The design and development of a test of inference ability in reading comprehension for grades 6, 7, and 8 (the Phillips-Patterson Test of Inference Ability in Reading Comprehension) are described. After development of a contemporary theoretical framework for the test of inference ability in reading comprehension, the design, item development, and test development iterations of the test are outlined. The test was administered to 999 students from schools in Alberta, Newfoundland, Labrador, Nova Scotia, and Ontario, Canada. Test score results were analyzed by province, sex, grade, and age group. Data analysis provided results on item difficulty, the relationship of item performance to overall performance and of story performance to overall performance, test wiseness, guessing, and Kuder-Richardson 20 Reliability Indices. A copy of the test is appended. (TJH)

ACKNOWLEDGEMENTS

The research reported in this monograph was supported by a grant from the Social Sciences and Humanities Research Council of Canada, Grant No. 410-85-1321. The views expressed are those of the author and not the granting agency. This monograph was prepared while the author was on sabbatical leave as a Visiting Scholar at the Center for the Study of Reading, University of Illinois at Urbana-Champaign. The author would like to thank the Center for the help of its support staff and the use of its facilities.

The cooperation of the students, teachers, and principals of the schools that participated in this project is appreciated. Mr. John Hart, Superintendent of the Placentia-St. Mary's School Board, and Mr. Hubert Furey, Superintendent of the Conception Bay Centre School Board, expressed interest in this project from the outset and extended the utmost cooperation for the duration of the project. I thank the following people for participating in the final data collection and for the tremendous amount of work in facilitating data collection in their province: Arthur Bull (Newfoundland), Ruth Eagan (New Brunswick), Frances Gatherall (Labrador), Gary Heck (Alberta), Brian McAndrews (Ontario), and Elizabeth Rice (Nova Scotia). I express my gratitude to all who participated in the project for without their cooperation this research would not have been possible.

I thank Cynthia Patterson, my research assistant, for her valuable contribution to the project. Special thanks go to Stephen P. Norris for providing insightful and constructive comments at different stages of this work.
CHAPTER ONE

INTRODUCTION

This report describes the design and development of a test of inference ability in reading comprehension for grades six, seven, and eight. The assumption that the ability to make inferences is necessary to reading comprehension is widely accepted by reading theorists and researchers. This observation coupled with the fact that no satisfactory procedures exist for determining the extent to which children make good inferences when attempting to understand text motivated this project.

During the last fifteen years significant strides have been made in unravelling the reading process. The assumption has been, and continues to be, that the more we understand how readers read and learn from text, the better able we will be to teach them to do so. One way to determine how well we have succeeded in teaching students is through tests which can help us measure our students' reading ability as well as the effectiveness of the instruction they receive. Unfortunately, most tests of reading comprehension yield at best superficial and vague information about reading ability.

Over a decade ago J. Jaap Tuinman (1973-1974) remarked that five major standardized tests of reading comprehension were so constructed that users of them were left guessing about whether or not they were valid. It seems that little may have changed in the testing of reading comprehension since that time. In an extensive review of the literature on testing reading (Farr & Carey, 1986), standardized tests of reading were found problematic because it was not easy to make any decision as to what the tests measure.

Based on the work of others and my experience, I present the following three points to highlight some of the problems taken to be most relevant to the development of a test of inference ability in reading comprehension:
1. Most tests of reading comprehension define reading comprehension broadly and vaguely, if at all, and simply test the component parts but ignore the integration of those parts;

2. Most tests of reading comprehension test general knowledge, not reading comprehension;

3. Most tests of reading comprehension are based on the assumption that when a reader selects the right answer (s)he has done so for the right reasons.

A recent issue of The Reading Teacher (April, 1987) is devoted to the state of reading assessment. The articles in the journal repeatedly condemn the way reading is assessed and claim that traditional tests do not assess what is currently known about the reading process (Calfee, 1987; Durkin, 1987; Johnston, 1987; Valencia & Pearson, 1987; Wittrock, 1987; Wixson, Peters, Weber, & Roeber, 1987). In sum, while it is generally agreed that significant strides have been made in reading theory, it seems evident that reading comprehension assessment is not in tune with advances in reading research and theory. Clearly, the time has come to recognize the contribution which research can make to educational reform in the testing of reading comprehension. The research described in this report recognizes such contribution.

The plan of this report is built around four components. Chapters One, Two, and Three offer a contemporary theoretical framework for the test of inference ability in reading comprehension and set the foundation for subsequent chapters. I describe the design, item development, and test development iterations in Chapters Four and Five. The discussion of the final data collection and results make up Chapter Six. The report concludes
in Chapter Seven with a summary of current research and a statement of future challenges for work on inference in reading comprehension.

The following chapter will discuss the need for and conceptualization of a test of inference ability. Reading comprehension and inference will be defined. Without a working definition of what it is we wish to measure, there would be no sound guidance as to what to look for as indicators of inference ability in reading comprehension.
CHAPTER TWO

THE NEED FOR AND CONCEPTUALIZATION OF A TEST OF INFERENCE ABILITY

Evidence abounds to suggest that poor reasoning is prevalent in our students. The National Assessment of Educational Progress (1994) reported large decreases in inferencing responses of 13 and 17 year olds over a ten-year period. Furthermore, the Nation's Report Card (Applebee, Langer, & Mullis, 1987) reports that only small percentages of students can reason effectively as they read and write. Such findings suggest that students are not being guided to perform reasoning activities which require analysis and interpretation.

These findings are not surprising when coupled with research on teaching practices. In the late 1970's Dolores Durkin reported that schools do not teach comprehension, precious little time was devoted to having students explain and substantiate their interpretations. The authors of the Report of the Commission on Reading (Anderson, Hiebert, Scott, & Wilkinson, 1985) lamented that there is very little direct comprehension instruction in most American classrooms. The increased evidence of poor reasoning has lead to claims about deficiencies in school programs and to appeals for action, such as more testing. Yet, most available tests are general and vague about the nature of reading comprehension and do not support instructional improvement. It would make sense that a test designed to specifically measure inference ability and to support instructional improvement would be an important place to start.

In my study of the literature on testing for reading comprehension, and particularly on testing for inference ability, standardized tests of reading are problematic because it is not easy to make any decision as to what measure. To highlight some of the problems, it is necessary to
recognize at the start that prominent researchers in the field declare that reading assessment bears a number of substantial flaws. To elaborate on a couple of pieces of research reported in Chapter One would serve to illustrate some of the flaws.

Tuinman (1973-74) investigated five widely used standardized tests according to the extent to which questions on the tests could be answered without reading the passages upon which those questions were based. Two points emerged. First, although Tuinman was cautious about his conclusions he found significant reason to believe that it was general knowledge and not reading comprehension which was being measured. He suggested that more exploration was needed to discover the extent of this test invalidity. Second, these five major tests did not provide any technical information on the extent to which items could be answered on the basis of information other than that present in the passage. That is, the major tests have failed to address this significant construct validity issue.

The question of validity is a major concern because the predominant approach to construct validity in standardized reading tests, that of correlations with other tests, has a significant weakness. It is based on rather circular reasoning because two tests may be intended to measure the same ability, be highly correlated, and still fail to measure what they were intended to measure. That is, they can possess what Embretson (Whitely) (1983) has called "nomothetic span", but still fail to be representative of the construct they are proposed to measure.

Many of the problems with standardized reading tests remain unresolved and by continuing to use poorly-produced tests we are not recognizing the concerns raised. Anderson (1972) reported that educational researchers have
not yet learned to develop achievement tests that meet the primitive first
requirement for a system of measurement, namely that there is a clear and
consistent definition of the things being counted. A search for definitions
of reading comprehension in the major established reading tests (many of
which were developed prior to the 1970's) reveals that for all intents and
purposes none exist. Generally, each of the manuals says nothing more than
that the test items measure specific skills to comprehend what is explicit in
the material, to judge what is implied, and to draw inferences with reference
to other situations. The tests do not identify which specific skills are
being measured by particular items, nor do the tests report separate scores
for specific skills. Rather, a composite score of comprehension, vaguely
defined, is reported.

Much work is required to give rise to orderly, sensible data in the
evaluation of reading comprehension in general and inference ability in
particular. It is my opinion that as a start much can be learned and applied
to reading from researchers in the field of critical thinking, who have
attempted to elaborate and clearly define the nature of inference (Govier,
1985; Hitchcock, 1983; Norris, 1984; Salmon, 1984; Scriven, 1976). In
particular, I refer to the extensive work of Robert Ennis (1962, 1967, 1981,
1985). His efforts in characterizing rational thinkers has been and
continues to be an invaluable source of ideas for the project, as were
available critical thinking tests (Ennis & Millman, 1985; Watson & Glaser,
1980) and a test of induction currently under development (Norris & Ryan,
1987) which include sections testing for inference-making ability.

Defining Reading Comprehension

As might be expected, reading comprehension has been defined in many ways.
Articles and books (Plato; Farnham, 1905; Huey, 1908; Thorndike, 1917; Richards, 1938; Gray, 1940; Carroll, 1964; Goodman, 1968; Anderson & Pearson, 1964) have been written on and about reading comprehension. While each article and book contributes to a more thorough understanding of reading comprehension, each is incomplete. At times, there are mismatches among the definitions of reading comprehension thereby suggesting that more is yet to be learned. It is beyond the province of this project to attempt to provide a complete and comprehensive definition of such a complex act as reading comprehension. For the purposes of this project, I preferred to remain tentative and prepared to alter my working definition of reading comprehension with subsequent information.

Reading comprehension is believed to be a collection of processes such as predicting, inferring, synthesizing, generalizing, and monitoring, which have been identified and labelled in various ways by different writers in the field (Collins, Brown, & Larkin, 1980; Fagan, 1987; Henry, 1974; Smith, 1971). It is widely accepted that reading comprehension involves more than knowing the correct pronunciation of the words, knowing their individual meanings, and being able to locate information in printed material (Norris & Phillips, 1987; Phillips & Norris, 1987; Spiro, 1977; Tuinman, 1986). Current reading theory defines reading comprehension, more or less, as meaning constructed by a reader through strategic and principled integration of the textual information and background knowledge.

Since an explanation of the intricacies of reading comprehension remains elusive, and since it is agreed that reading comprehension is a complex behaviour which continues to be perplexing, then one cannot set about assessing it in its entirety. Thus, it seems to make sense to study specific
aspects of the process as a means of seeking advancements in the assessment of the complete process of reading comprehension. It is with the process of inference as an aspect of reading comprehension that I am most concerned.

**Inference in Reading Comprehension**

At a general level, inference is a cognitive process used to construct meaning. Inferring in reading comprehension is a constructive thinking process, because a reader expands knowledge by proposing and evaluating hypotheses about the meaning of text.

Good inference-making in reading comprehension requires the thoughtful use of strategies (Collins, Brown & Larkin, 1980; Phillips, 1985; 1987; in press; van Dijk & Fintsch, 1983) and evaluative criteria. Inferences in reading comprehension tend to be good to the extent that readers integrate relevant text information and background knowledge to construct complete interpretations that are consistent with both the text information and background knowledge.

At a specific level, inference requires intelligent human judgement (Ennis, 1973), and necessitates the use of relevant text information and background knowledge. This dependence on background knowledge is important for at least three reasons. First, an inference in reading comprehension is the interaction of relevant information provided in the text and background knowledge. In other words, neither textual information nor background knowledge alone is sufficient to make good inferences. Second, background knowledge enables the generation of alternative hypotheses in inferring. Inference is the basis of understanding which often involves transforming, extending, and relating information (Markman, 1981). Third, without background knowledge one cannot evaluate the strength of inferences to
generalizations and explanations (Govier, 1985), thereby making background knowledge a necessary part of inferential reasoning.

The Objectives of the Test

Having implied the complexity of the reading comprehension process in general, and having described the process of inference as one aspect of comprehension in particular, it is important to reiterate that comprehension is a complicated cognitive process. Indeed, there may be considerable overlap and interdependence among inferring and the other comprehension processes of attending, analyzing, associating, predicting, synthesizing, generalizing and monitoring. A general test of comprehension ability would focus on each of the processes whereas The Phillips-Patterson Test of Inference Ability in Reading Comprehension (TIA), (1987) focuses specifically on the process of inference-making. Such a concentrated focus allows for detailed information on a particular process.

TIA is designed to appraise the inference ability of middle grade students on the basis of full length passages representative of the three kinds of discourse commonly found at the middle grade levels and of topics characteristic of classroom reading materials. TIA is designed to inform teachers about students' inference ability rather than to label students, and to provide diagnostic information for instructional decision-making purposes.
CHAPTER THREE
A PRINCIPLE OF INFERENCE APPRAISAL

The general guideline of ability test validation that directed this research was that the test would be valid to the extent that good inference-making leads to good performance on the test and that poor inference-making leads to poor performance. To be in a position to distinguish good inference-making from poor inference-making implies that there must be standards for making such distinctions. Reading educators should not be satisfied to accept just any inference merely because it reflects some level of the reader's cognitive competence. When we judge someone's inference to be normatively good we are comparing it to what we take to be some standard of expert competence. So, it is important that the best interpretations are inferences in accord with the best available principles. To be in a position to improve reasoning means to be in a position to distinguish good reasoning from bad. To do so, implies that there must be principles and standards.

To apply a set of standards to the quality of inference-making in reading comprehension certain assumptions about the reader, the task, and the text must be made in order to get off the ground. These presuppositions or necessary conditions are stated as follows:

I. A reader must:
   1. be competent with the difficulty level of the text;
   2. understand the demands of the task; and
   3. intend to understand the text.

II. A text must:
   1. be written coherently;
   2. adhere to conventions of communication by being:
      a. as informative as is required for the situation;
b. accurate or complete with adequate evidence for asserted information;

c. relevant to the ongoing situation; and

d. unambiguous and clear.

If these conditions are not met, poor performance on the inference task may be explained through failure to satisfy one, several, or all of these conditions, rather than as a lack of inference ability.

The satisfaction of conditions I and II is necessary for the application of the following principle of inference appraisal to judgments of readers' inference ability in reading comprehension:

Inferences in reading comprehension tend to be good to the extent that a reader integrates relevant text information and background knowledge to construct complete interpretations that are consistent with both the text information and background knowledge.

By complete I mean that the interpretation explains all relevant information. By consistent I mean consistent with what is known to be true: the interpretation does not contain statements that are known to be false, or require as assumptions statements that are known to be false. In short, the interpretation is possible given what is known. Completeness and consistency are thus the two criteria for judging interpretations. Neither criterion by itself is sufficient; they must be used in tandem.

In order to deal with situations where there are competing interpretations, the criteria must also be used comparatively. We must ask which interpretation is more complete, and more consistent, because often neither interpretation will be fully complete and fully consistent (Norris & Phillips, 1987; Phillips & Norris, 1987). Thus, the expression "tends to be"
good to the extent that" is an important part of the principle. The expression is a qualifier which signifies the limitations of the principle and emphasizes that it is not an absolute principle.

Justification of the Principle

The most extensive work done on inference criteria known to me is that of Robert Ennis (1969, 1981). He uses the expression "material inferences" and divides these into two categories: those which generalize the evidence which is offered, and those which derive their support from their power to explain the evidence. The latter category is most representative of the kinds of inferences made in reading comprehension and is thus the focus of this discussion. Ennis presents criteria for judging inferences to explanations. The inferences are justified to the extent that: 1. They explain a bulk and variety of reliable data; 2. They are themselves explained by a satisfactory system of knowledge; 3. They are not inconsistent with available evidence; 4. Their competitors are inconsistent with evidence; and 5. They are simpler than their competitors.

