The Levels of Computer Use assessment (LCU) was developed to classify teachers' use of computers so that variations of use could be studied. The LCU was derived from the model of Instructional Transformation of L. P. Rieber and P. W. Welliver. The model describes the process of the adoption of innovation, focusing on the adoption of the computer in education. It describes a teacher's five stages in the process of adopting the technology, from familiarization through the evolution that involves continuing practicing and learning. The LCU was developed to assess computer use through the paired comparison technique. Pairs of comparisons were pilot tested with 50 elementary school teachers, and a revised version was field tested with 23 elementary school teachers and another sample of 170 elementary school teachers. The estimated reliability was high, and results indicate that the model of Instructional Transformation identifies at least two progressive levels, defined as integration and utilization. While the model is useful in understanding a teacher's theoretical progression in the adoption of computers, the assessment offers a means for applying the theoretical model. One table lists the instrument items and the levels they represent. (Contains 21 references.) (SLD)
Title:
Procedures for Assessing Teachers' Computer Use
Based on Instructional Transformation

Authors:
Henryk R. Marcinkiewicz
Paul W. Welliver
The Levels of Computer Use assessment (LCU) was developed to classify teachers' use of computers so that variations of use could be studied. It was derived from the model of Instructional Transformation (Rieber & Welliver, 1989; Welliver, 1990). The development of the LCU was stimulated by the identification of the discrepancy between advocacy for the use of computers in education and their actual use by teachers.

It is widely believed that computer technology can help improve the educational system (see The National Task Force on Educational Technology, 1986; United States Office of Technology Assessment [OTA], 1988; Sheingold and Hadley, 1990; Shanker, 1990). At the same time, the availability of computers in schools has increased. In the period from 1983 to 1987, the average pupil-to-computer ratio in public elementary schools improved from 112.4 to 36.8 pupils per computer (OTA).

Despite the positive trends in computer availability, relatively few teachers have integrated computers into teaching. A recent national survey has shown that even in schools where computers were available at more than double the national average, only about one teacher per school had integrated the computer into the classroom (Becker, 1989; Sheingold & Hadley, 1990). Apparently, sheer availability of computers did not result in their increased integration into teaching.

Indeed, there is a strong sentiment of disappointment and disillusionment among teachers regarding educational technology (Becker, 1987; Bjerklie & Hollis, 1981; Dronka, 1985; Ely & Plomp, 1988; O'Neill, 1990; Roblyer, 1988). The poor opinion of educational computing by teachers does not agree with the views of its supporters and patrons in government, academe, and teachers' unions. This discrepancy in perceptions of educational computing deserves study because the result of it is that computers in education are underutilized. As a result, whatever hopes there are for educational computing to affect education may never be realized.

For the research on teachers' computer use, a fundamental question is, "What is meant by use?" This question has been addressed in the model of Instructional Transformation suggested by Rieber and Welliver (1989).

Instructional Transformation

The model of Instructional Transformation describes the process of the adoption of innovation. This is an area of human behavior that has been studied generally—types of adoption behavior based on length of time have been described (Rogers, 1983; Rogers & Shoemaker, 1971)—and specifically—a framework for analyzing the adoption of innovations among educators has been described (Hall, Loucks, Rutherford, & Newlove, 1975). The model of Instructional Transformation focuses on the adoption of a specific educational innovation—the computer—and describes a teacher's progression through five stages of involvement with computers (Rieber and Welliver, 1989; Welliver, 1990). First, a teacher becomes familiar with computers (familiarization); then, the teacher uses computers in teaching (utilization). A higher level of use is observed when the computers have become critical to the teaching (integration). An analogy to this scenario would be of one who upon learning to drive (familiarization), uses the car to improve one's general transportation in order to fulfill a variety of purposes (utilization). One may then schedule the use of the car so that the vehicle is critical to the function of fulfilling the purposes (integration). In education, this stage includes the teacher's awareness of the change of his or her role. With this new awareness of the restructuring of teaching activities, the teacher pursues an expansion and fine tuning of the computer-teacher-student relationship (reorientation). The final stage (evolution) is more of a suggestion than a condition, and that is to continue practicing and learning about how to develop the improvement of instruction through the systematic implementation of computer technology.

The definition of use for the Levels of Computer Use assessment was derived from the model of Instructional Transformation. Use was defined as the integrated...
Assessing Computer Use ...on Instructional Transformation

employment of computers in teaching. Two levels of use were designated—Utilization and Integration. At the Utilization level, a teacher shares and delegates teaching duties to the computer; however, the absence of the computer would not prevent the implementation of instruction. At the Integration level, teaching duties would also be shared by and delegated to the computer; however, the absence of computers would prevent the implementation of instruction. The distinction between the Utilization and Integration levels lies in the expendability of the computer technology. Expendability describes the relationship of computer technology to a teacher's planned instruction—whether or not instruction would be able to continue in the hypothetical event of, say the sudden absence of computer technology. It is this dimension of expendability that was identified as the cut-off for membership in either category. According to the model of Instructional Transformation, the Integration stage is further characterized by the dimension of a teacher's emergent self-awareness of a role change in teaching from teacher-centered to learner-centered. In a departure from the model, the assessment does not encompass the dimension of awareness of role change.

Development of the Assessment

The LCU is the result of several attempts at varying formats. In the original conception of the assessment, items were written for each of the five stages of the model of Instructional Transformation. This had been field tested and revised several times and was finally supplanted by the current format. The earlier forms of the assessment adhered to the progressive nature of the model and attempted to capture all of its dimensions, however, it was difficult to classify responses. This is because there are several dimensions that run throughout the model in a progressive overlapping manner. In the current form, one dimension is assessed. The most appropriate technique for this sort of assessment is the paired comparisons technique. This technique requires that a discrete definition be operationalized to determine the cut-off for the levels of use. Additionally, the levels need to be mutually exclusive and exhaustive. Nunnally (1959) considers this method "the most exact psychophysical tool..." useful for precise information concerning judgments or preference.

