed ag data, refer to the Pre-Training Research (PTR) section of Volume I). Absence of such information is often a problem for ag training programs conducted outside of the host country. A pre-training research trip can address this problem.

In lieu of a PTR trip, the next best solution is for the host country ag APCD to mobilize ag PCV's to compile the needed ag information and then mail or pouch it to the training center with sufficient lead time. Another way to incorporate relevant host country ag information is to include an RPCV with host country ag experience on the staff. Keep in mind, however, that such persons may lack accurate information on country regions beyond their own work area.

2. AGREE ON CROPS STAFF ROLES

In addition to apportioning responsibility for the various preparation tasks, the crops staff should mutually define each member's actual training role. When new trainers are involved, the most appropriate crops staff role definitions usually will not become apparent until after the first week of actual training when everyone has a much clearer idea of the training program, as well as each other's skills and preferences. Since some crops trainers also work in the other components, the role definition process also requires consultation among the component coordinators.

Another consideration is the issue of trainer vs. training assistant (TA). It is usually a mistake to rigidly delineate responsibilities on the basis of such titles, since it tends to load down the TA's with "chores" rather than foster meaningful involvement and learning. It is suggested that the TA position be treated as a working apprenticeship that includes some opportunity to design and run sessions.
DESIGN THE CROPS TRAINING AND MAKE A ROUGH SCHEDULE

As with crop production, training design is a very location-specific endeavor heavily influenced by program and site factors. In arriving at the most feasible and appropriate design for a particular training program, the crops staff should consider the following variables:

a. The host country program's goals, specific crops involved, and ag skill requirements.

b. The number of trainees and crops trainers: Both the trainer/trainee ratio and the actual number of trainers and trainees are important. Coordination problems increase almost geometrically with trainee numbers, even when trainer/trainee ratios are optimum. Activities that are smoothly accomplished in small programs require considerably more preparation and time to accomplish when groups are large.

c. Number of countries to be trained at once.

d. Number of hours available for crop training.

e. Length of training: A 4-6 week program will need more advanced plantings than a 12 week program to provide trainees working experience with the crops in all phases of growth. Likewise, short term programs with their much higher number of technical hours per week require more crops trainers.

f. Training site factors: Amount of land available and its proximity to classrooms and cafeteria; weather conditions that will affect growth rates and the amount of time spent on watering; opportunity for relevant experience on nearby small farms or research stations.

g. Kind and amount of additional ag training: If the first phase of training takes place outside the host country, the crops staff should be aware of the kind and amount of additional ag training that will occur during the in-country phase. Likewise, training programs occurring entirely in-country have the option of introducing or refining some ag skills during future in-service workshops.

With the above variables in mind, the following procedure can be used to plan the crops training design and the rough schedule:

STEP 1: Read over the next unit titled "Carrying Out the Crops Training Component" as well as the section on overall training design in Chapter II of Volume 1.

STEP 2: Determine which of the needed ag skills can be appropriately and adequately covered during this phase of training. Use the crops training objective list in this Volume's Appendix as an aid to defining specific ag skills.
STEP 3: Select the crops to be grown during training. Ideally, these should be the same crops the trainees will be working with as Volunteers. However, time constraints, growing conditions, and lack of planting material may necessitate substitutions. In this case, select related crops that can be used to teach the same skills. For example, if it is too hot to grow spinach and lettuce, you might use more heat tolerant greens such as mustard, amaranth, or New Zealand spinach.

STEP 4: Draw up a list of crops sessions with their tentative hour allotments, based on the program's skill needs and available training hours. Refer to the crops sessions list in Chapter II of this Volume. Some guidelines:

a. As a ballpark figure, the initial land preparation and planting sessions will take about 18-24 hours and total plot maintenance time about 25-35 hours. Allot 2 hours/week for exams and 1/2 hour/week for a postexam review session.

b. DON'T CRAM TOO MUCH INTO TRAINING—It's a big temptation but results in hurried overviews and early burnout of staff and trainees.

c. Aim for a mix of about 65-70% in-the-field activities and 30-35% classroom sessions.

STEP 5: Roughly map out the weekly flow of the crops sessions, but do not worry about daily progression yet. Useful guidelines:

a. The first priority is for the trainees to get their crops in the ground as soon as possible, preferably during the first week in a six week program.

b. Plot maintenance sessions can be plugged into the schedule on an approximate basis. Unless trainees are to take over the care of advance plantings right from the start, only an hour or two of maintenance time will be needed during the first week while the new plantings are emerging. A six week program with 120-160 hours of crops training will need about 30-40 hours of maintenance sessions. There is considerable flexibility in scheduling or changing maintenance sessions, because they can be easily swapped with crops classes or other field sessions without difficulty.

c. It's helpful to organize crops training around weekly themes such as planting, fertilizer use, and insect control so that trainees can focus their energies on one set of skills. Likewise, weekly themes of the three components should be coordinated to promote training cohesiveness and integration.

d. When possible, coordinate the introduction of a skills area with its actual field need. For example, the ideal time to begin the Insect Control unit is when insects first start to become a problem, usually during the second or third week. Likewise, the initial Units of Measure session should be done the first week when
trainees encounter the Metric system or unfamiliar traditional units of measure in the planting sessions.

e. Likewise, coordinate classroom activities with field activities so they reinforce each other. For example, the field session on applying insecticides with a sprayer should occur shortly after (within a day) the classroom session on insect control and insecticide safety.

f. Pace the flow of training. Look closely at each of your tentative weeks, and don't forget to consider the other components' activities. If trainees are hit with fertilizer use, fertilizer math, feed ration math, and a family live-in during the same week, the effect on trainee morale CAN BE DEVASTATING.

g. Avoid introducing much new material during the final week.

h. Don't forget to plug in the 1/2 hour post-exam review session, but let the trainees organize and run their own pre-exam review and tutoring sessions after hours.

STEP 6: Before attending the all-component meeting to draw up the overall daily and weekly training schedule, prepare a list of crops scheduling priorities and "givens". Some suggestions:

a. The first crops activity should ideally be a planting session to set an experiential pragmatic tone to training.

b. In hot weather, any high labor field sessions like land preparation and planting are best done in the mornings.

c. When possible, sit-down classroom sessions should not be scheduled for the final two hours of the afternoon; this is a good time for light duty field work or study.

d. Likewise, avoid Saturday classroom tech sessions in favor of maintenance activities or in-the-field instructions.

e. Usually the best time for the weekly crops exam is Friday morning right after breakfast for 1-2 hours. Since not all trainees will finish the exam on time, it's a good idea to follow it with a plot maintenance session which also provides a relaxing contrast.

i. DESIGN THE TRAINING PLOTS

Why Individual Plots for Each Trainee?

Successful crops training requires a heavy dose of hands-on field experience, not only to achieve entry level job competence, but to give trainees a realistic appreciation of the complexities of crop production. It is strongly recommended that each trainee have his/her own individual plots of the program crops for several reasons:
a. It is the best way to foster confidence building, responsibility, active learning, and enthusiasm.

b. Each trainee can easily monitor his/her own progress.

c. Likewise, trainers can evaluate trainees on their individual performance and provide useful feedback.

However, it may also be advantageous to include a group project such as a communal maize planting or rice paddy.

**Use of Advance (Staggered) Plantings**

Since PC crops training programs are usually shorter than the growing cycle of most crops, advance plantings may also be needed so that trainees can still experience the entire planting through harvest cycle and perform all the related cultural operations. For example, tomatoes require 50-90 days from transplanting to the beginning of harvest; trainees in a six week program would be unable to experience and work with this stage unless an advance transplanting had been made about 30-50 days prior to the start of training. While advance plantings may not always be possible, here are some suggestions for setting them up:

a. Training centers handling successive programs can easily maintain a system of advance plantings by holding over some of the plots from previous cycles. If the next program will deal with different crops, trainee labor can be used to make advance plantings during the prior cycle.

b. In the case of “one time only” programs or the first cycle of a series, outside labor may need to be hired. Alternatively, field trips to nearby farms or ag stations might be arranged to expose trainees to other growth phases, but this is less effective.

**Land Requirements**

**Size:** A 20 trainee vegetable training program that also includes some field crops (maize, etc.) will need roughly 2000-3000 sq meters for the new plots (including borders between plot blocks and alleyways individual plots). If advance plantings are also to be used, an additional 2000 sq. meters may be needed. Training centers that handle successive cycles and wish to maintain several advance plantings will need about 5000-10,000 sq. meters of land (based on 20 trainees/cycle).

**Land and Soils:** Ideally, the land should neither be unrealistically good, nor have limitations that significantly hamper field sessions or reasonable crops growth. Above all, it should be within easy walking distance of classroom and eating facilities. Good soil drainage will greatly help to minimize the disruption of field activities by rainfall or irrigation. Slope should not exceed 25%.

**Water:** Even if training occurs at a normally wet time of year, provision should be made for adequate supplemental irrigation (sprinkler, furrow, or hand watering). In the dry season, irrigation involves surprising amounts of water (7-20 liters per sq. per week).
Shade provision: During hot weather, both trainers and trainees need convenient access to shade during field activities. Miscellaneous: Protection from livestock and pilferage; adequate storage facilities for equipment and supplies.

How to Draw Up the Training Plot Design

STEP 1: Design the Individual Plots

The number and size of plots needed per trainee depend on the crops involved, their relative importance in the program, and the amount of land and training hours available. Plots should be large enough to provide sufficient experience and realism, yet not so much that they require an inordinate amount of training time for weeding and watering. As a ballpark figure, a trainee can plant and care for roughly 60 sq. meters of actual planted surface (not including alleyways between plots) in a typical vegetable program that also includes some field crop plots. In addition, he/she can take over and maintain a similar area of advance plantings. Below is an example of an individual plot design used in a typical training program:

<table>
<thead>
<tr>
<th>Plot</th>
<th>Plot Size per Trainee</th>
</tr>
</thead>
<tbody>
<tr>
<td>Direct planted veggies: Okra, leaf lettuce, Chinese cabbage, amaranth, beets, spinach, and radish* (2 rows each) planted on a raised bed in 1 meter long rows.</td>
<td>1 x 4 meters</td>
</tr>
<tr>
<td>In-the-ground nursery seedbed for producing transplants: 2 rows each of tomato, pepper, eggplant, cabbage, collard, and onion. This can be a 1 meter extension of the direct planted vegie plot above.</td>
<td>1 x 1 meter</td>
</tr>
<tr>
<td>Nursery seedbox: Same as above plot. Tomatoes, peppers, eggplant, cabbage, and collards transplanted onto a raised bed.</td>
<td>40 x 60 cm</td>
</tr>
<tr>
<td>Cucurbit plot: Squash, watermelon, and cucumbers planted in &quot;hills&quot; on a flat seedbed (2 hills per crop).</td>
<td>1 x 5 meters</td>
</tr>
<tr>
<td>Cereals plot: Maize, grain sorghum, and millet (2 rows each) planted on a flat bed.</td>
<td>5 x 5 meters</td>
</tr>
<tr>
<td>Pulse plot: Cowpeas, field beans, and peanuts (2 rows each) planted on a flat bed.</td>
<td>3.6 x 5 meters</td>
</tr>
<tr>
<td>* Even if radishers are not a program crop, their 3-4 week planting to harvest cycle is a morale booster.</td>
<td></td>
</tr>
</tbody>
</table>

Use of different treatments within plots: An effective way to broaden the trainees' exposure to crop growth problems and to illustrate good and poor management is to include different treatments (variations in
management practices) within plots. For example, a section of a row or a few plants of each crop should be left without fertilizer, or under-thinned, or unsprayed, etc. so that trainees can see the differences. Another option is to set up a result demonstration on one of the plot blocks such as maize and compare traditional practices with improved practices (i.e. improved variety, fertilizer, improved plant population and spacing, and insect control).

STEP 2: Determine the Size and Configuration of the Plot Blocks

Grouping the plots into blocks, usually by crop or crop group will facilitate the field layout as well as training. Some guidelines:

a. It's usually advantageous to organize the plot blocks by crop or crop group, rather than putting each trainee's 5-7 individual plots together. This arrangement enables trainers to focus on one crop or crop group (i.e. the cereals) at a time and have the trainees close enough to each other for convenient field instruction.

b. The individual plots within a block should be separated from each other on all four sides by a 1 meter alleyway (50 cm alleyways may be adequate for cereal and pulse plots). Refer to figure 1. Allow 1.5 meters between plot blocks.

c. A plot block's shape and dimensions will vary with the size and number of its component plots and with their possible configurations. For example, a block of 24 individual plots could be arranged in a 2 x 12, 3 x 8, or 4 x 6 pattern. When determining the dimensions of the selected configuration, don't forget to include the alleyways. The plot block shown in Figure 1 has an overall dimension of 9 x 27 meters.

d. When possible, use the same configuration (i.e. 4 x 6 or 4 x 5) for all of the blocks, because this makes it easier for the trainees to locate their individual plots each time they come to the field.

e. Crops trainers as well as those from other components are encouraged to plant plots along with the trainees, so be sure to include some extra plots in each block.

STEP 3: Draw in the Arrangement of the Plot Blocks, Using a Diagram of the Field

Guidelines:

a. Leave a 1.5 meter alleyway between plot blocks.

b. Avoid large, unused gaps between plot blocks; they quickly become overgrown with weeds.

c. Under conditions where irrigation will be needed, locate the more drought tolerant crops like peanuts, sorghum, and millet furthest away from the water source so that crops with higher and more frequent watering needs (i.e. the vegies) can be irrigated more easily.
Figure 1
Sample plot block layout (5 x 4 configuration) for 20 individual 1 x 6m raised beds with 1m alleyways.
d. If soil quality is a variable within the field, locate the vegetable plots on the better portions.

e. Be aware of possible shade interference from tall trees along the edge of the field.

The two other related tasks of preparing written planting instructions and staking out the plots are covered below under "Assemble Written Materials" and "Prepare the Site".

5. ASSEMBLE WRITTEN MATERIALS

This consists of ordering or preparing relevant tech handouts, manuals, and other references and preparing written planting instructions for the trainees.

Tech Handouts, Manuals, and Other References

Both trainers and trainees need access to practical crop production related references for use during training and on the job. Some suggestions:

a. The Crops Guidelines package in Chapter III of this Volume covers basic vegetable production practices from garden planning through harvest. It was developed and written by PC ag trainers for use both in training and on the job. It should be reproduced, hole-punched, and assembled in 3-ring binders for distribution to trainees and trainers.

b. Relevant PC/ICE manuals such as Soils, Crops, and Fertilizer Use and other useful crops references are listed in the crops Bibliography that follows the Guidelines in Chapter III of this volume. Note that some should be ordered on a "one per trainee" basis, while others can be ordered as single copies to build up an ag reference library.

c. Country-specific ag references: If available, the following host country specific ag information should be distributed to the trainees or placed in a resource room:

1. A conversion table for common and traditional units of measure.

2. An ag vocabulary list in the local language(s), especially if language training will occur simultaneously.

3. A yearly rainfall chart and superimposed cropping calendar for the work area(s) covering staple and program crops. Refer to the ag environment section of the Crops Guidelines.

4. A list of locally available ag chemicals, crop seeds, and other related inputs with their prices.

5. A list of recommended varieties of the program crops and their characteristics.
6. Copies or summaries of useful soil studies and soil test results for the work area(s).

7. Copies of ag extension pamphlets and farm magazines.

8. Market studies or price data on the program crops.

9. Sources of tech assistance in-country.

10. Sources of small farmer credit, their policies, and copies of borrower applications.

11. An organizational program of the counterpart agency.

12. Cost-return studies for program crop enterprises if these are based on small farmer and market realities.

Written Planting Instructions for the Trainees

With groups larger than 10-15, the initial planting sessions inevitably become disorganized without distributing detailed, written planting instructions. Refer to the Appendix for sample written planting instructions. With smaller groups, a blackboard or flipchart can be substituted.

Why not trainee generated methods?: While it might seem experientially sound to let trainees generate their own seedbed preparation and planting methods, this might be counterproductive for two reasons:

a. The practices used in the training plot should be similar to those of the host country work area. Both traditional and locally adapted improved practices should be included, as well as wet season and dry season seedbed styles.

b. Unlike tuning a carburetor where feedback is immediate and clear-cut, variations in ag practices may take weeks or months to show meaningful differences, and results would only be valid for the particular soil and climate involved.

6. ASSEMBLE SUPPLIES AND EQUIPMENT

As an aid for determining the kind and amount of supplies and equipment needed for the crops training component, a master list can be found in the appendix of this Volume.

7. PREPARE THE SITE

This includes the following:

Provide storage facilities for the supplies and equipment

Package the seeds

Prepare the land: Clearing, plowing or disking
Provide storage drums for hand watering
Provide for drinking water
Stake out the training plots

Storage Facilities for Supplies and Equipment

Ideally, the storage room should be pilfer-proof and located within a convenient distance of the field. Special care needs to be taken to assure that pesticides are stored safely. Once training starts, the trainees can assume responsibility for cleaning the storeroom and keeping it organized.

Seed Packaging

If small seeds are placed in cans from which trainees take what they need, seed waste will be high due to spillage and accidental cross mixing. For these reasons, small seeds should be individually packaged by type in the amount needed for each trainee, a task that trainees can help with before the start of training. Although seed can be bought in small packets, bulk seed is much less expensive per gram or ounce. The procedure for determining the amount of seed to buy in terms of grams or ounces can be found in the Crops Guidelines in Chapter III of this Volume. In the case of small vegetable seeds which tend to have emergence problems and high seedling mortality, it's a good idea buy twice the amount of seed calculated to have enough for replanting if necessary.

Land Clearing and Tillage

The land will usually require plowing or disk ing prior to staking out the training plots; in some cases, initial land clearing may be required first.

Storage Drums for Hand Watering

Under dry conditions, a 20 trainee program will need 4-6 55 gallon drums for storing water for hand watering; this will help avoid delays caused by trainees queuing up at a well or water faucet to fill their watering cans.

Provide for Drinking Water

If well or faucet water is not potable, other provisions need to be made. Most vinyl garden hose will contaminate water with residues that are possibly unsafe for consumption.

Stake Out the Training Plots

At least for the first planting session, it's recommended that the plot blocks and individual plots be staked out in advance; this can be done by the trainers from all components, preferably with the help of the trainees before the start of the actual training week. An alternative is to stake out most of the plot blocks in advance and then incorporate trainee help in the more laborious task of staking out the individual plots once training starts.

Using the 3-4-5 triangle method: This is the quickest way of laying out plots blocks so that their corners are "square" (90°). Follow this procedure:

- 12 -
a. Suppose you want to lay out a plot block measuring $20 \times 30$ meters. Start by laying out one side of the block (say 30m) using an appropriate reference line such as a road, adjacent plot, or irrigation ditch. Stretch strong twine between the two stakes and tie it.

```
+-------------------+
|                   |
|                   |
|                   |
|                   |
|                   |
|                   |
|                   |
|                   |
|                   |
|                   |
|                   |
|                   |
|                   |
|                   |
|                   |
|                   |
+-------------------+
```

b. The 3-4-5 triangle method is based on the fact that a triangle whose sides possess these proportions will always have a right angle ($90^\circ$) formed by the two shorter sides.

```
         5
        /|
       / |
      /  |
     /___|
```

Any multiple of 3-4-5 can be used such as 30-40-50 feet meters, 3-4-5 meters, etc.

c. If your tape measures in meters, place a stake 6 meters from stake A on the string line that runs toward stake B. We'll call this stake C.

d. Tie a second length of twine to stake A slightly longer than the 20 meter length of the next side. Mark off a point on this string that is exactly 8 meters from stake A. Now make up a third length of twine exactly 10 meters long and have another person hold one end of it on the ground right at the base of stake C.

```
A     C     B
|     |     |
|   6M|     |
```

Now pick up the loose end of the 10 m length of twine and also the second length of twine right at the 8 m mark. When the 8m mark inter-
sects with the loose end of the 10 m length and both lines are taut; the 8 m section forms a right angle with the first side (AB in figure 5 below). Place another stake in the ground right at that point and use it as a guide for extending this second side (AD) to its full 20 m length.

Note that you could also have used a 30-40-50 feet triangle or other 3-4-5 ratio instead of the 6-8-10 m triangle.

f. Lay out side DE using the same method. Once you have two corners "squared" off, the remaining two will be naturally square as long as AB = DE and AD = BE in length.

g. To verify your accuracy, measure the length of both diagonals with a length of twine. If diagonal DB equals diagonal AE, all four corners are square.

Using a String Grid to Facilitate Plot Staking: The string grid method can save a lot of time in laying out the individual plots. Here's the procedure:

a. Suppose you want to stake out the 20 individual 1 x 5 meter plots with 1 m alleys as in Figure 1. The overall block would measure 9 x 27 meters and should have its 4 sides traced out with taut twine connecting the four corner stakes.

b. First, put in stakes along the four sides of the block to mark off the outer corners of the outermost plots.

c. Now connect the opposing stakes of sides AO and BP (See Figure 1) with taut twine (i.e. C to D, E to F, etc.).

d. Distribute the appropriate number of stakes for marking out the individual plots by dropping them at their likely locations.
e. Have two people stretch a length of twine between stakes Q and R which then form a grid with the other lengths of twine running crosswise. Hammer in a stake at all 6 points where the strings intersect, and you will have staked out the first row of plots.

f. To lay out the remaining rows, move the twine from QR to ST and repeat the staking process, then to UV.
The crops training component is not a separate entity but rather one part of the integrated training design which is covered in Chapter II of Volume I. An explanation of the crops subject areas and the curriculum can be found in Chapter II of Volume III.

This section on carrying out the crops training component deals with:

1. Field and Classroom Sessions: Emphasis, Balance, Sequence
2. Planning and Facilitating Field Sessions
3. Planning and Facilitating Classroom Sessions
4. Peer Training
5. Independent Work
6. Farm Visits and Field Trips
7. Exams and Other Evaluation Methods
8. Adapting to Other Types and Lengths of Trainings
9. Connection to Other Materials and Resources

1. FIELD AND CLASSROOM SESSION: Emphasis, Balance, Sequence

The crops curriculum consists of about 65-70% field sessions and 30-35% classroom sessions and independent work. Field sessions include field instruction, field exercises, and maintenance.

a. Field exercises are organized hands-on learning activities that are largely self-directed and involve minimal formal trainer to trainee instruction. They are designed to provide the experiential basis for grasping tech concepts, to develop troubleshooting ability, and to refine hands-on skills. Examples are planting, sidedressing nitrogen, collecting insects, and troubleshooting.

b. Field instruction sessions are used to introduce hands-on skills and some of the related tech concepts behind them. They are usually conducted by the crops trainers.

c. Maintenance sessions are used for performing routine management tasks on the training plots such as watering, weeding, and thinning.

Classroom sessions are used to introduce and refine certain tech concepts and skills like plant nutrition and fertilizer dosage math that can best be handled in a classroom setting. However, most class sessions dealing directly with crop production such as soil characteristics and insect identification can be more effectively handled as field instruction sessions.
Independent work consists of doing assigned reading, working on a take-home exam, or pursuing a special project. While some independent work time is included in the training schedule, trainees are usually expected to use some evening and weekend time for this purpose.

Coordinating the Sessions to Achieve the Skill-Goals

Experience first—usually: Most crops skill areas are best introduced through a hands-on activity. Seedbed preparation, planting, and fertilizer application are good examples, but there are some exceptions. For instance, it's very unlikely that trainees can build a compost pile that will break down at a satisfactory rate without some initial dialogue with the trainers on composting techniques; a trial and error process would take too long. Likewise, trainees need some instruction in pesticide safety procedures before actually handling and applying pesticides.

Crops session sequence: Except for the general guidelines in the section on crops design and scheduling (refer to "Preparing the Crops Training Component" in this Volume), there is no one best crops session sequence in terms of subject area. Crops trainers will want to consider each program's crops and skill requirements, as well as training site factors (growing conditions, availability of advance plantings, likely onset of insects and diseases) in order to "customize" the most appropriate sequence.

Whatever the sequence, the crops sessions should complement and reinforce each other in such a way that each newly introduced ag skill is continually refined throughout the rest of training and tied into other ag skills. After all, crop production is a system of complementary management areas, the neglect of any of which will lower yields and returns. Whenever possible, the crops sessions should be coordinated with those of the other components so that training themes can be mutually reinforced (refer to Chapter II of Volume I).

The Field Plots as the Focus of Crops Training

Given the practical nature of producing crops and the average trainee's lack of experience, crops training will be greatly enhanced by having a field bias. This can best be achieved by focusing on good management of the training plots, which is more difficult to accomplish than might appear. In a typical program, it is very easy to become bogged down in the "academics" of training to the detriment of the plots. A good crops schedule will contain sufficient maintenance and field exercise time so that trainees can learn to manage their plots and to deal with "crises" such as pest outbreaks. For example, it seems inappropriate to be sitting in a classroom practicing pesticide dosage calculations while the bean plots are being devastated by Mexican bean beetles.

2. PLANNING AND FACILITATING FIELD SESSIONS

Land Preparation, Planting, and Transplanting Sessions

As already mentioned, these sessions usually begin during the first week of training, preferably as the first crops activity. They entail especially careful planning, organization, and supervision for success. Here are some guidelines:
a. Provide detailed, written planting instructions: See the section on preparing written materials under "Preparing the Crops Training Component" in this Volume.

b. Number the training plots: Since each trainee is likely to have five or more individual plots in as many different plot blocks, much confusion can be avoided by assigning each trainee a plot number that remains constant for each block. Using the same plot configuration and numbering sequence for all blocks is also helpful.

c. Use appropriate units of measure: Host country units of measure (official or traditional) should be used in the field right from the start. In most cases, this involves the metric system as well as traditional body-related measurements. Providing meter sticks made from 1 x 2" lumber and marked with useful centimeter gradations is recommended. While trainees should be encouraged to use body-related measurements, precision is sometimes required as in the case of ag chemical dosages and plant spacings.

d. Provide appropriate supervision: The planting sessions stimulate many questions from the trainees, and it's very tempting for trainers to answer all of them. This can set up a student-teacher relationship that leads to dependency, aside from being an appropriate model for skill transfer. Trainers can soon learn to decide whether a question merits a ready answer (some do) or rather a response like, "What do you think about it?" or "Why don't you check your references or ask another trainee?".

e. Encourage accurate recordkeeping: Since recordkeeping is an important aspect of crop management, each trainee should begin maintaining a field notebook from day one with detailed records of plot layouts, planting dates, spacings, ag chemical applications, crop problem, and yields. A sample field notebook page can be found in the Appendix of this volume.

f. Miscellaneous: Don't forget about access to drinking water and shade. Encourage trainees to bring hats to the field in hot weather.

Planning and Facilitating Other Field Exercises

Examples of other field exercises are sidedressing nitrogen on established crops, land measurement by pacing, laying out plots using the 3-4-5 triangle principle, and troubleshooting exercises. Field exercises that use a problem solving approach are usually the most effective. Some suggestions:

a. Exercises in troubleshooting: Trainees can be divided into small groups and asked to rotate through several stations in the field containing crop growth problems (insects, diseases, nematodes, faulty management, etc.) to practice troubleshooting.

b. Fertilizer application: When it comes time to sidedress a crop with nitrogen, trainees can be asked to determine the amount needed per hectare or acre, calculate the dosage needed per plant or per meter of row, and apply it.
Planning and Facilitating Field Instruction Sessions

Examples of field instruction sessions found in the crops curriculum are Soil Characteristics, Identifying Insect Pests and their Damage, and Composting (refer to the sessions list at the start of Chapter II of this Volume).

Some suggestions:

a. Use small groups: These sessions are most effective when the trainees are divided into small groups (no more than about 8 trainees/group), each one with its own trainer. If there are more groups than qualified trainers, those trainers involved in the session may be able to handle two groups in succession. Groups awaiting instruction can perform needed maintenance tasks on their plots as a “standby” activity. The small group approach seems to improve attention, comprehension, and participation. In addition, when two or more countries are being trained at once, trainees can be divided into country specific groups so that the session can be made more relevant and interesting.

b. Assure uniformity of information: When two or more trainers handle the same session simultaneously in small groups, omissions or discrepancies are likely to arise. This can be largely overcome by preparing, reviewing, and using duplicate content outlines.

c. Favor dialogue over lecture: Under some conditions, informal lecture can be a very appropriate training technique, particularly when the subject is likely to be unfamiliar to the trainees (i.e. nematodes). In other cases, a dialogue approach can be a very effective tool for placing the trainees in an active learning role. Dialogue is a two way trainer-trainee interchange sparked by the trainer’s questions that aid the trainees in deriving much of the intended information themselves, either through deduction or past field experience. For example, rather than starting off a field session on soil sampling by telling trainees why lab soil testing is the best way to determine fertilizer needs, the trainer might ask questions like, “You’ve all seen those boxes in garden shops labelled Tomato-Fertilizer or Vegetable Fertilizer. So why can’t a farmer just buy the type needed without soil testing?”

For specific ideas on handling field instruction topics, refer to the appropriate lesson plan in Chapter II of this Volume.

Planning and Facilitating Maintenance Sessions

Some suggestions:

a. Scheduling: Refer to the section on design and scheduling under “Preparing the Crops Training Component” in this Volume.

b. Avoiding Busy Work: It is usually difficult to strike the right balance between providing adequate hands-on experience and getting bogged down in excessive routine to the detriment of other training priorities. Careful planning when designing the plot sizes and numbers is important (See “Preparing the Crops Training Component”). Weather also has a big influence on labor needs, and special measures may be called for. For
example. a prolonged dry spell may increase hand watering requirements
to the point that some supplemental sprinkler irrigation may be a valu-
able time saver. Where the budget permits, a farm manager and other
outside labor may also be useful.

c. **Using Maintenance Sessions as a standby activity:** If there are not
enough qualified trainers to handle a field instruction session in
small groups simultaneously, those trainees on "hold" can be doing
maintenance work in their plots.

3. **PLANNING AND FACILITATING CLASSROOM SESSIONS**

Classroom sessions are reserved for those concepts and skills that can be
best handled in a classroom setting such as in the sessions titled "Plant Nutri-
tion Basics", "Units of Measure Conversions", "Fertilizer Math", and "Non-
chemical and Chemical Disease Control". Some suggestions:

a. Excessive reliance on lecture can lead to boring and ineffective class-
room sessions. Informal lecture has its place, but should be only one
of a number of methods in a trainer’s repertoire along with dialogue,
problem solving, and role playing.

b. By assigning relevant reading prior to a class session, lecture can be
minimized in favor of more active trainee participation.

For specific ideas on planning and facilitating classroom sessions, refer
to the appropriate lesson plans in Chapter II of this Volume.

4. **PEER TRAINING**

While peer training is a viable skill building exercise for the peer
trainer, experience has shown that it should be used judiciously as a means of
introducing new ag skills to fellow trainees. Given the newness and complexity
of much of the crops curriculum to generalist trainees, over-reliance on peer
training may result in omissions and distortions of content that can seriously
lower training quality. Here are some guidelines for maximizing peer training
effectiveness:

a. Choose straight-forward self-contained subjects that can be adequately
covered in 10-20 minutes; hands-on topics like double-digging, seed
treatment with a fungicide, and pruning tomatoes are good example.

b. Provide adequate preparation time and instruction to the peer
trainers.

c. Provide appropriate supervision of the session.

d. Provide feedback to the peer trainer.

When a training group is divided into separate tech tracks (i.e. livestock
or crops; field crops or vegies), there is an opportunity for organizing cross-
training sessions based on peer training. For example, the livestock trainees
could plan and present a 2-4 hour livestock overview to the crops trainees and

- 20 -

30
vice-versa. This might also be one basis for the Field Day described in the Extension component in Volume II.

5. INDEPENDENT WORK

Here are some guidelines for facilitating independent work:

a. Prepare a suggested reading list relevant to the coming week's classes and pass it out each Friday.

b. Trainee special projects should receive prior approval from the crops staff to help assure their relevance.

c. A good crops tech library will greatly facilitate independent work. Refer to the crops bibliography at the end of Chapter III in this Volume.

6. FARM VISITS AND FIELD TRIPS

Farm visits and field trips tend to be rather ineffective in their training value unless special consideration is given to selecting, organizing, and running them. Having a large group of trainees wander around a farm or garden project without a chance for relevant field work and troubleshooting or for meaningful dialogue with the farmer is a poor use of time. Productive visits are especially difficult to accomplish when training is held outside the host country where farming methods and even crops are likely to be markedly different.

Below are some suggestions for getting the most out of these visits:

a. Pick operations or projects that are reasonably relevant. Large mechanized farms or those growing non-program crops are not likely to be useful. State fairs, most ag fairs, and most non-host country experiment stations tend to be of doubtful training value.

b. Visiting several small farms ranging from poor to good management is helpful in developing evaluative ability.

c. Visit the farm or project in advance of the trip to judge its suitability, check out useful features (pests, diseases, management practices), and to gain rapport with the farmer or project participants. Make sure that the "hosts" understand the purpose of the visit (some farmers may not want trainees wandering through their fields). Arrange an activities plan that will hopefully involve the trainees in relevant hands-on experiences such as harvesting, transplanting, or troubleshooting, but don't overdo it.

d. Hold a pre-trip briefing session with the trainees to establish the goals of the visit and to generate a list of questions for the farmer or draw up a list of criteria for evaluating the operation. Perhaps a written assignment such as a management evaluation or troubleshooting exercise would be helpful.
e. It's virtually impossible to run a good visit with a large number of trainees, unless they can be split up into groups of threes or fours, each accompanied by a trainer. This may require pulling a few trainees out at a time during a work session at the farm or garden project.

f. Hold a post-trip session for processing and debriefing the experience.

7. EXAMS AND OTHER EVALUATION METHODS

Trainee progress and performance in crops training can be monitored through three evaluation methods: Weekly exams, a final comprehensive exam, and evaluations of the training plots and field notebooks.

Weekly Exams and the Comprehensive Final

Aside from serving as an assessment tool, the crops exams serve three other important functions:

1. They are designed to be a learning experience in themselves.
2. They clear up misunderstandings (and there are many) which could damage a Volunteer's credibility as well as the crop.
3. They provide feedback to the staff on the pace and effectiveness of training.

Weekly Exams: These can be either regular sit down exams or "take home" exams:

Regular sit down exams are usually "closed book" and take about 1-2 hours. They consist of situational problems, short answer questions, and a lab section allowing for some identification and troubleshooting practice. It's helpful to include review problems for areas that need reinforcement.

"Take home" exams are "open book" and consist of three or four long-answer situational problem dealing with several crops skill areas at once. Here the emphasis is on integrating crop production practices, learning to use references, and deductive problem solving. Take-home exams are best given during the middle to latter part of training.

A sample sit down and take-home exam can be found in the Appendix of this Volume.

The final comprehensive exam: This occurs during the last week of training and consists of a field section and a sit down section. It is designed to provide an overall review of troubleshooting, identification, recommendations, and problem solving. The field portion takes place in the training plots and consists of 15-20 lab stations through which the trainees rotate one by one (3-4 minutes/station). The field and sit down portions together take about 2-3 hours. A sample comprehensive exam can be found in the Appendix of this Volume.

Scheduling the exams: Weekly sit down exams are best held during the first two hours after breakfast on Fridays. This frees the trainees to concentrate on training the rest of the day and gives the trainers the weekend to correct the
exams. The final comprehensive exam is usually best held during the early part of the last week to allow time for correcting it and for dealing with trainees who do not do a satisfactory job.

"Grading" the exams: Using a percentage system of grading tends to promote an unnecessarily competitive atmosphere that detracts from learning. An alternative that has worked well in past programs is to mark each question or problem on an "OK" or "NOT OK" basis.

Tutoring and pre-exam review sessions should be organized and run by the trainees themselves after hours; this provides an excellent opportunity for peer teaching and encourages independence.

Post-exam review sessions of 30-45 minutes should be scheduled into training, ideally on the Monday or Tuesday following the exams.

Evaluating the Training Plots and Field Notebooks

Given the field emphasis of the crops training component, the evaluation of the trainee's plots and field notebooks should carry equal weight with the exams. Both the plots and notebooks can be evaluated at the same time with each trainee being accompanied by a trainer on a tour of his/her plots. For 6-8 week programs, two evaluations might be sufficient, while more might be needed for longer programs. The evaluations can be most easily conducted by using a maintenance session as a "standby" activity.

A sample page from a well-kept field notebook can be found in the Appendix of the Volume.

Some Criteria for Evaluating Training Plots

1. Land Preparation and Seedbed Appearance
3. Weed Control: Both in-row and between rows.
4. Insect and Disease Control
5. Water Management: Over- or under-watering.
6. Overall Health and Vigor of Plants
7. Harvesting at the proper stage.
8. Miscellaneous: Mulching placement and thickness; pruning, staking, trellising, tying.
8. ADAPTING TO OTHER TYPES AND LENGTHS OF TRAINING

The crops curriculum and methodology described in Chapters I and II of this Volume are based on a six week training program with 120-160 hours of crops sessions without a concurrent language training component. However, they can be readily adapted to suit other types and lengths of training.

9–12 Week Programs that Include Language Training

Programs of this length have less need for advance plantings, because trainees are present over a longer growing period. However, it is still recommended that one set of advance plantings be put in 4–6 weeks prior to the start date so that trainees will be able to work with the slower maturing crops like field maize, tomatoes, and eggplant in all phases of growth.

A concurrent language training component offers many opportunities for productive integration with crops training. Some suggestions:

a. The trainees’ activities in the plots are appropriate conversational topics in language classes.

b. Trainers and trainees can use increasing amounts of host country agriculture vocabulary and grammar during the maintenance sessions and field exercises. Language trainers can informally visit with trainees during the maintenance and field exercise sessions.

c. Method demonstrations and other trainee presentations can possibly be given in the host country language as proficiency improves.

For further suggestions on adapting the crops training design, refer to Chapter II of Volume I.

9. CONNECTION TO OTHER MATERIALS AND RESOURCES

This volume is meant to be used in connection with the PC/I.C.E. Technical Agricultural Manual. It is also a part of the integrated training design which is shared by both the Extension and Livestock component found in Chapter II of Volume I.
CHAPTER II: CURRICULUM OR THE CROPS COMPONENT

A. CROPS SESSION LIST ORGANIZED BY SKILL GROUP

(Based on 120-160 hours available for crops training).

This sessions list is organized by Skill Groups (subject areas) to facilitate scheduling. It is not meant to indicate the order in which the skill should be handled, because this will vary with each program due to growing conditions and other site factors. For example, if the training plots become seriously attacked by insects during Week Two, this is the best time to begin the skill group on insect control. Remember also, that one of the first priorities of crops training is to plant the training plots.

In most cases, the session order within each skill group reflects a logical progression, but there are some exceptions. Session #9 on Soil Conservation in Skill Group IV could occur anywhere in that group's sequence. Likewise, some of the sessions in Skill Groups IX (Vegetable Production) and X (Traditional Field Crops) could be equally well handled in a different order.

It's also very likely that sessions from different Skill Groups will be intermixed. For example, trainees might learn to prune and stake their tomatoes and then attend a session on nematode control later in the day.

TOTAL ADDITIONAL HOURS: 51-92

NOTE

1. The above sessions are not numbered as are those under the Skill Groups, because activities like maintenance and field exercises consist of a number of sessions interspersed throughout training.

2. Maintenance, field exercises, etc. are discussed in Chapter I of this Volume under “Carrying Out the Crops Training Component”.

3. Exam hours will vary with the proportion of sit down exams to “take home” exams as the latter do not take up training time. Refer to the section titled “Carrying Out the Crops Training Component” in Chapter I of this Volume.

4. Six week programs will need about 25-30 hours for maintenance, while 12 week programs may need up to 40.

B. SESSION PLAN FORMAT

The following page defines the elements of each session plan.

C. LESSON PLANS

Lesson plans for each of the crops sessions follow the lesson plan format.
# Session Plan Format

| Time: | Total time to present the session. |
| Goals: | Expected outcomes and skills transferred in this session, written to trainees. |
| Overview: | A brief summary of what is to happen in the session, mentioning related sessions, training events, and themes. |
| Activities: | The steps composing each session is composed are described in detail. 
| Summary: | The left column may include an optional phrase summarizing each step. |
| Materials: | Handouts and supplies used in the session are listed here. |
| Trainer Notes: | Advice and explanation of activities and steps; different opinions and approaches to the topic in the session are all included here. |
| Resources: | Books, manuals, and people providing information beyond the scope of this session are listed here. |
HOST COUNTRY AGRICULTURAL ENVIRONMENT:
INTRODUCTION AND SURVEYING TECHNIQUES

Time: 2-3 hr. Classroom Session
(Depending on trainer's stock of host country ag information.)

Goals:
1. To identify the main features of the host country agricultural environment.
2. To understand how climate, soils, infrastructure, and other ag environment features affect farming systems, practices, and returns.
3. To enable trainees to survey and interpret the important features of the ag environment of trainees' work site.

Overview:
This session focuses on the salient features of the agricultural environment in general, and specifically, on that of the host country. The extreme variability of the ag environment from one region to another is stressed to emphasize the location-specific nature of crop production. As a logical extension of the Extension Session, "Community Analysis", trainees develop a plan for surveying and interpreting the ag environment of their work sites.

Activities:

Time:

5 Min. Trainer states goals and relevance of the session.

20 Min. Trainer asks trainees to consider their own plots and farms with which they are familiar and to brainstorm elements which make up an ag environment and which influence farming systems and practices. These include: Climate and weather, topography, soils, ecology, transport, communications, storage and market facilities, farming systems and practices, ag credit, extension services, labor force, land tenure, available technologies, supplies, and equipment, and improvements to land, such as irrigation.

Trainer/trainees dialogue on ways in which each feature can affect farming and production, positively and negatively.

30-60 Min. Trainer presents overview of host country ag environment and distributes handouts developed during pre-training research of host country agriculture.
Trainees discuss how they plan to survey and interpret the ag environments of their work sites. They generate the elements of an introductory ag environment survey for use at their sites, as well as guidelines for carrying it out. Trainees should focus on issues developed in the Extension "Community Analysis" session: information gathering (including sources), filtering, organizing, and interpreting.

Trainees "role play" an interview with a local farmer to illustrate interviewing techniques and information filtering. Interview should include leading or biased questions as well as questions on sensitive or taboo subjects. "Farmer" should respond as local farmers would. Trainees practice interpreting information gathered from farmers with trainers' help.

Dialogue on various schemes trainees might use to organize information gathered from an ag survey. Trainees share knowledge and expectations of host country ag environment to draw up a cropping calendar/rainfall chart. Trainer distributes and discusses with trainees other examples of handmade charts, maps, and calendars reflecting local ag environment features.

Ask trainees to compare plans and guidelines for surveying and interpreting the ag environment with those in the handout, "Guidelines for the Orientation of the Ag Field Worker".

"Guidelines for the Orientation of the Ag Field Worker", Crops Guidelines. Cropping cycle information for host country regions. Rainfall and temperature charts for host country regions; other host country ag information, as available: soils, land tenure, etc.

List of appropriate sources of information on host country ag environment: private, governmental, and international ag development agencies, research stations and institutes, universities, etc.

It should be emphasized that the ag environment survey should be an on-going process throughout the volunteers' service with new information being added as volunteers' experience grows.

This session could be divided into two (2) sessions appropriately 1 1/2 hrs. long each, if desired. A logical break occurs at the end of the activity: "Trainer presents overview of host country ag environment, distributes handouts, etc......"

Crops Guidelines "How to Survey and Interpret your Work Area's Ag Environment" in Chapter III of this volume.
INTRODUCTION TO CROP PRODUCTION MANAGEMENT

Time: 1/2 hr. Classroom Session

Goals:
1. To foster an integrated approach to crop production management.
2. To provide a framework for understanding the concept of crop management and developing suitable management skills.

Overview:
This session takes place during the first week and introduces integrated crop management as a central theme of crops training as well as of farming in general. It divides crops management into two areas:

1. The farmer's ability to manipulate the ag environment by selecting and implementing an appropriate system of interrelated agricultural practices.
2. Standard managerial skills such as organizing and planning, timeliness, observing and scouting, recordkeeping, etc.

The location-specific nature of crop production and the lack of "cookbook" recipes is emphasized as well as the numerous agronomic choices faced by the farmer. The "package of practices" approach to improving crop yields is introduced.

Activities:

Time:
2 Min.
70 Min.

State the goals and relevance of the session.

Outline the two areas of crop management:

The manipulation of the ag environment by selecting and implementing an appropriate system of agricultural practices in thirteen interrelated areas: cropping systems, land preparation and soil management, fertilizer use and liming, planting and transplanting, water use, pest and disease control, equipment maintenance, miscellaneous growing practices (pruning, staking, hilling up), harvesting, drying and storage, marketing.
Standard managerial skills: Organizing and planning, resource allocation, timeliness, thoroughness, observing-scouring, record-keeping, and communication with farmers, researchers, and extensionists.

- Whenever possible, relevant examples should be given to highlight the above areas.

- The extreme variability of the ag environment (i.e. the location-specific nature of crop production) and the lack of "cookbook" recipes for success should be stressed.

- The many options within each management area should be emphasized, such as the different ways of applying fertilizer (i.e. broadcast, hole, band, half-circle). The appropriate choice varies with the crop, climate, soil, and other factors.

8 Min.

Facilitate discussion on the "package of practices" approach to improving crop yields. Points to include:

In most cases, there is more than one major limiting factor depressing a crop's yield: addressing these factors simultaneously may be needed in order to achieve a great enough yield increase to interest farmers. In fact, a synergistic effect is often obtained. For example, an experiment on wheat in Mexico:

<table>
<thead>
<tr>
<th></th>
<th>Yield Increase</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fertilizer</td>
<td>5%</td>
</tr>
<tr>
<td>Water</td>
<td>135%</td>
</tr>
<tr>
<td>Water &amp; fertilizer</td>
<td>700%</td>
</tr>
</tbody>
</table>

A package doesn't always have to involve considerable use of commercial inputs. For example, improved timeliness and thoroughness, better plant distribution, and recordkeeping involve no expense.

References: Crops Guidelines, Chapter III of this Volume.
UNITS OF MEASURE AND CONVERSIONS

Time: 1.5 hr. Classroom Session

Goals:
1. To become familiar with the basic units of measure used by host country farmers and ag technicians.
2. To make appropriate conversions between traditional, metric, and English standards of measure.

Overview:
Agricultural extension requires a familiarity with the standard units of measure used in the host country, as well as a facility in converting measurements from one system to another. This session provides a foundation for development of conversion skills trainees will need when dealing with pesticide and fertilizer applications, area measurement, and so on, in the field.

Activities:

State goals and relevance of the session.

Break down into small groups depending upon trainee experience with the metric system and conversions (advanced, average, inexperienced).

Trainer discusses with trainees how to put together a "picture" of the metric and/or traditional system of measure, covering units of weight, volume, length, and area. Trainees compare each unit to its English equivalent, both physically (by hefting a kilogram vs. a pound, for example) and mathematically.

Practice problems should be distributed and worked on either individually or by small groups.

Materials:
- Meter sticks/yard sticks
- Liter containers/quart containers
- Kilogram scales/pound scales
- Conversion charts
Trainer Notes: Classes dealing with math skills are greatly facilitated if trainees group themselves according to their skill (or confidence) level. This seems to lessen math anxiety among those who lack confidence in their skills, and allow them to work closely with a trainer at their own pace.

Trainees should group themselves by their own perceptions of their math proficiency - low, average, good. As the group works together, it will soon become obvious if someone is misplaced; in this case, the trainer should encourage him or her to change groups.

This is also a good opportunity to foster "helping" skills among trainees, by encouraging them to help each other with math problems after hours.

References: Crops Guidelines, see Chapter III of this volume.
LAND MEASUREMENT AND PLOT LAYOUT

Time: 1-2 Hrs.
Field Session

Goals:
1. To estimate land area (within 15%) by spacing.
2. To lay out a field plot so that all 4 corners are square.

Overview:
In this field session, trainees practice estimating the area of staked-off plots or of a particular field, and also learn the 3-4-5 triangle method of laying out plots with square corners.

Activities:

Time:

2 Min. Explain goals and relevance of the session.

10 Min. Trainees are shown pre-measured plots equal to an acre, hectare, and relevant traditional units.

15 Min. Trainees determine their average pace length in meters or feet by pacing off a measured distance between two stakes several times.

30 Min. Trainees estimate the area of staked-off plots or a particular field by pacing, and compare their results to the actual area.

10 Min. Divide into small groups and ask trainees how they would lay out a plot with all four corners square (i.e. 90°). Dialogue is used to generate the 3-4-5 triangle method.

45 Min. Each small group lays out two plots using the 3-4-5 triangle principle and checks the results by comparing the diagonal measurements.

Materials: .100 ft. or 30-meter tapes .Twine .Stakes .Hammers
Trainer Notes:  1. The "two hand clap" method, although less accurate than the 3-4-5 triangle, can also be used to square plot corners, as follows: Stand at the first corner to be squared, perpendicular to the baseline of the plot. Close eyes, stretch out arms, and bring them together in a clap. The direction in which they are pointing should be approximately 90° to the first baseline.

2. Where plot size permits, it is recommended that a 30-40-50 ft. or 6-8-10 meter combination to used for the 3-4-5 triangle measurement, to ensure accuracy.

References:  "Preparation for Crops Training", Chapter I of this volume.
BASIC SOIL CHARACTERISTICS AND TROUBLESHOOTING

Time: 2 hr. Field Session

Goals: To give the trainees the skills necessary to:

1. Evaluate farmers' soils in terms of five physical characteristics which determine potential productive and management problems: texture, tilth, depth, drainage, water holding capacity.

2. Make appropriate management recommendations to deal with soil physical problems.

Overview: Limiting factors such as poor drainage and poor tilth can seriously lower crop yields and hinder response to improved practices such as fertilizer use and high yielding varieties. Extension workers need to be able to identify soil physical problems and make appropriate management recommendations.

The session takes place in the field where trainees spend one hour at each of two learning stations.

Activities:

Time:

5 Min. Trainees are divided into two groups for learning stations A and B, which begin simultaneously.

Station A

1 Min. Trainer states goals and relevance of session.

15 Min. Discussion: What is soil; why soils vary so much; components of soil and their role (sand, silt, clay, organic matter); how to get to know the soils in one's area; the six vital signs of soil physical health (texture, tilth, depth, drainage, water holding capacity, and slope).

5 Min. Trainer/trainee dialogue on soil texture and its influence on productivity.

10 Min. Using the table in the fertilizer manual (page 11), trainees practice determining the texture of several types of soil ranging from sandy to clayey.
Discussion of the pros and cons of sandy and clayey soils and how to improve each type.

Dialogue on soil tilth; what is good and poor tilth, how to determine tilth.

Trainees determine the tilth of the field soil and identify methods of improving it.

Station B

Trainee states goals and relevance of the session.

Ask a trainee to dig a hole so they can see the difference between topsoil and subsoil. Trainer asks trainees to observe differences and a discussion follows of the roles of the two layers in crop productions.

Dialogue on soil depth: How to measure; actual vs. useful depth; how to cope with overly shallow soils.

Dialogue on soil drainage; its influence on crop yields, methods of determining poor drainage, and means of improving it. Topography, crop appearance, subsoil color, and standing water should be mentioned as possible indicators of poor drainage.

Trainees perform the subsoil "color" and "hole" tests for drainage. (See page 18-19 of fertilizer manual.)

Dialogue on soil water holding capacity: What is it; what determines it; how to improve it.

Trainees determine the relative water holding capacity of the field topsoil and subsoil, based on their textures.

Summary and wrap-up

Materials:

- Sponge and bucket of water for explaining the difference between drainage and water holding capacity.
- Samples of sandy, loamy, and clayey soils for practice textural determinations.
- Shovels for the drainage, depth, and topsoil-subsoil exercise.
- Water for the "hole test" used to evaluate soil drainage.
Trainer Notes: Each of the two stations should have no more than 8 to 10 trainees at a time. If enough trainers are available, the stations can be replicated.

To help explain the concepts of drainage and water holding capacity, use a sponge and bucket of water. Soak the sponge in water and hold it up; the water dripping from the sponge is equivalent to soil drainage above field capacity. The water remaining in the sponge after the dripping ceases is equivalent to maximum water holding capacity (field capacity).

Soil slope is also an important soil physical characteristic, but is best covered in the skills area on soil conservation. Slope should be mentioned in Station A as an important characteristic although it won't be covered in detail.

References: Soils, Crops, and Fertilizer Use. (PC/ICE, Reprint R8), pp. 1 to 21.
LAND PREPARATION AND SEEDBED STYLES

Time: 1/2-1 hr. Field Session

Goals:

1. To become familiar with host country small farmer land preparation methods and seedbed styles.

2. To enable trainees to select and employ the appropriate land preparation method and seedbed style for a particular crop and condition.

Overview:

Land preparation is a management factor that can have important influences on crop yields and returns. Extension workers need basic skills in this area to identify limiting factors in soil preparation and seedbed style, as well as to build credibility through their own plots. Trainees will have already prepared several types of seedbeds during the first few days of training when planting their individual plots. Additional topics such as double-digging, slash and burn farming may also be covered.

Activities:

Time:

2 Min. State goals and relevance of the session.

10 Min. Ask trainees to examine the crops on their plots and develop a list of characteristics of a properly prepared seedbed. Dialogue on how seed size and seedling structure determine the fineness of seedbed preparation.

10 Min. Ask trainees to compare the suitability of raised, flat, and sunken seedbeds under host country conditions.

15-30 Min. Make presentation on prevalent land preparation practices and seedbed styles in the host country and on slash and burn farming (if relevant).

3 Min. Summarize and conclude the session.

Materials:

Pictures of host country land preparation practices, and appropriate tools for any land preparation to be done in the field.
This session may vary in length depending upon the availability of host country information. Double-digging is a skill that can be taught by peer-teaching. (See Intensive Vegetable Gardening, pp. 72-73.)

This session should tie together all of the practical skills performed by trainees during their planting sessions.

References:

- Soils, Crops, and Fertilizer Use, PC/ICE
- Traditional Field Crops, PC/ICE
- Intensive Vegetable Gardening, PC/ICE
- Crops Guidelines in Chapter III of this volume.
PLANT NUTRITION

Time: 1.5 hrs.
Classroom or Field Session

Goal:
To understand the basic plant nutrition and soil fertility principles essential to developing skill in the use of organic and chemical fertilizers.

Overview:
The session covers plant growth basics; role of plant nutrients; macro- and micro-nutrients; phosphorus fixation; nitrogen fixation and legumes; Rhizobia bacteria; leaching; soil pH; likelihood of NPK deficiencies in host country soils; how the relative mobility of nitrogen, phosphorus, and potassium affects the timing and placement of fertilizer applications. Prior to this session, the trainees have already applied organic and chemical fertilizers to their plots.

Activities:

Time:

2 min.
Trainer explains the goals and relevance of the session.

5-10 min.
Dialogue on how plants grow and how and in what form they take in nutrients. This should be brief and practical, but cover photosynthesis, root hair absorption, and the general function of plant nutrients (see p. 37 of the ICE Soils Manual).

10-15 min.
Dialogue on the difference between the macro- and micro-nutrients in terms of relative amounts needed and the likelihood and seriousness of deficiencies. (See p. 44 of the ICE Soils Manual).

15-25 min.
Dialogue on NPK basics: (pp. 45-47 of the Soils Manual).

b. Likelihood of deficiencies in host country soils.

c. Behavior of N, P, and K in the soil. This should cover leaching losses, P tie-up (fixation), the relative mobility of the 3 nutrients, and how this affects the timing and placement of fertilizer.
applications. This is a very important concept. For example, fertilizer N is mobile and easily leached from the root zone; this means that only 1/3-1/2 of the total N required should be applied at planting or transplanting time and the remainder applied as one or more sidedressings later on.

**10 Min.**

Dialogue on N fixation. Points to cover:

- The symbiotic relationship between Rhizobia bacteria and legumes; definition of nodule, nodulation, N fixation, inoculation.
- Variations in N fixation ability among the legumes: peanuts, soybeans, cowpeas, mung beans vs. beans, peas.
- The need to match appropriate strain of Rhizobia to the particular legumes involved (i.e. cowpea family Rhizobia will not form nodules on soybeans, beans or peas).

**10-20 Min.**

Dialogue on soil pH. Points to cover: (pp. 40-43 of the soils manual).

- The pH scale.
- The pH range within which most crops will grow satisfactorily (i.e. roughly 5.5-7.5).
- Why soil pH can vary from farm to farm and from region to region.
- The effects of overly high and overly low pH on crop growth.
- Liming (if appropriate: see pp 137-143 of the soils manual).

