The papers presented in the social studies section offer a variety of ideas regarding the successful integration of technology in social studies preservice and inservice education. A theme running through each of the papers focuses on the potential power of technology for transforming social studies education. Suggested applications in the papers include internet and telecommunication, software use, and multimedia project development activities. Important issues and trends are also discussed in each paper with a strong emphasis placed on preservice teachers and students having a variety of hands-on experience with the technology.

Ledford and Hattler suggest that technology should be a tool to enhance the relevance of social studies for students. Their paper outlines internet applications in social studies methods and offers sample web sites that students included in planned units. The authors state that technology skills enable teachers and students to meet the challenges in education and the world.

Murray also focuses on internet applications for preservice teachers by integrating a variety of activities in social studies methods including e-mail, information seeking, listservs, and on-line mentoring. The author conducted a study of students' attitudes regarding computer and internet usage through a pre and post application survey. Initial findings indicated positive change among participants. Additional data analysis is forthcoming.

Cole Slaughter discusses a project that integrates multimedia and information literacy in social studies methods. The author developed a survey to determine student attitudes regarding technology. A model consisting of structuring, acquiring, analyzing, and synthesizing information (SAASI) was also designed to facilitate awareness of computer technologies. The author concludes by suggesting that educator-librarian partnerships can offer much in advancing information literacy and technology integration.

White suggests the merging of constructivism and technology to provide a transformative approach to social studies education. The author proposes a variety of technology applications in preservice social studies including telecommunications, software reviews and application, project development using authoring and presentation tools, and applications with students in classrooms. Integrating technology with the constructivist model including, modeling and applying, reflecting, involving students actively, and developing a community of learners is proposed.

Cameron White is an Assistant Professor of Social Studies Education in the College of Education at the University of Houston, CUIN 5872, Houston, Texas 77204-5872. Voice: 713 743-8678 Fax: 713 743-9870. E-mail: cswhite@uh.edu
Social studies teaching today presents challenges for teachers, new and experienced, with increased demands from our society and the world. Documents of reform such as Goals 2000: Educate America Act and Curriculum Standards for Social Studies (1994) call for a type of social studies instruction different than most preservice teachers experienced in their own schooling. Moreover, the National Council for the Social Studies (1992) in its standards for the preparation of social studies teachers, emphasizes the need for deliberate planning in the social studies:

...courses in social studies methods should prepare prospective teachers to select, integrate, and translate knowledge and methodology from history and social science disciplines in ways appropriate to students in the school level they will teach and give attention to the goals unique to the social studies and those shared jointly with the other areas of the school curriculum. Students should also be able to teach social studies utilizing a variety of curriculum approaches and in different types of settings.

To prepare teachers for the future, we must model the use of technology as a tool to connect the social studies to the world that is relevant to the student.

In the past social studies teachers were slow to integrate computers into their teaching. This was partially due to the limited amount of social studies software (Schug, 1988). However, the most meaningful learning takes place when students interact with concrete materials. Students have greater understanding when experiences are meaningful and manipulable. The computer environment offers equal, perhaps even greater control and flexibility to young students (Clements, Nastasi, & Swaminathan, 1993). Computer-based telecommunications through the Internet and on-line services provide tremendous potential for social studies instruction, involving students as active learners.

Testimonials abound from students and teachers concerning the usefulness of technology in the classroom. Teachers have reported that students as young as kindergartners use and eagerly await their turn on the computer. Young students can work in small groups and concentrate on computer learning tasks for long periods of time. Certainly, the potential for both learning and teaching has been minimally realized with technology as it is used today in social studies classrooms. Current social studies methods’ textbooks focus on the computer software for games, simulations, and databases. Limited discussion on the potential of the Internet is found (Chapin & Messick, 1996; Maxim, 1995; Michaelis & Garcia, 1996; Parker & Jarolimek, 1997).

What role can the Internet play in social studies instruction? Frankly, the value of the Internet lies in its users. Access to the Internet is available to both preservice teachers and students alike. The Internet stimulates curiosity and eagerness to learn. On-line, all students and teachers enter into a world beyond the walls of the classroom where they discover geography, social studies, politics, history, and current events. Unique opportunities for teachers and students include collaboration with other classrooms around the world, as well as accessing and retrieving information for use in their own classrooms. By connecting to the world via the Internet, preservice teachers, side by side with their students, overcome the traditional barriers of the classroom or building.

Preservice teachers use the Internet to find resources for a thematic unit, a requirement in the social studies methods course. Prior to this course, preservice teachers had an introductory Internet experience. To further explore the ever-growing possibilities of Internet resources of lesson plans, primary sources, documents, and data collection is their present assignment. The preservice teachers navigate through a myriad of links as they interact with on-line resources. Then, they integrate their Internet findings into social studies units.

Some examples of Internet resources included in preservice teachers’ units were:

The Census Bureau: http://www.census.gov

Students examine information about any city in the United States by accessing this Web site. Census data helps students discover the needs of the people of the
city which they investigate. Population data answers questions for students about the number, ethnicity, and age of people who live there. Relevant subjects on-line include: county and city data book, county profiles, economic information, household economic statistics and voter registration.

The Constitution:
http://www.1m.com/-cjp/whig/Constitution.html
This location provides the complete text of the Constitution of the United States and the amendments. By using this site students can explore the document to make discoveries about the electoral college.

The Jefferson Project:
http://www.voxpop.org/jefferson/
The Jefferson Project is a comprehensive directory of on-line politics. Included are mailing lists of web pages for the White House and all members of Congress. Two features include Netgrams and The Zipper. The Zipper allows you to enter your zip code to determine the members of the House and the Senate that represent you. It also allows you to communicate directly via e-mail or visit their home page. Students can send messages to the President or any member of Congress.

Map Quest: http://www.mapquest.com
Students can visit the small towns and cities of our country. They can plot an imaginary school bus trip to each location from their own hometown by using Trip Quest. This feature provides city-to-city directions and interactive maps. By opening Map Room, students can sharpen their knowledge of cartography.

Smithsonian: http://www.si.edu
This location, giving the history of the institution, links students to the 16 Smithsonian museums and the National Zoo. Its graphics bring this on-line tour of the Smithsonian to life.

Thomas: http://thomas.loc.gov
This site is a service of the U.S. Congress through its library. Floor activities are published each week. Major legislation, by topic, and bills, by number, can be followed. Bill texts from the 103rd and 104th Congresses can be read. Committee reports and home pages for members of the U.S. House and Senate are included. Historical documents, such as the Declaration of Independence and the Constitution, are accessible at this location.

Washington Post:
http://www.washingtonpost.com
Students can read and discuss the latest national and world news. In addition, students can locate updated weather reports to examine the weather at a variety of locations. Stock quotes and other financial and business topics can also be accessed.

Welcome to the White House:
http://www.whitehouse.gov/WH/Welcome-plain.html

The White House location provides a variety of information about the President and the Vice President, the Virtual Library containing White House documents, audio speeches, photos, and White House for Kids sections containing helpful hints for students to become more active and informed citizens.

Yahoo News Summary:
Students can read the top news story of the day by contacting this location. Yahoo News Summary includes ten news headlines with a paragraph about each.

If we are to meet the challenges in education, we must provide preservice teachers with the skills and opportunities provided through technology. As preservice teachers create effective units using the Internet, they begin to take advantage of the possibilities its resources provide. It is therefore incumbent upon all educators to modify traditional curriculum to reflect contemporary technology and explore cyberspace.

1007
INTERNET ACTIVITIES FOR PRESERVICE SOCIAL STUDIES TEACHERS: AN EXPLORATORY INVESTIGATION

C. Kenneth Murray
West Virginia University

Butler and Clouse (1996) note that each generation is presented with new technology that promises to be a cure-all for our instructional needs. In the 1940's the technological device promising to solve education's problem was the radio. During the 1950's it was television and late in the 1960's the computer was touted as being able to make student learning painless and more comprehensive while increasing productivity and excitement in the classroom. As we approach the conclusion of this century, the microcomputer is still being hailed as a technology that can revolutionize classroom teaching.

Becker (1986) reports that during the short period between 1983 and 1985, U.S. schools quadrupled their numbers of microcomputers from about 250,000 to over one million. Ross (1991) indicates that the most current statistics available indicate that of all U.S. middle and high schools, 95% and 97% respectively, use microcomputers for instruction. However, Risinger (1996) concludes that social studies teachers are the biggest laggards in utilizing microcomputers and information technology in the schools.

Searching to discover why social studies teachers are considered to be laggards in using microcomputers, White (1988) found that lack of training opportunities was a significant inhibitor of greater technology use. His research also found that teachers did not believe that there was sufficient inservice or preservice preparation for integrating microcomputers into social studies teaching and curricula. Moursund (1992) concludes that the need for our educational system to empower teachers to make appropriate and effective use of computer related technology is well documented.

Purpose

This paper will describe an exploratory effort (by an instructor with minimal experience with microcomputers) to introduce and assess the implementation of selected internet activities for preservice teachers in an undergraduate social studies methods course. Prior to mid-January, 1996, my experience with microcomputers was limited to word processing and a brief introduction to e-mail. I had no e-mail experience outside my own institution and I had no experience with listservs, or internet information seeking strategies.

As I started to explore the possibilities of the internet and as my own skill in the use of microcomputers started to develop, I concluded that the social studies methods students needed to be empowered to become proficient in using several computer applications relevant for professional educators. I designed a set of class activities dealing with computer applications to promote the sense that these preservice teachers could learn any new computer application without anxiety or excessive amounts of time or energy. I was hopeful that the activities would also promote an image of a professional teacher using computers to make teaching and learning more productive for themselves as a professional and for their students as learners.

Sample/Data Collection

The sample for this exploratory effort consisted of the twenty-five students (20 males; 5 females) who were enrolled in the social studies methods course during the 1996 Fall semester. Five students reported that they had prior experiences with e-mail and internet information seeking strategies. In an attempt to determine student perception of their overall knowledge of using microcomputers prior to class activities on computer applications, they were asked to indicate their knowledge on a 5-point scale (1= "none", 2= "minimal", 3= "adequate", 4= "more than adequate", 5= "superior"). The pre class activities mean for overall microcomputer knowledge was 2.52, placing the sample at mid point between minimal and adequate. The same mean for the five students who reported prior computer experience was 3.8.

Additional pre data collection consisted of administering the Computer Anxiety Rating Scale (CARS) based on an instrument developed by Raub (1981). I used the
Anderson (1996) modification in which the word microcomputer was substituted for computer. According to Anderson (1996), the Cars is a self-report inventory consisting of 10 statements designed to measure computer anxiety. The scale comprises a mix of anxiety-specific statements (e.g., “I feel apprehensive about using the microcomputer”) and positive statements (e.g., “I am confident that I could learn microcomputer skills”). The scale is scored on a five point Likert scale (1 = “strongly agree”, 5 = “strongly disagree”). The anxiety-specific statements were subsequently reverse scored before calculating anxiety scores. The scores range from 10 to 50. A score of 30 is used as the breakpoint between low scores and high scores on the computer anxiety scale. Those who score 30 or less are considered to be not anxious about using the microcomputer. Scores in excess of 30 are taken to indicate moderate to extreme anxiety about using the microcomputer. The pre class activities mean for the CARS was 22.68 which means that the class can be characterized as fairly comfortable with computers. Only four students scored in excess of 30 on the pre test.

**Computer Activities**

**E-mail**

During our initial class session we spent time in the microcomputer lab where each student activated their e-mail accounts and practiced sending messages to one another. Students were asked to select a special issue of Social Education for an upcoming assignment and I asked them to e-mail me before our next class session and provide a complete bibliographic citation for the issue they selected. Each student successfully completed this assignment.

**Information Seeking Strategies**

The next class session provided students with instruction for using search engines to seek social studies information and how to access a World Wide Web (WWW) site when they know the Uniform Resource Locator (URL) or address. During the week, I met with students in small groups to provide them opportunities to practice the information seeking strategies. The assignment for the information seeking segment of the computer activities was to select a social studies topic suitable for students in grades 5-12 and to identify 5 Internet/Web sites that focus on the topic. I want them to critique the information found in terms of whether they feel it would be useful/not useful to them as a teacher.

**Listserv**

The next activity was to ask each student to subscribe to a listserv for high school social studies teachers. I selected the H-HIGH-S listserv because it is the most active of the listservs to which I subscribe. Subscribers receive 10-15 posts each day. The H-HIGH-S listserv is described as a discussion group designed to facilitate an ongoing exploration of curriculum, instructional strategies, and educational resources involved in teaching history, social studies, and related subjects in secondary schools. I have asked students to use the listserv as a resource and no assignments were made for making a set number of posts to the listserv. Students were encouraged to send messages to the listserv if they felt that a response was appropriate. As an assignment, I asked students to select a thread that appears on the listserv, represented by at least 10 posts, and summarize the different points of view represented by the posts. As a soon to be teacher, I want them to reflect on these ideas/suggestions and discuss their response to the topic(issue). As always, I want them to provide a rationale for their response.

**On-line Mentor Activity**

The final computer activity was to assign each student to an on-line mentor. The on-line mentors are social studies classroom teachers from across the U.S. and Canada. I secured teachers to serve as mentors by sending a post to three social studies listservs and the response from classroom teachers was extremely positive. I had response from 35 teachers who were willing to participate with my class of 25 students.

The positive nature of the response to my request is reflected in the following excerpts from posts received from teachers. One teacher said: "This sounds like something neat and I am willing to help out in whatever way I can" (personal e-mail communication, July 19, 1996). After receiving an initial post from a student in my class, an on-line mentor posted me: "Shortly after I received your letter I also received a letter from my student. This is a very unique experience both for the student and myself. Thank you for inviting me along for the ride" (personal e-mail communication, September 11, 1996).

The students are expected to communicate by e-mail with their on-line mentors at least once a week until the end of the semester (12 weeks). I am asking students to summarize the topics discussed with their on-line mentors and to reflect on what they carry away from these discussions and why these ideas are important to them.

**Tentative Conclusions**

Although I have not had an opportunity to view and reflect on all the data related to this exploratory investigation, I feel that the outcome will be positive from both the preservice teachers and the on-line mentor teachers. An on-line mentor teacher recently posted me:

Your student and I have been keeping in touch almost daily. It has turned into a great intellectual discussion of all the major areas of education. From your student, I have had the opportunity to assess my own educational values of almost 33 years. Your idea was a great one - an on-line
education course. (personal e-mail communication, November 9, 1996)

I also noticed a listserv message which addresses the potential of the on-line mentor aspect of this project. A teacher posted:

Has anyone ever thought of connecting themselves with a teacher-partner through this listserv? I recently thought about all of the benefits a permanent teaching "buddy" would bring to both teachers, schools, classes, and students. Would anyone care to dance with me (be my teaching buddy)? (i.e., to share ideas, contact each other on a daily basis, discuss new web sources, strategies, controversial issues, relate differences in school administrations, theories on teaching history... (H-HIGH-S Listserv Digest, October 21, 1996)

Only one student has indicated to me that discussions with the on-line mentor teacher have not been as productive as the student anticipated. The student feels that the on-line mentor was very quick to reject the value of questions initiated by the student during the exchange of posts.

Two students reported positive initial interactions with their on-line mentors in regard to the H-HIGH-S listserv. In one instance, in an early post to the student, the on-line mentor suggested to the student that it would be a good idea for a preservice social studies teacher to subscribe to the H-HIGH-S listserv. The student was excited to be able to communicate with the on-line mentor that our entire class had already subscribed to H-HIGH-S. The other student mentioned to the on-line mentor that our class had subscribed to the H-HIGH-S listserv and described the posts that were on the list. The on-line mentor responded by asking how to subscribe and the student reported how good it felt to be able to provide the information for the on-line mentor.

Work In Progress

This is a work-in-progress and I will not collect all of the assessment data until the end of the Fall semester (12/13/96). Quantitative data will consist of pre and post scores on the Computer Anxiety Rating Scale and a self report of knowledge of using microcomputers. I will also collect data on how they have used the microcomputer during the semester. Qualitative data will be provided by reviewing student reflections on the listserv and e-mail mentor assignments, and a series of open ended questions that I will ask each mentor to respond to at the conclusion of the project.

References

The acronym, SAASI (Structure, Acquire, Analyze and Synthesize Information) describes the partnership that heightens prospective teachers’ awareness of communication and computer technology. Following a presentation in an university library of the SAASI concept, information literacy, the World Wide Web (WWW) and CD-ROM multimedia, students gain hands-on experience by independently exploring the electronic encyclopedias and social studies Web sites available. The course instructor schedules in-class time for teamwork and hands-on experience using a computer in an elementary social studies setting. Also, future teachers go to various computer labs on campus and in their communities to practice using electronic mail (e-mail) to provide feedback for the required presentation.

From examining the students’ reactions to all aspects of the classroom strategy (presentation, demonstration, and independent exploration of multimedia technology) in the last three years, feedback supports the idea that the library field trip has a positive impact on awareness. The following are some student comments that provide a sample of the types of responses the educational technology field trip evoke.

Table 1. Sample Responses from E-Mail

- I have always resisted technological changes. I learned, however, of the many benefits that technology can have in the classroom, and only hope that my own intimidation will not affect the use of technology in my future teaching career.
- I learned a great deal about CD-ROM. I also learned of the different maps and pictures and children’s books.
- The use of computers for research is overwhelming and I sometimes feel as if I don’t know where to begin. As a result of demonstrations in class, I feel more at ease about using computers, but realize it requires practice and time.
- I especially liked to look at the CD-ROM. I was never exposed to this information and I was excited at the prospect of being able to use it in my unit planning. I also appreciate the tour given throughout the library showing all the useful data and materials that I could use to supplement my unit plans.
- I was amazed by the "electronic encyclopedia" on CD-ROM!
- Actually, this is my first time using E-Mail and I’m kind of excited. I went through this about three times before I got it right.
- The presentation on media resources was very helpful. I learned how to use some of the multimedia and internet services, I have never used before. Earlier today I did some exploring on my own. I found lesson plans and pictures I can use for future lessons and units.
- I was fascinated by the capabilities of the CD-ROM! I have since visited the "electronic encyclopedia" in the Media Resources Department.
- I especially enjoyed learning more about the internet. We are using the internet in my Pedagogy 2 class and I had very little prior knowledge on the topic.
- ...the library field trip was informative. I have never used a CD-ROM, but I’ve always wondered about them. I can see how a child would really enjoy using a CD-ROM in the classroom. Also, it is so easy. I was very surprised by that!

These comments from prospective teachers who were enrolled in elementary social studies, suggest a clear direction for implementing computer technology in the curriculum to prepare future teachers.