The first criterion is covered in the principle of inference appraisal where it is stated that a reader integrates relevant text information and
background knowledge to construct interpretations that are complete, that is, interpretations that explain all relevant information. Ennis's second criterion (inferences are themselves explained by a satisfactory system of knowledge) and his third (inferences are not inconsistent with available evidence) are incorporated into the principle of inference appraisal where it says that interpretations are consistent with both the text information and background knowledge. That is, the interpretation does not contain statements that are known to be false, or require as assumptions statements known to be false. Competing interpretations that are inconsistent with available evidence would be judged to be poor given the principle of inference as it is stated, thereby automatically incorporating Ennis's criterion 4 into the principle. Ennis's fifth criterion (inferences are justified to the extent that they are simpler than their competitors) is embedded in that part of the principle where it is stated that a reader integrates relevant text information and background knowledge. Irrelevant information can lead to a convoluted interpretation rather than a straightforward one based on relevant information.

A second source of support for the principle derives from research on failures in everyday reasoning. According to Nisbett and Ross (1980) shortcomings in human inference-making reflect peoples' failure to use normative principles and instead to apply simplistic inferential strategies beyond their appropriate limits. They caution that human inference is prone to several major sources of error including, to mention two, an over-reliance on just the information which happens to be available, and an inappropriate weighing of data relevance. Evidence of these two errors has particular bearing for a principle of inference appraisal in reading comprehension. In
the case of the first error, readers often place greater reliance on the text information. In the second case, readers may place too great a reliance on some of the textual information or on their background knowledge thereby failing to properly integrate relevant information from both. The point is that any principle of inference appraisal in reading comprehension must emphasize the necessity of using both relevant text information and background knowledge and of properly weighing the relevance of each.

Nisbett and Ross (1980) also present evidence that more vivid or salient information is more likely to enter inferential processes than is less vivid information. Salient information may influence unduly a person's inference-making. Other research has illustrated the tendency for ideas, once formulated or adopted, to persist despite evidence which might be disconfirmatory (Holland, Holyoak, Nisbett, & Thagard, 1986; McCloskey, 1983). It seems people will point to scant positive evidence to sustain their original interpretation even though substantial negative evidence exists to suggest otherwise. Thus, when some people read and are faced with counterevidence, they will either tend to ignore or misconstrue the evidence to advantage (Phillips, 1987). It seems that a workable principle of inference appraisal must provide a standard against which readers can monitor whether their interpretations are the best explanations, that is, are consistent and complete, or are unduly influenced by one or all of the factors mentioned above.

A third source of support for the principle of inference appraisal is garnered from work in the philosophy of science on inference to the best explanation. Inference to the best explanation consists in accepting a hypothesis on the grounds that it provides a better explanation of the
evidence than is provided by alternative hypotheses. Three important criteria are proposed by Thagard (1978) for determining the best explanation: consilience, simplicity, and analogy. An explanation is more consilient than another if it explains more of the evidence than the other by unifying and systematizing the information while at the same time being informative. A simple, consilient explanation not only explains all that is necessary, but does so without making a host of assumptions with narrow application, merely derived for the moment. The first two of Thagard's criteria, consilience and simplicity, thus offer support for the standards of "completeness" and "consistency" defined in the principle of inference appraisal.

Another source of support for the principle of inference appraisal rests within the reading field. Ellen Markman (1981) in her work on comprehension monitoring acknowledged that distinguishing a good inference from a poor one is complex and closely tied to distinguishing better explanations or better theories. She posits the question of how readers decide whether or not they have understood. Markman shows how theories of comprehension inform theories of comprehension monitoring by describing two fundamental aspects of comprehension. She argues that well organized or tightly structured information is essential to reading comprehension, that comprehension often potentiates the making of inferences, and that the two are interrelated. I propose the following points based on Markman's work on comprehension monitoring: 1. good inferences are highly constrained by the context (text and background knowledge); 2. good inferences are based on warranted assumptions and are progressive in that they subsume previous ideas from the context; 3. good inferences are judgments confirmed by subsequent information.
from the context; and 4. good inferences are judgments having elegance and parsimony within the context. The constraints imposed by context (text and background knowledge), in the four points above, are embedded in the principle of inference appraisal, thereby indicating that context both provides the subject matter (relevant text information and background knowledge) as well as the parameters (... to construct complete interpretations that are consistent with both the text information and background knowledge) of the interpretation. Warranted assumptions (point 2), and inferences that have elegance and parsimony (point 4) are integrated into the principle of inference appraisal in reading comprehension through use of the words "complete" and "consistent" as defined earlier in this chapter.

A further elaboration and confirmation of the above four points is found in the work of Collins, Brown, and Larkin (1980) where adult subjects applied at least four different tests in evaluating the plausibility of the interpretations they constructed. The four tests include: 1. The plausibility of the assumptions and consequences of the model (when a default assumption or a consequence of the interpretation seems implausible, then subjects tend to reject the interpretation); 2. The completeness of the model (interpretations are evaluated in terms of how well the assumptions and consequences of the model answer all the different questions that arise); 3. The interconnectedness of the model (the assumptions or consequences of an interpretation are weighted with respect to how they fit together with other aspects of the model); and 4. The match of the model to the text (occasionally, readers seem to weigh the model in terms of how well its assumptions or consequences match certain surface aspects of the text). Within Collins, Brown, and Larkin's model the integration of text information
and background knowledge in the construction of interpretations is explicitly stated as well as criteria used by adults to test the "fit" of their interpretations.

Summary

The principle of inference appraisal proposed is representative of what is currently known about inference and provides a framework within which to better understand the process of inference-making in reading comprehension. The principle is intended to be neither canonical nor comprehensive but rather to be an advance toward a set of principles. The principle of inference appraisal must be considered tentative and alterable in the light of both further understanding and empirical evidence. However, as shown, it is supported by researchers in the critical thinking, philosophy and philosophy of science, cognitive psychology, and reading fields. There is a remarkable compatibility and overlap in the work, as can be seen by the notions of completeness, consistency, and clarity which all see as criteria of sound inferences.
CHAPTER FOUR

SPECIFICATIONS OF THE PHILLIPS-ATTERSON TEST OF INference ABILITY IN READING COMPREHENSION

It is difficult to separate the design and development of a test, however, since somewhat distinct decisions were made about each, I have opted to devote a separate chapter to each. This chapter will provide the specifications on the design of TIA.

Test Development Framework

Audience

The intended audience for TIA is students in the middle grades. Students in grades six, seven, and eight were selected for both theoretical and practical reasons.

Some of the basic tenets of reading development guided my theoretical decisions. While it is generally agreed that reading development is continuous, it is also agreed that there are stages of development. By the time students have advanced to the middle grades, they have read graded materials, content area subjects, and have generally achieved some degree of independence in the reading process. These facts make it more manageable to separate out inference ability problems, should they exist, from other problems such as vocabulary, syntax, or other failures (Anderson & Pearson, 1984; Gentner, 1983; Vosniadou & Ortony, 1983).

There is research which suggests that there are developmental differences in story comprehension (McConaughy, 1980). It seems that even grade five students focus more on the literal aspects than on the interpretative aspects. Another reason for selecting middle grade students is they have had some instruction in making inferences or in, what is generally referred to in basal reader manuals as, "reading between the lines".
A more practical reason resides in the fact that grades six, seven, and eight are the levels with which I am most familiar in terms of both teaching experiences and other research projects.

**Kinds of Discourse**

Discourse is typically classified as one of four types: (i) exposition, (ii) narration, (iii) description, and (iv) argument (Bock & Brewer, 1985; Brewer, 1980; Spiro & Taylor, 1987). Exposition answers real or imaginary questions. It presents facts or explains why something is important, how something works or what a thing means. Narration informs readers of what is happening; it is an account of events or action and includes characters, plot, theme, and style. Description is a discourse form used to appeal to the senses of the reader and is generally about the appearance of an object, a person, or an event. Argument is a form of discourse in which there is an attempt to convince or persuade through appeals to reason, emotions, or to both. Exposition, narration, description, and argument often overlap so this global classification omits much of the complexity of discourse. In practice, clear-cut classifications are not always possible.

Three of the four kinds of discourse are more familiar to students in the middle grades; argument is less familiar. Thus, it was decided that attention to the three more familiar forms would be sufficient on the TIA test to represent those discourse forms found at the middle grade levels. Exposition is the primary type of discourse found in content area texts. Expository materials are usually written using particular patterns of organization. The patterns which are commonplace are enumeration, time order, comparison-contrast, cause-effect, and problem-solution. Research shows that proficient readers can identify the main ideas and supporting information in expository
materials (Taylor, 1982; Meyer, Haring, Brandt, & Walker, 1980). Since expository materials make up a large percentage of what is read at the middle grade level, it was concluded that any test of inference ability in reading comprehension must contain an expository passage.

Similarly, narration is a familiar discourse form to middle grade students and for that reason is an important segment of TIA. Within literature, narrative pieces may be a creation of the author's imagination or it may be about real-life situations. Fiction makes up one of the largest categories of children's and adolescents' literature and includes fantasies, science fiction, adventure stories, mystery and detective stories, stories about animals, historical fiction, and stories which deal with personal and social issues. Narration is a discourse form commonly found in trade books and literature programs.

Description, while used in ordinary and technical characterizations such as house advertisements or computer manuals, it is often used in conjunction with the other discourse forms for effect.

The three full-length stories in TIA represent the common discourse forms found at the middle grade levels, thereby providing a more thorough appraisal of students' inference ability across a variety of reading materials than tests which assess performance on either isolated passages and questions or on one discourse form. Narrative, expository, and descriptive texts make distinct demands upon readers, readers' knowledge, and expectations about a task and have important consequences for cognitive processing and learning (Anderson & Armbruster, 1984; Brewer, 1980; Spiro & Taylor, 1987). For instance, narrative text is often argued to be easier to understand than expository text for both adults and children (Bereiter & Scardamalia, 1982;
Bock & Brewer, 1985) possibly because readers are less familiar with how expository texts are organized. Since the three discourse forms are an integral part of programs which students at the middle grade levels are expected to learn, then differences in comprehensibility between narrative, descriptive, and expository texts must be taken into account for diagnostic purposes.

**Topic Familiarity**

The role played by background knowledge in reading comprehension has attained such widespread acceptance that it no longer requires a justification. The prior or background knowledge that a person brings to a text is said to be one of the most important factors in understanding, remembering, and interpreting text information (Anderson, Spiro, & Anderson, 1978; Ausubel, 1963; Holmes, 1983; Johnston, 1984; Pearson, Hansen & Gordon, 1979). Furthermore, while topic familiarity or possession of requisite domain knowledge does not necessarily guarantee interest, it does affect the readability and comprehension of text (Phillips, 1987; Walker, 1987). Topic familiarity is seen to be necessary, but not sufficient, for comprehension.

Background knowledge alone is not sufficient for reading comprehension because a reader must know **how** to use that knowledge and **want** to use that knowledge. This is a particularly relevant point in the appraisal of inference ability because a reader must seek a complete interpretation that is consistent with both the text information and background knowledge in order to make good inferences. Since readers must integrate background knowledge with the text information to infer, then to try to separate background knowledge from the text information is to deny the role of background knowledge in reading comprehension. It is not clear what readers'
performance on such a test would mean. Therefore, it is necessary to assess what prior knowledge students have in order to make accurate appraisals of their inference ability in reading comprehension.

Furthermore, since it is an objective of TIA to serve as a diagnostic tool, then it must be realized that readers do not always integrate completely text information and background knowledge. Sometimes readers integrate only some of the relevant text information and background knowledge; other times, readers will select relevant text information and background knowledge, but fail to integrate the two. There are occasions where readers fail to do any of the above and as a consequence fail to make an inference, go off course in their interpretation, or make unwarranted assumptions.

A multiplicity of approaches were undertaken during the development of TIA to establish accurate estimates of middle grade readers' topic familiarity. A more thorough discussion of the procedures will be presented in a subsequent section "Item Development". At this point, it is sufficient to say that a group of graduate students were asked to list ten topics which they felt their students were interested in; one hundred and thirty teachers attending a workshop were asked to list ten topics that they felt their students were interested in; three hundred middle grade students were asked to list ten topics that they thought they could write about without difficulty; and twelve middle grade classes were selected to discuss some of the topics and to write about them. From these information sources three topics were seen to be common areas of interest and within the background knowledge of the intended audience of the TIA test.
Readability

The readability of text is generally assumed to refer to its legibility, ease of reading, and ease of understanding. Many readability formulae have been developed over the years, but they have not been without criticism. Traditional readability formulae have been criticized for having no point of reference (Manzo, 1970), for neglecting the importance of the structure, texture, and informational density of text (Amiran & Jones, 1982), and for lacking face validity (Coupland, 1978).

Alternative ways of estimating readability have been proposed, including the subjective text difficulty approach by Tamor (1981), the psycholinguistic approach by Holland (1981), and the conceptual approach by Rubin (1981). Tamor combines text-based information (readability estimates) and performance-based information (recall scores) to come up with a subjective text difficulty level for individual readers. Holland's psycholinguistic alternative focuses on assessing the meaning-making demands placed upon readers by the language and structure of the text. Rubin's conceptual approach focuses on the concepts conveyed by the text: how arguments are presented, the role of examples in a text, and how characters' interactions are developed and described.

I weighed and balanced the available evidence and decided not to use a readability formula in the traditional sense. Rather, I chose to use what may be described as a composite of both the traditional and alternate approaches to readability. That is, I chose to adhere to the principles of good story writing as well as to call upon the audience of my test as the primary source for deciding upon readability.

The TIA test was written on three topics identified to be familiar to
middle grade students. In the preliminary pilot studies, students were asked to read the stories aloud and to point out areas of difficulty. When the areas identified to be problematic were revised, the text was judged to be appropriate for the intended audience. In accord with Conditions I and II given in Chapter Three, it was important that the stories and inference questions be written coherently and adhere to the conventions of communication, and that a reader be competent with the difficulty level of the text, understand the demands of the task, and intend to understand the text. Otherwise, readers' poor performance on the inference task may be accounted for by a failure to meet these conditions, rather than as a lack of inference ability.

**Test Format**

*The Phillips-Patterson Test of Inference Ability in Reading Comprehension* (See Appendix A for a copy) contains three full-length stories (average of 465 words per story): a narration, an exposition, and a description. Stories consist of four to five paragraphs and twelve scaled-answer, multiple-choice questions. Questions follow each paragraph in the stories. Each question has four answers provided. To answer the questions students are to use information given in the story and information they already know. Students are given an example which is thoroughly worked through so that they will see that they are to consider all possible answers before deciding which answer they think is the "best" one.

The challenge in changing reading assessment is to come up with new means to evaluate our current conceptualization of reading and to diagnose areas where instruction is needed. Reading comprehension admits of degrees. However, credit has generally been given on most tests of reading
comprehension for one and only one correct answer. There has been no allowance for partially correct responses, that is, for evidence that a student may be capable of selecting relevant information without quite knowing what to do with it.

The challenge in the design of TIA was to provide diagnostic information about students' performance and to use that information to support instructional improvement. To achieve this end, TIA represents a creative molding of the old and new. The old format of selecting an answer is there with the new advantage of giving credit for answers that are not completely correct. TIA may be described as a "scaled-answer multiple-choice" test, since it attempts to account for variations in understanding. The four answer choices represent a range in values (0 - 3) assigned according to the quality of the answer selected. An answer that is consistent with both the text information and background knowledge is worth 3 points; a partially-correct answer is worth 2 points; a text-based answer is worth 1 point; and an erroneous answer is worth 0 points (A complete copy of the scoring guide is provided in Appendix B).