**Trainer Notes:**

This session should be pragmatic: getting bogged down in concepts like cation exchange and the chemical explanation of P tie-up is irrelevant to the needs of PCV's.

**References:**

Soils, Crops, and Fertilizer Use, PC/ICE
DETERMINING FERTILIZER NEEDS

Time: 1 hour
Field Session

Goals:

1. To assess the accuracy and suitability of various methods of determining fertilizer needs under host country conditions.

2. To enable trainees to collect soil samples correctly for laboratory analysis.

Activities:

Time:

5 Min.
Trainees divide into small groups to be handled simultaneously by several trainers or in shifts. Trainer explains goals and relevance of the session.

Dialogue to review the major factors that determine the kind and amount of fertilizer a farmer should apply to a particular crop and soil.

10 Min.
Dialogue on the accuracy and suitability of the following methods of determining fertilizer needs under host country conditions:

- Lab soil testing
- Portable soil test kits
- Tissue tests
- Diagnosing visual hunger signs
- Field trials
- The educated "guestimate"

(The above methods are discussed on pp. 51-57 of the PC/ICE Soils Manual.)

40 Min.
Soil Sampling: Principles and Practice

a. Trainer explains which nutrients can be measured by a laboratory, and why proper sampling is essential to assure accurate results.
b. Trainer explains the terms sampling units, subsample, and composite sample, then dialogues with trainees to generate the criteria for distinguishing sampling units from one another (i.e., soil color, topography, pest management).

c. Trainer explains the sampling procedure as to: depth, number of subsamples, areas to avoid, sample preparation, and completing the information sheet.

d. Trainees practice collecting composite samples from sampling units.

e. Dialogue on how to interview a farmer to obtain past yield and management information; how to teach a farmer how to take his/her own samples; how often to sample; how to convince a farmer of the value of soil testing.

Materials:

- Shovels
- Clean buckets
- Machetes or similar tool for preparing soil sample slices
- Soil sample information sheet from host country soil test lab or local lab
- Boxes for shipping samples

Trainer Notes:

If time permits, trainees can collect and send in a sample to the soils lab in time to receive the results back.
USING ORGANIC FERTILIZERS

Time: 1 hr. Classroom Session

Goals:

1. To evaluate the pros and cons of organic vs. chemical fertilizers.

2. To compare the nutrient value, application method (including dosage and timing), and appropriate collection and storage guidelines of various organic fertilizers.

3. Identify appropriate circumstances under host country small farmer conditions for using organic and/or chemical fertilizers.

Overview:

This session examines both sides of the "chemical vs. organic" fertilizer issue. After developing guidelines for the proper storage and use of organic fertilizers, trainees consider their value and appropriateness to small farmers in their host country.

Activities:

Time:

3 Min. Trainer states the goals and relevance of the session.

3 Min. Trainees are asked to define "organic matter" and "organic fertilizer".

10-15 Min. Dialogue comparing organic and chemical fertilizers in terms of:

- Nutrient content
- Soil conditioning value
- Amount needed
- Availability under host county conditions
- Purported adverse effects of chemical fertilizers on crop taste and nutritional value; note that studies have shown no connection.
- Why both are appropriate for small farmers.
5 Min. Lecturette/dialogue comparing organic fertilizers like manure and compost with low nutrient organic soil conditioners like rice hulls, sawdust, and peanut hulls.

20 Min. Lecturette on guidelines for collecting and storing manure; application rates and methods for compost and manure. The perishability of manure stored under sunlight and rainfall should be stressed as well as the need to immediately work it into the soil after application to avoid N losses.

5-10 Min. Lecturette on the pros and cons of green manure crops in terms of client farmer conditions.

4 Min. Trainees are asked to summarize the session and discuss the most viable ways for small farmers to use organic fertilizers.

Materials: Blackboard and chalk

Trainer Notes: The experiential basis for this session should already have occurred in the first few days of training, when trainees applied both organic and chemical fertilizers to their plots. The trainer may wish to use this past experience as a springboard for the discussion in this session.

References: Soils, Crops, and Fertilizer Use, PC/ICE Manual R8

COMPOST MAKING

Time: 1-1.5 hrs.
Field Session

Goals:

1. To develop the skills needed to build and maintain a compost pile; and troubleshoot a pile that does not heat up properly.
2. To build a compost pile and manage it so that decomposition progresses normally.

Overview:
The actual compost making is preceded by trainer/trainee dialogue on the what, why, and how of the process as well as guidelines for troubleshooting problem piles.

Activities:

Time:

5 Min.
Trainees divide into groups of 10 or less; trainer states goals and relevance of the session.

30 Min.
Dialogue on:

- What is compost?
- What's it made out of?
- Benefits of compost; a no-cost fertilizer and soil improver with all the good effects of organic matter.
- Feasibility of composting: Seldom feasible for anything but small plots due to amount of material needed.
- What goes on in a compost pile?
- How long does it take?
- The essentials of rapid composting: Finely shredded material; adequate carbon:nitrogen ratio; adequate moisture; adequate aeration; insulation.
- How to build a pile.
- Troubleshooting problem compost piles; failure to heat up properly; ammonia smell.

30-60 Min.
Each group prepares a compost pile using locally available materials and following the guidelines generated in the above dialogue.
Follow-up: Trainees continue to maintain (i.e. water and turn) the compost piles until the end of training.

Materials: Sufficient organic materials to build compost piles
Water
Machetes for cutting vegetation
Pitchforks for turning the piles

Trainer Note: Hints on effective compost making:

The use of soil in building the pile usually isn't necessary. The organic matter itself, especially if green, contains the micro-organisms needed for decomposition.

If very strawy or other low N material is used, the pile should contain a good quantity of relatively fresh manure or young green vegetation or it will have too little N to heat up well. Roughly a 50-50 mix of mature, yellow, strawy material to higher N material will produce a good C:N ratio.

Although the pile is constructed of alternating layers of different types of materials, it should be thoroughly mixed up after it is built. The layers are used only as a guide to the relative proportions of materials being added.

Few farmers will be able to shred material fine enough to allow rapid breakdown, so the process will take at least 2-3 months.

SKILL GROUP IV
SOIL MANAGEMENT AND FERTILIZER USE
SESSION #7, P. 1

USING CHEMICAL FERTILIZERS

Time: One Two Hr.

Classroom Session

Goals:

To enable trainees to help small farmers maximize their returns from the appropriate application of chemical fertilizers.

Overview:

In session #5, trainees identify appropriate circumstances for use of chemical fertilizers by host country small farmers. This unit focuses on types of chemical fertilizers, application methods, dosage determinations, and extension techniques for promoting the appropriate use of chemical fertilizers. A combination of lecturette, dialogue and problem solving is used.

Activities:

Time:

5 Min. Trainer states goals and relevance of the session. (This should include the fact that fertilizers are one of the key yield boosting inputs, yet most small farmers are not using them properly.)

10 Min. Lecturette or dialogue on fertilizer terminology and labeling; the three number system, fertilizer ratios, and why the three numbers don't add up to 100. (Soils, Crops, and Fertilizer Use, p. 72.)

5 Min. Dialogue on the suitability and cost effectiveness of soil-applied vs. foliar-applied fertilizers. (Pp. 86-87). (This may not be relevant to countries where foliar fertilizers are not available.)

10 Min. Dialogue on the pros and cons of the localized placement (band, hole, half-circle) and broadcast methods of fertilizer application and their most appropriate use under host country conditions. (Pp. 84-86).

10 Min. Dialogue on placement guidelines for each of the above methods as well as for sidedressing N later on. (Pp. 79-86). Trainees should be able to supply this information, since they've already applied fertilizers to their plots.

- 50 -
Dialogue on fertilizer "burn": causes, diagnosis, prevention, treatment. (pp. 87-88.)

Dialogue on determining fertilizer rates (pp. 89-91). Points to include:

- How rates are given (i.e., lbs./acre or kg/ha of N, P, K) and how to convert this to the amount of actual fertilizer needed.

- Low, medium and high rates for N, P, and K under small farmer conditions and the factors affecting their determination. (p. 90)

- Why small farmers with limited capital are better off using low to moderate rates of fertilizer.

Problem solving session on troubleshooting faulty fertilizer practices: Trainees examine 5-6 faulty fertilizer recommendations to spot common errors involving kind, amount, timing, and placement. (Pp. 92-94).

Discuss the relationship between fertilizer use and other management practices: why fertilizer use, by itself, is unlikely to prove successful unless complemented by other improved practices such as a better crop variety, pest and disease control, etc. This is a good time to stress the importance of integrated crop management.

Discuss extension guidelines for promoting the appropriate use of chemical fertilizers; how to set up a fertilizer demo plot.

Fertilizer application skills can be periodically reinforced during the field maintenance sessions and through outside reading of the soils manual.

Examples of various kinds of soil-applied and foliar-applied fertilizers.

5-6 faulty fertilizer recommendations relevant to host country conditions.
Trainers should review the relevant sections of the PC/ICE soils manual to make sure they have a firm grasp of the skills and concepts involved. Of special importance are the guidelines for effective fertilizer application (i.e. localized placement vs. broadcasting, timing, placement). Trainees will have already applied NP or NPK fertilizers at planting or transplanting on their individual plots.

References:
FERTILIZER MATH SKILLS

Time: 1-2 hr. Classroom Session

Goals: To develop the math skills for:

1. Calculating the most economical source of N, given the choice of two or more straight N fertilizers.

2. Calculating the amount of fertilizer needed per given area, per plant, or per meter of row length, given a dosage in terms of kg/ha or lbs./acre.

Overview: Since host country fertilizer recommendations are usually given in terms of kg/ha or lbs./acre, ag extension workers should be able to convert these dosages to a per plant or per meter of row length basis. In this session, trainees divide into 3 groups based on their math proficiency; in each group, a trainer presents the math steps involved in each type of calculation, and the trainees then work on practice problems.

Activities:

Time:

3 Min. Explain goals and relevance of the session.

30-45 Min. Trainees divide into 3 groups based on their math proficiency. In each group, a trainer presents the steps involved in determining the most economical N source, given a choice of several straight N fertilizers. Trainees then work on practice problems.

Note: This math skill may be irrelevant for countries where fertilizer selection is limited.

It's important to mention other considerations aside from the cost per unit of N, such as the sulfur content of ammonium sulfate and the poor handling characteristics of ammonium nitrate.

50-110 Min. In each group, a trainer presents the steps for calculating the amount of fertilizer for a given field size, per plant, and per meter of row length, given a dosage in kg/ha or lbs./acre. After each presentation, trainees work on the relevant practice problems.
Materials: Practice fertilizer math problems
Blackboard or flipcharts
Chalk, erasers, or markers.

Trainer Notes: 1. Classes dealing with math skills are greatly facilitated if trainees group themselves according to their skill (or confidence) level. This seems to lessen math anxiety among those who lack confidence in their skills, and allow them to work closely with a trainer at their own pace. Trainees should group themselves by their own perceptions of their math proficiency - low, average, good. As the group works together, it will soon become obvious if someone is misplaced; in this case, the trainer should encourage him or her to change groups.

This is also a good opportunity to foster “helping” skills among trainees, by encouraging them to help each other with math problems after hours.

2. Trainees should be given additional practice problems at the end of the session for further work.

In subsequent field exercises, trainees practice dosage calculations whenever fertilizer applications are needed.

In addition to learning how to calculate fertilizer dosages in terms of grams or ounces per plant or per unit of row length, trainees should be able to convert these weight dosages to a volume basis (see p. 108 of the fertilizer manual).

SKILL GROUP IV
SOIL MANAGEMENT AND FERTILIZER USE
SESSION #9, P. 1

SOIL CONSERVATION

Time: 3-4 hr.
Field Session

Goals: To enable trainees to:

1. Determine when erosion control measures are needed.

2. Select the most appropriate erosion control measures for a given field.

3. Construct and calibrate simple homemade devices for measuring soil slope and for laying out contour lines.

4. Lay out and construct a contour ditch and bank erosion control system.

Overview: Given the high intensity of tropical rainfall and the marginal land of high erosion risk that small farms often occupy, soil erosion losses are especially serious for many small farmers in the less developed countries. This unit provides a solid grounding in soil erosion fundamentals and basic conservation measures.

This field session should preferably take place in a field that has suffered some erosion losses. It covers the following:

- The process of soil erosion by rainfall and how it damages soil productivity and the environment.

- The influence of soil slope, slope length, rainfall intensity, soil permeability, and ground cover on the magnitude of soil erosion losses.

- The purpose, feasibility, and effectiveness of common erosion control methods for host country conditions.

- Construction, calibration, and use of simple measuring and contouring devices (string level, protractor and plumb line, A-frame).

- Lay out and partial (or full) construction of a contour ditch and bank erosion control system or suitable alternative.
State goals and relevance of the session.

Show examples of soil erosion damage to trainees, followed by a dialogue on the process of soil erosion. Ask trainees to consider how it damages soil productivity and the environment.

Ask trainees to list factors influencing erosion losses (rainfall intensity, soil slope, slope length, soil permeability, type of crop, and ground cover should be mentioned).

Trainees divided into groups of four. Each group constructs two simple homemade slope measuring devices (protractor and string level) following the instructions in the PC/ICF Soils, Crops, and Fertilizer Use Manual.

Each group practices measuring soil slope with the two devices and compares their readings with those of other groups and/or the trainer.

Each group builds and calibrates an A-frame contouring device following the instructions in the PC/ICF Soils, Crops, and Fertilizer Use Manual.

Progressing down a slope, each group lays out two master contour lines, spaced according to the table on p. 154 of the manual.

(Optional) Each small group constructs at least 3-4 meters of contour ditch and soil banks.

Show examples of other erosion control measures, followed by a dialogue on the effectiveness and feasibility of each: mulching, contour planting, contour ditches with barriers, rock walls, step terraces.

Conduct a role play or discussion on how to promote soil conservation practices with host country small farmers.

Materials: Suitable land for laying out and building the system: ideally, a slope which shows visible signs of soil erosion.

- Twine
- String levels
- Plastic 6" protractors
- Lumber (1" x 2") or cut poles
- Hammers
- Nails
- 50 ft. tape
- Pocket tapes
- Stakes
Trainer Notes: Talking about erosion and erosion control measures may be confusing unless trainees can first see actual results of erosion as well as examples of contour planting and terracing.

References: Soils, Crops, and Fertilizer Use, 1981 ed. PC/ICE; R8

Host Country manuals and extension pamphlets on locally adapted soil conservation practices for small farmers.
HAND WATERING YOUNG SEEDINGS and NEWLY SET TRANSPLANTS

Time: 1/2 hr.
Field Session

Goal: To enable trainees to handwater young plants in the correct amount and frequency to avoid moisture stress and leaching losses.

Overview: This session takes place entirely in the field with small groups and uses a combination of hands-on instruction and trainer-trainee dialogue. It is experientially generated if rainfall is inadequate and should occur shortly after seedling emergence or transplanting.

The areas covered are: when, how, and how much to water and the influence of watering management on damping-off disease.

Activities:

Time:

5 Min. Trainees divide into small groups to be handled simultaneously by several trainers or in shifts. Trainer explains goals and relevance of the session.

25 Min. Trainer-trainee dialogue and field instruction on:

Factors influencing the amount and frequency of watering (soil texture, humidity, wind temperature, etc.).

Underwatering and overwatering and their adverse effects (too-little-too-often, too-much-too-often).

Damping off disease and the influence of watering management.

The "scratch test" for determining when to water very young seedlings and newly transplanted plants.

The best time of day to water (i.e., morning) and why.

How to apply water to avoid excessive splashing, seedbed erosion, and seedling washout.
Materials: 
- Watering cans
- Young vegetable seedlings in need of watering

Trainer Notes: 
If this season precedes a maintenance session, trainees can begin watering their seedling beds following the guidelines they have just learned.

Reference: 
Crops Guidelines
HAND WATERING ESTABLISHED PLANTS

Time: 1/2 - 1 hr.

Field Session

Goals:

This session enables trainees to:

1. Handwater established plants in the correct amount and frequency to encourage deep rooting, high yields, and avoid moisture stress and leaching losses.

2. Select the most appropriate watering method for particular conditions.

3. Maximize water use efficiency, especially under marginal rainfall conditions.

Overview:

This session takes place entirely in the field and deals with watering established vegetables (after seedling and early transplant stage). It goes into much more detail than the previous session concerning water use factors; moisture stress symptoms; soil water holding capacity vs. actual moisture content; guidelines in terms of amount (liters/sq. meter) and frequency.

Activities:

Time:

5 Min. Trainees divide into small groups; trainer explains goals and relevance of the session.

40-55 Min. Trainer-trainee dialogue and field instruction:

1. Trainer asks trainees how they have been watering their plants in terms of frequency and amount and what guidelines they have been using. This leads to a dialogue on the factors influencing water use. Emphasis should be on host country soil and weather conditions.

2. How soil holds water; available vs. unavailable water; permanent wilting point.

4. Determining soil water holding capacity using the 'feel' test (see Soils, Crops, and Fertilizer Use, p. 16).

- 60 -
5. Using the "squeeze" test for determining whether a plot needs watering (p. 153).

6. Using a 0.5" tapered iron rod to determine the depth of watering.

7. Guidelines for watering in terms of amount (liters/sq. meter) and frequency according to type of crop, stage of growth, weather, and soil conditions.

Follow-up: Trainees continue to use the above skills to water their plot during the maintenance sessions throughout training.

Materials: Watering cans
0.5" tapered iron rod about 1-1.5m long

References: Crops Guidelines
Soils, Crops, and Fertilizer Use, PC/ICE
DRY SEASON WATERING

Time: 1 hr. Field Session

Co.: To learn techniques for maximizing the efficient use of water under arid or dry season conditions.

Overview: In most tropical regions there are distinct rainy and dry seasons. While dry season vegetable production can be very profitable, it is often limited by water shortages and the intensive labor of handwatering.

This session introduces trainees to alternative watering techniques which conserve scarce water resources while reducing the hand labor.

Activities:

Time:

5 Min. Trainees divide into groups of 6-8. Trainer states goals and relevance of the session.

5 Min. Trainees review principles of watering discussed in previous sessions.

15 Min. Discussion of country-specific conditions under which vegetables are produced during the dry season, general watering practices, and economic value of those crops. Cultural practices for improving water use such as mulching, shading, windbreaks, and double-digging should be discussed in terms of their relevance to host country conditions.

15 Min. Discuss four water and labor conserving techniques and their relevance to host country conditions:

- Pitcher irrigation
- Watering hole method
- Sunken beds
- Trickle irrigation

20 Min. Each group of trainees builds a raised bed and sinks a clay pot into it, makes a depression for the watering hole method, and makes a sunken bed. These beds can be transplanted into at this time or during a later transplanting session.
Materials:  
1 fired but unglazed clay pot per group (2-4 gallon capacity)  
2 shovels per group  
2 hoes per group  
2 rakes per group  
Transplants (if appropriate)

Trainer Notes: Pitcher and watering hole methods work best with transplanted vegetables.

The watering hole method uses the same principles as pitcher irrigation but does not require a clay pot. Five transplants are planted in a circle around a depression 4-6 inches deep. All five plants are watered by pouring water into the depression. A heavy mulch is essential. Tomato plants may be staked into a teepee over the watering hole.

When applying a nitrogen sidedressing to pitcher irrigated plants, place nitrogen around the plants and water conventionally (surface applications) for 2-3 waterings. Nitrogen needs water moving down from above it in order to be dissolved and carried up plant roots. By the way, don’t try placing the nitrogen fertilizer directly into the pot either. It will only be “reed up” by the clay, and quickly plug up the pores.

Trainee may want to do a special project on trickle irrigation if it is feasible under host country conditions.

References:  
Intensive Vegetable Gardening, pp. 73-74, 90-95 PC/ICE.
IDENTIFYING INSECT PESTS AND THEIR DAMAGE

Time: 1.5 hrs. Field Session

Goals: This session and subsequent follow-up activities enable trainees to:

1. Distinguish between insect and disease and to relate the type of damage to the likely class of insect involved.

2. Describe and contrast the life cycles of beetles, caterpillars, and sucking insects and identify the different metamorphic stages.

3. Identify common host country insects (both destructive and beneficial) in the field, including the egg stage, where useful.

Overview: This introductory session to the insect control skill group focuses on troubleshooting insect pests and their damage symptoms. It takes place entirely in the field.

Activities:

Time:

5 Min. Trainees divide into small groups (preferably 6 or less) to be handled simultaneously by several trainers or in shifts. Trainer states goals and relevance of the session.

5 Min. Trainer/trainee dialogue on the major ways insects damage crops and on the importance of insect control.

20 Min. Trainer/trainee dialogue on the major classes of insects that damage plants, (i.e. caterpillars, beetles, sucking insects) and on their life cycles.

NOTE: If possible, live examples should be shown. Otherwise, the Insect Pests book can be referred to.

Dialogue on how to relate the type of damage (i.e. holes, excrement) to the likely type of insect. This should be supplemented with visual examples of caterpillar, beetle, borer, and sucking insect damage.
50 Min. Field tour to point out common insects (destructive and beneficial) such as aphids, cabbage loopers, lady bugs, etc. Eggs identification should be included if possible.

Follow-up: During subsequent maintenance sessions, trainees practice their insect troubleshooting skills and make a collection of local insect pests.

Materials: Appropriate examples of:
- beetles (and their damage symptoms)
- caterpillars (and their damage symptoms)
- sucking insects (and their damage symptoms)
- hand lenses to facilitate identification
- 1 Insect Pests book per trainee

References: Crops Guidelines

CHEMICAL AND NON-CHEMICAL INSECT CONTROL

Time: 2-3 hr. Class Session

Goal: To compare various methods of insect control, their assets, liabilities, and appropriate use.

Overview: This 2 hour class session reviews the principle chemical and non-chemical insect control measures, emphasizing an integrated pest management system approach. Attention is called to the interaction between pests, host crops, environment, and relevant control measures.

Activities:

Time:

5 Min. Trainer states the goals and relevance of the session.

15 Min. Dialogue between trainers and trainees on the causes of insect pest problems, economic thresholds, and integrated pest management. Peace Corps experiences and host country control measures should be illustrated at this time.

30-45 Min. Trainer/trainee dialogue on non-chemical controls including: environmental, biological, cultural/mechanical controls; organic repellents and insecticides; their uses and effectiveness under host country conditions.

5 Min. Break

35-55 Min. Lecturette on characteristics of chemical insecticides. The lecturette should discuss the use of chemical insecticides in the host country, pesticide terminology (i.e. fungicide, insecticide, etc.), advantages and disadvantages of insecticides, toxicity ratings (LD50 ratings), classes of insecticides, three main chemical groupings, types of formulations, systemic and non-systemic insecticides.

20-30 Min. Perform a skit illustrating improper spraying pesticide application procedures. Trainees list faulty practices they observed. This leads into a discussion of proper spraying procedures, pesticide safety guidelines, and first aid measures in case of pesticide poisoning.

10 Min. Trainees briefly summarize the session.
Materials:
1 sprayer
Pesticide in various formulations
Crops Guidelines for reference use in class.

Trainer Notes: Trainers should focus on the interaction of crops, pests, control measures, and the general environment, emphasizing the need for a well planned, integrated pest management system. The safe use of chemical insecticides should be strongly emphasized as well. This session is better when two trainers participate. While one trainer is discussing chemical or non-chemical controls with trainees the other can emphasize important points on the blackboard.

This session could be followed by a spraying exercise in the training garden, if appropriate.

References: Crops Guidelines in Chapter III of this volume.

Insect Pests of Farm, Garden, and Orchard, Davidson, Ralph H., Lyon, William F.: Wiley Publishing Co.
SPRAYER MAINTENANCE, TROUBLESHOOTING, AND REPAIR

Time: 1.5 hr. Field Session

Goals:
1. To dismantle and reassemble both a knapsack sprayer and compressed air sprayer and discover the function of each part experientially.
2. To troubleshoot a malfunctioning sprayer of either type and correct the problem.
3. To learn how to maintain sprayers to maximize their operational life and minimize breakdowns.

Overview:
In most lesser developed countries, small farmers commonly use knapsack and compressed air sprayers to apply pesticides. Breakdowns are frequent and sprayer life shortened through neglect of routine maintenance procedures such as oiling, cleaning, and replacement of worn parts. In this session, trainees learn the relevant skills to help small farmers improve maintenance and troubleshoot common sprayer problems.

Activities:

Time:
5 Min. Trainer explains goals and relevance of the session.
20 Min. Trainees are divided into small groups; compressed air sprayers are distributed to each group. Trainees should discover how the sprayer works and be able to describe the function of each part, including the internal parts such as the one-way valve and pump leather. The groups should dissemble and reassemble the sprayers, and learn how to decompress the pressure chamber prior to opening the sprayer after usage. (Opening the sprayer before decompression can cause insecticide to be ejected with the released pressure.)
5 Min. Each group identifies the necessary routine maintenance procedures for maximizing sprayer life and minimizing breakdowns and suggests spare parts to have on hand.
10 Min. Each group is given a worn pump leather and worn one-way valve to substitute on the sprayers to see what symptoms develop.
The above steps are repeated for the knapsack sprayer which is a more complicated model. The group should substitute a worn plunger cup and worn one-way valve on the sprayer to see what symptoms develop.

**Materials:**
- Compressed air sprayer and knapsack sprayer for each group.
- Pliers, wrenches, screwdrivers for disassembling the sprayers

**Trainer Notes:**
This unit can be done experientially with little or no input from trainers.
APPLYING PESTICIDES WITH A SPRAYER

Time: 1-2 hr. Field Session

Goal: To enable trainees to mix up and apply pesticides with a sprayer, following recommended safety, dosage, and coverage guidelines.

Overview: Hand operate, compressed air and knapsack sprayers are commonly used by small farmers in developing countries for applying pesticides, often without adequate attention to safety and proper application. Preferably, this session should occur at the time when leaf-feeding insects first become a problem on the training plots and require an insecticide application. Trainees are shown how to mix and apply an insecticide with a sprayer. Instruction in sprayer calibration is included if this is a required job skill.

Activities:

Time:

5 Min: Trainees are divided into groups of 4-6, each with a trainer. Trainer explains the goals and relevance of the session.

1. Min: Trainer demonstrates how to mix and apply a wettable powder and/or liquid insecticide with a knapsack or compressed air sprayer. Points to cover:

- Make sure sprayer is in good operating order with no leaks.
- Be aware of the relative toxicity rating of the insecticide and its hazards to bees if present.
- Read label thoroughly to confirm recommended uses, dosage, and minimum application to harvest interval.
- Mix in a well ventilated area; pre-mix first in a bucket, adding water first; use sticker-sprayer if needed.
- Wear adequate protective clothing; use a mask if recommended.
- Don't spray on a windy day or against a breeze.

- 70 -
Don't spray when leaves are already wet or when rain is likely soon.

Thoroughness of coverage needed depends on location of insects and whether a systemic or non-systemic product is used.

Maintain a steady pace when spraying rows of small plants.

Use good pressure and a fairly fine spray, but avoid excessive drift.

Don't spray plants to the point of runoff.

Keep wettable powders in suspension by shaking the sprayer periodically.

1 hr. Trainees practice mixing and applying an insecticide to their individual plots where insect damage has reached the economic threshold. Water can be used if an insecticide is not needed.

15 min. Sprayer calibration: Dialogue on the accuracy and suitability of using generalized dosages (i.e., so many tablespoons/gal.) vs. those requiring sprayer calibration. Sprayer calibration is defined.

25 min. Trainer demonstrates the sprayer calibration procedure. A trainee in each group then trial sprays a length of row of measured area using water, and the group then calculates how much water would be needed for the field and how much actual insecticide formulation is required.

Materials:
- Sprayers
- Appropriate insecticide
- Sticker-spreader
- Measuring tape for sprayer calibration
- Plastic buckets, measuring spoons/cups, suitable receptacles for measuring water volume, sticks for stirring
- Water
- Pencils, paper for doing calibration math

Trainer Notes: Sprayer calibration is usually a required skill unless trainees will be working with herbicides.

Trainees should be asked to wear appropriate clothing for this exercise (no shorts or sandals).

In subsequent maintenance sessions, trainees apply insecticides as required in their plots.

References: Crops Guidelines, section on insecticides.
UNDERSTANDING AND IDENTIFYING PLANT DISEASES

Time: 2 hr. Field Session

Goals:
1. To be able to identify the basic characteristics of the main disease groups.
2. To be able to distinguish between insect damage and disease damage.

Overview: This session focuses on plant diseases and their impact on yield and produce quality. Trainees learn to distinguish between groups of plant diseases (viral, bacterial, or fungal) and to identify specific diseases. This session begins with a lecturette followed by a tour of the training garden to identify specific crop diseases.

Activities:

Time

5 Min. Trainees break into small groups; trainer explains the goals and relevance of the session.

5 Min. Trainer/trainees dialogue to define plant disease and distinguish between parasitic and non-parasitic diseases.

10 Min. Trainer initiates discussion on the four factors necessary for initiation of a plant disease epidemic (i.e. favorable environment, susceptible host, virulent pathogen, time), possibly through a skit (see Trainer Notes).

30 Min. Trainer/trainees dialogue on the characteristic reproduction and dissemination methods of the three main plant disease agents (fungus, bacteria, virus), as well as conditions favoring their growth.

20 Min. Using plant samples, the trainer illustrates characteristic disease signs and symptoms of fungi, bacteria, and viruses. The trainer also gives guidelines for distinguishing between leaf spots, root and stem rots, viruses, bacteria, insect damage, nutrient deficiencies, and normal growth.

5 Min. Break
Field tour of the training garden to identify and discuss characteristics of the diseases found. Special attention should be paid to diseases likely to be found in the host country.

**Materials:**
- Diseased plant samples.

**Trainer Notes:**
- The role play listed above can provide a humorous personification of the conditions necessary for a disease to exist in a farmer's field.
- This session can be done in the classroom with visual aids if no diseases exist in the training garden.
- Time permits, the trainer may discuss diseases of historical significance and worldwide in distribution such as ergot, late blight of potato, aflatoxin, and rust.

SKILL GROUP VII
DISEASE AND NEMATODE CONTROL
SESSION #2, P. 1

NON-CHEMICAL AND CHEMICAL DISEASE CONTROL

Time: 1-2 hr. Classroom Session
Goal: To develop skills in chemical and non-chemical disease control in order to help small scale farmers increase crop production and crop quality.
Overview: This session deals with the various non-chemical and chemical plant disease control methods in terms of their effectiveness, feasibility, and implementation. Special emphasis is placed on non-chemical preventative measures such as crop rotation and sanitation as well as the advantages of integrating non-chemical and chemical control methods. Likewise, the relationship between insects, diseases, and weeds is stressed as well as guidelines for integrated pest management.

Activities:

Time:
3 Min. State goal and relevance of the session.
5 Min. Dialogue concerning what can reasonably be accomplished by a good disease control program. It should be noted that while total eradication is usually impossible, the onset of many diseases can be delayed and their rate of development slowed. Prevention is much more feasible than cure.
10-30 Min. Dialogue on the effectiveness, feasibility, and implementation of non-chemical controls:

- Disease resistant varieties
- Disease-free seed
- Crop rotation
- Field sanitation
- Control of host plants and insect vectors
- Improving drainage
- Type of timing of irrigation
- Fruiting of diseased plants
- Avoiding overcrowding
- Soil sterilization by heat
- Tillage practices
- Avoiding cultivation of wet plants
- Avoiding tobacco products when working with solanaceous crops (tomatoes, etc.)
Dialogue on the effectiveness, feasibility, safety, and implementation of chemical controls:

- Fungicide seed treatments
- Soil applied fungicides (PCNB, etc.)
- Soil sterilents like Vapam, methyl bromide
- Foliar fungicides (non-systemic and systemic)

**NOTE:** It's helpful to contrast foliar fungicides with foliar insecticides in terms of function, time, and economic feasibility.

Summarize the session by relating disease control to insect and weed control. Ask trainees to give examples of integrating non-chemical and chemical controls for specific disease problems.

**Materials:**
Examples of common fungicides, etc. available in the host country.

**Trainer Notes:**
1. As an additional exercise, trainees can work in small groups on devising integrated control approaches to specific diseases. Plant samples can be brought into the classroom to illustrate common disease problems like early blight, damping off, etc. Trainees can use their Crop Guidelines and other available references and present their solutions to the group.

2. In subsequent maintenance sessions, trainees apply disease control measures as needed.

**References:**
Crops Guidelines in Chapter III of this volume
*Plant Pathology,* George N. Agris
SKILL GROUP VII
DISEASE AND NEMATODE CONTROL
SESSION #3, P. 1

NEMATODES AND THEIR CONTROL

Time: 1/2-1 hr. Field Session

Goal: To be able to recognize nematode damage in the field and to prescribe control and prevention measures appropriate to small farmers.

Overview: Nematodes are frequently found in warm climate soils and can significantly lower yields, especially those of high value vegetable crops, such as tomato, okra, and squash.

In this session, trainees:

1. Learn the nematode's life cycle, means of spread, and susceptible hosts.

2. Learn guidelines for collecting soil and root samples for nematode assay.

3. Identify possible symptoms of nematode damage in the field and conditions favoring nematode problems.

4. Examine the relative effectiveness and feasibility of various nematode measures under host country conditions.

5. Apply host country nematode control measures, if appropriate.

Activities:

Time:

5 Min. Trainees break into small groups; trainer states goal and relevance of the session.

20 Min. Trainer/trainee dialogue to define nematodes, how they damage plants, which type of plants are most susceptible, and means of spread. Above and below ground symptoms of nematode damage are described and differentiated from other pest damage. Chemical and non-chemical controls such as crop rotation, resistant varieties, exposure of roots to sunlight, flooding, and antagonistic plants are also discussed.
Summarize session; explain how nematodes controls fit into an integrated pest management system.

Organize a field tour to identify nematode damage in the training garden or use visual aids if no damage signs can be found. If chemical nematocides are a recommended practice and available in the host country, trainees should practice applying them.

Examples of nematode damage (field or pictures)
Nematocides - vapam, fumadan, or methyl bromide
Appropriate equipment for safe application of nematocides.

Except for obvious root knot nematode damage, a lab diagnosis is usually needed for positive confirmation of nematode problems. Above ground symptoms such as yellowing, stunting, and wilting can also be caused by other problems; trainees should be made aware of this.

Nematodes are invisible to the naked eye, and the efficacy of control measures varies and cannot be readily evaluated; for this reason this session tends to be more theoretical than experiential.

If chemical nematocides are used, the session may have to be extended for 0.5-1 h.

References: Crop Guidelines
INTRODUCTION TO WEEDS AND NON-CHEMICAL CONTROL METHODS

Time: 1 1/2 hr. Field Session

Goal: To recognize and control annual and perennial weeds through non-chemical methods.

Overview: This field session provides an orientation to weed identification, categories of weeds, their method of spread, and their effective non-chemical controls.

Activities:

Time:

4 Min. Divide trainees into small groups; explain goal and relevance of the session.

30 Min. Dialogue on how weeds lower crop yields.

30 Min. Trainees distinguish between broadleaf and grassy weeds using field examples.

10 Min. Trainees examine perennials like Johnsongrass, Bermudagrass, and nutsedge to note their non-seed methods of propagation. This occurs along with dialogue comparing annuals and perennials as to methods of spread and control measures.

5 Min. Dialogue to identify and compare various weed control methods and their relative feasibility and effectiveness under host country conditions. This should include: burning, mulching, growing crops in rows, and using hoes, machetes, cultivators, and herbicides.

5 Min. Dialogue on pre- and post-planting non-chemical weed controls which trainees could use in their own plots.

Follow-Up: During subsequent maintenance sessions, trainees practice identifying local weeds as well as follow the weed control guidelines developed in this session.

Materials: Shovels and hoes

Examples of representative broadleaf, grassy, annual, and perennial weeds.

References: Crops Guidelines, in C III in this volume

Traditional Field Crop

88
PLANTING SESSION - DIRECT SEEDED VEGETABLES

Time: 4 hrs. Field Session

Goal: To develop the skills needed to prepare individual seedbeds and raise vegetable crops.

Overview: This session takes place at the beginning of training to provide an experiential basis for the development of vegetable gardening skills.

Trainees will practice horticultural skills in individual seedbeds that they have prepared. Some of these skills, to be introduced later in training, are listed below:

- Watering
- Thinning
- Controlling diseases and pests
- Harvesting

The dimensions of plots and locations are predetermined and, if possible, set advance by trainees or staff. Following planting instructions (see Appendix), trainees prepare beds, apply manure and chemical fertilizer, mark rows, plant, mulch, and water newly-seeded beds.

Activities:

Time:

5 Min. Trainer states goal and relevance of the session, and orients trainee to plot layout. Trainer hands out planting instructions to each trainee.

3 hrs-55 Min. As the trainees work on their individual plots, the trainer circulates among the trainees observing and commenting on their work.

Materials:

- Planting Instructions
- Shovels
- Hoes
- Rakes
- Fertilizer
- Manure
- Meter sticks
Trainer Notes: The trainer may find it helpful to prepare a raised bed before the session as a model for trainees who are unfamiliar with this horticultural procedure.

References: Refer to sample written Planting Instructions in Appendix.
PLANTING CUCURBITS - FIELD SESSION

Time: 2 hrs.

Goal: To develop the skills needed to prepare individual plots and raise cucurbit crops.

Overview: This session takes place at the beginning of training to provide an experiential basis for the development of skills in growing host-country cucurbit crops. The dimensions of plots and their locations are predetermined and, if possible, staked out in advance by trainees.

Activities:

Time

5 Min. Trainer states goal and relevance of the session and orients trainees to plot layout. Trainer hands out planting instructions to each trainee.

115 Min. As the trainees work on their individual plots, trainer circulates among trainees observing and commenting on their work.

Materials: Planting instructions (see example in appendix)

-Hoes
-Fertilizer and manure/compost
-Sticks
-Watering cans
-Measuring cups, spoons
-Seeds
-Mulch
DIRECT SEEDING PRINCIPLES, PRACTICES

Time: 1 hr. Classroom Session

Goals:

1. To develop basic guidelines for seed spacing, planting depth, planting density, and planting patterns appropriate to specific crops and host country conditions.

2. To understand the importance of thinning garden crops as an integral part of good crop management.

3. To be able to calculate the amount of seed needed to plant a given area of field.

Overview:

This session builds on the trainees' previous planting experience in their training plots. Having planted several kinds of seeds at varying depths and spacing, trainees now learn the technical hows and whys behind it.

Trainees also learn how to calculate the weight and number of seeds needed to plant a given area.

Activities:

Time:

2 Min. The trainer states goal and relevance of session.

40 Min. Question and answer session on:

- Factors affecting planting depth: soil texture, moisture availability, seed size, and seed type (monocot, dicot).

- The suitability of different planting patterns to various crops: single row, double row, broadcast, equidistant, hill (cluster) plantings, and companion planting (intercropping).

- In-row and between row spacing requirements as determined by plant spread and cultivation practices.

- The necessity of overplanting direct seeded vegetable crops in contrast to direct seeded field crops, considering relative seedling survival rates and area of land planted.
The importance of thinning small area garden crops to obtain maximum yields and to reduce competition and disease.

10 Min. Trainer presents and solves (or more) sample seed calculation problem with trainees.

Sample: How many grams of radish seed are needed to plant a 1.8 meter bed, if seeds are to be spaced every 20 cm in rows 20 cm apart? (See Crops Guidelines: Calculating How Much Seed to Buy).

8 Min. Summary and review. Trainer distributes additional seed calculation problems for trainees to work on after hours.

Materials: Seed calculation problems

Trainee Notes: Trainer should present seed calculations and thinning as integral parts of good crop management. It is important to emphasize that thinning is an ongoing process which trainees will practice as needed during subsequent maintenance sessions.

References: Crops Guidelines, Chapter III of this volume.
VEGETABLE CHARACTERISTICS

**Time:** 2 hrs.  **Classroom Session**

**Goals:**

1. To describe vegetable characteristics to be considered in selecting appropriate crop types (i.e. tomatoes vs. maize) to plant in a given farming situation.

2. To describe vegetable characteristics to be considered in selecting appropriate crop varieties (i.e. bush beans vs. vining beans) to plant in a specific farming situation.

3. To select appropriate crop types and varieties to plant in a given problem/situation based on the above criteria.

**Overview:**

This session focuses on vegetable adaptation, nutritional values, management requirements, and varietal characteristics. A problem-solving exercise is introduced so that trainees practice selecting suitable types of varieties of vegetables to plant under varying host country conditions. This is a good setting for presenting specific information on climatic conditions and the type and varieties of vegetables grown in the host country.

**Activities:**

**Time:**

- **2 Min.** Trainer states goals and relevance of the session.

- **50 Min.** Trainers/trainees discuss factors to be considered in selecting appropriate types of crops (i.e. spinach vs. tomatoes) in the following situations:

  1. Climate, requirements (temperature, moisture, day length)
  2. Nutritional value
  3. Botanical classification (families)
  4. Soil factors
  5. Management and capital requirements
  6. Acceptability
  7. Ultimate purpose (market, home consumption fresh or preserved)
  8. Marketing, perishability factors
Trainer hands out a list of varieties which trainees have planted in the training garden. Trainer/trainees discuss the terminology and importance of varietal characteristics and develop a list of those to be considered in selecting appropriate varieties for a specific situation. Trainees suggest specific situations which could limit a farmer's choice of varieties. Characteristics to consider:

1. Size, shape, color, taste
2. Other physiological features (such as thick skin, low water content, absence of seeds, etc.)
3. Salt tolerance
4. Growth habit
5. Time to maturity
6. Disease, insect resistance
7. Resistance to physiological disorders
8. Hybrid vs. open-pollinated varieties

Trainees suggest specific situations which could limit a farmer's choice of varieties. Characteristics to consider:

Trainer/trainee discuss local sources of information for recommended varieties.

Trainer asks trainees to consider how and why vegetable characteristics should be used in farm and garden planning.

Trainer distributes problem statements involving the selection of vegetable types and varieties under varying host country conditions. Trainees work in small groups to:

1. Make appropriate selections based on the guidelines discussed in this session and/or
2. Generate a list of questions (pertaining to each problem statement) which trainees would first have to answer in order to have enough information to select appropriate crop types and varieties.

Small groups share their decisions and questions with the other trainees/trainees.

Materials:
- List of training crops varieties and their characteristics
- Problem statements concerning crop selection

References:
- Crops Guidelines in Chapter III of this volume
Time: 2 hrs.

Goal: To develop the skills needed to prepare individual sweet potatoes planting beds and plant sweet potato vine cuttings.

Overview: Sweet potatoes are grown throughout the tropics, where they thrive in the high temperatures. While they are grown mainly as a carbohydrate source, the tubers are an excellent source of vitamin A; sweet potato leaves are also a highly nutritious food which can be gathered without harming the tuber crop growing underground.

This session takes place at the beginning of training to provide an experiential basis for the development of skills associated with vegetative production of tubers.

The dimensions of plots and their locations are predetermined and, if possible, staked out in advance by trainees or staff. Utilizing printed planting instructions, trainees prepare planting ridges, apply fertilizer, and cut and transplant sweet potato vine cuttings.

Activities

Time:

5 Min. Trainer states goal and relevance of the session, and orients trainees to plot layout. Trainer hands out planting instructions to each trainee.

45 Min. After applying fertilizer to plant rows, trainees prepare broad, flat planting ridges (60cm wide by 20cm high) the length of each plant row.

5 Min. If appropriate, trainees make vine cuttings from nearby sweet potato plot. Otherwise, trainer provides cuttings for each trainee.

30 Min. Trainees plant vine cuttings in their beds, and water according to soil moisture conditions.

Materials: Planting Instructions (see Appendix)

- Hoes
- Shovels
- Chemical fertilizer
- Pocket knives (for cuttings)
- Sweet potato vine cuttings (if necessary)
TRANSPLANTING - FIELD SESSION

Time: 4-5 hrs.

Goals:

1. To understand the fundamentals of transplanting vegetable seedlings (i.e., what, why, when, and how).

2. To master the skills needed to transplant vegetable seedlings into a raised bed.

Overview:

This session takes place at the beginning of training to provide an experiential basis for the development of skills in transplanting host country vegetable crops. The trainees prepare raised beds during a preceding session.

After seeing a transplanting method demonstration by the trainer, trainees transplant vegetable seedlings into their plots. Printed planting instructions guide trainees through the steps of the operation, which include the following:

- Making and applying a starter fertilizer solution
- Making and applying cutworm collars
- Deep-setting tomatoes
- Applying chemical fertilizer
- Staking
- Mulching and shading

Activities:

Time:

2 Min. The trainer states goals and relevance of the session.

Trainees divide into small groups; one trainer is assigned to each group to discuss the following:

- Why transplant? Advantages and disadvantages?
- Which vegies are/are not transplanted? Why?
- When to transplant? Time of day and stage of growth?
- Hardening and blocking—what, when, why, and how?

30-45 Min. One trainer presents a method demonstration to each group, covering the following points:

- Pros and cons of transplanting
- Marking final spacing in plot
Preparing and using starter fertilizer solutions
Extracting transplants from nursery seedbeds or boxes
Making and applying cutworm collars
Setting out plants, including the "deep set" vs. "trench" method of setting out tomatoes
Applying nitrogen and phosphorus (NP) or nitrogen, phosphorus, and potassium (NPK) fertilizer around each plant
Making a shallow water catchment around each plant (except in high rainfall conditions)
staking tomatoes
Shading plants temporarily (paper hats, cones, or local material such as banana leaves)
Mulching
Watering

3 Hrs-15 Min. to 3 Hrs-30 Min. Trainer hands out transplanting instructions. Trainees transplant seedlings into prepared raised beds. Trainer circulates among the trainees observing and answering questions.

Materials:
Written planting instructions (see Appendix)
Transplants
Materials for collars and shade hats (newspaper, banana leaves, etc.)
Measuring spoons/cups for chemical fertilizer
Mulch
Fertilizer and/or manure, compost
Stakes (at least 160cm long)
Hoes, rakes and shovels if plots are to be prepared during the session
Starter fertilizer solution for method demonstration (trainer)
Watering cans for making starter fertilizer solution (trainees)

Trainer Notes:
The double digging method is well suited to transplant seedbeds since most of the crops are deeprooted. If trainees are to prepare double-dug transplant beds before or during this session, allow at least one hour extra for this exercise. See Intensive Vegetable Gardening for guidelines on double-digging.
See the Crops Guidelines for instructions on making and using starter fertilizer solution.
Trainees should organize themselves to mix a large batch of starter solution during the session.
Manure tea could be substituted for the above solution, but should be prepared at least one week before the session so that it is well-steeped.

Crops Guidelines
Soils, Crops, and Fertilizer Manual PC/ICE #R8 p. 126
Intensive Vegetable Gardening PC/ICE #25 pp. 110-113
PLANTING A NURSERY SEEDBED (OR SEEDBOX) - FIELD SESSION

Time: 1-3 hrs.
(Depending on whether seedbeds and/or seedboxes will be used; extra time is needed to construct seedboxes.)

Goal: To prepare individual nursery seedbeds or boxes and plant appropriate crops under conditions suitable for raising vigorous transplant seedlings.

Overview: This session takes place at the beginning of training to provide an experiential basis for developing skills in raising transplant seedlings.

Trainees prepare, fertilize, plant, water, and mulch seedbeds or boxes according to printed planting instructions.

(If nursery seedboxes are an appropriate host country practice, boxes can be constructed before or during this session).

Activities:

Time:

5 Min. Trainer states goal and relevance of the session.

0 Min. Trainer/trainees discuss pros and cons of raising seedlings in nurseries before transplanting. They compare the merits and relative suitability to host country conditions of in-the-ground seedbeds and seedboxes (flats).

Trainees develop list of specific guidelines for starting transplant seedlings, drawing as much as possible from previous planting exercises. Points to be covered include: soil mixes, fertilizer use, damping-off control, seed spacing, row spacing, planting depth, watering, and pre- and post-emergence mulching.

0-90 Min. (If seedboxes are to be used, trainees come up with an appropriate design and construct individual seedboxes).

0 Min. Trainees prepare soil or an appropriate soil mix for nursery, apply and work in fertilizer, and mark rows.

0 Min. Trainees plant and water seedbeds or boxes; they apply a fungicide drench to control damping-off (if appropriate) and a pre-emergence mulch to conserve moisture and prevent seed washout.
Materials: Seeds, fertilizer, mulch, hoes, watering cans, planting instructions (see Appendix for example)

Optional: Seedboxes or materials for constructing them: Hammers, nails, 1" x 4" lumber, bamboo, or appropriate local materials.

Soil mix materials: Sand, clay, sawdust, rice hulls, rotted coconut husks, compost, manure, etc.

Fungicide for soil drench

Trainer Notes: If this training program is to be followed immediately by another program, trainer may wish to schedule this session so that transplant seedlings grown by first group will be available for second group's transplanting session. Seedlings should be 4-6 weeks old.

This session incorporates skills from several other sessions (such as fertilizer use and disease control). For instance, trainees should calculate the amount of fertilizer needed per seedbed (based on a kg/ha or lbs./acre dosage rate), if the fertilizer math session has already been held. It may also be appropriate to sterilize the soil or use other damping-off controls (such as a captan drench) on the seedbeds.

Trainees continue caring for their nursery seedbeds during the subsequent maintenance sessions: watering, weeding, and thinning them.

RAISING TRANSPLANTS

Time: 1/2-1 hr. Classroom Session

Goal: This session enables trainees to calculate the number of transplants needed to plant a given field area at given spacings, the amount of seed required, and the seedbed area required.

Overview: This class session deals with transplant math and reviews transplant production guidelines developed during the nursery seedbed planting exercise.

Activities:

Time:

2 Min. Trainer explains the goal and relevance of the session.

10 Min. Trainer shows trainees as a group how to calculate the number of transplants needed for a given field size and plant spacing, the amount of seed needed, and the seedbed area required.

18-30 Min. Trainees divide into 3 groups based on their perceived math proficiency and work on practice problems.

Materials: Blackboard, chalk
Several practice transplant math problems

Trainer Notes: Trainees should be able to generate transplant-raising guidelines by referring back to the nursery seedbed planting exercise (if this session has been included in the program).

Trainees should be given several transplant math practice problems to work on outside of class time.

References: Crops Guidelines
STAKING AND PRUNING TOMATOES - FIELD SESSION

Time: 1 hr.

Goals: To enable trainees to:

1. Compare the pros and cons of pruning tomatoes (vs. not pruning them) as well as of other methods of pruning and staking.

2. Properly prune, stake, and tie tomato plants.

Overview: This session covers the pros and cons of staking and pruning tomatoes while providing practical experience for the trainees. Emphasis is placed on appropriate staking and pruning methods used in the host country. After the trainer demonstrates staking, tying, and single and multiple-stem pruning, trainees practice on their own tomatoes.

Activities:

Time:

5 Min. Trainer states goals and relevance of the session.

10 Min. Trainer/trainees discuss the pros and cons of staking and pruning. Trainees brainstorm staking materials available in host country.

20 Min. Trainer demonstrates appropriate methods of staking, tying, and pruning tomatoes. Points to cover include: when and how to stake (cage, tripod, single stake); tying techniques; when to prune; single- and multiple-stem pruning; removal of whole suckers vs. removal of growing tips only.

25 Min. Trainees stake, tie, and prune their own tomatoes (and continue to prune on an as-needed basis throughout the remainder of training).

Materials: Stakes
String, maize leaves, or rags (for tying)
Trainer Notes: Ideally, tomatoes should be staked right at transplanting time to avoid damaging roots of established plants.

If training program includes a tomato transplanting exercise, the pruning session should be scheduled 4-5 weeks after that exercise, when plants will be at a "pruneable" stage.

This session could be used as a peer-teaching exercise in which trainer "pre-trains" a few trainees who then organize and carry out this session for their peers.

References: Crops Guidelines
SUN DRYING FRUITS AND VEGETABLES

Time: 1 hr. classroom time followed by 1 hour of method demonstrations

Goals:
1. To understand the basic principles of preserving foods (especially vegetables and fruits) by sun drying.
2. To understand the importance and practical application of the four steps in food drying: pre-drying treatment, drying, post-drying treatment, and storage.
3. To sun dry fruits and vegetables using appropriate local technologies.
4. To practice teaching appropriate food drying technologies through method demonstrations.

Overview:
This session fits in with sessions on harvesting and storing food crops; it challenges the trainees to consider ways to ensure a continuous supply of stew and sauce ingredients, especially in areas where crop production is limited by dry or cold seasons.

The learning in this session is largely self-directed. While the trainer may wish to orient trainees to available references on food drying, responsibility for researching and teaching each other about the various techniques rests with the trainees. This allows trainees to become involved at various levels in the teaching/learning process and to practice extension techniques while learning about food drying.

Activities:

Time:
2 Min. Trainer (or project leader) presents goals and relevance of the session.
30 Min. Trainer/trainees dialogue to develop an understanding of the entire process, as well as the importance of each of the basic steps: pre-drying treatment, drying, post-drying treatment, and storage. Trainer/trainees discuss the advantages and limitations of solar drying. Trainees discuss applications which they have seen, used, and/or expect to find in their host country.

*See Trainer Notes for explanation of "project leader".
30 Min. Trainees divide into groups of 3-5. Each group works with one project leader to plan a self-teaching session on a single aspect of sun drying foods. Examples of projects might be: designing and constructing a solar food dryer from local materials; drying foods in the traditional manner; sulfuring fruits as a pre-treatment method; blanching vegetables as a pre-treatment method; etc.

(7 days) Each group then has up to one (1) week (or as time and weather permit) to learn about and practice its particular food drying technique. In addition, each group of trainees organizes to present a method demonstration of its technique to the others one (1) week later.

60 Min. Project groups present their method demonstration. After each, or as trainer/trainees critique it according to criteria such as those in Core Handout VI - 2 - A.

Materials: As needed by project groups; the following items may be included:

- Vegetables and fruit for drying
- Traditional drying equipment (straw mats, trays, etc)
- Loosely woven cloth or netting
- Scrap lumber, bamboo, or other building materials
- Kettle (for blanching)
- Sublimed sulfur
- Lemon juice or ascorbic acid, etc.

Trainer Notes: 1. Trainees who lead the various project groups are referred to as "project leaders" in this lesson plan. Several days before this session, trainer should solicit several volunteers to act as project leaders. (The number of project leaders needed depends on the size of the training group. This session is based on one project leader for every 3-5 trainees.)

2. Prior to the session, trainer and project leaders should plan a brief introduction to sun drying fruits and vegetables, to be presented during the first 15 minutes of class. During this planning session, project leaders should also select food drying projects which they would like to work on with their group of trainees.

3. Trainer should work closely with project leaders throughout this session, including the self-teaching sessions and method demo preparations which they are to facilitate. This is a good opportunity for trainees to practice problem-solving skills as they organize (and procure) their resources to complete their projects.

- 95 -
4. In critiquing each other's method demonstrations, trainees should focus on the effectiveness of each as a teaching tool, as well as on the presenter's skill in communicating with the "audience."

References:
SEED QUALITY AND STORAGE

Time: 1 hr. Classroom Session

Goal: To acquire the skills and knowledge needed to visually evaluate seed quality and to maximize the storage life of seed.

Overview: In this session, guidelines for visually evaluating seed quality and for prolonging the viability of stored seed are discussed. Trainees are asked to evaluate the quality of several seed samples of varying quality.

Activities:

Time:

2 Min. Trainer states goal and relevance of the session.

8 Min. Trainer presents brief lecturette on seed structural characteristics (i.e. embryo; germ, etc.) and their relation to seed viability. Trainees examine seed samples.

15 Min. Trainees are given seed samples of varying quality (i.e. broken seed, moldy seed, shrivelled seed, weevil infested seed) and are asked to derive visual guidelines for evaluating seed quality. The problem of internal seedborne diseases is discussed.

10 Min. Trainer/trainees discuss factors affecting seed viability.

15 Min. Trainer/trainees discuss practical guidelines for prolonging seed viability under tropical conditions.

Materials:

- Seed samples with various defects such as weevil damage, cracks, etc.
- Healthy seeds for trainees to examine structural characteristics and compare to damaged seed.

References: Crops Guidelines
SEED GERMINATION TEST

Time: 45 min. Classroom - Lab Session

Goal: To conduct a seed germination test in order to determine seed viability.

Overview: Seed viability is largely determined by the source of seed, the means of collecting it, and the conditions under which it is stored. All of these factors often result in seed of dubious viability for small farmers in the third world. This session teaches trainees a simple technique for testing seed viability before planting.

Activities:

Time:

Min. Trainer states goal and relevance of the session.

Min. Trainer/trainees discuss the importance of testing for seed viability.

0 Min. Trainer demonstrates a germination test, then distributes step-by-step instructions for trainees to follow.

0 Min. Each trainee sets up a germination test which he/she monitors over the next few days until completion.

Min. Trainers review and summarize the session.