Methodology

To assess information literacy skills, the course instructor and the university librarian designed a 21-item questionnaire. All students enrolled in the author’s sections of elementary social studies completed the questionnaire during the second week of the semester. The types of data collected in the study over a three year period (1994-1996)
include students’ demographic information for 120 students and a Yes/No response to 17 items dealing with their awareness and hands-on experiences with computers and communications technology. For example, the study collects data on prospective teachers’ familiarity with: facsimile, e-mail, the World Wide Web, and CD-ROM multimedia. Four of the questions ask students to name an educational journal in each of three designated categories of writing; for example, scholarly, practitioner, and popular treatment. These items give the SAASI team the opportunity to collect information on the types of journals students group in the three categories.

The course instructor discusses various definitions of information literacy in class prior to the scheduled field trip to Media Resources. Immediately following the field trip, the instructor uses a series of open-ended questions to debrief each class and facilitate student interactions to evaluate the importance of the trip. The class uses the remaining class time to become familiar with the computer, and sign-up for hands-on activities with teams. The instructor observes the student teams during class, only offering assistance when asked. In the following two weeks, students communicate their reactions to computer technology using their electronic mail (e-mail) accounts.

Figure 1 displays the changes in the percentage, between 1994 and 1996, for prospective teachers responding to items that deal with their familiarity of computers.

In our discussions of SAASI, we use the term multimedia to mean an integrated package such as CD-ROM or interactive video discs. We have introduced Geography Pal Ted in CD-ROM format to model how integrating technology in elementary social studies classrooms can be a powerful tool to engage young children in social studies.

Information Literacy and Multimedia - The Approach

As a theme, information literacy is a often discussed concept and there are differing viewpoints. A number of people from library science and teacher education have been involved with defining information literacy and how its concepts can be integrated into the teacher education
curriculum (Breivik, 1991; Fielder & Huston, 1991; Behrens, 1994; Lenox & Walker, 1994; ASCD Update, March 1995). This study uses the concept of information literacy from Doyle (1992) who defines it as the ability to:

- recognize a need for information,
- identify and locate appropriate information sources,
- know how to gain access to the information contained in those sources,
- evaluate the information obtained, and
- organize the information; and use the information effectively.

The strategy to incorporate information literacy and multimedia into social studies education examines the following aspects of being information literate:

- knowledge of various sources of social studies information,
- understanding how information is structured in these sources, and
- skill in delivering instruction using multimedia technology.

The decision to implement a classroom strategy to integrate information literacy and technology into the social studies classroom is an effective way to provide positive contact time with the computer and involve future teachers in exploring CD-ROM multimedia.

**Discussion - Summary**

The in-class survey results measuring information literacy suggest that prospective teachers continue to employ traditional media such as video-tape, camera, transparencies and the slide projector, which are twice as familiar to them than newer educational technologies such as a CD-ROM drive and a modem. Approximately, eighty-seven percent of the students enrolled in social studies have used a personal computer and a printer. Compared with their familiarity using camcorders (82.1 percent), the CD-ROM multimedia technology is half as familiar (41.1 percent) as a tool to future teachers enrolled in a elementary social studies course.

The SAASI classroom strategy to incorporate information literacy and CD-ROM technology in social studies supports changes in curriculum philosophy that implements traditional media. The students’ responses indicate a positive contact with computers which suggests that incorporating technology in unit planning for pre-service and student teaching experiences is a possibility. By presenting the concept of information literacy in the context of research and unit planning, prospective teachers increase their awareness of the different ways to deliver information given the various sources of information, many of which are technology based. From the reactions to the field trip for educational technology and the incorporation of CD-ROM multimedia to deliver instruction, it would appear as if an educator-librarian partnership has a great potential for advancing information literacy and integrating technology into education. This must be a goal in elementary social studies and in teacher preparation programs.

**1013**
Integrating technology throughout all levels of social studies education including preservice teacher education and K-12 classrooms is vital if we are interested in a transformative rather than a transmission or traditional approach to social studies. This paper discusses the status of social studies education, status of technology integration within social studies education, and provides models and examples for transformative approaches to technology integration in social studies education. The goal is to suggest that technology can provide opportunities to make social studies education empowering and transformative, but meaningful, student-centered, constructivist approaches are vital. It is also suggested that the transformative approach begin in teacher education with empowering technology and constructivist integration.

Social studies education remains dominated by tradition. Students are forced to participate in traditional endeavors dominated by direct instruction and an expanding environment. Social studies instruction remains primarily teacher-centered, with lecturing, reading the text, completing questions, and taking tests the dominant activities (Ellis, Fouts, and Glenn, 1992). A question is whether this traditional arrangement facilitates the development of students who can think for themselves and participate as responsible citizens in a changing world. Students are now challenging the relevance of social studies education. We must begin making a difference first in teacher education.

The National Council for the Social Studies recently established new curriculum standards for social studies (National Council for the Social Studies, 1994). "The integrated study of the social sciences and humanities to promote civic competence" was adopted as the formal definition for social studies. The new curriculum standards are organized into a framework of ten themes incorporating fields of study that correspond to relevant disciplines. These new standards provide direction for a more transformative approach to social studies education. Social studies methods should follow the lead.

The general goal of this endeavor is to stress the importance of technology integration throughout all levels of social studies education by focusing on the need to begin in teacher education and ensure support once teachers enter the "real world." The intent is to demonstrate examples for successful application and initiate a dialog for continued improvement. Examples include evaluating and using commercial software and multimedia, evaluating and developing projects using interactive software including Hyperstudio and Powerpoint, and interacting with the world wide web.

Starting with Preservice Education

Social studies teacher preparation is often questioned regarding the issue of meeting the needs of prospective teachers and educational needs in our society. As a result, many alternative approaches have emerged to address this issue. Traditional pre-service programs in colleges of education must change to meet the needs of educating teachers for our society. The state of Texas has assisted this effort by requiring school-based teacher education and establishing the Centers for Professional Development.

Such efforts provide impetus to the needed changes, but if pre-service courses are still taught traditionally in K-12 schools, little relevant teacher education is occurring. Often one finds courses taught through direct instruction or transmission of knowledge with students only observing in the school-based classrooms (O’Loughlin, 1989). Instruction in schools is primarily the transmission of knowledge rather than the process of interaction and construction of knowledge (Shor & Freire, 1987). The goal should really be to model effective teaching and learning, thus the pre-service methods courses should focus on a transformative approach.

This transformative approach to teacher education requires massive restructuring of the way we have always done things. Key elements include modeling "powerful" pedagogy that requires teaching and learning that is meaningful, integrative, value-based, challenging, and active (National Council for the Social Studies, 1994).
Related components to be integrated suggest aspects of constructivism that include modeling/applying, reflecting, involving students actively, and developing a community of learners (White, 1995). Constructivism empowers students to ask their own questions and seek their own answers (Brooks and Brooks, 1993). We cannot continue to teach the way we were taught! The integration of technology can play a central role to the achievement of transformative social studies.

**Survey and Interview Results**

The resulting social studies education courses were developed from four years of teaching similar courses and from surveys and interviews from pre-service teachers taking the course. Surveys were administered to 415 students at three large state universities over a four year period. Students were asked to agree or disagree with a series of statements using a Likert-type scale, with 1 representing strongly disagree and 5 representing strongly agree.

General findings indicate that pre-service teachers feel that social studies education focuses on knowledge and comprehension (74% chose agree or strongly agree), direct instruction (83% chose agree or strongly agree), is text-based (78% chose agree or strongly agree) and is boring (86% chose agree or strongly agree). Fifty-three percent (53%) agreed or strongly agreed that social studies should be critical and controversial. Fifty-eight percent (58%) agreed or strongly agreed that process is more important than product in social studies.

Survey findings also indicate that pre-service social studies teachers have mixed feelings regarding the successful integration of technology in teacher education, but feel that it is important in teaching. Students feel similarly in regard to student-centered approaches in social studies education. The findings indicate that close to 100% of the pre-service social studies teachers feel a student-centered approach is "definitely" important and that both technology integration and student-centered instruction "definitely" facilitates relevant social studies education. Students generally had mixed feelings regarding the value of all methods courses and teacher-centered instruction in schools.

Additional comments from survey participants included calls for additional technology integration and instruction in pre-service teacher education and more modeling of "constructivist" ideas. Concerns expressed included the need for continued technology and constructivist follow-up once students have their own classrooms. The survey findings are supported in random interviews from survey respondents. Sample responses follow:

"Social studies is rarely taught, and when it is, all you see are lecturing and dittos."

"The most creative thing I've seen in schools is playing Jeopardy to review for a test."

"We've got to do a better job with technology. It can really make a difference."

"Students just seem to tune out when the teacher always lectures during social studies time."

"Involving students in their own learning must be the approach in social studies education...technology helps with this."

**From Preservice to the "Real World"**

General goals for all levels of social studies education emerging from the previous information include developing an understanding and appreciation for social studies, developing critical thinking and problem solving skills, and integrating transformative, non-traditional curriculum and instruction.

A constructivist or student-centered orientation to teacher education is important if we are to encourage students in schools to develop problem solving and critical thinking skills, and to apply, analyze, synthesize, and evaluate knowledge, skills, and attitudes. Pre-service teachers should engage in these processes throughout the entire teacher education program if we have any hope for a transformative approach in the schools themselves. To transform teaching, teachers need to implement experiential learning in their classrooms (Hope, 1996).

According to White (1995), general goals for teacher education should include providing experiences and expectations that help teachers develop professionally, facilitating constructivism through modeling and applying, reflecting, involving students actively and developing a community of learners, generating a passion for teaching and learning, developing critical thinking and problem solving skills, and integrating transformative, non-traditional curriculum and instruction.

Technology is a major component of a constructivist approach and should be integrated throughout a social studies education. Information technologies motivate, provide variety, promote meaningful learning, and facilitate interactive instruction (White, 1992; Faison, 1994). Goals for integrating technology in teacher education beyond introductory courses according to White (1995), include developing an awareness of available hardware and software for use in schools, evaluating hardware and software available for use in schools, applying packaged software during all preservice teacher education experiences, applying emerging technologies including multimedia and telecommunications during all preservice teacher education experiences, developing and applying lessons and units integrating technology, and
engaging in problem solving activities regarding technology issues in schools.

The instructors should practice constructivism by indicating that students should be responsible for constructing their own learning. The focus of all activities is practical application into the classroom.

Social studies teacher education should be project-based and process oriented including the development of social studies projects focusing on general social studies activities, inquiry, literature, technology, simulations, learning centers, and cooperative learning. A thematic focus is also essential if we are to model expectations for the preservice teachers’ future classrooms. Students should be involved through a negotiation process in deciding course projects, themes, discussions, and assessment.

Technology integration should play a central role throughout the social studies. There really needs to be access to a lab or computers in the classroom. Even one computer that can be used as a learning center, presentation tool, or web access machine would offer huge possibilities. It is important that the instructor apply technology throughout the course and that technology be integrated in all projects. Commercial software integration in units, multimedia development, management through technology, and web integration are each powerful applications that will facilitate a transformative social studies. Preservice teachers and all students must be provided hands-on opportunities with technology and to integrate it in their teaching.

School-based teacher education programs are definitely a step in the right direction if an important goal for preservice teachers is promoting meaningful classroom interactions. Pre-service teachers must be provided ample opportunities to interact with students in classrooms in a variety of ways. Having methods class take place out in the field is also a good thing, but they must not be taught traditionally.

The merging of technology and constructivism offers much hope for the future of social studies education. A constructivist orientation to teacher education is important if we are to encourage students in schools to develop problem solving and critical thinking skills, and to apply, analyze, synthesize, and evaluate knowledge, skills, and attitudes. Pre-service teachers should engage in these processes throughout the entire teacher education program if we have any hope for a constructivist approach in the schools. It is important to note that teacher education doesn’t stop with the granting of a degree or license. Schools and universities must make a concerted effort to improve their relationships to facilitate lifelong teacher education. Technology integration could and should assist with this endeavor.

Integration Examples

Teacher education faculty must model and apply constructivist praxis and preservice teachers must be actively involved at all levels of the teacher education program for constructivism to have any chance in our schools. Modeling and applying constructivist ideas in social studies education should be accomplished by both the instructor and students. The role of technology in modeling and applying should include demonstrations by the instructor and students, integration of technology into daily activities, and application of technology by students into class projects and field experiences.

Examples might include demonstrations of exemplary packaged software for instructional or management use or the application of more powerful and interactive authoring and multimedia programs. Daily use of technology is essential, as is the development of technology classrooms. With technology classrooms students could work individually or in small groups at technology centers designed to enhance class activities and projects. Students should also be asked to integrate technology into demonstrations or lessons for the class and field experiences.

Reflection is another essential component of a constructivist teacher education program. Technology lends itself very favorably to individual and group reflection. Students should be asked to reflect often in class and through a variety of methods. Word processing is an obvious method for reflection, but emerging technologies such as E-Mail, the Internet, and blank databases are other arenas enabling reflection.

Examples applying emerging technologies could ask students to send e-mail messages to each other and to the instructor, as well as over the Internet, reflecting on various issues essential to preservice teacher education. Technology links between the university and the schools for sharing and reflection should also be a goal for teacher education. Again, this should be integrated as a daily, or at least weekly activity in teacher education programs.

A particular goal in the design of social studies curriculum is the development of critical thinking and problem solving. Controversy is good in the social studies, therefore a value-based and challenging curriculum promotes reflection. The philosophy is that teachers should make time and in their classrooms to promote the development of relationships for individual and shared reflection. Every activity and assignment should have a reflection component built in with all activities and projects shared to encourage critique and further reflection. This can be accomplished through a variety of assignments individually, in small groups, and in the whole class discussions.

Another important component of constructivist programs is active student involvement. It is absolutely essential that teacher education programs move from
instructor dominated modes to student centered methods of instruction. The integration of technology on a daily basis facilitates active student involvement. Class activities should be project based where students work individually or in cooperative groups to complete relevant activities.

Examples might include research projects, lesson and unit planning, development of learning centers and other student-centered projects, and activities integrating management, commercial software games and simulations, and multimedia software, as well as emerging technologies. Cooperative learning activities where students are encouraged to use the computers to gather research or interact through e-mail or the Internet to acquire information or ask questions programs would facilitate the integration of technology and constructivist ideas in teacher education. The application word processing, database, authoring, presentation, or multimedia would also help to achieve the goal of integration.

An essential component of a constructivist social studies classroom is student-centered, active involvement. This has been addressed somewhat in the sections on modeling and reflection. The intent is for students to be responsible for constructing their own learning by having a social studies a curriculum that facilitates active involvement. The suggestion is for social studies education to be project-based. Each project chosen can be modeled by the instructor and students present completed projects to class in small or large group format for reflection.

Possible projects related to the curricular themes might be presented to the students at the beginning of the semester for discussion. The class chooses projects to complete, prioritizes the projects and adds projects of their own. Examples for projects might include technology applications, simulations, community-based activities, problem solving, and other student-centered active learning activities. Specific social studies related topics and themes for projects, groups activities, and discussion within the class can be based on the new thematic stands for social studies mentioned earlier.

Developing a community of learners is also a major component of constructivist programs. Although addressed in modeling and applying, reflecting, and involving students actively, developing a community of learners is probably the key to a successful constructivist program and should be highlighted. Again, the integration of technology on a daily basis assists in the development of a community of learners. Technology labs and technology classrooms with computers available for a variety of uses including learning centers and project development facilitates the development of community.

Through the use of applying and modeling, reflecting, and involving the students actively, a social studies instructor will lay the foundation for a classroom comprised of a community of learners. A vital and relevant social studies curriculum can really assist in developing a classroom community. It is vital that the classroom environment and structure include the following components: creativity, humor, choice, variety, challenge, adaptation, and non-traditional curriculum and instruction in social studies.

A technology integration model consistent with the transformative, constructivist focus, described at length above, that includes the process of reviewing, exposing, modeling, applying, constructing, and evaluating involves students in the entire learning situation so that a change in attitudes regarding technology can occur. The real value of educational technology can be experienced by students who are able to apply technology in new situations. Students can become experts in various applications and are thus able to teach the applications to others. It is vital that technology be integrated throughout the social studies curriculum and be used by the students during all units.

Conclusion

We must strive to make social studies more meaningful for our students. The domination of the transmission of knowledge and traditional model in social studies education, has hindered education in this country. Social studies education should be modeled after a constructivist approach which stresses applying and modeling, reflecting, involving students actively, and developing a community of learners with a technology focus.

The integration of technology is important in teacher education; it is absolutely essential in a transformative, constructivist teacher education program. The major components of modeling and applying, reflecting, involving students actively, and developing a community of learners is facilitated by integrating technology. Our teachers and ultimately our students will then be better prepared to meet the future. Only through these approaches will we facilitate meaningful social studies and develop civic competence, empowering teachers and students, and thus establishing a new tradition. Transforming, not transmitting, needs to be our goal.

Cameron White is an Assistant Professor of Social Studies Education in the Department of Curriculum and Instruction in the College of Education at the University of Houston, CUIN 5872, Houston, Texas 77204-5872. Voice: 713 743-8678 Fax: 713 743-9870 E-mail: cswhite@uh.edu
As I read through the various articles in this section, I noticed an overall theme of 'technological curiosity' which was incorporated into many of the author's ideas. It is good to see that we have accepted technology as one of the tools which should be included in the arsenal of education. We are utilizing, manipulating, and adapting technologies to meet the continually changing needs not only of our students, but our colleagues and ourselves, as well.

Many practicing educators are returning to school to learn how to use these technologies in their classroom. Excitement is high about the potential for reaching those students who were once thought to be unreachable. More schools are getting the equipment and connections needed to access the Internet. More teachers are using technology. Does this mean that all is well?

I often cringe when I hear that company X has donated its ten year old 286/2MB computers with one 5 1/4" floppy drive to school Y. (Note to the CEO of Company X: Here's a suggestion - Buy new Macs and give them to the schools! Remember that these students may be working for you in the future.)

Every quarter I have teachers I work with who still don't have ANY type of technology in their classroom. I see fourth and fifth graders shuffled off to the computer lab once a week for forty-five minutes, simply because it's their allotted time. I show teachers how to access and incorporate the Internet into their classroom curriculum, knowing full well that their classrooms are neither wired nor connected. Yet, I am constantly amazed at the spark which appears with these teachers. Some of the same teachers who didn't have ANY technology in their classroom return and tell me of grants, and moneys which they have received and used to put technology in their classes. They tell me of watching the excitement in their students as they access the Internet or get e-mail from their parents or a friend in another city.