**Test Length**

The current version of TIA may be administered in a class period (fifty minutes). This allows time for giving instructions and the actual test-taking time. It is intended to be a power test, so students are given a reasonable time to complete all items. From teacher reports it appears that the average test-taking time is thirty minutes so this may be used as a rough guide if teachers wished to use it as a speed test.

**Item Development**

**Selection of Topics**
Differences in background knowledge among students and graders can be manifested in different ways. These differences may lead to variance in performance on reading comprehension tests and hence to invalid interpretations of students' performance. It is desirable that the world views, or empirical beliefs needed to interpret a story on which test items are based, be ones that most students share. If scores on TIA are to be taken as measures of inference ability in reading comprehension, then it is necessary to reduce as much as possible the effects of background knowledge. To minimize differences in performance which might be due to differences in background knowledge rather than to differences in inference ability, items were selected on the basis of their familiarity to students at the grades six, seven, and eight levels. Sensitivity to this issue of background knowledge led to a comprehensive study of topics for potential selection for item development. The six stages of the study are described next.

Stage One: Graduate Students. The first stage involved eight graduate students with a diversity of teaching experiences. Each student was asked to list ten topics which he or she felt students in grades six, seven, and eight would be interested in and have knowledge of, and to provide a justification for the choices. These are the ten topics which the graduates identified most frequently: travel, space, videos, sports, animals, money, friends, future, styles, and science fiction.

Stage Two: Teachers. In the second stage, 130 middle grade teachers attending a professional development workshop were asked to list ten topics which would interest their students and to justify their list. The teachers identified the following topics most frequently: cars, space, money, science fiction, holidays, music, mystery, computers, sports, and hobbies. The
graduate students' and teachers' lists overlapped on the following topics: space, sports, money, future, and science fiction.

Stage Three: Students (Topic Identification). In the third stage, the ideas of middle grade students were sought. Three hundred students at grades five, six, seven, eight, and nine were asked to list ten topics they thought they could write about without difficulty. Grades five and nine were taken in addition to grades six, seven, and eight to account for potential differences at the upper and lower limits of reading ability in the intended test group. What follows are the most preferred choices of the students: money, space things, sports, pets, getting out of school, holidays, movies, space friends, war, and travel. Overlap in topic choices among all three groups indicates that the most popular choices are money, space or space-related topics, sports, getting out of school, holidays, and pets.

Stage Four: Students (Unassigned Written Essays). In the fourth stage, middle grade students were asked to write on a topic of their choice. This was done to distinguish topics which students would choose to write about from those that might sound exciting but about which they would be unlikely or unable to write. Twelve classes of students in grades six, seven, and eight were asked to choose from the most common topics identified up to this point (money, space or space-related things, sports, pets, getting out of school, holidays) or any other topic and to write an essay.

The essays were generally about space, money, and pets in one way or another. Specific differences existed in the general topic, for instance, essays about pets varied from the time it takes to care for them to how pets are wonderful friends. Bearing in mind that each story on TIA was to be representative of the reading materials at the middle grade levels, then from
the most popular student topics three topics were selected: UFOs, Money, and a Newspaper Mystery.

Stage Five: Students (Assigned Written Essays). In the fifth stage, sixty-five students in grades five through nine were asked to write a story about UFOs, Money, and a Newspaper Mystery. These essays were studied for vocabulary-choice, sentence and idea complexity, and form.

Stage Six: Final Topic Selection. The sixth and final stage of topic selection went through three phases involving free recall and word associations, recognition, structured and unstructured questions and discussions on each of the three topics. These phases represent a synthesis of research on assessing background knowledge (Adams & Bruce, 1980; Anderson, Spiro, & Anderson, 1978; Holmes, 1983; Holmes & Roser, 1987; Pearson, Hansen, & Gordon, 1979; Spilich, Vesonder, Chiesi, & Voss, 1979; Walker & Yekovich, 1984) and are taken to be some of the best available ways to assess background knowledge. It took about five class periods to establish students' background knowledge of each topic.

In phase one, students were asked to free recall or to brainstorm on each of the topics. They were directed to think of all the information they would expect to find in a story about UFOs, a story about Money, and a Newspaper Mystery. Also, students were asked to come up with associations for UFO-related words like heavenly bodies, evidence, and explanations; for Money-related words like uses, forms, characteristics, and changes; and for Newspaper-related words like responsibilities, carrier, weather, and newspaper-related confusions.

The second phase involved recognition activities to identify any misunderstandings which students might have about each of the three topics.
These activities were developed from the phase one discussions. For example, it became evident that some students thought that scientists know what UFOs are and that UFOs are meteors and "stuff like that" in the sky. Students were asked to identify from a prepared sheet dealing with these matters several possible correct and incorrect answers to questions such as "What are UFOs?," "Is a meteor a UFO?" "Would there be UFOs if scientists know what they are?" The answers provided to these kinds of questions led into the final phase of topic selection.

Discussions guided by structured and unstructured questions completed the final phase of establishing topic familiarity. A structured question on the Money topic, for instance, was "What is money?" Such questions led to unstructured questions about the topic such as "Do all jungle tribes have money?", and lively discussions were held with the students on each of the three selected topics.

For the purposes of this project, students were assumed to have a sufficient amount of topic familiarity if they were able to speak to each topic according to a general outline as follows:

UFO Outline

1. What UFOs are believed to be
11. What UFOs are reported to look like
111. Where UFOs are reported to come from
1V. Available evidence
V. Why UFOs are studied

Money Outline

1. What money is
11. The characteristics of money
III. How money developed

IV. Functions of money

V. Why the form of money changes

Newspaper Delivery

I. Carrier’s responsibilities

II. Knowing the route

III. The importance of time

IV. How to deal with people

V. Potential problems

Furthermore, students were deemed to have sufficient relevant background knowledge if at least seventy percent of them were able to speak to these outlines. This provides a rough, but adequate for testing purposes, control for differences in background knowledge for topic. The chances of systematic bias against any student across all topics is minimal.

The comprehensive information gathered from the topics identified, the students’ written stories, and class visits guided the choice of topics for the stories in the TIA test. Three stories were written for the TIA test: UFOs, Money, and The Wrong Newspapers. The UFOs story was modified from previous research projects (Beebe & Phillips, 1980; Phillips, 1985) and continues to be a winner among students. It is a story about unusual phenomena, telling of different UFO reports, offering plausible explanations for some of the reports, and suggesting that with improved technology we may be able to explain UFOs. The Money story is a description of the everyday use of money, of how it works, as well as its historical development. The third and final story is a mystery entitled "The Wrong Newspapers" which involves a mix-up in newspaper delivery, with the culprit being the neighbor’s dog.
Principles of Story Writing

Story grammars have been developed to illustrate underlying text structures. The most common types of text used in the middle grade levels are narrative, descriptive, and expository. Each is organized in a particular way and it is believed that children use the structure, once they have it internalized, to assist them in understanding and recalling information (Thorndyke, 1977; Stein, 1983; van Dijk & Kintsch, 1963).

There is overlap in the classifications of narrative, expository, and descriptive structures since all three may be found in the one story. The Wrong Newspaper story fits more within the narrative classification than either the expository or descriptive. However, the UFOs and Money stories are harder to classify because they overlap considerably the exposition and descriptive forms.

The principles of story grammar were followed in writing the TIA mystery narrative entitled "The Wrong Newspapers". The principles may be summarized as follows: there should be a setting which introduces the characters and provides the time and place of the story; an initiating event should occur which sets the story in action; there should be a response to that action followed by an attempt to achieve a goal or to respond to an action; the consequences of that attempt woven with a reaction are provided. These principles coupled with a sensitivity to vocabulary choice, sentence structure, and sentence length were in our minds during the story writing process. Students' reading of the stories was then used to make final judgments on topic and story suitability.

Narrative provides a resolution or stopping point and therefore it is easier to identify its underlying structure or grammar than is commonly the
case in expository material. Expository material has six underlying structures: serial; topic; restriction and illustration; definition; argumentation; and comparison-contrast. The serial pattern may be considered the generic basic structure since the others are more general secondary structures. These five structures (topic, restriction and illustration, definition, argumentation, and comparison-contrast) are more perplexing than the serial structure from another perspective because within a serial pattern there may be occasions when other structures are used. Consider, the case in a social studies text where forms of travel are being studied in predominantly a serial fashion, but for a couple of paragraphs modes of travel are compared and contrasted followed at the end of the chapter with a generalization about the most efficient means of travel. So, it is common to see much overlap among text structures.

The TIA stories on UFOs and Money were written following primarily a serial pattern: a general concept is presented in each story; generalizations combined with examples are stated; a sequence of events unfolds; a conclusion follows. Care was taken to ensure that vocabulary choices were either known or explained and that sentences were coherent. The UFOs, Money, and The Wrong Newspapers stories were further subjected to the Anderson and Armbruster (1984) test of understandability: do the stories provide enough relevant information to achieve the author's purpose and to be meaningful to its readers? The evidence from the groups of students in grades six, seven, and eight who read and discussed the stories is that the test of understandability was passed.
CHAPTER FIVE
THE EVOLUTION OF THE PHILLIPS-PATTERSON TEST OF INFERENCE ABILITY IN READING COMPREHENSION

The present form of TIA (See Appendix A) represents six phases of evolution in design and development. This chapter will provide details of the modifications at each phase of the test development as well as a rationale for them. A description of the test validation techniques that guided the design and development of TIA will also be discussed.

Experimental Test Versions

Preliminary Test Version

The Preliminary Test Version contained three stories (UFOs, Money, and The Wrong Newspapers) and forty-eight short-answer questions. It was given to a graduate reading class and a colleague who was engaged in the development of a test of inductive reasoning in critical thinking.

On the basis of feedback from these two sources the test was edited and written more concisely. The number of test questions was reduced from 48 to 36 because the test was too lengthy even for these subjects. This task was made simple for two reasons: (i) 5 of the twelve questions were judged to be insufficiently related to the stories to allow for complete and consistent inferences to be made; and (ii) 7 of the twelve questions could not be easily identified as inference questions, so in cases of doubt the questions were dropped from the test.

Pilot Study One (Short-answer Version)

Trial One

Following the completion of the revisions to the Preliminary Test Version, the first pilot of TIA was conducted. A short-answer format, rather than a multiple-choice, was used to help understand what the questions measured. In
addition, this trial administration was done to check on test length, passage difficulty, vocabulary choices, clarity of instructions, and question ambiguities. The effects of story order were studied. Research shows that narrative text is generally easier to understand than expository text. If this is so, then differences in performance could be expected if the order of presentation of discourse types was altered. If differences were identified, then story order would be an important consideration in subsequent test development.

Sample and Procedure. Sixty-five students in grades six, seven, and eight participated. Test booklets were distributed randomly to students with the three stories (UfOs, Money, and The Wrong Newspapers) collated in the six story combinations. The directions and sample paragraph and inference question were discussed with the students. Students were told that they would have to use their background knowledge and the text information to answer the questions, that they would read three stories, and that each story would have four or five paragraphs and questions on each paragraph. Students were directed to read each paragraph, to write their answer to each of the corresponding questions, and to justify their answers. When all student enquiries were answered, then the test was started.

Results. The pattern of student responses to the inference questions was one of the most significant findings. Students' answers were of four types: an implausible response; a non-inference response; a partially-correct inference response; or a complete inference response (A more detailed description of these may be found in Appendix B).

It was found that the TIA test was too long, since it took on average one and one-quarter hours to complete, after directions had been given and the
sample item worked through.

No differences in performance on the basis of story order were found. Students may have acquired new knowledge while taking the test, however, it did not add to nor detract from their performance when story order was altered.

Test Revisions. From an examination of students' answers numerous revisions were made: (i) six questions were reworded to make their meaning more clear and one question was deleted because of ambiguity; (ii) three questions in the UFOs story (#8, 9, 10) were re-sequenced as #10, 8, 9 to match the text sequence; (iii) sentences in the text judged to be too similarly worded to the corresponding inference questions were deleted; (iv) some sentences were modified to be more general, and less explicit thereby making the corresponding inference questions more challenging; and (v) other sentences were changed to clarify meaning.

Upon completion of the revisions based on the results of trial one, the number of questions on TIA for the trial two study was 36, 12 for each story.

Trial Two

Trial two of Pilot Study One (short-answer version of TIA) was done to confirm whether or not the four types of responses identified in the student protocols of Trial One would be upheld. Whether the kinds of responses given by the students in Trial One were an artifact of the test, and whether the revised version would yield similar results was a concern. If the four types of responses were upheld, then subsequent test development would have to take these response variations into account, if test performance was to be taken as a valid indication of student ability.

Sample and Procedure. One hundred students in grades six, seven, and eight
took the short-answer version of the TIA test. The same procedure was followed as in the previous trial.

Results. Students' written responses and accompanying justifications for their answers were studied. The trend of reader response variations identified in Trial One was evident in the responses on this trial. Student responses for each question fell within one of four response patterns identified in Trial One. The four variations (an implausible response; a non-inference response; a partially-correct inference response; or a complete inference response) in student performance became a major factor in the future design and development of TIA.

Test Revisions. Since a multiple-choice format for TIA was the ultimate aim, the fourth version of TIA involved writing a scaled-answer multiple-choice set for use in the second pilot study. The questions on the modified version from Pilot Study One were changed to sentence stems, in order that the item form on the short-answer and multiple-choice versions of the test would be identical. For example, the question "Why do many people mistake heavenly bodies to be UFOs?" on the short-answer version became the sentence stem "Many people mistake heavenly bodies to be UFOs because..." on the multiple-choice version.

It was presumed that the sentence stem format might help to reduce writing time, 90 minutes on the short-answer version, to one class period. Distractors for the multiple-choice version of the test were taken or molded from students' answers on the written short-answer versions from Pilot Study One. Each set of four possible answers were scaled as follows: an implausible response worth 0, a non-inference response worth 1, a partially-correct inference worth 2, and a complete inference worth 3. This "scaled-answer
format" was used to afford students the option to select the type of response they would likely make if they were taking the short-answer version of TIA. Multiple-choice items were constructed such that distractors were of consistent grammatical style and vocabulary, and of equal length. Keyed answers were randomly selected for position placement (A, B, C, or D).

**Pilot Study Two (Short-answer/Scaled-answer Multiple-choice Versions)**

The second pilot study was conducted to serve four purposes: (i) to examine the degree of similarity of performance on the short-answer and the scaled-answer multiple-choice formats; (ii) to compare completion times required by both test formats; (iii) to corroborate whether the four patterns of responses identified in Pilot Study One would be displayed by the students in this pilot; and (iv) to identify potential item ambiguities, vocabulary difficulties, and other problems.

**Sample and Procedure**

Eighty-one students in grades six, seven, and eight participated in Pilot Two. Forty students wrote the short-answer version and the remainder wrote the multiple-choice version. The same procedure described in previous pilots was followed, with one exception. The students taking the multiple-choice version were provided with answer choices. The students were cautioned to consider all possible answers before deciding the answer they thought was the best one.

**Results of Multiple-choice Format**

Test completion time ranged from 50-75 minutes on the multiple-choice format for classes in grades six, seven, and eight. This represented an average reduction of ten minutes over the short-answer format, a reduction less than was expected.
Item analysis of the multiple-choice format showed a KR-20 reliability of 0.68 and a test mean of 17.5 items correct out of total possible 36 items, with a standard deviation of 4.73. The test means for grades six, seven, and eight were 14.0, 17.1, and 19.6 respectively. Item/test biserial correlations and item difficulty indexes were computed and are presented in Table 5-1.