In the format of the LCU, each item from one level is paired alternately with each item from the other level (See Table 1). For example, if there were four items, two from the first level (1a, 1b) and two from the second level (2a, 2b), the paired comparisons would be (1a/2a), (1a/2b), (1b/2a), and (1b/2b). The respondent is forced to endorse one item per pair. The paired comparisons technique allows only one combination of responses to indicate membership at either level. There are four pairs of items in this version. Two items indicate the Utilization level and two the Integration level. If, for example, a value of 1 were assigned to responses indicating the Utilization level, consistent responses for 4 items would score 4 points. A value of 2 for responses indicating the Integration level, would result in consistent response scoring of 8. Acceptable scores would be 4 or 8. Scores of 6 or 7 indicate an inconsistency. The four items were selected from a field testing with a sample of 50 elementary school teachers because those items had the highest response consistency. In that testing, there were 15 items. Items which generated response inconsistency or which introduced an additional dimension were eliminated.

In a subsequent field testing, twenty-three elementary school teachers responded; there were 2 inconsistent responses. The estimated reliability of the LCU for the second field trial using the Coefficient of Reproducibility (CR) was .74. One of the items was reworded. The LCU was then administered to 170 elementary school teachers. The CR was estimated at .96. A CR of .90 is the criterion for demonstrating that items form an ordered scale of allowable response patterns (Crocker & Algina, 1986). The teachers were also asked to respond to a control item about their self-reported computer use; the responses were matched with those of the LCU and

Marcinkiewicz & Welliver

681
providing additional data for estimating criterion-related validity. The consistency of classification of the measure was estimated computing Cohen's kappa ($Kappa = .72$). The results are important for two reasons: 1) the estimated reliability is high, and 2) the demonstration of an ordered scale suggests that the model of Instructional Transformation identifies at least two progressive levels.

The LCU has been used in several studies. It has been used to establish a dependent variable—level of computer use—in a study of elementary school teachers (Marcinkiewicz, 1991, in press) and in a longitudinal study of preservice undergraduate teachers (Marcinkiewicz & Grabowski, 1991). It has been adapted by the Grosse Pointe (Michigan) Public School System for use in its Staff Computer Skills Survey (J. Corbett, personal communication, February 21, 1992). It is being used to establish a dependent variable—levels of computer use—relative to the subjective norms of rural teachers. It should be noted that prior to this writing, the assessment has been referred to as the LU assessment. As of this discussion, the assessment is referred to as the LCU—Levels of Computer Use—assessment. This modification has been made to reflect the purpose of the assessment more accurately. This modification also underscores the ongoing study of the assessment and of the model of Instructional Transformation.

Discussion

There is a fundamental notion in computer implementation that is often overlooked—not all intended computer users do use them. As with most innovations, people vary in their adoption of computer use. By focusing on a specific profession such as teaching, the study of how its members—teachers—differ in their use of computers is more manageable. They differ before they begin to use computers and they differ once they have begun to use them. Before use, they differ in the time it takes to adopt the idea of using the technology. After teachers adopt the notion of using computers, they differ in the nature of their computer use. The importance of the model of Instructional Transformation is that it addresses the fundamental variance in the adoption of computer use. It describes the progression of a teacher from the onset of the adoption of computers. In application, this theoretical model will help educators in several ways: 1) to identify the range of expected behaviors
Assessing Computer Use ...on Instructional Transformation

applicable to a teacher's computer use—what can we expect a teacher to become? 2) to identify the level of a teacher's computer use; 3) to identify whether a teacher is progressing in computer use; 4) to identify how the nature of a teacher's instruction changes due to his or her computer use; 5) to identify how the nature of teacher’s professional self-perception changes due to computer use.

When educators can identify these aspects of teachers, the professional growth and development of teachers relative to computer use can be understood. With this understanding there is a basis for recommending staff development, remediation, or differential staffing. The LCU assessment was developed so that educators could implement the model of Instructional Transformation. Some applications of the assessment include assessing a school's teachers to determine the current computer utilization/underutilization levels before a purchase order for computers is issued, so that the likelihood of future use can be estimated. Also, as a school is designing its restructuring plans, the LCU can be used in needs assessment to identify discrepancies in the levels of computer use. A school may also study the assessment and the model of Instructional Transformation to learn what the extent of possibilities of computer use in education are. In doing so, a school can be helped in clarifying its goals in the application of computer technology.

The LCU accomplishes the classification of teachers into two levels of computer use. When used for this purpose, the assessment addresses point #2 mentioned above. The current form of the LCU is markedly different from earlier versions. The way in which the current and past forms differ needs to be pointed out to highlight the strength of the current version as well as to identify directions for future research. Most importantly, the past and current versions differ in that the former comprised several dimensions—as does the model—attempting to measure all dimensions. This proved to be confounding since the dimensions share characteristics. It was decided that it was not practical or perhaps possible to capture all the dimensions simultaneously. In the LCU assessment, there is one dimension—the expendability of computers—that is measured. This is the central dimension of the model. Measures of the other dimensions need to be developed; such as for the degree of awareness of the changing of one’s role as a teacher.

The successful development of the LCU establishes it as a part of the assessment arm of the model of Instructional Transformation. The model is useful in understanding a teacher's theoretical progression in the adoption of computers. The assessment offers a means for applying the theoretical model.