As an educator, I see a growing awareness of the importance of making all of our teachers not only aware of the potential of technology but active technology users. As I read through each of the varied articles in this section, I find new ideas and new insights into ways that I can become a better teacher. The authors provide a wide spectrum of information which provides additional perspectives in which to view difficult educational experiences. As I read through these articles, I find myself learning new ways to approach issues which I face nearly every day in my teaching.

I do think that Opie would have been a better student if Helen Crump had today's technology available to her. And then Andy wouldn't have had to take away his bicycle for making poor grades. These are just some of the questions that I was never able to ask in school.

Ray Braswell is an Associate Professor of Educational Technology at Auburn University Montgomery.

Recently a new tendency has appeared on the labor market through the use of linked computers called telework; timidly in Belgium and in Italy, more in other countries. There are estimates that more than 60% of the work implied in the production of goods is the processing of information. This information is increasingly computerized. The possibility of teleworking is therefore huge in principle. The employer can benefit from savings in investments and consumption in buildings and furniture and a large flexibility. For the worker, one invokes also the flexibility that allows for better conciliation of work, family obligations and leisure. The diminution of travel is to the advantage of the whole society by decreasing the pollution and bottlenecks and to the advantage of the worker in avoiding the loss of time and money, the fatigue and the stress. The different advantages for the worker also benefit the employer through theoretical increase in productivity and quality of work.

For persons whose handicap reduces mobility, telework is an obviously attractive solution. For those whose mobility is reduced, or that request frequent assistance and care, telework from their domicile or the institution where they work is practically the only solution to participate through an active contribution in the economic life and to find a broader socialization. For a mobile person, telework can involve less social relationships compared with on-site work could offer; but, for handicapped persons isolated by the impossibility of usual work relationships, telework allows a significantly larger socialization compared to their isolation (Volpentesta, 1995). Therefore, for these handicapped persons, telework offers a unique chance to break out of the barriers of their handicap. Of course, teletraining is the first necessary step to prepare disabled people for telework; it makes trainees familiar with technologies, methods and organizational structures for teleworking activities.

EXPERTISE (EXchange and Promotion of TElematic and Robotic Technologies for vocational training and employment of the dISablEd) is a transnational project to promote high-level formation and employment of handicapped people in the HORIZON/EMPLOYMENT Initiative of Europe Union. It involves numerous regions of different European countries (Spain, Germany, Austria, Belgium, Italy) and its main objectives are to provide effective tools and innovative methodologies for the vocational training and employment of disabled people using the most recent technologies to promote exchange of technology and knowledge among all European regions involved in the project. In particular, in Wallonie and in Calabria, we’ve focused our attention on teletraining and teleworking. In the rest of the paper we discuss: the technological infrastructures used at Le Réseau (Wallonie - Belgium) and at Brutium (Calabria - Italy) to support project activities; telematic services which are used either as communication media for distance education and as means for teleworking; didactic methodologies; and, some considerations about first results.

**Technological Infrastructures**

Regional occurrences of the project in Wallonie (Belgium) and in Calabria (Italy) are based on the same starting architecture that has led to similar infrastructures, even if they have some technical implementation differentiations. Project activities are hosted in a vocational center, where most training activities take place, and in some peripheral nodes (non-profit organizations and trainees’ homes) for distance training and net services delivery.
The main purpose is to have a place where trainees can meet and configure telework modules. As shown in Figure 1, a digital laboratory has been set up in the center and can be accessed physically or virtually, with a remote access, by trainees. A coordination staff is always available to a trainee for tech or medical assistance. In the digital laboratory, a set of Web/FTP servers are installed for local Intranet and world-wide Internet users; the purpose is to make available a group of services to the trainees and to disseminate project results and some works developed by trainees themselves.

The labs aims to give many different kinds of support to disabled persons: selection and integration of new software/hardware technologies and useful utility tools; as vocational guidance site; as vocational guidance site; in coordination of training and work activities; in management of the technical infrastructure; to arrange a physical place for periodic meetings and socialization; to make available a place where trainees can deploy part of their working modules; to make available computing and telecommunication resources; as an interface to possible interested enterprises which need teleworker; in coordination of training and work activities; in management of the technical infrastructure; to arrange a physical place for periodic meetings and socialization; to make available a place where trainees can deploy part of their working modules; to make available computing and telecommunication resources; as a router and gateway to ISDN and Internet; to activate base network services as file transfer and e-mail; to promote local services; to disseminate information on available technologies; to adapt workplaces for disabled people; to create job opportunities for qualified handicapped people.

Both centers, in Wallonie and in Calabria, use multimedia personal computers and workstations to enable audio/video interaction. Noted below are brief characteristics of each technical solution; some miniature differences in technological implementations can be noted. At Brutium we have installed a LAN extended all over the rooms in the laboratory building. The LAN is a Fast Ethernet 100Mb/s to allow video/audio conferences inside the lab. A gateway to Internet at 64Kb/s. We’ve plugged in to the LAN 15 Win95 Net Clients PC all with audio capabilities, two of them have speech recognition software, three have video grabbing cards, two have CD-R drivers for multimedia production. We’ve also configured three Internet servers one Intel Linux, one Intel Windows NT 4, one PA-RISC HP-UX. As additional accessories we make available digital cameras, color printers, scanners, VGaToPAL converters, VCRs and a LCD projector. Moreover, all recent Multimedia Technologies, Intranet and Internet facilities have been set up. We have provided the possibility, for people with severe handicaps, to remotely attend lab activities (teletraining) via HFTV and Intranet technologies. At Le Réseau we’ve given each student at the site where he/she is receiving the teletraining (home or institution) a PC Pentium 133 with 16Mb RAM, CD-ROM drive, sound card, Windows 95 and a printer. In our center, (where we are also providing vocational training in classrooms) all the (about forty) computers (trainees, trainers, administration) are linked in a LAN Thin Ethernet 10Mb/s. At the software level, it is a mixture of Windows 3.11 and Windows 95, with a Windows NT 3.51 server. Our server is equipped with a DIVA Quadro ISDN card from Eicon Technologies, providing eight channels (four 2-channels Basic Accesses). The remote students also have a Basic Access to the phone company and an ISDN card in their computer.

We do not use Internet or other private networks. People can get relatively inexpensive Internet access through analog telephone lines but ISDN Access is only proposed at corporate rates which are still rather expensive. Instead, the remote students call our server directly over telephone lines. Belgium is a small country. Even with (not so long) long distance calls, we pay less than what we would pay to the Internet access providers (plus local calls).

In both training centers we focus on outcomes concerning professional profiles in the following sectors: digital audio-visual production; system and network administration; office and home automation; software design and prototyping; CAD, computer graphics.

**Telematic Services**

Some basic and advanced telematic services have been made available to teachers, tutors, and trainees as support in teletraining and management/coordination procedures and to promote socialization through entertainment. Such services have been based on the usage of suitable telematic software tools.

The first set of tools integrates Internet technologies. In particular it essentially consists of some Internet modules and interfaces between them (Fasano, Frega, Greco, & Volpentesta, 1996). On the Internet side we’ve built-up a Mailing List (to broadcast e-mail messages among Internet
EXPERTISE is MAGDA: a multimedia collaborative environment where users can play some card game on a virtual table. They communicate with each other by a chat service, while they work together. Giuda Lab, we've developed an entertainment shell where users can insert a couple of interactive card games online (Frega, Greco, Pisculli, & Volpentesta, 1996). The system may be regarded as an environment that allows users to communicate with each other by a chat service, while they are playing some card game on a virtual table.

The last prototype we have developed and used in EXPERTISE is MAGDA: a multimedia collaborative agenda (http://tre7.deis.unical.it/magda/magdafrm.htm). At a local level the agenda is used as a support tool for project management: to coordinate teachers, tutors, trainees and their teletraining activities; didactic collaborative work; to allow trainee groups to create and present multimedia material about topics selected and scheduled by teachers and tutors. At a transnational level, the agenda is used to setup European partners meetings; to give each subscriber a view at meeting schedules; and, to multicast messages to predefined workgroups.

We do not use videoconferencing. As mentioned below, our training is largely practical. Trainees and trainers interact mainly by sharing directories and files, by e-mail and by telephone. We felt that videoconferencing was not the priority in our situation. Another issue related to videoconferencing is that this medium is most appropriate to broadcast real-time teaching. On the contrary, we want to allow our remote disabled students to adapt their time schedule to their particular situation and their learning rhythm.

**Didactic Methodologies**

In the starting phase of the project most of the trainees didn't have a clear view of what computers are, what they are used for in the economical world, and how they themselves will fit in. Still, if they did come to us, they had a project or some hope to find a job after training. It is along their training that we’re examining and developing their project with them. We help them to gradually better understand where they desire to go and what training is needed to go there. There is no a priori program (except for the first weeks). The program is tailored to each individual following his/her needs, inside what the centers are able to offer.

In regard to the didactic method we use, it is very different from classical one-way knowledge transfer from one teacher to all students; it’s quite individualized. Trainers give few classical lessons. They give explanations on some points and then tasks that allow students to try by themselves. This is the method that we are transposing in teletraining, providing multimedia materials instead of spoken information and instructions: the trainers give to distant trainees explanations and instructions through the network to allow them to work autonomously, in principle, for one day. These works are retrieved, through the network, to be evaluated by the trainer who then decides the next step. Of course, writing information and complete instructions are large undertakings and we are searching for all existing pedagogical tools that could ease the task for us; this is also true for the work in the center, because all the time that the trainers can save by using the existing pedagogical tools is more time devoted to individual follow up. “On the job” individual training and group collaboration are also encouraged by providing network applications and communication tools for promoting exchanging with other EXPERTISE partners. Trainees are also encouraged to use e-mail between them. Distant and in loco trainees keep track on the agenda through recording all of their training activities. This diary can be accessed at any moment by the staff. Meanwhile, a recording software traces all actions on the computer.

**Formation**

Since we deal with persons with more severe handicaps, we think that the training could be slower. Some of them receive care that takes a good part of their daytime. For its content, the training benefits from the competence that both centers have developed. Globally, the objective is to master the use of networked computers and traditional software in business work (word processing, electronic publishing, spreadsheets, databases, accounting software) which would, in turn, give access to a large variety of jobs in the tertiary sector. Other possible training orientations are analysis and programming, the computer-assisted design (CAD) or computer graphics. Possible basic training shortcomings are taken in account in the project to make it accessible to the largest number, including the most disadvantaged.

**Conclusions**

In this paper we have discussed some technological and methodological solutions that we have adopted for the execution of teletraining actions in a European international project.

Issues about such solutions have dealt with: a telematic infrastructure (Internet/WWW/BBS) linking all interested sites and relevant public and private institutions (for ex. HANDYNET nodes) involved in the project; experimentation of teletraining and other distance education activities; usage of telematic software tools in order to support teletraining and management/coordination procedures.
and, providing technical aids to prepare people with severe handicaps to telework.

Collaborative drawing (CD) have received much attention from researchers and tool developer in last years (Peng, 1993). Observational studies of group interaction in sharing a drawing space have been led to design requirements for CD tools. Many of them have been embodied in research prototypes and commercial applications (Krueger, 1982).

On the other hand, the World Wide Web (Web) has emerged as a popular and powerful infrastructure for group-oriented activities. Thus, it has seemed useful to us to make available on the Web a CD tool which satisfies some of those design requirements.

CODEE is the name of our prototype, and it has been developed at GiudaLab to support distance education and teletraining activities during the execution of Expertize (Exchange and Promotion of Telematic and Robotic Technologies for vocational training and employment of disabled), a trans-national project to promote high level formation and employment of handicapped people in the Horizon Employment Initiative of European Union.

The following paper presents: the basic set of functionality we have implemented in CODEE; the CODEE architecture and client-server communication protocols; usage scenarios and a first observational study future works about some extension which take into account lessons we have learned during the usage of CODEE.

Tool Functionality

In contrast to other approaches on the Web oriented to support synchronous painting activities on a same space (Krueger, 1982), our tool is a multi-user program for asynchronous drawing on multiple-shared canvases; each of them can be accessed by an authorized group.

The tool embodies classic functions that can be normally found in most draw programs. In a vertical toolbar on the left of the drawing area, a user can select among five type of objects: rectangle, circles, lines, freehand and text. Rectangles and circles are available in both outlined and filled style. A sixteen-color palette is available on the same toolbar. Objects can be selected and then deleted, resized or moved on the document. Moreover they can be grouped together in order to enable complex objects manipulations and locked to avoid further modifications.

Multiple documents can be simultaneously present on the client side, a user can select any of them and move/copy objects from one to another. Figure 1 illustrates the client interface.

A file menu provides options to save, load and delete documents. A group-oriented password system is provided as a support to collaborative work; actually members of a group share the same drawing space and documents in this space can be accessed only by them. Figure 2 shows the interface for groups management.

All documents are grouped in directories, stored on the remote server file system, and can be accessed by any Java-compatible browser.
Figure 2. Interface for users groups management Architecture and Protocol.

CODEE is based on the client-server paradigm (see Figure 3). The server consists of a Java stand-alone, multi-threaded application which manages the communication with Java applet clients via sockets. The server's primary function is the management of a shared workspace (basically a dedicated file system) where graphical documents are organized and stored for successive retrievals; moreover, a password system protects both individual and group works. The tool client side runs as an applet in any Java compatible Web browser.

The client applet and the server application communicate by using a stateful protocol over TCP/IP through Java Socket and ServerSocket classes.

The server makes available to a client the following functions: list of available files, load a file, save a file, delete a file, create a new users group, control user access. The client-server communication protocol consists of the following steps:
1. The server is ready and listening on a predefined port (called randevouz port) waiting for a client request.
2. When the server detects a client connection on the port, it sends an “OK” string and sets a new bi-directional communication channel for the rest of the session; moreover it forks a child process (thread) to handle this session and goes back listening on the randevouz port.
3. After receiving the “OK” signal, the client sends a service code (i.e. sends “FL” for a list of available files).
4. After receiving a code, the server sends a sync signal, then sets itself ready to send the requested data (in the example above, a file list).
5. The client waits for the sync signal then sets itself ready to receive the data.
6. Once the data are transferred, the server sends an “OK” code in the case of successfully transmission or a “BAD” code to notify any error condition. As a final step the server sends a “BYE” and closes the connection.

Usage Scenarios

EXPERTISE (EXchange and Promotion of TElematic and Robotic Technologies for vocational training and employment of the dISablEd) is a transnational project to promote high-level formation and employment of handicapped people in the HORIZON/EMPLOYMENT Initiative of Europe Union. Such a project aims at providing effective tools and innovative methodologies for the vocational training and the employment of the disabled by exploiting most recent results in the area of information and rehabilitation technologies. In our sub-project participants have been split up into groups composed by social assistants and disabled persons in order to better organize and control teletraining activities. Moreover each group is supported by a tutor and all workgroups are supervised by a teacher.

Teletraining activities are supported by a distributed technology infrastructure which connects a digital lab center to peripherals nodes. Some of them consist of specific tasks to be performed by using distributed information tools; CODEE is one of them. In particular, we have considered two possible usage strategies: as a media of asynchronous graphical communications, as a tool for collaborative design management. In the first case, CODEE turned out to be a useful tool for improving
communication among group members. In the second case, it made possible to collaboratively carry out simple drawing exercises in some training modules. CODEE is available at http://sungiuda.deis.unical.it/java/HTML/Draw/.

**Future Works**

In some ongoing work we are trying to extend the tool capabilities. Such extensions deal with the implementation of two different interfaces; one for the trainees and one for the trainer. In fact, the trainer needs a way to control the actions of the trainees and to direct groups composition. The integration of suitable features to enable an easier access to people with some kind of disabilities, and the integration of a mail system to enhance the communication among groups members and to handle FAQ collection and distribution will also be useful tools.

Better Than a Hunch: Technology and Teachers’ Informal Decision-making

Michael Madden
Francis Marion University

Educational assessment formulates conclusions about the nature and extent of a particular student’s academic difficulties to develop appropriate intervention strategies (McLeod, 1982; Salvia & Ysseldyke, 1988). Informal investigative techniques supplement test information to evaluate hypotheses as to what needs to be retaught and how knowledge already mastered could serve as a point of departure for instruction.

Diagnostic probing is one informal strategy used to specify a student’s procedural knowledge. For example, an experienced teacher might ask a small number of questions and, depending on the student’s responses, pose additional items to delineate what the student understands and form hypotheses as to what concepts or procedures are problematic.

Explicit models, such as generalizability theory (Cronbach, Gleser, Nanda & Rajaratnam, 1972), provide a means of evaluating conclusions based on formal tests. However, justifying conclusions reached using informal probes often depends on more nebulous foundations, such as “common sense” or experience. While the conclusions may be valid, an objective review would deem arguments that appeal to common sense less than compelling; moreover, without a common frame of reference, the expertise of proficient assessors is difficult to communicate. Consequently, practitioners develop their own insights, leaving unrealized any potential for the analysis of individual difficulties to become a more distinct and comprehensive body of knowledge.

Goal of the Research

The goal was to develop and evaluate a provisional model to represent inferences about the content-specific knowledge of individuals. The inferences depict processes proficient practitioners employ to justify judgments made using diagnostic probes. The skill area selected was adding and subtracting fractions and mixed numbers. The model was viewed as an analogue for the procedure experienced diagnosticians use in deciding if administering a particular item would provide information that could not be safely inferred from observations already made. The problem of selecting appropriate probe items was conceptualized as one of using a student’s observed performance on a set of questions to predict whether that individual would correctly respond to particular questions in a finite “universe” of items.

Model of Inference Concerning Individual Performance

A model depicting inferences must be consistent with ways practitioners justify their judgments. The investigator observed experienced diagnosticians and interviewed them about collecting information and basing decisions on their observations. Their reasons for selecting probe items were frequently framed in terms such as “if Fred was correct answering questions like 5/7 + 2/9 =, I could be fairly safe in predicting he would correctly answer 1/3 + 1/3 =.” When asked about the basis of such judgements, relationships between specific skill elements figured prominently in their explanations. For example, a judgment could be expressed in the form, “If a student can add two fractions in which the common denominator can be found by multiplying the denominators of the terms in the question, he should be able to add two fractions that already share a common denominator.”

Propositions developed for the study had two components:

1. an assertion predicting whether a given student would correctly answer a specific question; and
2. a reason for the prediction, based on the procedural knowledge needed to respond to the questions.