It can be seen from Table 5-1 that three of the thirty-six questions had negative biserial correlations (questions 18, 20, and 35). Examination of these three items coupled with students' short-answer responses revealed the answer sets for questions 18 and 35 to be ambiguous. Question 20 required students to consider a historical perspective, but it appears that most students answered it from a current events perspective.

Questions 8 and 28 had very low biserial correlations. It was clear, upon examination, that the problems with questions 8 and 28 were vocabulary-related. It seems that many students did not note the relevance of particular examples which were cited. For instance, "meteors" were cited as an example of "astronomical events", but students did not see the relevance in answering item 8 which read "Other kinds of astronomical events that people mistake to be UFOs are". It seems students did not understand "astronomical events", so it was replaced with "heavenly bodies". Revisions were made to all aspects of the test identified to be either definitely or potentially problematic.

The item difficulty levels also pointed to problems with questions 18 and 35 discussed in the preceding paragraph. Question 13 was among the more difficult items, it seems that a word in the question stem was interpreted differently by many students from the test authors. The question read "Money is needed in at least two different ways," students interpreted the question by focusing on the word "needed" as necessities. The test authors intended

the item to get at the idea of commonality of money. Clearly, the problem with the item was with the wording and not with how the students interpreted it. Item 13 was revised to read "Money is a familiar part of our lives because".

Results of Short-answer Format

Students' responses on the short-answer format were examined and the type of answer identified (implausible response, non-inference response, partially-correct inference, complete inference). Again, the pattern of student responses was consistent with the two previous trials under Pilot One. This result was taken as compelling evidence that a valid test of inference ability would have to allow for variations in student performance.

Student responses on the short-answer format were compared to the multiple-choice key to assess the agreement between the number of responses per item that received full credit. The results are presented in Table 5-2. It should be pointed out that for purposes of this analysis an item on the short-answer format was not considered correct unless it expressed the same meaning as the keyed answer on the multiple-choice format, consequently the percentages of agreement between the two are necessarily lowered. For instance, consider item 30 which says "Ann wanted to hand deliver Mr. Jones's newspaper because". The keyed response on the multiple-choice format and the one required on the written short-answer format would be "to make sure he got it and to talk to him about the mystery." So, unless students responded on the short-answer version with a compound answer, they were not scored as completely correct even though they may have been partially correct. A lower percentage of agreement was found on those items that required students to synthesize story information. It seemed that if questions required students

to pull together more than one piece of information to formulate a complete response, then they experienced difficulties or did not consider all available relevant information. Question 26, for instance, required the synthesis of three pieces of information; however, the most common response written on the short-answer test and selected on the multiple-choice test was a partially-correct one.

The mean on the 36 item short-answer test was 12.97. A recognized restriction of this pilot was that one and only one answer was deemed acceptable, which undoubtedly ignores a range of answers which may have been partially correct. Bearing in mind this restriction on acceptable answers, then it seems reasonable to expect that the level of overall performance may have been reduced. The mean on the multiple-choice test was 17.15, which reflects a significantly higher level of performance. Another explanation for the lower performance on the short-answer could be related to the fact that students had to construct and write an answer, which would seem to be a more demanding task than selecting an answer on the multiple-choice test. Student performance on the multiple-choice test may be a "better" indication of their reading ability than the short-answer test where performance is confounded with students' ability to express their ideas in writing. Also contributing to lower scores was the fact that students tended to leave more items unanswered on the short-answer test than on the multiple-choice test.

Test Revisions

Passage, question, and answer modifications were made to TIA prior to the next pilot. Revisions were made to each of the three stories. For instance, on the UFOs story, it was found that students failed to attend to the word "not" in the sentence, "Many of the older reports are not complete so we need
to continue to study UFOs", consequently leading to an erroneous response. The sentence was modified to "Many of the older reports are incomplete so we need to continue to study UFOs".

Some questions were replaced because they did not require students to make inferences, and some answers to other questions were replaced because of ambiguity. Other revisions included substitutions in word-choices and changes in information placement. Further revisions included making answer selections more parallel with one another. For instance, "plastic cards" was replaced with "club cards" in item 23 to make it more parallel with the other options: "trade items", "credit cards", "chocolate bars".

**Pilot Study Three (Verbal Reports as Data)**

Pilot Study Three was conducted using a verbal report methodology. Verbal reports were used as a method to validate whether a complete inference had been made when students selected the keyed answer to help ensure that multiple-choice test questions were functioning effectively as inference questions. In addition, such an approach is particularly useful in test development for revealing potential item ambiguities, vocabulary problems, and hidden cues.

Care was taken to develop interview procedures which would not jeopardize the quality of information to be collected and conclusions to be drawn. Two trial verbal report sessions with six students each were held to ensure that the two interviewers understood the demands and limits of the approach, as well as to determine whether the information needed from the students was being acquired.

**Sample and Procedure**

Thirty-six students in grades six, seven, and eight participated. Students
were each assigned to one of the three stories on TIA. They were told that to answer each question they would have to use information given in the story and information they already knew. They were told that the story would not directly answer the questions and they would have to use their common sense and the story information. Students were advised to consider all possible answers before deciding which answer they thought was the best one. A sample item was worked through with them. Once the sample item was completed and students' questions were answered, students were asked to read aloud each paragraph, to read the corresponding test questions, to select one of the four answers provided, and to tell why they thought that answer was the best.

Interviewers questioned students only if there was a lack of clarity in a response, such as an unspecified pronoun antecedent or an answer so terse or vague that it was too incomplete to follow. At the end of the test interview, general questions were asked about students' interest in the story, about whether the passage vocabulary gave them any problems, and about whether there were other things that were unclear to them. Each verbal report protocol was transcribed and a scheme developed to code the quality of students' responses.

**Scoring Responses**

In order to reflect the range of responses shown by students in the verbal reports, a scoring system was devised to allow credit for partially correct as well as complete inferences. Scores from 0 to 3 were assigned on the basis of the range of completeness of the student responses. See Appendix B for the criteria for grading the test of inference ability.

The following question (Q1) and its possible answers (A, B, C, or D) illustrates the scoring system.
Q1 UFOs are sometimes called other names because

(A) people name them according to their shape or probable origin.

This answer is a complete inference and therefore, is given a score of (3). The relevant textual information was contained in sentence three, "People sometimes call UFOs flying saucers, spaceships from other planets, and extraterrestrial spacecraft". Using background knowledge it can be concluded that the naming criteria for UFOs in this story are based on either shape ("saucers") or probable origin ("other planets" and "extraterrestrial"). The integration of the relevant textual information and background knowledge makes (A) the best inference response for question 1.

(D) people don't know what to call them so name them by shape.

This answer is given a score of (2). It is a partially correct inference for question 1 because it only considers one of the naming criteria, shape, when the textual information supplies two criteria. The criterion of shape was selected for this alternative instead of the criterion of origin because shape was focused upon in all instances of explanations by students in the verbal reports.

(C) people see an area with many coloured lights in the sky.

This answer is given a score of (1). It is based on textual information from sentence five. However, the relevant textual information is contained in another area of the text (sentence 3). Although the textual information selected deals with the appearance of UFOs, it is not the most relevant part of the text.

(B) people know they are unidentified flying objects in the sky.

This answer is scored as (0). It is the least correct answer because it makes no sense either in relation to the text, or in relation to background
knowledge. People do not know for certain that what they see are unidentified flying objects, and this is not the reason given in the text that synonyms exist for UFOs.

**Answer Set Revisions**

The process of revising answer sets based on students' verbal reports had two complementary facets. One facet dealt with editing existing answer sets and the other with developing new answer sets which would reflect the range of answers students gave in their verbal reports.

Answer sets were revised where students' explanations of their choice of answer showed either that students made an inference but still selected a less than best answer, or that they used inadvertently placed cues in the answer set to select the best answer. The second facet is discussed in the next section with questions revisions.

**Vocabulary and Question Revisions**

A number of terms which students did not understand became apparent in the verbal report data. Samples of vocabulary revisions include the following substitutions, "scientific equipment" for "technology" and "heavenly bodies" for "astronomical events". Care was taken to maintain the intent of the text and use of precise terms while substituting appropriate vocabulary for students at the grades six, seven, and eight levels. For example, in looking for a substitution for "astronomical events" children's science texts, children's science encyclopedias, and science reference books were consulted.

Eleven questions were deleted from this test version. Five of the eleven questions were judged to be based too heavily on student's background knowledge. The five questions did not meet the principle that a good inference question is one that requires a reader to integrate relevant text
information and background to construct complete interpretations that are consistent with both the text information and background knowledge. Four of the five questions required students to give answers based on word knowledge. For instance, one of the items stated "The word independence in this story means" which could have been answered without reading the text. In another item, students' lack of background knowledge hampered students in making a complete inference, so the question was deleted. The deleted item read "Money might be more risky to use than credit cards because", but according to students' verbal reports, they did not know that credit cards could be cancelled, and therefore less risky to lose than money.

The remaining six questions were deleted for a variety of reasons. Difficulty level indices from previous pilots indicated question 13 as one of the most difficult questions (see Table 5-1). Student verbal reports indicated differences in word interpretations from those intended by the authors. For instance, item 13 says "Money is reused by", it seems students interpreted "reused" to refer to the same money being used over and over or saved by a single individual and not the circulation of money.

Questions requiring students to make time frame shifts were identified to be problematic as evidenced in their verbal reports and item analysis results. For example, students' verbal reports showed that they responded to item 20 which read "Years ago, cows, coffee, and shells did not keep their value as well as money today because" from a current events perspective. A typical response was "they are not wanted by everyone, whereas money might be because if you traded with people from the city they might not need cows." Item 20 had gone through three revisions and yet students seemed to focus on the current rather than the past, so the item was deleted. The remaining two
questions did not function well as inference questions because they were judged to be too text-dependent, so they were deleted.

Students' verbal reports also pointed to item ambiguities (items 9, 18, and 35). For example on item 9, students interpreted "find out" to mean discover new facts, when the intended meaning was "learn". So the item stem "Using the reported information we would find out the most about UFOs by" was changed to "Using available information people learn the most about UFOs by". This modification required students to make the inference that the "available information" was the reports described in the story.

**Story Passage Revisions**

The final section of test revisions in this pilot deals with the story passages. The major change was with the "Money" story. Due to the fact that the first five inference questions in the "Money" story were deleted, the first two story paragraphs were also deleted. Two new paragraphs and five new inference questions on the functions and characteristics of money were written for the "Money" story.

Minor changes were made to other paragraphs through deletion and addition of sentences. Sentences were added to story paragraphs in instances where more textual information was required for a specific inference question or where a new test question had been added. For example, the sentence "Weather conditions are checked when scientists study available information about UFOs" was added to the second UFOs paragraph to complement the question "Weather conditions affect UFOs sightings in the sky because" (UFOs Q5). The sentence in the third paragraph of the "Money" story "Large animals made trade difficult because there was too much price difference in items" was deleted. There was insufficient story information about trade items for
students to answer the corresponding inference questions. Changes of specific vocabulary in story paragraphs were discussed under editing of test vocabulary. Remaining changes were cosmetic in nature.

Pilot Study Four (Expert Sample)

The revised scaled-answer multiple-choice test was given to two fourth year college classes in the Faculty of Education at Memorial University of Newfoundland. Sixty-one students participated in this pilot. The purpose was twofold: first, to have an expert adult sample confirm the researchers' rating decisions for young students' responses on the TIA test; and second, to have the experts take the test and to note on it any questions or answers which they found to be ambiguous, and to make comments on any aspect of the test where they felt revision might be necessary.

It is realized that so-called experts may be quite unreliable judges of items written for younger students because the adult conception of what is and is not familiar may be quite different from that of younger students. For example, the item "Money might be more risky to use than credit cards," required students to know that credit cards may be cancelled. A study of students' verbal reports revealed this to be a piece of information which they did not know. Consequently, while adults consistently made a complete inference on this item, the middle grade students never did. The item was dropped because it did not measure students' inference ability.

For 85 percent of the items the experts rated the young readers' responses consistent with the ratings assigned by the researchers. The remaining 15 percent were taken to need further revisions. In addition, comments and queries made by the experts were studied and appropriate changes made.

The test mean for the two college classes was 23.95, out of 36 items, with
a standard deviation of 3.68 and a KR-20 reliability of 0.58. There seemed to be distinct divisions among the expert sample about some of the items. For instance, there were adults who wrote "there is no best answer here," on an item that required them to synthesize two or more pieces of information. It seemed some of the experts would indicate the right information needed for an answer, but would not pull the information together to make a complete and consistent inference. The remaining experts seemed to have little difficulty making complete inferences consistent with those of the researchers. Thus, the majority of the experts were taken to be reliable judges of the best answers.

Pilot Study Five

Test Validation

The fifth pilot study was designed to study the relationship between students' answer selections and their thinking processes in making those selections. One purpose was to find out the quality of students' thinking when they selected their answer for each test item. Understanding students' thinking processes is of fundamental importance because students often arrive at good answers without thinking well and at less than good answers even though they may have thought well. A second purpose was to find out whether the verbal report process either improved or worsened students' performance. Specifically, four issues motivated the validation procedure: (i) to find out whether students understood the task, that is, that they were to use information from the text and from their background knowledge to answer the inference questions; (ii) to find out whether students understood each test item and reasoned well when they picked the best answers; (iii) to find out whether students who chose an incorrect answer to an item did so because they...
did not reason well; and (iv) to find out whether there is a difference in performance between the verbal report and written cohorts.

The challenge was to design and develop a test so that students make inferences and that they do so for the "right" reasons. For a test of inference ability to be valid, the test should require that students make a complete inference when they select the best answer for an item (Phillips, 1986). One assumption in multiple-choice test construction is that when students select the best answer for a test item, they do so for the right reason. However, it is possible that students might select the best answer for a test item without fully understanding it. For example, there may be some inadvertent cue prompting students to choose the right answer. A second assumption is that students who choose the incorrect answer do so because they are not reasoning well, yet students might select an incorrect answer for a good reason. For example, there may be an alternate interpretation from that intended by the authors, leading students to choose a less than complete answer even though they reasoned well. Thus, it is important to have students explain their reasoning when they select their answer for each question.

Students' thinking ability was examined by having them verbally report why they had selected their answers. These verbal report protocols were used in conjunction with the students' answer selections to provide information for test validation. The general principle followed was that tests would be valid to the extent that good inference-making led to good performance and poor inference-making led to poor performance.

Sample and Procedure

One hundred and eighty-three students in grades 6, 7, and 8 at three schools participated in this pilot. The students were selected at random.
from intact classes and assigned randomly to either of two test conditions. There were 95 students tested in the verbal report condition and 88 students in the written test condition. Table 5-3 is a summary of the number of students by school and grade.

Students in the written test condition wrote the multiple-choice test in their classrooms. The same administration procedures described in Pilot Study Two were followed. Two interviewers conducted the verbal report interviews using the same procedure described in Pilot Study Three. Students in the verbal report cohort were assigned to one of the three stories on a rotating basis. That is, the first student was assigned story 1, the second assigned story 2, the third did story 3, and the fourth student did story 1 thus starting a repeat of the cycle. The total administrations per story were as Table 5-3.

follows: 34 students completed the 'UFOs' story, 32 students completed the 'Money' story, and 29 students completed 'The Wrong Newspapers' story.

**Coding**

Three sets of data were collected: reading scores from the written cohort; and reading and thinking scores from the verbal report cohort. Written cohort responses were scored according to criteria developed in Pilot Study Three (See Criteria for Grading TIA in Appendix B). The reading score for an answer ranged from 0 (implausible) to 3 (complete). Students' total reading scores were the sum of the values assigned to all answers selected by students. The total possible score is 108.