Materials:

- Newsprint or burlap for wetting and wrapping seed
- Water
- Seeds
- Written instructions
- Waterproof pens for labelling individual germination tests
- Plastic bag for storing trainees' tests

Trainer Notes: Use 50 or 100 seeds so a percentage of germination can be easily calculated.

Have trainees perform individual tests. If not possible, have them work in small groups.

Set aside a few minutes three to four days later to observe and record results of germination.

This exercise should follow as closely as possible the exercises on seed storage, quality, and production.

References: Crops Guidelines
SEED PRODUCTION

Time: 1 hr. Classroom and Field Session

Goals: 1. To develop skill in selecting plants from which seed will be saved for replanting.
2. To harvest and process seed in preparation for storage.

Overview: In many developing countries, high yielding seed of good quality and local adaptation may not always be available, especially at the village level. Small-scale farmers may collect seed from local varieties but often use inappropriate criteria in selection. This session identifies appropriate criteria for collecting and saving seed and allows trainees to practice proper collection procedures on their own vegetable crops.

Activities:

Time:

5 Min. Trainer states goals and relevance of the session.

25 Min. Trainer/trainee dialogue on the pros and cons of home vegetable seed production; how and when to extract seeds from annual, biennial, and perennial, self-pollinated, and cross-pollinated crops; selection of plants for seed production, and criteria for collecting and extracting seed.

15 Min. Method demonstration: After trainer demonstrates proper technique for collecting tomato seeds and fermenting them to control bacterial canker, each trainee prepares his/her own fermentation jar.

15 Min. If appropriate, trainees proceed to field where they practice extracting seed from mature vegetable crops.

Materials: Mature tomatoes and other mature vegetables (from which seeds can be extracted).
Knives
Mixing cups and spoons
Seed envelopes
Small jars
Trainer Notes: Seed production can be a risky business, possibly encouraging the spread of seedborne diseases and reducing overall seed quality. If available and inexpensive, farmers should be encouraged to use good quality commercial seed.

References: Growing and Saving Vegetable Seeds, Rogers, Marc Garden Ways Publishing Co.

Crops Guidelines

GARDEN PLANNING EXERCISE

Objectives:
- 4-6 hrs. (2-4 hrs. Independent work, 2 hrs. Classroom Session)

To plan the inputs and activities involved in the management of a garden project in the host country.

Overview:
This exercise takes place during the final week of training and helps trainees assimilate and apply many of the skills and concepts covered throughout their training: vegetable production management, nutrition, and project planning.

Focusing on a problem/situation appropriate to their future job assignments, trainees work in small groups to design garden management plans, taking account of various "givens": host country specific data on climate, soils, available inputs, pest and disease problems, marketing factors, and other management constraints presented in the problem.

Activities:

Time:

5 Min.
- Trainer states goals and relevance of the session.

- Trainer distributes garden planning situation to trainees. (See sample Garden Planning Exercise, following this lesson plan.) Discuss briefly to ensure that everyone understands the assignment. Point out specific resources which trainees may find useful for this exercise.

- 5 hrs.
- Trainees work in small groups to develop appropriate plans. Trainers remain available for consultation if necessary.

- Each group presents its plan to the full group for feedback.

Materials:
- Appropriate Garden Planning Exercise prepared by trainer and/or trainees.

Trainer Notes:
- Alternative problem/situations:
  - Design a garden project for a local primary school which would serve initially to train children in vegetable production and, later, to supplement the school lunch program.
Design a year round management plan for the training site land, including training gardens, and use of land between programs.

References:

Crops Guidelines

Available agricultural, nutritional, and marketing references, especially those relevant to host country conditions.

Example of a Garden Planning Exercise

You are working with a village women's group of twenty members planning to grow vegetables for one of the following market situations:

1. Nearby hotel - during the tourist season frequented by British and American tourists.
2. Long distance market (300 kilometers away in a major capital).
3. Local market (10 miles away)
4. Home consumption

Local climatic conditions: Rainfall, 800mm/year, falling April - September. The rest of the season is dry. However, you should count on handwatering your crops from a nearby well. Elevation: 6000 feet, temperature, daily highs in 80's, lows in 50-60's. Soils, low in N,P,K.

Locally adapted vegetables: Cabbage, tomatoes, eggplant, pepper, sweet maize, green beans, squash, lettuce, spinach, carrots, beets, onions, radishes, broccoli, cauliflower, potatoes, hot peppers, peanuts, peas, collards.

Your mission, should you decide to accept it, is as follows:

1. Choose 5-6 vegetables suitable to your gardening situation. Justify your choices. What varietal characteristics should you consider when choosing varieties of each vegetable?
2. Decide amount of land you will need for your project.
3. List all the inputs you will need, and the general quantity of each.
4. Choose one vegetable and describe how you will plant it to assure a uniform flow of produce. Give a sample planting/harvest schedule.

In addition, you should answer the following questions:

1. Where will you get your equipment/inputs?

2. If you need money for purchasing equipment, where will this come from?

3. How will you involve the women in planning this project?

4. How will you harvest each of your crops? - entire plant at once, leaf by leaf, staggered pickings according to varieties?

5. Which crops would be dried or otherwise preserved?
PLANTING CEREALS - FIELD SESSION

Time: 2 hrs.

Goal: To develop the skills needed to prepare individual plots and raise cereal crops.

Overview: This session takes place at the beginning of training to provide an experiential basis for the development of skills in growing host-country cereal crops.

The dimensions of plots and their locations are predetermined and, if possible, staked out in advance by trainees.

Trainees prepare, plant, fertilize and water cereal plots according to printed instructions.

Activities:

Time:

5 Min.

Trainer states goal and relevance of the session and orients trainees to plot layout. Trainer hands out planting instructions to each trainee.

2 hrs.

As the trainees work on their individual plots, trainer circulates among trainees, observing and commenting on their work.

Materials:

Planting Instructions (see Appendix for example)

- Meter sticks
- Hoes
- Fertilizer or manure
- Watering cans
- Measuring cups, spoons (for chemical fertilizer)
- Seeds

Trainer Notes: As cereal seed is characteristically hardy, and usually planted over large areas, meticulous land preparation as practiced in vegetable garden plots is impractical and unnecessary. Trainees should prepare their cereal plots with a minimum of tilling.

If the soil is very dry, sprinkler irrigation can be used instead of hand watering to save time.
PLANTING PULSES - FIELD SESSION

Time: 2 hrs. Field Session

Goal: To develop the skills needed to prepare individual plots and raise pulse crops.

Overview: This session takes place during the beginning of training to provide an experiential basis for the development of skills in growing pulse crops in host countries. The dimensions and locations of plots are predetermined and, if possible, staked out before the session by the trainees.

Trainees prepare, plant, fertilize and water pulse plots according to printed instructions.

Activities:

Time:

5 Min. Trainer states the goal and the relevance of the session, orients trainees to plot layout, and hands out planting instructions to each trainee.

115 Min. As the trainees prepare their individual plots, the trainer circulates among them, observing and commenting on their work.

Material:
- Planting instructions
- Hoes
- Fertilizer or manure
- Meter Sticks
- Watering cans
- Measuring cups (for chemical fertilizer)
- Seeds

Trainer Notes: Small farmers plant pulse crops on relatively large areas, and the pulse seeds are large and hardy. These crops don't require as fine a seedbed as the small seeded vegetables.

If training takes place during the rainy season, the trainer may wish to rely solely on rain for crop irrigation.
INTRODUCTION TO TRADITIONAL FIELD CROPS

Time:  1-2 hrs.
Classroom Session (depending on program emphasis and the amount of specific host country information available).

Goal:  To compare and contrast general characteristics of field crops as a background for understanding individual field crops production practices (covered in later sessions).

Overview:  This introductory session draws together information on field crops from trainee’s readings and prior experience (in their training plots), and from specific host country references.

Dialogue and informal lecture are used to cover the following field crop topics:

<table>
<thead>
<tr>
<th>Importance</th>
<th>Uses</th>
</tr>
</thead>
<tbody>
<tr>
<td>Distribution</td>
<td>Nutritive Value</td>
</tr>
<tr>
<td>Adaptation</td>
<td>Yields</td>
</tr>
<tr>
<td>Characteristics</td>
<td>Opportunities for Yield Improvement</td>
</tr>
</tbody>
</table>

Activities:

Time:

3 Min.  Trainer states goal and relevance of the session.

5-10 Min.  Trainer helps trainees to define and provide clarity to the following terms: cereal, pulse, legume, grain legume, oil seed, row crop.

20-40 Min.  Trainer/trainee dialogue to compare relevant field crops in: soils and climatic adaptation, drought resistance, photosensitivity, and other outstanding characteristics.

10-20 Min.  Trainer/trainee dialogue on the geographic distribution, uses, and nutritive value of the field crops.

20-40 Min.  Trainer presents brief lecture on traditional vs. potential yields of relevant field crops, and on the opportunity for yield improvement within the host country.
Materials:  
- Blackboard, chalk  
- Specific host country information on traditional field crops

Trainer Notes:  
Trainees should read pp. 35-72 of the Traditional Field Crops manual in advance of the class.

References:  
Traditional Field Crops, PC/ICE Manual M-13, pp. 35-89
STAGES OF GROWTH AND RELATED MANAGEMENT
NEEDS AND PROBLEMS

Time: 1-2 hrs.
Field Session (depending on program emphasis and amount of specific host country information available).

Goal:
To enable trainees to identify the major stages of growth in each of the training field crops and to correlate them with management needs and likely problems.

Overview:
This exercise should ideally take place in a plot that contains 3-4 growth stages of each of the training field crops (seedling stage to maturity).

Trainees examine and identify the major stages of growth for the cereal and pulse crops and discuss the management needs and likely problems of each stage.

Activities:

Time:

3 Min.
Trainer explains goal and relevance of the session.

25-50 Min.
Field tour of the cereal plots. The following stages of growth should be identified and discussed:

- Planting/pre-germination
- Vegetative stage (including position and function of growing point)
- Tasseling/booting
- Pollination
- Grain formation (milk stage, soft dough stage, hard dough stage)
- Physiologic maturity

30-60 Min.
Field tour of the pulse plots. The following stages should be identified and discussed:

- Planting/pre-germination
- Seedling stage
- Flowering
- Pegging (if program includes peanut production)
- Pod development
- Maturity

- 108 -

118
Materials: Pictures or slides of field crops in different growth stages if examples aren’t available.

Trainer Notes: The cereal crops (maize, sorghum, millet) should be considered as a group and compared with each other. Likewise, cowpeas, beans, and other bean types can be handled as a group. Peanuts should be considered separately.

Each stage should be discussed in terms of its duration, nutrient and water needs, likely pest and other environmental problems; and their effect on yields. Associated management needs such as weeding, hilling up, and sidedressing should also be covered.

Other aspects important to an understanding of pulse crops are: time to maturity, vining vs. bush varieties, and nodulation. Trainees should learn to identify adequate nodulation and to distinguish it from nematode damage.

Also, trainees should learn how to determine maturity in peanuts, if appropriate.

References: Traditional Field Crops, PC/ICE Manual pp 45-50, 57-59, 67-68, 70
FIELD CROP PRODUCTION PRACTICES (FROM LAND PREPARATION TO MATURITY) - CEREALS AND PULSES OTHER THAN RICE

Time: 1-2 hr.
Classroom Session (depending on program emphasis and amount of specific host country information available).

Goal: To enable trainees to analyze a given set of field crop production practices and, if called for, select an appropriate "package" of improved practices to apply in that situation.

Overview: In the introductory field crops session, opportunities for improving small farmer field crop production were discussed in a general way. In this session, the elements of locally adapted packages of improved practices for each of the field crops are closely examined as to what, why, when, and how.

Activities:

Time:
3 Min. Trainer explains goals and relevance of the session.
50-110 Min. Dialogue on the what, why, when, and how of each practice in a locally adapted package of practices for each of the training field crops: Management areas that should be considered:

1. Land preparation
2. Variety selection: Traditional vs. improved vs. synthetic vs. hybrid
3. Seed selection and quality
4. Plant population and spacing and their effects on yields
5. Planting depth
6. Fertilizer use and liming
7. Water management: Irrigated or rainfed
8. Weed control
9. Insect control
10. Disease and nematode control
11. Bird and field rodent control (where relevant)

Trainer Notes: Improved practices in harvest, drying, and storage are covered in Skill Group X, Session #6.

The package of practices concept has already been introduced in Skill Group II, Session #1.

Determination of maturity, harvest, drying, and storage are covered in Skill Group X, Session #6.

References: Specific host country information concerning locally adapted and tested improved practices for the training field crops.

Traditional Field Crops, PC/ICE manual M-13
GRAIN DRYING AND STORAGE

Time: 1.5–2 hrs. Classroom Session

Goal: To acquire the entry level skills and knowledge needed to help small farmers minimize losses from mold, rodents, and insects during drying and storage of grains.

Overview: Grain losses during drying and storage caused by molds, insects, and rodents are estimated to be about 30% worldwide. Small farmers are especially vulnerable to such losses, because their traditional drying and storage methods are often inadequate. This session covers the basic principles and techniques of safe drying and storage.

Activities:

Time:

0 Min. Trainer states the goal and relevance of the session. Points to include under relevance:

- High drying and storage losses a serious problem.
- Doesn't pay to increase crop yields if much will be lost after harvest.
- Benefits of improved drying and storage: more food; better quality seed for planting; lower incidence of toxic molds like aflatoxin that affect people and animals; farmers can store grain and sell it several months after harvest when prices are higher.

0 Min. Lecturette on principles and techniques of drying. Points to cover:

- The purpose of drying: to avoid heating and molding of grain and to reduce activities of storage insects.
- How dry? No need for 0%; 12–35% moisture content form which stored, and type of container. Determining grain moisture content: salt and bottle, oven, and oil methods.
- Principles of rapid drying: warm, dry, moving air.
- Drying methods compared: fuel heated and/or forced air drying, dryer/storage cribs for ear maize.
Lecturette on storage principles and techniques; points to cover:

- Principles of safe storage: adequate drying; undamaged, clean (winned) grain stores 2-5 times longer than cracked, dirty grain; insulate stored grain from fluctuations in outside temperature; adequate protection from storage insects and rodents; waterproof storage facility; store new grain away from old grain; use old grain first; check every 2-3 weeks for signs of heating and insects.

- Traditional storage methods and their pros and cons: hanging from rafters, clay pots, woven baskets, gourds, etc.

- Improved storage methods and their pros and cons: sacks, silos and bins, airtight storage, crib storage for ear maize.

- More details on dryer/storage cribs for ear maize: special advantages (earlier harvest and storage, cheap construction) and disadvantages (susceptibility to insects); design details (width, height, rat guards).

Lecturette on insect control in stored grain; points to cover:

- Types of storage insects and how to identify: weevils, bruchid beetles, moth larvae.

- Extent of damage: their rapid multiplication; life cycle.

- How infestations begin: some like maize and rice weevils, can fly and begin infesting the crop before harvest.

- Factors favoring infestations: temperature (50-80°F), moisture, faulty storage practices.

- How to check for infestations: early recognition important; check for hot spots, exit holes in grains, cobweb accumulations.

- Pre-storage guidelines for minimizing insect problems: well dried and cleaned grain; clean out storage facility; spray or dust facility with improved insecticide; disinfect used grain sacks with boiling water, placing on hot tin roof, or approved insecticides.

- Non-chemical storage insect controls: Sunning, smoking, mixing materials with grain (sand, wood ash, vegetable oil, etc.), airtight storage.
Chemical controls: use of approved insecticide sprays and dusts such as Malathion, Actellic.

10 Min.
Lecturette on rodent control in stored grain; points to cover:

- Basic facts on rats, mice: extent of damage, ability to jump and climb.
- Basic control methods: keeping brush down around the storage facility; rat guards and other rodent proofing measures; traps; poison baits.

10 Min. 
Lecturette on where to find further sources of information on grain drying and storage. Final wrap up.

Materials:
- Slides or pictures of traditional and improved methods of drying and storage
- Live specimens of common grain storage insects such as maize weevils, cowpea bruchids, and the Angoumis grain moth.
- Samples of moldy and insect infested grain

Trainer Notes:
Trainees should ideally build an improved storage facility like mud brick silo or maize dryer/storage crib and store their harvested grain crops in them.

III. UNITS OF MEASURE

Goals

A. To familiarize trainees with the basic units of measure used by host country farmers and ag technicians.

B. To enable trainees to make appropriate conversions between units of measure.

C. To enable trainees to layout field plots with square corners.

Objectives

A. Make selected conversions within each of the following measurement groups, using a conversion table. (Example: 4 gallons = x liters).
   1. AREA: Sq. ft. sq. meters, acre, hectare, etc.
   2. WEIGHT: Gram, kilogram, ounce, pound, etc.
   3. VOLUME: cc, ml, liter, pint, quart, gallon, fl. oz. teaspoon, tablespoon, etc.
   4. LENGTH: Inch, foot, yard, mm, cm, km, mile, etc.

B. Convert crop yields from a small plot basis to a kg/hectare or lbs./basis.

C. Pace off a given area by foot so that it agrees within 20% (area width of its taped off measure.

D. Lay out a field plot using the 3-4-5 triangle method so that all 4 sides are square (90°).

IV. SOIL MANAGEMENT AND FERTILIZER USE

A. Basic Soil Characteristics and Troubleshooting

Goals

To enable trainees to:

1. Evaluate their client farmers' soils in terms of 5 physical characteristics that largely determine potential productivity and management problems.

2. Make appropriate management recommendations to deal with soil physical problems that lower crop yields.

Objectives

1. Explain why your host country is likely to have dozens of distinctly different soils and why it's possible to find several kinds on one farm.

A-2
PRE-GERMINATING AND NURSING RICE - FIELD SESSION

SKILL GROUP X: B
RICE OVERVIEW
SESSION #1, P. 1

me: 2 hrs.

At the end of this session trainees will be able to:

1. Pre-germinate rice seed.
2. Prepare four different types of nursery seedbeds.
3. Determine the amount of seed needed to plant a given area.

This field session gives trainees hands-on experience in rice nursery production. Trainees work in groups of 3-4 to pre-germinate rice seed, prepare and plant wet, sunken, dry, and dapog nursery seedbeds. The pros and cons of each nursery method are discussed in the context of host country conditions.

Trainees divide into groups of 3-4.

Trainer explains goals and relevance of the session.

Trainer/trainee dialogue. Pre-germination of rice is defined and the advantages of pre-germination are discussed:

- Culls out unfilled seeds
- Improves germination rate
- Increases sprouting rate
- Protects against rat and bird damage

Trainer demonstrates pre-germination techniques (soaking, incubating, and periodically washing seed), using samples of seeds in various stages of pre-germination.

Trainees determine the amount of seed required to plant the training rice plot. Trainer provides them with the number of seeds per gram.
Trainees measure out the calculated amount of seed and begin soaking it.

45 Min.

Trainer/trainee dialogue to differentiate between the four styles of rice nursery and discuss their pros and cons. Each group prepares a wetbed, sunken bed, dry bed, and dapog nursery. (Pre-germinated seed should be available for them to nurse in these beds. Beds should be large enough to nurse seeds for the group's training plot.)

5 Min.

Trainees summarize the important factors and the assets and liabilities of the four major nursery seedbed methods.

Materials:
- Rice seed
- One bucket/group
- Water
- Shovels
- Rakes
- Hoes
- Manure, fertilizer
- Measuring equipment

Trainer Notes:
This session can be completed all at once or split into three shorter exercises. Pre-germination can be done the first day. The wetbed, sunken bed, and dry bed nurseries could be planted three days later. The dapog nursery should be planted four days before transplanting; pre-germinated seed should be available at that time. If the session is to be completed in one day, enough pre-germinated rice should be at hand to plant three types of seedbed.

Rice Production, PC/ICE
INTRODUCTION TO RICE

Time: 2 hrs. Classroom Session

Goal: To be able to identify the general characteristics of rice in terms of adaptability, nutritional value, morphology, stages of growth, varieties, and water needs.

Overview: This session gives trainees a basic introduction to rice in preparation for later sessions on rice production practices.

Activities:

Time:
5 Min. Trainer states goal and relevance of the session.
50 Min. Lecture/dialogue on nutritional value, morphology, stages of growth, and photo-period sensitivity of rice.
5 Min. Break.
45 Min. Lecture/dialogue on varieties, spacing, ratooning, water and weed control, and general rice production practices.
10 Min. Concluding remarks and summary by the trainer.

Materials: Rice plants or charts for use during explanation of rice morphology and growth stages.

Trainer Notes: This is a long session for one trainer to handle; it might be helpful to team teach. Use as many visual aids as possible.

References: Rice Production, PC/ICE
PADDY RICE LAND PREPARATION - FIELD SESSION

Time: 2 hrs.

Goal: To construct a rice paddy and prepare the soil for transplanting.

Overview: This session covers the purpose and methods of preparing a rice paddy for transplanting, the application of NPK fertilizer and the problem of denitrification of flooded soils. Trainees learn and practice guidelines for plowing, building levees, land leveling, irrigating, and harrowing. (The practices should follow recommended land preparation practices under host country conditions.)

Activities:

Time:

5 Min. Trainer states the goal and relevance of the session.

45 Min. Trainer/trainee dialogue, outlining: initial plowing, levee construction, weed control, land levelling, harrowing, NPK fertilizer application, denitrification, and water application during the land preparation process. Special attention is paid to the need for adequate water supply systems before paddy rice production is initiated.

10 Min. Trainees divide into groups of 6-8 and move to the training rice plots.

60 Min. Trainees construct levees on land that has already been plowed. Weeds are removed and the paddy is then flooded, levelled, and given its initial harrowing. (The paddies for each group can be quite small — 5 x 10 meters; this is sufficient to teach the basic production skills if time does not permit the construction of a large paddy.)

Materials:

- Shovels - 3 per group
- Rakes - 3 per group
- Hoes - 3 per group
- Water for flooding paddy
- Spike-toothed harrow (if available)
Trainer Notes: The second and third harrowings should follow at one week intervals with fertilizer applied just before the final harrowing. Final harrowing should occur as the seedlings in the nursery are ready for transplanting so that trainees can transplant their own seedlings. Final harrowing can be completed during maintenance time.

RICE PRODUCTION PRACTICES

Time: 1-2 hrs. Classroom Session

Goals:
1. To recognize and understand causes of basic soil nutrient problems associated with flooded soils.
2. To identify pests of rice (insect, disease, bird, rodent) and their associated damage.

Overview:
The session provides a background into the particular problems of dealing with rice in paddy conditions. It also includes a brief description of the many pests associated with rice production. This session may also serve as a conclusion to the rice production section within the Traditional Field Crops Skill Group.

Activities:

Time:
3 Min. Trainer states goals and relevance of the session.
25 Min. Trainer presents a lecturette on the problems associated with flooded soils: fertilization, denitrification, and nutritional disorders.
25 Min. Trainer presents a lecturette on pests of rice, using visual aids or live examples if possible.
7 Min. Trainees summarize main points of class.

Materials:
Charts
Slides
Insect collection
Blackboard, chalk, and erasers

Trainer Notes:
It might be difficult to cover the above material in only one hour. Try to keep the information as general as possible. Charts or handouts describing denitrification would be helpful as well as slides or a collection of pests.

TRANSPANTING RICE - FIELD SESSION

Time: 2 hr.

Goals:
1. To learn appropriate timing and placement of fertilizer in flooded soils.
2. To transplant rice into a prepared paddy.

Overview: This session opens with a discussion on the timing and placement of fertilizer in a flooded rice paddy comparing it to conventional fertilizer application procedures. Trainees then transplant rice seedlings from their nursery beds into the prepared paddy.

Activities:

Time:
3 Min. Trainer states goals and relevance of the session.
20 Min. Trainer/trainee dialogue on the placement of fertilizer in flooded soils, frequency of application, and types of fertilizer to use.
10 Min. Trainer discusses the reasons for planting rice in rows and the use of a knotted rope to space plant groups within the rows.
5 Min. Trainer demonstrates the proper technique for uprooting seedlings and transplanting rice into the paddy.
80 Min. Trainee groups of 6-8 transplant rice in rows into the paddies they had prepared during the session on rice land preparation.

Materials:
- Rice paddies prepared for transplanting
- Rice seedlings
- Ropes knotted at desired spacing intervals
- Stakes
- 1 hammer per group
- 1 tape measure per group
- 2 shovels per group
- Source of water
Trainer Notes: This session can serve as a valuable review of rice production techniques studies up to this point.

Maintenance time can be used if more time is needed to water the paddy and finish the transplanting.

COMMON UNITS OF MEASURE AND CONVERSIONS

Area

1 HECTARE = 10,000 sq. meters = 2.47 acres = 1.43 manzanas (Central America)

1 ACRE = 4000 sq. meters = 4840 sq. yards = 43,500 sq. ft.
   = 0.4 hectares = 0.58 manzanas (Central America)

1 MANZANA (Central America) = 10,000 sq. varas = 7000 sq. meters =
   8370 sq. yards = 1.73 acres = 0.7 hectares

Length

1 METER = 100 cm = 1000 mm = 39.37" = 3.28 ft.
1 CENTIMETER = 10 mm = 0.4"
1 INCH = 2.54 cm = 25.4 mm
1 VARA (Latin America) = 32.8" = 83.7 cm
1 KILOMETER = 1000 m = 0.625 miles
1 MILE = 1.6 km = 1600 m = 5280 ft.

Weight

1 KILOGRAM = 1000 g = 2.2 lbs. = 35.2 oz.
1 POUND = 16 oz. = 454 g = 0.454 kg
1 OUNCE = 28.4 g
1 METRIC TON = 1000 kg = 2202 lbs.
1 LONG TON = 2240 lbs; 1 SHORT TON = 2000 lbs.
1 QUINTAL = 100 lbs. (Latin America); 112 lbs. (British); 100 kg (metric)

Volume

1 LITER = 1000 cc = 1000 ml = 1.06 U.S. quarts
1 GALLON (U.S.) = 3.78 liters = 3780 cc (ml)
1 FLUID OUNCE = 30 cc (ml) = 2 level tablespoons (measuring type)
   = 6 level teaspoons (measuring type)

Miscellaneous Conversions

Lbs./acre x 1.12 = kg/hectare; lbs./acre x 1.73 = lbs./manzana
Kg/hectare x 0.89 = lbs./acre; kg/hectare x 1.54 = lbs./manzana
Lbs./manzana x 0.58 = lbs./acre; lbs./manzana x 0.65 = kg/hectare

Temperature:
   C° = (F° - 32) x 0.55
   F° = (C° x 1.8) + 32

1. With liquids, 1 level tablespoon equals 18 cc (ml) due to surface tension.
2. 1 level teaspoon (measuring type) = 5 cc with solids; 6 cc with liquids.
HOW TO CONVERT YIELDS FROM A SMALL PLOT BASIS
TO A KG/HECTARE OR LBS./ACRE BASIS

Sample problem: Poro tells you that she harvested 130 kg of tomatoes off a plot measuring 8 x 10 meters, but her friend Suheyla says her own plot yielded 75 kg and measures 5 x 6 meters. What are the relative yields in terms of kg/ha?

Solution: The easiest way is to set up a proportion like so:

\[
\frac{\text{plot area in } m^2}{10,000 \text{ m}^2} = \frac{\text{yield of plot in kg}}{\text{kg/ha yield}}
\]

In Pora's case:

\[
\frac{80 \text{ m}^2}{10,000 \text{ m}^2} = \frac{130 \text{ kg}}{\text{kg/ha yield}}
\]

Cross multiply:

\[80 \times \frac{\text{kg/ha yield}}{10,000} = 130 \times \frac{10,000}{80}\]

\[\text{kg/ha yield} = 16,250 \text{ for Pora}\]

In Suheyla's case:

\[
\frac{30 \text{ m}^2}{10,000 \text{ m}^2} = \frac{75 \text{ kg}}{\text{kg/ha yield}}
\]

\[\text{kg/ha yield} = \frac{75 \times 10,000}{30} = 25,000 \text{ for Suheyla}\]

Alternate Method: Use this formula:

\[
\text{Yield in kg/ha} = \frac{10,000 \times \text{plot yield in kg}}{\text{plot area in m}^2}
\]

What about lbs/acre?: The English system is more cumbersome since an acre equals 43,560 sq. ft. or 4840 sq. yards. However, you can use 4000 sq. meters which is close enough (1 acre actually equals 4050 sq. meters). Work the lbs/acre problems in the same way as above.
UNITs OF MEASURE PRACTICE PROBLEMS

1. 15 acres = _____ HECTARES
2. 5 Hectares = _____ ACRES
3. 8000 m² = _____ HECTARES
4. 60 cm = _____ INCHES
5. 1500 mm = _____ INCHES
6. 6 inches = _____ cm
7. 100 km = _____ MILES
8. 40 miles = _____ km
9. 10 meters = _____ FEET
10. 20 feet = _____ METERS
11. 50 kg = _____ LBS.
12. 1000 lbs. = _____ kg
13. 12 ounces = _____ GRAMS
14. 800 g = _____ LBS.
15. 5 gallons = _____ LITERS
16. 10 liters = _____ gallons
17. 10 fl. oz. = _____ cc (ml)
18. 120 cc (ml) = _____ fl. oz.
19. 30°C = _____ °F
20. 100°F = _____ °C

ANSWERS: 1) 6 ha 2) 12.5 acres 3) 0.8 ha 4) 23.6" 5) 60" (59"
6) 15" (15.2) 7) 62.5 miles 8) 64 km 9) 32.8 ft. 10) 6.1 meters
11) 110 lbs. 12) 454 kg 13) 341 g 14) 1.76 lbs (1 lb. 12 oz.)
15) 18.9 liters 16) 2.65 gals. 17) 300 cc. 18) 4 fl. oz.
19) 86°F 20) 37.7°C
The purpose of this chapter is to show you, the agricultural field worker (AFW), how to survey and interpret the important features of the local agricultural environment and the individual farm units which are a part of it. This is vital to your effectiveness as an extensionist, since it will enable you to fully comprehend your work area's farming systems and practices, as well as its individual farm units.
A. THE AGRICULTURAL ENVIRONMENT

The local ag environment is made up of those factors which influence an area's agriculture. The most important of these are listed below and are the ones on which we'll concentrate:

The Main Features of the Local Ag Environment

Rainfall

In dryland (non-irrigated) areas of the tropics with year-round growing temperatures, rainfall is the major environmental factor that determines which crops can be grown, when they're planted, and what they yield. Rainfall varies greatly from place to place, often within surprisingly short distances, especially under mountainous or hilly terrain. The dryland farmer is keenly aware of his area's seasonal rainfall distribution and the frequent deviations from the "normal" cycle such as "early" or "late" rains or unseasonal drought. Too much rain which can drown out the crop, delay harvest, and accelerate soil erosion can be just as serious as too little. It may be too wet for plowing one day, yet too dry the following week for good seed germination; rare is the rainy season that receives no complaints from farmers.

When gathering rainfall data for your work area, you should keep several points in mind:

1. Annual rainfall averages have little meaning: seasonal distribution and reliability are far more important in terms of crop production. For example, Ibadan, Nigeria is located in the transition zone between the humid and sub-humid tropics and receives about the same annual rainfall (1140mm or 45") as Saramu, Nigeria which is located to the north in the savanna zone. Ibadan's rainfall is spread out over 9 months from March to November in a bi-modal pattern (i.e. 2 rainy seasons).

1. The infrastructure refers to those installations, facilities, goods, services, and inputs that encourage ag production.
seasons with a drier period in-between). The first season is long enough for a 120 day maize crop, although there is some periodic moisture stress; however, the second season is shorter, and soil moisture is usually adequate for only 80-90 days, so a 120 day crop suffers seriously. On the other hand, Samaru's equal rainfall is spread out over 5 months in a uni-modal pattern so that the maize crop is much less prone to moisture stress.

2. Seasonal rainfall distribution gives a good general indication of the amount of moisture available for crop production, but it doesn't give the full story. The amount of rainfall that actually ends up stored in the soil of a farmer's field for crop use depends on other factors too such as water run-off and evaporation from the soil surface, and the soil's texture (i.e. sandy vs. clayey) and depth.

3. When interpreting the rainfall pattern of your work area, don't get bogged down in what is "average" or "normal". Annual and especially monthly totals can deviate widely from the averages. Variations are the rule not the exception, even though the general seasonal distribution curve usually maintains a consistent shape. The chart below gives an excellent illustration of this.

![Monthly Rainfall Pattern, Managua, Nicaragua, 1958-67](image)

- Wettest year, 1958: 1437 mm (56")
- Driest year, 1965: 757 mm (30")
- Average, 1958-67: 1090 mm (43")

How cropping cycles are related to rainfall pattern: In the tropics, cropping cycles are closely tied to seasonal rainfall distribution; you can see this by comparing the cropping calendar on the next page with the rainfall chart above.

1. This chart is from the PC/Latin America Agric. Program Manual, Part III, Unit I: The Agricultural Environment, p. 4; prepared under John Guy Smith and published by Peace Corps in 1970.

4. The farmer as a weather "expert": Official weather station rainfall data is handy to have if it's representative of your work area and is reliable, but it isn't essential. You can find out nearly all you need to know about rainfall distribution by talking with experienced local farmers; they are the local weather "experts".

The following chart and graph were developed from the comments of a small Nicaraguan farmer who lived only a mile away from the national weather station but had no access to its data. Notice how closely the curve derived from his remarks matches the station's average curve based on 10 years of data.

GUIDELINES FOR THE ORIENTATION OF THE AGRICULTURAL FIELD WORKER

These guidelines are designed to help you as a newly assigned agricultural field worker (AFW) to orient yourself to the local ag environment and its individual farm units within 1-2 months after your arrival. When using the guidelines, keep in mind the following:

1. Don't undertake a highly detailed survey of local resources at the start of your assignment unless your host agency specifically requests it. Otherwise, you're likely to arouse local suspicions, especially if you're overzealous or overbearin in your initial contacts.

2. Your host agency may give you a basic orientation to your work area, but it may be very limited.

3. If you discover discrepancies between the information gathered from local sources (farmers, etc.) and that from outside or official sources, trust your local "grass roots" information until proven otherwise. Local farmers are the ultimate authorities on the local ag environment.

4. The guidelines that follow are organized mainly by subject area but don't have to be followed in a set order. You'll be picking up bits and pieces of information from a single informant that may deal with a number of areas and will have to put them into their proper context.

FIRST PHASE (INTRODUCTORY) ORIENTATION

This initial phase focuses on the local ag environment in general and is designed to help you orient yourself to it and to adjust your work schedule and activities to the seasonal rhythms of your area's agriculture. Unless severely limited by your local language ability, you should be able to complete this phase in 2-4 weeks if you're energetic about covering your work area and spend several hours a day talking with local farmers and other sources of ag information.

A. GET ORIENTED TO FARMERS AND TO OTHER LOCAL RESIDENTS WHO HAVE A VESTED INTEREST IN AGRICULTURE

You're urged to spend a major part of your time talking with and listening to farmers and other knowledgeable sources who have a vested interest in agriculture.

1. These guidelines are a condensation of "Guidelines for the Orientation of the Agric. Field Worker" from Part III, Unit I of the PC/Latin America Agric. Program Manual prepared under John Guy Smith and published by the Peace Corps in 1970. Their use is gratefully acknowledged.
1. Local Farmers
   a. Get a general idea of how farmers are distributed geographically.
   b. Get a specific idea of where your likely client farmers are located (i.e. those with whom your job description deals).

2. Locate other knowledgeable individuals
   Such as ag technicians stationed or working in the area, local buyers of farm produce, local ag supply dealers, and local truckers.

3. The Sample: Selecting reliable local informants
   Don't let your earliest contacts bias you overall impressions. Likely initial contacts are: your landlord's relatives, the local mayor or other local official, the more easily accessible talkative farmers; or the "pet" farmers of the agency. At the early stage, your contacts don't have to be completely representative as long as they're knowledgeable.

   The value of your agency counterparts or supervisor as informants should be judged in terms of their actual experience (both in terms of time and among different classes of farmers).

   The best farmer-informants are usually among the more progressive farmers. However, a good informant for orientation purposes is one who represents his own class of farmers. For example, a progressive small farmer will provide more information and insight into small farming operations than a larger scale commercial farmer.

   Keep a careful record (diary entries) of all initial contacts.

4. How to Interview
   a. Introducing yourself: Ideally, you should have a third party make the initial contact and introduction; if this isn't possible, be prepared with a practiced explanation of your presence. It's important that you emphasize that you are the learner at this stage.
   b. Suggested techniques: Allow the farmer to talk as spontaneously as possible; any leading questions on your part almost always get "yes" responses. Use a memorized interview schedule rather than a written one which is likely to inhibit responses. Avoid over-formality.
   c. Recording your results: It's generally not a good idea to take written notes in front of a farmer, although in some cases he may expect you (as a "technician") to do so. Some farmers may view written notes as having some possible connection with future tax collections, etc. It's best to wait until an unobtrusive moment such as the mid-day break to summarize your information in written form.
B. GET ORIENTED IN SPACE AND TO THE PRINCIPAL PHYSICAL AND DEMOGRAPHIC FEATURES OF THE ENVIRONMENT

In order to locate farms, farmers, ag suppliers, etc., you should pinpoint their locations with reference to the road and trail network and the dominant topographic features. You'll also want to locate or understand the principal physical and demographic features of your work area.

1. Using maps
   a. Sources of maps
      (1) Geographic or geodetic service of the government; in a number of LDC's, the military geographic service may be the only source of relief (topographic) maps.
      (2) National resource inventory maps: They're useful for understanding the regional dispersal of resources but not much help in making a local inventory of resources.
      (3) Road maps: those secured from public works agencies will show more detail than the usual service station maps.
      (4) Special sources: National and regional soil survey maps or land use maps; regional development authorities; regional studies done by international agencies.
      (5) Homemade maps: Most official maps may not have a large enough scale to accurately pinpoint the location of farms, secondary irrigation systems, unimproved roads, etc. You can enlarge official maps yourself by hand.
   b. Using plastic overlays
      Use a separate plastic overlay for each class of information to avoid marking up the base reference map.
   c. Using xerox or carbon copies
      You'll save time by xeroxing or making carbon copies of your base map.

2. Check List: xerox or carbon copies
   a. Topographical features: altitude, streams, principal features (landmarks) recognized locally as reference points, valleys, farm and non-farm lands.
   b. Communications (roads and trails): seasonal access, distances, travel times and modes of travel between points.
   c. Demographic: Locations of communities (and their local names), farmers.
d. Infrastructure: Irrigation systems, drainage systems, ag supply stores, schools, extension offices, etc.

C. GET ORIENTED TO CLIMATE AND WEATHER PATTERNS

1. Sources of Information

a. Weather station records

Obtain all available meteorological data from the official weather station nearest to your area of assignment. Its orientation value will depend on the station's proximity and how well it represents your area's conditions.

b. Relief maps

Altitude is the main temperature determinant in the tropics; remember that for every 1000 ft. rise in altitude, average (mean) temperature will drop about 3.5°F (0.65°C per 100 meters).

c. Local farmers

Official weather data is nice to have if it's relevant to your work area and is reliable, but it's not essential. You can learn all you need to know about local climate and weather conditions from experienced local farmers. After all, they have every reason to be the local weather "experts".

You can draw a rainfall chart which is accurate enough for the initial orientation simply by systematically recording farmers' comments about the seasonal distribution of rainfall; the same can be done as far as seasonal temperature variation. (See rainfall chart on p. 8).

When recording farmer's observations about climate and weather, you'll need a common reference point. In the example on p. 8, the observer understood that the word "dry" meant no rain, and this was the reference point.

2. Climate and weather checklist

a. Rainfall

   (1) Monthly distribution of rainfall

   Make tables and/or charts showing the month to month distribution using the following criteria:

   (a) Dry to wet scale (see rainfall section, p. 8)

   (b) Rainfall frequency: the number of times it normally rains in a week or month.
(2) Variations from seasonal norms and risk factors

If reliable long run climate data isn't available (10 years or more), talk with local farmers who have lengthy local experience.

Risk factors associated with climate and weather (i.e. droughts, hail, high winds, flooding) can be established by having farmers recall bad crop years over a span of years. Be sure to distinguish weather factors from other causes such as insects and diseases.

b. Temperature

(1) Monthly temperature averages.
(2) Periods of significantly high or low temperatures.
(3) Occurrence of first and last killing frosts.

D. GET ORIENTED TO PREVAILING FARMING SYSTEMS AND PRACTICES

1. Identify the major crop and livestock enterprises in your work area.

2. For each of the crop enterprises which predominates in the area, indicate the following and note any local variations:
   
   a. Indicate the growing season
      (1) Normal growing season and its variations (early-late)
      (2) Make a cropping calendar using line bar graphs (see p. 16)
   
   b. Describe production practices

   Don't confuse the practices recommended by extension with those generally accepted by farmers. Your interest is in the prevailing practices used by most of the farmers in your area. Make note of any significant differences among different groups of farmers.

   (1) Describe the principal land preparation practices along with their earliest and latest dates of application.

   (2) Indicate the following for every practice
      
      (a) What the practice is called locally. For example, in many areas of Central America, the practice of hilling up maize (throwing soil into the row) is called the "aporque".

      (b) The kind and amount of input or inputs associated with the practice and the amount applied as well as the method and timing of application. This includes man days of labor.

1. The use of the term "man days" is not meant to imply that all farmers are men!

- 136 -
c. **Estimate yields and returns**

At this stage of your orientation, you're advised not to make a detailed account of the costs and returns; seeking such data can arouse local suspicions or fears of future tax levies. You should be after rough estimates of production costs, and gross and net returns.

1. **Reported yields per unit of land.**
2. **Recent prices at normal time of sale.**
3. **Multiply recent prices by approximate average yield to get approximate gross returns.**
4. **Subtract approximate production costs from gross returns to obtain approximate net returns.**

There are 2 ways to do this: net return to capital, land, and family labor where the only labor costs you account for are hired labor; or net return to land and capital in which case an opportunity cost (exchange value) must be assigned to family labor and subtracted from the gross return. The first way is the easiest.

4. **Indicate the relative disposition of production**
   a. **Estimate the percentage that is marketed.**
   b. **Identify the principal local market outlets (buyers).**
   c. **Seasonality of marketing and prices**
      1. Seasonal movement of the production off the farms: is it sold at harvest, some sold at harvest, some held for higher prices, etc.?
      2. **Seasonal price fluctuations (average over several years).**

5. **List the outside production inputs which are available locally.**  
   ("Available" means when needed)
   a. **Crop production supplies (give brands, grades, and unit prices):**
      fertilizers, insecticides, fungicides, herbicides, hand tools, hand operated equipment, seeds, etc.
   b. **Agricultural machinery and equipment (if used):** tractors (horse-power and make), implements, irrigation pumps, etc.
   c. **Services**
      1. **Custom machinery services and rates charged.**
      2. **Professional services (indicate whether public or private):** technical assistance, soil testing, etc.
E. SUMMARIZE YOUR INFORMATION, GET ORIENTED IN TIME

Every area's agriculture is tuned to a time schedule or seasonal rhythm to which you must adjust your work schedule and activities. That's why getting oriented in time (or better put, ahead of time) is so vital to your job effectiveness. Unless you have a clear picture of the local ag calendar, you could easily waste the first growing season.

We strongly recommend that you summarize this initial phase of your orientation by making graphs and calendar charts that show your area's seasonal rhythm of climate, agriculture, and social or religious activities.

The following graphs, charts, and observations were obtained by a group of Peace Corps Volunteers assigned as rural credit agents in the Pacific region of Nicaragua during an orientation training exercise. The principles involved apply worldwide.

1. **Make a generalized climate and weather calendar**
   
   **a. Normal monthly distribution of rainfall**
   
   (1) As related by farmers using terms such as dry, wet, some rain, wettest time, rainfall drops off, etc. There are 2 ways to do this:

   **Using the Frequency of Rainfall to measure seasonal distribution**

   ![Frequency of Rainfall Chart](chart.png)

   **Using a Dry to Wet Scale:** See graph on page 8.

   (2) Measured in millimeters or inches if you have access to reliable meteorological data.

   **b. Indicate the range and frequency of possible deviations from normal rainfall patterns:**

   (1) As related by farmers
   (2) As recorded by weather station (see graph on p. 6).

2. **Making a calendar of agricultural activity**
   
   **a. For each of the major crop enterprises, display the following:**

   (1) Length and possible range of growing season including likely variations in planting and harvest times.
Example: Crop Calendar, Crops and Order of Importance in the Esteli Area of Nicaragua.

1. Maize, long season
2. Rice, dryland
3. Beans
4. Improved, non-photosensitive sorghum

(Dotted lines indicate likely deviations)

J F M A M J J A S O N D J

(2) Indicate time for performing critical operations and relative labor requirements of those operations.

Example: Distribution of Work and Timing of Principal Farming Operations in the Esteli Area of Nicaragua

1. Land clearing
2. Land preparation
3. Principal seeding
4. Weeding
5. First harvest
6. Second planting
7. Harvest

(1) Seasonal labor demand: Indicate periods, if any, of movement of labor into or out of the area.

(2) Seasonal demand for other critical inputs: An input isn't considered critical unless farmers feel it is. For example, if fertilizer is not generally used, it's not presently a critical input.

3. Make a calendar of economic activity related to agriculture.

a. Indicate relative demand for short term production credit.
Example: Demand for Production Credit, Branch Office of the National Bank of Nicaragua

<table>
<thead>
<tr>
<th>Number of Credit Applications per Month</th>
<th>200</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>100</td>
</tr>
</tbody>
</table>

b. Indicate seasonal marketing patterns (the area at which the crop is marketed).

4. Make a calendar of social activity that includes religious holidays and other holidays or seasonally determined social obligations.

THIS CONCLUDES THE INITIAL PHASE OF YOUR ORIENTATION, and you should now be able to schedule your work activities intelligently and have a good understanding of the local ag environment and farming practices.
C. UNDERSTANDING THE INDIVIDUAL FARM UNIT

Classifying Farm Units

Each farm has its own unique characteristics, but those located in the same environment usually share enough similarities to allow grouping them into several general types of farm unit such as subsistence, market oriented field crop, plantation, etc. If your work area's environment is fairly uniform with equitable land distribution, only one type of farm unit may predominate. If it is characterized by irregular topography and lopsided land distribution, it may have several or more different types of farm units.

There are 8 basic criteria that can be used to differentiate types of farm units:

1. Location
2. Type of occupancy; owner occupant vs. tenant vs. squatter
3. Size of farm, parcelization, and land use potential
4. Size of the farm business
5. Type of farm enterprise
6. Production practices
7. Farm improvements
8. Farm labor supply

1. Location

The principal factors here are:

a. Natural characteristics such as soil type, slope, soil depth, drainage, access to water, etc.

b. Proximity to the transportation network and other infrastructural factors such as public irrigation and drainage systems.

c. Location in relation to other farm units.

d. Local name of the farm's location.

2. Type of Occupancy

The principal considerations are:

a. Who owns the land?

b. If not owner-operated, what is the tenancy arrangement (i.e. cash rent, crop share, or work share) and on what specific terms? How secure is the arrangement?

c. If no one has legal title to the land, is it occupied under squatters' rights that are protected by law?

d. Who manages the farm unit and makes the basic decisions?
3. **Size of Farm, Parcelization, and Land Use**

a. Total farm size in terms of local units of measure.

b. Location of farm parcels: If they're dispersed, how far are they from the farmer's house?

c. Actual land use: tillable vs. pasture vs. forest; irrigated vs. non-irrigated.

d. Characteristics of its soils: local name, color, texture, depth, drainage, slope, plus farmer's opinion of them.

4. **Size of the Farm Business**

a. Land value of the farm unit

b. Value of other fixed assets

c. Amount of operating capital employed per land or livestock unit

d. The value of production per land or livestock unit.

The value of the farm unit compared to its number of workers indicates whether it is capital intensive or labor intensive. The value of production per land unit indicates the intensity of land use.

5. **Type of Farm Enterprise**

Some farms are engaged in only one enterprise such as sugarcane, coffee, rice, etc., but this type of monoculture is unusual among small farms. More likely, some form of mixed agriculture will exist. The main considerations are:

a. Relative importance of each enterprise.

b. The yields obtained from each enterprise

c. The disposal of the products from each enterprise (subsistence or cash sale) and where sold.

d. Crop rotations and associations.

e. Relationship between crop and livestock production, if any.

6. **Production Practices**

a. The specific inputs.

b. Rate, method, and time of application.
7. **Farm Improvements**
   a. Condition of the farm family home (or the farm manager's and farm workers' homes).
   b. Presence and condition of fences, wells, irrigation works, field access roads, storage facilities, livestock shelters, corrals, etc.

8. **The Farm Labor Supply**
   a. Degree of reliance on the family's own labor force and the composition of that force.
   b. Degree of dependence on hired labor.
   c. The seasonal nature of work requirements.
   d. Use of animal or tractor drawn equipment.
D. DESIGNING A QUESTIONNAIRE

The quality of the information which you are able to gather from local farmers depends heavily on the quality of your questionnaire. Even the most elaborate survey will fail to elicit accurate information if you have not taken care to design clear, unbiased questions. The following "Sample Survey" outlines one procedure for designing effective questionnaires.

**Sample Survey**

One of the most useful and economical means of gathering information about a population is the sample survey. The instrument used to collect data is known as a questionnaire. Before starting to construct a questionnaire, you should be able to answer the following questions:

a. In what areas do you need information?

b. Why do you need this information?

c. How will you analyze the data collected?

A questionnaire may appear to be easy to construct and use but in fact it requires a great deal of care and expertise. The following guideline should be sufficient for your work in the community. It is not meant to train you in the methods necessary for scientific research. If you are interested in collecting more detailed information, seek assistance from a social scientist in your area.

**Steps in Designing a Sample Survey**

I. Constructing the Questionnaire

A. Before writing the questions, several decisions should be made:

1. **How to relate the content of the questions to the objectives of the survey.** In certain studies such as population census, the relationship between the goals of the survey and the questions is usually obvious. But when the aim is to obtain information on motivation, intentions, feelings, etc., the wording of questions is more difficult.

When choosing issues to be raised, how to ask the questions and what vocabulary to use, try to be sensitive to people's backgrounds. A common problem found with inexperienced personnel in the field of survey research is the tendency to assume that the respondent has the same level of knowledge in the area studies as they do. Following are some reasons that may explain the respondent's inability to answer a given question:

a. The respondent may not have enough knowledge in a given field.

- 144 -

155
b. The respondent does not have access to the information. This is true in studies which ask respondents to report about the characteristics of other family members or neighbors.

c. The respondent has forgotten facts that happened in the past.

d. The respondent may not understand the question.

2. Wording of questions

Having decided about the content of the questions, you should then give attention to the actual wording of these questions. Precise, clearly-worded questions will give you clear answers. Following are some suggestions you can use in writing them:

a. The language should be simple, direct and at a level which can be understood by all respondents. You should avoid two extremes: don't use technical terms and jargon which are familiar only to those with a certain level of education and avoid "talking down" to the respondent by using ungrammatical constructions and colloquial phrases.

b. The question should be specific and should deal with only one idea. For example, if a respondent were asked "Do you think that the community needs more family privies and are you planning to build one for your family?" The answer could be "No."--which might mean that he/she does not think that the community needs more privies or it might mean that the community does need more privies, but that he/she is not going to build one for the family. In any case, there is always a risk that the respondent is answering "yes" or "no" to only one part of the question.

To avoid these difficulties, it is better to limit the question to a single issue and then combine the responses later if this is necessary.

c. The question should not make unnecessary assumptions about the respondent. For example, the question "What is your present occupation?" assumes that the respondent actually has an occupation and would not be applicable to those who are unemployed. To avoid these dangers, it is best to use what is known as a "filter" or the "skip pattern" device. These questions have at least two parts: the first determines whether or not the respondent qualifies for further investigations, while the second part will give more detailed information on those who qualify. For example:

(1) "Have you ever worked?"

(a) yes (b) no (skip to question 2)

If yes,

"What was your occupation?"
d. Avoid using indefinite words. One type consists of words that are indefinite in time, such as "frequently," "often," "rarely," etc. "Frequently" may mean "once a day" or "once a week," etc.

There are, of course, many other ways in which questions can be unclear, but these examples serve to illustrate some of the more common mistakes.

3. Types of questions

There are basically two types of questions used in a questionnaire: the "closed" and "open-ended" questions. The first one is illustrated by items such as:

"Do you think that the drinking water supply of the community is:

a. quite good?"
b. only fair?"
c. not good?"

where the respondent is asked to choose one out of a list of possible answers.

With "open-ended" questions, the respondent is free to use his/her own words to reply. For example: "How satisfied are you with the community's drinking water supply? Why do you feel this way?" The majority of questionnaires contain both "open-ended" and "closed" questions.

4. Ordering the questions

There is no correct format for a questionnaire but certain principles are found to aid efficiency. These principles are:

a. The first impressions should be that the questionnaire is relevant, clear and easy to complete.

b. The first questions should ordinarily be terms that are emotionally neutral and easily answered.

c. The questionnaire should be as short as possible. Do not include questions on the basis that information might be useful for some purpose at some time in the future.

d. The questions should follow each other in a logical order and should not be repetitive, except when you are attempting to be sure that you are getting accurate information.

5. Culturally sensitive questions

In every culture there are some questions that cannot be asked, or must be asked very carefully in a survey. Sensitive ques-
tions should be carefully written during the initial drafting of the questionnaire and carefully analyzed for possible revision after the pretest (discussed below).

B. Types of Questionnaires

There are two types of questionnaires:

1. The self-administered questionnaire in which the respondent completes the answers to the questions.

2. The interview-questionnaire in which the questions are asked and recorded by an interviewer.

Advantages and disadvantages are found in both methods. However, for your work in the community, you might consider using the interview-questionnaire which will give you an opportunity to get to know the people on a personal basis. The interview-questionnaire has the following advantages:

1. It reduces the problem of non-response. The presence of the interviewer can sometimes serve as an incentive to respond.

2. It can be used with persons of almost all educational levels.

3. It allows probing for more detailed information and the interviewer can clarify misinterpretations. It is also possible to combine the two methods. The interviewer can visit the respondent, explain the purpose of the study and leave the questionnaire to be completed with the respondent.

II. The Pre-test

Once the questionnaire has been assembled, it should be tried out with people similar to those to whom it is to be administered. That is, it should be administered to households not included in the sample (See Section III).

It is only by doing this that errors and confusing questions can be corrected before time and effort are wasted on the actual survey. Five or 10 interviews are enough to know if the questionnaire works well or not. After the pre-test interviews are taken, you should review the questionnaire, any inadequacies should be corrected, and ideally, the modified questionnaire tested again. Following are some points you should consider in the pre-test.

A. Does the question ask for information that is needed for the purposes of the survey? Are you sure you need to ask this question?

B. Are the questions and words interpreted in the same way by people of different social groups, ethnic groups, educational level, sex, and locations?
C. Are there certain questions which seem to create irritation or embarrassment?

D. Are any questions confusing to the respondent? What would make these questions more clear?

E. Is the questionnaire too long?

F. Is there enough space to record the answer? Nothing is more annoying to the respondent or to the interviewer than having to write a lot of information into too small a space.

G. Are there repetitive questions?

Pre-test is an essential part of questionnaire design and should not be omitted on the grounds that the questionnaire can be properly evaluated by you and your team of local people.

III. Selection of the Sample

It is nearly impossible for you to ask everybody in the community a set of questions. What you can do is to select a small group of people (the sample) to whom you will administer your questionnaire. The aim of this process is to obtain information from the sample which will apply to the total population of the community when the information gathered is analyzed.

There are several sampling techniques, but for the purpose of your study, you need not get into complicated statistical calculations. Following is one simple method:

Make a list of all the households street by street or block by block, then select one household out of every five, 10 or 15 households, depending on the size of your sample.

For your study, 20 to 30 interviews are sufficient. Select equal numbers of male and female respondents. Very often, the community may have several different ethnic or social groups. In this case, be sure to include in your sample representatives of each major group, in numbers proportional to its size.

Remember that the population of your sample must represent and have as much as possible the characteristics of the population of the whole community.

IV. Interviewing

You must keep in mind that the questionnaire is a tool that helps you to collect information for a better understanding of the community. Accept answers without showing any doubt; do not change replies that do not sound correct to you.

First, set up a friendly relationship with the respondent. Explain the purpose of the study in such a way that the respondent's curiosity and
interest are stimulated. He/she must see that the study is worthwhile and that his/her cooperation is needed. Another important aspect of interviewing is probing. This is the technique used by the interviewer to encourage and stimulate the respondent to give further details. You can use a neutral question or comment such as "What do you mean?" or "I see" or remain silent, suggesting to your respondent you understand the answer given but you know that she/he has more to say.