Predictive Assertions

A predictive assertion pertaining to two hypothetical sets of items, A and B, would be “if the student has correctly answered all four questions in set A, the student will give a correct answer to question 1 in set B.” The questions of set A constitute the “predictor set,” while question 1 of set B is the “target item.”
Reasons for Assertions

Analyses of procedural knowledge needed to add and subtract fractions and mixed numbers (Birenbaum & Shaw, 1985; Novillis, 1975) were used to generate reasons for predictions. Fifteen procedures, describing three types of functions, were defined. Preliminary transformations involve procedures (designated 1 - 7) to change terms in a question into equivalent terms with common denominators. Core operations (procedures 8 - 11) represented knowledge needed to add and subtract fractions and mixed numbers sharing the same denominator. Transformations of interim results identified knowledge (procedures 12 - 15) needed to express answers in correct form.

The solution to a particular item was represented as a sequence of procedures. For example, the question “3/8 + 3/8 =” could be solved by (a) adding two fractions with the same denominator (Procedure 8), and (b) transforming the interim result, 6/8, to express the final answer in proper form (Procedure 14). Its solution sequence could be expressed as (8 14).

Propositions made predictions about how a prototypic individual would respond to a finite set of items, an adaptation and extension of the inference strategy described by Scandura (1973; 1977) for constructing structural learning theories. To operationalize the propositions, sets of items were systematically generated, and a solution sequence was specified for each question, such that questions in an item set shared the same solution sequence. Thus, for example, the items 3/4 + 3/4 =5/6 + 3/6 =8/9 + 4/9 = 7/8 + 3/8 = comprised an item set for which the postulated solution sequence was (8 13 15). An item’s solution sequence was viewed as a possible (but not the sole) path to a correct response. Further, it was not assumed that a given student followed this procedural sequence could generate an answer.

In outlining a theory of performance testing, Scandura (1973; 1977) used the principle of inclusion to limit the number of items administered. The present study distinguished between complete and partial inclusion of postulated solution sequences in formulating reasons for assertions. Complete inclusion served as a rationale for propositions in which all procedures in the target item’s solution sequence were a subset of the predictor set’s solution sequence. For example, one proposition predicted that an individual correctly answering all four questions for items such as “5/6 + 9/14 =” would correctly answer “7/8 + 3/8 =.” The reason given was that the target item’s solution sequence (8 13 15) is a subset of (6 8 13 15), the solution sequence of the predictor set.

Partial inclusion provided a rationale when some, but not all, elements of the target item’s solution sequence are also elements in the predictor set’s sequence. For example, it was asserted that those correct answering all four items in set with questions like “5/6 + 9/14 =” would answer “2/5 + 3/4 =” correctly. The reason given was that the solution sequences of the target item (3 8 13) and the predictor set (6 8 13 15) have procedures 8 and 13 in common.

Reasons using partial inclusion were stated in two parts. The first identifies elements of procedural knowledge shared by both sequences. The second asserts that students for whom there is evidence that a more advanced element is available should also have a related, but less complex element, as part of their repertoire. Thus, if one can solve problems in which the lowest common denominator (LCD) is the least common multiple of the given denominators (Procedure 6), one should be able to solve those in which the LCD is the product of the given terms’ denominators (Procedure 3).

The Investigation

The study used propositions to assess the extent to which the inferential strategy made valid predictions about whether individuals would be correct in answering specific items from a finite “universe.” At issue was the extent of variability in intra-individual patterns of performance. The predictive success of the propositions also served to evaluate the adequacy of the model developed to account for performance in the skill domain under investigation.

Method

Each proposition was considered a hypothesis to be investigated. Propositions were tested using responses by 481 subjects from six predominantly rural school divisions in the Canadian province of Saskatchewan. All but a small percentage were in the seventh grade. Each of the six groups took a different test, though all tests had items requiring addition and subtraction of fractions and mixed numbers. Each student answered between 112 and 116 questions, distributed over four sessions, each lasting about 45 minutes and given at one-week intervals.

Questions were arranged in two sections, with items calling for addition of fractions and mixed numbers in one, and subtraction of fractions and mixed numbers in the other. Students were asked to solve the questions, to show the steps they used to obtain the answer in the space provided, and to express answers “in lowest terms”.

Variables

Propositions were differentiated in terms of the type of prediction (affirmative or negative), operation (addition or subtraction), number type (fraction or mixed number) and degree of inclusion (complete or partial). The accuracy of each assertion was evaluated using prediction analysis for examining cross-classified categorical data (Hildebrand, Laing, & Rosenthal, 1977) to indicate the extent to which use of a subject’s responses to the predictor set resulted in reducing the percentage of incorrect predicted outcomes on the target item.
The dependent variable for evaluating each proposition was the percentage reduction in predictive error, defined as the percentage of observations for which a given proposition incorrectly predicts the outcome on the target item. This measure compared (1) the percentage of errors observed when a subject’s known status on a predictor set was used to anticipate outcome on the target question with (2) the percentage of errors that could be anticipated if a proposition of the same scope and precision were to predict performance on the target item without reference to a subject’s status on the predictor set.

Scope is defined as the proportion of the population for which it is possible for an assertion to make an error in predicting outcome on the target item. Precision refers to the specificity with which each category of the predictor set can be located with respect to outcome on the target item. Its effect is estimated in terms of the unconditional probability that a prediction is in error, and is a direct reflection of a target item’s difficulty.

**Data Analysis**

The predictive accuracy of each proposition was evaluated on the basis of participants’ intra-individual patterns of response. Data were analyzed in four steps:
1. the response to each item was scored as correct or incorrect;
2. each subject’s status was determined on the set of predictor items specified in the propositions being evaluated;
3. respondents were cross-classified according to whether they were correct or incorrect in their response to the target item for each proposition; and
4. the rate of predictive success of each proposition was evaluated to determine if the percentage reduction in predictive error was greater than could be anticipated on the basis of chance.

Results of each prediction were summarized in contingency tables. Each proposition was tested under “ideal” conditions, so that only subjects correct in answering all four items on the predictor set were used to evaluate affirmative propositions. Conversely, only those incorrect in answering all four questions in the predictor set were used to evaluate negative propositions. This restriction was imposed to permit testing of relationships postulated by the model without confusions arising from inconsistent patterns of response. The rate of predictive success for each proposition was evaluated against the null alternative (p<.001) that use of the subject’s known predictor status resulted in no reduction in percentage of error in predicting outcome on the target item.

**Results**

Table 1 summarizes the performance of the negative propositions according to the number type, operation and degree of inclusion. Percentages corresponding to the number of hypotheses accepted and propositions committing no predictive errors are indicated in parentheses.

**Discussion**

The inferential strategy viewed an individual’s responses as evidence that specific elements of procedural knowledge were available, and used that information to predict whether particular items would be answered correctly. The percentages of negative propositions for which the research hypothesis was supported validates the contention that an individual’s observed predictor status can be used to make valid assertions as to what questions the individual would be unable to answer. Moreover, it was notable that a significant number of negative propositions made no predictive errors. The data thus suggest that, when making negative inferences, the strategy appears to rest on a firm foundation. The results also provide sugges-
tive evidence that formulating negative predictions on the
basis of the inclusion of specific elements of procedural
knowledge represents a viable strategy for constructing
inferences to depict the status of individual learners.

In contrast, the summary presented in Table 2 suggests
that, in general, affirmative propositions were less success-
ful in predicting outcome on target items. This difference
was anticipated, as an assumption is being made that
respondents generate answers that are consistent with the
availability of procedural knowledge, and that other
factors, such as carelessness or incorrect recall of number
facts, do not intrude in the process. In practice, however,
responses are not "error free." The discrepancy between
rates of predictive success for affirmative and negative
propositions serves to emphasize that availability of
procedural knowledge is a necessary but not sufficient
condition for a correct answer.

Initial perusal of the collective success of the affirm-
ative propositions, reported in Table 2, suggested only
moderate support for the inference strategy. However, due
to the manner in which the dependent variable is defined,
there are three situations in which it would not be possible
to reject the null hypothesis for affirmative propositions.
The first, in which a large percentage of observations are
inconsistent with the predicted outcome on the target item,
is the only one that would challenge the conceptual
foundation of the predictive strategy. Propositions with
predictive error rates that exceeded the moderate range
(2.5% to 3.5%) comprised only 6% of the propositions
evaluated. The second, involving restricted precision,
would apply in cases where few predictive errors were
made but the difficulty of the target item was low. Percent-
age reduction in predictive error depends upon the
precision of the proposition, which reflects the difficulty of
the target item. This relationship reduces the likelihood of
rejecting the null hypothesis, even when only a small
proportion of incorrect predictions are made. When few
make errors on the target item, knowing a subject's
predictor status simply provides little improvement in
predictive success.

The effect of restricted scope reflects the impact of
small sample sizes, when a limited number of respondents
satisfy the condition of correctly answering all four
questions in the predictor set. In such instances, minor
fluctuations in the number of observed errors can seriously
influence estimates of an assertion's tenability.

Detailed analysis of the data also identified a group of
propositions in which low difficulty of the target item and
limited scope interacted to reduce their index of predictive
success. While the research hypothesis could not be
accepted for these propositions, their performance never-
theless provided qualified support for the inferential
strategy's viability.

The impact of restrictions in precision and scope
provide context in considering the performance of the
affirmative propositions, and suggest that the inference
strategy has greater support than an initial glance at
acceptance rates for research hypotheses would denote.

Conclusions

Each proposition made an a priori prediction based on
a model of procedural knowledge. The number of tenable
assertions suggested that an inferential strategy that
predicts whether individuals will correctly answer specific
items from a finite "universe" is viable.

As the model of procedural knowledge is explicit, there
is support for the contention that making inferences on
limited samples of behavior from specific students
represents a corpus of knowledge. Stating those inferences
in propositional form permitted assertions to be evaluated
empirically. Articulating the conceptual basis for each
assertion provides a starting point to challenge theoretical
assumptions and formulate alternative frameworks.

The propositional structure representing assertions as
logical inferences builds on Toulmin's (1972) conceptual
framework for evaluating statements of matters of fact. As
such, it is sufficiently general to provide a basis for
communication, both within education and with other
disciplines. Viewing judgments as logical inferences also
has important ramifications for the status of individual
assessment. One way conceptualizes the assessment of
individuals as a process whereby teachers apply crude
"rules of thumb" to make judgments about an individual's
state of knowledge, so that the resulting conclusions are of
unknown validity. Such a view emphasizes the role of the
diagnostician's "insight" into the idiosyncratic perfor-
mances of individual learners, but the process by which
that insight occurs remains the province of the particular
diagnostician. This investigation represented judgements
of diagnosticians as conclusions based on evidence, on
patterns of performance open to empirical verification, and
considered the basic model for diagnosis to be hypothesis
testing. While the role of "insight" is not eliminated in the
latter view, its prominence is diminished, as the emphasis
is on the extent to which the process is objective and
capable of explicit representation. The results suggested
that effort expended developing and refining such analytic
models could be worthwhile.

The percentage reduction in predictive error, by
providing an objective index of the likelihood that a
judgment is in error for a given individual, addresses the
problem of undetermined validity. One could object that it
does not have the inferential power of measures based on
generalizability or item response theories; however, a
fundamental difference in approach must be kept in mind.
Measurement models represent the status of individuals in
relation to an underlying trait, universe of items and/or a
comparison group. By contrast, the present effort sought to represent judgments of diagnosticians and the specific evidence on which they are based. In doing so, the legitimate functions of measurement models are being neither supplanted nor usurped.

**Implications for Research**

One dilemma confronting educational diagnosticians is obtaining detailed information about a child's performance while limiting the number of questions asked. Adaptive testing models, in which item selection is contingent upon a subject's previous responses, have built upon the work of Lord (1971) and other theoretical models, including item response theory (IRT), and latent class theories (Macready & Dayton, 1989). Computers have made implementing these models feasible (Weiss & Kingsbury, 1984). The inferential strategy examined in this study provides an alternative for addressing this problem in ways that approximate procedures used by skilled diagnosticians.

Another avenue of exploration would investigate the utility of predictions that do not require completely consistent performance on the predictor set. Consideration of such alternative constraints would increase the utility of the model in realistic contexts. The data gathered from the present study will be re-examined to address these questions.

The public is placing increasing pressure on schools to help growing numbers of students with difficulties in mastering skills, but multiplying the number of teachers is not an option. The potential of computers to provide sophisticated instructional support has just begun to be tapped, and realizing that potential will require a re-examination of how technology can be employed. One of the most crucial aspects of a teacher's involvement with a student is the ability to make effective decisions to guide the student's learning. If technology can make skills of experienced practitioners more widely available, addressing the needs of a broad range of students is a more attainable goal. Progress in that area may produce a corresponding shift in public perceptions.

**References**

The use of educational technology is becoming commonplace. Classrooms use computers, the Internet and educational software available on compact disks (C.D.) and disks, which include movies, sound clips and musical scores. Laser disk players are also being incorporated into classrooms, sometimes replacing less versatile videotape players. Teachers need to be current in these technologies to optimally benefit students and employ labor-saving technology. This paper will discuss the use of newer technologies in three areas: regular education, reading education, and special education. In addition, a global overview will be offered.

Technology and Regular Education

In the regular education classroom, teachers may have students with learning disabilities, reading problems and other deficits. Programs working with different subject areas are useful and can help students with dictionary concerns, encyclopedia usage and can remediate specific skill deficits.

In some cases, these technologies such as laser disks can facilitate the writing process, and provide students with a quick reference to specific instructional material. In the regular education classroom, even gifted students can benefit from the advanced technology and can pursue independent study on their own, thus freeing the teacher to work with other less able students. In addition, aids can assist students who may have been "mainstreamed" and provide additional assistance toward their goals.

Shaughnessy (1996a) has indicated that with mainstreaming and inclusion, there will be more and more students with multiple handicaps being served in the regular education classroom. We need to provide training for teachers as we approach the year 2000. A book edited by Shaughnessy (1996a) details the various realms of education, and reflects on how technology can be integrated and infused into various aspects of education, i.e., gifted education, middle school education, vocational education. Siegel, Good, and Moore (1995) provide an extensive list of various software that can be used by regular educators and special educators. They catalog software by specific streams i.e. assessment, behavior management, methods for literacy, spelling, art, phonics, study skills and writing.

Technology and Special Education

In the special education classroom, many programs can provide one to one instruction and provide a grill and drill format for students needing to review basic concepts. These programs can cover vocabulary, categorization, same/different concepts, word identification by function, and association and can operate in Spanish and English, and will "read" along with the student. With the increase in Spanish speaking students in many sections of this country, this assistance will provide relief for many already overworked, overburdened teachers.

Special education students can be assisted by computer-aided instruction because these programs are self-paced and individualized to the student's area of weakness. These computer programs also allow for additional drill, practice and individualized instruction for special needs students who are often taught in the regular classroom. Research has shown that computer-aided instruction motivates, teaches and empowers special needs students as well as helping to improve their communication skills (Bitter, 1993, Holzberg, 1994).

At a more advanced level, students and teachers may search databases for a wide variety of information.
Students can visit and create worlds including castles, local neighborhoods, the ocean, rainforests and time-travel from the 1600s to today. Some include sample stories and useful factbooks.

Teachers also have a specific program to enable them to write I.E.P.'s relatively quickly and design classroom setups, grade books and class schedules. Teachers can employ this technology so that they are able to concentrate on teaching and spend less time on laborious paper work and management.

For exceptional students, there are a number of programs which can be used to facilitate language. There are programs which can be used by individuals with impaired motor skills to manage their computer from all aspects with their voice alone; some programs even learn to recognize individual voice patterns, and speeds up after saving extensive voice patterns and tones.

For students with physical disabilities there have been augmented keyboards, touch pads, voice commands, and other technologies which assist teachers towards help students master the physical requirements of computers. Computers also have been a major component of the communication devices used by nonverbal or limited verbal individuals (Bigge, 1991). There is also a body of evidence, that computer-aided instruction can be highly effective when used with students who have learning disabilities (Bahr & Rieth, 1989). There is useful software available to assist special education teachers with administrative duties (Van Geldern, 1991). Other technology, such as programmable keyboards, allow instructors to modify keyboard settings and layouts to meet individual student's physical needs, ranging from the profoundly challenged to students who are simply new to the keyboard. Arrangements such as an alphabetized keyboard can help students overcome fear of using computers and the software run on them.

Another option for the physically challenged student is a "touch screen window," which fits over a regular monitor. The touch screen replaces the use of a mouse, allowing students to make on-screen choices by touching the various appropriate locations on the desktop or within other programs. Teachers can modify the window settings to accommodate a range of motor skills.

There is now a computer program to assess hyperactivity and attention deficit disorder that is objective. It is a computer driven program that can assist special educators and school psychologists in the diagnosis of attention deficit disorder, impulsivity and hyperactivity. In the past this diagnosis was highly subjective in nature. This test which takes about twenty minutes to administer, provides an in-depth print out regarding the performance of the child being tested.

Teachers can also use assessment printouts to locate specific deficits and deficiencies without investing valuable time with item analysis. Many programs now provide such item analyses. This allows the teacher to address individual specific needs immediately following assessment. Other computer generated test protocols offer suggestions for remediation of weaknesses. Technology will increasingly be the best friend of the special education teacher as we approach the year 2000.

**Reading Education and Technology**

In the area of reading, there are a number of programs which can be modified to suit individual readers needs. Many of these are based on current movies. Once teachers begin to become familiar with the software, they will begin to recognize certain companies which cater to their specific needs. More advanced technologies will be able to help students read faster and with more comprehension. Tachistoscopes, which have in the past been unavailable are now increasingly becoming accessible to classroom teachers. As technology advances, more and more students will have their own computers and C.D. players at home and be able to work at home on assignments employing said technology.

There are some concerns regarding the use of C.D.'s in reading. These programs, on the positive side, are engaging, interactive and motivating. There are often couched in game format, and can provide high success, high stimulation and high feedback. They can be individualized for low learners. On the other side, most are mass market produced. Some of these programs also limit creativity, imagination, and higher order thinking skills. The language in many of these "books" is more talk and verbal than the written language in books. Other programs provide continuous stimulation and visual changes which are not available in books. There are explosions, clicking, loud stereophonic music, and songs (often linked to the movie) and the images change every few seconds. In effect what we have is television in the schools, and we all know what type of wasteland and talking heads are on television. What is often lost with these programs is the ability to create in one's mind. There is some concern as to whether students will be able to transition back to actual books after being exposed to these programs. Is society abandoning books in favor of movies and animation? And what will be the long term consequences?