Verbal report explanations of students in the verbal report cohort were assigned thinking scores. The quality of students' explanations for each answer was rated according to specific criteria (See Appendix C for a copy of the Thinking Rating Scale). Thus, for each item there was a reading score for the answer selected and a corresponding thinking score for a student's explanation of why that answer was chosen.

A trial sample of thinking protocols was selected at random from the three stories and grades. Two raters independently assigned a thinking score to each answer justification. Any inconsistencies between raters' scoring of thinking protocols were studied. The initial rating of this small sample of the verbal report protocols allowed changes in the category descriptions of the thinking rating scale before all the protocols were scored. For instance, it was observed that sometimes students simply repeated the answer they had selected as their explanation. In the initial thinking rating scale there was no provision for such a response. Consequently, a change was necessary and a thinking score of (0) was assigned for such responses.
Both total and individual item thinking scores assigned by the two raters were compared. Inter-rater reliabilities on both comparisons resulted in correlation coefficients greater than .90. Any explanations assigned different thinking scores by the raters were discussed and re-rated. With a high level of reliability on the rating of students' explanations established, it was concluded that the remaining protocols could be consistently scored. About 25% of the remaining protocols were checked at random and found to have a similarly high level of inter-rater reliability (> .91).

Data Analysis

The data analysis examined six questions: (1) To what extent were students' reading scores and thinking scores on each test item in the verbal report cohort correlated? That is, did students who reasoned well select the best answer and did students who reasoned poorly select an incorrect answer? (2) To what extent were students' total reading and thinking scores for each story in the verbal report cohort correlated? (3) How did students' reading scores in the verbal report cohort compare with reading scores in the written cohort? (4) How is performance on each item related to overall test performance? (5) Did students' reading scores vary by grade level? and (6) Were there interviewer effects on test performance?

Results and Discussion

Reading and Thinking Relationships for Items. Table 5-4 presents Pearson's correlation coefficients between students' reading and thinking.

*p < .05  **p < .001
scores by test item. A positive correlation significant at less than the .05 level between reading and thinking scores was found for 34 of the 36 items with an average correlation of .55. Reading and thinking scores for item 10 were not significantly correlated and for item 17 they were negatively correlated. These two items were examined, but no problems were apparent. The results of the previous pilot studies were examined and no indications of problems with items 10 and 17 were found. The final decision was to leave the items without changes and to examine them in the next trial.

For 94 percent of the items good thinking was significantly correlated with good reading and poor thinking to poor reading performance. This result provides strong evidence that generally when students thought well they selected the best answer and when students reasoned poorly they selected an alternate answer. The significant correlations between reading and thinking scores for items is one piece of evidence that TIA is a valid test of inference ability.

Reading and Thinking Relationships for Stories. The reading and thinking relationship for each item is by necessity related to this relationship for each story. Twelve items accompany each story, therefore items 1-12 accompany story 1 'UFOs', items 13-24 accompany story 2 'Money', and items 25-36 accompany story 3 'The Wrong Newspapers'. Table 5-5 presents Pearson's correlation coefficients between total reading and thinking score for the three stories. The correlation coefficients were similar, high, and significant at the .001 level for the three stories.

It is reasonable to conclude that students understood the items and that students who selected the best answers thought well. Thus, the significant reading and thinking relationships for stories is taken to be another piece

of evidence that TIA is a valid test of inference ability.

Reading Performance Relationships Between Verbal Report and Written Cohorts. Table 5-6 presents story reading score means by cohort. The maximum reading score for a story would be 36, as each story has 12 test items, with a total possible score of (3) per item. Means for story 1 and story 2 were very similar for the verbal report and written cohorts. Means for story 3 differed by 2.8 in favour of the verbal report cohort. It is not clear why a difference occurred. This difference translated into test performance would amount to the verbal report cohort doing better on 1 item. Across the entire test, the overall mean for the verbal report cohort is 24.7 and 23.3 for the written cohort. A difference between means of 1.4 which translates into less than half an item correct in favour of the verbal report cohort. Thus, the difference in means on story 3 was not taken to be large enough to invalidate the verbal report methodology. Asking students to think aloud does not significantly alter their performance.

Mean reading scores per story for both the verbal report and written cohorts were compared using ANOVA to determine more specifically whether the verbal report process altered performance. Tables 5-7, 5-8, and 5-9 present the ANOVA results for UFOs, Money, and The Wrong Newspapers, respectively. There were no significant effects for cohort for either the UFOs or Money stories. However, cohort showed a significant effect (p < .05) for The Wrong Newspapers story. It is not easy to explain why a difference in performance by cohort was found on only The Wrong Newspapers story.

Grade had a significant effect on students' reading scores for story 1 (UFOs) but was not significant for stories 2 or 3. The discourse type may account for the grade effect found for story 1. Students in grades six, seven, and eight may all be familiar with the descriptive and narrative discourse forms of stories 2 and 3. But, students' reading scores on expository material (story 1) might show an improvement for students in grade seven and eight when compared to grade six students.

There was no significant interaction effect between grade and cohort.

In sum, reading performance between the verbal report and written cohorts

was taken to be highly similar. Assuming that verbal reports are an accurate representation of the thinking that went on during the test-taking and that reports are an accurate representation of the thinking of those in the written cohort, then it can be concluded from the evidence presented that students understood the task and reasoned well when they picked the best answer. In addition, the usefulness of verbal reports to understanding students' reasoning and to validating tests is strongly supported.

The Relationship of Item Performance to Story Performance. Students in the verbal report cohort completed only one story, so item analysis results are presented by story for both the verbal report and written cohorts. Tables 5-10, 5-11, and 5-12 show the item/biserial correlations between reading scores on test items and total reading score for the given story.

The item/test biserial correlation coefficients were positive for all test items and ranged from a low of .163 (item 17) to a high of .693 (item 3).
The correlation coefficients show that generally students' performance on individual test items was positively related to overall test performance.

The difficulty indices were computed as the proportion of students picking the best answer. This is not the best indicator of difficulty for a scaled-answer items because it does not take account of students scoring 1s and 2s. In Chapter Six an index computed as average score on an item is used, but the rough index based on rights and wrongs will suffice here. A low difficulty index (.100) would indicate a more difficult test item than a test item with a high difficulty index (.600). Tables 5-10, 5-11, and 5-12 show the difficulty indexes of the test items which range from a low of .197 (item 1) to a high of .746 (item 12). The range in the difficulty level of items was expected and is within normally recommended bounds.

The KR-20 reliabilities calculated separately for each of the three test stories (12 items each) for the combined verbal report and written test cohorts were 0.57, 0.23, and 0.50 for stories 1, 2, and 3. The written test cohort completed all 36 test items with a KR-20 reliability of 0.69.

In sum, the results of the relationship of item performance to overall story performance was taken as evidence that students understood the task and that students reasoned well when they chose the best answer. Thus, it is concluded that TIA requires students to make a complete inference when they select the best answer.

Reading Scores by Grade. Students' reading scores by grade level were also examined. Since only the written test cohort in the fifth pilot study completed all 36 test items, then only their scores were used in this part of the analysis. As the highest reading score for each test item was (3), the maximum reading score for 36 items was 108. Reading score means and

standard deviations are presented in Table 5-13 for grades six, seven, and eight students.

A one-way ANOVA was performed with reading score as the dependent variable and grade as independent variable. Grade was found to have a significant effect at the .01 level (See Table 5-14). The overall trend in mean performance from grades 6 to 8 was a desirable result. It is assumed that students would perform better in making inferences with each passing grade. Since TIA is intended as a measure of inference ability in grades 6, 7, and 8, then a significant difference by grade suggests that TIA is sufficiently discriminating to detect differences in performance, should they exist, at each grade level.

Interviewer Effect on Test Performance. Verbal report students' reading and thinking scores were analyzed by story with interviewer as the independent variable. Two separate one-way ANOVAS were performed for each of the three stories. Therefore, for each story there was one analysis with reading score as the dependent variable and a second analysis with thinking

</table>

score as the dependent variable. No significant effect for interviewer was found at the .05 level for any of the six ANOVAS calculated. Interviewer, therefore, did not seem to affect students' reading or thinking performance in the verbal report cohort. This was an encouraging result which provided support for the usefulness of trial interviews to eliminate potential interview problems which may affect the primary data collection.

Summary

The data analysis and test results discussed in the preceding sections show the development and statistical support for TIA as a test with both construct validity and reliability. Each subsequent version of the TIA test was an improvement over each previous version and it was not clear what would be gained from further data collection, so the pilot studies were considered to be complete and the TIA test ready for final data collection.
CHAPTER SIX

FINAL DATA COLLECTION: ANALYSIS AND RESULTS

This chapter reports the demographics of the samples, the final data collection procedures, and the basic statistics. It also discusses potential extraneous influences to test performance and presents the reliability estimates of The Phillips-Patterson Test of Inference Ability in Reading Comprehension.

Samples and Data Collection

Nine hundred and ninety-nine students in grades 6, 7, and 8 from schools in Alberta, Newfoundland and Labrador, Nova Scotia, and Ontario comprised the samples for the final data collection (Data from New Brunswick arrived too late to be included in this report). Contact was made with educators at schools and school board offices and their cooperation was sought for the administration of the TIA test.

When approval was granted to proceed with the project, the contact persons were forwarded the necessary materials. They either arranged to give the tests themselves or for classroom teachers to administer them during scheduled language arts classes. Each participating teacher was given a copy of the directions sheet in Appendix D. The original contact person was the facilitator for each province. That person took responsibility for distributing the materials, ensuring their proper administration, collecting the materials, and returning them to The Institute for Educational Research and Development at Memorial University of Newfoundland. The final data collection took place during the winter and spring of 1987.

Sample Demographics

Students in the Alberta sample were from an urban centre with a population of approximately 60,000. It is a trading centre for an agricultural-based...
The students were described by their teachers as mostly middle class. The schools range in population from 150-650. Less than 4 percent of the school population is English as a second language students (ESL) or native students. Classes were described as having a few bright students, a majority of average students, and some students requiring additional assistance with instruction through remediation classes or learning assistance programs.

The Newfoundland and Labrador sample of students were from two large rural centres. In one centre the population, including surrounding villages, is approximately 10,000. The area may be described as economically depressed with the majority of families described as low to middle class. The students were from a school with a total population of 430 students. None of the students are ESL students, however, some have been and are involved in French immersion programs. Classes were described as heterogeneous. The other rural centre has a combined population of approximately 14,000 people in two adjacent towns. It is a mining centre with a high employment rate and, for the most part, middle class families. The students are from schools ranging in size from 350-600 students. There are no ESL students, but French immersion programs are common. The classes were described as heterogeneous. Teachers reported an extensive availability of resources and extracurricular opportunities in these schools.

Students in the Nova Scotia sample were from two rural areas ranging in population from 2000-5000 people. The economy is farm-based, with the communities comprising a mixture of lower and middle class families. The populations of the two schools were 200 and 275 with no ESL students. Classes were described as heterogeneous. About half the students participated in
sports activities and school clubs. Students were generally described as enthusiastic and willing to learn.

Students in the Ontario sample were from an urban centre with a population ranging from 60,000 to 110,000 including the surrounding areas from which children are bussed to the city schools. The students were from a wide range of economic levels, and many from single parent homes. Classes were described as heterogeneous with about 20 percent of the students requiring remedial instruction. Less than 3 percent of the school population includes ESL students, and brighter students often go into French immersion programs after grade 4. The economy in the area is built on service and government institutions.

Analysis and Results

Students recorded their answers to the TIA questions on a standardized answer sheet. Each question has four possible answers (A, B, C, or D). Each answer is worth a value of either a 0, 1, 2, or 3 dependent upon the quality of the selected response. The appropriate value was assigned to each selected response and the assigned values totalled to constitute the test score for each student (See Appendix E for Key to TIA Answer Scales).

Test Score Results for Province, Sex, Grade, and Age

The mean scores for each province (total possible score is 108) are presented in Table 6-1. No claims about the representativeness of these means for each province are made. They are probably more a reflection of local rather than provincial factors.

Table 6-1 also presents mean performance scores for the entire sample by sex, grade, and age. The mean for the entire sample of students for whom data was complete (N = 974) is 73.57 with a standard deviation of 13.63. Table 6-2

shows the ANOVA main effects on these same variables. Of particular relevance in this report are the main effects of sex, grade, and age on test score.
In the case of significant sex differences, the females' mean performance is higher than the males'. A comparison of the means presented in Table 6-1 indicates a difference of about two points. Based on the perplexing welter of research findings on differences between males and females, it seems many questions remain unanswered (Downing, May, & Ollila, 1982). Questions about such matters as the effects of different cultural expectations, genetic factors, and teacher-model differences all seem to point to the necessity of further research prior to the drawing of any conclusions. Differences in this

</table>
data on the basis of sex are minimal. Furthermore, differences in performance between the sexes are small in comparison to the range of differences in performance within a sex. For these reasons it is not believed that the TIA test is biased in favour of any sex, nor that the data is untrustworthy for generalization purposes regardless of sex.

Table 6-2 shows grade and age significant at $p < .05$ level. In the case of significant differences by grade it is important to know whether the differences are between grades 6 and 7, grades 7 and 8, and grades 6 and 8. Sheffé's a posteriori comparison of means test was done (Kirk, 1968). While Sheffé's $S$ method allows for the calculation of significant differences in means when there are unequal n's, it does set the highest critical statistic of all the multiple comparison tests. The only critical difference in means on the TIA test was between grades 6 and 8 where the difference in means (5.70) exceeds the critical value of 3.87. It is likely that had it been appropriate to use a less rigorous test that differences between grades 6 and 7 and between 7 and 8 would have been found. Nevertheless, the significant differences between grade 6 and grade 8 indicate a general tendency for performance to improve with grade level.

Age differences are not easy to separate from grade differences. The mean of grade eight students is higher than the mean of thirteen and fourteen year olds. In addition, the number of thirteen and fourteen year olds is 114 more than the number of students in grade eight. It seems that some of the thirteen and fourteen year olds are outliers and repeaters. Those students who are age and grade appropriate generally perform better. Therefore, the mean of the grade eight students is higher than the means of the thirteen and fourteen year olds. So, age and grade may not represent the same differences.
in performance.

Item Statistics

Item Difficulty

Typically, difficulty level indices reported on a multiple-choice test are given as the proportion of students getting an item right, but on a standard multiple-choice test the only scores are 1 and 0, where 1 is for the correct choice and 0 is for any other choice. Thus, the proportion of people getting the item right, that is the difficulty level, is just the average performance on the item. So by extension, the difficulty level index for the TIA test in which possible scores are 0, 1, 2, or 3 is again the average performance on the item. See Table 6-3 for the percentage breakdown of students who chose an answer worth 0, 1, 2, or 3 for each test item (total of 36 items). The percentage of students who chose answers other than the best (the most consistent and complete) for each item reflects the variability in performance. Item difficulties are given in Table 6-4. When reading this table, note that the higher the difficulty level index the easier the item. As can be seen from Table 6-4, there is a range of difficulty levels across the test. For instance, many students found item 12 fairly easy whereas item 4 appears to have been more difficult for them. These indices represent a range of challenge for students.