The important point to keep in mind is that you should not impose your ideas upon your respondent to a point that she/he feels obligated to give the answer that you want—an answer that does not reflect his/her own feelings.

V. Analysis of the Data Collected

In conducting the community survey, your goal is not to gather statistical information such as the number of persons in different age groups or the number of persons having a certain illness, but rather to gain a better understanding of the people's traditions, knowledge, and beliefs of the community's felt needs, of what could and should be done for the well-being of the people.

For example, if you want to know what the community thinks about the services given at the health clinic, your analysis may present itself under this form:

"Reasons for not using the health center by ...."

a. sex (male/female)

b. marital status (single, married, divorced, widow(er))

c. education (know how to read and write, primary education, secondary education, etc ...)

d. income

e. location

f. and others

Examining the responses to this question for each of these categories will help you to understand why the health center is not used. For example, the location may not be too convenient for some people because of the lack of public transportation, or women say that the midwife-nurse's manners are rude, or the villagers, especially those with little education, consider the health center as the place for dying patients. This kind of information will help you to plan your educational activities accordingly.
INTRODUCTION TO CROP PRODUCTION MANAGEMENT

Good crop production management involves attention to two major areas:

1. **Standard managerial skills** like timeliness and recordkeeping that are essential to the success of any enterprise.

2. The farmer's ability to manipulate the ag environment by selecting and implementing an appropriate system of cropping practices from land preparation through marketing.

**STANDARD MANAGERIAL SKILLS**

Most of these skills apply as much to extension workers as to farmers:

An *systemic approach:* This means treating crop production as a *system* composed of interrelated management practices. Another term for this is integrated crop production management.

Organizing and planning: From land preparation through marketing.

Recordkeeping: For example, maintaining an accurate account of costs and returns; keeping a field notebook to record planting dates, dates and dosages of ag chemicals, rainfall, and general observations on the crop's progress. This is a much neglected management skill.

Observing-scouting to spot problems like insects and diseases so that timely action can be taken.

Timeliness and thoroughness: Delays in planting, fertilizing, weeding, watering, spraying, and harvesting can markedly lower yields. Carelessness and haste have a similar effect.

Equipment maintenance and repair: Sloppy maintenance not only raises equipment costs but the resulting delays can also lower yields.

Communication with other farmers, researchers, and extensionists to provide feedback and to keep abreast of new developments in cropping practices. In addition, farmers need to keep informed of market trends concerning their crops.

**MANIPULATING THE AG ENVIRONMENT**

No other endeavor is subject to more variables than outdoor crop production. The countless variations in soils, climate, pests and diseases, farmer management ability, available capital, and available inputs (improved varieties, fertilizers, etc.) make such agriculture a very location-specific enterprise with few "cookbook" recipes for success.

Despite the vagaries of Nature, a farmer still has a good deal of control over his/her specific cropping situation by choosing those management practices which can overcome or moderate limiting factors and often make the difference between profit and loss (or hunger and subsistence). Whether
consciously or not, most successful managers and extensionists view crop production of an integrated system made up of the following management areas which each contain numerous options:

I. CROPPING SYSTEMS: How much of what to grow; type of rotation.
II. SOIL MANAGEMENT & LAND PREPARATION
III. PLANTING/TRANSPLANTING
IV. FERTILIZER USE
V. LIMING
VI. USING WATER EFFICIENTLY

VII. WEEK CONTROL
VIII. PEST & DISEASES CONTROL
IX. OTHER PRE-HARVEST GROWING PRACTICES
X. HARVESTING
XI. DRYING AND STORAGE
XII. MARKETING

NOTE: These management areas are presented in detail at the end of this section.

The "Package of Practices" Approach to Crop Management

In most cases, low crop yields are caused by several major limiting factors present simultaneously, rather than by one single obstacle. When farmers implement a locally adapted "package" of practices designed to overcome these multiple yield barriers, the results are usually much more impressive than those obtained by concentrating on only one barrier. Some examples:

1. In a trial in India, a hybrid maize variety yielded only slightly more than a native variety when both were grown under traditional methods (2000 kg/ha vs. 1800 kg/ha). However, the same hybrid yielded 8000 kg/ha compared to 2000 kg/ha for the native variety when both were grown under improved practices (fertilizer use, insect control, proper plant spacing and population).

2. Results from a trial conducted with wheat in Mexico:

<table>
<thead>
<tr>
<th>Treatment</th>
<th>Yield Increase</th>
</tr>
</thead>
<tbody>
<tr>
<td>Irrigation</td>
<td>135%</td>
</tr>
<tr>
<td>Fertilizer</td>
<td>5%</td>
</tr>
<tr>
<td>Irrigation + Fertilizer</td>
<td>700%</td>
</tr>
</tbody>
</table>

A typical crop "package" consists of a combination of several locally proven new practices which are also tested in their combined form. Few packages are readily transferable without local testing and modification to suit conditions. Most packages consist of several of the following practices: an improved variety, fertilizer use, changes in plant population and spacing, improved control of weeds-pests-diseases, and improvements in land preparation, water management, harvest, and storage.

It's important to realize that a package doesn't always have to involve considerable use of purchased inputs. In fact, extension efforts can often
effectively focus initially on improving basic management practices and skills that require little or no investment (i.e. timeliness, weeding, land preparation, seed selection, changes in plant population and spacing, etc.). This helps assure that small farmers benefit at least as much as larger ones, especially in regions where ag credit is deficient.
A GUIDE TO CROP PRODUCTION MANAGEMENT FACTORS

I. CROPPING SYSTEMS

A. How much of what to grow.

B. Intercropping (several crops at once) vs. monocropping; monoculture (same crop year after year) vs. crop rotation

II. SOIL MANAGEMENT AND LAND PREPARATION

A. Soil conservation practices to lessen soil erosion losses on sloping fields.

B. Improving soil physical limitations: texture, tilth, depth, drainage.

C. Choice of seedbed type: raised, flat, sunken.

D. Seedbed fineness required for the particular crop.

E. Handling of previous crop's residues.

F. Tillage vs. no-tillage

G. Depth of tillage

H. Choice of equipment or implements.

III. PLANTING/TRANSPLANTING

A. Direct seeding vs. transplanting.

B. Direct seeding (field crops, some vegies)

1. Date of planting and its correlation with rainfall and temperature cycles.

2. Choice of crop variety: native vs. improved vs. hybrid plus choices within each of these groups.

3. Seed quality, purity, and germination.

4. Depth of planting: small vs. large seeds, soil texture, moisture.

5. Plant spacing: in the row, between rows; broadcasting vs. row planting; "hill" vs. "drill" planting.

6. Plant population (density).

7. Planting method: hand vs. mechanical.
C. **Transplanting**

1. **Size and age of transplant.**
2. **Container-grown vs. bare-rooting vs. blocking.**
3. **"Hardening".**
4. **Depth of setting.**
5. **Shading.**

IV. **FERTILIZER USE**

A. **Organic vs. chemical fertilizer; use of green manure crops.**

B. **Determining fertilizer needs: soil sampling for soil lab tests, diagnosing hunger signs, field trials, "guesstimates".**

C. **Kind and amount of fertilizer: chemical, compost, manure.**

D. **Timing of applications: pre-plant, at planting, sidedressing.**

E. **Placement**

   1. **Broadcast vs. localized placement (band, hole, half-circle).**
   2. **Distance from the seeds or plants.**
   3. **Special placement considerations for furrow irrigated soils, foliar applications.**

V. **LIMING**

A. **Deciding if liming is needed.**

B. **Kind, amount, application method and placement, timing.**

VI. **USING WATER EFFICIENTLY**

A. **Rainfed Crops**

   1. **Choice of variety (drought resistance, length of growing period).**
   2. **Plant population (especially important with cereal grains in marginal rainfall areas).**
   3. **Timing of planting.**
   4. **Mulching.**
   5. **Weed control.**
6. Fertilizer use.

7. Soil conservation to lower runoff losses.

B. Irrigated Crops

1. Irrigation method: hand watering, surface (furrow or flooding), sprinkler, etc.

2. Timing, amount, and frequency.

VII. WEED CONTROL

A. Method: Burning, mulching, hand implements, mechanical, herbicides.

B. Thoroughness.

C. Timeliness.

D. Avoiding crop injury: root pruning, herbicide toxicity, herbicide residues.

VIII. PEST AND DISEASE CONTROL

A. Birds (seed eating, seedling injury, grain eating): seed treatment, scaring (people, string-flagging, etc.).

B. Rodents (field): traps, baits, seed treatment.

C. Insects, slugs, snails

1. Non-chemical controls
   
   a. Crop rotation.

   b. Resistant varieties.

   c. Intercropping.

   d. Biological controls: bacillus thuringiensis, predator insects, etc.

   e. "Organic" controls: collars, "organic" sprays, stale beer for slugs, etc.

   f. Trap (barrier) crops.

2. Chemical controls

   a. Deciding when to use insecticides.

   b. Choice of insecticide: toxicity to humans and the environment, systemic vs. non-systemic.
c. **Type of formulation:** spray, dust, granules, baits.

d. **Application dosage, frequency, and timing.**

e. **Coverage required,** use of sticker-spreader.

D. **Diseases**

1. Non-chemical controls: resistant varieties, crop rotation, sanitation, roguing, improving drainage, intercropping, weed control, control of insect vectors, use of disease-free seed, timing and frequency of watering, sterilizing nursery seedbed soil with heat or boiling water.

2. Chemical controls: seed treatment with a fungicide, fungicide drench, chemical nursery seedbed sterilization, foliar fungicides, systemic vs. non-systemic fungicides.

E. **Nematodes**

1. Non-chemical controls: Resistant varieties, crop rotation, flooding, sugar, plowing up crop roots, antagonistic plants.

2. Chemical controls: Nematocides.

IX. **OTHER PRE-HARVEST GROWING PRACTICES, etc.**

A. Thinning of direct seeded veggies.

B. Pruning, staking, trellising.

C. Hilling-up of certain field crops like maize, beans, etc.

D. Equipment management; maintenance, adjustment.

X. **HARVESTING**

A. **Determining maturity:** especially important with veggies and peanuts.

B. **Interval between maturity and actual harvest:** farmers may allow field crops to dry down in the field before harvest, but losses to weevils, birds, rodents, and rots may be serious in some cases.

C. **Harvest method.**

XI. **DRYING AND STORAGE**

A. **Drying** (cereal and pulse crops): in the field vs. patio vs. crib vs. artificial methods.

B. **Storage** (cereal and pulse crops).
1. Form: threshed vs. unthreshed (or ear vs. shelled maize).

2. **Type of container:** sacks, gourds, clay pots, baskets, silos & bins, cribs, airtight containers.

3. **Moisture requirements** for safe storage and their measurement.

4. **Controlling storage insects**
   a. **Pre-storage mgt:** drying and cleaning of grain, cleaning & repair of facility, spraying or dusting of facility, disinfection of sacks.
   b. **In-storage mgt:** sunning, smoking, mixing materials with the grain (veg. oil, ashes, etc.), airtight storage; use of insecticide sprays, dusts, fumigants.

5. **Controlling rodent losses:** rodent proofing, baits, traps.

**XII. MARKETING**

1. Market analysis and price monitoring.

2. Crop quality control.

3. Cooperative marketing.

A GUIDE TO TROUBLESHOOTING COMMON CROP PROBLEMS

It takes a lot of practice and detective work to accurately troubleshoot crop problems. Some abnormalities like wilting or leaf yellowing can have numerous causes.

How to Troubleshoot: First, learn to distinguish normal from abnormal growth when you walk through a farmer's field. Keep a close watch for telltale trouble signs such as abnormal color, stunting, wilting, leafspots, and signs of insect feeding. Make a thorough examination of affected plants, including the root system and the inside of the stem, unless the problem is obvious. Obtain detailed information from the farmer concerning all management practices that might have a bearing on the problem (i.e., fertilizer and pesticide applications, name of crop variety, etc.). Note whether the problem occurs uniformly over the field or in patches; this can provide valuable clues; since some problems like nematodes and poor drainage seldom affect the entire field.

Troubleshooting tools, etc.

1. A pocketknife for digging up seeds or slicing plant stems to check for root and stem rots or insect borers.
2. A shovel or trowel for examining plant roots or checking for soil insects or adequate moisture.
3. A pocket magnifying glass to facilitate identification of insects and diseases.
4. A reliable soil pH test kit for checking both topsoil and subsoil pH; especially useful in areas of high soil acidity. Beware of cheap kits, especially those using litmus paper. The Hallige Truog kit is one of the best and costs about $15 (U.S.).
5. Disease, insect, and hunger signs guides: Refer to the Bibliography at the end of the Crops Guidelines.

Troubleshooting Guide  (cont'd)

CROP APPEARANCE

POOR NODULATION ON PEANUTS, COWPEAS, SOYBEANS, OTHER LEGUMES THAT ARE EFFICIENT FIXERS (Carefully dig up the root system and check for nodulation; clusters of fleshy nodules, especially on the taproot, and with reddish interiors are signs of good nodulation. Don't confuse nodules with nematode galls!)

PROBABLE CAUSES

Soil lacks the correct type of Rhizobia; seed inoculation is needed. Improper inoculation: wrong strain, inoculant too old or improperly stored.
Exposure of inoculated seed to excessive sunlight or contact with fertilizer or certain seed treatment fungicides.
Excessive acidity (soybeans are especially susceptible to Molybdenum deficiency).
Plants are too young (it takes 2-4 weeks after plant emergence for the nodules to become visible).

</table>

1. In-the-row spacings are final spacings after thinning. Between row spacings vary greatly depending on seedbed style, variety size, and need for foot or equipment passage.
2. T = commonly transplanted.
3. Soak these seeds overnight to improve germination speed and rate.
4. Time til harvest varies with variety and weather conditions.
5. Refers to "drill" planting. Space "hills" 75-90 cm apart in the row, plant 6 seeds/hill, and thin to 3 plants.
6. Bulb onions are usually grown from transplants or sets rather than direct seeding (except under very good management).
7. Staked tomato plants can be spaced much closer together than unstaked ones.
8. A vegetable's yield can vary greatly with growing conditions and management. A good yield in one area might be considered average or mediocre in another area.
9. Some direct planted veggies like chinese cabbage, okra, lettuce, swiss chard, and mustard can be cluster planted at 3 seeds/hole using the after-thinning spacing in Column 1.
HEAT TOLERANCE OF VEGETABLES

Heat tolerance varies greatly among vegetables and also among varieties of a vegetable. It's an important consideration in garden planning. It's impossible to give hard and fast maximum temperature tolerances, since high daytime temperatures can be somewhat offset by low night temperatures. Here's a rough table:

<table>
<thead>
<tr>
<th>Monthly Average of Daytime Highs</th>
<th>Vegetables Whose Yields Won't be Seriously Affected</th>
</tr>
</thead>
<tbody>
<tr>
<td>up to 95°F, 39°C</td>
<td>Eggplant, Hot Pepper, Okra, Watermelon, Sweetpotato, Corn, Cowpeas</td>
</tr>
<tr>
<td>up to 90°F, 36°C</td>
<td>Squash, Cucumber, Muskmelon, Pumpkin, Beans, Collards, Sweet Pepper, Lima Beans (vining types), N.Z. Spinach</td>
</tr>
<tr>
<td>up to 85°F, 33°C</td>
<td>Tomatoes, Radish, Bush Lima Beans, Cabbage (heat tolerant varieties), Chinese cabbage, Onion, Garlic, Leek</td>
</tr>
<tr>
<td>up to 80°F, 30°C</td>
<td>Mustard, Irish Potatoes, Carrots, Beets, Cabbage, Leaf Lettuce, Kale, Swiss chard</td>
</tr>
<tr>
<td>up to 75°F, 27°C</td>
<td>Broccoli, Spinach, Turnip, Brussels sprouts, Cauliflower, Celery</td>
</tr>
</tbody>
</table>

Practices like mulching and partial shading may help offset the effects of high heat.

COLD TOLERANCE OF VEGETABLES

Some vegetables (mainly the heat tolerant ones) are very susceptible to frost and also have their growth checked by cool temperatures. Young plants are more susceptible to frost than older ones; a few days of gradually cooling temperatures helps plants prepare for frost.

Very hardy (survive down to 20°F [-7.5°C]): Broccoli, Brussels sprouts, cabbage, chives, collards, garlic, kale, kohlrabi, leek, mustard, onion, parsley, peas, radish, rhubarb, rutabaga, spinach, turnip. (Based on young plants)

Half-hardy (young plants survive light frosts): Beet, carrot, cauliflower, celery, chard, Chinese cabbage, endive, lettuce, potato.
VEGETABLE FAMILIES

**Why It's Important**

1. Vegies of the same family share many of the same insects and diseases. You'll encourage a buildup by growing family relatives continually in the same section of the garden or field—especially for the Crucifer and Solanaceous families.

2. Family members also share many similar traits re characteristics and growing practices. The Crucifer family (cabbage, broccoli, etc.) prefer cool to semi-warm temperatures, and most are shallow rooted.

- 166 - 177
NUTRITIONAL VALUE OF VEGETABLES

Vegetables make several important contributions to tropical diets:

a) They enrich the diet with nutrients, particularly vitamins and minerals.

b) They render the staple food more palatable and hence improve the intake.

c) They improve digestion because of their high fiber content.

The addition of vitamins, minerals, and other nutrients to the diet is the most important factor. In fact, in many countries, vegetables (and fruits) may be the only significant sources of vitamins A, C, folacin (a B vitamin), and of the mineral iron.

Of the vitamins, carotene (vitamin A) and vitamin C are the most important. Carotene is deficient nearly everywhere in the tropics, with the exception of West Africa where red palm oil is used in food preparation. The low intake of fat hampers the absorption of carotene in the body. Vitamin C is less abundant in cereal than in tuber-consuming regions.

Veggies whose edible parts are deep green, deep yellow, or deep orange are good sources of vitamin A, but there's little correlation between color and vitamin C content. In leafy veggies, a deep green leaf color (and therefore high vitamin A) is highly correlated with leaf exposure to sunlight. That's why cabbage and head lettuce are much lower in vitamin A than their open leaved relatives collards and leaf lettuce.

One feature of vitamin A is that it is fat-soluble and can be stored for up to a year in the body's fat tissues. This is especially significant in light of the seasonality of vegetable availability in many countries. A person in good health can consume all of his/her yearly vitamin A requirement in one season, and draw on the stored reserves during seasons when vitamin A-carrying produce is in short supply.

In contrast, vitamin C is water-soluble (stored in body fluids); the latest research indicates that vitamin C intakes above 100 mg/day are probably excreted from the body. This suggests that regular, daily intakes of vitamin C are important in maintaining good nutrition. Vitamin C availability in vegetables is further complicated by the fact that it is found only in growing plants (not seeds or grains) and that it is destroyed by high temperatures and exposure to oxygen. Therefore, cooking vegetables in water for long periods of time effectively robs that food of its vitamin C.

In general, the protein content of vegetables is considered to be relatively unimportant. Some greens like spinach and cassava leaves contain

over 25 percent protein on a dry weight basis, but because they are usually consumed fresh (containing up to 90% water), the bulk of greens which would have to be consumed in order to meet one's daily protein requirement is a major limiting factor. However, it's likely that many of the local varieties of greens commonly eaten in the tropics are more important sources of protein in those areas than they are given credit for by nutritionists in the developed countries.

The fibre content of vegetables is less important in the tropics than it is in developed countries, due to the generally coarser nature of prepared food in the tropics. In this context, it should be noted that a high intake of fibre effectively prevents constipation and digestive problems.

The important minerals, calcium and iron, are often lacking in diets in the tropics. Calcium deficiency may occur more frequently if the basic food consists mainly of cereals. A high iron intake is important since anemia caused by malaria, bilharzia, and intestinal parasites occurs very frequently. Pulses such as cowpea are rich in calcium and iron.

The nutrient content of some vegetables compared with that of cereals, tubers, and pulses is presented in the following tables, "Nutrient Composition of Some Vegetables" and "Vitamin Value of Selected Vegetables."

1. Per 100 gram portion (3.5 oz.) of cooked vegetable unless normally eaten raw.
2. Daily vitamin A requirements are about 5000 I.U. for active men and 4000 for active women.
3. Daily vitamin C requirement is about 45 mg. for both.
4. Calorie requirement is about 2700/day for men and 2000 for women and up to 50% more if very active.
CALCULATING HOW MUCH SEED TO BUY

Most commercial seed is sold by weight, not by number of seeds. Imported commercial vegetable seed usually comes in 1 lb. cans and is then sold by the ounce or gram to small farmers. Buying seed by the packet is much more expensive, and it usually hasn’t been treated with a fungicide.

To find out how many ounces or grams of seed to buy, first calculate the approximate number of seeds needed given the seeding rate and row spacing to be used. Then convert seed number to weight needed by using the table below.

<table>
<thead>
<tr>
<th>Number of Seeds per Ounce and Per Gram</th>

A Sample Seed Calculation Problem

1. Determine the dimensions of the plot where the crop will be planted.

   For example, suppose you wanted to plan a 1 x 6 meter seedbed to Chinese cabbage.

2. Determine your between-row spacing (i.e., the row width).
   
   a. Use a planting chart such as the one on p. 41 of the "Crops Guidelines".
   
   b. Or use common sense or experience (see p. 58).

   How many rows will fit across your plot?

   For example, suppose you settle on a row spacing of 40 cm for the Chinese cabbage with the rows running the short way across the 1 x 6 m bed. You'd end up with about 15 rows:

   \[
   \frac{6 \text{ meters}}{0.4 \text{ meters}} = 15 \text{ rows}
   \]

   1 row every 40 cms. for 6 meters.

3. Determine your final in-row plant spacing (what it would be after thinning). Consider the following:

   a. The chart on p. 41.
   
   b. Vegetable type and variety (head lettuce needs more room than leaf lettuce; okra needs much more space than radishes).
   
   c. Growing conditions: Are conditions (climate, etc.) ideal for optimum growth and size?

   How many plants at final spacing will fit into one of your rows?

   For example, suppose you decide on a 30 cm final spacing for the Chinese cabbage. You would have 4 plants per 1 meter of row at the final spacing:

   \[
   = 172 \div 4 = 43.5
   \]
Determine the amount of overplanting needed to provide the final stand you're aiming for. Consider the following:

**Vegetable crops:** Usually overplanted 3-10 fold, depending on soil and moisture conditions, germination rate of the seed, and typical seedling survivability. Excess seedlings should be thinned gradually over the first 2-3 weeks of growth to achieve the final stand. Weaker seeds and seedlings like carrots, lettuce, beets, and onions need more overplanting than stronger ones like radish, spinach, and Chinese cabbage.

**Field crops:** Usually overplanted only 15-25% (1.15-1.25 fold) due to their hardiness and higher seedling survival rates compared with the veggies. Thinning is seldom practiced with field crops.

**A Note on Germination Rates:** Good quality seeds should have a germination rate of at least 70%. Seed whose germination is much below 60% is likely to produce weak seedlings and shouldn't be used if possible.

In our example, Chinese cabbage has a relatively good seedling survival rate and probably needs only a 3 or 4 fold overplanting rate.

Determine the amount of seed needed for your total planting area:

\[
\text{Number of rows} \times \text{Plants/row (at final spacing)} \times \text{Amount of overplanting needed (i.e., 3-fold, 8-fold, etc.)} = \text{NUMBER OF SEEDS NEEDED!}
\]

In our example, it would work out like this:

15 rows x 4 plants/row x 3-fold overplanting = 240 seeds

Determine the grams (or ounces) of seed needed, because seeds are usually sold by weight, not by number.

See conversion chart on p. 48 of the Crops Guidelines. In our example, 240 Chinese cabbage seeds weigh slightly less than 1 gram.

If purchasing seed, buy at least 25% more than you think you will need in case you need to do some replanting.
Determine the **actual seed spacing** in the row, given the amount of overplanting and whether you'll be "cluster" planting the seed or "drilling" them (dribbling them out).

In our example, suppose we will cluster plant the Chinese cabbage. Since we're overplanting 4 fold, we'd plant 4 seeds per group with the groups 30 cm apart (i.e. final spacing).

If we decided to "drill" plant the seeds instead, we'd plant one seed every 7.5 cm:

\[
\text{30 cm final spacing} = \frac{30}{4} \text{ cm between seeds}
\]

4 fold overplanting
SELECTING THE RIGHT TYPE AND VARIETY OF VEGETABLE

I. VEGETABLE TYPE

There are a number of factors that determine the types of vegetables (i.e., carrots vs. tomatoes, etc.) grown by farmers or school garden projects. Let's look at the main ones:

1. Climate

Temperature: Look over the chart on page 42 and you'll see that not all vegies tolerate hot weather well, while others actually prefer it. Heat tolerant vegies like eggplant, cucumber, and okra will do quite well in mild weather too (as long as night temperatures are above the low 40's), but "cool season" ones like head lettuce, peas, and cauliflower won't produce reasonable yields in hot weather.

If close to the Equator, your area's elevation will largely determine the feasibility of growing cool season vegies. Generally, the choice of vegetable types increases with elevation. If you're more than 15° from the Equator, there's likely to be significant seasonal temperature variations which will affect crop choice.

Mulching and partial shading may help minimize heat stress on cool season vegies or those in the "touchy" category.

Rainfall and Humidity: Diseases are generally most prevalent under high rainfall and humidity, but some crops may suffer less than others. Tomatoes, eggplant, peppers, cucumbers, and melons are among the more sensitive.

2. Marketing Factors

Market price as determined by supply and demand influences crop choice but in a rather haphazard manner. Farmers often tend to get locked into a monoculture pattern which limits their flexibility even though feasible crop alternatives exist.

Many vegies are highly perishable which limits their transportability to more distant markets unless refrigeration is available. Others like cabbage, carrots, beets, sweet potatoes, and other root crops store and ship well.

Consumer preference is a critical consideration and must be determined before embarking on a vegetable that's new to an area.

3. Soil Conditions

Most vegies grow well on a wide variety of soils as long as drainage and depth are adequate. Root crops usually prefer sandy or loamy type soils since high clay content may hinder root or tuber growth as well as harvest operations.
4. **Management and Capital Requirements, Labor**

Crops like radish, beans, mustard, beets, and squash require less management ability and capital input (especially for fungicides and insecticides) than tomatoes, broccoli, peppers, eggplant, potatoes, and cauliflower.

5. **Nutritional Value and Consumer Acceptance**

Commercial farmers rarely consider this a factor, but it's important for home and school garden projects. Look at the table on page 47, and you'll see that veggies vary markedly in their vitamin content. Eggplant, cucumber, onion bulbs, and beet roots are notably low in food value, while carrots, collards, mustard, and broccoli are excellent. Note that vitamin content (especially vitamin A) is closely correlated with leaf exposure to sunlight in the case of leafy veggies. That's why open leaf collards have about 60 times more vitamin A than their tight headed relative, cabbage. Of course, taste acceptance by the family or school kids is essential. Turnip and radish greens (high in vitamins) are much more palatable if disguised in a stew or mixed with other veggies.

II. **THE RIGHT VARIETY**

Successful vegetable production starts with the selection of a suitable adapted variety. The yield difference between an adapted variety and one that isn't can easily make the difference between profit and loss. One common mistake PC has made in some countries is to recommend that PCV's bring seeds with them from the states without stating which varieties of a vegetable they should buy.  

Vegetable varieties vary considerably in the following characteristics:

1. **Time to Maturity:** Varieties are classed as early, medium, and late. Although early varieties reach harvest sooner, yields tend to be lower than with longer duration varieties. However, they may be advantageous in terms of hitting the early market, avoiding disease buildup, and enabling more crops to be grown in the same field.

2. **Resistance to disease, nematodes, and physiologic disorders:** Resistance to these problems varies a lot with the variety and is a very important consideration in selection. For example, the tomato hybrid Better Boy VFN is resistant to Fusarium and Verticillium wilts as well as nematodes. The Walter tomato variety is resistant to Fusarium wilt, gray leaf spot, and radial fruit cracking (a physiologic disorder).

---

1. The Ministry of Agriculture in your host country should be able to provide a list of recommended vegetable varieties for different regions of the country.
3. Color, shape, size, quality, storability, etc.: Variations are numerous. Market considerations have a lot to do with the choice.

4. Heat or cold tolerance: In most PC countries, heat tolerance is an important factor, and there is some variation among varieties, especially among the less heat tolerant veggies. The K-K and K-Y Cross cabbage hybrids have been specially developed for the tropics.

5. Growth habit and duration of harvest: Det. vs. indet. tomato varieties, bush vs. vining beans, etc.

**Hybrid vs. Open-pollinated Varieties**

In horticulture, the word "variety" (or "cultivar") refers to an agriculturally derived plant (i.e. evolved by farmers or plant breeders). Varieties may be either open-pollinated or hybrids.

An open-pollinated variety is produced through natural pollination which may be cross-pollination (i.e. corn, cabbage family, beets) or self-pollination (tomato, beans, lettuce).

A hybrid variety is produced through man-aided cross-pollination between two more distinct varieties. This requires much more care and effort than that involved in producing open-pollinated varieties, so seed is usually quite a bit more costly. However, hybrids generally have improved vigor and disease resistance, and are often more uniform in size. Just as much care is needed when selecting among hybrids for an adapted variety as with open-pollinated varieties. Unlike open-pollinated varieties, the seed harvested from planting a hybrid can't be replanted since it will degenerate back into the original (and usually weaker) varieties from which it was developed.
STORING SEED AND TESTING GERMINATION

I. SEED STORAGE

Seed viability deteriorates rapidly under high humidity and temperatures and becomes a serious problem in the tropics. High temperatures speed up the seed's life processes which causes further heat and encourages molds and fungus; high humidity accelerates mold and fungus growth.

Under cool, dry conditions, fresh corn, onion, and okra seed store well for up to 2 years, while most other seeds are good for up to 5 years. High temperatures and humidity can ruin seed in a matter of days or weeks.

Moisture guidelines: Beans and cereal crops (corn, rice, etc.) should contain no more than 13% moisture to ensure safe storage; most vegetable seeds should not exceed 9%, though they're also harmed by excessive drying (like below 4-5%). Vegetable seed moisture content is difficult to measure without a special meter, but these figures emphasize the importance of dryness.

Temperatures: Best place to store seed is in a refrigerator just slightly above freezing.

Most of the commercial imported vegetable seed you'll see overseas comes in one pound sealed cans which have far better storage life (until opened) than packet seed. All reputable seed is dated so check the label. By the way, it's much cheaper to buy seed in bulk (by the ounce, etc.) than in packs compared to the cost of an equal amount of seed in packages. Also, most "canned" seed has been treated with a fungicide—not so with packet seed.

Storage Tips:

1. Store seed in airtight containers (jars, etc., partially filled with a desiccant like calcium chloride, quicklime (burned lime, calcium oxide), or silica gel. Be sure to separate the seed (placed in envelopes) from the desiccant with a layer of cardboard or cotton, etc. Oven dry rice kernels are an excellent desiccant.

2. Never allow seed to become damp; even if redried, its germination will be reduced.

II. HOW TO TEST GERMINATION

In the tropics, it's always a good idea to run a germination test on seed before it's planted. Here's a simple but reliable way to do it.

1. Some seed companies use a foil lined pack which should keep out damaging humidity until opened.
Count out 100 seeds and place them about 1/2" apart on a square of moist newspaper several layers thick. Carefully roll up the newspaper several layers thick. Carefully roll up the newspaper so that the seeds remain separated from each other and remain pressed to the newspaper. Place in a plastic bag or periodically remoisten the newspaper so it won't dry out. Sprouting time varies a little with temperature and seed type, but begin checking after 4 days. Pepper, parsley, parsnip, okra, eggplant, and asparagus may take 7-10 days. Good seed should have a germination rate of at least 80%.

Up to a point you can compensate for low germination by planting more seed, but seed with a germination much lower than 50% or so usually produces less vigorous seedlings.

CHOOSING A VEGETABLE GARDEN LOCATION

Here are some important factors to consider:

1. Soil factors: Good drainage is a must and can be enhanced by using some form of raised seedbed. Very clayey or sandy soils can be improved by large additions of organic matter (compost, manure for both; rice hulls help loosen up clay). Try to avoid very rocky or shallow (less than 18") soil. If the slope is much more than 3-4% (3-4 ft. drop per 100 ft.), some erosion control measures will be needed like contour planting or mulching.

2. Shade: Less of a problem in the tropics due to the higher sun angle, but beware of nearby tall trees. Most veggies prefer at least 7-8 hours of sun a day. However, partial shading may be beneficial when trying to grow heat sensitive veggies like lettuce in hot weather. Watch out also from competition from tree roots.

3. Availability of water: Even very rainy climates have dry spells, but provision for irrigation water is vital in areas with a distinct dry season.

4. Protection from animals: Many garden projects have been temporarily devastated by animals, especially cattle, pigs, and goats. Some type of protective fencing is necessary.

5. Wind Protection: Exposed plants can be seriously damaged by whipping or stem breakage due to heavy winds. In hot, semi-arid areas such as along the Senegal River in Mauritania, hot, drying winds can literally dry up plants. Some windbreak protection is usually needed for most gardens (i.e. buildings, a hill, planted windbreaks, trees).

6. Protection from pilferage: The best security is locating the site near a house.
USING THE RIGHT TYPE OF SEEDBED

The right type of seedbed varies more with climate and soil than with the crop. The common ones are:

RAISED BEDS OR RIDGES: Under conditions of high rainfall and/or poor drainage, crops are usually planted on raised up beds or ridges to keep them from getting 'wet feet'; they're also essential when furrow irrigation is used. (In some areas, at the start of the wet season when rains are lighter, field crops like maize, sorghum, and beans are planted on flat beds and then gradually hilled up as the season progresses; this only works with plants that have enough stem height and leaf clearance to tolerate this partial burial).

Raised beds are especially well suited for intensive vegetable growing for reasons beyond drainage:

1. They keep the soil looser since there's no need to walk on them. The bed's width should allow all the plants to be reached by hand from the alleyways (about 1-1.5 meters is best).
2. There's less bending over involved.
3. You end up with a double thick layer of topsoil.
4. They reduce the incidence of soil-borne diseases caused by poor drainage.
5. The raised bed makes it possible to use very narrow rows or even equidistant plant spacing, since you don't need to walk among the plants.

Raised beds can also be used under low rainfall or for sandy soils, but their height should be reduced (maybe 8-10 cm high vs. 15-20 cm high). Mulching would help cut down the extra moisture losses raised beds are subject to under dry conditions. Making a "lip" around the edge of the bed will also help.

Wet season style raised bed

Raised bed with a "lip" to help retain water under drier conditions

FLAT SEEDBEDS: Used where moisture is adequate for crop growth and there are no drainage problems.

SUNKEN SEEDBEDS: Under low rainfall or very sandy soil conditions, veggies may be planted in slightly sunken beds or in slightly sunken furrows to improve moisture availability. In arid conditions, shallow rooted crops like onions that have frequent watering needs can be grown in sunken beds a few centimeters below normal soil level.
FLANT SPACING GUIDELINES

Several factors influence row spacing:

1. **Plant "spread"**: It's obvious that radishes, carrots, and beets can be grown in narrower rows than tomatoes, cucumbers, or squash. Trellising and staking both enable row widths to be reduced through the "skyscraper" principle.

2. **Type of equipment used and need for foot traffic**: The use of tractor or animal-drawn equipment requires wider row widths than when only hoes and hand-operated sprayers are used. Using raised beds allows for the closest row spacing possible or even equidistant spacing. Some of the popular bio-dynamic gardening books promote these close spacings in which the plants form a "living mulch". Yields are often considerably higher in mild climates, low humidity areas where these methods first were used (Europe, California, New England). However, under hot, humid conditions, super close plant spacings may accentuate fungal and bacterial leafspots.

There are numerous ways of arranging rows. They can be spaced uniformly with alleyways on each side for machinery or foot traffic. Groups of close spaced rows can be alternated with alleyways without using raised beds.

What about in-the-row spacings?

This depends mainly on plant "spread" (width), although some crops like beans respond positively to super close in-the-row spacings far above what their size might seem to suggest. However, cramming plants too tightly causes legginess (spindly plants), excessive plant competition (especially for sunlight), and lower yields. Leafy veggies (those whose leaf parts are the real product) like cabbage, lettuce, and Chinese cabbage will produce overly small heads if too crowded. Beets, carrots, turnips, and radishes can be spaced much more closely in the row than peppers, tomatoes, eggplant, cabbage, and broccoli. It's mainly common sense.

What about Broadcast, Band, and Equidistant Planting?

Some "small spread" veggies like carrots, radishes, and leaf lettuce can be broadcast planted (scatter planted) insinuating a definite row arrangement. Carrots and radishes can also be planted in bands 8-12 cm wide and then thinned to stand 3-4 abreast. The edge of single row planting is ease of weeding. Broadcast planting must be confined to beds 1-1.5 meters wide with alleyway left between the beds so that weeding is possible without stepping on the beds.

**Equidistant planting**: Again, this is part of the bio-dynamic approach and uses a hexagonal plant spacing pattern to achieve maximum plant populations with minimum competition for sunlight.

Example of equidistant spacing
Leaf lettuce might be planted on 20 cm equi-spacings. Naturally, a bed arrangement is also necessary for this method. Such a pattern also utilizes the shade effect of the vegies to help keep down weeds and form a "living mulch." However, under high humidity, such close spacing may accentuate fungal and bacterial leaf spot problems.

INTERCROPPING

Intercropping consists of growing two or more different crops together at once, either side by side or in adjacent rows. It's also called "interplanting" or "companion planting." Experience and research have shown that certain crop combinations are especially well suited to this practice which has several benefits:

1. **Better use of space:** Growing a quick maturing crop like radishes, leaf lettuce, and spinach in between rows of a slower crop like tomatoes, peppers, and eggplant takes good advantage of the vacant space surrounding these latter crops early in the growing period. Radishes and carrots are another compatible combination.

2. **Shade provision:** Cucumber, squash, and pumpkin tolerate or even appreciate some shade and grow well when interplanted among sweet maize or field maize. The maize may also benefit from the soil mulching provided by the other crop's leaves. Likewise, the adverse effect of hot weather on cool season crops like lettuce and spinach may be partially offset by interplanting them among taller crops like tomato, eggplant, and pepper.

3. **Insect control:** The use of aromatic herbs like mint and thyme or other pungent plants like onions and garlic as companion crops to other veggies may reduce insect damage somewhat, but this effect is generally much overrated. However, stands of a single crop by itself tend to be more vulnerable to insect attack than interplantings, whether or not herbs or onions are used.

4. **Miscellaneous:** Pole (vining) beans are often interplanted with maize whose stalks serve as supports. Beans are a nitrogen fixing legume, although only of moderate effectiveness; nevertheless, a small but significant amount of N is passed on to the maize. See pp. 95-98 of the PC/ICE Traditional Field Crops Manual for more details.

SUCCESSION PLANTING: SYSTEMATIZING PRODUCTION

Succession planting is a very useful planting strategy which will greatly benefit any garden project. Its goal is to coordinate the planting-harvest cycles of the garden's crops into an efficient system so that land is kept in continual production and the flow of produce made more uniform throughout the growing season. Succession planting requires careful planning and timing; here are some helpful guidelines.
Timing Transplant Production

If tomatoes are to follow a crop of beets, the preparation and planting of the tomato nursery seedbed should be timed so that the transplant will be ready for field setting as soon as the beets are harvested.

Staggering Plantings of a Crop

A common problem for most garden projects is that each crop's production flow tends to be very uneven. This "feast or famine" syndrome can be largely overcome by making a series of staggered plantings of the crop at weekly to monthly intervals rather than one planting alone. Another means is to plant early, medium, and late maturing varieties of a crop simultaneously to extend the harvest period.

Aside from evening out the flow of produce for home consumption, staggered plantings have several important advantages for market gardens:

a. Buyers are usually partial to producers who can provide a reliable supply of produce over a long period.

b. By spreading out the marketing period for a veggie, growers can usually take advantage of favorable market price fluctuations, rather than gambling on a good price for a single marketing. Also, there is less likelihood of glutting the market and causing drastic price declines.

In selecting an appropriate time interval between staggered plantings, it's important to consider the harvest duration of each planting. Some suggestions:

a. A planting of sweet corn will remain at a harvestable stage for only 7-10 days; thus, succession plantings would be needed at 7-10 days intervals for an even flow of produce. Another approach would be to plant an early (about 65 days to maturity), medium (80 days), and late (90 days) variety at the same time which would provide a harvesting period of about a month.

b. The harvest duration of tomatoes varies greatly with the type. The short, bushy, determinate varieties have a harvest duration of only 2-3 weeks, while the tall growing, indeterminate varieties can continue producing for several months if the plants aren't killed off by fungal leaf spot diseases.

c. Some veggies such as Swiss chard, spinach, leaf lettuce, mustard, and collards can be harvested either all at once (i.e. pulling out or cutting off the entire plant) or they can be picked a few leaves at a time over a number of weeks (new leaves continue to be produced from the base).
WATERING VEGETABLES
WHEN? HOW OFTEN? HOW MUCH?

There are no quick and easy methods for determining how much water plants need and how often it should be applied. The so-called "shiny" or "shiny layer" method popularized in some garden books just isn't reliable enough. (With this method, the soil supposedly has received enough water when a shiny layer of water remains on the soil surface for a certain number of seconds when watering is stopped). However, if you're willing to learn some fairly straightforward concepts and figures, you'll be able to greatly improve on "eyeball" methods. Here goes:

1. The frequency and amount of watering plants need depend on: soil texture, root depth, crop stage, crop type, temperature, humidity, and wind. As temperature and/or wind increase and humidity decreases, water needs go up. We'll cover the other factors farther on.

2. Sandy soils need more-frequent (about twice as often) but lighter waterings than clayey soils since they can store only about half as much water per unit of depth.

3. The shallower the root system of the soil, the more often watering is needed. Tiny seedlings with roots only a few centimeters deep may need water 1-2 times a day on a very sandy soil and once every 1-2 days on a clay or clay loam soil (depending on temperature, humidity, and wind). As roots grow deeper, watering intervals can be spread out. However, well-established lettuce, onions, cabbage, and other naturally shallow rooted crops will need more frequent (but lighter) waterings than tomatoes, eggplant, field corn, and other deeper rooted crops.

4. Crops themselves vary in the weekly and total amounts of water needed to grow them, but there's much variation among field crops than among vegies. Millet is the most drought resistant, followed by sorghum, and then peanuts and cowpeas.

5. Plant demand for water increases with growth and reaches a peak around flowering or fruiting time which continues until harvest is over for vegies. Field crops which are harvested in a much more mature state (hard, dry seeds) taper off from this peak as maturity sets in.

Some useful figures: In warm weather, most very young plants will use about 19-25 mm (1.9-2.5cm or 0.75-1.0") of water per week. This is equivalent filling up a flat tub that is as big as the planted area to a depth of 19-25mm. This includes soil evaporation and plant usage.

1" of water = 7 gallons (25 liters) per sq. meter

Peak usage rates for established crops run around 45-75mm (4.5-7.0 cm or 1.75-2.75") a week, depending on temperature, wind, relative humidity, and crop type (not a real important factor with vegies).
This equals 12-19 gallons (45-70 liters) per sq. meter (11 sq. ft.) per week.

6. Surprised at the high amount of water established plants need? That's the reason why most people overwater young plants (in terms of frequency and amount) and underwater older plants by putting on too little too often. Shallow watering produces a shallow-root system, since roots won't penetrate into dry soil. It's a self-perpetuating cycle since the plants begin showing moisture stress signs far too soon after each watering, which sets them up for more of the same treatment.

On the other hand, putting too much water on can cause drainage problems and leaching losses of nutrients like nitrogen and also accentuate soil-borne fungal and bacterial diseases. Watering too often (regardless of quantity) promotes "damping off" in seedlings and fungal and bacterial leafspots in older plants plus soil-borne fungal, bacterial wilts.

NOTE: 1 mm = 1 liter per sq. meter

Pre-irrigation: Farmers in low rainfall, irrigated areas should usually pre-irrigate the soil to full eventual rooting depth before planting to avoid getting behind later on in the season when demand really increases. It's a good idea, since the water will not be lost except for a small amount that evaporates from near the soil surface. The only water that drains downward is excess water that the soil's small pore spaces can't hold. Check the PC/ICE Soils, Crops and Fertilizer manual (pp. 15-16) for a full explanation.

How Can I Tell When Plants Need Watering?

Wilting, leaf curling (or rolling), and, in some cases, color changes (maize turns bluish green, bean leaves turn dark green) are the initial signs of moisture stress (lack of water). Yellowing and eventual browning ("firing") of the leaves, starting at the tips, are very advanced symptoms that occur after days of continuous moisture stress. However, most of these symptoms can also be caused by anything else that interferes with water uptake or water transport such as nematodes, soil insects, fungal and bacterial wilts, stem borers, and even very high temperatures. N deficiency can cause yellowing too.

Although young plants can usually tolerate the initial symptoms (wilting, curling, color change) without any significant yield drop, older plants (especially those that are flowering and fruiting) should not be allowed to reach this stage or yields may be seriously affected. For example, if corn wilts for 2-4 days during pollination, yields are usually cut by 50%.

Now for some more guidelines:

Very young plants: when roots are very shallow, you can use a simple "scratch" test. Take your finger and scratch down a few centimeters. If the soil is dry more than 2-3 cm down, it may be time to water if
seedlings are small and still shallow rooted. Look at the seedlings too for signs. Remember, young seedlings need frequent but light waterings; frequency will depend on weather and soil texture as well as root depth.

Older plants: Check over the water quantity guidelines on the previous page. As plants get older, you want to make less frequent but larger applications. The amount per application will range from about 25-65 mm (1-2.5" or about 25-65 liters per sq. meter) and will depend on weather, soil texture, and root depth. The frequency will be inversely proportional to the amount applied and will vary from about one up to as much as 3 times a week. For example, in warm weather, cabbage might need two 30 mm waterings per week since it's shallow rooted, while deeper rooted tomatoes might require a 60 mm watering (60 liters/sq. meter) once very 4-6 days. Remember that hardpans and excessive sub-soil compaction can restrict root growth.

Other Guidelines for Older Plants: Another guide is to apply water before one half of the root zone's available water has been used up. Sounds complicated, but hold on. Plants take up about 40% of their water needs from the top quarter of the root zone; once this top quarter gets down to 0% available water, it will soon be time to apply more. You can get a very good estimate of the percentage of available water remaining by using the "squeeze test" on p. 153 of the "Soils, Crops, and Fertilizer Use manual" (don't confuse this with the "feel" test for texture.

Measuring the Depth that Water has Penetrated: Use a 10-15mm (about 0.5") diameter iron rod about 1-1.5 mm long that is slightly tapered at one end. Wait about 1/2-1 day after watering and then push it into the ground. It should penetrate fairly easily until it strikes dried out soil (hardpans may affect the accuracy of this method).

What about Rainfall?: Buy a rain gauge or make one out of a tin can for checking rainfall, since its frequency and amount will affect the need for supplemental watering. Amounts much below 6 mm (1/4") aren't much use to plants, since much of this is lost by evaporation from the upper soil surface. Don't try to "eyeball" rainfall - it's very deceiving. Remember also that heavy downpours result in a lot of useless water runoff.

What about the Best Time of Day to Water?: This is important for minimizing "damping off" problems with seedlings and fungal and bacterial leafspots with older plants. Water in the morning whenever possible to give the foliage and the soil surface opportunity to dry out as the day wears on. Watering late in the afternoon is not a good practice. You can water in the heat of the day without fear of "burning".

Other Application Tips: Water gently to avoid splashing and erosion, especially when plants are young and the soil exposed. When possible, avoid watering the leaves themselves to help cut down on foliar diseases.
SOMETHING TO TRY: The Evaporation Pan Method

Water needs of plants can be closely correlated with the amount of water evaporation from a pan or can exposed to the elements. Rather cumbersome set-ups are used at research stations, but there are some good homemade substitutes. One of them uses 5 quart (4.7 liter) oil cans 9.5" (24 cm) high. Paint the can with metallic zinc paint for uniformity and to prevent rust. Set the can with 1/4 of its height in the ground, and fill it with 7" (17.5 cm) of water as soon as you finish watering your plants. It will be time to water again once the water level in the can has fallen an amount equal to that applied at each irrigation. Fill the can up to the starting level each time you water the plants or following a rainfall that's equal to or greater than one of your waterings, but make some allowance for runoff if you get a real downpour. Smaller rains will contribute water to the pan as well as the soil, maintaining both in balance. Note that the can also serves as a rain-gauge.

Location criteria for the can: Level ground, preferably surrounded by grass, away from trees, buildings, and bushes. Keep the weeds or grass right around the can below its height. No shadows should hit the can except for brief periods near sunrise and sunset.
I. WHY TRANSPLANT ANYWAY?

TOMATOES, CABBAGE, BROCCOLI, HEAD LETTUCE, EGGPLANT, PEPPER, and ONIONS are usually sown in seedboxes or nursery seedbeds and then transplanted to the field a few weeks later. Transplanting takes extra labor and lengthens the growing period by a week or two, but it's well worth it. Here's why:

1. A seedbox or nursery seedbed provides more controlled and protected conditions for young seedlings compared to direct field planting. Also, small seeds like tomato, lettuce, and cabbage usually have a poorer germination rate when field planted due to cloddiness, insect, and variations in soil moisture.

2. It's much easier to care for the young plants in a concentrated area.

3. More efficient use of garden space
   a. During the 3-6 weeks it takes to grow transplants, the garden can be used for short term veggies like radishes.
   b. Transplants can be started while another crop is still finishing up in the garden.

4. Better final plant spacing in the field. Direct planting often makes for lots of gaps where seedlings died or seeds didn't germinate; healthy transplants have a high survival rate.

5. In cooler climates, transplanting makes for a crucial jump on the market since plants can be started indoors or in a cold frame long before frost is over.

6. Plants can be started in dry season.

Some say that transplanting stimulates a stronger root system due to branching at the ruptured root ends, but tests don't prove it.

Why Not Transplant All Veggies?

1. Not all will tolerate it. Broccoli, brussels sprouts, cabbage, cauliflower, lettuce, and tomato easily survive transplanting; celery, eggplant, onion, and pepper take more care; beans, corn, cucumber, peas, turnips, and melons are usually severely set back by transplanting.

2. It's not worth the effort to transplant a crop that has very close field spacing like radishes, beets, carrots, etc. A wide spaced veggie like tomato has a high field area-to-seedbox area ratio—1 sq. ft. of seedbox provides enough transplants for 40-200 sq. ft. of field.
II. HOW TO GROW SUPER TRANSPLANTS

Growing healthy, vigorous transplants is the old science-and-an-art trip. Without good management, you'll end up with entries for an ag gong show.

THREE WAYS TO START 'EM: Nursery Seedbed, Seedbox, Individual Containers

1. In-the-Ground Nursery Seedbed Method: The plants are grown outdoors on raised seedbeds made from ordinary soil or preferably a specially prepared soil mix (see p. 67). Seeds are planted in rows 2-3" apart and then transplanted to the field 3-6 weeks later. In the rainy season, a removable thatch roof of permanent clear plastic roof should be built over the seedbed to prevent damage from heavy rain. Partial shade may be necessary if heat and sunlight are intense.

2. Seedbox Method: A good seedbox can be made from 1/2" wood and should be 3-4" deep and an easy to handle size (no bigger than 16 x 24" or so) with drainage holes in the bottom. A soil-compost, rice hull-soil, or other loose and well-drained mix is used. The seedbox is kept in full or partial sunlight either outdoors with a removable or clear plastic roof or else in a greenhouse; it should be raised up on blocks or stilts to cut animal and ant damage. Seedboxes offer more controlled, protected conditions than nursery seedbeds and are recommended when only a few hundred transplants are needed. About 400 transplants can be grown per sq. meter of seedbox space.

The plants can remain in the seedbox until full transplant size if properly spaced and progressively thinned to give at least a 2" x 2" final spacing. Some growers prefer starting out seeds in shallow flats a couple of inches deep and then transplanting to a deeper seedbox or nursery seedbed when the seedlings have formed their first pair of true leaves (as opposed to the initial pair of "seed" leaves). The only real advantage of this double transplant method is that most of the seedlings can be used instead of throwing the thinnings away. There's no evidence that transplanting stimulates a better root system.

3. Individual Container Method: Seedlings are raised in individual peat, plastic, or paper (homemade) pots. A special potting mix like vermiculite or peat-lite can be used or you can easily make your own (see p. 67). Two or three seeds are planted per pot and thinned to one plant at the first true leaf stage. Big advantage of containers is that root injury is minimized during transplanting.

Whatever method you choose, remember that care and management are more important than the actual method.
SOIL MIXES FOR TRANSPLANTING

Straight soil seldom makes a good planting medium compared to a mix. It's either too clayey (makes it tight and poorly drained) or too sandy (low water holding ability). When confined in a shallow pot or seedbox, most natural soil tends to become very poorly drained near the bottom no matter how many drainage holes you make—there's no soil below to provide a suction force to draw the water away, and gravity by itself isn't strong enough. That's the main reason you should use an extra coarse soil mix which will facilitate drainage yet still hold an adequate amount of moisture. Soil mixes also are usually lighter than regular soil, making it easier to move seedboxes around.

Here are a few recipes for soil mixes (variations are endless):

1. 1:1:1 sand-soil-compost. Modify the ratio to suit the soil you're using. Well rotted manure can be used.

2. A 2:1 or 1:1 rice hulls-soil mix.

3. A 1:3 sand-compost mix. Rotted coconut husk fibers run through a 1/4" mesh screen make great compost.

FERTILIZING

Don't rely on compost alone to supply the needed nutrients; it's a low analysis, slow release source. Compost that's only partly rotted is not adequate.

Too much or unbalanced fertilizing produces overly succulent and leggy plants (makes 'em especially prone to damping-off disease. Use an NPK fertilizer with a high P ratio (like 12-24-12 or 10-30-10). Aim for an application equal to 80-100 lbs. (kgs) N, 150-250 lbs. (kgs.) P2O5, and 100-200 lbs. (kgs.) K2O per acre (hectare). That's equal to 80 grams per sq. meter of 12-24-12 or 10-30-10 or about 5 level tablespoons (about 1/2 tablespoon per sq. foot).

How to Apply Fertilizer: Mix it in thoroughly with the seedbox soil mix or broadcast and work it into the top 4" of the nursery seedbed.

Nitrogen Deficiency: May show up after a few weeks due to the extra high leaching losses occurring in shallow containers. Leaves start turning a pale yellow. Water the seedlings with 1 tablespoon ammonium sulfate (or 1-1/2 teaspoons urea) dissolved in 1 gal. of water. Once should do it. Wash off leaves with plain water afterwards.

SOIL STERILIZATION BEFORE PLANTING

This control soil-borne fungus and bacterial diseases as well as nematodes. It's a must, especially in the hot, moist tropics. Here are several methods:
1. NON CHEMICAL:

Boiling Water: Convenient for small areas, like nursery seedboxes. Really sock it on.

Baking the Soil: Wet soil heats up better, and the resulting steam helps. An oven can be used for small amounts. For larger quantities, use half of a 55 gal. drum split lengthwise supported over a fire or use galvanized roofing the same way. 1/2 hour at 185°F does the trick; don't overcook the soil as it may release toxic amounts of certain elements. One way of checking is to bury a potato or sweetpotato midway down in the soil; when it's cooked, the soil is ready (and you get a snack too).

Steaming: Very effective.

Burning Debris on the Surface: Burning rice straw or other residues on the soil surface is not an effective method.

2. CHEMICAL: Fumigants like methyl bromide, Basamid, and Vapam are broad-spectrum sterilants. Formaldehyde controls fungus and bacteria but not nematodes. See pp. 150-152 for details.

Whatever method you use, be sure to sterilize the entire soil mix (compost and manure included). Seedboxes should be sterilized with boiling water. Avoid recontaminating the soil with unsterilized implements, etc.

CONTROLLING DAMPING-OFF DISEASE

Damping-off is a fungus disease caused by any of several soil-borne fungi that attack the germinating seed or young seedlings at the base of the stem.

Symptoms of Damping-off

Pre-emergence damping-off attacks the germinating seeds and can cause many to rot. Low germination (if not due to poor seed) may be a sign of damping-off.

Post-emergence damping-off attacks seedlings soon after they emerge while their stems are still young and tender. The plants collapse at the base of the stem. A closer look shows a water soaked constriction of the stem where it meets the soil. (High heat can sometimes cause a similar girdling of the stem.)

Prevention and Control

1. Soil sterilization should control it unless the soil becomes recontaminated by unclean tools or further additions of unsterilized soil.