**Administrative Concerns**

The authors have established an Educational Software Clearinghouse for teachers to preview software prior to purchase. This is essential so that teachers can procure the needed and appropriate materials for their specific students without wasting a lot of time. Obtaining and reviewing educational software is a highly time-consuming effort. Cataloging, storing and updating educational programs requires significant staffing and space to house PC's, Macintosh computers, and the program disks. In addition,
space is required for video disk players, printers, supplies, program manuals and maintenance will be required to repair disk drives, hard drives and speakers. On-going up grading will also be needed and in service training for teachers will be absolutely necessary. Even the staff will be required to sharpen their skills periodically. Because programs up date and platforms are continually being modified and improved, the individuals involved will need to keep current. Once teachers and others fall behind, it will become increasingly difficult to "maintain the cutting edge ". Some teachers are even less computer competent than the students. Students like computer animation, whereas teachers may not be comfortable with that mode of instruction.

Security is another minor concern which should be addressed. Obviously, theft can deplete resources rather quickly. One wants students and teachers to avail themselves of this technology, but security is also imperative. There must be staff to monitor C.D.'s and other valuable educational equipment, software and hardware. Licensing and registering copies of software is another administrative headache and involves much paperwork. Legal concerns regarding copyright must be addressed. Siegel, Good and Moore (1995) have discussed the integration of technology into pre-service teacher's curriculum. The technology is out there and available. However, student teachers must be familiar with the technology and be able to use it or else it will simply gather dust.

Obviously research on the use of technology in regular, reading education and special education will become needed. As our technology increases, so will our capacity to conduct classroom research to ascertain the effectiveness of different technological approaches to the remediation of educational problems and deficits. Some programs contain built in systems for monitoring student progress. Teachers can employ many of the statistical packages for comparing student progress across programs.

Summary and Conclusions

This paper has attempted to cursorily review the current use of technology in regular education, reading education and special education. It has discussed some of the main uses of technology with both regular and exceptional children. Teachers should be encouraged to avail themselves of this technology to improve their pedagogy and for the ultimate benefit of their students.

Declining budgets in post-secondary settings have led to a corresponding reduction in secretarial assistance to instructional staff. Faculty members are suddenly finding themselves with a computer and are expected to produce documents that have a professional appearance. In response, they are throwing their hands up in frustration, as their lack of knowledge and experience in page layout places them at a significant disadvantage. For individuals accustomed to being in control, this situation may also contribute to the reluctance of many to utilize the available technology. Some faculty have openly stated that if they simply refuse to do it, the university will have no option but to return secretarial support to the levels to which they had come to expect.

Too often, professionals have taken for granted the skill that has resided in their secretarial pool when it comes to producing a polished looking document, even something as simple as a letter. Now, suddenly placed in the role of having to duplicate these same results through their own efforts, it has become obvious that office professionals were doing more than “just typing.” An attractively designed letter, syllabus, or paper is a professional’s calling card; their representative to another individual when personal contact is not always possible. A good impression is important.

The Challenge

Within every institution or setting, there tends to be a spectrum of personal skill when it comes to technology. When focusing on those who display reluctance to involve themselves with computer technology, one of the most frequent comments is that it wouldn’t make sense for them to spend time using the computer because they are unable to type. Naturally, the urge is to suggest a popular, computer-based typing program which would assist them in acquiring the skills. There is no doubt that the individual who can touch-type has an advantage when it comes to producing a document. Exploring further, though, is important. Given that they would have low to moderate keyboarding skills, the next question arises: what are they going to do with them?

Knowing how to operate a kitchen machine doesn’t make one a chef. Along the same vein, knowing how to type doesn’t necessarily guarantee an attractive final product; yet, it is often presumed that before someone can produce a piece of which they will be proud, they are first going to have to master keyboarding. Perhaps the reverse is really the way around this. Show a professional how to produce an attractive document their first time out, and just maybe that will serve as the incentive to become more skilled at both keyboarding and computer technology.

Let the final product be the incentive rather than the diligence to master keyboarding eventually leading to a reward. Your aim is to motivate and as Boylan (1996) states, motivation creates momentum. Motivating someone creates “an energized attitude” which in turn leads to motivation. “What’s motivation? Getting people excited so that they act in a focused direction” (Boylan, 1996, p. 157). Institutions need to find an array of possibilities that might serve to motivate and engage the individual at the personal level. Change may be mandated from top-down but lasting change only occurs from the inside-out. The individual is the lowest common denominator in the change process, and the most powerful.

Implications

A private conversation with a Dean at a large university recently revealed that this issue is having larger ramifications for post-secondary institutions. His own college had faced secretarial cut-backs a few years before, and faculty were now producing their own documents without guidance. It wasn’t until he encountered samples of these documents out in the community that he realized that faculty knowledge of page layout was impacting the impressions people were forming of the university. He saw this as a more serious issue when it came to competing with surrounding institutions for students, especially when it came to contract classes. (Contract classes are situations where businesses or school districts have a population of students drawn from their work place settings and universities are contracted to provide the instruction for those individuals.) His concern was that outside agencies would interpret a poorly designed document as reflecting the skill level of the faculty at the institution.
Williams (1994) produced an excellent resource that addresses the needs of novices, "The Non-Designer's Design Book: Design and Typographic Principles for the Visual Novice." In the opening statement the author, speaking from the perspective of a professional designer, says the book was produced for students who understand that a better-looking paper often means a better grade, the professionals who realize that an attractive presentation garners greater respect, the teachers who have learned that students respond more positively to information that is well laid out, the statisticians who are seeing that numbers and stats can be arranged in a way that invites reading rather than sleeping, and on and on (Williams, 1994, p.11) The point is, the design of a document is an important issue, that it does have an effect on the way information is received, and, at the heart of that, it may combine with personal reluctance to form another barrier to impede effective utilization of technology among post-secondary instructors with limited skills.

Is There Another Way of Looking at This?

Rather than view this refusal to adopt technology as a lack of co-operation, it is more important to see it as an ego-protection device. Highly educated individuals, unaccustomed to feeling inept, are suddenly placed in situations where they have limited, if any, support and little experience. Culbert (1996) argues that the key to motivating individuals to change is understanding the psychological perspective of that person. How do they see what's happening? "Self-interests and personal, work-related effectiveness agendas significantly impact - even wholly determine - how people see events at work, and ultimately how they think to operate given those perceptions" (Culbert, 1996, p. 30). He points out that all people wish to be seen as competent and effective in both their work place and personal settings.

While every institution needs to communicate a vision of where they want their people to be, and the goal they are striving to fulfill, Culbert (1996) reinforces the importance of the individual in this process. Instead of pointing to a mark on the wall and telling someone that's what they're going to have to aim for, he suggests administrators need to look at where the person really is. His advice is to "engage them where they actually are" (Culbert, 1996, p. 33) and facilitate ways of having them incorporate the larger vision into their personal agenda. So, when it comes to getting faculty to use computer technology for everyday tasks, what is the pay-off for them?

The budget cuts that have reduced secretarial support are not likely to be reversed any time soon, so that faculty have no choice but to take personal ownership for much of their work. At the same time, these individuals also want their work to be seen in a positive light; an important aspect of which is a professional look. Practicality suggests that running all faculty through a design course is not feasible. Apart from heavy workloads limiting available time to fit in another workshop or meeting, design is not only a skill; it is a talent. Recognizing that mastery of page layout will be uneven among faculty, how then can institutions facilitate people producing documents that reflect well on the individual and the institution? How can administrators give faculty, especially the reluctant user, the confidence and ability to produce an attractive, credible document their first time?

The answer to the question is far simpler than it appears. Surprisingly, a tremendous number of people using common word processors are not aware of the page layout features built into the software. Even reluctant beginners can produce a newsletter or brochure that compliments their professional selves. People have tended to use the word processor as a typewriter without a carriage return resulting in underutilization of the many features that can make the job easier and the results quite professional-looking.

Recently, a faculty person with very limited computer skills, saw a newsletter this author had produced. Complimenting the final product, the faculty person commented that they would never be able to produce anything like that. Knowing the computer system that had recently come to reside on the individual's desk, the author pointed out that if the faculty person wanted, she, too, could produce a document that was a mirror image of the one she was presently admiring without having to know much more than how to type in the content. The secret is templates.

A Look at the Possibility of Templates

All of the major word processing packages residing on faculty desks have built-in templates. These templates are professionally designed documents covering a variety of tasks, including business letters, brochures, newsletters, signs, and a number of other categories. Most of the latest versions also include the ability to convert certain features to HTML. In addition to those already in the software packages resident in the building, commercial design packages are also available for purchase; many cover a vast array of possible projects.

The only effort required on the part of the end-user is the content. A faculty person can call up the newsletter template (usually there are three or four designs to choose from), follow the on-screen instructions, enter their information, and a while later, they have a beautifully designed document. A complete novice to word processing will need some assistance getting up and going using templates, just as they would regular word processing facing a blank screen; but the end result is what is different in the two scenarios.
The valuable feature about templates is that they can also be generated. Electronic templates of these forms can be easily produced and distributed to faculty, decreasing effort. Another point to consider is that faculty supervising students have a variety of communication tasks, many of which are common to all colleges. Producing a document template for each situation assures administrators that students are all receiving the same core information while, at the same time, allowing faculty opportunities to personalize the letters in a fraction of the time. At the most rudimentary level, templates incorporating the institution's letterhead can be stored in electronic format so there's never the need to hunt for the right stationery again.

Most high-end word processing packages also allow for the incorporation of "macros" into documents. This would allow templates to be produced which would prompt the user for information. Think of it as word-processing with a guide.

Finally, use of templates also serves as a teaching function. Using professionally-designed templates exposes faculty to models of how documents should look. They learn that a Times Roman font is more appealing than a Courier font. They see how professionals would design a page. Inevitably, they will begin to utilize some of those same features when they produce original work.

Templates are nothing amazing; in fact, they're very ordinary. But most faculty are unaware that they have such powerful and flexible assistance only a couple of mouse clicks away. As technology, regardless of its sophistication or complexity, is fundamentally a tool, the critical question for most in higher education is whether a given tool can improve the caliber of their work. As templates address issues of format and layout, instructors can be freed to focus on the clarity of a document's content. If an attractive product that clearly communicates has been produced by leveraging their existing skills rather than demanding that they acquire new ones, faculty may regard the technology as a empowering tool rather than an impending threat. Thus, readily available templates can be valuable tools in reaching faculty who need to master technology skills and don't know where to begin.

Technology and teamwork are essential components of Utah State University's distance education preservice training of special education teachers. This field-based certification program is designed to increase the number of certified special educators in the Intermountain region by providing access to the same quality of instruction and supervision available to students on campus at Utah State University in Logan. The field-based component features on-site supervision by local cooperating teachers with support through e-mail. Cooperating teachers from the rural areas attend a summer training designed to strengthen supervision skills and provide technology training required during the supervision phase. Didactic courses are designed and delivered to rural locations using two-way interactive video technology. As students and faculty gain experience with distance education and the technology, overall procedures and discussion formats emerge to support learning.

Prior to development of the distance education program, it is critical to maintain ongoing communication and collaboration between the distance education coordinator and the faculty members delivering instruction to the rural sites. Without the expertise and support of faculty members in the special education department, the program would not survive. Dillon and Walsh (1992) examined and analyzed faculty attitudes toward distance teaching. These studies report that faculty who teach at a distance have positive attitudes toward distance teaching. As faculty become more familiar with the technology and logistics of distance teaching, faculty attitudes improve. Faculty members have also expressed an interest in connecting technology used in distance education with on-campus courses.

The distance education coordinator at Utah State University is a member of the special education faculty, has an office in the same area as other faculty members, and is available as a support to faculty members teaching distance education courses. Other responsibilities include contacting students, coordinating sending and receiving materials, and addressing technical problems in delivery.

**Technology Uses**

**E-mail**

The distance education program for preservice special education teachers requires frequent and explicit communication between professors, adult students, advisors, cooperating teachers, district administrators, and the program coordinator. Students receive weekly e-mail messages from the program coordinator dealing with needed assignments and/or checking progress. They are encouraged to check in with professors to ask questions, send assignments, and comment on the content and application of the class material. It is also important for faculty members to use e-mail to communicate with each other as they develop skills in distance education.

The following challenges are addressed on an ongoing basis: availability of computers with e-mail networks, teachers needing training on e-mail, and local technical support. Participating school district personnel team with university distance education faculty and staff to address those challenges unique to each student and situation.

**Fax**

Sending material via fax is the preferred method of delivering material for several of the sites. Fax machines are available, easy to use, and can be used at convenient times to both the sender and the receiver. In several instances the site coordinators at the rural locations have a fax machine in the classroom, but must go to the media center for access to e-mail.

**Web Page**

Web pages are used as a support for the student, offering opportunities to expand and enrich topics of interest. Several commercial Web page developers are user-friendly and support is available for creating Web pages for faculty members in the technology center on campus. Students can access the extended syllabus, a
listing of topics and overheads per class period, as well as connect to related topics made available by the professor.

**Hypertext**

Future educators are instructed on how to use hypertext technology to adapt regular classroom materials for use by students with special instructional needs. The adult students receive training in how to use hypertext and hypermedia in curriculum adaptation as they work with students who have disabilities and in their university assignments.

University students also receive instruction on methods concerning how to determine the appropriateness of hypertext for scaffolding instruction during curricular modifications. For example, for students with reading comprehension difficulties, hypertext adaptations can be used to add pictures, simple definitions, graphic organizers, or computer-generated speech to support existing knowledge. It is important to make decisions about the use of hypertext in making curricular modifications that support student learning and access materials for students in the schools. Hypertext can be used for students with language difficulties to help point out relationships between words and phrases in the text (Dyck, Pemberton, & Woods, 1996).

**Two-way Interactive Video**

The primary model for the didactic component of the program is through EDNET, an interactive video network. Instructors deliver courses from an electronic classroom on the USU Logan campus to the rural sites. Instructors receive training and support in the use of video and graphics capabilities, extended syllabi, Web pages, group discussions, and case studies. Several professors model using hypertext to teach certain course objectives.

**Remote Supervision**

Remote supervision of preservice special education teachers in field practica and student teaching experiences begins with a summer training workshop for cooperating teachers. During the workshop the technology and observational skills required to accomplish the supervision are demonstrated and practiced. Technology mentors for cooperating teachers and students are identified. The distance education program coordinator travels to the various rural sites to offer support, problem solve and encourage students and cooperating teachers dealing with issues of supervision and technology. As areas become more proficient in the use of technology as a means of communicating and teaching, the on-site support will diminish and communication through technology will increase.

As the special education certification program through distance education develops, additional uses of technology are added. Courses are offered on a two-year cycle, with the first cohort group graduating in May, 1997. Additional sites will be added during the 1996-97 school year and a second cohort group will begin taking classes Fall, 1997.

**Future Plans**

The next step in Utah State University's distance education certification program is to access technology that would support observation and conference opportunities in remote locations. A resource library is located at each site currently housing students, and a database for locating information and a process for checking out materials is in the process of being developed.

In the Department of Special Education in Logan there are three areas in distance education: early childhood, K-12, and rehabilitation. Beginning Fall Quarter, 1996, faculty members and doctoral students interested in distance education meet monthly to discuss current technology developments and offer support to the various programs. Technology and distance education are ongoing topics, with the challenges of remote supervision drawing special attention.

At Utah State University, students are developing skills in technology while obtaining the special education certification program. Educators working with students with special needs must use teamwork and technology as they work with other professionals and parents to address the needs of all children.

The presence of technology in American classrooms is gradually transforming the image of the ideal learning setting from one in which students sit silently in neat rows, paying close attention to the teacher's every word, to one in which students are productively engaged in investigations, problem solving, and critical thinking. Although the latter depiction suggests a noisy, perhaps chaotic environment, educators with a constructivist perspective are convinced that active learning strategies are far and away the most desirable for building thinking skills. Furthermore, educators who embrace experiential learning models suspect that students who participate in relevant, engaging activities are likely to spend more of their classroom time on task.

Common sense tells us that increasing time on task is likely to increase student achievement. Yet some controversy exists in our ability to measure time on task. While one student staring into oblivion appears to be distracted and off task, another may appear to be in deep thought. Distractibility is considered so onerous for school children that some architects, thinking that they had the learning interests of children at heart, have designed schools without windows in order to reduce the distracting effects of gazing out the window.

At a chronic level, a child's distractibility has come to be diagnosed and labeled as a disability. While Attention Deficit Disorder (ADD) is not restricted in definition to children, its impact on learners has earned it extensive national attention, and is defined within the legal statutes of our country (Irland, 1992). A refinement of the classification system added yet another category: Attention Deficit Hyperactivity Disorder (ADHD). Legal definitions notwithstanding, children who appear unable to sit quietly for extended periods, listen attentively, complete complex tasks, or engage in focused discussion are often labelled ADD.

The Council for Exceptional Children estimates that three to five percent of children have ADD or ADHD (1992). While researchers may argue about the finer points of diagnosis and identification, clearly more than one million children exhibit a noticeable level of inattentiveness. It is not the intention of this report to summarize the research on the causes, indicators, and remedial strategies for children with ADD. (For the sake of brevity, this paper will refer to both ADD and ADHD as ADD, as do a number of authors on the subject.) This paper will attempt to examine the potential of technology to provide a highly focused learning environment for children with attention deficits. The design and results of a modest study on the subject will be presented and followed by a discussion of implications for teacher education and classroom application.

A Modest Study

In early 1994, a study of the literature on ADD/ADHD was undertaken in order to establish the applicability of technology in decreasing students' waiting and listening times and increase the time they are actively engaged in new learning. In the education literature, "wait time" refers to the deliberate pause between a teacher's question and students' response. Thus, the term "waiting time" will be used to identify those periods when teachers expect students to pause quietly before they proceed to the next instruction or activity. "Listening time" is meant to identify periods in which teachers expect students to attend to what they and other students are saying, including lecture, discussion, procedural instructions, and questioning, and non-verbal listening to music or other sounds.

The literature review yielded a surprisingly small number of selections in which computers or technology appeared along with studies or discussions of ADD. Some studies focused on the use of computer-based interventions to increase the child's ability to self-monitor, keep calm, and increase concentration. In the special education literature intended for teachers, references concerning the use of technology tended to relegate computer use to...
reward structures for good behavior or achievement. Conversely, some of the literature on ADD fails to take into account some obvious benefits of technology. For example, a Web page outlining remedial practices for ADD students with poor handwriting suggests reducing standards of acceptable handwriting and avoiding recopying, but omits any suggestion that these students might enjoy gains in both written composition and self esteem by switching their environment to a word processor.

In recent years, a number of textbooks have been written that provide extensive suggestions concerning the use of technology for children with a wide variety of disabilities. The discussion of computer use for children with attention disorders, however, tends to be limited to those generalizations that apply to children with learning disabilities. Some of these textbooks omit the discussion of attention deficits altogether.