The Relationship of Item Performance to Overall Performance

Typically, the item/test correlation is computed using a biserial correlation coefficient. This is a correlation between dichotomous (0,1) and continuous variables (0-3 range of items). However, on the TIA test item scores are not merely dichotomous variables, but rather interval variables (0, 1, 2, and 3), so the appropriate statistic is the Pearson's r. Table 6-4

presents the item/test correlations. Performance on individual items is typically assumed to be positively related to performance on the test as a whole. Since TIA is a test of inference ability in reading comprehension, then each item should be an inference question, so it would be expected that similar results would be attained across items. However, inference-making is complex. Some inference questions may be logical, informational, or evaluative in nature and yet be broadly related by general categories such as beyond text or across text (Wixson, Peters, Weber, & Roeber, 1987). Thus, it can be imagined that inference questions may be unrelated on other dimensions. One such dimension is context. Context affects reasoning (Bloome & Greene, 1984; Spiro & Myers, 1984; Stanovich, 1980). Each question is presented within the context of an unfolding story, yet each question is presented in a slightly different context, so similar correlations would not be expected on all items.

Guided by this presumption, any items with essentially zero or negative item biserial correlations were noted. Table 6-4 shows that there was one negative item/test biserial correlation (item 14) and one which was essentially zero (item 17). Item 14, as can be seen from Table 6-4, was answered by the greater proportion of students as a non-inference question (a score of 1). In other words, students chose a text-based response. Such a response by the majority of students points to a problem with either the wording of the question or a perceived high similarity among answer choices on the part of the students. A reexamination of students’ verbal reports from the last pilot study indicated a problem with word-choice with item 14. A revision has been made for future uses of TIA. Item 17, also on the Money story, demanded a high level of understanding of the features of money which
may have been unfair to the students. A reexamination of students' verbal reports corroborated the suspicion that in order to choose a 2-point answer, they made a sophisticated, complete, and consistent inference. The scoring key was modified for item 17.

The Relationship of Story Performance to Overall Performance

The Phillips-Patterson Test of Inference Ability in Reading Comprehension is made up of three of the most common discourse forms found in the middle grades. Research indicates that narrative, descriptive, and expository texts make distinct demands upon readers, thus it seems that differences in comprehensibility between narrative and descriptive and expository texts should be expected. Table 6-5 shows the percentage of all responses obtaining scores of 0, 1, 2, 3 by grade level and story. Seventy-two percent of all responses on The Wrong Newspapers are quality responses (scores of 2 and 3) compared to sixty-six percent on the UFOs story and sixty-eight percent on the Money story. The Wrong Newspapers story is a narrative, the discourse form taken to be the easier of the three, yet the differences in performance are not as dramatic as expected. This result raises an interesting question.

A question which remains to be studied is whether particular types of inference questions, regardless of discourse form, present more of a challenge to students than others. There is circumstantial evidence from the pilot studies and from questions rated as difficult on the final study to support such a suspicion. Logical inference questions on TIA that required the synthesis of several pieces of information were more likely to be answered in an incomplete manner than informational inference questions such as elaboration or setting the context, regardless of the discourse form. A
plausible explanation for the minimal performance differences as displayed in Table 6-5 is that inference questions requiring the synthesis of several pieces of information were asked on all three discourse forms. If students experience difficulty with logical inference questions as suggested, then perhaps the type of question asked is an important variable in addition to the discourse form being studied.

Potential Extraneous Influences

Potential extraneous influences on performance on the TIA test include such factors as test-taking strategies, test wisdom, and guessing. While these are mutually exclusive, I will deal with each separately.

Test-taking Strategies

Care was taken to provide clear, unambiguous directions to all TIA test-takers. Students were informed that they were to use information provided in the story and information they already knew in deciding upon the best answer. They were told to think about which answer out of four they thought was the
best one. A sample item was done with the students (See Appendix D for a copy of the complete instructions). Special mention was made of the importance for students to consider all possible answers before deciding on the best one. Students were informed of the scoring system.

TIA is a power test, so no strict time limits were set. Students were told that it takes about a class period or so to do the test. Teacher reports of the final data collection indicated that most students were finished the test in about 30-35 minutes, excluding time for directions (total time approximately 40-45 minutes). The intent was to allow students time to think and to carefully consider their answer choices without the pressure of a speed component. Test users may use the average completion time of 30 minutes as an indication of how their classes compare with others in time taken to do the test.

During the development of TIA, attention was paid to a host of simple but important rules for test construction which are in harmony with sound established measurement principles (Standards for Educational and Psychological Testing, 1985). Rules such as avoiding items with negative questions, using cautiously qualifiers such as "always" and "usually", and avoiding item stems similar to text information. Other factors which may have contributed to test-taking strategies were considered in the test refinement process and have been reported in Chapter Five.

Test Wiseness

There is a sense in which test wiseness has to do with general wiseness or perceptiveness. Students may capitalize upon cues of various sorts which would result in improved performance on a test for reasons other than use of the ability being tested. Students' verbal report protocols were studied in
each of the pilot studies for evidence of use of such cues. Test revisions were made if cues were suspected. Test revisions were discussed in Chapter Five.

Guessing

In the case of a short-answer test students guess only if they construct a response, which reduces the risk of attaining a higher score due to guessing. On the other hand, in the case of a multiple-choice test the probability of attaining a higher score due to guessing is greater (Slakter, 1967).

The scaled-answer scoring system (scores of 0, 1, 2, 3) used on TIA further complicates the issue of guessing, because the probability of a student getting some positive score for each item on TIA is .75. Contrast this with the standard four-option multiple-choice test with one correct answer where the probability of getting a positive score is only .25 on each item. Given the unusual scoring system used on TIA, it would be instructive to examine the distribution of scores which could be obtained through guessing (Johnson & Kotter, 1977; Larsen, 1969).

Table 6-6 presents the distribution of total possible test scores (0-108) and their corresponding cumulative probability under the assumption of random guessing on each item. Note that since there is a considerable chance of scoring points through guessing it is virtually impossible to guess and receive less than about 40. Even for a total score of 5%, which would be 50 percent, there is a 47 percent chance of attaining at least this high by guessing. However, if you look at a total score of 58, only 4 points higher, the chances of attaining a score of 58 or higher are dramatically reduced to 25 percent.

The overall mean score on TIA is 73.48 and as can be seen from Table 6-6

there is virtually no chance of a student getting this score or higher from guessing. Indeed the chances of getting any score of 60 or higher through guessing are quite low. The pattern of probability distributions displayed in Table 6-6 indicates that while scores up to about 60 can be expected to reveal very little about inference ability because of the guessing factor, scores above this point are virtually unattainable through guessing.

You will recall from the discussion of Pilot Study Five in Chapter Five that there were highly significant correlations between reading scores and thinking scores (see Table 5-4) and that there were no significant differences in performance (see Tables 5-6, 5-7, 5-8, 5-9) between the verbal report and the written response cohorts. These two points are worth mentioning here in terms of rounding out this discussion on guessing. The first point provides evidence that generally when students thought well they selected the best answer and that students who reasoned poorly selected an alternate answer. An examination of the verbal report protocols showed that despite the opportunity of having a best-answer option, students generally chose the answer that made most sense to them, the one that they could justify. It would seem then, that there was much more going on than guessing.

The second point that there were no significant differences in performance between the verbal report and written cohorts may point to a uniqueness in the nature of the task. Recall that Pilot Study Two showed minimal differences in the amount of time taken by students to complete the multiple-choice and short-answer formats, suggesting that the reasoning demands of the task were similar. TIA is a test of inference ability, that is the ability to integrate relevant textual information and background knowledge and requires reasoning regardless of response format. In other words, determining the best
answer on TIA requires making an inference regardless of the format of the test. This argument is very similar to one found in the area of mathematics where it has been argued that format does not matter in test performance (Traub & Fisher, 1977).

Kuder-Richardson 20 Reliability Indices

Table 6-7 gives means, variances, and KR-20 reliabilities for each story and for the total test. The Kuder-Richardson 20 reliability estimates are conservative, they give a lower bound estimate of reliability on a test. Nevertheless, it would be fair to say that TIA's reliability of .79 is highly satisfactory given the number of test items (36) and the reported reliabilities of similar tests requiring students to reason well such as the following: Test on Appraising Observations (50 items) .69; Cornell Critical Thinking Test, Level X (71 items) .85; and the Watson-Glaser Critical Thinking Appraisal, Form A (60 items) .80.

CHAPTER SEVEN

SUMMARY OF PRESENT EFFORTS AND FUTURE PROSPECTS

This report has described the design and development of a test of inference ability in reading comprehension. It is a scaled-answer multiple-choice test intended for use with students in grades six, seven, and eight.

The Phillips-Patterson Test of Inference Ability in Reading Comprehension is based upon what is currently known about inference and is in accord with the best available principles and information as described in Chapter Three. The principle of inference appraisal and the work reported here are not meant in any sense to be definitive, but rather are meant to be a chart in what is an uncharted testing area. It is to be seen as an important starting point open to extension. The objectives, design, and evolution of the test reported in the preceding chapters represent a comprehensive methodology aimed at validly appraising inference ability in reading comprehension.

In order to have construct validity in tests of reading comprehension we must seek out the causes of performance on them (Phillips, 1986). Responses on measures of reading comprehension may be correct or incorrect for very different reasons. Correct responses are not sufficient evidence of comprehension because sometimes they are the result of minimal reasoning. Conversely, incorrect responses are not sufficient evidence of a lack of comprehension, because sometimes they are a result of comprehension. Students' verbal reports and written explanations as to why they made their choices are ways to seek out causes of performance.

The final version of the Phillips-Patterson Test of Inference Ability in Reading Comprehension, a copy of which is provided in Appendix , represents a reform over conventional tests of reading comprehension in at least three ways. First, TIA is an aspect-specific test aimed at providing detailed
information on young readers' inference ability in reading comprehension rather than being a general test of reading comprehension. Unfortunately, most tests of reading comprehension yield at best superficial and nondescriptive information about reading ability. Part of the problem may be attributed to the complexity of the reading comprehension process. While a thorough definition of reading comprehension remains elusive, it seems that a worthwhile approach is to study aspects of the reading process. The TIA test is the first test known to me which focuses specifically on inference in reading comprehension. This is not to say that considerable overlap does not exist among inference and the other reading processes in the actual process of reading comprehension. To study the nature of such overlap would be an interesting project.

The second unique feature of the TIA test is its balanced concentration on the appraisal of inference ability across the three most representative discourse forms found in the middle grades: narration, exposition, and description. This gives TIA a higher degree of content validity than most general tests of reading comprehension that do not take the three discourse forms into account.

The final feature and perhaps the most important for instructional purposes is that TIA allows for ranges of sophistication in inference ability. Inference-making is often a less than complete process, so a scaled-answer scoring system was developed to offer credit for partially correct responses rather than a conventional model where credit is given only for the correct answer.

Central to this work are future prospects. The completion of a manual which will allow for diagnostic information for instructional decision-making.
presents is the next immediate project. Diagnostic information will be reported in a manner that describes students' performance in terms of the quality of the inferences they have made, and the variations in inference ability across question types and across discourse forms. Such assess-oriented information provides the necessary understanding of where students need instruction (Frederiksen, 1984), and to that end specific teaching suggestions will be offered. The development of a short-answer form of the test which would allow for a more direct evaluation of the effect of background beliefs and levels of sophistication on students' performance is also planned.

Other prospects include a study to identify the kinds of strategies students' use in attempting to understand the various discourse forms, to measure the effectiveness of those strategies, and to explore the claim that reading well is thinking well by studying the relationships among inference strategy use, good inference-making in text comprehension, overall reading comprehension, and critical thinking performance.

A future prospect of a more collaborative nature is to study the seemingly multiple perspectives on the appraisal of inference ability through an examination of the types of inference demands made by the TIA test compared with those on current but more general comprehension assessment projects (Valencia & Pearson, 1987; Wixson & Peters, 1987).

Appendix A

THE PHILLIPS-PATTERSON TEST OF

INFERENCE ABILITY IN READING COMPREHENSION
DIRECTIONS

Do Not Mark On This Booklet

You will read three different stories. Questions follow each paragraph in the stories. Each question has 4 answers provided. You are to choose the best answer and blacken its letter on the answer sheet.

There are 36 questions and you should try to do all of them. To answer the questions you have to use information given in the stories and information you already know. The stories will not directly answer the questions. You will have to use your common sense and the story information.

Here is an example:

Example X: Chris had to write a story. Words like tennis, hockey, football, swimming, baseball, and skiing came to mind. So, Chris started to write a story on all of these.

X. Chris wrote a story about
   (A) hockey.
   (B) nothing.
   (C) sports.
   (D) games.

Remember: you must choose the best answer. You may think that more than one answer is good, but you must choose the best answer from the 4 provided.

Be sure to read and think carefully before you decide which answer is the best one.
UFOs

Thousands of people around the world believe that they have seen unidentified flying objects. Anything in the sky that people do not understand may be called a UFO. People sometimes call UFOs "flying saucers," "spaceships from other planets," and "extraterrestrial spacecraft." Sometimes weather satellites, clouds, and bright stars are thought to be UFOs. Stories have been told that UFOs light up an area with many coloured lights and that creatures of different sizes and colours have been seen in them. Another story is that UFOs drain power from any electrical sources in the immediate area. The weather, the time of day, and the number of people may make the UFO stories different.

1. UFOs are sometimes called other names because
   (A) people name them according to their shape or probable origin.
   (B) people know they are unidentified flying objects in the sky.
   (C) people see an area with many coloured lights in the sky.
   (D) people don't know what to call them, so they name them by shape.

2. Something in the sky which is not understood may be called a UFO because
   (A) that is a term used when people do not know what it is.
   (B) that is an idea about which stories have been told.
   (C) that is what people call it when they jump to conclusions.
   (D) that is the shape of whatever it is in the sky overhead.

3. It is not known where UFOs come from. It seems they
   (A) could be from Earth, because we have the materials and people to build such crafts.
   (B) couldn’t be from Earth, because if they were people would know what they are.
   (C) could be from almost anywhere, because things in the sky might be misnamed.
   (D) couldn’t be from almost anywhere, because the story said they come from other planets.

4. UFO stories may be very different from each other because
   (A) people tend to exaggerate what they see and think of different names for UFOs.
   (B) people think different things like weather satellites, clouds, and bright stars are UFOs.
   (C) people may not be sure of what they see when they see different things in the sky.
   (D) people may see many kinds of things in the sky at various times and places.
Scientists became interested in the different UFO stories and decided to investigate them. Scientists use three kinds of reports to study UFOs. Sight reports by people indicate that UFOs are seen during the day and night. Sometimes when people report seeing a UFO, radar stations report unusual events at the same time. Radar shows the direction and speed of things in space such as storms, aircraft, and meteors, as well as unusual events. Reports of physical proof such as ground prints, burned patches in fields, and melted patches in pavement are also studied by scientists. Weather conditions are checked when scientists study available information about UFOs. Many of the older reports are incomplete so we need to continue to study UFOs.

5. Weather conditions affect UFO sightings in the sky because
   (A) it may be stormy so people may be unsure of what they see.
   (B) the story says conditions are checked by scientists in their work.
   (C) they interfere with how well people can view and identify what they see.
   (D) they cause damage to UFOs and interfere with how they work.

6. The three kinds of reports used by scientists to study UFOs are
   (A) sight reports, radar reports, and reports of physical proof.
   (B) sight reports on storms, aircraft, and meteors.
   (C) sight reports on ground prints, burned patches, and melted patches.
   (D) sight reports, radar reports, and reports of objects in space.