2. Seed treatment with a fungicide dust: Use Captan (Orthocide) or
Araan (thiram). Provides good seed protection but won't protect the seedlings. Most commercial bulk seed (as opposed to packet seed) is already treated; check the label or look for a purple or reddish tinge to the seed. NOTE: Demosan (Tersan, chloroneb) seed treatment is highly effective on post-emergence damping-off as well and is used on beans, cotton, and sugar beets in the U.S.

3. Keep the soil surface dry: Avoid excessive shade and watering too frequently; a continually wet soil surface is a turn-on for damping off fungi. Water thoroughly once a day in the morning rather than making several light waterings.

4. Don't crowd plants!: Keep the rows a minimum of 2" apart and thin plants as required. Overcrowding makes for spindly plants with tender attack-prone stems.

5. Keep'em growing!: Damping-off is only a problem during the first week or two of growth. After than, stems toughen up and become resistant. Anything that slows down growth (lack of sunlight or fertilizer, etc.) is a no-no.

6. A fungicide soil drench will help prevent damping-off if no sterilization was used; it'll also help control damping-off if an outbreak erupts. Here's 2 recipes:

   a. 1-1/2 - 2 level teaspoons (7-1/2 - 10 c.c.) of Captan (Orthocide) per gal. of water. Apply at the rate of 1/2 gal. per sq. yard (9 sq. ft.) immediately after planting or as soon as damping-off symptoms occur.

   b. For cabbage and broccoli: a drench of 1 level tablespoon of PCNB (Terrachlor, Brassicol) + 2 tablespoons Captan 50W per gal. of water applied at 1 gal. per 50 sq. feet of seedbed immediately after planting.

PLANTING THE SEEDS

Use Adapted Seeds

Numerous varieties are available for each vegetable, but only a few are adapted to any particular area. Varieties vary in their time to maturity, disease resistance, and heat tolerance, etc. Check with your host country extension service for recommended varieties. DON'T use CARE seeds even though they're free - they're seldom the correct variety and are usually old.

Run a Germination Test First

Once out of a freshly opened sealed can, seed can deteriorate rapidly under hot, humid conditions. Test the germination by either making a trial planting or placing 100 seeds inside wet newspaper and counting the germination in a few days. (See p. 55 for storage tips.)
Planting Depth

1/4-1/2" (.6-1.2cm) deep for small seeded vegies. If too shallow, soil may dry out too quickly; if too deep, they may have trouble pushing through or may rot. Planting too deep is a common mistake.

Seed Spacing

Rows should be 5-7cm apart. There are 2 ways of spacing seeds in the row:

1. Dribble them out uniformly at about 15-30 seeds/foot (about 1 every centimeter). Since you'll be thinning them progressively for a final 5-7cm spacing, you'll waste a bit of seed unless you double transplant.

2. Cluster planting: plant in groups of 3 seeds per group with 5-7cm between groups; thin to one seedling per group once the first true leaves start forming. If care is taken to align the groups both in the row as well as from row to row, blocking is greatly facilitated (see next page). Use a board with mounted dowels to mark out the holes.

3. Container planting: 3 seeds per container and then thinned to one plant each.

Other Planting Tips

1. Firming the soil over the seed will help improve contact between seed and soil moisture.

2. In some cases, you can improve the emergence percentage of difficult seeds like carrots and lettuce by covering them only with a thin layer of sawdust or rice hulls.

3. Covering the seedbox or seedbed with a 5-10cm thick mulch of straw or grass (newspaper works too) helps hold in moisture and protects against seed washout. However, be sure to remove the mulch as soon as seedlings start emerging to avoid leggy, weak plants and increased damping-off problems. Before applying the hay or straw, dry it out well in the sun to help decontaminate it from damping-out organisms or use a Captan drench over it. You can also try using a "grow through" mulch like rice hulls about lcm thick or so.

Seedling Care

1. Overplanting and underthinning are common mistakes. You're shooting for strong, stocky seedlings, so overcrowding is a no-no.

2. In high rainfall conditions, a clear plastic canopy or removable thatch roof set-up will be needed.
3. During the early stages of growth, partial shade may be needed under high temperature, intense sunlight conditions, but don't overdo it.

4. Water in the mornings; this helps keep the soil surface dry to minimize damping-off problems.

5. Insects: Malathion 50% or 57% liquid at a 3 cc/liter (2 teaspoons/gal.) or Sevin 80% WP at 10 cc/liter (2 tablespoons/gal.) will control most leaf feeding insects (Sevin won't control aphids well). Don't spray unless needed!

6. Leaf spot fungus diseases: use Maneb or Manzate (Dithane M-45) at 6 cc/liter (1.5 tablespoons/gal.) or Captan 50W at 8-12 cc/liter (2-3 tablespoons/gal.).

7. Hardening and blocking: See "Tips on Transplanting Vegetables" (p. 72)
TIPS ON TRANSPLANTING VEGETABLES

I. PRE-TRANSPLANT GUIDELINES

Size & Age of Transplants

Use only healthy, vigorous transplants. Over-planting and under-thinning produce spindly, weak seedlings - so does too much fertilizer (especially N) or excessive shade. Follow the tips above in "How to Grow Super Transplants" and shoot for sturdy, stocky seedlings that are disease-free.

In warm climates, it takes about 3 1/2-6 weeks to grow seedlings to transplant size. Tomatoes, cabbage, broccoli, and leaf lettuce (leaf lettuce is usually direct planted) are the quickest and pepper and eggplant the slowest:

Most plants are ready when they have 4-6 true leaves (i.e. not counting the first 2 "seed" leaves). Size and appearance should be like so:

**TOMATOES:** 15-20cm tall, pencil thickness stem; should be stocky (wider than tall) and not leggy.

**CABBAGE:** 6 leaf stage; use stocky plants.

**PEPPER, EGGPLANT:** 10-12cm tall.

Don't use overly old seedlings; the growth check is much greater since more roots are damaged during transplanting and older roots don't regenerate as well. Also, old seedlings are likely to have stunted root systems due to confinement in a limited area. Tomatoes are somewhat of an exception (see p. 74).

Hardening and Blocking

Hardening toughens up seedlings and prepares them for the shock of transplanting; the process slows growth, increases food storage, and toughens up plant tissue. When transplanted, hardened plants produce new roots faster and are more resistant to moisture stress and temperature extremes.

The hardening process should be started about 7-10 days before transplanting and consists of one of the following:

1. Exposing plants to below optimum temperatures for growth; not practical in the tropics.

2. Gradually reducing the water supply, but don't let the plant bed dry out suddenly or let the seedlings wilt severely. Blocking the plants (see below) may be enough to produce adequate hardening by itself.

Blocking consists of cutting the seedbox soil to full depth by passing a sharp knife length-wise and cross-wise between the plants about 7-10 days before transplanting. A 5x5 or 5x8cm plant spacing facilitates the operation. Blocking lessens transplant shock in several ways:
1. It keeps the roots of adjacent seedlings from entangling each other which causes lots of root loss when the seedlings are removed.

2. It stimulates root branching within the seedling's soil cube which helps hold it all together when lifted out.

3. The severed roots have a chance to at least partially recover before transplanting which causes little additional root damage.

Exposure to Full Sunlight

If the seedlings have been grown under partial shade due to intense heat and sunlight, they must gradually be acclimated to full sun during the 2 weeks prior to transplanting. It's a good idea to use as little shade as possible; overdoing it slows down growth, makes for leggy plants, increases damping-off problems, and may cause increased transplanting mortality.

II. THE TRANSPLANT OPERATION

Weather Conditions: Transplant in the late afternoon or on a cloudy day - it helps avoid severe wilting. Shading the transplants (see p. 74) for the first couple days is often necessary if heat and sun are intense.

Extracting the Seedlings: Try to retain as much of the seedling's root system as possible when removing it from the seedbox. Blocking (see above) is a big help; soaking the soil may help too.

Using a Starter Fertilizer Solution

A liquid starter fertilizer solution poured into the transplant hole helps get the plants off and running again. Use a fertilizer with a high ratio of P like 12-24-12 or 10-30-10, or 5-10-5 if possible (P helps stimulate new root growth). Or use:

Manure Tea: 1 part manure to 3 parts water. Probably not a quick release source of P.

Recipe: 2-4 level tablespoons of fertilizer per gallon of water (8-15 cc/liter). Don't expect it all to dissolve (using hot water and mashing the fertilizer will help).

Dosage: About a cup (250 cc) per transplant hole. Pour it in before transplanting and let it drain completely before setting the plants.

Remember that the starter solution is only a temporary "fix", since the amount of NPK applied is pretty small. In addition, a regular application of NPK fertilizer should be placed in a half circle 8-10 cm deep and 8-10 cm out from the plant's stem. Or you can try relying completely on a high rate of manure or compost (at least 4 kg./sq. meter; half this for poultry and sheep manure; it should be broadcast and worked into the top 15-20 cm of soil about a week or two before transplanting).
How Deep Should Transplants be Set?

Eggplant, pepper, and cabbage family transplants should be set slightly deeper (like 1-2 cm) than they were originally. Setting cabbage family plants as deep as the first true leaves will prevent leaving lots of curly stem above ground that might be broken by wind knocking the plants around.

Tomatoes are a very special case since any portion of the stem that is buried will form roots. In fact, tomatoes love being set super deep in the soil, since it gives them a better root system. You can bury them deep by setting them in vertically, but if the plants are very old and leggy (much above 20 cm or so, use the horizontal method shown below, but be careful not to snap off the top part of the plant by bending it too much. The horizontal method avoids setting the plants too far down into subsoil that might be too cold, poorly drained or very infertile. You can set plants 30-50 cm tall (way too old to be ideal) leaving only 10 cm above ground, and it'll help turn back the clock.

Don’t be afraid to pinch off some of the lower branches in order to “deep six” the tomato plants; they like it.

Setting the Plants In (Normal tomatoes and other)

Hold the plant gently (don't squeeze the stem) so the roots dangle down vertically and aren't scrunched up. If the plants are container grown, take off the container and loosen up the roots a bit. Set the plant in to the proper depth and fill in soil so no air pockets are left. Firm the soil around the plant to assure no air pockets (they cause roots to rot).

Leave a slight depression around the plant (above 20 cm diameter) to help retain water unless conditions are very wet.

Watering and Shading

Water the plants well immediately after transplanting. If the soil is dry, put on about 25 liters/sq. meter broadcast to help build up the moisture reserve; the young transplants won't actually need much at once due to their tiny root system, so you may have to water every day or two with a much smaller amount in addition to this initial deluge.

Shading: In hot, sunny weather, the plants will usually need shading (possibly not if they were container grown under full sun) to prevent high mortality from water stress. Make party hats (or cones - they're quicker) out of newspaper or use banana leaves, etc. Put a ventilation hole in the party hats. Shade may be needed for several days and can be gradually withdrawn.
Mulching

In most cases, a 10-15 cm layer of mulch around the plants is very beneficial. It reduces evaporation of water, cools the soil (not good in cool weather), cuts down weeds, and eventually adds organic matter to the soil. Mulch may attract termites (dry areas especially), crickets, or slugs and snails (wet conditions). It may also encourage "damping off" if placed too close to young seedlings.

GUIDELINES FOR INDIVIDUAL VEGETABLES

Tomato  Cucumber
Eggplant  Squash
Pepper  Onion
Cabbage & Chinese cabbage

There's no one right way to grow vegetables so the guidelines below are very general. The specifics depend on the soil, climate, available inputs and equipment, and the farmer's management ability and capital.

TOMATOES

Days til harvest: 55-90 from transplanting

Good yield: 2-6+ kg/sq. meter depending on conditions.

Determinate varieties are low growing and bushy; blossoms and fruit develop over a short period, and harvest lasts only 1-3 weeks. Indeterminates keep on producing more leaves, stem, flowers, and fruits; harvest may last several months if not cut short by diseases. Indeterminates are usually staked.

Choice of variety is very important since there's much variation in disease resistance, time til harvest, size and shape of fruits, and use. Here are some common ones - get local recommendations from the ministry of ag.

Growing Transplants: (See section titled "How to Grow Super Transplants"). Ideal transplant has 4-6 leaves (not counting original seed leaves), is 6-8" tall with pencil thickness stem, and is stocky not leggy. Allow 4 sq. in. per plant in the seedbox.

Transplanting: Set them deep so first leaf is just above soil. Leggy plants should be set extra deep (lay part of stem horizontally underground after pulling off some of the lower leaves). Remember that tomatoes are one of the few vegies that have the ability to produce roots from the buried stem.

How to root cuttings: A quick way to produce transplants. Cut a 6" long healthy sucker at a slant; dip in rooting hormone and insert into a moist medium like peatmoss, compost, etc. Will root in a couple of weeks.

Blossom drop: Nite temperatures above 75°F (24°C.) may cause blossom drop in some varieties. Same with night temps below 55°F. Hot, dry winds may cause blossom drop.

---

1. "I" = indeterminate, "D" = determinate
2. F = race 1 Fusarium wilt, F₂ = race 2; V₁ = race 1 Verticillium wilt, N = nematodes; radial fruit cracking and graywall are physiologic disorders.
3. Disease resistance doesn’t imply 100% immunity but only better tolerance.
Fertilizing

Seedbox: See: "How to Grow Super Transplants" or Soils, Crops, and Fertilizer Use manual (PC/1CE)

At transplanting: Use a starter solution (see "Tips on Transplanting" or the fertilizer manual) as well as the usual solid fertilizer application (use half-circle method). Good managers can profitably use up to 200 lbs. P2O5/acre (kgs./Ha.) and 60-150 lbs./A (kgs./Ha.) K2O. Total N can go as high as 100-150 lbs./A (kgs./Ha.) but apply only 1/3 at transplanting and sidedress the rest 3-4 week intervals.

Sidedressing: Use N only unless under high rainfall or very sandy conditions where K losses may be high. Apply 30-40 lbs./A N every 3-4 weeks.

Tomatoes are especially susceptible to Calcium, Magnesium, boron, and manganese deficiencies.

Staking and Pruning

In the States, the tall growing indeterminates are staked while the bushy determinates are often allowed to sprawl on the ground; especially if a protective plastic mulch is used. Under wet tropical conditions, staking is often essential for both types to prevent fruit rot and foliage diseases being aggravated by ground contact. Instead of staking the bushy determinate varieties, you could try heavy mulching with straw or rice hulls, etc.

Under drier conditions, unstaked plants will usually outyield staked plants on a per plant basis, but allowing them to sprawl exposes the fruit to more sunscald than under staking. On a per area basis, however, staked plants usually yield more, since they can be spaced twice as close as unstaked plants. Use stakes at least 1.6m long and sink them at least 30cm into the ground. Best time to put in the stakes is right at transplanting.

Wire Cages: Cages 45-60 cm in diameter made from strong wire mesh (10-15cm mesh) is ideal for supporting tomato plants. Concrete reinforcing wire can be used, but cost is a big problem. The plants need no pruning with this method.

Pruning: The main purpose of pruning is to facilitate staking and tying by cutting down on the number of stems per plant. Pruning to a single stem will speed up maturity by a week or two, but at the expense of yield. Usually, pruning to leave 2-3 stems is ideal and also gives better foliage coverage to protect the fruits from the sun. One way to obtain an early initial harvest and later sun protection is to remove all "suckers" (potential stems that form in the joint between the stem and the leaf branches) up to about 40-45 cm and let the others grow to form a canopy effect. A common and effective pruning method is to let one or two suckers grow out from near the plant's base to form a 2-3 stem plant. Note that each of these 2-3 stems will also produce further suckers which need to be removed; pruning is a fairly continual process. A TIP: Allow the suckers to develop two side
leaves, and then pinch off the shoot above the side leaves—it makes for better foliage coverage for fruit protection. Severely pruned plants (one stem) are more susceptible to blossom and rot.

**Insects:** Aphids, tomato fruitworms (corn earworms), hornworms, cutworms, and stinkbugs are some of the more common pests. (See the insect control section below.)

**Nematodes:** Tomatoes are especially susceptible to rootknot nematodes (see nematodes section of this tech reference package).

**Diseases**

Fusarium wilt, Verticillium wilt, bacterial wilt, early and late blight, gray leaf spot, Septoria leaf spot, and several viruses are the more common problems. Use resistant varieties whenever possible where the fungal wilts are a problem. Benlate (benomyl) as a soil drench (500 cc/plant of a solution made of 1 gram Benlate per 3 liters water) applied in the transplant hole before transplanting has proven very effective as a preventative against Verticillium (also helps with Fusarium). For leaf fungal diseases, prevention applications of foliar fungicides should be made every 4-10 days (depending on rainfall frequency and disease severity) beginning around blossom time. Practice crop rotation (especially good for soil-borne disease control) by not growing tomatoes, peppers, eggplant, potato or tobacco on the same ground within 3 years. Don't use tobacco products when working with tomatoes—it spreads tobacco mosaic virus. Wash hands well with strong soap, rubbing alcohol or skim milk (the latter is very effective) before entering the field if you're a tobacco user.

**Physiologic Problems**

**Blossom drop:** see start of tomato section.

**High temperatures:** Nighttime temperatures over 85° (29.5°C) prevent ripening fruit from attaining a normal red color.

**Blossom End Rot:** Water soaked spot at blossom end of fruit that enlarges to cover up to half the fruit; usually hits when fruit is 1/3-1/2 grown. Most common when a dry spell follows a period of rapid growth. Unusually heavy rain, excessive N, wide fluctuations in the water supply, and heavy pruning can also be factors. The main problem is really a calcium deficiency. Calcium isn't moved from older to younger tissues, so it doesn't take long for a deficiency to injure new growth (i.e. the fruit). Control: Spray the foliage once or twice a week when problems arise with a solution of 4-5 lbs. of calcium chloride per 100 gals. water (4.8-6 grams/liter). Higher rates may burn the crop. Apply only during the period of unfavorable conditions. Liming a very acid soil also gives good control (see the soils and fertilizer manual).

**Leaf Curling (Rolling):** Some kinds are normal and are more pronounced in some varieties. Overwatering, prolonged heavy rainfall, or severe pruning promote it. This normal curling consists of upward rolling of the leaflets on the lower leaves, making for a cup-like appearance.
Graywall: Gray to grayish-brown blotches on the surface of green fruits; also called "blotchy ripening." May be caused by low light intensity, high soil moisture, soil compaction, or cold weather. Resistant varieties are the best control.

Cat-facing: Fruit shows a severe malformation and scarring at the blossom end; fruit is puckered with irregular, swollen protuberances at the blossom end. Thought to be caused by any serious disturbance (stress) during flowering; 2,4-D herbicide damage can cause it too. Varieties vary in their susceptibility.

Growth Cracks: The cracks can be either concentric or radial (down the sides) and are most common during high rainfall and temperatures which favor extra rapid growth. Varieties vary in their susceptibility. In dry areas, avoid irrigating tomatoes right before harvest.

Sunscald: Due to sun exposure of the fruit and very common where plants have been prematurely defoliated due to leaf spot diseases. Excessive irrigation or rainfall can also kill the older foliage. First symptoms are a yellow or white patch on the side of the fruit facing the sun; it may remain yellow, but usually a blister-like area forms and later shrinks to a large, grayish-white spot with a paper-like surface. Covering the fruits (if the plants are sprawling and unstaked) with a light layer of straw helps. Sunscald is most common on immature, green fruit.

**EGGPLANT**

Time to harvest: 75-100 days from transplant.

Good yield: 2-4+ kg/sq. meter depending on conditions

Characteristics: Likes hot weather; usually grown as an annual but it's a perennial; requires care in transplanting; soaking seeds overnite improves germination.

Varieties: Purple, yellow, white fruits; small and large fruited varieties; some are resistant to bacterial wilt, a very destructive disease.

Transplanting: Care is required (keep as much soil as possible around the roots when the plants are pulled). Set out plants in the field when 12-18 cm tall. Can also be grown in 5 gal. containers.

Plants may need staking. Control plant size by pinching off the growing point.

Fertilizing: see peppers.

Diseases: Bacterial wilt, verticillium wilt, anthracnose. Don't plant eggplant, pepper, tomato or potato on the same ground within 2 years.

Insects: Flea beetles, aphids, hornworms, lace bugs, etc.
PEPPERS (Sweet)

Time til harvest: 60-90 days after transplanting.

Good yield: 12,000 lbs./acre (kgs./Ha.)

Characteristics: Not as heat tolerant as eggplant; hot peppers have better heat resistance. Bell (sweet) peppers ripen from green to red, sometimes yellow. Night temperatures above 75°F (24°C) or much below 60°F (15-5°C) encourage blossom drop as well as daytime highs above 90°F (32°C). Some natural blossom drop occurs even at ideal temperatures so the plant doesn't overload. Seed germinates slowly.

Transplanting: It takes 6-8 weeks to grow transplants; set out in field when 8-12cm.

Fertilizing: Good managers can use up to 80+ lbs. N, 80-200 lbs. P₂O₅, and 0-100 lbs. K₂O per acre (kgs./Ha.) according to soil test results and capital available. Apply all the P and K at planting (unless K leaching is likely to be high) and 1/3 of the N. Sidedress every 3-4 weeks afterwards with about 30 lbs. N/acre (kgs./Ha.). Also use a starter fertilizer solution at transplanting time.

Varieties: Here are some of the more common ones with their characteristics:

Yolo Wonder: Resistant to tobacco mosaic. Medium season. Yolo Wonder L is a taller type with better fruit protection against sunscald. 78 days (fr. transplant)

Early Calwonder: Early season with a medium thick wall. Yields over a shorter period.

Worldbeater: Thinner walled than Calwonder types, less blocky in shape. 70 days.

Florida Resistant Giant: Thick walled Calwonder type that's resistant to tobacco mosaic.

Insects: Aphids, flea beetles, armyworms, leaf miners, cutworms, pepper weevil.

Nematodes: Susceptible to rootknot, sting, and several other types.

Diseases: Common diseases are mosaic virus, bacterial wilt, bacterial leaf spot, anthracnose, and several other leaf spots. Foliar fungicides will control foliar spots if applied regularly; use copper base sprays on bacterial leaf spots. Don't use tobacco products while working with peppers; wash hands thoroughly before entering the field if you're a tobacco user to avoid spreading mosaic virus. To avoid bacterial soft rot, don't handle plants when wet and avoid wounding the fruit. Practice crop rotation by not planting pepper, eggplant, tomato, or potato on the same field within 2 years.
Sweet vs. hot peppers: Sweet varieties are less heat and drought resistant than hot varieties. Sweet varieties are usually harvested at the mature green stage, while hot varieties are picked at the mature red stage (hot wax types are picked when yellow).

CABBAGE

Time til harvest: 61-90 days after transplanting.

Good Yield: 2-6 kg/sq. meter

Characteristics: Prefers mild temperatures but passable yields can be obtained in warmer areas if heat tolerant varieties like KY and KK Cross (hybrids) are used; mulching helps reduce soil temperature. Heads weighing 2-4 lbs. are possible in warm weather while 4-6 lbs. heads are common when it's cool.

Transplanting: Transplants can be grown in about 4 weeks and are ready at the 4-6 leaf stage. If shooting for large heads, space plants about 20" (50cms) apart, otherwise 12-16" (30-40cms). Use a starter fertilizer solution (see "Tips on Transplanting") in addition to the usual NPK solid fertilizer. Set them firmly into the ground to avoid air pockets.

Other tips: Cabbage is shallow rooted and easily injured by cultivation deeper than 1-1/2". Large heads sometimes split during hot weather; splitting can be prevented by harvesting a bit early or twisting the plant 1/4-1/2 turn near maturity till you hear some roots snap - it'll slow growth. Some variety hybrids are available.

Fertilizing: Good managers can apply up to 100-120 lbs. N (1/3 at transplanting), 60-150 lbs. P2O5, and 60-150 lbs. K2O per acre (kgs./Ha). Apply the remainder of the N in 1-2 side-dressings. Cabbage is susceptible to magnesium, sulfur, boron, and molybdenum deficiencies.

Insects: Cabbage loopers, diamond back moth caterpillar, aphids, leaf miners, cutworms, wireworms. Try Bacillus thuringiensis (Dipel, Biotrol, Thuricide) for loopers, diamond back moth, imported cabbageworm.

Diseases: Bacterial black rot (Xanthomonas), bacterial soft rot, and leaf spots like Alternaria, Cercospora, and downy mildew. Foliar fungicides will help control downy mildew and leaf spots. Don't grow cabbage family members on the same land within 2 years of each other if possible. Club root and Fusarium yellows are 3 other soil-borne diseases.

Nematodes: Susceptible to rootknot, sting, cyst, and several other nematodes.

Consider growing COLLARDS: Collards are a non-heading cabbage and have 2 advantages: They're much higher in vitamin A (50-60 times higher) than cabbage, tolerate heat better, and can be harvested leaf by leaf. Cabbage loop control is easier since there's no head for them to hide in.
CHINESE CABBAGE

Time til Harvest: 70-90 days after direct seeding

Characteristics: One of the easiest and most productive veggies in the tropics, although it prefers cooler weather. Tolerates direct field planting well. Doesn't store or ship as well as cabbage. Can be cooked or eaten fresh. Forms a semi-loose cylindrical head. Can be harvested at maturity when heads are 6-9" across or you can pick the outer leaves as they reach about 6-8" in length; new ones will continue developing for many weeks. Once the heart starts to form, tying the leaves together at the top and bottom will help blanch (whiten) the leaves.

CUCUMBER

Time til harvest: 45-65 days

Good yield: 0.8-3.2 kg/sq. meter depending on conditions

Characteristics: Prefers hot weather but does best under low humidity; good root system but easily burned by fertilizer.

Fresh market (slicing) vs. pickling cucumbers: Most pickling cucumbers are black spined while fresh market ones are white spined. WS varieties turn a creamy color when mature, but BS varieties turn yellowish orange inside. Fresh market cucumbers are long and narrow while pickling types are short and fat, but they can be used interchangeably.

Flowering and Fruiting: Most of the standard open-pollinated varieties have a mix of male and female flowers (monoecious). Male flowers open first but don't set fruit. Female flowers open about a week later—you can tell 'em by the miniature cucumber right beneath the flower. Many of the new hybrids are gynoecious—they have nearly all female flowers; they're packaged with a few normal seeds (dyed for identification) to supply pollen. They have higher yield potential and often better disease resistance. All varieties are pollinated by bees, and commercial growers in the U.S. use 1 hive for every 3-5 acres. Apply insecticides only in the late afternoon (when bees have returned home) to avoid bee kill during flowering. Don't use Sevin since its residue is toxic to bees for 7-12 days.

Varieties: Here's a list of some of the more common fresh market varieties and their characteristics:

Ashley: Open-pollinated, dark green, 7-8" long, early to midseason, resistant to downy mildew, fairly tolerant to powdery mildew. Until recently, all varieties were of the vining type. Now there are several bush varieties which take up less space.
Poinsett: Dark green, 8-8-1/2" long, mid-season; tolerant to downy and powdery mildew, anthracnose, and angular leaf spot (bacteria). Open-pollinated.

Victory: A gynoecious hybrid, 7-8" long, dark green, early variety, resistant to down mildew; moderately tolerant to powdery mildew, scab, anthracnose, and angular leaf spot.

Gemini: A gynoecious hybrid, dark green, 7-8" long, mid-season; tolerant to downy mildew, powdery mildew, scab, mosaic, and anthracnose.

Sprint: Dark green gynoecious hybrid, 7-9" long; high tolerance to scab; tolerant to angular leaf spot, cucumber mosaic, downy mildew, powdery mildew, and one race of anthracnose.

Slicemaster: Gynoecious hybrid, dark green, early variety, 7-9" long; high tolerance to anthracnose, scab, mosaic, angular leaf spot; and downy and powdery mildew.

Row vs. Hill Planting—Trellising uses less space and produces more attractive fruit (straighter).

Row planting is the best system when trellising is used. Plant 4-5 seeds per foot and thin to one plant every 10-12" with the rows 4-5 ft. apart. Plant on a slight ridge, especially during the rainy season. Use 3-ft. rows if trellised.

In hill planting, sow 6 seeds per hill and thin down to 3 with the rows 4-5 ft. apart. The "hill" should be a slight mound, but first dig out a 2-ft. diameter hole about 12-18" deep and fill with well rotted manure or with compost half-way up. Mix in soil and build up the mound so it's about 3" or so above ground in the center (don't make it too high or it'll tend to dry out quickly). Space the hills about 3 ft. apart. Hill planting makes for easier watering.

Fertilizing: see squash next page.

Insects: Cucumber beetle, vine and fruit borers, aphids, leaf miners, flea beetles, stink bugs, cutworms, armyworms.

Nematodes: Very susceptible to rootknot and sting nematodes.

Diseases: Downy mildew (likes high humidity), powdery mildew (more common under low humidity), cucumber mosaic virus (transmitted by aphids from wild host plants and other cucumbers), angular leaf spot (use copper base fungicides), scab and anthracnose. The mildews, scab, and anthracnose can be controlled with fungicide sprays.

Other tips: Train vines into the row to keep them out of pickers' way—stepping on them greatly reduces the yield. Harvest starts about 7-10 days after female flowering.

Bitterness: Most likely caused by lack of H2O or too much variation in soil moisture.
**SQUASH**

**Time till harvest:**
- 50-60 days (summer squash)
- 85-125 days (winter squash)

**Good yield:** 2-8 kg/sq. meter, depending on conditions

**Summer vs. Winter Squash:** Summer squash varieties are bred to be picked in the young tender stage; winter squash types are picked in the mature hard stage. Zucchini and Yellow Crookneck are summer squash types; butternut and acorn squash are winter types. Each country has many native varieties (especially winter types) but they tend to be low yielders (but good disease resistance).

**Vining vs. Bush Varieties:** Vining types need 8-10 ft. between rows, bush types need about 5 ft. between rows.

**Flowering and fruiting:** Like cucumber, squash has both male and female flowers; only the females produce squash. Pollination is by bee. Commercial growers in the U.S. use one hive per 3-5 acres. Apply insecticides in the later afternoon when bees have gone home to reduce bee kill; don't use Sevin during flowering since its residue is toxic to bees for 7-12 days.

**Planting:** Use the "hill" method as with cukes and plant 6 seeds, thinning down to 3 plants. Plant vine types in hills 3 ft. apart with about 8-10 ft. between rows; plant bush types in hills 3 ft. apart with 5-6 ft. between rows.

**Fertilizer:** Good managers can use up to 75-100 lbs. kg/ha. N/acre (kgs./Ha.) with 1/3 applied at planting along with 50-125 lbs./A (kgs./Ha.) P₂O₅ and K₂O according to the soil's estimated P and K status. Use the half-circle method at planting and make it 3-4" deep and 4" from the seeds. Instead, you can broadcast the NPK fertilizer over the hill and work it in well (use this method if you have chucked in a lot of organic matter when making the hill; it'll help protect the broadcast P from tie-up).

**Insects, Diseases, Nematodes:** See cukes

**ONIONS**

**Time till harvest:**
- 100-140 days (bulb onions)
- 45-60 days for green onions

**Good yield:** 1.5-6 kg/sq. meter (bulb onions)

**Bulb vs. Green Onions:** Bulb varieties can be eaten as green onions if harvested early (plant 'em close together so they'll form long white stems instead of bulbs). True green bunching onions have no distinct bulb but continue to form new shoots during the growing season; these multiplier types are sometimes called scallions.
Daylength and Bulb Production: Some onion varieties need long days (14 hours or more) to bulb. Bermuda types will bulb under short days but Spanish and American types won't. If you're closer than latitude 24° to the Equator, daylength never exceeds 14 hours even on the longest day. Bulb onions usually do best if planted so that bulb maturation occurs during the time of the year when daylength is increasing.

Bulb Onion Varieties: Bermuda onions store poorly (yellow types store better than white types but still no more than a few weeks at best). Here are some short daylength varieties and their characteristics:

- **Yellow Bermuda**: Flat bulbs, soft-mild, short storage life.
- **Tropicana**: Red, resistant to purple blotch disease, pungent, stores well.
- **Red Creole C-5**: Red skinned, resistant to purple blotch, small, very pungent, stores well.
- **Texas Grano 502**: Large size, yellow skinned, stores well.
- **Granex**: Hybrid, very resistant to pink root disease. Both yellow and white skinned varieties are available.
- **Excel**: Amber skinned, medium size, very resistant to pink root disease.
- **Eclipse**: White skinned, very resistant to pink root.
- **Early Grano**: Straw colored, soft-mild, short storage life.

Direct Planting vs. Transplanting: Direct planting bulb onions speeds up maturity by about a month. The catch is that onion seedlings need abundant and uniform moisture which is more easily provided in a nursery seedbed. Weeds are also more of a problem with direct planting. Onions are ready for transplant when stems are about pencil size.

Fertilizer: Good managers can apply up to 100 lbs./A N (1/3 at planting or transplanting) and 50-150 lbs. P2O5 and K2O per acre (kgs./Ha.) depending on the soil's P and K status. Use the band method and place the NPK fertilizer 3-4" deep and 2" from the row (2-3" if transplanting).

Insects: Thrips, leaf miners, cutworms, wireworms.

Diseases: Purple blotch (Alternaria), Botrytis leaf blight, and downy mildew can be controlled with foliar fungicides; pink foot can be controlled with resistant varieties or using soil fumigants like Vapam.

Nematodes: Onions are very susceptible to rootknot, sting, and several other types of nematodes.
Other tips: Emerging seedlings are very easily damaged by windblown particles like sand so windbreaks may be needed in some cases. Maintaining a uniform moisture content is especially important once bulbs start maturing; water should be cut down during maturation since excess water encourages the sprouting of new roots which hinders curing.
WHEN TO HARVEST VEGETABLES

BEANS, green: Harvest bush beans while the pods will still "snap" and before they become lumpy. Bush bean varieties have a harvest period of about 2-3 weeks; pole (vine) varieties have a 6-8 week harvest period, and the pods are picked when large and thick.

BEETS: Ready to harvest as soon as they're 1-1/4-2" in diameter (about golf ball size). Sugar content increases with age but so does toughness.

BROCCOLI: Harvest just after the individual flower buds become distinguishable but before the clusters begin to open and turn yellow. Center head is usually 3-6" across; side shoots continue developing after center head is cut and will reach 1-3" in diameter. Making a slanting cut may help prevent stem rot.

CABBAGE: Can be harvested as soon as the head has formed since flavor doesn't change much with maturity—you'll sacrifice yield though. Use a sharp knife and cut close to the head. Heads will sometimes split during hot weather when large; twist the plant about 1/4-1/2 turn til you hear some of the roots snap—it'll slow growth and reduce splitting (do it near maturity). If bacterial soft rot is a problem, dip knife and stem of cabbage in a 1% solution of household bleach in water (10 c.c. bleach per liter).

CARROT: Harvest can start when the roots are about 1" in diameter at the crown; don't let 'em get more than 1-1/2".

CANTALOUPE (Muskmelon): A common guide is the ease of melon removal from the vine; fully ripe ones (called "full slips") separate easily and leave a clean stem cavity; full slips have poor storage life except under refrigeration. Half slips are less mature and take more pressure to detach (about half of stem next to the melon remains attached) and store longer. Both full and half slip melons are fully netted and the color has changed from cucumber green to mottled green and light yellow.

CAULIFLOWER: Timely harvest is important to prevent ricey or fuzzy curds. If weather is warm, heads can mature within 3-5 days after blanching (see below) starts but can take up to 2 weeks in cooler weather. Mature heads are fully developed, compact, and clear white; about 6" is the best size for harvest. Use a large knife to cut the heads from the plants and leave one or more sets of leaves attached to protect the curds; avoid overmature, open heads.

Blanching: Curd becomes discolored and sometimes off-flavored if exposed to sunlight; when small, they're protected by the inner leaves; as curds enlarge, in most varieties they force the inner leaves apart, so blanching is needed. Gather longest leaves together over the curd and tie with soft twine; since the plants
mature at different rates; you'll need to go through the field every 2-3 days to do blanching: using different color twine each day will aid in maturity detection. Some self-blanching varieties are available.

CHARD, Swiss: Harvest outer leaves first as they reach tender maturity (blade will be about 6-10" long); new ones will continue developing.

CHINESE CABBAGE: There are 2 ways to harvest Chinese Cabbage:

1. Harvest when heads are solid and 6-8" across. Cut with a knife at the base of the head and remove any dead, yellowed or dirty leaves around the outside. It doesn't store or ship as well as regular cabbage; the heads can be packed loose in boxes or first rolled in newspaper. Letting the heads wilt before boxing them helps prevent breakage—buyers can recrisp them by soaking them for a few minutes.

2. Harvest the outer leaves as they reach about 6-8" in length; new ones will continue developing for many weeks. They'll also be much higher in vitamin A due to better sun exposure (i.e. compared to the paler leaves inside a head).

CHAYOTE (Guisquil, Vegetable Pear): 25-30 days after fruit set.

COLLARDS: Two ways to do it:

1. Harvest outer leaves when full size but still tender.

2. Harvest the entire plant at once before leaf stems become tough and fibrous.

CUCUMBER: Fresh market (slicing) cucumbers can be picked at any size, but a medium size, dark green cucumber is best. Don't let them reach the full yellow ripe stage since it'll reduce total yield. Picking should be done every 2-3 days; hold the vine and twist off the fruit (pulling may damage vines).

EGGPLANT: Higher total yields are attained if the fruits are picked before reaching full size; they're ready anytime after the fruit is 1/3 size with skin showing a slick luster; skin should be firm to the touch. If the seeds are brown or the skin remains indented after being pressed with the thumb, it's over-ripe. Cut off the fruit, don't pull, leave the calyx (cap) attached to the fruit. Handle carefully to avoid bruising.

GARLIC: Ready to harvest after the tops have died; in rich soil, tops may need to be broken over to prevent too much top growth. Plants are pulled and placed in windows with tops covering bulbs to prevent sunscald. Curing takes several days and can be done indoors if rainy.
LETTUCE: Leaf lettuce is ready as soon as the leaves are big enough; the entire plant can be harvested or you can prolong the harvest (up to 2 months or more) by picking the outer leaves as they develop.

MUSTARD: Pick outer leaves when 4-6” long; plant will continue producing new leaves.

NEW ZEALAND SPINACH: Pinch off about 3” of branch tips with leaves; more side shoots will keep appearing.

OKRA: Pods are usually picked 3-5 days after flowering when 2-3” long; pick pods daily to keep plant producing and to avoid overmaturity. Okra deteriorates rapidly after harvest.

ONIONS: Can be harvested either as green bunch or mature bulbs; suitable for green bunch harvest from the time they’re pencil size. As mature bulb stage nears, some of the tops will fall over at the neck. Break over all tops at this time to assure uniform maturity. In the dry season, they can be cured in the field—shade the bulbs with the tops to minimize sunscald. One half to one inch of top is usually left on the bulb to prevent disease entrance.

Once way to speed up maturation and get larger bulbs is to break over the tops when the outer leaves turn yellow; 2 weeks later, loosen the bulbs by pushing a spading fork beneath them and lifting slightly; in another 2 weeks, lift them out after they’re dried; spread out in a warm, airy place for a few days to cure, then braid ’em together and hang ’em up.

PEPPER: Bell peppers are usually picked while still green (before they turn yellow or red); they can be harvested for home use when quite young, but the fruit will wilt quickly. Cut, don’t tear the fruit from the plant and leave a portion of the stem on the fruit.

POTATO: Can be harvested at any size but usually best to let them grow to full size (until the vines die off), barring market considerations. The vines should be dead before harvest for 2 reasons: (1) So the skins will “set” (harden); (2) To prevent transfer of late blight spores from the vines to the tubers which can cause them to rot; vines can be killed by topping or with Gramoxone or Reglone. Handle carefully to avoid bruising.

RADISH: Harvest can start as soon as they reach small acorn size. Once much bigger than 1”, they begin to split and get hot and pithy. Normal harvest is 3-4 weeks after planting. Use the tops as greens (much higher in vitamins, minerals).

SQUASH: Summer varieties like Zucchini and Yellow Crookneck are ready when the thumb makes an imprint on the skin; winter types are ready when the skin resists thumb pressure; cut off the fruits, don’t twist or pull (avoids vine damage).
SWEET POTATOES: Best way is to dig up a few and see if they're the size you want; small fruits have more flavor and are easier to bake; large tubers mean larger yields. Yellowing of the lower leaves is usually a sign of approaching maturity.

TOMATO: For canning and pasta, harvest fully ripe; for local markets, pick at the hard ripe to pink stage. For distant shipping, at the mature green stage. The longer they can be left on the vine, the higher the quality. Mature greens ripen in 6-20 days at 70°F and don't color faster at higher temperatures; keep out of sun; ripen best in dark.

Mature green test: Cut cross-wise with a sharp knife; if the seeds give way without being cut, it's mature; fruit also has a brownish ring at the stem scar after the calyx (cap) is removed, and the light green color at the blossom end has turned yellow green.

Hard ripe stage: nearly all red or pink but flesh is firm.

Over-ripe: Fully colored but soft.

Leaving fruits on the vine won't reduce yields.

TURNIPS: When roots reach 2 to 2-1/2" in diameter; use the tops as greens; they're much higher in vitamins and minerals.

WATERMELON: Don't harvest immature or won't have good flavor or color; here's several tests:

1. "Thump" test: Green ones have a metallic ring; mature ones, a muffled sound.

2. Watch the tendrils (pig tails) on the stem near the fruit; the 1st tendril going to the fruit will die (wither) first, but don't pick yet; wait till the tendrils on either side of the one attached to the fruit die.

3. Watch bottom of melon where it rests on the ground; when it changes from white to light yellow with little or no green, it's ready.

4. The melon will lose its shine and have a slight cast to it. Leave about 2" of stem attached to the fruit when picking.
INTRODUCTION TO INSECTS AND INSECT CONTROL

I. SOME IMPORTANT FACTS ON INSECTS

How Insects Damage Plants

Insects can often be identified by the type of damage they cause:

1. Chewing and Boring Insects

   a. Caterpillars are larvae of moths. They damage plants by feeding on leaves and making holes in them or by boring into stalks, pods, and maize ears. The cutworm caterpillar is unusual in that it lives in the soil and emerges at night to cut off plant stems near ground level.

   b. Beetles feed on plant leaves and chew holes in them; some beetles of the weevil family bore into pods and seeds and deposit eggs inside. Certain beetles can also transmit bacterial and virus diseases.

   c. Most beetle larvae like white grubs, wireworms, and rootworms live in the soil and damage roots and the underground portion of the stem by chewing or boring. A few beetle larvae such as those of the Mexican bean beetle and Colorado potato beetle live above ground and feed on leaves.

2. Sucking Insects

   Aphids, leafhoppers, stinkbugs, harlequin bugs, whiteflies, and mites have piercing and sucking mouthparts and feed on plant sap from leaves, pods, and stems. They transmit a number of plant diseases, especially viruses. Sucking insects do not make holes in the leaves but usually cause leaf yellowing, curling, or crinkling.

Insect Life Cycles

A general understanding of insect life cycles will also help you identify insect problems in the field. Beetles and moths go through a complete metamorphosis (changes in form) of 4 stages, while aphids, leafhoppers, whiteflies and other sucking insects go through only 3 stages.

\[
\begin{align*}
\text{(Adult stage)} & \quad \text{MOTH} \quad \text{EGG} \quad \text{CATERPILLAR} \quad \text{PUPA} \\
\text{(Does no damage)} & \quad \text{(Usually feeds on leaves)} \quad \text{(Dormant stage; turns into a moth)}
\end{align*}
\]

\[
\begin{align*}
\text{(Adult stage)} & \quad \text{BEETLE} \quad \text{EGG} \quad \text{LARVA} \quad \text{PUPA} \\
\text{(Feeds on leaves, pods)} & \quad \text{(Grubs, wireworms, rootworms, etc. Feed on plants roots.)} \quad \text{(Dormant stage; turns into a beetle.)}
\end{align*}
\]
II. HOW TO IDENTIFY INSECTS AND THEIR DAMAGE

1. BE OBSERVANT! Troubleshooting takes practice, but a sharp eye is essential. When walking through a field, closely examine the plants for insects or their damage symptoms. Check both sides of the leaves since many insects prefer the undersides of leaves. A magnifying glass can be very helpful.

2. Identifying Insect Damage:* Very often you'll be able to identify insects by the damage they cause.

   a. Holes in leaves: Caterpillars, beetles, crickets, snails, and slugs; snails and slugs aren't insects but do attack plant foliage (look for slime trails on leaves). Caterpillars leave green or brown sawdust-like excrement.

   b. Wilting: Soil insects like white grubs and wireworms if root feeding or tunneling of the underground portion of the stem has been serious; stem borers. Remember that wilting can be caused by other factors too: dry soil, very high temperatures, root rots, bacterial and fungal wilts, and nematodes.

      (1) Dig up the affected plants and check the root system and underground portion of the stem for insect and disease damage; look for soil insects.

      (2) Slit the stem lengthwise with a pocket knife and check for borers or rotted tissue.

   c. Leaf curling, crinkling, or yellowing: Sucking insects, especially aphids, leafhoppers, and mites. Viruses and some nutrient deficiencies also produce these symptoms. Nematodes and poor drainage cause yellowing too.

3. Identifying Insects: Spend time with locally experienced extension workers in the field and have them point out the prevalent crop insect pests (and beneficial predator insects) in your work area. Seek out host country or regional insect guides such as extension bulletins. The publications listed below are also very useful:

* Refer also to the troubleshooting guide to common crop problems on pp. 158-162.
III. THE USE OF SCIENTIFIC NAMES FOR INSECTS

Each insect is known by many different local names throughout the world, which can make proper identification confusing. Fortunately, all insects (as well as plants, animals, and diseases) are assigned standardized scientific names derived from Latin.

Example: The corn earworm has been given the scientific names of Heliothis zea. The first word of the two part name refers to the insect's genus and the second part of its species.

Host country agronomists and extension workers may often refer to insects using their genus such as "Heliothis". Farmers will usually use local names for insects. Since this genus-species is being continually revised, an insect may have more than one commonly used scientific name; for example, the fall armyworm has had its scientific name changed from Laphygma frugiperda to Spodoptera frugiperda. When referring to several insects of different species that are all within the same genus, publications will often place the abbreviation "spp." after the genus. Thus, Heliothis spp. refers to several types of heliothis caterpillars.

IV. METHODS OF INSECT CONTROL AND THEIR EFFECTIVENESS

Let's compare the effectiveness of non-chemical, chemical, and integrated insect control methods:

NON-CHEMICAL METHODS

Natural Balance

Many natural controls act to keep insects in balance:

1. Weather factors like temperature and rainfall can restrict the distribution of an insect species; for example, mites and leafhoppers are usually more prevalent under dry conditions.

2. Geographic barriers like large bodies of water, mountains, and deserts can also limit insect distribution.

3. Frogs, toads, lizards, moles, and birds are some of the many animals that feed largely on insects.

4. Beneficial predator insects like lady bugs feed on aphids, while others like the braconid wasp and tachinid fly lay eggs on or
certain pests which are killed by the developing larvae. Some predator insects like praying mantis also eat beneficial insects as well, however.

5. Insects are also attacked by viruses, fungi, and bacteria which help keep populations down.

As agricultural activities have increased, many of these natural balances have been upset and can no longer be relied upon to keep harmful insects under control. Monoculture and the existence of vast areas under cropping have led to marked increases in a number of insect pests. Many of the traditional crop varieties, despite their lower productivity, have better insect resistance than some of the improved varieties. Indiscriminate use of pesticides has also resulted in an actual buildup of harmful insects in some cases.

Biological Control

Biological control is the purposeful introduction of predators, parasites, or diseases to combat a harmful insect species. About 120 different insects have been partially or completely controlled by this method in various parts of the world. Microbial insecticides such as Bacillus thuringiensis (effective against a few types of caterpillars) are now commonly used by farmers and gardeners in many areas. Unfortunately, biological control measures are presently effective against a very small portion of harmful insect species.

Cultural controls

Cultural controls such as crop rotation, intercropping, burying crop residues, timing the crop calendar to avoid certain insects, and controlling weeds and natural vegetation that harbor insects are all effective control methods for some insects. In most cases, however, cultural controls need to be supplemented by other methods.

Varietal Resistance

Crop varieties vary considerably in their resistance to certain insects. For example, maize varieties whose ears have long, tight husks show good resistance to earworms and weevils; CIAT found that some bean varieties were relatively unaffected by leafhopper damage during the wet season, while others suffered yield losses up to 40%. Screening for insect resistance is an important part of crop breeding programs.

"Organic" Controls

"Organic" control refers to non-chemical methods in general, including the application of homemade "natural" sprays made from garlic, pepper, onions, soap, salt, etc., and the use of materials like beer to kill slugs and wood ashes to deter cutworms and other insects. Some of these "alternative" insecticides are slightly to fairly effective on small areas like home gardens and where insect populations are relatively low. They are seldom feasible or effective on larger plots, especially under tropical conditions that favor insect buildup.
CHEMICAL CONTROL

Chemical control refers to the use of commercial insecticides in the form of sprays, dusts, granules, baits, fumigants, and seed treatments. While some of these insecticides like Bacillus thuringiensis, rotenone, and pyrethrin are naturally derived, most are synthetic organic compounds that have been developed through research.

Advantages of Insecticides

1. Rapid action.
2. They are the only practical means of control once an insect reaches the economic threshold of damage on a commercial size plot.
3. Insecticides are available in a wide range of properties, species effectiveness, and application methods.
4. They are relatively inexpensive, and their proper usage can often return $4-$5 for every $1 spent.

Disadvantages of Insecticides

1. Insect resistance to pesticides is a growing problem. In 1961, about 60-70 species had developed resistance to certain products, and the number had increased to around 200 by the mid-1970's.
2. Outbreaks of secondary pests: Few insecticides kill all types of insects, and some actually promote the increase of certain pests. For example, continual use of Sevin (carbaryl) in the same field may increase problems with some types of aphids which it doesn't control well.
3. Damage to non-target species such as beneficial predators, bees, and wildlife.
4. Residue hazards: Some chlorinated hydrocarbon compounds like DDT, Aldrin, Endrin, Dieldrin, and Heptachlor are highly persistent in the environment and may accumulate in the fatty tissues of wildlife, livestock, and humans. It's important to realize that many other insecticides are broken down into harmless compounds fairly rapidly.
5. Immediate toxicity: Some insecticides are extremely toxic in small amounts to humans and animals. Again, it's important to realize that insecticides vary greatly in their toxicity.

Current Status of Insecticide Use

At the present time and for the immediate future, insecticide usage will often be an essential part of any package of improved practices for the reference crops. For this reason, we urge all ag field workers to learn the basic principles of safe and effective insecticide application. Even though you may be personally opposed to these chemicals, you should realize that farmers throughout the LDC's are using them, often in an unsafe and indis-
criminate manner. Most of these countries have few, if any, pesticide regulations or restrictions on environmentally harmful products like Aldrin or highly toxic ones like Parathion. By instructing farmers in safety precautions and in the appropriate choice and use of insecticides, the incidence of human poisoning and possible environmental damage can be greatly reduced.

INTEGRATED PEST CONTROL

The disadvantages of total reliance on insecticides have given rise to integrated pest control or pest management which involves the judicious use of these chemicals based on the following guidelines and principles:

1. The development and use of cultural and other non-chemical control methods to avoid or reduce insect problems.

2. (Economic Threshold) Determining crop tolerance to pest damage based on the principle that complete freedom from pests is seldom necessary for high yields. Nearly all plants can tolerate a surprising amount of leaf loss before yields are seriously affected.

3. The appropriate timing and frequency of treatments to replace routine, preventative spraying. Treatments are not initiated before the particular insect has reached the economic damage threshold which will vary considerably with the species. Insect scouting and population counts are an essential part of this system.

The advent of integrated pest control dates back to the early 1970's, and much of the efforts have been directed at cotton where insecticides frequently account for up to 80% of total production costs. Some remarkable successes have been achieved with other other crops as well. In terms of the reference crops, integrated pest control is still in the very early stage, especially in the LDC's.
SOME "ORGANIC" (NON-CHEMICAL) PEST CONTROLS

CUTWORMS: Place a collar made of cardboard or a paper cup around the stem so that it extends from about 2 cm below the soil surface to about 5 cm above ground. Don't place the collar deeper or you may restrict the root system of the transplant. Wrapping the stem with several layers of newspaper or a couple layers of tin foil works great too. So do small juice cans or beer cans cut down to the right size.

SLUGS & SNAILS: Stale beer (or water and yeast) placed in shallow pans in the garden is very effective at attracting and drowning the critters. However, if the container is placed on top of the mulch, slugs are unlikely to reach it. Other remedies are:

1. Place a wide board on the ground in the late afternoon. By next morning, lots of slugs and snails can be found under it; crush them.

2. Sprinkling coarse sand, wood ashes, lime, or diatomaceous earth around the plants' base will repel them. (Caution: too much lime may raise the pH too much.)

3. If using mulch, keep it several inches away from the plant rows; slugs like to hide and feed under it.

4. Keep the field clean of weeds and debris.

ANTS: Pouring boiling water over nests is very effective for fire ants. Steamed bone meal supposedly repels ants (don't try making your own bone meal out of old cattle bones; they can harbor dangerous anthrax disease).

NEMATODES

1. Crop rotation: Sometimes difficult or impractical since most types of nematodes have many crop hosts (see section on nematodes later on in this tech reference package).

2. Resistant crop varieties: Varieties of a crop will vary in their resistance, and some (i.e. Roma VFN and Better Boy VFN tomatoes, Nemagold sweet potatoes, and others) are good enough to rate the name "nematode resistant variety". Check out what's available in your host country.

3. Plowing up roots of nematode infested crops right after harvest will expose them to sunlight and drying, which will kill many of the nematodes; however, many are likely to be left in the soil itself.

4. Flooding: One month of flooding followed by a month of drying and a further month of flooding will greatly reduce nematode problems but is seldom practical.
5. **Antagonistic plants.** Many organic garden books suggest interplanting marigolds among susceptible crops to control nematodes. Unfortunately, research has shown that marigold species vary in their nematode fighting ability which is also limited mainly to certain types of nematodes (root knot, root lesion). Furthermore, nematodes aren't killed by marigolds but only repelled or starved out; this means that interplanting marigolds among susceptible crops isn't effective, since the nematodes still have a food source. You would need to plant marigolds solidly and exclusively for a few months. (See p. 270)

Two legume green manure or cover crops, Crotalaria spectabilis (showy crotalaria or rattlebox) and Indigofera hirsuta (hairy indigo) can reduce populations of most types of nematodes. Showy crotalaria is poisonous to livestock.

6. **Good soil fertility and high organic matter levels help somewhat.**

7. **Sugar:** 8 kg of sugar/sq. meter worked into the top 15 cm of soil is said to control root knot nematodes; this may be worth a try if you're in a low cost sugar area.

COCKROACHES: 1 lb. borax acid crystals mixed with 1 can of condensed milk (the thick, sugary stuff). Make pea size pellets out of this, place on pieces of tin foil and use one per room. Will keep a year under refrigeration. Results vary from mediocre to fairly good.

BIRDS: Soaking large seeds like maize in turpentine before planting may be a fair repellent to seed eating birds. An effective method for vegetable gardens and larger plots is continuous string flagging which uses cloth or plastic streamers 5-6 cm wide and 50-60 cm long. The streamers are attached at 1.5 meter intervals to string twine which is strung along heavy stakes at least 1.2 m tall which are spaced about 15 m apart.

ANOTHER CUTWORM REMEDY: Tie wild or cultivated onion stems around the stems of susceptible plants at the soil surface.

CORN EARWORM: Inject 1/4 of a medicine dropper's worth of mineral oil into the tip of each corn ear; begin as soon as silks appear and repeat every 3 days until silks begin to brown.

HAND PICKING: Very feasible for small areas and larger insects like beetles and caterpillars.

INTERPLANTING GARLIC AND ONIONS among other crops to repel insects: Gives poor to sometimes fair control of some insects, but don't rely on it under high insect pressure.

BENEFICIAL PREDATOR INSECTS: Lady bugs, lacewing bugs, tachnid flies, braconid wasps, praying mantids are among the more common. Where they occur naturally, they can make a big contribution. Trying to introduce them is seldom effective, since they tend to disperse.
BIOLOGICAL INSECTICIDES

1. Bacillus thuringiensis (Dipel, Thuricide, Biotrol): Made from a natural bacteria that kills many types of caterpillars such as cabbageworms, earworms, armyworms, and hornworms. Non-toxic to humans and animals. Slow acting—insects don't die immediately but stop feeding within a few hours; apply while they're still young for best results.

2. Bacillus popillae: Causes milky spore disease in Japanese beetle grubs and some other beetle grubs when applied to the soil.