The motivation for a study of technology use for children with attention deficits arose from the realization that most children appear to attend to computer-based tasks for countless hours, along with the fear that the use of rapid shooting games might exacerbate hyperactivity in some learners. The task at hand was to test the hypothesis that children's attention span was longer with the use of computers than in a traditional setting of "waiting and listening," and that children with attention deficits benefited from increased periods of attention without complex interventions.

Research Question

The research question that was formulated for this study was, "How does percentage of time on task while using computers compare with time on task in traditional instructional settings for children with and without attention deficits?"

Setting

The setting for this research was an urban junior high school in the Pikes Peak Area of Colorado. This school was selected because a recent grant had provided a new computing facility in the school. The school was typical of many schools acquiring technology: they chose a lab setting for the placement of equipment, and they assigned a paraprofessional to monitor the lab and maintain the equipment. The school served an ethnically diverse population, and teachers assured us that at least 100 students in their school suffered from significant attention deficits. We expected to randomly select 10 to 12 students with ADD and another 10 to 12 students without ADD who were comparable in age, grade, sex, and ethnicity.

Sampling

The reality was shockingly different. First, fewer than ten students in the school had been officially diagnosed with ADD, and all but one were currently on medication to control their condition. Second, the process of obtaining parental permission took more than two months and yielded only four subjects with ADD. Third, the selection of a comparison group was problematic. All of the students diagnosed with ADD were placed in special education classrooms, and their peer group in such classrooms could not be deemed to be representative of the general population of students without attention deficits. Indeed, the teachers who taught these children complained that the study was probably invalid since many of their students were "more ADHD" than the identified subjects. We decided to proceed, assuming that our data would allow us to identify students who had pronounced attention problems, whether or not they had been diagnosed.

The final sample of students was made up of four male students diagnosed with ADD and a comparison group of six male students with similar characteristics. We designed the study so that observations were conducted on an ADD student and a non-ADD peer simultaneously, and we needed at least six comparison subjects to ensure that one comparison group peer would be in the observed class setting at any given time.

Limitations of the Study

Along with the limitations in sampling, sample size, and generalizability, the study was slowed by the difficulty of determining what behaviors might fall into the "inattention" category, as opposed to being distinguishable as "attentive" behaviors. The ADD literature yielded a wealth of discussions about these difficulties, and some instruments exist that measure defined categories of behavior in a variety of settings, but few of them were designed for classroom use.

Design

We decided to use behavior classifications that would lead to the greatest interrater reliability; that is, we kept the categories simple so that the graduate students who performed the observations and coding of behaviors would achieve a high level of agreement between them. An average interrater reliability score of 94% was achieved in 36 observations coded by both assistants.

We employed a momentary time sampling method in which the observer coded a student's behavior as "attentive," "inattentive," and "other." The "attentive" behaviors were those in which students appeared to be appropriately engaged according to the intent of the teacher. For example, the student who is attentive is writing when others are writing, listening when others are speaking, moving about the room when instructed to fetch materials, talking with other students when instructed to engage in a discussion, etc. The "inattentive" behaviors were those in which the student was inappropriately talking, moving around, distracted by objects or other students, or not attending to the book, screen, person, or object intended by...
the teacher. "Other" behaviors were those in which the student was neither off task nor engaged in a designated task. These included "waiting time," and moving about without specific instruction but without any particular expectation that this behavior was undesirable.

The momentary time sampling allowed the observers to code a student's behavior every ten seconds over a 15-minute interval, alternating between an ADD subject and a comparison group subject. Observers wore headphones attached to portable cassette players. Tapes had been pre-recorded with cues at 10-second intervals. This process yielded 40 to 50 pieces of data for each observation, for each subject. The observer then converted his data to percentage of attentive time, percentage of inattentive time, and percentage of "other" time.

Findings

One hundred observations were conducted; 54 of these were observations of ADD subjects, while 46 were of comparison group subjects. Also, 52 of the observations were conducted in a computer lab setting, and 48 were in classrooms.

Figure 1 displays the data on "attentive" behaviors in the lab and classroom settings for the ADD group and the comparison group. With a group mean of 76.0% attentive behavior in both settings, the data clearly indicate that ADD students significantly increased their attending behaviors in the lab setting.

Figure 1. Attentive Behaviors Across Settings by Student Group.

The Analysis of Variance displayed in Table 1 indicates a significant difference in attentive behaviors for the entire group between settings and a significant difference in attentive behaviors by student type.

No conclusion can be drawn about the variance among student types by setting. That is, we cannot specifically conclude that a lab setting generally increases attending behavior for ADD students.

An examination of the results for ADD students, taken separately, helps to reveal why this may be. Figure 2 displays the inattentive behavior data for ADD students only. Clearly, a large proportion of the variance between settings is attributable to the dramatic drop in the inattentive behaviors of Student #3. In fact, two of the ADD students appeared to increased their inattentive behaviors in the lab setting.

Discussion and Implications

The findings of this small study of ten students may at first appear to provide little information, aside from dramatic results for Student #3. For this reason, it seems useful to examine the data on inattentive behaviors of all ten students. These are displayed in Table 2. Students #1 through #4 are the students who were identified with ADD.

We can conclude that, at least for some students, whether diagnosed with ADD or not, the use of technology appears to help increase attentive behavior. If only one student in a sample of four with ADD is capable of a large increase in attentive behavior over his classroom rate with no specific intervention, then teachers have reason to deliberately assess technology use and to design interventions that maximize its potential.

Research Implications

The lessons learned in this small study provide some guidelines for the design of future studies on the implications of technology for students with attention deficits. First, a researcher might attempt a district-wide study to ensure a sizable sample of ADD subjects. A reasonably large sample might allow for distinguishing between medicated and non-medicated subjects, ADD and ADHD subjects, male and female subjects, and subjects in regular classrooms as opposed to special classrooms.

Given an opportunity to study a large sample of ADD and ADHD students, the authors would also choose to investigate variables within the computer lab. For example, we would examine teachers' choices of software to determine whether differences occur in applications such as keyboarding practice, word processing, simulations, educational games, etc. We would also seek to examine the effects of pairing and group work, compared with single user settings.

A third variable that would add richness to the study would be teacher behavior. We would formulate hypotheses about the amount of interaction time between teacher and group, teacher and subject, and postures such as "lecturing" and "guiding." We would compare group sizes and whole group versus small group instruction. We are also interested in the effects of interventions for teachers in which they learn strategies for increasing time on task for ADD students in both settings. Finally, we would study the effects of providing a computer for each ADD student within the classroom setting, as opposed to the distant lab setting.

Implications for Teacher Education

Aside from the obvious need to operate a computer with some degree of confidence, the needs of preschool and inservice teachers who are preparing to use technology with children who have attention deficits appear to cluster into three categories: knowledge, classroom management, and assessment. Participants in a class titled "Technology for Learners With Special Needs" articulated these needs in the summer of 1996.

Knowledge Base

In examining technology for learners with attention deficits, students previewed a variety of software types and were able to decide for themselves which were likeliest to captivate and hold students' attention. Some software titles were rejected because they emphasized high speed performance or because the timing of stimulus questions and response time were not designed to be adjusted by the teacher. Students concluded that reward systems for correct responses were particularly important in programs designed to provide drill on facts, since several were suspected to provide excessive distraction to the user. Open-ended environments such as the word processor were examined for their benefit in helping students concentrate on their writing. Participants in the class concluded that some of their students could benefit from increasing the print size and decreasing the window size to avoid overwhelming the writer with a large amount of text on screen or a large area of white space. Participants who had extensive experience with students with attention problems welcomed the opportunity to "chunk" computer experience into small segments—a practice that is often recommended in the literature on ADD.

Classroom Management

Students found that explanations of the various causes of ADD/ADHD and the associated remedial practices were abundant in the traditional research literature and on the World Wide Web. A study of these remedial practices are applicable to the design of educational environments that include computers and other technology. Teachers must design a suitable learning environment for students who experience difficulty in attending to classroom material for reasonable periods of time. They should decide when group work is appropriate; when isolating a student is desirable; when short activities might be scheduled to alternate with longer activities that are easier to sustain; and when students need manipulatives, visuals, open ended environments, interaction, speed, or quiet time.

Assessment

Many educators are overwhelmed by the complexity of technology augmented classrooms. Regular education teachers who include students with disabilities are understandably nervous about dealing with students who might be regularly disruptive. Factoring in some fear of technology, crowded spaces, and unclear expectations, we get a picture of the complexity that might deter a teacher from attempting to use computers with students who have special needs. The single factor that might convince teachers to pursue these solutions is evidence. Teachers must have a repertoire of strategies for ascertaining what effects, if any, computer use might have on their special students. We used some of our class time to discuss ways in which a technology intervention for students with disabilities might be measured for both behavioral and learning effects. For example, a classroom aide or parent volunteer in the classroom might conduct observations similar to those described in the study: momentary time
sampling in 15 minute intervals, once a day for two weeks. These can be compared with baseline data on the student’s behaviors.

**Conclusions**

Data from a study comparing ten students’ attentive behaviors in a traditional classroom with those in a computer laboratory indicate that, for three of the students, a remarkable increase in attentive behavior occurs when students are engaged in a computer-based activity. Two of the three students were identified and treated for ADD and the third showed a high degree of inattention in regular classrooms. Although not generalizable by any means, these findings do at least suggest that technology should be considered as an option for students with attention problems. Teacher training should include the development of skills in program development, learning environment design, and assessment that teachers will need in order to ascertain whether technology use is, in fact, beneficial to individual students. A large scale study of computer use by students with patterns of inattention is needed to determine the specific applications that enhance or inhibit a student’s ability to sustain a learning activity.

The research described in this article was funded in part by the Committee on Research and Creative Work of the University of Colorado at Colorado Springs. The opinions and conclusions expressed herein are those of the authors and do not necessarily represent the position of the University.

The Internet has many capabilities that make it especially useful with students who benefit from a highly visual presentation of information. These students include those who have auditory learning difficulties or hearing impairments, as well as those who have experienced educational difficulties because they are "at risk" or are second language learners. Because of potentially poor reading and academic achievement, using reading as their primary access to information for these students may be neither efficient nor effective.

The Internet can provide teachers with access to a wide variety of visually-based resources for use in the classroom to enhance textual materials or to provide information in a non-text or text-supported format. These resources include a wide variety of photographs, maps, graphic images, and video. In addition, these resources are archival and currently offering real-time opportunities to participate in events that are still developing as well as to become involved with the narrative, opinions, and personal histories of individuals from the past. This involvement can help stimulate interest and provide primary as well as contextual information that will serve to support other text-based information.

Both the teacher and students can research the Internet and use computer capabilities to identify graphic information for use as primary or supplemental resources. In addition, this information may be easily represented in another conceptual and visual format, such as conceptual maps or semantic webs. Imagery strategies which identify relationships between ideas and chunking of information have been found to be effective in assisting students to process new learning (Dwyer, 1994). Many computer application and word processing packages include spreadsheet and graphic capabilities that can be used to portray information in a visual form.

The combined textual and visual presentation information can assist all students in increasing their conceptual understanding through a more thorough representation and refinement of the concepts to be learned. Some researchers believe that a visual vocabulary precedes a verbal one, such that strengthening the visual vocabulary will assist verbal learning and response capabilities (Hortin, 1994); such an enhanced learning environment ultimately can lead to increased academic achievement (Dwyer, 1994). However, any lessons, regardless of new or unusual formats used, need to be effectively designed and implemented (Hannafin & Peck, 1988).

**Effective Planning and Design**

Despite the inherent novelty and, therefore, initial motivation in using computers and the Internet, conceptualizing lessons and planning research activities for students need to be based upon principles of instructional design. Based upon recommendations from Hannafin and Peck (1988), effective computer-assisted lessons should:

1. be based on the teacher's instructional objectives;
2. match learner characteristics, such as knowledge and skill levels of students, abilities with various input devices, and type of screens and output used;
3. maximize interaction by asking for meaningful and thoughtful responses;
4. be individualized and adapted to teach topics of interest as well as remedial instruction needed;
5. maintain learner interest through intrinsic merit of the lesson;
6. approach the learner positively, taking advantage of the nonthreatening, patient, and "forgiving" nature of the computer which does not penalize for errors or time taken;
7. provide a variety of feedback: positive when doing well particularly for younger students; and, corrective feedback for older learners and those who desire more efficiency and information about their performance;
8. fit the instructional environment to require minimal teacher involvement, such that lessons can be started and completed without assistance, and will record student performance to be reviewed later when the teacher has sufficient time;
9. evaluate performance appropriately based on meaningful, measurable objectives with accurate assessment of their accomplishment to include the following:
   a. asking the right questions, not just those in the most convenient format;
   b. avoiding ambiguous or poorly worded questions by using the same vocabulary as found in the lesson and that support a correct interpretation by students;
   c. judging answers thoroughly and to include unanticipated responses;
   d. are not confusing an inability to respond with ignorance of the correct answer or procedure;

10. uses the computer's resources wisely with a recognition of the screen's poor resolution in comparison to printed materials, but uses to advantage its capabilities for static and animated graphics, colors, flashing, and sound to amplify ideas and concepts;

11. is based on principles of instructional design to:
   a. motivate the learner;
   b. inform the learner of the lesson objectives;
   c. review prerequisite skills required for lesson success;
   d. present well-organized instruction;
   e. evaluate progress frequently;
   f. provide adequate feedback;
   g. allow for adequate practice; and
   h. evaluate the final performance of both the student and the lesson itself (Gagne & Briggs, 1979);

12. has been evaluated thoroughly and over time, when possible, for instructional quality, affective considerations, cosmetic appeal, curricular relevance, accuracy of the program, and monitors the achievement of the objectives and learners' attitudes toward the lesson.

Internet research lessons and projects are well suited to these principles. A thoughtful and relevant project provides students with a framework for using and expanding their conceptual understanding towards more in-depth learning. In addition, they are allowed to select World Wide Web (Web) sites and resources that portray information in a manner that is most effective for them as individuals. Choice helps to maintain motivation as well as truly individualizing the learning and response format. Group projects allows students also to receive feedback from peers in addition to that provided by the teacher and allows the teacher more time to monitor those that may require some additional assistance.

The quality most often credited as contributing to the effectiveness of computer-based learning is interaction (Hannafin & Peck, 1988). The active exchange of information between student and computer is key, and the ability to individualize is largely responsible for learning efficiency. Use of the Internet for resource searches as well as interactive and multimedia programs provides a forum for high levels of student engagement.

Any project must be carefully designed. With limited access to a computer lab or limited numbers of computers available within the classroom, the logistics of such an activity must be thoughtfully planned. Hannafin and Peck (1988) suggest the following steps in creating a lesson:
   a. a needs assessment phase to clearly define and specify the project taking into account the students' needs as well as classroom and scheduling constraints;
   b. a design phase to determine the sequence of activities and to select the best, or several potential, solutions as necessary for each instructional objective; and
   c. a development and implementation phase which transfers the ideas to a useful format including testing and debugging, formative and summative evaluations, and revision.

Designing a lesson or project using visual materials requires identifying strategies to effectively incorporate visual formats that also address the development and expansion of student concepts and literacy skills; however, not all use of visuals assists with student learning (Dwyer, 1994). Research has found that learners possessing higher intelligence do better with complex visual displays. Yet, by varying the degree of realistic detail within a visual image, a teacher can reduce differences in performance of learners bring different levels of prior knowledge to the learning situation (Dwyer 1987 as cited in Dwyer, 1994). The teacher can suggest certain visuals for certain students, however the variety of resources on the Internet allows individual students to access visuals from which they can choose those which are most meaningful and helpful to them.

Enhanced Learning Using the Internet

Examples of using the Internet effectively include enhanced conceptual development by using (1) topical searches to expand students' knowledge base, (2) to create or expand information presented as graphic organizers (e.g., semantic webs and conceptual maps), and (3) access to video encyclopedias or resources that provide footage of real-world events and their impact on our lives. Topical searches using one of the many search engines can lead students to learn and understand with increasing depth. There are a number of search engines available, some of which may come with your Internet access program. Some of the more common search engines include:
   a. Alta Vista (http://altavista.digital.com/): claims to be the largest Web index and is updated daily
   b. Excite (http://www.excite.com/): provides a search engine and Web directory by category, with daily news summaries, reviews of Web sites, but does not display URLs;
c. Lycos (http://www.lycos.com/): creates abstracts of pages based mainly on headers, titles, and first words and doesn’t do well on complex (Boolean) searches;

d. InfoSeek Guide (http://guide.infoseek.com/): claims to be the fastest index and includes reviews and newsgroups;

e. World Wide Web Worm (http://www.cs.colorado.edu/wwwww): is one of the oldest search tools and indexes 3 million sites;

f. WebCrawler (http://www.webcrawler.com/): displays page title and relevancy rankings, works best with simple searches and mainstream information;

g. Internet Search (http://search.internetmci.com/): allows complex searches and restrictions to portions of documents (e.g., header only), provides a list of closest matches and links to document files;

h. Yahoo (http://www.yahoo.com/): is really a Web directory but is the largest and most popular with sites arranged hierarchically by topic, includes a search engine that will search an entire site; and

i. Magellan (http://magellan.mckinley.com/): also is a directory that rates sites on a scale of 1 to 4 stars.

Information from many Web sites and resources can be imported into word processing and other application programs directly, thus facilitating the creation of visual displays within textual material. Access to online and video encyclopedias provide a source of maps, visuals, photographs, in addition to textual material. Graphic representations can be created by using spreadsheet programs (such as Lotus 123, Excel, in addition to those associated with many word processing programs) that make pie charts, line graphs, bar graphs, and other visual images.

Encyclopedias and References

Online news services also provide video segments, photographs, and visual images useful in presenting textual information. A number of these resources are subscription-based but can be a very useful resources for classrooms (Internet World, 1996, October; Technological Horizons in Education Journal, April 1995, April; 1996, August):

a. Britannica Online subscription service (800-554-9862), 32 volumes with bibliographies, links to related topics within Britannica and to Internet are continually updated by Britannica; http://www.eb.com (librarians and educators can receive free 2-week preview).

b. CNN online (very popular site); http://cnn.com.

c. The Electric Library, K-12 (800-304-3542), free trial version; www.k12.elibrary.com

d. iWORLD Internet news and daily information; links to Internet World, Web Week, and Web Developer magazines; http://www.iworld.com.

e. MSNBC (Microsoft-NBC) 24-hr cable news program, news and high-tech information, audio and video clips for NBC network shows; http://www.msnbc.com

f. National Geographic Online, dramatic photography, original illustrations, maps and interactivity (chats with persons in the field); “visitors” accompany writers, photographers, scientists, and explorers on adventures, receive their images, journals, etc, features rotate weekly, are archived monthly; records people, places, cultures; http://www.nationalgeographic.com.

g. The San Jose Mercury News, the first full-service news site online; http://www.sjmercury.com.

h. Scholastic Online (800-246-2986), K-12 learning organized by curriculum areas: Scientists as Mentors (collaborative), Global Kid Reports (student teams with monthly reports from 7 countries), Animals in the Wild (track and share results daily), Writers Workshops (pair with published authors), Witnesses to History (talk with persons present); daily activities and projects (updated & created by editors, writers, artists, educators); weekly/monthly schedules to integrate into curriculum; professional forums, guides, and mentors for teachers; http://scholastic.com. (variety of purchase options available).