7. Using available information people learn the most about UFOs by
   (A) collecting radar reports and interviewing spectators.
   (B) checking radar stations which report unusual events.
   (C) studying many of the older reports about UFOs.
   (D) combining the information contained in all reports.
UFOs

Scientists in the United States, Canada, and many other countries have studied UFOs for many years. In 1969, one group of scientists concluded that there was not enough evidence to prove that UFOs are real and that UFOs were not worth further study. It seems that many people mistake heavenly bodies such as meteors for UFOs. But some people are still interested because even scientists agree that ten percent of UFO sightings are not explained.

8. Many people mistake heavenly bodies to be UFOs because
   (A) both might be bright objects in the sky.
   (B) people wish they could see a UFO.
   (C) people think both look different in the sky.
   (D) scientists have studied UFOs for years.

9. The percentage of UFO sightings that are explained is
   (A) 10 percent
   (B) 90 percent
   (C) 100 percent
   (D) 80 percent

10. Some people think the study of UFOs should be continued because
    (A) other people are still interested in UFOs.
    (B) the evidence about UFOs is not complete.
    (C) not all sightings of UFOs are understood.
    (D) some scientists think UFOs are not real.
UFOs

People are curious about UFOs. They want to know what has been seen. More studies might be done on UFOs using weather cameras in satellites. These cameras take pictures of cloud patterns and could photograph any high-flying objects. People are finding out more about space and the universe and many explanations are being given for UFOs. So, in the future UFOs may be known as IFOs.

11. More evidence is available today about UFOs than years ago because
   (A) we have more books to get information.
   (B) there are more explanations being given.
   (C) there are more people observing space.
   (D) we have more scientific equipment.

12. IFO means
   (A) identified flying orbits.
   (B) identified flying objects.
   (C) imaginable flying objects.
   (D) unidentified flying objects.

This is the end of the UFOs story. The next story you will read is called “Money”.

Go on to next page --
Money

Most people in our country use money almost everyday. You may know that money is used for buying and selling without realizing how important it is. Money serves at least four important functions. It is a medium of exchange for goods, such as candy or a movie, and for services, like dental care. It is a way of telling how valuable goods are. For example, we know that a car is more valuable than a bicycle because we spend more for the car. Money also serves as a unit of account, which means that payments, loans, and transfers of money may be made from one person, company, or country to another. Money is also a store of wealth, which means that it may be saved for later use.

13. Centimeters are used as a measure of height, degrees are used as a measure of temperature, and money is used as a measure of
   (A) account.
   (B) function.
   (C) value.
   (D) cost.

14. Money is a familiar part of our lives because
   (A) we use it to buy and to save.
   (B) we use it almost everyday.
   (C) we cannot exchange without it.
   (D) we earn it, spend it, and save it.

15. If a chocolate bar and seventy-five cents are equal in value, then they would be an even
   (A) amount.
   (B) exchange.
   (C) buy.
   (D) unit.

Go on to next page --
Money

The topic of money has fascinated people for centuries. "Why don't they make enough money for everyone to have a lot?" is a common question. There is no simple answer to that question, but money must have certain characteristics. It must be rare or obtained as a result of work. For example, if money were to grow on trees, there would be too much of it so it wouldn't have any value. When goods and services are plentiful they usually cost less. Money should be easily recognized by buyers and sellers. It must be divisible, easy to carry, and able to take lots of use. The kind of money used in the past was not like the cash, checks, and credit cards we use today.

16. Umbrellas cost more when it is raining; oil costs more when it is scarce. It seems that the price of goods goes up when
   (A) people are fascinated by money.
   (B) people just have to buy them.
   (C) people are about to purchase.
   (D) people do not have to buy them.

17. Diamonds are rare and valuable but are not as usable as money because
   (A) they do not have the same features as money.
   (B) money must be something that everyone knows.
   (C) they do not divide easily and may not be easy to carry.
   (D) money must be rare or obtained as a result of work.

18. If there were not enough money for everyone to have some, then money would become
   (A) unpopular.
   (B) expensive.
   (C) valuable.
   (D) divisible.
Money

Thousands of years ago, people made trades among themselves to get whatever they needed. For example, if you kept cows but needed more land, you would have to find someone who needed cows and had land they were willing to exchange. It might cost you ten cows for a piece of land. If you needed a cooking pot then it might cost you a cow, but it might not be worth a whole cow. So, small items such as shells, whales’ teeth, tobacco, coffee, and salt started to be used for trade. Hundreds of years ago, people started using metal such as coins for trading. More recently, paper money came into use when countries started trading farther from home.

19. It was difficult to give someone change using trade items because
   (A) a pot might have cost a whole cow.
   (B) it was hard to know what change was.
   (C) a cow was not very easily divided.
   (D) they were usually exchanged whole.

20. It became necessary to use paper money when countries started trading farther from home because
   (A) people could not trade conveniently with exchange items.
   (B) they had already started to trade items by using metal.
   (C) nobody could be sure of what type of items to trade.
   (D) it did not make sense to use anything else to trade items.

21. The money system is different from the trade system because
   (A) money gives things a standard unit whereas trade does not.
   (B) one animal could be worth more in trading than another.
   (C) it might cost you ten cows for a piece of land in trading.
   (D) money is newer and is what people use all the time.
Money

Money forms are necessary and have changed over the years from cows, to whales' teeth, to paper, to plastic. A credit card may be used for goods and services because people agree to pay the bill at a later date. Credit cards are used today almost as widely as money to buy things such as meals, clothes, records, gas, or bus passes. No one knows what form of money people will use in the future. It seems more and more money will be handled by computers. Some kind of money system will always be a part of our lives. In the future, perhaps we will look at money the way we now look at trade items. You might be using a credit card to buy a chocolate bar and a computer to take care of your money.

22. A credit card is sometimes called plastic money because
(A) it can be used to pay for goods and services.
(B) it is made of plastic and can be used like money.
(C) it is plastic and not metal like money used to be.
(D) it can be used when you do not have money with you.

23. Complete the following to show how money systems have changed over the years: cow is to money, as money is to _______.
(A) trade items.
(B) club cards.
(C) credit cards.
(D) chocolate bars.

24. Some kind of money system is needed because
(A) people need to buy and sell things necessary for living.
(B) no one knows what people will use in the future.
(C) without money there would be no people to use it.
(D) people need to buy goods and services for daily living.

This is the end of the Money story. The next story you will read is called “The Wrong Newspapers”.

Go on to next page --
The Wrong Newspapers

Ann pedalled her bicycle faster as she headed up the hill to the last house on her paper route. The driveway was long, so she had been told that she could throw the paper from the road. "Strange!" she thought. "Yesterday's paper is still lying there." The newspaper, in a plastic bag, lay in a puddle left from yesterday's storm. She knew that Mr. Jones wasn't away. Ann was late for dinner so she rode on. She could feel the rain starting again as she turned to look at the White's dog barking at her. The last two weeks had been sunny, until Monday.

25. The newspaper was in a plastic bag because
(A) it was the last paper so Ann left it in the bag.
(B) it was raining yesterday and the paper would have gotten wet.
(C) it was too stormy yesterday for Mr. Jones to get it.
(D) it was lying in the driveway since yesterday.

26. Yesterday's paper was still lying in the puddle because
(A) it was in a plastic bag.
(B) someone should have picked it up.
(C) something odd has happened.
(D) the weather was too wet.
The Wrong Newspapers

As Ann came in the front door, the phone was ringing. "Ann, this is Mr. Jones. Yesterday I received a newspaper that wasn't the right copy. Tonight it has happened again. What's going on?"

"Mr. Jones, I just delivered your newspaper fifteen minutes ago. I saw yesterday's newspaper lying in a puddle at the end of your driveway. Haven't you been picking them up?" Ann asked.

"Of course I have a newspaper! Tomorrow, I want tomorrow's paper delivered," Mr. Jones yelled, and slammed the phone.

Ann scratched her head, puzzled. The rain drummed down on the roof and the thunder roared. The mystery would have to wait until tomorrow.

27. What had happened to Mr. Jones's newspapers two days in a row?
   (A) Ann thought he had not picked them up.
   (B) The papers were coming a day late.
   (C) Ann saw yesterday's paper in a puddle.
   (D) He had not gotten the right day's paper.

28. The mystery Ann has to solve is
   (A) to check why yesterday's paper is lying in a puddle.
   (B) to find out where the wrong papers are coming from.
   (C) to find out when and where the papers are disappearing.
   (D) to check why there is a problem with the papers.
The Wrong Newspapers

The next day, Wednesday, Ann picked up her papers as usual and rode around her paper route. It was raining again. She skipped the White's house, as they had been away on vacation since Sunday, and headed up the Jones's driveway. She would hand deliver Mr. Jones's newspaper. Ann saw Monday's and Tuesday's papers still lying in the driveway. As Ann rang the doorbell, she could see Mr. Jones sitting in the living room. He waved at Ann to come in. Mr. Jones had a cast on his leg, and his crutches rested against a chair. Ann wondered how Mr. Jones had been getting a newspaper since he lived alone.

29. What was the first day Ann noticed the newspaper lying in the driveway?
   (A) Sunday
   (B) Monday
   (C) Tuesday
   (D) Wednesday

30. Ann wanted to hand deliver Mr. Jones's newspaper
   (A) so she could ask him where he was getting his newspaper.
   (B) because she wondered how he had been getting a newspaper.
   (C) to make sure he got it and to talk to him about the mix-up.
   (D) to show him she had been delivering her papers every day.
The Wrong Newspapers

Ann asked Mr. Jones what had happened to his leg. Mr. Jones responded that he had fallen from a ladder on Monday. Mr. Jones was upset by the weather since he could not get outside for a couple of days. Just then, Skippy, the White's dog, came trotting in the living room. In his mouth was a newspaper, which he gave to Mr. Jones. Mr. Jones handed Skippy a cookie. Ann smiled and thought that part of the mystery was solved.

31. The part of the mystery that was solved was
   (A) the way Mr. Jones got the newspapers.
   (B) the way Mr. Jones broke his leg.
   (C) that Skippy was handed a cookie.
   (D) that Skippy was part of the puzzle.

32. The part of the mystery still to be solved was
   (A) where Skippy was going everyday.
   (B) where the right newspapers had gone.
   (C) where the wrong newspapers were coming from.
   (D) why Mr. Jones handed Skippy a cookie.

33. Ann could find out where the wrong newspapers came from by
   (A) following the dog.
   (B) giving the dog a cookie.
   (C) asking Mr. Jones.
   (D) calling the paper company.

Go on to next page --
The Wrong Newspapers

"May I borrow one of your cookies, Mr. Jones?" Ann asked. Ann showed Skippy the cookie. "Get the paper, Skippy!" Skippy jumped through a hole in the fence and ran to his owners' house just next door. They watched Skippy take a rolled-up paper from a stack of old papers on the White's porch and run back to the Jones's house. The right newspapers were lying at the bottom of Mr. Jones's long driveway. Ann had solved the mystery of the wrong newspapers!

34. The White's dog was with Mr. Jones because
   (A) the dog would get his newspaper for him.
   (B) he cared for Skippy while they were on holidays.
   (C) the dog lived in the house next door.
   (D) he needed the dog to help because of his broken leg.

35. It was quicker for Skippy to get an old newspaper than the right one because
   (A) the old ones were on Skippy's porch so he knew just where to go.
   (B) the old ones were closer and the right ones were at the end of the driveway.
   (C) the right papers were in a bag and the old papers were rolled up.
   (D) the right newspapers were lying at the bottom of the long driveway.

36. The mystery of the wrong newspapers happened because
   (A) the right newspapers were left in the driveway.
   (B) Mr. Jones had his leg broken and the newspapers could not be delivered.
   (C) Mr. Jones accepted the old newspapers from Skippy.
   (D) Skippy did not go to the right place to get the newspapers.

This is the end of the test.
Check your answers if you have time.
Appendix B

READING RATING SCALE FOR
PHILLIPS-PATTERSON TEST OF INference ABILITY IN READING COMPREHENSION
Reading Rating Scale for Phillips-Patterson Test of Inference Ability in Reading Comprehension

The reading score is based upon the quality of the interpretation given by students.

TIA contains 36 items. For each item a student is assigned a score of 0, 1, 2, or 3 for a possible total of 108 points if a student made complete inferences on all items. For each item, reading will be rated according to the following scale.

**TIA Reading Evaluation**

3 points (complete inference)

The student integrates relevant text information and background knowledge to construct complete interpretations that are consistent with both the text information and background knowledge. Thus, the student has given a complete inference answer.

2 points

The student integrates some text information and background knowledge but fails to take into account the available relevant information. The student's answer is consistent with some relevant text information and background knowledge but is incomplete. Thus, the student has given a partially-correct inference answer.

1 point

The student locates relevant text information but fails to integrate it with relevant background knowledge. Thus, the student has given a non-inference answer.

0 points

The student makes an inconsistent use of the text information and background knowledge. Thus, the student has given an implausible answer.

Each of the scale graduations are exemplified in the subsequent section. Examples are taken from selected items on TIA. Test item stems are provided with student answers in bold. Evaluator's comments are also provided.

3 points (complete inference)

The student integrates relevant text information and background knowledge to construct complete interpretations that are consistent with the text information and background knowledge. Students substantiate their answers with relevant evidence from both text information and background knowledge in a logical and coherent manner. Examples include the following:

(1) "Using available information people learn the most about UFOs by combining the information in all the reports." In this example, the student
recognizes the story says that scientists use three kinds of reports to study UFOs. The most information about UFOs would be attained by putting all three, thus the preceding answer is consistent and complete with both text information and background knowledge.

(2) "Increased evidence is available today about UFOs than years ago because we have more scientific equipment to study UFOs." In this example, the student uses the text information about potential use of weather cameras in satellites and increased knowledge of the universe to compare the present to the past. This information is then used to further reason that scientific equipment is an important factor in learning more about UFOs, thus the preceding answer is consistent and complete with both text information and background knowledge.

2 points (partially-correct inference)

The student gives an answer that indicates an integration of some text information and background knowledge but fails to take into account available, relevant information. The answer is consistent with some text information and relevant background knowledge, but is incomplete. Examples of partially-complete inference answers follow:

(1) "UFOs are sometimes called other names because people don't know what to call them so name them by shape." In this example, the student reasoned from some relevant text information but did not provide alternate interpretations. The student did not appear to monitor for consistency and completeness with available text evidence, that is, UFOs are called other names because of their probable origin, thus the preceding answer is only partially-correct.

(2) "Something unidentified in the sky may be called a UFO because that is what people call it when they jump to conclusions." In this example, the student reasoned from some relevant text information but did not remain tentative. The preceding answer is a case where such a statement may be true, but it does not represent a complete interpretation of available, relevant text information pertaining to the question posed.

(3) "It is not known where UFOs come from, it seems they could be from Earth because we have the materials and people to build such craft." In this example, the student reasoned from an unwarranted assumption to a justifiable alternative interpretation. The student has constructed an interpretation, but overlooks the fact that we do not know what UFOs are, so how could we construct them? On the other hand, the student may be thinking that some UFOs are misnamed spacecraft from Earth which makes the answer partially-correct.
1 point (non-inference)

It may be that the student did not understand the task, or that the student is more accustomed to non-inferential questions which often require the mere location of information than to inference questions which require the integration of relevant text information and background knowledge. In the latter case, students give an answer directly related to the text, or an answer which reflects minimal substantiation with the text evidence. Examples of non-inference answers follow:

(1) "UFO stories are very different from each other because people sometimes think things like weather satellites, clouds, and bright stars are UFOs." In this example, the answer given by the student is directly from the UFOs story.

(2) "It is not known where UFOs come from, it seems they couldn't be from almost anywhere because the story said they came from other planets." In this example, the student seemed to forego other possible answers for the sake of specific text information.