HOMEMADE ORGANIC SPRAYS

All of them except nicotine spray (which isn't really "organic") will only repel some types of insects to varying degrees and may need daily application.

Bug Juice Spray: You need a strong stomach for this one, and it's of fickle effectiveness. Collect up to half a cup of a bad guy insect like cabbage loopers, stinkbugs, etc. Add 2 cups of water, place in a blender, and whiz it up. Organic Gardening says this solution can be diluted up to 1:25,000 but that sounds like a misprint! Try it 1:5 or 1:10 for starters. Use it within an hour or two or freeze it to prevent possible contamination by Salmonella bacteria (food poisoning). Clean your blender well. In some cases, bug juice actually attracts insects; cutworm juice is known to attract cutworms. Some success has been reported with aphids, cabbage loopers, and stinkbugs plus a few more. Don't use flies, ticks, fleas, or mosquitoes since they may harbor diseases or parasites.

Plant Juice Spray: Find a non-poisonous weed or plant leaf unbothered by insects; choose smooth leaf plants, not hairy ones, and then dilute no more than 5 fold with water. Wormwood is said to kill slugs, crickets, and aphids.

Hot Pepper Spray: Grind hot pepper pods and mix with an equal amount of water. Add a little soap powder. Try it at a 1:20-1:30 dilution with water. Be sure to strain it well before putting it in the sprayer tank.

Garlic-Pepper-Soap Spray: 4 crushed garlic cloves, 4 tablespoons hot pepper, one cake of strong soap, one cup of hot water. Strain and dissolve in 2-4 gallons warm water. Use as a general purpose spray. Results are variable.

Citrus and Banana Peel Spray: Let banana and citrus peels soak in a pail for several days. Spray the mixture on plants and place the spent peels at their base.

Milk Spray: Using milk full strength is deadly to many bugs but what a waste of protein! By the way, it's been shown that dipping one's hands periodically in milk or a powdered milk solution when transplanting tomatoes can significantly cut down the spread of mosaic virus by contact from plant to plant.
Salt Spray: A tablespoon in 2 gallons of water supposedly gives fair to good control of cabbage worms; 2 tablespoons/gallon supposedly controls spider mites but test a plant or two for leaf burn first with the spray.

Molasses spray: Diluted 1:50 with water and used as a general purpose spray. Sounds doubtful.

Vegetable oil: Apply with a sprayer; may kill insects by plugging up their pores.

Soap spray: For soft bodied insects like aphids, thrips, whiteflies, mites, but not leafhoppers. Vegetable or plant derived soaps are better for this than petroleum derived ones.

Nicotine Extract: For sucking insects like aphids, leafhoppers, whiteflies, thrips, and spider mites along with many other non-suckers. Most effective during warm weather. Soak 1-2 cheap shredded cigars overnite in 1 gallon water. Strain and add one teaspoon of household detergent. CAUTION: Nicotine is poisonous to humans and animals; it can be absorbed through the skin in harmful amounts. It can also spread tobacco mosaic virus to tomatoes, peppers, eggplant, and potatoes.

MISCELLANEOUS

Flour: Sprinkle on cabbage plants in early morning when dew is heavy. Supposedly controls cabbageworms and their moths by sticking to them and then hardening as it dries out.

Wood ashes: May repel some types of insects if sprinkled on plants; if spread in a ring around plants and moistened, they may repel cutworms.
USING CHEMICAL INSECTICIDES

Before using any insecticide, be sure you've read over and understood the Safety Guidelines on pp. 227-228.

I. SOME IMPORTANT FACTS ON INSECTICIDES

Pesticide Terminology

Pesticide: A general term referring to chemicals that control crop insects, weeds, diseases, and nematodes.

Miticide (acaricide): A pesticide that kills mites; mites are more related to spiders than insects and not all insecticides will kill them. Some pesticides like dicofol (Kelthane) control only mites, while others like Diazinon (Basudin) and Malathion kill mites and other insects. Sevin (carbaryl) won't control mites.

Nematocide: A pesticide that kills nematodes (see p. 268). A few insecticides like Furadan and Mocap will also control nematodes, but most will not. Some nematocides like Nemagon control only nematodes, while others like VAPAM, Basamid, and methyl bromide are general soil sterilants that kill insects, weeds, fungus, and bacteria as well.

How Insecticides Kill Insects

Nearly all modern insecticides are contact poisons that kill insects by being absorbed through their bodies. Contact poisons act as stomach poisons if eaten by insects.

Systemic vs. Non-Systemic Insecticides

Most insecticides are non-systemic and are not absorbed into the plant. Systemic insecticides are absorbed into the plant sap, and most are translocated (transported) throughout the plant. Most systemic insecticides like Metasystox, Dimethoate (Rogor, Perfekthion), and Lannate are sprayed on plant foliage. Others like Furadan, Thimet, and Di-syston are applied to the soil in a band along the crop row where they are absorbed by the plant roots and then translocated to the stems and leaves. Some of these soil applied systemics will also control certain soil insects.

When choosing between a systemic and non-systemic insecticide, you should consider the following:

1. Systemic insecticides are especially effective against sucking insects like aphids, leafhoppers, stinkbugs, and thrips since these feed on the plant sap. However, many non-systemic contact insecticides will also control sucking insects adequately.
2. Most systemics are less effective against caterpillars and beetles but may give good control of some stem borers.

3. Foliar applied systemics may remain in the plant for up to 3 weeks. Soil applied systemics may provide control for up to 6 weeks. However, this also means that they must not be applied close enough to harvest time to cause residue problems.

4. Most systemics will not harm beneficial insects.

5. Foliar applied systemics are not broken down by sunlight or washed off the leaves by rainfall as with non-systemics.

6. Since they are translocated, systemics don't require uniform spray coverage when they are applied to the leaves. New growth occurring after application is also protected.

7. Some systemics like Thimet, Di-syston, and Systox are highly toxic both orally and dermally. However, the same is also true with some non-systemics like Parathion and Endrin. See pp. 251-257.

Types of Pesticide Formulations

Most insecticides are available in several types of formulations:

1. WETTABLE POWDERS, SOLUBLE POWDERS: These range in strength from 25-95% active ingredient and are meant to be diluted with water and applied with a sprayer. Wettable powders are often abbreviated as "WP" or "W"; for example, Sevin 50 W is a wettable powder containing 50% pure Sevin by weight. Once mixed with water, wettable powders require periodic agitation (shaking or stirring) to keep them from settling to the bottom. Soluble powders ("SP") are completely soluble and do not require agitation.

2. EMULSIFIABLE CONCENTRATES ("EC" or "E") are high strength liquid formulations. Like wettable powders, EC's are meant to be diluted with water and applied with a sprayer. They contain about 20-75% active ingredient (pure chemical).

Labeling Systems for EC's: In countries using pounds and gallons, a label that reads "Malathion 5 E" would refer to a liquid formulation of malathion that contains 5 lbs. active ingredient per gallon. Where liters and grams are used, EC's are often labeled in terms of grams of active ingredient per liter; for example, Tamaran 600 is a liquid formulation of Tamaran containing 600 grams of active ingredient per liter.

3. DUSTS ("D"): Unlike WP's and EC's, dusts are low strength formulations (about 1-5% active ingredient) and are meant to be applied without dilution by a duster. Dusts are usually more expensive than WP's or EC's due to higher transport costs per unit of active ingredient; however, if dusts are blended within the country, they
may be competitive cost-wise and are especially suited to situations where a farmer has difficulty transporting water to his field. They do not stick to the leaves as well as sprays and are more easily washed off by rainfall; retention is improved if they are applied while the leaves have dew on them. Dusts pose more of an inhalation hazard than sprays. They should never be mixed with water.

4. GRANULES ("G"): Like dusts, granules are low-strength formulations meant to be applied without dilution. They’re especially well suited for soil applications and for placement in the leaf whorls of maize and sorghum to control armyworms. Granules can’t be effectively applied to leaves, because they roll off. Furadan 3G is a granular formulation that contains 3% pure Furadan.

5. BAITS are usually the most effective formulation for controlling cutworms, crickets, slugs, and snails. Most contain about 3-5% active ingredient mixed with a carrier like sawdust, bran or corn meal; usually an attractant like molasses is also added. Commercial baits may be available in your country, but it’s usually cheaper to make them up on the farm.

6. FUMIGANTS are available as pellets, granules, liquids, and gases whose fumes kill pests. They are used to kill insects in stored grain or applied to the soil to kill insects, nematodes, and other pests.

Chemical Classes of Insecticides

Most manufactured insecticides fall into 3 main chemical classes or groups:

1. CHLORINATED HYDROCARBONS (Organochlorines): Most of the insecticides in this group such as DDT, Endrin, Aldrin, Chlordane, and Heptachlor have long residue lives and have caused environmental problems. However, other members like Methoxychlor are readily biodegradable. Toxicity to humans and animals varies greatly within this group (See pp. 251-257.)

2. ORGANIC PHOSPHATES (Organophosphates): OP's such as Malathion, Dipterex (trichlorfon), Diazinon, and Parathion have much shorter residue lives than most of the Ch’s. Their toxicity to humans and animals varies greatly. Some like Parathion, TEPP, AND Thimet are highly dangerous, while others like Malathion, Gardona, and Actellic are among the safest chemical insecticides available.

3. CARBAMATES: Relatively few chemical insecticides belong to this group and they tend to be of moderate to low toxicity for humans and animals. However, a few like Furadan and Lannate (methemyl) have high oral toxicities. Sevin (carbaryl) and Baygon (propoxur) are probably the best known carbamate insecticides. The residual life of the carbamate group varies from short to moderate.
II. INSECTICIDE SAFETY GUIDELINES

1. READ AND FOLLOW LABEL INSTRUCTIONS: If the label is vague, try and obtain a descriptive pamphlet. Not all insecticides can be applied to all crops; inappropriate use can damage plants or result in undesirable residues. The label should state the minimum allowable interval between application and harvest.

2. Never buy insecticides that come in unlabeled bottles or bags; you may not be buying what you think. This is a serious problem in the LDC's where small farmers often purchase insecticides in Coke bottles, etc.

3. When working with farmers, especially those using backpack sprayers instead of tractor sprayers, NEVER use or recommend those insecticides in toxicity Class 1. Their safe use requires extraordinary precautions and safety devices (gloves, special respirators, protective clothing, etc.). Whenever possible, avoid using Class 2 products. Unfortunately, extension pamphlets in many LDC's commonly recommend Class 1 and Class 2 products.*

4. If using Class 2 insecticides, wear rubber gloves and a suitable respirator (good ones cost $15-$25), as well as long pants and long sleeve shirt; wear rubber boots if using a backpack sprayer. This clothing should be washed separately from other garments.

5. Don't handle plants within 5 days after treatment with a Class 1 insecticide or with Guthion (Guthion). Don't handle plants within one day of using methyl parathion.

6. Class 1 and 2 insecticides are likely to be especially common in tobacco and cotton growing areas.

7. Don't smoke or eat while applying pesticides; wash up well afterwards.

8. Repair all leaking hoses and connections before using a sprayer.

9. Prepare insecticide solutions in a well ventilated place, preferably outdoors.

10. Never spray or dust on very windy days or against a breeze.

11. Notify beekeepers the day before spraying.

12. Insecticide poisoning hazards increase in hot weather.

13. Store insecticides out of reach of children and away from food and living quarters. Store them in their original labeled containers which should be tightly sealed.

* Refer to toxicity table on pp. 251-257.
14. Leftover spray mixtures should be poured into a hole dug in the ground well away from streams and wells.

15. Don't contaminate streams or other water sources with insecticides either during application or when cleaning equipment.

16. Make sure insecticide containers are never put to any other use. Burn sacks and plastic containers (don't breathe the smoke): punch holes in metal ones and bury them.

17. Make sure that farmers are well aware of safety precautions. It's important that they understand that insecticides vary greatly in their toxicity, but that all are dangerous.

18. Make sure that you and your client farmers are familiar with the symptoms of insecticide poisoning and the first aid procedures given below.

19. Observe the minimum application to harvest interval for the particular insecticide and crop involved. (See table on p. 231.)

A Special Note on ALDRIN, DIEELDRIN, ENDRIN, DDT, HEPTACHLOR, and CHLORDANE:
Use of these chlorinated hydrocarbon insecticides has been severely restricted or banned in the U.S. and several other countries due to their persistence in the environment, fish kill, and accumulation in the body fat of humans and animals. Few LDC's have enacted pesticide regulations, so expect to see these freely marketed.

What about Fungicides?: Except for mercury based fungicides used for seed treatment like Agallol, Semesan, and Ceresan, fungicides pose relatively little hazard to health. Their oral toxicity is comparatively low, and there is little danger of dermal absorption. Some may cause allergies in sensitive people through skin contact and can be eye irritants as well.

What about Herbicides?: PARAQUAT (Gramoxone) has an unusually high oral toxicity and even a small amount can be fatal. Give clay or activated charcoal (mixed with water) orally immediately to deactivate the poison.

RELATIVE TOXICITY RATINGS FOR INSECTICIDES

Insecticides vary greatly in their relative toxicity to humans which is measured in terms of an LD₅₀ rating (LD = lethal dosage). The LD₅₀ rating indicates the amount of 100% strength chemical (i.e. active ingredient) needed to kill 50% of the test animals (usually rats or rabbits). Both oral and dermal (skin absorption) ratings are determined.

Before using any insecticide, you should be aware of its particular LD₅₀ rating. Ratings for most insecticides can be found in the toxicity tables on pp. 251-257.

III. SYMPTOMS OF INSECTICIDE POISONING

Organic Phosphates & Carbamates (Parathion, Malathion, Sevin, etc.)
Both groups affect mammals by inhibiting the body's production of the enzyme cholinesterase which regulates the involuntary nervous system (breathing, urinary and bowel control, and muscle movements).

**Initial Symptoms:** Dizziness, headaches, nausea, vomiting, tightness of the chest, excessive sweating. These are followed or accompanied by blurring of vision, diarrhea, watering of the eyes, excessive salivation, muscle twitching, and mental confusion. Tiny (pinpoint) pupils are another sign.

**Late Symptoms:** Fluid in chest, convulsions, coma, loss of urinary or bowel control, loss of breathing.

NOTE: Repeated exposure to these organic phosphate and carbamate insecticides may increase susceptibility to poisoning by gradually lowering the body's cholinesterase level without producing symptoms. This is a temporary condition. Commercial insecticide applicators in the U.S. usually have their cholinesterase levels routinely monitored.

**Symptoms of Chlorinated Hydrocarbon Poisoning (Aldrin, Endrin, Chlordane, Dieldrin, etc.).**

Apprehension, dizziness, hyperexcitability, headache, fatigue, and convulsions. Oral ingestion may cause convulsions and tremors as the first symptoms.

**IV. FIRST AID MEASURES**

1. In severe poisoning, breathing may stop which makes mouth to mouth resuscitation the first priority; use full CPR if the heart has stopped.

2. If the insecticide has been swallowed and the patient has not vomited, induce vomiting by giving a tablespoon of salt dissolved in half a glass of warm water; an emetic like Emesis (syrup of Ipecac) may be more effective. This should be followed by 30 grams (1 oz.) of activated charcoal dissolved in water to help absorb the remaining insecticide from the gut.*

3. Get the patient to a doctor as soon as possible. Bring along the insecticide label.

4. In the meantime, make the patient lie down and keep warm.

5. If excessive amounts are spilled on the skin (especially in the concentrate form), immediately remove clothing and bathe the skin in generous amounts of water and soap.

6. If the eyes have been contaminated by dusts and sprays, flush them immediately for at least 5 minutes with copious amounts of water; insecticide absorption through the eyes is very rapid.

* Activated charcoal is made by heating charcoal to drive off its absorbed gasses.

- 229 -
WHAT ABOUT ANTIDOTES?

Whenever possible, antidotes should be given only under medical supervision. Too much or too little can be fatal. If the patient is unconscious or vomiting, antidotes need to be injected.

Antidotes for Organic Phosphate Insecticides

Atropine (atropine sulfate) is the general antidote, especially in the early stages. Diazepam (an anti-convulsant) is often used along with atropine. 2-PAM (2-pyridine aldoxime methiodide) is used in the advanced stages of organic phosphate poisoning where atropine becomes ineffective.

Atropine Dosage: Usually 2 tablets (1/100th grain each) are given immediately, followed by additional dosages at hourly intervals until the pupils of the eyes dilate (enlarge). Up to 0.3 grains per day (30 tablets) may be given to control respiratory symptoms if needed. CAUTION! Atropine may give only temporary relief of what may prove to be a serious case of poisoning; if treatment is halted too soon, symptoms may reappear. DO NOT TAKE ATROPINE AS A PREVENTATIVE!

Antidotes for Carbamate Insecticides

Use atropine as above. DO NOT USE 2-PAM for carbamate poisoning. Diazepam (an anti-convulsant) is often used along with atropine.

Antidotes for Chlorinated Hydrocarbon Insecticides

Diazepam or phenobarbitol are often used to control convulsions.

WARNING: Do not treat lightly what appears to be only a mild case of poisoning. Always seek medical attention, especially when antidotes have already been used—they may wear off and bring on a recurrence of symptoms.

BEE POISONING HAZARD OF PESTICIDES

Most bee poisoning occurs when insecticides are applied during the crop's flowering period. Spray drift is another hazard. Avoid bee kill by:

1. Not applying insecticides toxic to bees when crops are flowering.
2. Not dumping unused quantities of dusts or sprays where they might become a bee hazard; bees will sometimes collect any type of fine dust when pollen is scarce.
3. Using insecticides of relatively low toxicity and residual effect for bees.
4. Plugging up or covering the hive entrances the night before spraying and then reopening them once the residual effect is over.

### V. GUIDELINES FOR APPLYING INSECTICIDES

When is Treatment Necessary?

1. **Farmers should apply insecticides in response to actual insect problems rather than on a routine and indiscriminate basis. Ideally, insecticides should be used only when damage has reached the economic threshold which varies with insect species, the crop, and the type and extent of damage.**

2. **General guidelines (see also the unit on major reference crop insects):**

   a. **Soil insect problems should be treated preventatively in the sense of making pre-planting or at-planting insecticide applications if a known problem exists. Treatments after planting are generally not effective except in the case of cutworm baits.**

   b. **Leaf eating insects (beetles, caterpillars): Crops can tolerate considerable defoliation as long as new leaves are being**
continually produced. However, loss of leaf area becomes more serious as the vegetative stage nears its end, although defoliation in the very late stages of grain development won't have a big effect on yield.

c. When present, stem borers usually cause more serious damage at much lower populations than most leaf eating insects. The sorghum shoot fly, sorghum midge, and one species of bean leafhopper (Empoasca kraemeri) are other examples of insects that reach the economic threshold of damage at relatively low populations.

d. Sucking insects: Not all species of aphids and leafhoppers spread virus diseases. For example, CIAT found that bean yields were reduced about 6% for each Empoasca kraemeri leafhopper present per leaf, even though this species does not transmit any viruses. Bean plants can tolerate aphids well unless they are of a species capable of transmitting common bean mosaic virus.

USING A SPRAYER EFFECTIVELY

Achieving the Correct Coverage

The extent and uniformity of coverage needed depend on the insects' location and whether or not a systemic insecticide is being used. In some cases such as armyworms feeding in the maize leaf whorl, the insect is very localized, so general coverage isn't needed. Other insects are more general feeders and require thorough spray coverage over the whole plant. Since they are translocated, systemic insecticides do not require as uniform coverage as non-systemics.

How Much Water is Needed for Adequate Coverage?

This varies with plant size, density, type of product (systemic vs. non-systemic), and insect location, but here are some rough guidelines:

Water rates for insecticides: When covering the entire foliage of full size plants, use at least 500-550 liters of water per hectare (55-60 gals./acre) when using conventional sprayers. When spraying is localized or plants are very small, water volume may be only 1/4 this amount.

You can tell if too much spray is being applied if there is a visible amount of runoff from the leaves, although this can also be caused by not using enough wetting agent (spreader; see below).

Use a Spreader and a Sticker to Improve Coverage and Adhesion

A spreader (wetting agent) reduces the surface tension of spray droplets, allowing them to spread out rather than remain as individual globules on the leaf surface. Spreaders markedly improve the uniformity of spray coverage and also help prevent droplets from rolling off the leaves.
A sticker (adherent) is a glue-like substance that helps the spray stick to the leaf surface and resist being washed off by rainfall or sprinkler irrigation.

Many commercial stickers and spreaders are available, including combination sticker-spreaders. Some insecticide formulations already contain them (check the label), but many do not. In some cases, a sticker and/or spreader isn't recommended (check the label). If spraying the soil, neither a spreader or a sticker is needed; when spraying the leaf whorl of maize, a spreader isn't needed though a sticker might be helpful. Use of a sticker and spreader is especially important when applying most foliar fungicides.

Homemade stickers and spreaders: Egg white, cassava (yuca, manioc) flour, and corn starch can be used as stickers at about a tablespoon (15 cc) per 15 liters. Liquid dishwashing detergent makes a satisfactory spreader at about one half the above rate. Commercial stickers and spreaders are relatively cheap. Dissolved hand soap can also be used.

Non-ionic spreaders: Paraquat (Gramoxone) and diquat (Reglone) post-emergence herbicides are unusual in that they require the use of special non-ionic spreaders in order to avoid deactivation (loss of effectiveness). Such spreaders do not ionize into + and - charged molecules as with most types. Ortho-77 is one commonly available non-ionic spreader.

Choosing the Right Type of Spray Nozzle

Spray nozzles are available in a wide variety differing in output, spray pattern angle, and type of spray pattern. Proper nozzle selection has an important influence on pesticide effectiveness.

Nozzle Output: Many backpack (knapsack) sprayers come equipped with adjustable nozzles which allow the farmer to vary the output by making the spray finer or coarser. This would seem to be an advantage, but such nozzles usually don't maintain their setting well and output can change considerably during application; this is unsatisfactory where accurate dosages are necessary, and it makes sprayer calibration difficult. Fixed orifice nozzles are available in a wide range of outputs and should be used whenever possible.

Spray Pattern Angle: See under flat spray nozzles below.

Type of Spray Pattern: Care should be taken to choose the right spray pattern for the job.

1. Flat (Fan) Spray Nozzles are ideal for making broadcast (full coverage) applications of insecticides or herbicides over the soil surface and small weeds. The application rate decreases at both edges, so the spray patterns of adjacent nozzles should be overlapped about 3-4 fingers width at the soil surface to achieve even distribution (see boom sprayer guidelines in section H of this chapter). Fan nozzles don't provide as good a coverage as cone nozzles when used to spray crop foliage. Fan nozzles are available in several different angles of spray width; wider angles allow the spray boom to be carried closer to the ground and this lessen spray drift problems on windy days.
2. **Even Flat (Fan) Spray Nozzles** should be used for making "band applications of pesticides to the soil." Spray output does not decrease at the edges, so spray patterns should not be overlapped and used for broadcast applications.

3. **Solid Cone Spray Nozzles** provide better coverage of plant foliage than fan nozzles but should not be used to apply herbicides and insecticides to the soil.

4. **Hollow Cone Spray Nozzles** offer somewhat better foliar coverage than solid cone nozzles due to greater leaf agitation as the spray pattern passes over the plants.

5. **WhirlChamber (nonclog) Spray Nozzles** are special wide angle hollow cone nozzles that can be used in place of fan nozzles. Their design reduces clogging, and drift is minimized because of the wide angle pattern (enabling lower boom height) and larger droplet size.

**Nozzle Screens:** Nozzles used on tractor boom sprayers usually have mesh or slotted strainers to help prevent clogging. Some backpack sprayers have strainers or can have them added on. Routine cleaning is required, especially when wettable powders are used.

**Tips on Using Backpack Sprayers to Apply Insecticides**

1. Use good pressure and a fairly fine spray; pressure is too high if excessive spray drift (misting) occurs.

2. Maintain a steady pace through the field; avoid pausing at each plant unless the crop is very large.

3. Rotate your wrist while spraying so that the spray hits the foliage from different angles.

4. Keep the nozzle far enough away from the foliage so that the spray has a chance to spread out before hitting the leaves.

5. If using a wettable powder, remember to periodically shake the sprayer to keep the pesticide in solution.

6. Keep a piece of soft wire handy for cleaning out clogged nozzles, but use it gently to avoid damaging the nozzle opening.

7. Don't spray plants when their leaves are wet or when rain is likely within a few hours afterwards.

8. Don't add wettable powders or EC's directly to the sprayer tank but first mix them thoroughly in a bucket with several liters of water; make sure wettable powders are completely dissolved.
PESTICIDE COMPATABILITY

Most pesticides are compatible with each other in the spray tank, but check the label to make sure. In some crops like peanuts and vegetables, foliar insecticides and fungicides are often applied together. Maneb, Zineb, Captan, Manzate, and the Dithanes are compatible with most insecticides. Most copper base fungicides are incompatible with most insecticides; lime sulfur and Bordeaux fungicides are incompatible with each other and nearly all other pesticides.

Spray compatibility charts are available from many pesticide companies.

Water pH

Water with a pH of 8.0 or above (alkaline) causes a rapid breakdown of organic phosphate insecticides like Malathion, Dipterex, and Diazinon. Such high pH water is usually confined to limestone or low rainfall areas. Special buffering agents are available to lower the pH if necessary.

Plant Sensitivity to Insecticides

Certain insecticides are phytotoxic (injurious) to certain crops. Always check the label instructions.

Sorghum: Dipterex (trichlorfon) causes severe injury; Azodrin (Nuvacron, monocrotophos) and methyl parathion cause some injury.

Peanuts: Minor foliar injury which shows up as reddish brown spots on the earliest leaves is sometimes caused by soil applications of Furadan (carbofuran), Thimet, and Disyston. The plants usually outgrow the damage with no yield reduction. Runner varieties on sandy soils are the most sensitive, and dosage should be reduced by 25% under these conditions.

NOTE: In the case of sensitive crops, wettable powder formulations tend to be less phytotoxic than EC's, especially at temperatures over 32°C (90°F).
TABLE 21

General Effectiveness of Some Insecticides

Most insecticides will not give satisfactory control of all types of insects. For additional information in this manual, refer to the insecticide descriptions and recommendations put out by your country's extension service as well as the insecticide's label; ask for technical information from pesticide distributors.

</tbody>
</table>

1. These products pose safety and/or environmental hazards; see pp. 226-230.
2. B. thuringiensis is effective only against certain caterpillars, among which are cabbage loppers and hornworms.

NOTE: + = effective
- = little or no effectiveness
VI. SOME INSECTICIDE RECOMMENDATIONS FOR THE REFERENCE CROPS

Contents: 
- Baits for cutworms, slugs, and snails.
- General dosage recommendations for common insecticides and product information.
- Some specific insecticide recommendations for the reference crops.

Some Important Advice

1. Whenever possible, rely on the insecticide recommendations of your country's extension service if they are known to be effective and if they do not involve the use of high toxicity Class I chemicals (see pp. 251-257).

2. Before using any insecticide, refer to the safety guidelines on pp. 227-228 and toxicity data on pp. 251-257. Always know the relative toxicity and environmental hazards of the products you use or recommend.

Baits for Cutworms, Slugs, and Snails

Cutworms are most effectively controlled with baits rather than with sprays. Scatter the baits near the plants in the late afternoon if rainfall is unlikely. Don't leave the bait in clumps which might poison birds or livestock. One kg of bait should cover about 400 sq. meters (4300 sq. ft.).

Cutworm bait recipe:

- 25 kg of carrier (sawdust, rice bran, maize flour, etc.)
- 3 liters of molasses
- 1 - 1.25 kg active ingredient of Dipterex (trichlorfon) or Sevin (carbaryl)

Add water, if needed, to make the bait moist.

Slugs and snails can be controlled by applying baits in the late afternoon in a band along the field's borders or within problem areas. Don't apply if rain is expected that night.

Slug and snail bait recipe:

- 25 kg maize flour or bran
- 10 liters molasses
- 65 grams metaldehyde (a stomach poison of low dermal toxicity) or 0.5 kg active ingredient Dipterex (trichlorfon) or 0.5 kg active ingredient Sevin (carbaryl).
Information on Common Insecticides and General Dosage Rates*

General dosage are given for the insecticides listed below. Whenever possible, follow label dosage instructions rather than relying solely on this manual.

NOTE: All tablespoon and teaspoon recommendations are in terms of level ones and are based on measuring spoons.

Some Conversions

1 TABLESPOON (measuring type) = 3 teaspoons = 15 cc.
1 LITER = 1000 cc = 1000 ml = 1.06 U.S. quarts
1 U.S. GALLON = 3.78 liters = 16 U.S. cups = 128 fluid oz.
1 FLUID OUNCE = 30 cc = 2 tablespoons
1 KILOGRAM = 1000 grams = 2.2 lbs.
1 POUND = 454 grams = 0.454 kg

Bacillus thuringiensis  Kelthane (dicofol)  Methyl Parathion
Diazinon (Basudin)  Lannate (methomyl)  Sevin (carbaryl)
Dimethoate (Perfektion)  Labaycid (fenthion)  Tamaron (Monitor)
Dipterex (trichlorfon)  Malathion  Volaton (phoxim)
Furadan (carbofuran)  Metasystox

Lannate, methyl parathion, and Tamaron are Class 2 toxicity (dangerous) but frequently used by small farmers. Their dosage are given below not to encourage their use but so that at least you'll know if farmers are using higher rates than needed.

BACILLUS THURINGIENSIS

A biological insecticide made from a natural bacteria that kills only certain types of caterpillars; most effective against cabbage loopers but also against hornworms (Protoparce) and earworms (Heliothis). Non-toxic to humans and animals. Insects don't die immediately but stop feeding within a few hours—it may take a few days for them to die. Apply before the caterpillars are large for best results. Needs no sticker-spreader for most formulations. Compatible with most other pesticides. Don't store the diluted spray for more than 12 hours. Dosage varies widely with the particular formulation.

DIAZINON (Basudin, Diazol, etc.)

Fairly broad-spectrum including control of many soil insects but not as effective on beetles (except for the Mexican bean beetle). Highly toxic to bees (see p. 230).

Above-ground insect control: 4 cc/liter or 1 tablespoon/gallon of Diazinon 25% EC or Basudin 40% WP.

* If you are unfamiliar with methods of stating pesticide dosage, refer to pp. 244-245.
Soil insects: See the specific reference crop recommendations at the end of this unit.

DIMETHOATE (Perfekthion, Cygon, Rogor, etc.)

A systemic insecticide of moderate toxicity to humans (Class 3). Specifically for sucking insects (aphids, leafhoppers, thrips, stinkbugs, mites, etc.) and leaf miners. Should provide control for 10-14 days. Don't apply within 14-21 days of harvest. Highly toxic to bees with a 1-2 day residual effect.

General dosages for the 3 most common formulations (all EC's) are given below:

<table>
<thead>
<tr>
<th>Formulation of dimethoate</th>
<th>Dosage Fl. oz/100 gals.</th>
<th>cc/100 liters</th>
</tr>
</thead>
<tbody>
<tr>
<td>200 grams active ingred./liter</td>

<td>100-200</td>
</tr>
<tr>
<td>400 grams a.i./liter</td>
<td>7-13</td>
<td>50-100</td>
</tr>
<tr>
<td>500 grams a.i./liter</td>
<td>7-10</td>
<td>50-75</td>
</tr>
</tbody>
</table>

DIPTEREX (Trichlorfon, Dylox, Danex, Klorfon, etc.)

Provides fairly broad-spectrum insect control but not as effective on aphids, mites, and thrips. Dipterex causes severe injury when applied to sorghum. Low to high toxicity for bees with 2-5 hours residual effect. Class 3 toxicity for humans.

General above-ground insect control: 125-250 cc (100-200 grams) of Dipterex SP 95 per 100 liters of water or 5-10 cc (1-2 teaspoons) per gallon.

Armyworms or earworms feeding in the leaf whorl of maize: Dipterex 2.5% granules give longer control than sprays; apply a pinch in each whorl which works out to about 10-15 kg/ha (lbs./acre) of granules. 100 cc of the granules weigh about 60 grams.

FURADAN (Carbofuran)

A systemic insecticide-nematocide available in 3 granular formulations (3%, 5%, 10%) and as a wettable powder. The pure strength chemical has an extremely high oral but very low dermal toxicity (see p. 133). Furadan is usually applied to the soil either in the seed furrow or in a band centered over the crop row; it kills soil nematodes and soil insects but is also absorbed by the roots and translocated throughout the plant where it controls sucking insects, stem borers, and leaf feeding beetles and caterpillars for up to 30-40 days. Band treatments are recommended for root feeding soil insects, while seed furrow applications can be used for foliar insects. Furadan can also be band applied during the growing season if it is cultivated into the soil or can be applied to the leaf whorl or maize.
May cause minor foliar injury to peanuts; do not place in contact with sorghum or bean seed.

**KELTHANE (Dicofol, Acarin, Mitigan, Carbax)**

Kills mites only; not harmful to beneficial insects. Gives good initial control of mites and has good residual activity against them; non-systemic. Spray undersides of leaves. Don't feed crop residues to dairy or slaughter animals. Low toxicity (Class 4).

**General dosage:** Use the 35% WP formulation at 4-5 cc per liter of water or 1 tablespoon per gallon. Use the 18.5% EC at 1.5 cc per liter of water or 1 teaspoon per gallon.

**LANNATE (Methomyl, Nudrin)**

A partially systemic carbamate insecticide especially effective against caterpillars, beetles, and aphids. High oral but moderate dermal toxicity (see pp. 128-134); toxic to bees, fish, wildlife if used improperly. Don't apply within 20-25 days of harvest on peanuts or dry beans (3 days for green beans).

**CAUTION:** Wear an effective respirator mask (charcoal filter), gloves, long pants and shirt, and rubber boots when applying Lannate; goggles are advisable.

**General dosage for Lannate:** General dosages aren't advisable; Lannate is usually applied at 0.17-1.0 kg active ingredient per hectare (0.15-0.9 lbs. a.i./acre).

**LEBAYCID (Fenthion, Baytex, Baycid)**

A relatively low toxicity (Class 3) organic phosphate for chewing and sucking insects, including mites. Don't spray plants when temperatures exceed 32°C (90°F). Very toxic to bees with 2-3 days residual activity.

**General dosage for Lebaycid:** Use Lebaycid 40% WP at 1.5-2 grams per liter of water; use Lebaycid 50% EC at 1-1.5 cc/liter of water.

**MALATHION (Cythion, Unithion, Malaspray)**

A broad-spectrum insecticide of low human toxicity (Class 4). Not as effective on armyworms, earworms, and flea beetles. Its residual activity is decreased if mixed with water above pH 8.0.
Can be mixed with other pesticides except Bordeaux and lime sulfur. Liquid formulations are moderately toxic to bees with less than 2 hours residual effect; wettable powder formulations are highly toxic but have less than 1 day residual effect on bees.

**General dosage for Malathion:** 4-5 cc of Malathion 50% or 57% EC per liter of water (1 tablespoon/gallon). Use Malathion 25% WP at 12 cc/liter or 3 tablespoons per gallon.

**Household uses:** For ants, cockroaches, and spiders, use Malathion 50% or 57% EC at 40-50 cc per liter of water or kerosene (10-12 tablespoons/gallon). For fleas, use 40 cc/liter of water. For bedbugs, use 20 cc/liter of water and spray the slats, frame, and springs; spray mattress very lightly. Cythion is a special premium grade of Malathion with less odor.

**Lice on swine:** Use Malathion 50% or 57% EC at 8 cc per liter of water (2 tablespoons/gallon); don't spray pigs less than 1 month old. Repeat in 2-3 weeks if needed.

**Lice or mites on poultry:** Use Malathion 50% or 57% EC at 20 cc per liter of water or 4.5 tablespoons/gallon; spray roosts and bedding at 1-2 liters per 25 sq. meters (1-2 gals/1000 sq. ft.).

**METASYSTOX**

A systemic used mainly for sucking insects. High oral toxicity for humans; moderate for bees (no residual activity for bees). Won't harm beneficial insects. Gives control for 10-14 days. Most labels say not to add a sticker or spreader. Don't apply within 21 days of harvest.

**General dosage for Metasystox:** Bayer Leverkusen recommends that its 25% EC formulation be used at 100 cc/100 liters of water or 4 cc/gallon. Use the 50% at 50 cc/100 liters.

**METHYL PARATHION** (Folidol M, Parathion M, Nitrox, etc.)

Very toxic to humans both orally and dermally but commonly used by small farmers in many countries since it's effective against a broad range of insects. Methyl parathion is also very toxic to bees with a residual effect of less than 1 day. Rubber gloves, respirator mask (charcoal filter); full coverage clothing, and goggles should ideally be worn during application and mixing. Stay out of the field for a day after spraying. AVOID USING whenever possible. NEVER use methyl parathion's close relative, ETHYL PARATHION (E-605; Bladan, Niran, Folidol E, etc.) since it has an even greater dermal toxicity.
(Methyl parathion, continued)

General dosage for methyl parathion: Bayer recommends that its Foliol M-48 EC (49% strength) be used at 25-50 cc per 15 liters (4 gals.) of water. Don't apply within 14 days of harvest; check sprayer carefully for leaks before application. Again, avoid using whenever possible.

SEVIN (carbaryl, Vetox, Ravyn, etc.)

Broad-spectrum insect control except for aphids and mites. Very low toxicity for humans (Class 4). Very toxic to bees with a 7-12 day residual effect.

General dosage for Sevin: Use the 50% WP at 8-16 cc/liter (2-4 tablespoons/gallon). Use the 80% WP at 5-10 cc/liter or 1.25-2.5 tablespoons/gallon. Can be applied right up to harvest time on the reference crops.

Household dosages: For cockroaches and ants, use as a 2.5% strength spray (active ingredient basis); this equals about 100 cc of Sevin 80 WP per liter of water or 25 tablespoons per gallon; don't use more than twice a week.

Ticks, lice, fleas, horn flies on beef cattle, horses, swine: Use 20 cc Sevin 80% WP per liter of water (5 tablespoons/gal.). Don't spray within 5 days of slaughter.

Mites, lice, fleas on poultry: Use at same rate as for beef cattle and apply about 4 liters per 100 birds; don't apply within 7 days of slaughter.

TAMARON (Monitor, methamidophos)

A broad-spectrum insecticide-miticide with systemic and contact action. About as toxic to humans as methyl parathion and highly toxic to bees. AVOID using if possible. Follow the same safety precautions as for methyl parathion; don't use within 3 weeks of harvest.

General dosage for Tamaron: Bayer's Tamaron 600 (600 grams a.i. per liter) is recommended at 12 cc per 15 liters of water (4 gals.); use Tamaron 400 at 20 cc per 15 liters of water (see Appendix M).

VOLATON (Valexon, phoxim)

A less toxic and persistent replacement for Aldrin for soil insect control. Low toxicity for humans. Also available as a liquid formulation for leaf insects.

General dosage for Volaton: Use the 2.5% granules at 60 kg/ha (lbs./acre) for furrow application and 120 kg/ha for broadcast application. Work into the top 5-7.5 cm (2-3") of soil.
VII. INSECTICIDE MATH AND DOSAGE CALCULATIONS

This section applies to all types of pesticides. There are 4 basic ways of stating dosages:

1. Amount of active ingredient (pure chemical) needed per hectare or acre.
2. Amount of actual formulation (i.e. Sevin 50 WP or Furalon 3 G, etc.) needed per hectare or acre.
3. Amount of actual formulation needed per liter or gallon of water.
4. As a percentage concentration in the spray water.

Type 1 and 2 dosages are suited more to large plots or to those pesticides (especially herbicides) needing very accurate dosage application. Sprayer calibration (p. 248) is needed in both cases to determine how much water to use and how much pesticide to add to each tankful.

Type 3 and 4 are very general recommendations best suited to smaller plots or where dosage accuracy is not critical.

Let's look at each of these 4 types of dosages in detail to clear up any questions:

1. AMOUNT OF ACTIVE INGREDIENT NEEDED PER HECTARE (ACRE): For example, a dosage might be given as 2 kg active ingredient (ai.) Sevin per hectare. This means 2 kgs. of pure (100%) Sevin. Since actual pesticide formulations vary in strength from 1% up to 95%, it takes some math to figure out how much of a given formulation is needed to supply a given amount of active ingredient. If the local ag supply store sells Seven 50% WP, the farmer would need 4 kg for each hectare in order to supply 2 kg active ingredient.

Note that nothing is said about how much water the farmer should mix with the pesticide when he sprays it on the plants. This will depend on plant size, plant density, and the degree of coverage desired. The only way to find out how much water is needed is to calibrate the sprayer.

2. AMOUNT OF ACTUAL FORMULATION NEEDED PER HECTARE OR ACRE: For example, a recommendation calling for 4 liters of Malathion 50% EC per hectare or another one for 2.5 lbs. of Sevin 80% WP per acre. This type of recommendation is somewhat simpler than type 1 since it's given in terms of actual formulation rather than active ingredient. However, the farmer still needs to know how much formulation he needs for his field's area and how much water it will take to provide adequate coverage with his sprayer. This requires sprayer calibration.

3. AMOUNT OF ACTUAL FORMULATION NEEDED PER LITER OR GALLON OF WATER: For example, 5 cc of Malthion 50% EC per liter of water or 2 tablespoons of Sevin 80% WP per gallon of water. This type of recommen-
dation is much more convenient than types 1 and 2 since no sprayer calibration or dosage calculation is needed. The drawback is that the actual amount of pesticide the farmer applies on his field depends entirely on how fast he/she walks while spraying, how coarse or fine the spray is, and how much pressure is used. However, if proper guidelines are followed, type 3 recommendations are precise enough for most conditions and are the most feasible for small farmers. They should not be used for most herbicides where accuracy of dosage is critical.

4. **AS A PERCENTAGE CONCENTRATION IN THE SPRAY WATER:** This is basically the same as type 3, except that the concentration of pesticide in the spray water is given in terms of percent rather than cc/liter or tablespoons/gallon. Such recommendations are usually based on percentage by weight, although sometimes a volume basis is used when dealing with EC's (the actual differences are slight). In addition, the percentage figure given may refer to active ingredient or to actual formulation. We'll go over the calculations in the pesticide math selection below. As with type 3 recommendations, no sprayer calibration is needed, and dosage accuracy is not as good as with types 1 and 2.

### Pesticide Math

1. **How to convert recommendations from an active ingredient basis to an actual formulation basis.**

   a. **For solid formulations (WP's, EC's, G's)**

   \[
   \text{Amount of a.i. recommended (kg/ha, lbs./acre)} = \frac{\% \text{ active ingredient in formulation}}{\text{of actual formulation needed}}
   \]

   **Example:** A recommendation for aphids calls for using Malathion at 2 kg active ingredient/hectare. How much Malathion 40% WP would be needed per hectare?

   **Solution**

   \[
   \text{kg/ha of Malathion} = \frac{2 \text{ kg}}{40\%} = 5 \text{ kg}
   \]

   b. **For liquid formulations (EC's)**

   \[
   \text{liters/ha of EC needed} = \frac{\text{kg/ha of a.i. recommended}}{\% \text{ a.i. in EC}}
   \]

   OR

   \[
   \text{liters/ha of EC needed} = \frac{\text{kg/ha of a.i. recommended} \times 1000}{\text{grams of a.i. per liter of EC}}
   \]

   \[
   \text{Gallons/acre of EC needed} = \frac{\text{lbs./acre of a.i. recommended}}{\text{lbs. of a.i. per gallon of EC}}
   \]
Example: How much Perfekthion 20% EC would be needed per hectare if a recommendation for mites calls for 0.2 kg a.i. Perfekthion per hectare?

Solution

\[ \text{liters of Perfekthion 20\% EC needed} = \frac{0.2 \text{ kg}}{20\%} = \frac{0.2}{0.2} = 1 \text{ liter} \]

2. How to determine the amount of actual formulation needed for a farmer's field, given the dosage per hectare or acre.

Once you know how much actual formulation is needed per hectare or acre, you can easily calculate how much is needed for farmer's fields of varying sizes.

**Hectare basis**

\[ \text{Amount of formulation needed for a farmer's field} = \frac{\text{Amount of formulation needed/acre} \times \text{Field area (sq. m)}}{10,000} \]

**Acre basis**

\[ \text{Amount of formulation needed for a farmer's field} = \frac{\text{Amount of formulation needed/acre} \times \text{Field area (sq. ft.)}}{44,000} \]

Example: The local extension service recommends applying Volaton 2.5% strength granules broadcast at 120 kg/ha for controlling soil insects in maize. If Leticia's field measures 35 x 40 meters, how much Volation will she need?

Solution

\[ \text{kg of Volation 2.5\% granules needed for Leticia's field} = \frac{120 \times 1400 \text{ sq. m}}{10,000 \text{ sq. m}} = 16.8 \text{ kg} \]

3. How to follow a percentage strength spray recommendation.

Determine first whether the spray's percentage strengths to be calculated in terms of active ingredient or in terms of actual formulation. For example, you might see a recommendation for 2% strength spray in terms of pure Malathion for controlling household fleas; another recommendation might call for using a 0.1% strength spray in terms of Lebaycid 50% EC for controlling thrips on peanuts.

Use the metric system: Percentage spray calculations are much simpler in the metric system compared to using lbs., oz., and gallons. 1 liter = 1000 cc (or ml); 1 liter of water weighs 1 kg (1000 g); 1 U.S. gallon = 3.78 liters; 1 lb. = 0.454 kg = 454 g; 1 kg = 2.2 lbs.
For wettable powders

When using WP's, a percentage strength spray is based on weight of pesticide to weight of water. Since 1 liter of water weighs 1 kg, we can use these formulas:

**Active ingredient basis**

\[
\text{Grams of wettable powder} = \frac{\text{% strength spray desired} \times 1000}{\text{needed per liter of water}} \times \frac{\% \text{ a.i. in wettable powder}}{100}
\]

Example: How many grams of Malathion 40% WP should be added per liter of water to make up a 2% strength spray (active ingredient basis) for controlling household fleas?

Solution

\[
\text{Grams of Malathion 40% WP} = \frac{2\% \times 1000}{40\%} = 20 \text{ g}
\]

NOTE: Remember that in order to multiply by percent you first must move the decimal point two places to the left (i.e. 2% = 0.02; 0.1% = 0.001).

**Actual product basis**

\[
\text{Grams of wettable powder} = \frac{\text{% strength spray desired} \times 1000}{\text{needed per liter of water}}
\]

Example: How much Dipterix SP 95 is needed to make up a 0.15% strength spray (actual product basis) for controlling armyworms in maize?

Solution

\[
\text{Grams of Dipterex SP 95} = 0.15\% \times 1000 = 0.0015 \times 1000 = 1.5 \text{ g}
\]

b. For liquids (EC's)

**Active ingredient basis**

\[
\text{cc (ml) of EC needed} = \frac{\text{% strength spray desired} \times 1000}{\text{% a.i. in the EC}} \times \frac{1}{\text{per liter of water}}
\]

Example: How much Malathion 57% EC should be added per liter of water to make up a 2% strength spray (active ingredient basis) for controlling household fleas?

Solution

\[
\text{cc (ml) of Malathion 57% EC needed per liter of water} = \frac{2\% \times 1000}{57\%} = \frac{20}{0.57} = 35 \text{ cc (ml)} = 247
\]
HOW TO CALIBRATE BACKPACK AND TRACTOR SPRAYERS

When and Why Should Sprayers be Calibrated?: The farmer should calibrate his/her sprayer when a pesticide needs to be applied at an accurate dosage in order to avoid applying too much which wastes money and might injure the crop or to avoid applying too little which might make the product ineffective. When working with small fields, farmers can usually use generalized recommendations given in cc/liter or tablespoons/gallon for insecticides and most fungicides. However, most herbicides require more accurate application which means that sprayer calibration is usually needed.

The Principles Involved

When a pesticide recommendation is given in terms of kg/ha or lbs./acre of active ingredient or actual product, the farmer needs to know 2 things before he/she can apply the correct dosage:

1. The amount of pesticide needed for his/her particular field.
2. The amount of water needed to convey the pesticide to the plants or soil and give adequate coverage.

Once these are known, it's a simple matter of mixing the correct amounts of water and pesticide together and then spraying.

CALIBRATION OF BACKPACK SPRAYERS

NOTE: Only backpack sprayers with continuous pumping action should be used when calibration is needed; compression type sprayers (the garden variety that needs to be set down to be pumped up) are not suitable because of their uneven pressure.

STEP 1: Fill the sprayer with 3-4 liters of water and begin spraying the soil or crop using the same speed, coverage, and pressure that will be used in applying the pesticide. Measure the area covered by this amount of water. Repeat this procedure several times to determine the average area sprayed. You can measure the area in terms of sq. ft., sq. meters or in terms of row length.

STEP 2: Based on the area covered, you can calculate the amount of water needed to cover the field. For example, if 3 liters covered 60 sq. meters, it would take 30 liters of water to cover the field.

STEP 3: Determine the number of sprayer tankfuls of water needed to cover the field. For example, if the backpack sprayer holds 15 liters, it will take 2 tankfuls to cover the field.

STEP 4: Determine how much actual pesticide is needed for the field. If 4 kg of Sevin 50% wettable powder are needed per hectare and the farmer's field is 600 sq. meters, this would mean that 240 grams of the insecticide are required. Here's how we worked it out:
STEP 5: Divide the amount of pesticide needed for the field by the number of sprayer tankfuls of water to determine how much pesticide is needed per tankful:

\[
\frac{240 \text{ grams Sevin 50% WP}}{2 \text{ tankfuls}} = 120 \text{ grams Sevin/tankful}
\]

NOTE: A sprayer should be recalibrated each time it's used on a different crop, different stage of crop growth, or when another pesticide is used.

Alternate Method Using Row Length

When a pesticide is to be applied to a crop grown in rows, you can use row length instead of area as the basis for calibration.

PROBLEM: Label instructions advise Juan to apply Malathion 50% strength liquid at the rate of 4 liters per hectare. His field measures 40 x 50 meters and the bean rows are spaced 60 cm apart. His backpack sprayer holds 15 liters, and he needs to know how much Malathion should be added to each tankful.

SOLUTION

1. Follow the same procedure as with Step 1 of the first method but measure the amount of row length covered by the 3-4 liters instead of area. Suppose that Juan was able to cover 150 meters of row length with 3 liters.

2. Find out how many meters of row length his field has. Let's say the crop rows are running the long way (i.e. 50 meters).

\[
\text{Number of rows} \times 50 \text{ meters} = \text{field's total row length}
\]

\[
\text{Number of rows} = 40 \text{ meters (i.e. the field's width)}
\]

\[
\frac{40 \text{ m}}{0.8 \text{ m (80 cm)}} = 50 \text{ rows on Juan's field, each of them 50 mts. long}
\]

\[
50 \text{ rows} \times 50 \text{ meters} = 2500 \text{ meters of row length in Juan's field}
\]

3. Find out how much water will be needed to cover the 2500 mts. of row length based on 3 liters per each 150 mts.

\[
\frac{150 \text{ m}}{2500 \text{ m}} \times \text{X liters}
\]

\[
150 \times 1500 = 22500
\]

\[
X = 50 \text{ liters of water needed to cover the field}
\]
4. Find out how much Malathion 50% liquid will be needed for the field based on 4 liters of the pesticide per hectare. (10000 sq. m). Since Juan's field measures 40 x 50 mts., its area is 2000 sq. mts.

\[
\frac{2000 \text{ sq. m}}{10000 \text{ sq. m}} = \frac{X \text{ liters Malathion}}{4 \text{ liters Malathion}}
\]

X = 0.8 liters or 800 cc of Malathion needed.

5. Find out how much Malathion is needed per sprayer tankful based on a capacity of 15 liters.

\[
\frac{50 \text{ liters of water needed}}{15 \text{ liters tank capacity}} = 3.33 \text{ tankfuls needed}
\]

\[
\frac{800 \text{ cc Malathion}}{3.33 \text{ tankfuls}} = 240 \text{ cc of Malathion 50% liquid needed per sprayer tankful}
\]

NOTE: There are several different ways of doing the math involved, and we have shown only one.
INSECTICIDE TOXICITY TABLES

I. A QUICK REFERENCE INSECTICIDE GROUP AND TOXICITY GUIDE

The table below gives the relative human toxicity of common insecticides on a scale of 1 to 4 as follows: (Both oral and dermal toxicity is considered)

1 = most dangerous, 2 = dangerous, 3 = less dangerous, 4 = least dangerous

It also gives the chemical group to which each insecticide belongs as follows:

- CH = chlorinated hydrocarbon
- OP = organic phosphate
- C = carbamate
- M = miscellaneous

As you’ll see, the antidote for poisoning varies with the chemical group. Aside from this difference, it’s hard to make meaningful distinctions between these chemical groups. For example, Aldrin, DDT, Endrin, Heptachlor, Lindane, and Kelthane (dicofol) have long residual lives and are all CH’s; however, in terms of their immediate toxicity, they vary greatly—DDT is a Class 4 (least dangerous), while Endrin is a Class 1 (most dangerous). Other CH’s like Methoxychlor have relatively short residual lives. The OP’s and C’s break down fairly quickly but, like the CH’s, also vary greatly in toxicity.

Insecticide Names: Note that each insecticide may be marketed under several or more different trade names. Many extension bulletins refer to insecticides by their non-commercial chemical names (i.e. carbaryl is the chemical name for Sevin). This can create much confusion in identifying insecticides.

**LD50 RATINGS OF COMMON INSECTICIDES**

The LD<sub>50</sub> (LD = lethal dose) rating measures the amount of 100% strength chemical (i.e., active ingredient) that is needed to kill 50% of the test animals (rats or rabbits) when given orally and dermally (placed on the skin); this amount is measured in terms of milligrams of pure chemical per kilogram of animal body weight. One milligram = 1/1000th gram or about 1/28000th of an ounce. The LD<sub>50</sub> rating gives a good indication of the relative toxicity of pesticides to humans and other mammals. The lower the LD<sub>50</sub> rating, the higher the pesticide's toxicity.

Before looking at the LD<sub>50</sub> ratings below, keep the following in mind:

1. Moderately long residue life (1-3 years).
1. The LD$_{50}$ ratings are based on the amounts of 100% strength chemical. However, insecticides as marketed vary in strength from 1% up to 95%. After dilution with water for spraying, actual strength may only be about 0.1-0.2%.

2. The LD$_{50}$ ratings give little information on the cumulative effect of repeated exposure.

3. If spilled on the skin, liquid insecticides are more readily absorbed than wettable powders or dusts.

4. Note that some insecticides like TEPP and Phosdrin are about as toxic dermally as they are orally.

5. Even Class 4 (least dangerous) insecticides like Malathion can cause severe poisoning if enough were ingested or spilled on the skin, especially in the concentrated form.

6. The LD$_{50}$ rating has no relation to an insecticide's effectiveness against insects.

I. TYPES OF DISEASES AND THEIR IDENTIFICATION

Parasitic vs. Non-parasitic Diseases

Parasitic diseases are caused by certain types of fungi, bacteria, and viruses that invade plants and multiply within their tissues. Nematodes and parasitic weeds like Striga (witchweed) can also be included in this category, but we'll deal with them separately below.

Non-parasitic (non-infectious) diseases are caused by unfavorable growing conditions or other non-parasitic factors such as:

a. Excesses, deficiencies, or imbalances of soil nutrients.

b. Excessive soil acidity or alkalinity.

c. Temperature extremes.

d. Poor drainage or drought.

e. Mechanical, fertilizer, or pesticide injury.

f. Air pollutants like ozone and sulfur dioxide.

Some of these non-parasitic conditions produce symptoms easily confused with those of parasitic diseases.

Fungal Diseases

Fungi are actually tiny parasitic plants without roots, leaves, or chlorophyll which feed on living or decaying organic matter; they reproduce and spread by means of microscopic seeds called spores. Some fungi are beneficial such as those that help break down crop residues into humus; others can penetrate directly into seed, leaf, or root tissue or can enter through wounds or nature openings.

General types of fungal diseases: Leaf spots leading to possible defoliation; rotting of seeds, stems, stalks, roots, grain heads, pods, and ears; storage molds; wilts.

Diseases caused by fungi are by far the most common, because the spores are highly resistant to unfavorable conditions. They are easily spread by wind, water, soil, and farm implements, but some types can also be carried by the crop seeds themselves. Most fungal diseases develop and spread much more readily under high humidity and moisture. An important characteristic of fungal diseases is their ability to mutate to produce new races that are resistant to certain fungicides; this is not common, however.