Other resources are video or CD-ROM based but are interactive and multimedia-based:

a. The Heinemann Children’s Multimedia Encyclopedia (Reed Technology & Information Services, 800-922-9204), text with video, sound, animations, photos, illustrations, other graphics; articles organized by subject instead of alphabetical listings designed for children 6-12 years old to explore easily; large icons for controls and graphical interface positions.

b. Microsoft’s Encarta multimedia encyclopedia (206-882-8080); current affairs, political developments, social and cultural trends, scientific and technological advancements; Pinpointer search tool to find facts, conduct research, browse and create specific lists; academic versions include teacher’s activity guide.

Curriculum-based Resources

English literacy skills are supported by (1) text that includes pictorial, graphic, or video footage, (2) student presentations or explanations using both textual and visual information, (3) written communication in participating in bulletin boards, e-mail, and collaborative projects with other classes or Internet users, and (4) communication skills in accessing and researching real-time or information services such as the weather and news. Language arts skills are supported by several specific Web sites and interactive CED-ROM programs, as well as social studies, science, and math-based resources.
Reading and Language Arts

a. Pulpless.Com providing downloadable books (few authors of name yet); $9.95 per book (some special rates); http://www.pulpless.com.

b. Random House horror serial novels, episodes posted twice weekly, setting at fictional Wintervale Univ. with title creature taking over minds of innocent college students and pits against each other; http://www.randomhouse.com/turknerfiles.

c. Universal Press Syndicate comic strips (Doonesbury, For Better or Worse, Dilbert, etc.); http://www.azcentral.com.

e. On CD-ROM is "Poem Finder '95" (Roth Publishing, 800-899-ROTH) which indexes nearly 500,000 poems from anthologies, single-author collections, and periodicals. It is available on a subscription basis with two discs each year and can be searched by title, first/last line, keyword, date, author's name, pseudonyms, birth/death date, gender, religion, nationality, and profession. It provides definitions of poetic forms and meters.

Science

c. The Biology Place (888-TBP-SITE), focus on inquiry learning; organized around 8 topics: bio-chemistry, cells, genetics, evolution, diversity, plants, animals, ecology; learning activities, research updates, and "The Best of the Web" links (free until 9/13/96); http://www.biology.com.

e. "Where in the World is Carmen Sandiego?" Junior Detective Version for primary students (Broderbund, 415-382-4400); requires no reading, challenges the students' strategies, memory, and matching skills. It includes full-color photos of international locations, regional maps, animated characters; contains teacher's guide and companion geography book.

Mathematics

a. Paws and Pyramids (GAMCO Education Materials, 800-351-1404), students find a formula to save cats from an evil queen (Egyptian theme). They discover the formula by answering questions about perimeter, area, volume, surface area while using critical thinking skills; includes 22 skill levels and a report of student progress is stored for the teacher.

b. 3001: A Reading & Math Odyssey (702-597-5032), a journey through Greek mythology using painted screens, 3D graphics and animation, and 150MB of speech to teach arithmetic, fractions, decimals, and pre-algebra. Skills are tested on a range of levels, sessions are saved and can be completed in intervals, students may practice math without doing game sequence; online help screens are available.

Social Studies

a. Destination: Time Trip, USA; Destination: Pyramids (Edmark Corp, 800-691-2985), student tools to produce interactive electronic books, movies, and printed works while learning about the program's theme; learning destinations have richly illustrated backgrounds with character "stickers" that animate to create a "movie" including text and sound; individual and group activities in writing, creativity, and communication while creating scenes, choosing and animating characters, planning plots, writing stories, adding music to create interactive adventures; stories can be played back onscreen or printed in color or B&W to share; http://www.edmark.com.

b. On CD-ROM: Canada's Visual History (National Film Board of Canada, 212-596-1770), 2,200 photos, rare paintings, original maps, articles to examine urban growth, conflict, social issues; Keyword Index allows browsing, text in French or English.

c. U. S. Geological Survey CD-ROMs (Geological Survey, Earth Science Information Center, 800-USA-MAPS); structure and composition of locations across the North American continent, photographs of historical mining operations, geological maps; aerial photos arranged by country with applications for vegetation management, habitat analysis, soil erosion assessment; most titles sell for $32.

d. Vietnam, an interactive CD-ROM narrated by photo-journalist Drew Pearson who worked for NBC News (Medio Multimedia, 800-788-3866) with 30 minutes of archival footage, original video, hyperlinked text from two books, 200 photos, maps, and timetables; interviews with officials, soldiers, and civilians from U.S. and South Vietnam covering key events 1854 -1982.

e. "Where in the World is Carmen Sandiego?" Junior Detective Version for primary students (Broderbund, 415-382-4400); requires no reading, challenges the students' strategies, memory, and matching skills. It includes full-color photos of international locations, regional maps, animated characters; contains teacher's guide and companion geography book.

Several available programs and projects involve e-mail and other communication links between classes and students. The Logo Telecommunications Project (Logo Foundation, 212-765-4918) links students with peers in foreign countries via learning activities. Communication
occurs using text, images, and graphics through several Logo-based application programs. Houghton Mifflin Company's School Division, Education Place (617-351-5000) helps teachers K-8 navigate Internet resources and integrate into existing curricula. Activities are divided into reading and language arts, math and social studies, with extensive links and project ideas (http://www.eduplace.com).

In addition to these services, the Internet allows access to topical chat lines and bulletin boards for establishing specific communication and interaction opportunities for students and the teacher. Some news and information services provide on-line "experts" that students can access. Students who have difficulty in communicating through writing will have functional and "live" opportunities during which it is important that they write clearly. Successful experiences will build their confidence and help them learn strategies that can support them through their difficulties, such as asking peers for assistance or reading messages "orally" to themselves prior to sending them.

Summary

Lessons which incorporate a variety of visual information using the Internet can provide current and motivating content for students who otherwise have difficulty learning from text-based information. Classroom presentations and discussions are likely to improve as a result of students having had initial learning experiences accessing materials that are best suited to their learning styles and based upon their personal preferences. Students will be better prepared to participate in sharing and explaining what they have learned resulting in further development both of their own and others' understanding. Simultaneously, they will be increasing their linguistic and communication skills, both in interpreting information for understanding and in expressing it to others.

Both the teacher and students can use the Internet to meet individual and unique requirements in creating projects, lessons, and activities. Learning is flexible and students assist in making resource choices which will best support their own individual learning and conceptual needs. Incorporating the principles of learning and following systematic procedures for lesson design will result in enhanced academic growth through learning opportunities most suitable for each individual student.

BUILDING AN ELECTRONIC COMMUNITY TO SERVE CHILDREN WITH SPECIAL NEEDS

Betty G. Beacham
East Carolina University

Diane D. Kester
East Carolina University

Martha Kaufman
North Carolina Division of MH/DD/SAS

Those of us who work in public schools and other human services agencies historically have been separated by time, space, policy, and organizational structure. In many cases, we have duplicated our services in our attempt to serve children and their families. Unfortunately, this practice of services duplication continues today: we ask children and families to visit multiple agencies to get the same service; we ask them to understand and implement multiple service plans; and, we ask them to be passive consumers of professional services.

In our present climate of decreasing federal funding, changing family structure, increasing ethnic and cultural diversity, and a myriad of other changing social conditions, the challenge is before us to create systems of care which integrate the organization, coordination, and delivery of services for children and their parents. At the same time, we must create systems of care in which families are active, equal partners in the organization, coordination, and delivery of services. Such models operating from an ecological perspective can assess relationships between and among children, families, schools, other human services agencies, institutions, and communities to design a single unified family plan.

The PEN-PAL Project: A System Of Care

The Pitt Edgecombe Nash-Public Academic Liaison (PEN-PAL) Project is a community, family, university, and public school partnership to build a community-based system of services for children with special needs and their families. The Project includes three counties (Pitt, Edgecombe, and Nash) in eastern North Carolina along with their school systems, local mental health centers, juvenile justice, health departments, social services, community organizations such as the Boys and Girls Club and ministerial associations, the public schools, community colleges, and East Carolina University. Funding for the project comes from the Center for Mental Health Services (CMHS), Washington, DC. The grant is administered by the North Carolina Division of Mental Health, Developmental Disabilities, Substance Abuse Services, Child and Family Services Section, Raleigh, North Carolina. The long-term goal of the grant is to design a model to provide new and innovative services for children and adolescents with serious emotional disturbances in North Carolina and the nation.

A major assumption underlying the PEN-PAL Project is that integrated, interdisciplinary, interagency services are critical elements of positive, lasting outcomes for children and their families. Through interagency-community-parent collaboration and coordination, services are co-planned and co-delivered, thus reducing or completely eliminating duplication and fragmentation of services.

Goals and Objectives

The primary goals of PEN-PAL at the system-level are:

1. to meet the service needs of children with serious emotional disturbances so that they can remain in their communities,
2. to work as partners with families to plan and provide services that meet their unique needs,
3. to build on strengths of all community groups and local child-serving agencies to develop a seamless local system of services,
4. to provide intensive services in the community to avoid unnecessary separation of children and their families, and
5. to prepare local agency staff and university students in new ways to provide family-centered community services.

Specific objectives for the children being served include:

1. reduction in out-of-home placements,
2. decrease in school suspensions,
3. decrease in referrals to juvenile justice,
4. decrease in school absenteeism,
5. increase in graduation rates, and
6. increase in positive functioning of individuals and families.
The long-term outcomes for the children and their families are to decrease formal service dependency and strengthen naturally occurring community support systems.

Implementation Requirements

The PEN-PAL Project requires in-service teachers, administrators, school social workers, school psychologists, therapists, case workers, and others to have the skills, competencies, and attitudes to work within a collaborative system of care. Such changes in skills, competencies, and attitudes require intensive training as well as on-going technical assistance for those in the field implementing new collaborative ways to work with families and other professionals. The Project also requires an infrastructure to manage and administer the grant requirements. To build this infrastructure and provide training and technical assistance, the PEN-PAL Project proposed the design and creation of a Training and Technical Assistance Resource Center to serve the three counties.

The PEN-PAL Training and Technical Assistance Resource Center

The PEN-PAL Project enlisted the help of East Carolina University to provide personnel, space, and academic computing support. This year faculty from the School of Education and the School of Medicine have worked together to develop the PEN-PAL Training and Technical Assistance Resource Center. The Resource Center's primary goals are to identify training needs, develop a comprehensive training program to meet those needs, develop a core of peer trainers, and provide technical assistance upon request.

Building the Infrastructure to Support Systems Change

The first operational goal of the Resource Center was to create an electronic infrastructure to connect the community agencies in the three counties to area schools, the East Carolina School of Education and the School of Medicine. Using telecommunications, project participants from the three counties could access resources from Web sites, request resources from the Resource center, communicate more effectively and efficiently, and engage in discussions about best practices.

Phase One. A needs assessment for electronic connectivity was conducted through written surveys, interviews, and on-site visits to community agencies. Strategies for providing e-mail and Internet access were developed utilizing existing computer systems as much as possible. An analysis was conducted on the forms, policies, manuals, letters, and data files to determine how these could be shared across the PEN-PAL partners. A Web presence was developed to allow participants to share information, moving to a digital environment.

Phase Two. The second initiative was to provide training in how to use the Internet and technical assistance to install the hardware and software to create the electronic network. The School of Education, as a component of the Microsoft Professional Development Project Program, provided hands-on instruction and practice in using productivity software as well as the initial instruction in using the technologies for distance learning.

Phase Three. The third step was to use distance education to provide training to participants in the three counties. Using e-mail, online conferencing software, video conferences, and the North Carolina Information Highway, a series of staff development opportunities were designed. The East Carolina University School of Medicine, a pioneer in the use of telemedicine as a training and diagnostic tool, extended its delivery to members in the project. In addition, online tutorials are in the development stage. These tutorials, to be available on our Web site, will enable participants to work at their own time and their own speed.

Conclusion

The PEN-PAL Project's electronic network is in its early stages. By June 1997, the expectations are to have installed the hardware and software, to have completed initial staff development for all users, and to have presented our first series of best practices workshops via distance education. The challenge has been to weave together the assorted computer systems, agency software, and personnel skills while also addressing the issues of individual agency policies, confidentiality, and the rights of individual clients. As we move forward during the next three years, the PEN-PAL Project can provide invaluable information about the benefits and the barriers to such electronic multiagency initiatives.

ASSISTIVE TECHNOLOGY AND TEACHER EDUCATION: A COURSE DESIGN PROCESS

Evelyn M. Dailey  
Paul Jones  
Robert Wall  
Towson State University

Recently, the preparation of teacher candidates of students with disabilities included in general education classrooms has received attention from teacher education programs throughout the nation (Behrmann, 1993; Bowser, 1995; LaPlante, 1992). Due to the increasing number of students with disabilities in the general education classroom, many teacher education programs require pre-service teachers to take classes in special education. Similarly, all students who are being prepared for teaching careers at Towson State University are required to successfully complete one course in special education. This introductory special education course addresses the basic issue of including students with special needs in the general education environment. Although students become familiar with the definition, characteristics, and causes of various exceptionalities as well as numerous teaching strategies and modifications necessary for success in the general education classroom, little attention is given to the various adaptive devices students with disabilities may need to use in the classroom in order to access the general education curricula. Moreover, few instructors in higher education are familiar with the wide array of adaptive technology used by students with disabilities and even fewer faculty understand how to prepare teacher candidates to assist students who use those devices (Behrmann, 1993). In response to the need to prepare pre-service teachers for the demands of students with adaptive technologies, a group of faculty members initiated the process of designing a course for pre-service teachers that would address those issues. The purpose of this paper is to present an overview of the course design process and to report on some preliminary data collected and its implications for teacher education programs.

Project Goals and Objectives

The current project is an important component in the design of an undergraduate major in special education at Towson State University. It also represents a collaboration between faculty in the areas of special education and instructional technology and the Baltimore County Public Schools Office of Special Education. This collaboration brings together expertise across disciplines and strengthens the relationship between the teacher education program at the university and the surrounding schools. It is hoped that this collaboration will bridge theoretical and practical issues related to adaptive technologies and classroom practices that will ultimately result in a course of great value to future teachers. There is also a need for an in-service course for those teachers currently teaching who must deal with students with special needs using adaptive devices.

Methods and Activities

During the summer of 1996, faculty members attended the Tri-State Assistive Technology Conference held in Alexandria, Virginia. At that conference, the issue of preparing teachers to assist students with adaptive technologies was discussed in a variety of sessions. Materials were collected regarding the variety of technologies used by students with disabilities as well as programs to educate classroom teachers on the issue. Following that conference, meetings of faculty in instructional technology and special education were held to discuss the feasibility of developing a course in adaptive technology.

In September, a representative from the Office of Special Education of Baltimore County Public Schools met with Towson State University faculty from the respective disciplines in order to discuss the topic of adaptive technology from the perspective of Baltimore County Public Schools. It was decided that a survey of teacher education students should be conducted to determine their familiarity with adaptive devices and their level of comfort in working with students using adaptive technology. The survey form was created and distributed to "core" classes in teacher education (Table 1). The sample included special education, instructional technology, and educational...
research classes. 211 undergraduate students and 110 graduate students were included in the survey. When completed, the survey forms were analyzed in order to determine the extent to which students were familiar with commonly used adaptive devices, and their degree of comfort in working with students with disabilities requiring adaptive technologies. Results of the survey are reported in Table 2.

Table 1.

*Chi-square analysis showed a significant difference (p<.05) between graduate and undergraduate students for these items. The numbers in the table represent percentages for each level of experience and comfort.

Outcomes and Impact

There were several important outcomes of this project. First, it was apparent that few pre-service teacher education students were familiar with most of the commonly used adaptive technologies. Second, it was clear that even fewer students considered themselves to be comfortable in working with students with disabilities who might require their assistance in the classroom while using these technologies. Specific information from the survey will be used to design the course "Adaptive Technology and Special Needs Students." Based upon the survey results, a case can be made to include such a course in the new special education major at Towson State University. It also indicates that there are differences in the needs of graduate and undergraduate students, suggesting that a graduate course should also be developed.

Timeline and Completion Dates

Data analysis were completed in November of 1996. Based upon that analysis, the proposed new course will be submitted to the curriculum committee of the Department of Reading, Special Education and Instructional Technol-
ogy at a department meeting in February. If approved, the course will then move through the curriculum approval process of the university. That process involves approval by the College of Education Curriculum Committee and by the University Curriculum Committee. Pending the approval process, the course could be scheduled to be taught in the fall semester of 1997.

**Evaluation Plans**

Quantitative data were collected which indicated the need for such a course in the preparation of teachers at Towson State University. In addition, collaboration with the surrounding school system indicated the need for in-service work by classroom teachers. Based upon this collaboration, the preliminary course will be evaluated by Baltimore County Public Schools, Office of Special Education, and comments from that office will be considered in the design of the course. Once developed the course will be evaluated by students and faculty at the end of each semester, and modifications will be made as needed.

Current dissemination plans include sharing of the course contents with the surrounding school systems of Baltimore City, Anne Arundel County, Howard County, Harford County, and others where appropriate. In addition, presentations at the Eastern Educational Research Association and the Maryland Association of Teacher Educators are planned.

Webster's New World Dictionary defines diffusion as the “dissemination of news, cultures, etc.” This definition offers a good perspective for this section of the Technology and Teacher Education Annual. Too often onlookers think about the diffusion of technology only in terms of the spread of hardware and software. But the news of technology integration often involves complex issues of how we do business—how we think about teaching and learning and how we relate to the procedures and cultures of our educational institutions. A second definition from Webster’s characterizes diffusion as a “scattering of light rays.” In a metaphorical sense, this definition is also apropos as this section documents numerous examples of innovative projects and insights that illuminate new methods and directions.