0 point (implausible answer)

It may be that the student did not understand the task, or that the student's answer is unsubstantiated. Examples of implausible answers follow:

(1) "UFOs are called other names because people know they are unidentified flying objects in the sky." In this example, the student's answer is circular, it does not answer the item.

(2) "Some people think the study of UFOs should be continued because some scientists think UFOs are not real." In this example, the student makes inappropriate use of text information. The text says, "In 1969 one group of scientists concluded that there was not enough evidence to prove that UFOs are real and that UFOs are not worth further study." The answer given is implausible.

(3) "Something unidentified in the sky may be called a UFO because that is the shape of whatever it is in the sky." In this example, the student was vague. The answer is unclear because it does not say what the shape is, nor specify what it in the sky is.

(4) "UFO stories are very different from each other because people tend to exaggerate what they see and think of different names for UFOs." The student did not take into account available text information which says, "The weather, the time of day, and the number of people watching UFOs may make the stories different" in formulating an answer.
Appendix C

THINKING RATING SCALE
Thinking Rating Scale for Phillips-Patterson Test of Inference Ability in Reading Comprehension

One of the variables derived to appraise the quality of TIA is a thinking score. The score is based upon an analysis of verbal report interviews as students cited why they chose a particular answer as the best answer on the test.

TIA contains 3 stories each with 12 items, students were asked to think-aloud on one of the three stories. For each item a student’s thinking will be rated between 0 and 3 for a total of 36 points if a student thought well on all twelve items. For each item, thinking will be rated according to the following scale.

**Rating**

**TIA Thinking Evaluation**

3

The student cites all relevant textual and background information in the explanation of an answer choice. That is, the student considers the question and the available textual and background information pertinent to it in the formulation of a response which is complete and consistent.

2

The student cites some of the relevant textual and background information in the explanation. That is, the student considers either a part of the question and the available textual and background information pertinent to it, or the student considers the question and part of the available information pertinent to it in the formulation of a response which is consistent but incomplete.

1

The student cites insufficient relevant textual and background information in the formulation of a response. That is, the student’s response is not sufficient to indicate a clear understanding of either the question or the story. It is in need of elaboration and contains information which is partially correct and partially erroneous. However, it does reflect minimal integration of relevant information.

0

The student cites irrelevant or erroneous or repeats textual, background information, or both in the formulation of a response. That is, the student either misunderstands, misinterprets the story, or repeats the selected answer or textual information with no interpretation.
It is important to be cognizant of at least two precautions in rating students' thinking. The first is that this scale is fundamentally a measure of reasoning ability, not expressive ability. The goal is to focus on the quality of thinking in the verbal report interviews, rather than on the quality of effective speech.

The second precaution concerns the context of student justifications of answer choice on TIA. When students give a justification or what is intended to be a justification they do so having made an answer choice, so the story, the item stem, and the answer selected by the student create the context for the verbal report interview. In other words, when students tell why they selected a particular answer to be the "best" the context of a student response must be used in rating the quality of student thinking.

Each of the scale graduations are exemplified in the subsequent section. Examples are taken from student verbal report interviews for each of the 3 stories on TIA. Test item stems are bolded and student "best" answer choices complete the test item. Student interview comments are then presented followed by an evaluator's comments.

Item 1 on the UFO story is evaluated as follows:

3 points

UFOs are sometimes called other names because people name them according to their shape or probable origin.

Student says, "I think that's the best answer because we do not really know what they (UFOs) are. UFOs are called 'flying saucers' and 'spaceships from other planets' and other names in the story, so since we don't really know what they are or where they come from, or if they come from anywhere, then people give them names that kinda makes sense according to their shape or where they might be from."

Shape and origin are the factors which must be inferred by a student from the textual information and background information in order to best explain why UFOs might be called other names.

2 points

UFOs are sometimes called other names because people don't know what to call them so name them by shape.

Student says, "I think that's the best answer because people don't know what to call them so they exaggerate about the shape, cause like they call them 'flying saucers'."

Shape was only one of the factors to be inferred about why UFOs might be called other names, the student's reported thinking reflects the use of some relevant textual and background information. The student did not incorporate the textual information "spaceships from other planets" and "extraterrestrial spacecraft" into reasoning for the best answer.

1 point

UFOs are sometimes called other names because people see an area with many...
coloured lights in the sky.

Student says, "I think that's the best answer cause it says in the story" (student points to text).

An interviewer says "So, why are UFOs sometimes called other names?" and student responds by reading from the text:

"Stories have been told that UFOs light up an area with coloured lights and that creatures of different sizes and colours have been seen in them."

In this instance, the student failed to make the intended inference in response to the question but does seem to indicate awareness of related textual information. The selected response and reasoning are examples of insufficient use of relevant textual and background information.

0 point

UFOs are sometimes called other names because people know they are unidentified flying objects in the sky.

Student says "It's strange to see unidentified flying objects in the sky and mostly they are UFOs which is a name they gave them.

In this instance, the student failed to answer the question nor to provide quality reasoning, indeed the student response begs the question.

Item 9 on the Money story is evaluated as follows:

3 points

The money system is different from the trade system because money gave things a standard unit whereas trade did not.

Student says, "I think that's the best answer because in the old days people could never be sure they got the same exchange value for their trade products. Like a cow might not really be the same value as say a piece of land but if one fellow wanted the land and the other fellow the cow, then they exchanged because they needed it even though the trades might not be fair. Money is better because say if a cow costs three hundred dollars, then people know if that is a good price, three hundred dollars is three hundred dollars no matter what you're buying, and with money there's change. Another thing is that cows might be worth different amounts."

To successfully answer this question a student must reason as to the differences between the money and trade systems by using both textual and background information, which the above student has done.

2 points

The money system is different from the trade system because one animal could be worth more in trading than the other.

Student says, "because one cow could be a good healthy cow giving milk and stuff but another cow might be old and sick, so they wouldn't be a fair trade for a piece of land. The cows and the land wouldn't be worth the same." This response addressed only part of the test item. The student used textual and background information to cite the inequities of the trade system but did not speak to the money system.
The money system is different from the trade system because it might cost you ten cows for a piece of land in trading. Student says, "because that's what it says up in the story." Upon further enquiry as to why the two systems are different, the student does not add further clarification. This student response does not represent an integration of the textual with background information, the student merely offered related information without any indication of having reasoned through the question.

The money system is different from the trade system because money is what people use all the time so it is newer. Student says, "everybody knows what money is and how to use it." In this particular instance, the student used background information to respond with an irrelevant statement which does not answer the item.

Item 3 on The Wrong Newspapers story is evaluated as follows:

3 points

Yesterday's paper was still lying in the puddle because something odd has happened. Student says, "it seems from the story that Ann knew Mr. Jones was home and it was peculiar that he didn't pick up his paper. It couldn't have been the rain because Ann was able to deliver her papers, so something must have happened. Anyway the title is a clue that something strange has happened." In this item, the student must incorporate the textual and background information to answer why the paper might be lying in the puddle.

2 points

Yesterday's paper was still lying in the puddle because the weather was too wet. Student says, "more than likely it was too wet for Mr. Jones to come out to get it, so it was still in the puddle." In this example, the student used only some of the relevant information to formulate a justification, and appears to have relied more upon background than upon an incorporation of both textual and background information.

1 point

Yesterday's paper was still lying in the puddle because it was in a plastic bag. Student says, "It says in the story that's how Ann left the paper." In this instance, the student did not incorporate the relevant textual and background information but the response indicates an awareness of related
textual information.

0 point

Yesterday's paper was still lying in the puddle because it should have been picked up.

Student says, "because she knew that Mr. Jones was away and she knew that there was someone in the house and should have been picked up."

In this case the student offered a subjective response, misread the textual information, and failed to answer the item.
Appendix D

DIRECTIONS TO TEACHERS
The teacher should be familiar with the test directions prior to administering the test because some discussion with the students is necessary. Teacher comments to be read aloud to students appear in bold type.

An approximate administration time including directions is 40-50 minutes.

1. Distribute test booklets and answer sheets to the students. Keep a copy for reference.

2. Make sure each student has a pencil and eraser.

3. Inform students about the Test of Inference Ability in Reading Comprehension.

Say: The reading test which you are going to do will help educators learn about students' reading ability. Students in grades 6, 7, and 8 all across Canada are cooperating in the study. You are a very important part of future improvements in the teaching of reading. This test does not require you to study beforehand. You are to use the reading skills that you use all the time when you read something. Try to do the best that you can on this test.

4. Direct students to their answer sheet and have them complete the information section on the answer sheet.

Say: Look at your answer sheet. Print the name of your school, your grade, your age, and circle 'M' for Male or 'F' for Female in the space provided at the top. You do not put your name on anything.

Allow time for the students to complete the information requested.

5. Direct the students to look at the front page of the test booklet. Advise them not to mark on the test booklet. Point to the 'Directions'. Ask if everyone is looking in the appropriate place. Scan the class to make sure.

Say: Follow along as I read aloud the 'Directions'.

Draw the students' attention to Example X. Read aloud Example X and the corresponding question X.

Say: Think about which answer you think is the best one.

Allow time for the students to read and to think about their answer.

Say: Turn to your answer sheet. Find Example X on the answer sheet. Circle the letter which corresponds to the answer that you think is the best one.
6. When all the students have marked the answer which they think is best, direct the students' attention back to the front of the test booklet and work through the 4 answers provided.

Note: It is important that students understand why they should consider all possible answers before deciding which answer they think is the best one and why they have to use information given in the story and information they already know in deciding upon the best answer. The following discussion guide should help to make these points.

Say: What about answer A, hockey? Is that a good answer? Why?

It is important for students to understand that even though "hockey" is mentioned, so are "tennis, football, swimming, baseball, and skiing".

Some of us might like to write about "hockey" because we like it or because it is fast and exciting, but what information in the paragraph would suggest that Chris would write about hockey more than tennis, football, or any one of the others? There isn't anything, so we should study the other answers. Let's continue with B.

What about answer B, is it a good answer? If we go back to paragraph X, it says "Chris started to write a story", so Chris must have written about something. If Chris wrote about something, then it would not make sense to say Chris wrote about nothing which means B is probably not a good answer. Let's take a look at answer C.

Answer C is "sports", is it a good answer? If we go back to paragraph X, it says "words like tennis, hockey, football, swimming, baseball, and skiing kept coming to mind". All these words have to do with "sports", so maybe it is a good answer. We should take a look at answer D before we decide which answer is the best answer.

Answer D is "games". Is it a good answer? If we go back to paragraph X, it says "tennis, hockey, football, swimming, baseball, and skiing". Are all these games? Tennis is a game; hockey is a game; football is a game. What about swimming? Is it usually called a "game" or a "sport"? Baseball is usually called a game. Skiing and swimming are usually called "sports". So, "games" would not include "swimming" and "skiing".

So, out of the 4 answer choices, Answer C, "sports" is the best one. "Sports" is a term used to include all the activities mentioned in the paragraph, so it is the one answer that includes all the things Chris was thinking about.

Be sure to read and to think carefully. If you picked answer A you would have scored 1 point. Answer B is not worth any points. Answer D would have given you 2 points. Since answer C is the best answer, then you would get 3 points if you chose that one.

If you have marked a different answer, you may erase it if you wish. It
doesn't really matter because Example X is just for practice.

Does anybody have any questions?

Are there any questions about the example we have done?

Are there any questions about how the answers are scored?

7. If there are no questions or comments,

Say: There are 3 stories in the test booklet. The first story is called *UFOs*; the second, *Money*; and the third story, *The Wrong Newspaper*.

Read each paragraph and the questions which go with it. Decide which answer you think is best and circle that letter on your answer sheet.

8. Direct students' attention to the answer sheet. Point out that there are three columns on the answer sheet, one for each of the stories. There are 36 questions. Advise students to make sure that the number on the answer sheet matches the number of the question they are working with in the test booklet.

Are there any questions about how and where to mark the answer sheet?

Are there any other questions?

9. If there are no further questions,

Say: You have about 3½ minutes to complete the test. Try to complete all of the questions. You may open your test booklets and start now.

Note: You may wish to move around the classroom to ensure that students are not experiencing procedural difficulties. If students ask for assistance with vocabulary or any of the test content, do not offer help. Students are to do as well as they can on their own.
Appendix E

KEY TO TIA ANSWER SCALE
### UFOs

1. (A) = 3  
   (B) = 0  
   (C) = 1  
   (D) = 2  

2. (A) = 3  
   (B) = 1  
   (C) = 2  
   (D) = 0  

3. (A) = 2  
   (B) = 0  
   (C) = 3  
   (D) = 1  

4. (A) = 0  
   (B) = 1  
   (C) = 2  
   (D) = 3  

5. (A) = 2  
   (B) = 1  
   (C) = 3  
   (D) = 0  

6. (A) = 3  
   (B) = 0  
   (C) = 1  
   (D) = 2  

7. (A) = 2  
   (B) = 1  
   (C) = 0  
   (D) = 3  

8. (A) = 3  
   (B) = 2  
   (C) = 0  
   (D) = 1  

9. (A) = 1  
   (B) = 3  
   (C) = 0  
   (D) = 2  

10. (A) = 1  
    (B) = 2  
    (C) = 3  
    (D) = 0  

11. (A) = 0  
    (B) = 1  
    (C) = 0  
    (D) = 3  

12. (A) = 0  
    (B) = 3  
    (C) = 2  
    (D) = 1  

### MONEY

13. (A) = 1  
    (B) = 0  
    (C) = 3  
    (D) = 2  

14. (A) = 2  
    (B) = 1  
    (C) = 0  
    (D) = 3  

15. (A) = 0  
    (B) = 3  
    (C) = 2  
    (D) = 1  

16. (A) = 1  
    (B) = 3  
    (C) = 2  
    (D) = 0  

17. (A) = 3  
    (B) = 0  
    (C) = 2  
    (D) = 1  

18. (A) = 0  
    (B) = 2  
    (C) = 3  
    (D) = 1  

19. (A) = 1  
    (B) = 0  
    (C) = 2  
    (D) = 3  

20. (A) = 3  
    (B) = 1  
    (C) = 2  
    (D) = 0  

21. (A) = 3  
    (B) = 2  
    (C) = 1  
    (D) = 0  

22. (A) = 1  
    (B) = 3  
    (C) = 0  
    (D) = 2  

23. (A) = 0  
    (B) = 2  
    (C) = 3  
    (D) = 1  

24. (A) = 3  
    (B) = 1  
    (C) = 0  
    (D) = 2  

### NEWSPAPERS

25. (A) = 2  
    (B) = 3  
    (C) = 0  
    (D) = 1  

26. (A) = 1  
    (B) = 0  
    (C) = 3  
    (D) = 2  

27. (A) = 2  
    (B) = 0  
    (C) = 1  
    (D) = 3  

28. (A) = 1  
    (B) = 3  
    (C) = 0  
    (D) = 2  

29. (A) = 0  
    (B) = 2  
    (C) = 3  
    (D) = 1  

30. (A) = 2  
    (B) = 1  
    (C) = 3  
    (D) = 0  

31. (A) = 3  
    (B) = 0  
    (C) = 1  
    (D) = 2  

32. (A) = 2  
    (B) = 0  
    (C) = 3  
    (D) = 1  

33. (A) = 3  
    (B) = 2  
    (C) = 0  
    (D) = 1  

34. (A) = 2  
    (B) = 3  
    (C) = 1  
    (D) = 0  

35. (A) = 2  
    (B) = 3  
    (C) = 0  
    (D) = 1  

36. (A) = 1  
    (B) = 0  
    (C) = 2  
    (D) = 3