Bacterial Diseases

Bacteria are microscopic single cell organisms that multiply by cell division. Like the fungi, some bacteria are beneficial and perform essen-
rual functions like converting unavailable organic forms of soil nutrients to available inorganic (mineral) forms. Others invade plants and cause diseases that produce leaf spots, wilts, galls, and fruit and stem rots. For several reasons, bacterial diseases are generally much less prevalent than fungal diseases.

a. Bacteria lack a resistant spore stage and are very dependent on favorable temperature and moisture conditions.

b. Unlike the fungi, bacteria can't forcibly penetrate into plant tissue but must enter through natural openings or wounds.

c. Although bacterial diseases can be spread by wind driven rain, field equipment, and certain types of insects (mainly some beetles), they are much less readily transmitted than fungal diseases.

Viral Diseases

Viruses are microscopic particles consisting of a core of nucleic acid (genetic material) surrounded by a protein coat. Viruses can multiply by diverting living host cells into the production of more virus particles and can also mutate to produce different strains. They are largely spread by sucking insects (aphids, leafhoppers, thrips); the relationship between these insect vectors and the viruses is sometimes very specific; for example, peanut rosette virus is transmitted by only one species of aphid. Some species of weeds are susceptible to certain viruses and serve as alternate hosts to provide sucking insects with a steady source of inoculum.

Viruses usually don't kill plants but can greatly reduce yields and quality. A wide variety of symptoms are produced such as leaf mottling (blotching), leaf curling, chlorotic (yellow) or necrotic (dead) spots on the leaves, leaf malformation, leaf striping, and excessive branching.

How to Identify Plant Diseases

Some plant diseases can be readily identified by non-professionals right in the field; in other cases, however, accurate diagnosis requires a good deal of field experience or even the expertise of a trained plant pathologist and lab facilities.

Troubleshooting Disease Problems

Helpful items: Magnifying glass, pocket knife for slitting stems, pictorial disease identification guides (see below).

1. Symptoms of some fungal, bacterial, and viral diseases can be easily confused with each other or with those caused by nematodes, non-parasitic diseases, or insects. Use the troubleshooting guide on pp. 158-162 to help narrow the problem down.

2. Examine the plants closely. If root, stem, or stalk rots are suspected, carefully remove some plants from the soil along with part of the root system; look for signs of damage such as soil insects.
root feeding, root discoloration. Slit stems and stalks lengthwise and check for rotting, discoloration or borers.

Disease Identification Guides For the Reference Crops

This section gives verbal descriptions of common reference crop diseases, but pictures are definitely worth a thousand words when it comes to identification: Ag field workers will find the following pictorial disease guides invaluable:

Maize

Sorghum and Millet

"Sorghum Diseases", Bulletin 1085, Texas Agricultural Extension Service, Texas A & M Univ., College Station, Texas, U.S.A. 77843. Also gives some control measures.

Beans

"Field Problems of Beans in Latin America", CIAT, Apartado Aereo 6713, Cali, COLOMBIA, S.A. $5.60 (U.S.) plus postage. Includes diseases, insects, and hunger signs. Available in English and Spanish. Also gives some control measures.

Soybeans

II. METHODS OF DISEASE CONTROL AND THEIR EFFECTIVENESS

Prevention vs. Cure

Most diseases such as viruses and the bacterial and fungal rots of seeds, seedlings, roots, stalks, and stems can't be controlled once they enter plant tissue. Fair to good control of fungal leaf spots can be achieved with foliar fungicides but this is usually uneconomical with low value crops like maize, millet, and sorghum. Disease control methods are therefore geared much more toward prevention rather than cure. Let's look at the principal non-chemical and chemical control practices.

Non-Chemical Disease Control Methods

1. Resistant varieties: Plant breeders have located genetic sources of resistance to some of the more serious diseases, especially viruses and other types that lack effective or economical chemical control measures. However, resistance does not mean 100% immunity, and the ability of viruses and fungi to mutate into new races has posed some problems. Disease resistance is a top priority among plant breeders.

2. Sanitation and Cultural Practices
   a. Disease free seed: Some diseases like bacterial blight and common mosaic virus of beans can be carried by the seeds. The use of certified seed (see Section C) that is disease free is an important management practice in many bean growing areas where these problems exist.
   b. Controlling host plants and insect vectors: This is especially important for controlling certain viral diseases and involves the removal of host weeds and other natural vegetation that serve as sources of inoculum. In some cases, non-susceptible barrier crops are planted around a field in a 15-20 meter wide strip to "decontaminate" sucking insects before they reach the susceptible crop (this is usually not practical). Also included is the roguing (removal) of diseased crop plants attacked by viruses; roguing is not effective for most fungal and bacterial diseases.
   c. Crop residue management: The burning or plowing under of crop residues is an effective prevention method for a few diseases like peanut Southern (Sclerotium) stem rot.
   d. The following practices may help minimize certain disease problems: not cultivating plants while they are wet; avoiding crop injury at or before harvest; irrigating in the morning when sprinklers or hand watering are used so that crop leaves

* Fair control of most bacterial leaf spots can be obtained using copper base fungicides.
are dry at night; using raised beds to improve drainage; disinfesting tools.

e. Crop rotation can reduce the incidence of many fungal and bacterial diseases, especially those that are soil borne, but will have little effect on viruses. There is nothing wrong from a disease standpoint as long as resistant varieties are being continually developed and introduced in response to new problems; however, this is unlikely in the LDC's.

f. Intercropping may reduce or intensify disease problems, depending on the crop mixtures involved and whether they share some diseases in common.

Chemical Disease Control Methods

1. Fungicides can be applied to planting seeds, the soil, and crop leaves and will provide fair to good control of certain fungal diseases. They are mainly applied as protectants.

   a. Seed treatment with a fungicide dust or liquid will effectively prevent seed rots (pre-emergence "damping off") caused by soil fungi and will also kill any fungal diseases borne on the seedcoat surface such as loose smut and covered smut which attack adult sorghum plants.

      Since seed treatments mainly protect the seed, they are not as effective at preventing seedling blights (rots) and seedling root rots. A systemic seed treatment fungicide called Vitavax Carboxin gives somewhat better control.

      Seed treatments will not control any soil-borne or air-borne fungal diseases that attack older plants such as leaf spots, stalk rots, stem rots, and root rots.

   b. Fungicide applications to the soil: Some fungicides like PCNB (Terrachlor), Vitavax (Carboxin), and Benlate (Benomyl) can be applied as sprays or dusts to the seed furrow or to the row soil during crop growth to control certain fungal stem and root rots.

      Such soil applications are seldom necessary or economical for maize, sorghum, and millet but are usually profitable on high yielding peanut and bean crops if such disease problems exist.

   c. Foliar fungicides can be applied as dusts or sprays to control fungal leaf spot diseases. Most foliar fungicides act as protectants to help prevent the occurrence or spread of leaf spots. Some of the recently developed systemic

* Especially soil-borne ones.
fungicides like Benlate (benomyl) and Mertect (Thiabendazole) also have erradicant properties.

Most foliar fungicides have little or no activity against bacterial leaf spots, but copper base fungicides provide fair to good control.

Foliar fungicides are usually not economical for field crops like maize, sorghum, and millet, but are often essential for control of Cercospora leaf spot in peanuts and can be very profitable in this case. Their use on beans may be justified where yields are in the medium to high range and fungal leaf spots become serious. The use of foliar fungicides on high value vegetable crops such as tomatoes, squash, and potatoes is usually very cost effective where foliar fungal diseases are a problem.

2. Soil sterilants like methyl bromide, formaldehyde, Basamid, and Vapam will control soil fungi, bacteria, insects, weeds, and nematodes. They are applied in advance of planting and allowed to dissipate before the seeds are sown. Soil sterilants are frequently used on seedbeds for growing tobacco and vegetable transplants but are too expensive for use with the reference field crops.

3. Antibiotics like Streptomycin and Terramycin are bactericides used as foliar sprays or transplant dips to control certain bacterial diseases. Other antibiotics like Kasumin (Kasugamycin) and Blasticidin are effective against certain fungal diseases such as rice blast and are widely used in Japan. Their high cost makes them uneconomical for use on the reference crops. There are several problems associated with antibiotics, namely residues, the development of resistant races of fungi and bacteria, and occasional phytotoxicity (plant injury).

4. Use of insecticides to control insect vectors: This is seldom completely effective since 100% control is impossible.

Integrated Disease Control

Integrated disease control involves the combined use of non-chemical and chemical methods. Except for the mercury base fungicides sometimes used as seed dressings, the fungicides pose few toxic or environmental threats, unlike some insecticides. The main impetus for integrated disease control is based on economics and the fact that many diseases cannot be adequately controlled with chemicals.

RECOMMENDATIONS FOR FOLIAR FUNGICIDES

Protectant vs. Erradicant Fungicides

Most fungicides like Maneb, Zineb, Difolatan, and Manzate act as protectants: by remaining on the leaf surface to prevent fungal spores from germinating and penetrating the plant; they have little or no erradicant
ability to stop the progress of an existing infection. However, a few fungicides like Benlate (benomyl) and Thiazolidone (Mertect) are actually absorbed into the leaf tissue and translocated outwards toward the margins; these systemic fungicides act as eradicators as well as protectants and also have other advantages:

1. They are not vulnerable to being washed off the foliage by rainfall or sprinkler irrigation.

2. Since they are translocated within the leaf, uniform foliage coverage isn't as important as with the non-systemic protectant fungicides.

The main disadvantage of the systemic fungicides is that they are effective against a narrower range of fungal diseases than most of the protectant fungicides, so more care must be taken to match the product to the disease. Another problem is that a few fungal diseases have developed resistance to some of the systemics (this hasn't occurred with the non-systemics).

Guidelines for Applying Foliar Fungicides

Type of Crop: Foliar fungicides are seldom economical for maize, sorghum, and millet; they will give the best benefit/cost ratio (cost-effectiveness) when used on well-managed peanuts and beans under conditions where fungal leaf diseases are a limiting factor and on high-value vegetable crops.

When to apply: Ideally, applications should be started slightly before the onset of infection or at least before the disease signs have become very evident. This is especially important when non-systemic protectant fungicides are used. In most growing areas, the major fungal leaf diseases are often rather predictable as to their date of first appearance, so that preventative applications can be begun in advance. Fungicides are too expensive to be used on a routine basis from the time the plants emerge; besides, most fungal diseases don't infect plants until around flowering time or after.

Frequency of application: This depends on disease severity, rainfall, and type of fungicide. The non-systemic protectant fungicides can be washed off the foliage by rainfall (or sprinkler irrigation), but the systemics remain safely within the plant once they've been absorbed. Under frequent rainfall, the protectants may have to be applied as often as every 4-7 days. Under less-wet conditions, intervals of 10-14 days regardless of rainfall frequency. Disease severity also affects application frequency but is usually closely related to rainfall and humidity (as well as varietal resistance).

Uniform and thorough coverage of crop foliage is very important when applying fungicides. This is especially true for the protectant products which are effective only on those portions of the leaf surface they actually cover. An attempt should be made to cover both sides of the leaves when using protectants. Stickers and spreaders (see pp. 233-234) are recommended for nearly all fungicide sprays to encourage and adhesion; Duter is one exception, since these additives increase the likelihood of crop injury from that particular product. Some fungicides already contain stickers and spreader, so be sure to read the label.
Dusts vs. Sprays: See PP. 225-226.

Amount of water needed for adequate foliage coverage: This varies with plant size, crop density, and type of sprayer. When using backpack (knap-sack) sprayers on full size plants, at least 700 liters/ha (75 gals./acre) of water is needed. Excessive water volume increases runoff which carries away spray droplets.

Nozzle selection and sprayer operation: See insecticide section.

Dosage Recommendations

Always follow label instructions and the recommendations of your country's extension service if the latter are based on sound adaptive research. The following recommendations are meant to serve as general guidelines.

Peanut Cercospora Leafspot: Benlate and Duter have generally proved the most effective although most other products such as Dithane M-45, Antracol, Bravo (Daconil), Difolatan, copper-sulfur dusts, and copper base sprays also give satisfactory control. The following recommendations come from North Carolina State University (U.S.A.) and Australia.

- **Duter 47% WP**: 425 grams actual formulation per hectare (6 ounces/acre); don't use a sticker or a spreader.
- **Benlate 50% WP**: 285 grams actual formulation/ha (4 oz./acre) plus sticker-spreader. Control is enhanced by combining 285 grams Benlate + 1.7 kg Dithane M-45 or Manzate 200 + 2.3 liters non-phytotoxic crop oil per hectare; the oil improves penetration.

**COMMON FOLIAR FUNGICIDES**

They are of relatively low toxicity (compared to insecticides) and have minimal dermal absorption (the dermal LD50 for Captan is over 10,000).

- **ANTRACOL** (Prolineb): Not registered in the U.S., but widely used overseas. A zinc base product by Bayer. Especially effective against early and late blight. Compatible with most other pesticides. Use at 75-125 cc per 15 liters (5-8 tablespoons per 4 gallons) and apply at 4-10 intervals depending on weather and disease severity.

- **BENLATE** (Benomyl): One of the few systemic fungicides; has an eradicant effect as well as a protective effect but it is not broad spectrum; mainly for powdery mildews, Cercospora leafspot (peanuts), Botrytis (Gray mold) of tomatoes and lettuce, and brown rot of fruit trees. For small areas, use 1-2 teaspoonfuls per gallon (5-10 cc/gal.). Also prevents mite eggs from hatching. Repeat at 10-21 day intervals. Use a sticker-spreader.

- **BORDEAUX** (copper sulfate + hydrated lime + water): One of the first original manmade fungicides. Has a protectant effect and also repels some insects. Don't let the solution stand in the sprayer for long periods. You can make it yourself. Two common formulas are 8-8-100
and 10-10-100 (first 2 numbers refer to lbs. of copper sulfate and hydrated lime; the last number refer to gallons of water). Each lb. of copper sulfate in 100 gals. of water equals 1/3 tablespoon (5 cc) per gallon. Each lb. of hydrated lime (slaked lime or calcium hydroxide) per 100 gals. equals 1 tablespoon (15 cc)/gal. To make 1 gallon of the 8-8-100 formula, dissolve 40 cc copper sulfate in 1/2 gal. of water; then dissolve 120 cc of hydrated lime in the other 1/2 gal; then mix both together. May cause leaf burn if made too strong.

CAPTAN (Orthocide, Merpan): Very safe broad-spectrum fungicide (also for seed treatment). Use the 50% WP at 3.5-5 tablespoons per gallon (13-20 cc/liter). As a seedbed drench for damping off prevention, mix up 2-3 cc/liter of water and apply with a sprinkling can at the rate of 2-3 liters/sq. meter immediately after planting veggies (if seed is not treated) or as soon as the seedling emerges.

COPPER COMPOUNDS (Aside from Bordeaux): For broad-spectrum foliar fungal control, but also more effective than other types for bacterial leafspots. Don't mix these with Diazinon insecticide. Copper oxychloride and Cupiavit Blue are two examples and are used at 400-500 grams/100 liters water.

DACONIL (Bravo W-75, Termil): Broad-spectrum foliar fungal control; toxic to fish. Compatible with most other fungicides. Don't apply within 5 days of harvest. Use at 2.5-3 tablespoons per gallon (10-12 cc/liter).

DUTER (fentine, etc.): An organic tin compound used on potatoes for its unusually good control of early and late blights. Also widely used for Cercospora leafspot of peanuts. Has some insect anti-feeding properties. Do not use a sticker-spread or leaf burn may result.

MANEB (Dithane M-22, Manzate 200, Lonocol M): Manganese base broad-spectrum fungicide available as an 80% WP. Used at 1.5-2.5 tablespoons/gal. (6-8 g/l) or 1.5-2.5 lbs./100 gals. Don't apply within 5 days of harvest.

MANZATE (Dithane M-15, Mancozeb, Fore): A manganese-zinc combination. Manufacturers claim it's better than Maneb on tomatoes. Use same dosage as for Maneb. Don't apply within 5 days of harvest. Also used as a seed piece dip on potatoes to control seed piece decay.

MINEB (Dithane Z-78, Lonocol Z, Polyram Z): A zinc base product. May injure squash and cucumber and tobacco. Don't apply within 5 days of harvest. Use same dosage as for Maneb.

PCNZ (Terrchlor, Brassicol): A soil fungicide usually applied pre-plant either broadcast or in a band; also used as a soil drench at transplant time. Mainly for damping-off, Sclerotinia, and Rhizoctonia. For cabbage family crops, it's used as a seedbed drench right after planting. Use 1 tablespoon Terrchlor 75W + 2 tablespoons Captan 50W per gal. of water and apply it over 50 sq. ft.
FUNGICIDES FOR SEED TREATMENT

Remember that treating seed with a fungicide inhibits surface-borne fungi on the seed coat and protects against soil-borne ones. Most fungicide seed treatments offer no protection to the seedling. However, some of the newer systemic fungicides for seed treatment such as Vitavax (carboxin) can offer some protection during the early stages of seedling growth. Seed treatment will not control any soil-borne or air-borne fungal diseases that attack older plants like leaf spots, stalk rots, root rots, etc.

ARASAN (Thiram, Fersan): A low toxicity compound usually available as a 50% or 75% dust.

BENLATE-T (Thiram + Benlate): For control of soil-borne Pythium, Fusarium, Rhizoctonia damping off and early root rots of beans and peas. Benlate (benomyl) is a systemic. Low toxicity.

CAPTAN (Orthocide, Merpan): Another low toxicity seed treatment fungicide that's also used as a foliar fungicide.

FERNASAN: A combination of Arasan and Lindane (an insecticide) that comes in several formulations. Fernasan 75W contains 75% Arasan and 1% Lindane—only enough insecticide to protect seeds during storage, not once in the ground. Fernasan 60/15 contains 60% Arasan and 15% Lindane for better control of seed eating insects in the soil. Both formulations are used at rates of 100-150 grams per 100 kg of seed. Smaller seeds require the higher dosage (more surface area).

MERCURY COMPOUNDS: Mercury compounds have been virtually banned in the U.S. as seed treatments. The problem wasn't a build-up of mercury in the soil but the accidental (or unwitting) ingestion of mercury treated seed by livestock or even people. Mercury is very effective and even has a penetrating effect into the seed, but avoid using it whenever possible. Common mercury-base seed treatment compounds are Ceresan and Semesan. Agallol is a mercury base dip for potato seed pieces, but Zinab or Manzate can be substituted. Skin absorption of organic mercury compounds (Ceresan, Semesan, Agallol) is minor but not so with inorganic like bichloride of mercury. Avoid breathing the vapors of any mercury product.

APPLYING SEED TREATMENTS: Arasan, Captan, and Fernasan can be applied as dusts to the seed at the rate of about 2-3.5 grams per kg of seed (smaller seeds need the higher rate). A baby food size jar works perfect for small quantities of vegie seeds and you can "eyeball" the rate (it takes much less than you think); seed should look uniformly covered but not "burl" with the fungicide. Wash hands afterwards. Always store treated seed out of reach of children and NEVER feed leftovers to humans or animals (i.e. treated maize, sorghum, bean seed, etc.)
I. BASIC FACTS ON NEMATODES

What are nematodes?: They are tiny, colorless, threadlike, unsegmented roundworms; they are not related to earthworms. Some types of nematodes, like hookworms, roundworms, and pinworms, attack man as well as animals. There are several dozen species that attack plant roots, as well as a few that injure stems and leaves. These plant feeding nematodes live in the soil and most are too small (0.2 - 0.4 mm) to be easily seen with the naked eye.

How do they damage plants?: The root feeding nematodes are the most common types attacking plants. They feed on or inside plant roots using needle-like mouthparts (called stylets) for piercing and sucking. The root knot nematode causes portions of the roots to swell into galls or knots, while root lesion nematodes produce dark colored lesions on the roots. Sting nematodes and stubby root nematodes prune the root system, making it appear stubby and sparse. Affected plants have trouble absorbing enough water and nutrient and become much more vulnerable to soil-borne fungal and bacterial diseases. In fact, those tomato varieties resistant to Fusarium wilt lost that resistance when attacked by nematode.

How serious is the damage?: Heavy infestations can lower crop yields by 30-80%.

Where are nematodes found?: Nematodes can be found in virtually any soil but are most prevalent and active where soil temperatures are warm; they seem to prefer sandy soils or those portions where moisture and soil fertility are low.

How do nematodes spread?: Nematodes reproduce by eggs, and life cycles of some types can be as short as 18-21 days in warm soils. Although a typical nematode will move less than half a meter during its life, they are easily spread by soil carried on tools, feet, or transplants or by water run-off from a field.

What crops are most affected?: Nearly all crops are susceptible to some type of nematode but veggies and pulse crops are generally more vulnerable than cereal crops.

Some crops especially susceptible to root knot nematode damage: Squash, cucumber, watermelon, cantaloupe, tomato, pepper, beans, peas, okra, lettuce, carrots, and strawberries.

Some crops especially susceptible to root lesion nematodes: Citrus, pepper, potato, sweetpotato, strawberries, cowpeas, peanuts, soybeans.

Varieties within a crop vary greatly in their resistance to different types of nematodes.
II. HOW TO DIAGNOSE NEMATODE PROBLEMS

Nematode damage is not often obvious or easily differentiated from other problems. In fact, a lab analysis is usually needed to confirm nematode damage and the type of nematode, except in obvious cases of root knot nematode infestation.

Above Ground Symptoms

Above ground symptoms aren't distinctive enough to make a conclusive diagnosis without also examining the root system, but the following are possible indications of nematode damage.

1. Plant stunting and lack of vigor is the most common but can also be caused by other problems such as low soil fertility, lack of moisture, diseases, insects, etc.

2. Yellowing of the leaves, although diseases, some older signs, insects, moisture stress, etc. can cause similar symptoms.

3. Wilting, even when soil moisture appears adequate and heat isn't excessive; soil insects, stem borers, and diseases can also cause wilting.

4. A distinguishing feature of nematode damage is that it almost always occurs in scattered patches in the field and is rarely uniform.

Root Symptoms

Carefully dig up the roots and look for the following:

1. Galls or knots on roots indicate root knot nematode damage. Don't confuse them with Rhizobia bacteria nodules attached to legume roots. Nematode galls are swellings of the actual root itself and have a white, granular appearance inside. Rhizobia nodules are pink to red inside and can be easily detached from the roots.

2. Root damage by other species is less obvious and takes the form of dark colored lesions (wounds), stubby roots, and general stunting of the root system. Don't confuse these symptoms with those caused by rootworms, white grubs, or other soil insects.

Laboratory Diagnosis

Plant pathology labs in most countries can test soil and root samples for nematodes. Take 5-10 random sub-samples within the field right next to plants, using a shovel. Dig down about 20-25 cm (8-10") and discard the soil from the top 5 cm and from the sides of the shovel. Place the remaining 15-20 cm deep strip in a pail, and be sure to include some roots. Mix the sub-sample together and place about a half-liter (pint) of the soil into a plastic bag. Protect the sample from sunlight and exposure to excessive heat. Fill out the lab's information form completely.
HOW TO CONTROL NEMATODES

Successful nematode control requires an integrated approach that combines several non-chemical methods and the likely need for chemical nematicides. The use of nematicides alone is unlikely to provide satisfactory control.

Non-chemical Controls

1. Avoid spreading nematodes into uninfected areas: Clean off soil from tools and equipment; avoid using transplants of unknown origin that might harbor nematodes. Some types of trees introduced for shade or windbreaks such as Prosapig species harbor nematodes.

2. Crop rotation: Designing an effective rotation requires a nematode lab analysis to determine the types of nematodes present; given the many types of nematodes and susceptible crops, a nematologist should be consulted. A farmer's cropping options may not allow for an ideal rotation.

3. Resistant varieties: Nematode resistance varies greatly among varieties of a particular crop, although complete immunity isn't possible. Furthermore, even a resistant variety may still be susceptible to several types of nematodes. Vegetable varieties with the letter "N" following their names have some resistance to nematodes (usually certain types of root knot nematodes).

4. Plowing up crop roots and exposing them to sun and drying winds: This will significantly reduce nematode populations.

5. Flooding: Month of flooding, one month of drying, and another month of flooding will reduce nematode problems but isn’t often practical.

6. Good soil fertility and high soil organic matter levels help reduce the severity of nematode damage.

7. Antagonistic plants: Many garden books recommend interplanting marigolds among susceptible crops to control nematodes. However, research has shown that marigold varieties vary in their effectiveness which is also limited to certain types of nematodes (root knot and/or root lesion, depending on the authority). Furthermore, marigolds don’t kill nematodes but starve them out; this means that interplanting isn’t effective, since the nematodes would still have a food source. Marigolds should be planted solid (about 15-20 cm apart) and allowed to mature. Keep the area completely weed and crop free where the marigolds are growing. Select the mature heads before they shatter (drop their seeds). Where root rot nematodes are a problem, marigolds should be planted every other year. French dwarf types such as "Tangerine", "Petite Gold", and "Harmony" are known to be effective.
Two legume green manure or cover crops, *Crotalaria spectabilis* (showy crotalaria or rattlesnake) and *Indigofera hirsuta* (hairy indigo) can reduce populations of most types of nematodes.

8. **Heat sterilization of soil using clear plastic**: A good method for hot, sunny areas. Cover the soil with plastic and bury the edges. Leave it on for 3-4 weeks which should heat up the soil to 130-140°F several inches down. This will also kill harmful fungi and bacteria as well as weed seeds.

9. **Heat sterilization of nursery seedbox soil with boiling water, steam, or bawing.**

10. **Deep setting of tomato plants helps assure a larger root system more capable of withstanding nematode damage.**

**Chemical Controls**

Soil fumigants like methyl bromide, Vapam, Basamid, and EDB are often used on vegetables or transplant beds but are either too expensive or require specialized application equipment. Some are very dangerous.

Non-fumigant nematocides like Mocap (ethoprop), Furadan, and Basamit can be applied as granules to the crop row and are also effective against some insects. Under small farmer conditions, their use in other crops and other cereals for nematodes only would be uneconomical except in cases of heavy infestations and high potential yields. There may be exceptions where their use is justified on the pulses, especially peanuts. Here are some product use guidelines for some of the more common nematocides:

**NEMAGON (DBCP, Fumazone):** Comes as a liquid or granules but has been virtually banned in the U.S. as a possible carcinogen; prolonged exposure over the years has caused testicular atrophy in males. Stay away from this one.

**FURADAN (Carbofuran):** See description on pp. 240-241. Has a very low dermal but very high oral toxicity. Nematode application guidelines are shown below:

- **Peanuts:** Apply in a band 30-35 cm wide over the row before planting; use 2.2-4.5 kg of active ingredient/ha. Needs to be worked into the soil 5.5-15 cm deep.

- **Maize:** Apply in a band 18-36 cm wide over the row before planting and work into the top 5-10 cm of soil. Use 1.1-2.25 kg of active ingredient/ha.

**MOCAP (Ethoprop, Propheos):** Kills nematodes and soil insects but is very toxic both orally and dermally; applied like Furadan at the rate of 1.7-2.25 kg active ingredient/ha. Not recommended for most small farmers. Non-systemic.

**TERMIX (Aldicarb):** A systemic insecticide/nematocide with extremely high oral and dermal toxicity. Avoid it.

NEM CUR (Phenamiphos, Fenamiphos): A systemic product for nematodes, soil insects, above-ground sucking insects. Class I toxicity. Applied to peanut-like Furadan at 1.7-3.55 kg active ingredient/ha. Handle with care. Use Furadan instead if possible due to its much lower dermal toxicity.

NEMATOCIDES & SOIL STERILANTS

Soil sterilant is a vague term. Some products kill just about everything (nematodes, insects, fungus, bacteria, weeds) while others are less comprehensive. Some nematocides control only nematodes (i.e. like Nemagon) while others are really soil sterilants in the broad sense.

Do soil sterilants also hurt the "good guys" like beneficial bacteria, fungi, and earthworms? You bet, but it's only temporary and confined to the top 6-8". Where disease problems (soil borne ones) are severe, some form of sterilization may be the only answer.

Non-Chemical Soil Sterilization

1. Applying boiling water to seedbox soil is very effective if the soil is thoroughly soaked.

2. Heating the soil in an oven or over a fire works great too. Partly wet soil heats up better and the formation of steam helps. Soil can be placed on a piece of zinc roofing supported over a fire or use half of a 55 gal drum split the long way. About one hour at 180°F does the trick; don't overcook the soil as it may release toxic (for plants) amounts of certain elements. One way of checking is to place a potato or sweet potato midway down in the soil, when it's cooked, the soil is ready.

Be careful not to recontaminate the soil by further additions or by adding compost or manure afterwards.
Chemical Soil Sterilants and Nematocides

BASAMID Granules (DMTT)

A multi-purpose soil sterilant for nematodes, insects, fungi, bacteria, and weeds, has a fumigant (gaseous) action. Moderate toxicity for humans. Applied broadcast or band. Soil should be clod-free, loose, and semi-wet, and free of undecomposed plant residues. In sandy and loamy soils, use 35-40 grams per sq. meter (11 sq. ft.) broadcast and immediately worked into the top 6-9" of soil. Uniform mixing is important for good control. Prevent escape of the fumes by watering lightly after application (1/4" of water or about 2 gals. per sq. meter) and then once again 3-4 days later or covering with plastic for a few days (sounds better). Wait 10-14 days before planting in warm climates (soil temp. above 68°F). Stir soil thoroughly 7 days after application. Can also be applied 20 cms. (8") wide centered over the row and incorporated 8" deep for tobacco and tomato transplants; wait 4 weeks before transplanting.

FORMALDEHYDE (Formalin)

Controls everything but nematodes and weed seeds. There are various recipes but here's a couple of old standby's:

1. 1 gal. of commercial formaldehyde (about 37% strength) mixed with 30 gals. water. Drench soil at 1 quart per sq. ft. (10 liters/sq. meter). Water heavily afterwards and apply plastic. Remove plastic after 48 hours and work up the soil as soon as it's dry. Wait 10-14 days before planting (make a small test planting first).

2. Quickie Method for small amounts of soil: 1 part formaldehyde in 5 parts water. Apply at 1 tablespoon per 2-1/2 sq. feet (0.25-sq. meter) of sandbox soil and thoroughly mix or stir. Plant after 24 hours but water right after planting.

Formaldehyde fumes are irritating to the eyes and nose and poisonous to nearby growing plants.

FURADAN (Carbofuran)

A systemic nematocide-insecticide available as a 3% and 5% granular formulation and a 75% WP. The pure material has a high oral but very low dermal toxicity. Usually applied as a band treatment centered over the row. It's absorbed by the roots and then translocated throughout the plant. Controls soil nematodes, soil insects, plus many chewing and sucking foliage pests like flea beetles, aphids, leafhoppers, and leaf miners.

On vegetables, the rate of Furadan 5% granules is 30-40 grams per 10 meters of row length applied at transplant or seeding time. There are 4 recommended methods of application:

1. Placing it in a 15-25 cm. (6-10") wide band centered over the row.
2. In a circle around each transplant or seed.
3. Mixing with the row fertilizer and applying it in the bottom of the furrow, covering with a couple inches of soil and then seeding. Make the furrow a couple inches off to the side to avoid fertilizer burn.

4. For nursery seedbeds, use 10-15 grams per sq. meter (5% granules) and work into the top 4-6" of soil.

**NEMAGON (Fumazone, DBCP)**

For nematodes only. Unfortunately, Nemagon has been found to be a possible carcinogen and is being phased out in the U.S. on some crops. Of moderate oral and dermal toxicity. Fumazone is a liquid; Nemagon comes as both a liquid and granules. Do not repackage Nemagon granules or those that have been exposed to the sun for several days--all the vapor leaves the granules in 7-10 days when exposed to air. Not for tobacco, sweetpotatoes, potatoes, beets, onions, or garlic. When transplanting tomatoes and peppers, it's best to wait 8-10 days after treatment. Both liquid and granules need to be applied 6-8" deep and then covered (make a furrow for each crop row). Plant seed or transplant over the furrow. A quart size jar with 2 holes in the lid (opposite each other) makes a good liquid applicator. See label for dosage as there are several different formulations. Has a fumigant action.

**METHYL BROMIDE (DOWfume MC-2)**

A general soil sterilant sold in a can as a liquid under pressure which volatilizes into a gas when opened. Highly poisonous to all living things. The gas will severely burn the skin and inhalation can be fatal. Most formulations are spiked with tear gas (chloropicrin) as a warning agent. Don't use on onions, garlic or celery.

Must be applied under a sealed plastic tarp to look semi-wet soil tilled to at least 8". Soil should be free of crop residues. 1-2 lbs. needed per 100 sq. ft. Keep plastic on for at least 48 hours after application, then stir up the soil to help dissipate the chemical (no danger of human toxicity after 48 hours). Planting can be done 3-7 days after the plastic is taken off. Usually used only for nursery seedbed soil (i.e. for starting out seeds for transplants).

**NOCA+ (Ethoprop, Jolt, Prophoils)**

A non-systemic insecticide-nematicide for controlling soil insects and nematodes. Highly toxic both orally and dermally. Readily absorbed through the skin. Has a residual activity of about 8 weeks in the soil. Requires only light incorporation (1-2" deep) as it moves downward rather than upward (no fumigant action). Rubber gloves are a must when handling. It's too dangerous a chemical for most farmers.

**VAPAM (VPM)**

A liquid broad-spectrum soil fumigant effective against insects, nematodes, bacteria, weeds, and fungi. For treating small areas, it can be
mixed with water and applied with a sprinkling can. Cover the soil with plastic for a couple days after application or drench with plain water to move the chemical downward. Allow at least 21 days before planting; dosage is usually 1-2 quarts per 100 sq. ft. in 15-20 gals. water. READ THE LABEL. Vapam has low oral and moderate dermal toxicity.

When using a soil sterilant, don't recontaminate the soil by adding additions of compost and manure (do it first). Unclean tools or boots can track in disease and nematodes too.

Some agronomists recommend that any N fertilizer applied after sterilization should contain about half its N in the mobile and more available nitrate form. Sterilized soil won't have enough good guy bacteria to convert ammonium N (doesn't move much and is less available) to nitrate N.
WEED CONTROL

I. HOW WEEDS LOWER CROP YIELDS

1. They compete with the crop for water, sunlight, and nutrients.
2. They harbor insects, and some weeds are hosts for crop diseases (especially viruses).
3. Heavy infestations can seriously interfere with machine harvesting.
4. A few weeds like Striga (witchweed) are parasitic and cause yellowing, wilting, and loss of crop vigor.

Extent of Yield Losses

Numerous trials in the U.S. have shown maize yield losses ranging from 41-86% when weeds weren't controlled. A trial in Kenya yielded only 370 kg/ha of maize with no weed control compared to 3000 kg/ha for clean weeded plots. A CIAT trial with beans in Columbia a yield drop of 83% with no weeding.

Of course, all farmers weed their fields to some extent, but most of them could significantly increase their crop yields if they did a more thorough and timely job. A University of Illinois (U.S.) trial showed that just one pigweed every meter (40") along the row reduced maize yields by 440 kg/ha (390 lbs./acre). By the time weeds are only a few inches tall, they have already affected crop yields.

Relative competitive ability of the reference crops: Slow starters like peanuts, millet, and sorghum compete poorly with weeds during the first few weeks of growth. Low growing crops like peanuts, bush beans, and bush cowpeas are fairly effective at suppressing further weed growth once they are big enough to fully shade the inter-row spaces. However, tall growing weeds that were not adequately controlled earlier can easily overtake these "short" crops.

II. SOME IMPORTANT FACTS ON WEEDS

Broadleaf vs. Grassy Weeds

Broadleaf weeds have wide (broad or oval shaped) leaves with veins that form a feather-like pattern. Grassy weeds are true grasses and have long, narrow leaves with veins that run up and down in a parallel pattern. A few weeds like nutsedge (nutgrass) belong to neither category but are sedges, all of which have triangular stems. Some chemical herbicides are more effective on broadleaf weeds, while others give better control of grassy types.

How Weeds Reproduce and Spread: Annuals vs. Perennials

Annual weeds live only a year or so and reproduce by seed: they are the most common weeds in many fields. In the tropics, annuals may live more
a year if rainfall is sufficient. Most annuals produce tremendous amounts of seed, some of which may not germinate for years. When you stir the soil with a hoe, harrow, or cultivator to kill weeds, you destroy one crop of them but encourage another by moving more weed seeds closer to the surface where they can sprout.

You can help lower a field's population of annual weeds by controlling them before they produce seed. Permanent eradication of annual weeds isn't possible because most fields contain millions of weed seeds waiting to germinate, and the supply is continually replenished by more seeds brought in by wind, water, animals, animal manure, and by contaminated crop seeds.

Perennial weeds live more than 2 years. Most produce seed but many also propagate by means of creeping above-ground stems (stolons) and creeping underground stems (rhizomes): Johnsongrass, Bermudagrass, quackgrass, and nutsedge are some of the more effective perennial weeds. Hoeing or mechanical cultivation may actually aid in spreading them around the field. Most herbicides will kill the topgrowth, and there is enough food in the underground parts to continue propagation.

Identifying Weeds

Where weeds are being controlled by hoeing or mechanical cultivation, their specific identification is usually not important. However, where chemical weed control is used, you and the farmer should have a good idea of which specific weeds are present, because most herbicides do not give broad-spectrum control. The following extension publication is an excellent identification guide and has pictures and descriptions of some 150 common weeds found throughout the tropics and sub-tropics:

"Weeds of the Southern United States, available from the Cooperative Extension Service of Clemson University, Clemson, South Carolina, U.S.A. 29631

III. A LOOK AT DIFFERENT WEED CONTROL METHODS

Let's look at the pros and cons of the following weed control methods:

1. Burning
2. Mulching
3. Shading (the row crop principle)
4. Hoe and machete cultivation
5. Animal and tractor-drawn cultivation
6. Herbicides

1. Burning

When land is cleared by burning, standing annual weeds are killed along with weed seeds very near the soil surface. However, burning will not kill weed seeds or reproductive underground parts of perennial weeds if they are deeper than 4-5 cm (2'). Furthermore, as the brush is often placed in windrows or piles before burning, much of the soil may not be affected by the fire. Some perennial tropical grasses such as Guinea (Panicum maximum) and...
speargrass (Imperata cylindrica) are actually stimulated into dense regrowth by burning. On the other hand, weeds may be less of a problem under slash and burn farming, because the soil is usually not turned by plowing or cultivation to bring up more weed seeds.

2. Mulching

Mulching the soil surface with a 10-15 cm (4-6") layer of crop residues, dead weeds, or grass can give very effective weed control and provide a number of other benefits:

a. Erosion is greatly reduced on sloping soils.

b. Soil water loss by evaporation and runoff is greatly reduced.

c. In very hot areas, soil temperatures are reduced to a more beneficial level for crop growth.

d. Organic matter is eventually added to the soil.

In trials conducted by IITA in Nigeria, mulching increased maize yields by 23-45% and greatly reduced the heavy labor requirement for hand weeding which accounts for a 50-70% of the hours needed to grow maize in that area.

3. The Row Crop Principle

Arranging crops in rows facilitates hand weeding but also makes possible mechanical cultivation (weeding) with tractor or animal-drawn equipment. The rows also permit the crop to exert better shade competition against the weeds.

4. Hoe and Machete Cultivation

Weeding with hand tools is an effective method if sufficient labor is available. However, small farmers who rely on this method commonly fall behind in weeding, and crop yields often suffer.

5. Animal and Tractor-drawn Cultivation

Disk harrows, field cultivators, and spike tooth harrows can provide excellent pre-planting weed control. The spike tooth harrow can also be used to control emerging weeds up until the crop is about 7.5-10 cm (3-4") tall without serious damage.

Animal and tractor-drawn row cultivators can be used from the time the crop is a few inches tall; they do a much more rapid job than hand weeding, and a one-row animal-drawn model can easily cover 3-4 hectares/day (7.5-10 acres) unless the rows are very narrow. They can be adjusted to throw soil into the row itself to kill small weeds by burying them. If operated too deeply or too close to the row, serious root pruning may result.
Herbicides can greatly reduce labor requirements and permit a farmer to grow a larger acreage; they also avoid root pruning damage, soil compaction, and stand reduction which are caused by hand tools or mechanical equipment. In a number of cases, herbicides like Gesaprim (atrazine, see herbicide section) and 2,4-D have proven competitive with hand labor in maize production in the LDC's. IITA is working on improved methods for small farmer application of herbicides such as granular forms and ultra low volume sprayers.

Herbicides do have some very definite disadvantages that must be considered when working with small farmers:

1. They are less reliable than hand tool or mechanical weeding and most require careful and accurate application. This can be achieved by small farmers using backpack sprayers, but it requires some training.

2. Weed control is seldom complete; most herbicides are not broad-spectrum, and it's important to analyze the type of local weed species present before choosing a product.

3. Most soil applied herbicides require a certain amount of rain within a week after application in order to move the chemical into the zone of weed seed germination. Others need immediate incorporation into the soil with a disk harrow or rototiller.

4. Improper application may damage the crop.

5. Nearly all herbicides are unsuited for use in intercropping involving cereals and legumes due to crop injury; these products are crop-specific as well as weed-specific.
USEFUL CROP PRODUCTION
REFERENCES FOR TRAINEES AND TRAINERS

Aside from the crops tech reference package (see Printed Materials Section), which should be given each crops trainee and trainer, the following additional references are very useful:

I. Suggested vegetable related references to be ordered for each trainee:

Soils, Crops, and Fertilizer Use, 1980, ed. PC/ICE Reprint R8, 160 pp. A how-to guide on essential hands-on and tech skills needed for trouble-shooting soils, soil conservation, and maximizing returns from the appropriate use of organic and chemical fertilizers under small farmer conditions.

"Tomato Diseases and their Control", USDA Agric. Handbook No. 203, 109 pp., $1.00. Sometimes available free through PC/ICE. Complete pictorial and descriptive guide to tomato diseases and their control methods. A much shorter (10 pp.) USDA bulletin, "Controlling Tomato Diseases in the Home Garden" is usually available through PC/ICE.

Intensive Vegetable Gardening for Profit and Self-sufficiency, PC/ICE Reprint R-25, 160 pp. Contains some very practical information on small scale gardening, particularly tool selection, home fabrication of tools and water lifts, garden planning, and basic production practices. However, the manual is based on Jamaican conditions and tends to oversimplify important areas like soil fertility and fertilizer use, watering, and pest and disease control.

II. Suggested vegetable and field crop related references for inclusion in a training center ag library: (In some cases, such as the field crop pocket disease guides, they may be worth ordering for each trainee.)

VEGETABLE PRODUCTION

Producing Vegetable Crops, Ware and McCollum, 3rd ed., 1980, Thompson Publications, Box 9335, Fresno, CA 93791, $18.00. Geared to commercial production but still useful.
The Self-Sufficient Vegetable Gardener, J. Seymour, Dolphin Books, Garden City, N.Y. 1980; $9.95. Probably the most reliable and complete of the home gardening books. Covers land preparation through harvest practices plus drying, canning, and more. Like most such books, it is based on temperate zone conditions. Well illustrated.

Handbook for Vegetable Growers, J. Knott, John Wiley and Sons, N.Y. 1962. Despite its age, it contains many useful tables on irrigation, crop adaptation, time to maturity, fertilizers, etc.

All About Vegetables; Ortho Book Series, Chevron Chemical Company, 175 Market Street, San Francisco, California 94105, $4.98. Often available in garden and book stores. Another useful supplemental vegetable gardening guide; well illustrated; based on temperate zone conditions. A good beginner's guide for home gardening. Tends to oversimplify.

Down to Earth Vegetable Gardening Know-How, D. Raymond, Garden Way Publications, Charlotte, Vermont, 05445, $5.95. Very useful guidelines for selecting, processing, and saving seed, but does not address the problem of seed-borne diseases.

How to Grow More Vegetables, J. Jeavons, Ten Speed Press, Box 7123, Berkley, California 94707, 115 pp., $5.95. This popular book on the biodynamic/French intensive method of organic gardening offers some useful advice on double-digging, deep bed preparation, and hexagonal planting. However, it oversimplifies watering (i.e. the “shiny” method), and gets bogged down in unproven statements and doubtful practices such as planting by the moon, relying on portable soil test kits, the “poisoning” effect of chemical fertilizers. The benefits of companion planting are overstated.

INSECTS, DISEASES, WEEDS, NEMATODES

General

Thompson Guides. Book I: Insecticides; Book II: Herbicides; Book IV: Fungicides, Thompson Publications (see address above). $13.50 each. Lists and describes the most widely used pesticides including common names, uses, rates (per acre), pests controlled, toxicity (oral only), and precautions.
One of the most practical texts available.

Color Handbook of Garden Insects, A. Carr, Rodale Press, Emmaus, PA, $12.95. Contains 300 full color pictures of common harmful and benefi-
cial insects (including eggs in some cases). An especially good insect
guide.

"Handbook on Biological Control of Plant Pests", Brooklyn Botanic Gar-
dens, 1000 Washington Avenue, Brooklyn, New York 11225, $2.55, 1960, 97 pp. Covers predator insects, microbial insecticides, other non-
chemical controls. Good pictures of lace bugs, lady bugs, aphid lions, etc.

"Nematode Control", Bul. 652, Coop. Extension Service, Univ. of
Georgia, College of Agriculture, Athens, Georgia 30602. Covers diag-
nosis and control of nematodes. Well illustrated, very helpful.

Agricultural Pests of the Tropics, 1975, D. Hill, Cambridge University

Maize Diseases

"Maize Diseases: A Guide for Field Identification", Information Buile-
tin No. 11, CIMMYT, Apartado Postal 6-641, Mexico 6, D.F., $2.50.
Available in English and Spanish. Pocket pictorial guide for diagnosis
but does not give control measures.

"A Compendium of Corn Diseases", 2nd edition, 1980, American Phyto-
pathological Society, 3340 Pilot Knob Road, St. Paul, Minnesota 55121,
$11.00. Well illustrated and complete descriptions and control mea-
sures for diseases and nematodes; also includes hunger signs and envi-
ronmental problems.

Sorghum and Millet Diseases

"Sorghum and Pearl Millet Disease Identification Handbook", Information
Bulletin No. 2, ICRISAT, P.O. Patancheru 502 324, Andhra Pradesh, INDIA
or Texas Agricultural Experimental Station, Texas A & M, College
Station, Texas 77843. Pocket guide, illustrated, but does not give
control measures.

"Sorghum Diseases", Bul. 1085, Texas Agricultural Extension Service,
Texas A & M University, College Station, Texas 77843. Pictorial guide
that also discuss controls.

Rice Diseases, Insects

"Field Problems of Tropical Rice", IRRI, 1970, available from Unipub,
345 Park Avenue South, New York, New York 10010, $5.00. Pocket picto-
rrial guide that also covers hunger signs.
Peanuts Disease

Bean Diseases, Insects

"Field Problems of Beans in Latin America", 1978, CIAT, Apdo. Aereo 6713, California, Columbia, $5.60 plus air postage ($3.50 for U.S., $2.50 for Latin America, $6.00 for Asia and Africa). Available in English and Spanish; includes diseases, insects, and hunger signs; 136 pp., pictures.

Bean Production Problems: Disease, Insect, Soil, and Climatic Constraints of Phaseolus Vulgaris, ed. by H. Schwarz and G. Galvez, 1980, CIAT (see address above), $15.00 plus air postage; 424 pp.

Soybean Diseases

"Soybean Diseases Atlas", Cooperative Extension Service, Clemson University, Clemson, South Carolina 29631.

Potato Diseases

"The Potato: Major Diseases and Nematodes", *1 International Potato Center, Apartado 5959, Lima, Peru or Box 25171, Nairobi, Kenya or Box 1237, Islamabad, Pakistan or c/o PCARR, Los Banos, Laguna, Philippines; one copy free, others $3.00 each. Pocket pictorial guide; does not give control measures.

Compendium of Potato Diseases, 1981, American Phytopathological Society, 3340 Pilot Knob Road, St. Paul, Minnesota 55121, $11.00, 142 pp, 192 illustrations. The best available; also gives control measures.

Soil Management, Fertilizer Use

Southern Gardener's Soil Handbook, W. Peavy, Pacesetter Press, Box 2608, Houston, Texas 77001, $4.95, 81 pp. Down to earth tech and hands-on coverage of improving clayey soils, composting, organic and chemical fertilizers, mulching, and watering by an extension horticulturist.

*1. Available in English, French or Spanish.
IRRIGATION

FIELD CROP PRODUCTION

Traditional Field Crops, 1981, PC/ICE. Covers maize, sorghum, millet, beans, peanuts, and cowpea production under small farmer conditions. Detailed information on characteristics, adaptation, cropping systems, land preparation, planting, pest control, fertilizer use, liming, harvesting, drying, and storage.

Small Farm Grain Storage, PC/ICE, 1976, 500 pp. Must reading for anyone contemplating work in grain storage. This well written and detailed manual covers principles and practices of drying, storage, and rodent-insect control. Includes designs for grain dryers, cribs, silos, and bins.

Crop Production Handbook, PC/ICE Reprint R6, 1969, 147 pp. Too academic an overview to be of much use.

Maize Production

Modern Corn Production, Aldrich & Leng, 2nd ed., 1978, Thompson Publications, Box 9335, Fresno, California 93791, 360 pp., $21.75. The best in-depth yet practical guide to maize growing available. Well illustrated and geared toward the field.

**Millet Production**

**Rice Production**

A Farmer's Primer on Growing Rice, IRRI, 1979, 221 pp., Unipub, (see address above), $14.50 plus postage. Covers basic growing practices for flooded rice.

**Peanut Production**

**Soybean Production**

**ROOT AND TUBER CROPS**

IITA (International Institute of Tropical Agriculture) has an extensive research program in tropical yam (Dioscorea spp.) production. CIAT (International Center for Tropical Agriculture) does work with cassava (Manioc). Both institutes have useful publications available on these crops which can be obtained by requesting a catalog from the addresses below:

IITA, PMB 5320, Ibadan, Nigeria, West Africa

CIAT, Apartado Aereo 6713, Cali, Columbia, South America
TROPICAL AGRICULTURE - General

AGRICULTURAL EXTENSION

"Agricultural Extension: The Training and Visit System", D. Benor and J. Harrison, 1977, 55 pp., World Bank, 1818 H Street, N.W. Washington, D.C. 20433. Explains the operation and advantages of using a systematic program of continual in-service training for village extension workers, combined with fixed schedule visits by them to the fields of "contact" farmers who play an important role in extending new practices to others. Many of the suggestions are suited to PC agricultural programs.

Agricultural extension manual to be published by PC/ICE in 1982.
I. INTRODUCTION TO THE AG ENVIRONMENT AND HOST COUNTRY AGRICULTURE

Goals
A. To explain and illustrate the effects of the ag environment on farming systems, practices, yields, and returns.
B. To enable trainees to survey and interpret the important features of their work site's ag environment, once they become Volunteers.
C. To provide a general overview of host country agriculture.

Objectives
A. Explain how the following physical features of the ag environment affect crop production in your host country: temperature, annual rainfall, rainfall pattern, humidity, wind, % cloud cover, hail, topography, soils.
B. Explain how the following non-physical ag environment features affect small farmer crop production in your host country: land tenure and distribution, markets, storage facilities, transport, the agricultural labor force, availability of ag supplies and equipment, production credit, farmer advisory services, ag research, the existence of adapted improved farming practices.
C. Explain the rationale concerning planting and harvest dates of your work area's major field and vegetable crops, given a graph of the annual rainfall pattern and a cropping calendar.
D. Give effective guidelines and techniques for surveying and interpreting your future work site's ag environment through farmers and other resources.

II. INTRODUCTION TO CROP PRODUCTION MANAGEMENT

Goals
A. To foster an integrated approach to crop production management.
B. To provide an integrated framework for developing suitable management skills and extending them to farmers.

Objectives
A. Explain why agriculture (especially crop production) is a very location-specific endeavor with few cookbook recipes for success.
B. Explain and clarify the two sectors of crop production management: 1. Manipulation of the ag environment by the farmer; 2. Standard managerial skills.
C. Explain the concept of integrated crop production management, and discuss the role and appropriateness of the "package and practices" approach within this framework.
4. Briefly explain the difference between sand, silt, and clay particles in terms of size, contribution to natural fertility, and other influences on soil productivity. pp. 2-4

3. a. List 5 ways that organic matter in the form of humus improves soil. p. 4

b. Explain why it is especially difficult to maintain a beneficial level of soil organic matter in the tropics. p. 5

c. Suggest 5 ways that your host country client farmers can use to increase or at least maintain their soils' humus level, and discuss their feasibility for large vs. small plots. p. 6

4. Distinguish between topsoil and subsoil in the field, give 3 differences between them, and explain why both have an important influence on crop yields. p. 2

5. a. List 3 ways of getting to know the soils in your work area. p. 8

b. Give effective guidelines and techniques for learning about your work area's soils through your client farmers. p. 9

6. List the 6 major soil physical characteristics that largely determine a soil's potential productivity and management problems and which can be readily evaluated right in the field. p. 10

7. Texture

a. Using the "feel" test for texture, distinguish between samples of sandy, loamy, and clayey soil. p. 11

b. Give the pros and cons of sandy and clayey soils and 2 ways of improving each. p. 11-12

8. Tilth

a. Define the term "tilth" and explain its influence on crop production. p. 13

b. Determine the current tilth of 2 types of soil in the field. p. 13

c. List the 3 main factors that determine tilth, and explain why a soil's tilth can vary from day to day. p. 13-14

d. List 3 feasible methods that your client farmers could use to improve their soils' tilth. p. 14

9. Depth

a. Explain how to measure a soil's depth and how depth influences crop production. p. 20

b. Explain why there's often a big difference between actual depth and useful depth. p. 20
c. Give 2 useful management methods for coping with overly shallow soils.

10. Watering Hold Capacity
   a. Briefly explain how soils hold water and why plants will wilt long before a soil is completely dry. p. 15
   b. Briefly explain how a soil's water holding capacity influences crop yields and why clayey soils have about twice the water holding capacity of sandy soils. pp. 15-16
   c. List 2 feasible methods for improving the water holding capacity of a soil. p. 16

11. Drainage
   a. Define "drainage" and explain why poor drainage adversely affects crops yields. p. 18
   b. Explain why topography, crop appearance, and subsoil color are useful indicators of drainage problems. pp. 18-19
   c. Determine the drainage ability of a local soil by using both the subsoil color and water infiltration tests. p. 19
   d. Explain why nursery seedboxes are especially prone to poor drainage and how to improve it. p. 19
   e. List 3 ways of improving soil drainage in the field. p. 19

12. Slope
   a. List 2 ways that soil slope influences crop yields and soil productivity. pp. 16-21
   b. Using a string level and/or a homemade protractor device, measure soil slope so that your reading agrees within 5% of your instructor's. pp. 21-23

13. Given a description of 2 host country soils in terms of texture, depth, topography, and subsoil color, identify their main limiting factors and make appropriate management recommendations.

B. Land Preparation for Planting

Goals

1. To familiarize trainees with host country small farmer land preparation methods and seedbed styles for the program crops.

2. To enable trainees to help farmers choose and implement the most appropriate land preparation methods and seedbed styles for the program crops.
Objectives

1. List 3 characteristics of a properly prepared seedbed that favor optimum germination and growth.

2. Explain how seed size and seedling structure determine the fineness of the seedbed required, and compare the seedbed requirements of maize, beans, lettuce, and radish.

3. a. Compare the pros and cons of raised, flat, and sunken seedbeds for the reference crops under host country conditions during the wet season and dry season.

   b. Using a shovel, hoe, and rake, prepare the appropriate types of seedbeds for your reference crops; they should be conducive to good germination and growth.

4. a. Describe the prevalent land preparation methods and types of seedbeds used for the reference crops by your client farmers, and discuss their pros and cons.

   b. Discuss slash and burn farming (shifting cultivation), in terms of: the cropping and fallow sequence, yields obtained, maintenance of fertility, and the breakdown of the system under increasing population pressure.

   c. Compare the function and suitability of the following implements in land preparation under host country conditions: shovel, digging hoe, rake, wooden plow, moldboard plow, disk plow, etc.

5. Prepare at least one of your seedbeds using the double-digging method, and explain its advantages and suitability under host country conditions.

6. List 2 harmful effects of excessive tillage and give guidelines for avoiding it.

C. Plant Nutrition Basics

Goals

This unit gives trainees a grounding in basic soil fertility principles essential for developing appropriate skills in the use of organic and chemical fertilizers.

Objectives

1. Briefly explain the process of plant growth including photosynthesis and how and in what form plants take in nutrients from the soil.

2. Explain the difference between macronutrients and micro nutrients.
3. Briefly define and explain the significance of the following: nutrient tie-up, P fixation, N fixation, legume, Rhizobia bacteria, leaching, negative charge, soil pH.

4. NPK Basics
   b. Discuss the relative likelihood of N, P, and K deficiencies in host country soils, and give examples of "high need" crops among the reference crops for each nutrient.
   c. Contrast the relative mobility of N, P, and K in the soil, and explain how this affects the timing and placement of fertilizer applications.

5. Soil pH
   a. Define soil pH and explain why it can vary markedly from farm to farm.
   b. List 3 ways that pH affects crop growth and give the general pH range within which most crops grow satisfactorily.

6. Determining Fertilizer Needs
   Goals
   1. To assess the accuracy and suitability of various methods of determining fertilizer needs under host country conditions.
   2. To enable trainees to collect soil samples for lab analysis.

   Objectives
   1. List 4 major factors that determine the kind and amount of fertilizer a farmer should apply on a particular field.
   2. Briefly discuss each of the following methods of determining fertilizer needs in terms of accuracy, factors affecting accuracy, and suitability under host-country conditions: lab soil testing, portable soil test kits, tissue tests, visual hunger signs, field trials, and the educated "questimate".

   3. Soil Sampling
      a. Divide a hypothetical farm into soil sampling units so that each unit reflects a likely variation in soil fertility due to differences in color, texture, slope, parent material or past management.
      b. Given a host country soil sampling information sheet, describe effective techniques for eliciting the requested data on past management and yields from a client farmer.
E. Using Organic Fertilizers & Soil Conditioners

Goal
To help small farmers and garden projects use organic fertilizers and soil conditioners effectively.

Objectives

1. Compare chemical and organic fertilizers in terms of the following: soil benefits, nutrient content, effect on crop taste and nutritional value, cost/benefit, and availability under host country conditions.

   Reference pp. 58-60

2. Based on host country small farmer conditions, describe the most appropriate circumstances for recommending either chemical or organic fertilizer.

3. Compare the fertilizer and soil conditioning value of rice hulls, peanut hulls, sawdust, seaweed, manure, and compost.

   Reference pp. 60-67

4. Give the pros and cons of green manure crops in terms of client farmer conditions, and give 2 feasible green manure crops for your work area.

5. Composting
   a. Build a compost pile and manage it so that decomposition progresses normally.
   b. Briefly describe what goes on during the composting process, and list the 5 essentials of rapid composting.
   c. Give the causes and remedies for these composting problems: failure to heat up, ammonia smell.

6. Apply compost and manure to your crop plots following the guidelines in the PC/ICE fertilizer manual.

7. Give guidelines for applying compost and manure in terms of how, when, and how much.

F. Using Chemical Fertilizers

Goal
This unit enables trainees to help small farmers maximize their returns from the appropriate use of chemical fertilizers.

Objectives

1. Explain the standard 3-number fertilizer labelling system, and give the N-P-K content of 16-20-0 and 0-21-0 fertilizers.

   Reference pp. 72
b. Define the term "fertilizer ratio", and compare the ratios of 12-24-12, 5-10-5, and 10-30-10. p. 72

3. Fertilizer Application Methods
   a. Compare the pros and cons of the broadcast and localized placement (band, hole, half-circle) methods of fertilizer application and give their most appropriate uses in terms of the reference crops and small farmer conditions. pp. 84-86
   b. Give placement guidelines for the methods in 3a.
   c. Apply fertilizer to your crop plots using each of the methods in 3a. and following appropriate placement guidelines

4. Describe the symptoms and causes of fertilizer burn, and explain which fertilizers are most likely to cause burning and how to avoid and treat it. pp. 87-88

5. Fertilizer Math Skills
   a. Given a recommendation in terms of lbs./acre or kg/ha of N, P₂O₅, and K₂O and a price list of available fertilizers, calculate the kind and amount needed for a given field size. pp. 97-99
   b. Give the amount of fertilizer needed per acre or per hectare, calculate the actual dosage needed per plant or per meter or row length. pp. 103-108
   c. Given the nutrient content and prices of 3 straight N fertilizers, determine which one is the cheapest in terms of cost per lb. or kg of N. pp. 99
   d. Convert fertilizer dosages from a weight to a volume basis. pp. 108

6. Troubleshooting Fertilizer Recommendations
   Given 6 faulty fertilizer recommendations, revise them to reflect the proper placement, timing, and kind of fertilizer needed for optimum growth. pp. 92-94

7. Getting the Most Out of Fertilizer Use
   a. Explain why low-budget farmers are usually better off using moderate rather than high rates of fertilizer. pp. 89-90
b. Explain why each of the following factors must be considered when determining the best fertilizer rate for an individual farmer: management level and available capital, limiting factors, type of crop, soil fertility level, fertilizer cost, crop price.

c. List 15 limiting factors that can seriously lower a crop's response to fertilizer.

d. Discuss extension guidelines and techniques for promoting the appropriate use of chemical fertilizers among small farmers and ways of minimizing farmer risk. Give guidelines for setting up an effective fertilizer demonstration plot.

G. Soil Conservation Overview

Goals

This unit gives trainees the relevant skills needed to:

1. Determine when erosion control measures are needed.
2. Help small farmers select and implement the most appropriate erosion control measures for a particular field.

Objectives

1. Explain the process of soil erosion by rainfall and give 3 ways that it damages soil productivity and the environment.

2. Explain how the following factors affect the amount of soil erosion occurring on a field soil slope, slope length, rainfall intensity, soil permeability, amount of ground cover.

3. Discuss the purpose, effectiveness, and feasibility of the following erosion control methods in terms of host country conditions: mulching, contour planting, contour ditches with soil barriers, living barriers, rock walls, step terraces.

5. Using a string level or homemade protractor device, measure soil slope so that your reading agrees within 5% of your instructor's.

6. Progressing down a slope, lay out 3 contour lines using an A-frame so that the lines are in agreement with the instructor's, and construct a ditch and bank system.
V. WATER MANAGEMENT

Goals

During this unit trainees will acquire the relevant skills and knowledge to help small farmers:

1. To apply the correct amount and frequency of dry season and supplemental irrigation to the program crops to favor optimum yields and rooting depth, while maximizing water use efficiency.

2. To select the most appropriate irrigation method for the particular conditions.

Objectives

1. If rainfall is inadequate, water your plots so that both moisture stress and excessive leaching are avoided and maximum rooting depth is encouraged.

2. Describe the symptoms of moisture stress in the reference crops, and identify it in the field.

3. Explain the influence of soil texture, root depth, crop stage, temperature, humidity, and wind on the amount and frequency of dry season watering, and give general guidelines in terms of inches per week, liters or gallons per sq. meter, and total inches/crop.

4. Determine soil water holding capacity using a reference table and the "feel" test for texture.

5. Determine actual soil moisture content using the "squeeze" test and a reference chart, and explain how to use the squeeze test to determine when to irrigate.

6. Determine the depth of watering by using a 1/2" tapered rod.

7. If required, lay out a furrow irrigation system for your crop plots and give guidelines in terms of slope, length of run, and stream size per furrow.

8. Design an irrigation schedule in terms of frequency and amount base on crop stage, root depth, soil type, and weather conditions.

9. Make the following conversions with the aid of references: inches of water needed per area to gallons needed per area, cubic ft. per minute to gals. per minute.

10. Give guidelines for maximizing water use efficiency under marginal rainfall or dry season conditions using the following methods: sunken pitcher, watering hole, trickle irrigation, sunken beds, mulching, double digging.

VI. INSECT CONTROL

A. Identifying Insect pests and their Damage

Goals

This unit enables trainees to:

1. Distinguish between insect and disease damage and to relate the type of damage to the likely class of insect involved.
2. Identify common host country beneficial and harmful insects found on
the program crops.

Objectives

1. List the major ways that insect pests adversely affect crop produc-
tion, and describe 3 common damage symptoms.

2. Given 6 plant samples, distinguish between insect and disease damage
and relate the damage signs to the likely type of insect involved
when relevant.

3. Compare the life cycle of beetles, caterpillars, aphids, leafhoppers,
and stinkbugs.

4. Identify the following destructive insects in the field or lab and
compare their damage symptoms: white grubs, cutworms, rootworms,
wireworms, aphids, leafhoppers, stinkbugs, thrips, flea beetles,
cucumber beetles, Mexican bean beetle, armyworm, earworm, hownworm,
cabbage worm, mole cricket, leaf cutter ants, snails, slugs, (others
as needed).

5. Identify the following beneficial insects in the field or lab: lady
beetles, aphid lions, etc.

B. Non-Chemical Insect Controls

Goals

1. To examine and determine the feasibility and effectiveness of common
non-chemical insect controls re the program crops and host country
conditions.

2. To apply relevant non-chemical control methods on your individual
crop plots.

Objectives

1. Compare the pros and cons, general effectiveness, and feasibility of
the following insect control methods under host country conditions:
biological controls, cultural controls, "organic" controls, chemical
insecticides, integrated pest management.

2. Cultural Controls: Discuss the following cultural controls in terms
of their effectiveness and feasibility: deep tillage, plowing under
crop residues, timing of planting, crop rotation, overall good man-
agement, weed control.

3. Mechanical Controls: Do the same as in 2, above for: hand picking,
cutworm collars, traps, trap crops, flooding.

4. Biological Controls: Do the same as above for: host plant resis-
tance, introduction of predator insects, use of insect diseases such
as Bacillus thuringiensis.

5. "Organic" sprays and other deterrents: Discuss the following in
terms of their effectiveness, feasibility, and safety: garlic-
pepper-onion sprays, soap sprays, "bug juice" sprays, stale beer,
wood ashes, nicotine spray.

6. Try at least one control from each of the above categories on your
plots.
C. Using Chemical Insecticides

Goal

This unit gives trainees the relevant skills and knowledge to help host country small farmers apply chemical insecticides in an appropriate, effective, and safe manner.

Objectives

1. Compare the following insecticide formulations as to application methods, suitability, and handling characteristics: wettable powders, soluble powders, liquids, dusts, granules, baits, fumigants.

2. Compare the 3 main chemical classes of insecticides (i.e. CH, OP, C) as to relative human toxicity and residual life.

3. Define the following: Pesticide, miticide (acaricide), active ingredients, broad-spectrum.

4. Explain the differences between a systemic and non-systemic insecticide in terms of their action, effectiveness, appropriate use, and safety.

5. Explain the functions of a sticker and a spreader (wetting agent) and when they should be used; list 2 homemade stickers, one locally available spreader, and one commercial sticker-spreader available in your host country.

6. Name 4 broad-spectrum insecticides of relatively low human toxicity available in your host country and 3 highly toxic ones.

7. Name 2 relatively safe and effective insecticides for controlling household pests like fleas, cockroaches, and bedbugs in your host country.

8. For each of the pests listed in V. A. 4., recommend an effective chemical control of low to moderate toxicity available in your host country.

9. Give guidelines for combining 2 insecticides or an insecticide and a fungicide in terms of compatibility and appropriateness; give 2 suitable examples relevant to the reference crops.

10. Explain and follow recommended safety guidelines for handling, applying, and storing pesticides.

11. Explain the LD$_{50}$ oral and dermal rating system for comparing the mammalian toxicity of pesticides.

12. List 3 progressive symptoms of insecticide poisoning for each of the 3 main chemical classes; list 5 vital advisability of non-medically supervised administration of antidotes like atropine.

13. List the principal antidote for each of the 3 main chemical classes of insecticides.

14. Give 2 important guidelines for minimizing bee kill due to insecticide use.

15. Mix and apply both a wettable powder and a liquid insecticide with a backpack sprayer and or/hand sprayer and achieve adequate plant coverage without excessive run-off or spray drift; follow label instructions.
16. Apply a soil insecticide for control of soil insects using the broadcast or band method and follow label instructions.

17. a. Mix up and apply an insecticide bait for cutworms following your instructor's guidelines.
   b. Apply slug and snail commercial bait following label instructions.

18. Given small farmer conditions, compare the accuracy and suitability of using generalized insecticide dosages vs. those requiring sprayer calibration.

19. Given an insecticide dosage in terms of kg (lbs.) of active ingredient per hectare (acre), calculate the actual amount needed for a given field size.

20. Given a % strength spray recommendation, calculate how much actual insecticide formulation is needed per given volume of water.

21. Calibrate a sprayer so that you're able to apply a given amount of pesticide over a given area.

D. Sprayer Maintenance, Troubleshooting, and Repair
   
   Goal:
   
   To enable trainees to maintain, troubleshoot, and repair pesticide sprayers.

   Objectives
   
   1. Dismantle and reassemble a backpack (knapsack) sprayer and hand sprayer, and describe the function of each part.
   2. Given a malfunctioning sprayer of either type, diagnose and correct the problem.

VII. DISEASE AND NEMATODE CONTROL

A. Understanding and Identifying Crop Diseases
   
   Goal:
   
   To enable trainees to acquire the relevant skills and knowledge to help host small farmers identify relevant reference crop diseases and to distinguish between disease damage, insect damage, and normal growth.

   Objectives
   
   1. Compare the following groups of plant diseases as to symptoms, method of spread, and general control and preventative measures:
      fungal leaf spots, bacterial lead spots, root-rots, stem-rot, and wilts caused by fungi and bacteria; viruses, non-parasitic diseases.

   2. Distinguish between samples of diseased and healthy plants in the field or lab, and classify the diseases involved into the following general categories: fungal or bacterial leaf spots, stem rot, root rot or wilt caused by fungi or bacteria, virus.
3. Identify the following specific reference crop diseases in the field or lab, and give suitable preventative and control measures: damp-off (all crops); early and late blight (tomatoes, potatoes); bacterial and fungal wilt (tomatoes), downy mildew (cucurbits).

B. Non-Chemical Disease Control Methods

Goal

This unit enables trainees to acquire relevant skills and knowledge to help host country small farmers implement feasible and effective non-chemical disease control measures for the program crops.

Objectives

1. Compare the pros and cons, general effectiveness, and feasibility of the following disease control methods: cultural controls, biological controls, physical controls, chemical controls, and integrated pest management.

2. Give guidelines for implementing the following non-chemical disease control measures, and discuss their effectiveness for the reference crops: crop rotation, resistant varieties, improving drainage, roguing out diseased plants, avoiding tobacco products, equipment sanitation, weed control, type and timing of irrigation, intercropping, controlling insect vectors, plant density, soil sterilization by heat, disease-free seed.

3. Employ relevant non-chemical control measures in your crop plots.

C. Chemical Disease Control Methods

Goal

To assist trainees during this unit to acquire the skills needed to help host country small farmers implement appropriate chemical disease control measures safely on the program crops.

Objectives

1. Discuss each of the following chemical control methods in terms of types of diseases controlled, effectiveness, cost-effectiveness, and feasibility for your client farmers: fungicide seed treatments, soil fungicides, soil sterilants, non-systemic foliar fungicides, systemic foliar fungicides, antibiotics, insecticides for insect vectors.

2. a. Sterilize nursery seedbed soil using one or more of the following methods, and compare their effectiveness against diseases and nematodes: boiling water, baking, steaming, captan drench, formaldehyde, Vapam, methyl bromide, Basamid.

b. Give guidelines and safety precautions for employing each of the above methods.

3. Treat seed with a fungicide dust and achieve uniform coverage.

4. Give guidelines for using foliar fungicides as to: when to begin treatments, frequency of application, using a sticker-spreader, water volume needed, toxicity to humans, safety precautions.
5. Mix up and apply a foliar fungicide with a sprayer and achieve uniform coverage without excessive runoff or spray drift, follow label instructions, explain why uniform coverage is more important with fungicides than insecticides.

D. Nematodes and their Control

Goal

To enable trainees to acquire the relevant skills and knowledge to help small farmers diagnose and control nematode problems.

Objectives

1. List 3 above-ground symptoms and 2 root symptoms of nematode damage.
2. Identify root knot nematode damage in the field or lab.
3. List those reference crops especially susceptible to nematode damage.
4. Discuss the relative feasibility and effectiveness of the following nematode control measures: nematocides, crop rotation, resistant varieties, plowing up and exposing crop roots to the sun, interplanting marigolds, flooding, maintaining a high humus level.
5. Give guidelines for collecting soil and root samples for lab diagnosis of nematodes, and collect samples.
6. Apply Vapam, methyl bromide or other nematocide or soil sterilant to a nursery seedbed following label instructions and give guidelines as to safety precautions, covering, soil condition, and waiting period.
7. Apply Furadan (carbofuran) granules using the broadcast or band method following label instructions, and give guidelines as per 6 above.

VIII. WEED CONTROL

Goal

This unit enables trainees to acquire the relevant skills and knowledge to help host country small farmers improve their weed control management so that weeds are no longer a significant yield limiting factor.

Objectives

1. List 4 ways that weeds lower crops yields.
2. Distinguish between broadleaf, grassy, and sedge-type weeds in the field.
3. Distinguish between annual and perennial weeds in the field, compare their methods of propagation and explain how this effects their control.
4. Identify the following weeds in the lab or field and give their method of propagation: nutsedge, Bermudagrass, Johnsongrass, pigweed, etc.

5. Introduction to Weed Control Methods: Discuss the effectiveness and feasibility of each of the following weed control methods: burning, mulching, the row crop principle, hoe and machete, animal-and tractor-drawn cultivation, herbicides.

6. Keep your plots weeded so that weeds are not a limiting factor.

7. Give guidelines for pre-planting weed control in the reference crops as to timing and number of cultivations.

8. Give guidelines for post-planting weed control in the reference crops as to timing, number of cultivations, avoiding root pruning, soil moisture condition.

9. Give guidelines for operating, adjusting, and maintaining an animal-drawn cultivator if relevant.

IX. VEGETABLE PRODUCTION SKILLS

A. Vegetable Characteristics, Adaptation, Variety Selection, Nutritional Value

Goals

To enable trainees to demonstrate the relevant skills and knowledge to help host country small farmers:

1. Make appropriate choices of which vegetable to grow based on climatic and soil conditions, nutritional value, marketing factors, and management and capital requirements.

2. Select the appropriate variety of a vegetable in terms of time to maturity, shape, color, taste, disease resistance, hybrid vs. open pollinated, etc.

Objectives

1. Circle those vegetables below that have especially good heat tolerance, and underline those with poor heat tolerance: POTATOES, SWEET POTATOES, TOMATOES, PEPPERS, EGGPLANT, OKRA, CABBAGE, SQUASH, CUCUMBER, WATERMELON, BEETS, RADISH, ONIONS, CELERY, SWISS CHARD, CHINESE CABBAGE, HEAD LETTUCE, LEAF LETTUCE, SPINACH, N.Z. SPINACH, BROCCOLI, CAULIFLOWER, COLLARDS, CARROTS.

2. Describe the most reliable visual indicator of a veggie's general vitamin content (esp. Vitamin A), and circle 12 of the following that are notably good vitamin sources: GREEN BEANS, RADISH ROOTS, RADISH TOPS, TURNIP ROOTS, TURNIP TOPS, EGGPLANT, OKRA, BELL PEPPER TOMATO, CUCUMBER, MUSTARD, CABBAGE, COLLARDS, SQUASH, ONION BULBS, ONION GREENS, SWISS CHARD, N.Z. SPINACH, CAULIFLOWER, HEAD LETTUCE, LEAF LETTUCE, CARROTS.

3. Identify the following seeds: TOMATO, PEPPER, EGGPLANT, CUCUMBER, SQUASH, ONION, CARROT, LETTUCE, CABBAGE FAMILY, BEETS, COWPEAS, SWEET CORN.
4. Identify the following seedlings in the field or lab: TOMATO, PEA- PER, EGGPLANT, CUCUMBER, SQUASH, ONION, LETTUCE, CABBAGE FAMILY.

5. List 5 factors that determine the kinds of vegetables grown in a particular region.

6. List 4 vegetable characteristics that vary greatly with the variety (cultivar) selected, and why choice of variety can make the difference between success and failure.

7. Explain the difference between an open-pollinated variety and a hybrid variety in terms of yields, uniformity, and the replanting of harvested seed.

8. List 6 factors that should be considered when selecting a plot of ground for vegetable growing.

B. Direct Planting

Goals

Acquire the relevant skills and knowledge to:

1. Direct plant relevant program vegetables so that a satisfactory stand is attained.

2. Give sound guidelines for plant spacing, amount of seed needed, and thinning.

Objectives

1. Direct plant the following vegetables and obtain a satisfactory stand of plants as determined by your instructor: (List varies with host country).

2. Given the seed spacing involved and a seeds/oz. or seeds/gram table, calculate how many ozs. or grams of seed are needed to plant a given area.

3. Give specific guidelines for planting depth for each of the reference veggies according to seed size and sandy vs. clayey soil.

4. List 3 factors that determine the optimum row spacing for a particular veggie and the main factor that determines in-the-row spacing.

5. Give the pros and cons of single row, band, and broadcast seeding, and give 2 appropriate uses of each reference crops.

6. Discuss companion cropping in terms of benefits and problems, and give 4 appropriate combinations of the reference crops; try at least one combination on your field plots.

7. Protect field planted seeds from "wash out" by using a temporary or grow-through mulch.

8. Give guidelines for proper thinning, and thin your seedlings to favor maximum yields.
C. Raising Transplants

Goal

Acquire the relevant skills and knowledge to help host country small farmers produce vigorous transplants using a seedbox or in-the-ground nursery seedbed.

Objectives

1. Using a seedbox or in-the-ground nursery seedbed, plant and produce vigorous tomato, pepper, eggplant, and cabbage transplants, give plant spacing guidelines.

2. Give 2 recipes for making up an appropriate seedbox soil mix using host country available ingredients, and list the advantages over ordinary soil.

3. For a given size and plant spacing, calculate the seedbox or nursery seedbed area needed to produce the required number of transplants.

4. "Harden" and "block" your transplants, and explain the benefits.

D. Transplanting

Goal

Acquire the relevant skills and knowledge to properly transplant vegetable seedlings and give concise guidelines for why, when and how.

Objectives

1. List 4 benefits of transplanting over direct planting plus one disadvantage; list those reference veggies that respond well to it, and explain why the others are best direct planted.

2. Transplant tomatoes, peppers, eggplant, and cabbage following the guidelines in the "Tips on Transplanting" handout.

3. Make up and apply a liquid "starter" fertilizer solution to transplants, and give the recipe and the purpose.

4. Give concise guidelines for transplanting as to: size and age of transplants, depth of placement, time of day, preparation and handling, shading, and watering.

E. Staking, Pruning, Trellising

Goal

To acquire the relevant skills and knowledge to prune and stake tomato plants and to build appropriate trellising for those vegetables requiring it.

Objectives

1. List 4 available mulching materials in your host country.
2. Prune and stake your tomatoes, and give guidelines as to when, how, and why or why not.

3. Construct appropriate trellising for those of your crops that require it.

F. Vegetable Harvest, Drying, and Storage

Goal

Acquire the relevant skills and knowledge to harvest vegetables at the appropriate stage and to maximize their storage life.

Objectives

1. Harvest your reference veggies at the appropriate time, and give guidelines for optimum harvest stage.

2. Measure the yields of your harvested veggies and convert them to a kg/ha or lbs./acre basis.

3. Compare the relative storage life of root crops, leafy veggies, and fruit type veggies under non-refrigerated conditions, and give feasible storage measures for host country conditions.

4. Construct a vegetable drier, and properly dry 3 of the program veggies.

G. Seed Storage, Quality, and Germination Testing

Goal

Acquire the skills and knowledge needed to visually evaluate seed quality and to maximize the storage life of seed.

Objectives

1. Give guidelines for prolonging the viability of stored seed under tropical conditions.

2. Give 3 visual guidelines for judging seed quality, and distinguish between good and poor quality seed given 6 samples.

3. Conduct a seed germination test on 3 types of seed so that your results agree within 5% of those obtained by your instructor.

H. Seed Production

Goal

Acquire the skills and knowledge to help small farmers grow, select, and save their own seed for replanting.

Objectives

1. Discuss the pros and cons of growing and saving vegetables seeds for planting under host country conditions.
2. Harvest and process seed for replanting from the following veggies: Tomatoes, pepper, (others depending on program).

3. Give guidelines for selecting plants from which seed is to be saved for replanting.

I. Vegetable Production Planning and Recordkeeping

Goal

Acquire the skills and knowledge needed for planning a small scale vegetable production enterprise and for keeping adequate field and cost-return records.

Objectives

1. Maintain a field notebook with detailed and organized records of your plot layouts, planting dates, fertilizer and pesticide applications, crop problems, and yields.

2. Using your references and a list of input prices, draw up a plan for a 1000 sq. meter communal or private vegetable garden using 8 adapted veggies. The plan should include the following: approximate planting and harvest dates, area allotted to each crop, row and plant spacing, estimated production, amount of seed and transplants, kind and amount of specific fertilizers and pesticides and their costs, kind and amount of all other inputs, estimated returns.

X. TRADITIONAL FIELD CROP PRODUCTION OVERVIEW - Cereals and Pulses other than Rice

Goal

Acquire the entry level skills and knowledge needed to help host country small farmers improve their yields and returns from cereal and pulse crop production.

Objectives

A. Characteristics, Adaptation, Uses, Nutritional Value, etc.

1. Define the following: cereal, pulse, legume, grain legume, oilseed row crop.

2. Compare the reference crops as to climatic and soils adaptation, relative water needs, nutritional value, uses, and host country distribution.

B. Growing Practices and Crop Management

1. Compare the growing practices and relative yields for the reference crops under traditional and improved methods in your host country.

2. Outline the major stages of growth for each of the reference crops along with associated management needs and problems.

3. Manage your reference crop plots so that optimum growth is encouraged.
4. Seed Selection, Land Preparation, Planting
   a. Compare the pros and cons of native, improved, synthetic, and
      hybrid varieties under host country small farmer conditions.
   b. Give guidelines for selecting plants in the field from which
      seed will be saved for replanting.
   c. Prepare appropriate seedbeds and plant each of the reference
      crops so that a satisfactory stand is attained.
   d. List the factors that determine the best plant population and
      spacing on a particular farmer's field, and explain their influence.
   e. Give recommended plant population and spacing guidelines for the
      reference crops under host country conditions.

5. Crop Nutrition
   a. Compare the relative fertilizer needs and responses of the
      reference crops.
   b. Using your references, estimate general fertilizer recommenda-
      tions in terms of kg/ha of N-P-K for each of the
      reference crops under host country conditions.
   c. Compare the feasibility and effectiveness of the following fer-
      tilizer application methods under host country conditions:
      band, half-circle, hole.
   d. Apply fertilizer at planting to the reference crops; sidedress
      the reference cereals with N; give guidelines for timing and
      placement.
   e. Give guidelines for facilitating fertilizer application under
      small farmer conditions.
   f. Describe and identify in the field or lab the following visual
      hunger signs: N, P, and K in the reference cereals; others as
      needed.
   g. Distinguish between adequate and inadequate nodulation in the
      reference pulses, and give guidelines for seed inoculation as
      to when needed, method, and precautions.

6. Insect, Disease, Weed Control
   a. Describe and identify in the field or lab the principal insects
      and diseases of the reference crops in your host country, and
      give recommended controls.
   b. Give guidelines for weed control as to when, how, and avoiding
      root pruning or other crop damage.
7. Water Management
   a. Identify the critical water demand periods for each of the
      reference crops, and describe and identify symptoms of moisture
      stress.
   b. Give guidelines for improving water use efficiency under sub-
      optimum rain-fed conditions.

C. Harvesting, Drying and Storage

1. Describe the traditional harvest, drying, and storage method for the
   reference crops in your host country, and identify feasible improve-
   ments.

2. Harvesting Skills
   a. Give guidelines for determining maturity in each of the refer-
      ence crops ("peak maturity" in peanuts), and identify maturity
      in the field.
   b. Conduct a pre-harvest yield estimate on one or more of the
      reference crop plots, and convert to kg/ha of dry shelled grain;
      give guidelines for achieving reasonable accuracy.
   c. Harvest and thresh (or shell) one or more of the reference
      crops.

3. Drying and Storage Skills
   a. Explain the relationship between mold, heat, moisture, insects,
      and grain storage losses; give general guidelines for minimizing
      losses.
   b. Give grain moisture guidelines for safe storage for each of the
      reference crops under the following conditions: crib, sack,
      silo or bin, airtight.
   c. Determine grain moisture content using one or more of the fol-
      lowing methods: oven, salt and bottle, tooth test.
   d. Convert the pros and cons of the following grain storage methods
      under host country conditions: cribs (maize), silos and bins,
      sacks, gourds, clay pots, airtight storage.
   f. Construct a maize storage crib suitable for drying and storging
      ear maize and/or a silo for shelled grain.
   g. Calculate the storage capacity of a crib, bin or silo, given the
      dimensions.
   h. Identify the following grain storage pests and describe their
      life, cycles, maize and rice weevils, Angoumis grain moth,
      cowpea bruchids, etc.
   i. Describe and compare the effectiveness and feasibility of avail-
      able non-chemical and chemical methods of storage insect and
      rodent control.
j. Employ suitable storage insect and rodent control measures in your storage facility as needed.

D. **Integrated Crop Management**

Give guidelines for developing and implementing a locally adapted package of improved practices for each reference crop under host country conditions.

XI. **RICE PRODUCTION OVERVIEW**

**Goal**

Acquire the entry level skills and knowledge needed to help small farmers improve their yields and returns from rice production.
APPENDIX B
SUPPLY AND EQUIPMENT LIST
FOR THE CROPS TRAINING COMPONENT

Use this master list as a guide in drawing up a list suited to your particular program and budget.

Instructional "Software"
(One per trainee)

3-ring loose-leaf binders (1.5" diameter rings or larger) for holding the guidelines, other handouts, and notes.
8.5 x 11" college ruled spiral notebooks (80+pp.) for taking notes.
6 x 9" college rule spiral notebooks for use as field notebooks.
Plastic 12" English-metric ruler with holes for fitting in a 3-ring binder.
Pens, pencils.

Crops Supplies, Equipment, and Tools

100 ft. tape or metric equivalent
6-8 pocket tapes 10-25 ft. or metric equivalent
Hammers
Saws
Nails
Pliers
10-12" adjustable wrench
Wire cutters
Lumber for seedbox and A-frame (soil conservation contour device) construction
Strong twine for tracing out plots (baling twine is excellent)
Stakes for marking out plot blocks and individual plots
Files for sharpening tools
Jars for seed and insect samples (baby food size)

5/8-3/4" reinforced garden hose if piped water is available
Sprinkler head(s) and riser(s) for emergency irrigation
Watering cooler or other large container for drinking water
1-gal buckets with handles for hauling manure, compost
Wheelbarrow(s)
Hoes, shovels, rakes: ideally, one per trainee
Homemade measuring sticks 1 meter long, made from 1" x 2" lumber with cm markings filled in by trainees
Pitchforks for turning compost
Portable handing scale for measuring yields
Measuring spoons; cups or accurate substitutes for measuring ag chemicals
Plastic rain gauge for keeping rainfall records

55 gallon drums for storing water for hand irrigation

Machetes

3 lb. hammer for driving stakes

Pocket magnifying glasses (10x) for insect and disease identification (one per trainee; available in coin and stamp stores)

Thermometer for measuring compost temperature cup to 160°F.

Backpack (knapsack) sprayers (15 liter or 4 gal. capacity); one per 6 trainees; one Stateside source: Root-Lowell Co. in Michigan, tel. 616-897-9211.

1.5-2 gal. compressed air sprayers

Dusters

Hand pushed or animal-drawn cultivators, planters, etc.

Soil pH test kits if relevant; do not buy the common garden type; the Hellige-Truog kit is one of the best. NOTE: Do not buy portable soil test kits for measuring N-P-K; they are notoriously inaccurate, especially in tropical soils.

4 or 6 mil thickness clear plastic (6-8 ft. wide) for greenhouse use or for a soil fumigation cover.

Transplants (tomato, pepper, eggplant, cabbage, collard, etc.).

Seeds for planting and for seed samples (see lesson plan on land preparation and planting sessions)

Seed envelopes for packaging small seeds to avoid wasteage

Mulching material: hay, straw, peanut hulls, rice hulls, sawdust, etc.

Newspaper or rags for germination tests

3-in-1 type oil for tool and equipment lubrication

Manure and/or compost: 2-4 kg/m² on vegetable plots (cow, horse, pig); 1-2 kg/m² for poultry or sheep manure.

Chemical fertilizer: a 1:2:1 ratio is ideal for planting or transplanting applications; for sidedressing, use urea, ammonium nitrate or ammonium sulfate

Lime if needed

Fungicide for seed treatment like Captan (Orthocide) or Arasan (thiram)

Fungicide for seedbed drench (Captan, Ferbam, PCNB, etc.)

Foliar fungicides like Maneb, Zineb, Manzate, Benlate, etc. for field and instructional use

Relevant insecticides: Malathion, carbaryl (Sevin), trichlorfon (Dipteres), etc.

Herbicides if relevant: Gesapri (Atrazine), paraquat (Gramoxone) etc.

Other relevant ag chemicals: Vapam, methyl bromide, etc.

Legume seed inoculant for soybeans, peanuts, etc.
APPENDIX C
SAMPLE PLANTING INSTRUCTIONS

PC/Kenya Program, 9/82

YOUR PLOT #:

PLANTING INSTRUCTIONS

Plot 1: Direct Planted Vegies

We'll be spending a lot of time in the field the first week or so preparing land and planting:

Radish
Okra
Lead lettuce
Chinese cabbage
Spinach
Squash
Cucumber
Tomato
Pepper
Eggplant
Cabbage
Collard
Onion
Sweetpotatoes
Pearl Millet
Beans
Groundnuts
Grain sorghum
Maize

You'll each have your own individual plots containing these crops.

We'll start off by making a raised seedbed and planting OKRA, RADISH, LEAF LETTUCE, CHINESE CABBAGE, and SPINACH. Check out the planting diagram below:

(NOTE: 100 centimeters = 1 meter)

NOTE: that one row of each vegie will receive chemical fertilizer, while the other row will be left without for comparison. In addition, we'll work manure into the entire bed.
Planting is one of the most delicate and critical parts of crop production, especially with tiny seeds. Care and attention to detail really pay off. Sloppiness and haste will give you results likely to win an ag gong show. Please follow the instructions carefully, and do it right the first time. Replanting is a drag!

STEP 1: MAKE A RAISED SEEDBED

During the wet season in Kenya, veggies are often sown on raised up beds 10-20 cm (4-8") high. A raised bed makes for better drainage, less bending over when working with the plants, and the soil stays much looser since you can reach all the plants without walking on the bed. Also, plants can be spaced much closer together, because there's no need to walk between the rows.

Since this field's soil is very sandy and tends to dry out very quickly, DON'T MAKE YOUR RAISED BED HIGHER THAN 10 cm. Here's how to do it:

A. Check out the raised beds left by the last group to get an idea of what yours should look like. Your bed should have an actual planting surface of 1 meter x 3.8 meters as outlines by the 4 stakes marking your plot. Note that the sides slope outward at about a 45° angle to lessen erosion.

B. Use a shovel to loosen up the soil inside the 4 stakes to a depth of about 20 cm (8").

C. To raise up your bed, throw in more soil from the 4 alleyways surrounding your plot; add enough soil so that the final bed height will be about 10 cm above the surrounding ground. Manure should be added at the same time (see D. below).

HINT: When excavating soil from the alleyways, don't dig down very deep. Instead, dig very shallow and wide until you have used up all the width of each alleyway; your immediate neighbors will share the remaining halves.

D. Add about 5 shovelfuls of cow manure while building up the bed, and mix it well into the soil with a hoe. Fresh manure like this may "burn" seeds and seedlings unless well dispersed.

E. Smooth over and level out the surface of the bed with a rake (teeth down usually works best). Make the bed surface as level as possible. Be sure you have ended up with a planting surface that's 1 meter x 3.8 meters (not counting the sloping sides).

F. Smooth out all 4 alleyways around your bed so there are no big dips or undulations.
STEP 2: MARKING OUT THE PLANTING FURROWS

Note from the diagram on page 1 that the rows run the short way (1 meter long). Use your measuring stick to measure off and mark out the rows according to the centimeter spacings in the diagram. You can make straight rows easily by lightly pushing the measuring stick into the soil to make a 1 meter long trace mark.

You should end up with 10 traced out rows and still have 1 meter left over beyond the last spinach row for the nursery seedbed which we'll plant later. Mark out the row ends on both sides with small sticks.

STEP 3: APPLYING CHEMICAL FERTILIZER

Why use chemical fertilizer - aren't we going to a lesser-developed country? True, manure and compost are excellent substitutes for chemical fertilizer and also greatly improve the physical condition of the soil; but, very large amounts are needed to do the trick (like 20 tons/acre or more); few small farmers in Kenya have enough organic fertilizers available to cover any more than a small portion of their land. This means that there are appropriate and profitable opportunities for the use of chemical fertilizers too.

We'll cover both organic and chemical fertilizers in training and how farmers can get the most out of each.

OK, check out the diagram again on page 1, and you'll see that the first row of each vegie gets no chemical fertilizer, while the second row does.

Application method: For each of the 5 fertilized rows, apply the fertilizer in a continuous band about 6-8 cm deep and 5-6 cm to the side of the seed row.

Trace out the fertilizer furrows by pushing your measuring stick lightly into the soil and then using your hand to deepen the furrow. Only one furrow is needed per fertilized row.

Application rate: We'll use 5-10-10 fertilizer (5% nitrogen, 10% phosphorus, 10% potassium) at the rate of 600 kilograms per hectare (a hectare = 10,000 sq. meters or 2.47 acres) which works out to:

OKRA: 36 grams per row or 2.5 level tablespoons per row.

RADISH: 12 grams per row or slightly less than 1 level tablespoon per row.

LEAF LETTUCE, CHINESE CABBAGE, SPINACH: 18 grams/row or 1 slightly rounded tablespoon per row.
STEP 4: PLANTING THE SEEDS

Fungicide seed treatment: Pick up your seed packets and ask a trainer to show you the what, why, and how of treating seeds with a fungicide dust to help prevent seed rot caused by damping off disease (a fungus disease). Don't smoke or put your hands in your mouth while handling the treated seed; wash your hands when you finish planting.

Planting Depth: Planting too deep is a common mistake. Little seeds don't have the oomph to push through soil. Besides, seed depth has little or nothing to do with eventual rooting depth. Make the seed furrows (whose ends you've marked out with the sticks) this deep:

- OKRA: 1.5 cm
- RADISH, CHINESE CABBAGE, SPINACH: no more than 1 cm deep
- LEAF LETTUCE: these seeds actually like being planted super shallow so that they even get some light exposure. Barely cover them with soil (or sawdust if available).

Seed Spacing

- OKRA: "Cluster plant" 4 seeds in a group with 3 groups per row like so:
- CHINESE CABBAGE: Cluster plant 4 seeds/group with 20 cm between groups, starting 10 cm in from the edge. You should be able to fit in 5 groups/row.
- RADISH, CHARD, SPINACH: Space out the seeds about like this:
- LEAF LETTUCE: Space them out about like this:

CAUTION: Try not to overplant. It wastes seed and necessitates very laborious thinning of the crowded seedlings.

After planting, fill in the furrows with soil (or with sawdust in the case of the lettuce) and lightly tamp them down with a rake.

STEP 5: MAKE A LIP AROUND THE BED'S EDGE to HELP RETAIN WATER

Use your hands and/or a rake to form a slightly raised lip around the 4 edges of the planting surface to help keep water from running off the bed.
STEP 6: APPLY MULCH TO THE BED

To help conserve moisture and prevent seed "washout" by heavy rains or over-zealous watering, apply a hay mulch over the entire bed (minus the nursery area). Put it on thick enough so that you can't see any soil through it (usually about a 10 cm thickness). Mulch the sloping sides of the bed too.

STEP 7: WATER THE BED

The amount of water the bed will need depends on how dry the soil happens to be the day of planting. The trainers will tell you how many watering cans of water will be needed.

Water gently to allow the water to seep in rather than running off the bed or ponding in depressions and running off from higher areas of the bed.

FOLLOWUP TASKS

1. The bed should need no further watering until the seedlings emerge if you put enough mulch on to retard water evaporation.

2. Removing the mulch: As soon as seedlings begin to emerge, the portion of the mulch directly over the seed row must be removed. Otherwise, shade will quickly make the plants turn spindly and yellow, and they'll also be more prone to damping off fungus disease which also attacks the young stems as well as the seeds.

3. Mulching between the plant rows: You'll probably have to remove most of the mulch between the rows when the plants are tiny to avoid shading them. However, as the plants get bigger, you'll want to build up the mulch between the rows to help conserve soil moisture, keep weeds down, and reduce soil erosion on the bed.

4. Thinning: Since most veggie seeds aren't very hardy, we purposely overplanted by 4-10 fold to help assure an adequate stand of plants. This means you'll need to thin out plants from the rows off and on during the first three weeks or so of growth to achieve the optimum final spacing. Thinning is something that's done gradually on several occasions, rather than all at once.
**July 3**

1) Prepared raised bed as above; mixed in 5 shovelfuls of composted cow manure.

2) Added 5-10-10 at rate of 600 kg/ha.
   - okra: 36 gm/row or 2½ T.
   - radish: 12 gm/row or 1 level T.
   - all the rest: 18 gm/row or 1 rounded T.

3) Treated seeds with captan (a fungicide) to prevent damping off.

4) Planting depth:
   - okra: 2 cm
   - radish, mustard: 1 cm
   - lettuce, amaranth: ½ cm

5) Watered - 14 gallons; mulched.

**July 5**

Radishes emerged - removed mulch from them.
Rain = 45 mm - overnight, (flattened radishes !)

**July 8**

Lettuce emerges.
Radishes have damping off - replant!
Insect Troubleshooting

While visiting Suheyula's vegetable garden, you notice a number of insect damage symptoms. For each of the symptoms listed below, match up the likely insect culprit by placing its number next to the relevant symptom. Some symptoms can be caused by more than one culprit.

### Symptom

<table>
<thead>
<tr>
<th>Possible Insect Culprits</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Holes in leaves or ragged edges on leaves (no slime trails)</td>
</tr>
<tr>
<td>2. Sawdust-like or granular excrement (green or brown):</td>
</tr>
<tr>
<td>3. Puckering, crinkling, yellowing or curling of leaves:</td>
</tr>
<tr>
<td>4. Damaged roots showing signs of insect feeding:</td>
</tr>
<tr>
<td>5. Wilting (if caused by insects):</td>
</tr>
<tr>
<td>7. Young seedlings and recently transplanted transplants cut off at the soil surface.</td>
</tr>
<tr>
<td>8.</td>
</tr>
</tbody>
</table>

EGG------ LARVA------ PUPA------ MOTH

EGG------ LARVA------ PUPA------ BEETLE

EGG------ NYMPH------ ADULT

a. Circle those life cycle stages shown above that actually damage plants.

b. Name one insect for each of the 3 types of life cycles above.
c. Which kinds of insects are most often transmitters of diseases, especially viruses?

3. Identify the insect specimens on the table and give the type of damage they cause (sucking, chewing, etc.).

<table>
<thead>
<tr>
<th>Insect</th>
<th>Type of Damage</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Chemical and Nonchemical Insect Control

4. While visiting one of your women's group's vegie projects, you spot several insect pests whose damage is obviously near or above the economic threshold. For each of these pests listed below, match up the appropriate control options by their numbers next to the relevant pest.

NOTE: In some cases, there may be more than one appropriate control for a pest; also, some of the controls may be appropriate for more than one pest.

<table>
<thead>
<tr>
<th>Insect Pest</th>
<th>Controls Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cut worms</td>
<td>1. Bacillus thuringiensis (Dipel)</td>
</tr>
<tr>
<td>Crickets</td>
<td>2. Placing collars around stems</td>
</tr>
<tr>
<td>Slugs &amp; Snails</td>
<td>3. Sevin spray</td>
</tr>
<tr>
<td>Cabbage loopers</td>
<td>4. Parathion/or Endrin spray</td>
</tr>
<tr>
<td>Aphids</td>
<td>5. Making up a bait of rice bran, molasses, and appropriate insecticide.</td>
</tr>
<tr>
<td>Colorado potato</td>
<td>6. Hand picking</td>
</tr>
<tr>
<td>beetles</td>
<td>7. Leaving boards on the ground in the plot overnite and then stomp on them.</td>
</tr>
<tr>
<td></td>
<td>8. Lady bugs (the women tell you their numbers are rapidly increasing).</td>
</tr>
</tbody>
</table>
5. Suppose the local ag store sells Folidol M (oral LD$_{50}$ of 14), Endrin (oral LD$_{50}$ of 1) and Malathion (oral LD$_{50}$ of 1375). What, if anything, do these LD$_{50}$ ratings tell you about the relative toxicity of these products to humans, the advisability of their use by small farmers, and their relative toxicity to insects?

6. What information do the 3 insecticide labels below tell you?

- Sevin 80W
- Malathion 57% EC
- Lindane 5D

7. Mark the following statements true or false. IF FALSE EXPLAIN WHY.

a. Wettable powders and soluble powders both require periodic agitation during spraying. T F

b. As a general rule, small farmers should never use Class I insecticides and should avoid using Class II products whenever possible. T F

c. Dusting plants with an insecticide dust provides more uniform and lasting leaf coverage than spraying insecticides on plants. T F

d. Rubber gloves and a respirator should be used when applying Class III and IV insecticides. T F

e. Organic phosphate insecticides are usually much more toxic than chlorinated hydrocarbon insecticides. T F

f. The antidote for insecticide poisoning varies with the product's chemical class (i.e. OP, CH, C). T F

g. A systemic insecticide should be used for sucking insects because non-systemics (contact insecticides) are ineffective. T F

h. Most chlorinated hydrocarbon insecticides like Aldrin and Dieldrin and DDT have much longer residue lives than organic phosphates and carbamates, but there is little relationship between human toxicity and chemical class. T F

8. What is the function of a STICKER and a SPREADER and when should they be used?
9. List 2 homemade stickers readily available in your host country and one readily obtainable spreader.

10. List 4 cultural and/or mechanical practices that would be effective in minimizing insect infestation:
   a. 
   b. 
   c. 
   d. 

11. Akugid's 3 year old son had just swallowed some methyl parathion stored in a Coke bottle.
   a. What first aid measures would you apply at this stage?
   b. Suppose that despite your efforts the boy goes into convulsions and then loses consciousness and stops breathing, although his heart is still beating. What do you do now?

12. Lin Pao has been applying Azodrin (Class II) with a leaky sprayer and complains of dizziness and nausea. What immediate action should be taken? How about long term?

13. What is the feasibility and effectiveness of using "organic" repellent sprays like garlic-hot pepper?

14. The local farmer's co-op has just brought several knapsack sprayers. No one has ever used a sprayer before, but several farmers have serious problems with aphids on their tomatoes and you have recommended Malathion 40WP.
   a. How thoroughly should the leaves be covered (top sides only, bottom sides only, both sides) and why?
   b. How can they tell if they are putting too much spray on?
Watering I

15. Name 3 factors you would consider in determining the weekly watering needs of a plot of young seedlings:
   a.
   b.
   c.

16. Overwatering is a very common mistake when vegetable seedlings are young. What disease is encouraged by overwatering?

   What are the symptoms of this disease?

17. Answer TRUE or FALSE:
   a. Sandy soils need more frequent but lighter waterings than clayey soils.
   b. The shallower the roots the less often watering will be needed.

18. Identify each of the sprayer parts on the table and explain its function.

   PART A NAME: 
   FUNCTION:

   PART B NAME: 
   FUNCTION:

19. What's wrong with each of the 2 types of sprayers out on the patio? (NOTE: There are 2 backpack sprayers and 2 compressed air sprayers, but the duplicates have the identical problem, so you only need to look at one of each type.)

Transplanting

20. Give 3 reasons for transplanting which you might use to convince a farmer of its benefits to her/him.
   a.
21. When is the best time to transplant if no materials are available for shade?

22. What two ways can you make a starter solution and why would you want to use a starter solution?

**Vegetable Characteristics**

23. List or describe two factors about Vitamin A which you consider important information for a Peace Corps Volunteer working with women in Kenya. Do the same for Vitamin C. (Do not say "essential for health"--be specific!)

Vitamin A: 1.
2.
Vitamin C: 1.
2.

24. Circle the vegetables in the following list which are excellent sources of Vitamin A:

- eggplant
- cabbage
- collards
- sweet potato
- okra
- beets
- leaf lettuce
- hot peppers
- tomatoes
- head lettuce
- carrots

25. List two advantages and two disadvantages of using hybrid seed.
CROPS EXAM #3 – TAKE-HOME

You stop by Gado’s farm to visit her and find she has a question for you. The
PCV you replaced was totally into organics and said never to use chemical fertil-izers, but the other extension agents in the area say to use only chemical fer-
tilizers and not to worry about such things as composting and organic ferti-
lizers.

Gado has collected 200 kg of cow manure and has received an ag credit loan suf-
ficient to buy 500 kg of chemical fertilizers. She’s getting ready to plant the
following crops:

Ten 1 x 5 meter beds of tomatoes, collards, and lettuce
An 80 x 100 meter plot of maize using improved practices
A 40 x 50 meter plot of cowpeas

She'd had her soil tested at the lab which has recommended the following:

<table>
<thead>
<tr>
<th></th>
<th>KILOGRAMS PER HECTARE</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>N</td>
</tr>
<tr>
<td>Maize Plot</td>
<td>60</td>
</tr>
<tr>
<td>Cowpeas</td>
<td>0</td>
</tr>
<tr>
<td>Vegies</td>
<td>80</td>
</tr>
</tbody>
</table>

If the following fertilizers are available, which ones should she use on each
plot, how much of each, and how and when should they be applied?

200 kg of cow manure 15-15-15
16-20-0 Ammonium sulfate (20-0-0)
10-20-20 Single superphosphate (0-20-0)

HINT: Be sure to consider plot size and the basic rules of fertilizer applica-
tion (i.e. spoonfeeding B, etc.). The recommended NPK rates are total
rates not just at-planting rates.
**FINAL COMPREHENSIVE CROPS EXAM**

**Field Section**

There are 14 numbered field stations, and you'll have 3 minutes at each one:

**STATION 1:** Identify these 4 seedlings:

Seedling A:
B:
C:
D:

**STATION 2:** Troubleshoot this raised bed of vegies and list 4 faulty management practices that you notice.

1.
2.
3.
4.

**STATION 3:** Identify the insects on the chair and their type of damage (suckling, chewing, boring).

<table>
<thead>
<tr>
<th>Sample</th>
<th>Insect Name</th>
<th>Type of Damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>A.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>B.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>D.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>E.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>F.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**STATION 4:** If farmer Jomo wants to get his farm's soil (see scale model on ground) analyzed, how many soil samples should he send into the lab?

How deep should the samples be taken?

If his farm's soil was tested 2 years ago, would you recommend that he send in samples this year?

**STATION 5:** Troubleshoot this just transplanted transplant and list 4 faulty management practices that you notice.

**STATION 6:** For each of the 3 designated tomato plants, state whether or not it has been properly pruned, and explain why or why not.

Plant A:
Plant B:
Plant C:
STATION 7: What would be an appropriate use of this grain moisture test?

In this case, what do the results tell you?

STATION 8: By now you're all pretty anxious to get on that Silver Bird for Kenya. Since you're already pacing, pace out the area demarcated by the 4 stakes and estimate the area of this plot in square meters.

STATION 9: Farmer Mary asks you to look at her pulse plot and tell her what's wrong. List at least 4 limiting factors that you notice.

STATION 10: What's wrong with each of these plants. Be as specific as you can.

Plant A:
Plant B:
Plant C:
Plant D:

STATION 11: Mystery Pesticide Time:

A. From a safety standpoint, would you recommend that small farmers use this product?

B. What chemical category does it belong to (i.e. organic phosphate, chlor. hydrocarbon, carbamate) and why would this be valuable to know?

C. Is it a systemic?

STATION 12: Determine the texture of these two soil samples and classify them as to sandy, loamy or clayey.

Sample A:
Sample B:

STATION 13: Check out the seed samples on the chair for visually identifiable quality defects, and explain what, if anything, is wrong with each.

Sample A:
B:
C:
D:

STATION 14: Troubleshoot this transplant bed and list 4 limiting factors you notice.

STATION 15: Why won't this sprayer function properly?
An Example of a Final Comprehensive Crops Exam: Sitdown Portion

FINAL CROPS EXAM
Sitdown Section

Name ____________________________

1. Why do sandy soils need more frequent but lighter waterings than clayey soils?

2. Circle the materials below that are relatively good sources of N which would be best for mixing with low N materials for a compost pile.

- sawdust
- young grasses
- rice straw
- wood ashes
- fresh manure without bedding
- Millet stalks after harvest
- peanut hulls
- rice hulls

3. What are 4 essentials for rapid composting?

4. You have finally convinced two farmers to start compost piles. One farmer's pile does not heat up and the other farmer's pile stinks to high heaven of ammonia. What are the likely causes of each problem and how would you correct them?

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Mostly Likely Cause</th>
<th>Correction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pile doesn't heat up</td>
<td>Ammonia smell</td>
<td></td>
</tr>
</tbody>
</table>

5. How can you recognize good sources of Vitamin A in vegetables? How would you prepare foods so the vitamin A content is not destroyed?

6. Name 3 vegetables that are good sources of vitamin C. How would you prepare them so that the vitamin C content is not destroyed?

7. Your women's group wants to plant tomatoes for marketing. When you and the group go to buy seed, you find several different varieties to choose from. Name five factors you would consider in helping them select an appropriate variety.

8. Kihanya has several problems with her sweet corn:

1. corn leaf aphids
2. corn earworm (pupate in the soil)
3. Johnsongrass (reproduces by rhizomes)
4. MDMV, Maize Dwarf Mosaic Virus (spread by corn leaf aphids, harbored by Johnsongrass)
List 3 chemical and/or non-chemical controls that will, as a group, reduce pest damage by all 4 pests to Kihanya's crop next season.

9. Your farmer friend Rosa had her soil tested, and the fertilizer recommendation calls for applying 12-24-12 at 300/kg per hectare at tomato transplanting time. She knocks on your door at 5:00 A.M. and asks for some help with the following:

   a. Her tomato field measures 20 x 20 meters. How much 12-24-12 should she buy?

   b. How many grams of 12-24-12 should each tomato transplant receive if the rows are 1 meter apart and the plants spaced 40 cm apart in the rows?

10. Maria has 3 disease problems on her tomatoes, fusarium wilt (a soil borne fungal stem rot), fungal leafspots, and a virus disease associated with aphids. List 2 controls either chemical or non-chemical that she should use next year to control these diseases.

   Fusarium wilt:
   Fungal leafspots:
   Virus:

11. Under that circumstances would you use insect baits?

   How are they applied?
   What ingredients would you use to make a bait?

12. While visiting one of your women's group's vegie projects, you spot several insect pests whose damage is obviously near or above the economic threshold. For each of these pests listed below, match up the appropriate control options by their numbers next to the relevant pest.

   NOTE: In some cases, there may be more than one appropriate control for a pest; also, some of the controls may be appropriate for more than one pest.

<table>
<thead>
<tr>
<th>Insect Pest</th>
<th>Controls Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cutworms</td>
<td>1. Bacillus thuringiensis (Dipel)</td>
</tr>
<tr>
<td>Crickets</td>
<td>2. Placing collars around stems</td>
</tr>
<tr>
<td>Slugs &amp; snails</td>
<td>3. Sevin spray</td>
</tr>
<tr>
<td>Cabbage loopers</td>
<td>4. Parathion or endrin spray</td>
</tr>
<tr>
<td>Aphids</td>
<td>5. Making up a bait</td>
</tr>
<tr>
<td>Mexican bean beetles</td>
<td>6. Hand picking</td>
</tr>
<tr>
<td></td>
<td>7. Leaving boards on the ground in the plot overnight and then stomping on them.</td>
</tr>
<tr>
<td></td>
<td>8. Lady bugs (the women tell you their numbers are rapidly increasing).</td>
</tr>

</table>
13. Under what circumstances would you want to use a systemic insecticide?

14. How do pulses and cereals compare nutritionally?
   Why is each one important to a person's diet?
   What is the nutritional advantage of eating them together?

15. Rank the three cereal grains -- sorghum, maize, millet -- according to drought resistance and heat tolerance.

16. What are the first aid procedures to follow for:
   a. oral insecticide poisoning
   b. dermal insecticide poisoning

17. What if anything is wrong with each of the following fertilizer recommendations:
   a. 100 kg/ha urea 45-0-0 applied when maize is planted followed by a side dressing of 300 kg/ha 10-20-10 when maize is tasseling.
   b. 400 kg/ha 12-24-12 applied at tomato transplant time in a half circle cm deep and 30 cm from the plant followed by an N sidedressing every 3-4 weeks placed in a half circle 10 cm out from the plants.

18. Mary is about to store 1000 kg of shelled grain in a silo.
   a. What preventative measures should she take to help minimize weevil infestation?
   b. Suppose that six weeks later, Mary finds hot spots in the grain caused by weevil buildup. What can she do?