The first group of papers documents various aspects of integrating technology into teacher education programs. Cooper, Browne and Maeers describe a four-year plan to infuse instructional technology into their elementary teacher education curriculum. The authors examine obstacles that they have encountered and critique their attempts to solve them. Paccione, McWhorter and Richburg tell about the Project Promise model for coaching preservice teachers in technology use. The program, which has evolved at Colorado State University over the past eight years, is in its second year of infusing a rigorous technology component. The model includes three main “chunks” of direct instruction followed by lengthy and diverse field experiences.

Sanche, Haines and Robertson describe an innovative project in which special education faculty have integrated a software system specifically designed for collaborative teams working with special needs students. The CoPlanner software has built-in features that help teams explore the needs of students, create a personal program plan, implement the plan, monitor the student’s progress, and communicate with other team members.

Dirksen and Tharp document their use of the Concerns-Based Adoption Model (CBAM) to determine preservice teachers’ concerns about technology use and their ability to integrate technology into their teaching. Results of the stages of concern questionnaires, which were administered on three separate occasions throughout the study, are presented.

The next two papers focus on university/school district collaboration. LeBlanc and Oates describe a project, funded by the U.S. Department of Education’s Funds for Innovation in Education, to develop, implement, and evaluate a model for providing district-wide teacher training employing a “train the trainer” model. Evaluation data show substantial change of teaching behaviors for project participants. Hoskisson and Stammen describe a collaborative effort of university and school district personnel to create training materials for inservice and preservice teachers in the area of computer-based multimedia. The authors document their efforts to transform print-based training materials into interactive, CD-ROM-based modules.

K-12 planning and inservice efforts are addressed in the next two papers. Dexter reports on a two-year case study that examines technology planning in a large suburban school district. The author uses symbolic interactionism as a lens to examine the planning process and analyze how various stakeholders and administrative structures shape implementation. Garcia, Johnson and Dallman detail an elaborate and structured inservice program designed to expand the use of technology for meeting curricular goals at the elementary level. Their model includes expectations of active leadership by the school principal to motivate, support, and reward teachers to help overcome resistance to change.

K-12 issues are further explored in two papers that report on surveys of current technology use by teachers. McKenzie, Kirby, Clay and Davidson surveyed all the technology trainers and media specialists in two school districts to determine what hardware and software teachers are using and what problems they encounter. Isaac and
Ganske surveyed teachers in Alberta to find out how teachers are using "low-tech" media (i.e., media that are "pre-microcomputer") and how the push for "high-tech" media is influencing patterns of usage of the older tools. The authors found that traditional media are still commonly used in K-12 classrooms and conclude that more attention to "low-tech" media should be given in teacher education programs.

The papers in the final group address various aspects of technology integration. Twining offers an analysis of the literature on educational change designed to help readers evaluate if pursuing a particular technology-based project is the worth the effort. He suggests a three-question decision tree and discusses details involved in each of the questions posed. Bowers, Rodríguez, Budd and Campbell examine the reflections of four educators as they consider their experiences in learning to use technology in an educational setting. In this paper, a special education teacher, classroom teacher, principal, and university inservice provider present their thoughts on the often intimidating process of technology integration.

Tykwinski, Thompson and Grooters describe the use of notebook computers at one university. The authors provide information on hardware and software as well as improvements to classrooms, networking capabilities, and training. Meyer and Schranz describe an informal group of computer-users at one university who voluntarily meet weekly to address computing problems on campus. While holding no official responsibility, the university has come to recognize the group as a valuable resource and calls upon them for advice regarding funding priorities, etc. The authors suggest that this model could work in other university and secondary school settings.

Finally, Broughton provides guidelines for incorporating the use of the Internet in secondary schools. She presents issues for determining which lesson plans might include an Internet component, suggestions for implementing an Internet project, and resources for teachers that can be accessed directly from the World Wide Web.
Let us imagine a school. It is on the edge of a city. The streets around it are residential. A school zone, with a speed limit of 20 mph regulates traffic flow around it. Down at City Hall a group of forward thinking officials decide the city needs a freeway to keep the city safe and prosperous, to bring tourists and new business. The best route for the freeway goes right by the school. After much debate it is built, but there are no access ramps near the school. The school and the freeway seem to exist in separate worlds.

This is very like the situation in which teacher educators find themselves when they begin to use computer-related technologies (CRT) in teacher education. The authors work in an elementary teacher education program. This paper describes our experiences as we began to try to integrate CRT into our work in an existing program. The problems which we faced are described, some attempts to solve them are outlined and critiqued.

The Problem

Whether we like it or not, technology is changing what teachers do. The public expects teachers to know how to work with children using new tools of CRT. Many children are technologically sophisticated. Often, preservice teachers are less so. Teachers are asking teacher educators (and our newly-trained preservice teachers) to provide in-service in the use of technology in schools.

When we at the university try to respond to these demands we become aware that we are located in an institution where change is always carefully examined and gradual (Kapuscinski, Browne, Krentz, Cooper & Goulet, 1995; Lanier & Little, 1986). To make a program or course change one must navigate several levels of committees. Moreover, the pragmatic need to realign the contents of the teacher education program to include advanced technologies is not as important to our institutions as publications in established refereed (hard copy) journals. We may be in a time of rapid change and realignment, but the requirements for promotion and tenure in the university are the same as they have been for 20 years. Expectations have increased and resources have not.

Attempting to provide teacher education which will enable teachers to work well with CRT in this institutional environment is like trying to drive at freeway speed in a school zone.

Our Story

This story began when we decided to include the Internet, e-mail and some presentation software in the classes we teach. Naively, we thought we could just begin. We asked students to reflect, in electronic journals, on what they had learned in our classes. But there weren’t enough computers in the computer lab. The computers and the mainframe were often down. We had no one to teach the students how to use e-mail and the e-mail programs available were not user friendly. Problems multiplied.

We began to use the Internet as a source of teaching materials. We tried to use software packages such as Powerpoint with our students and in our own teaching. We tried to learn to use everything at once. We began to recognize gaps in our knowledge and even more gaps in our technical support. There was no one to teach us to use the technologies, so we spent many unproductive hours teaching ourselves. We needed immediate access to computers with large memory and these were jealously guarded by the lab technicians. We couldn’t get them moved to offices or classrooms. Hours were spent ordering free materials and demonstration hardware and software in an attempt to solve our problem outside of budgetary restraints. The new programs we ordered were complex and required hours of learning time. In our busy lives this meant that many of them sat on the shelves unused.

We approached our superiors and outlined the problems. They responded in the usual way. Committees were set up. One of the authors of this paper was on six technology related committees. There were sub-committees of standing committees, ad hoc committees, and a standing committee that was advisory, but no committee which had any control over budget.

Some faculty were resistant to the use of CRT. Their eyes glazed as we talked about computers in teacher education. They couldn’t understand where we found the time to “play” with our computers while they were busy writing papers for publication. We were “wasting our time,” “nuts,” or “not thinking about our pensions.”

In addition to all this, teaching and learning using computer-related technologies required us to think about
knowledge in unconventional ways. Recent research clearly documents the importance of knowing "how, where and why," not simply knowing "what" or knowing "about" (Skemp, 1989). This research is particularly relevant to problems of teaching and learning using CRT in teacher education. We wanted to model what we were expecting students to do. One of us developed a personal web site to post ideas, readings for weekly classes. She tried to develop and use new materials with multimedia programs, only to be tripped by details such as: "Which cable should I use to make the data projector work with the Mac?", "How can the server machine for the web site and the CPU connected to the data projector be on at the same time?" and "I need to teach myself Power Point this weekend so that I can use it for my class presentation."

We spent time with each other and our students, teaching each other, trouble-shooting, talking, and solving problems. We were not simply giving the students autonomy to be part of the decision-making in learning—we were, in many cases learning from them. They made decisions and in some cases we were their assistants; they facilitated our learning, by what they knew and how they worked with us to enable us to learn, or by virtue of the fact that we were learning together. The student teachers saw their professors in various roles, as learners, as confused learners and as frustrated and angry learners. The workplace had changed dramatically for us all. In the end, we found no solutions, but we have learned so much. Having acquired a taste for the fun and excitement of "playing" with CRT we are determined to continue.

The Four-Year Plan

In an attempt to solve some of the technical problems and develop a reasonable sequence for teaching student teachers to use CRT, a faculty committee (on which one of us served) developed the following proposal.

In the first year students would use e-mail to communicate with school students to enable them to learn HOW to do e-mail. They would learn basic key-boarding skills, basic word processing and basic spreadsheet applications. Progression into year two of the program would be possible when students could illustrate proficiency in the above areas. Students would also explore the Internet using URL and various search engines. They would find and explore kid links and teacher links, and compile a report on these activities.

In the second year students would continue to build facility in skills from year one. They would do an assignment using a multi-media program such as Hyperstudio. In the second semester, when students move into subject specific methods courses, they could be introduced to subject-specific software, web sites, CD-ROM material, etc.

In the third year students would continue use of subject-specific software, web sites, etc. in subject area classes.

They would use e-mail, computer, and Internet skills to locate resources and make pedagogical decisions about those resources and begin to use this information in their lesson planning and teaching. They would also learn the basics of designing a home page, and create a personal/professional home page.

In the fourth year, which has one semester of practicum and one of coursework, students would propose and complete a project using advanced multi-media and/or Internet. They would mentor a first or second year student in instructional technology.

The plan is a valiant attempt to address all aspects of the problem while concentrating on preparing teachers who can use the tools of CRT to educate children. The proposal, which was created by one sub-committee, is now in between committees.

The Critique

School zones can be frustrating places. They make us drive slowly but they exist for good reason. They protect. In this they are analogous to the bureaucratic structure in a University faculty. Procedures and committee structures frustrate. They make change very difficult. They also protect. Without their gatekeeping function, many ill-considered changes, program and practices might become part of the faculty. So it is with the time honored administrative structures of our faculty.

The freeway brings new products, new possibilities to us. But it also has no speed limits, or speed limits far too fast for those who live and work in the school zone. It encourages the development of faster and faster cars. It encourages the development of wider, better freeways. These eat land and resources. Everything begins to move so fast it is very difficult to make careful decisions. As we need to learn special driving techniques to safely navigate the freeway, we need to learn to think about many problems in unconventional ways if CRT is to become a useful tool for teachers.

Our story demonstrates the practical problems which face those who are beginning to use CRT in teacher education. Underlying these practical problems are several problematic assumptions. Beginners, institutions and individuals mistakenly assume that existing organizational principles and structures will be capable of constructing solutions in this new problem environment. Committees, for example, are valuable gatekeepers, it is true, but CRT problems change so rapidly (you just learn gopher and it’s gone) that committee decisions are often obsolete before they’re made.

This is closely related to another problematic assumption, the assumption that the Internet is analogous to a library and software programs to books. They are not. They grow, change, mutate faster than decisions about their use can be made. The problem is that teacher educators are
used to making careful choices which will govern action for a considerable time. This view of change is challenged by the speed of the development of CRT.

Finally, in the midst of such speed and uncertainty, it is easy to confuse learning about a tool such as Hyperstudio with learning how to use this tool to teach children. This error is wasteful of an already critically scarce resource, time. It is so difficult to direct one's attention away from the glamour and glitz of the technology and towards the uses we might sensibly make of it.

To begin to understand how we might solve some of our problems with CRT, we must look differently at the goal of faculty procedures for decision making about technology acquisition and curriculum change. We must learn not to ask first “How will we teach our students to use CRT and how will we get the resources to do so?” Our first question must be “What must our students understand about teaching and learning using CRT?” The answer to this question can be used to guide a constantly changing process of decision making which will be able to match the constantly changing state of CRT available to teacher educators. It will help us to avoid the seduction of the technology until we understand more clearly the purpose for which it is best used in schools.

Technology is changing the way we teach and learn and is changing our concept of how a faculty should enable students to become teachers. The classroom of tomorrow, tomorrow’s teacher and tomorrow’s learner will be quite different from what most of us have experienced. If faculties of education continue to promote and propagate instructional notions of the traditional academy, they cannot ethically be preparing teachers to cope with and excel in the classroom of tomorrow.

**Knowledge and Knowledge Acquisition**

Our views of knowledge and knowledge acquisition must change. Some of our faculty and preservice students believe knowledge can be packaged in “containers” to be “transmitted.” They hold the traditional view of teachers as authorities who have knowledge and know precisely what to do. Computer-related technologies challenge this belief.

We must ask how a novice becomes an expert in CRT? What does it mean to be an expert in technology? What does it mean to be a teacher in this kind of situation? What does it mean to be a teacher educator working with tomorrow’s teachers? We think it means a complete reconceptualization of what constitutes knowledge, and how this new concept of knowledge should be “delivered.” We can begin this reconceptualizing by thinking about knowledge and its uses.

We should ask ourselves how can Elementary Preservice Teachers learn CRT with understanding, in a relational and connected way, not in a rule bound, instrumental manner? (Skemp, 1989) Pirie and Kieren (1991) provide help in this. They developed a model which depicts mathematical understanding as an evolving process of organizing one’s knowledge structures. In relation to CRT, this view of coming to know is developed into the following model.

![Figure 1: Phases for Coming to Understanding Informational Technology.](image)

**Ethnotechnological Knowledge (ET)**

This is a starting place for growth in any IT component. People know a great deal about technology from how they have lived, from popular culture. “I know this is something new and something I should know how to do, but I don’t.” ET is the starting place for learning CRT and may be different for every person. It is defined by the culture they have grown up in, the culture of their peers, the familial, social, and historical experiences that have disposed them to learning CRT.

**Concept Making (CM)**

When faced with a new technology, learners build concepts through specific doing. They need specific instructions. Without specific instructions these learners randomly explore. They cannot make a personal plan of action, but are dependent on support—either a manual, a guide, or a more able learner (Wertsch, 1981). A concept maker would be seen surfing the web erratically, entering a specific URL, finding sites by chance or trail and error, with no plan to retrace steps to such a route.

**Concept Organization (CO)**

At this level learners have had several experiences on the web. Separate concept making activities are related to each other. Learners may have a mental image of where they're going and be able to plan a route to get there. It's not always an efficient route, but they understand what the technology can do and they can figure out a way to do it. A person in the concept organization phase recognizes increasing sophistication in his or her understanding of the sub-components of CRT.

**Analytic Processing (AP)**

This phase is characterized by sophisticated analysis. Learners evaluate tools and select the most appropriate. They can explain their procedure for web usage or for word
processing documents. This is where we want our teacher educators to be.

Student teachers and teacher educators seem to need to reach the analytic processing stage in their understanding of computer-related technologies before they are able to begin to understand the difference between learning about an exciting tool (a specific CRT) and planning to use it in ways which will foster student learning about all of the concepts and skills which make up an educational curriculum.

If this is true, then faculties of education must spend money to ensure that a majority of faculty members have reached this level of understanding. Until they do we have the blind leading the blind, unaware of the distinctions between the freeway and the school zone, unable to plan a productive relationship between them. In this sad case many teachers and children will be hurt, not helped by the existence of the CRT freeway near their schools.

**Conclusion**

The school must take advantage of the freeway without being blinded by its speed and glittering promises. The school must build a footpath over the freeway on which children may safely pass its dangers while their teachers help them to learn the things they will need to use it productively. This footpath will be constructed of a new view of change and of coming to know. In the Elementary Program of our Faculty of Education those of us who have been exploring the use of CRT believe that preservice teachers need more than a basic skills approach to informational technology. It simply is not sufficient for students to have technological expertise. They need to understand these technologies as pedagogies. They need to know how to determine appropriateness and usefulness. They need to explore and become familiar with the new technologies. Their knowing about CRT precedes discriminate and critical use of CRT. Knowing about CRT precedes integration of these new technologies into effective teaching and learning.

COACHING PRESERVICE TEACHERS IN TECHNOLOGY: 
THE PROJECT PROMISE MODEL

Angela V. Paccione  Barbara A. McWhorter  Robert W. Richburg
Colorado State University  Colorado State University  Colorado State University

In 1994, schools across the U.S. collectively spent about $3 billion on technology related to networks and computers. President Clinton and Vice President Gore spent a weekend installing telecommunications cables in California schools. The general populace has become infatuated with the internet. However, the question remains, to what degree are Schools of Education equipping future teachers to use this technology for effective instruction?

Between the years 1983-1995, the number of students per computer in U.S. public schools shrank from 125 to nine (Glennon and Melmed, 1996). Despite this rapid growth microcomputers have yet to spark a broad revolution in teaching and learning. While personal computers and networking may have revolutionized the business world and captivated the imagination of the general population, they have yet to revolutionize the field of education. It is our contention that until teachers master the use of technology in the classroom, the revolution will continue to bypass education.

In this paper we will describe how Project Promise, an experimental teacher training program at Colorado State University is training its preservice teachers for a future of technology. Project Promise is a Colorado Commission on Higher Education (CCHE) designated “Program of Excellence” in teacher training (Richburg, Knox, Carson, & McWhorter, 1996). The purpose of the project is to use “best practices” in the training of future teachers. Within the Project Promise Model the training and subsequent mastery of technology occurs gradually over the ten and a half month program. This gradual process produces mastery and accommodates the varying degrees of technological knowledge each student brings to the class.

Inservice teachers who have mastered the use of computers in education report that they have done so through a gradual process with the support of others along the way (Sheingold and Hadley, 1990). The cohort of 20 Project Promise students provides the requisite support and encouragement for preservice teachers to become proficient in the use of technology. The Project Promise staff works diligently to bring all of the preservice teachers up to the level of mastery.

Whole-Part-Whole Strategy

Project Promise is attempting to train a new generation of teachers who are at ease in front of a computer terminal. Our approach includes a whole-part-whole strategy often found in the arena of athletic coaching. To achieve optimal results, coaches examine the whole performance and then scrutinize and remediate the component parts. Coaches understand that the success of the finished product is dependent upon the precision and mastery of the component parts. Therefore, if they can recruit their athletes, coaches will select those who have demonstrated command over the details of the sport. Once the athletes have mastered those components, a coach will reassemble the parts into a more effective and more productive whole. This step requires creativity and a vision for what will be successful. For the final product to be successful, it must accomplish precisely what the coach has envisioned. This whole-part-whole strategy is repeated until the desired outcome is achieved. Project Promise attempts to replicate this model.

In technology training the whole is a fundamental shift in the pedagogical environment towards promoting student achievement rather than simply the acquisition of new skills. Glennen and Melmed (1996) found that educational technology has significant potential for improving student learning. In the Project Promise Model, preservice teachers are continually encouraged to be facilitators of students’ success. One way this is accomplished is by using technology in tailoring educational experiences to meet the needs of the learners. Kulik (1994) found that students usually learn more in classes in which computer-based instruction is used. Therefore, Project Promise students are trained to use technology as an instructional tool to enhance the potential for learning of all students. In addition, research indicates that students enjoy classes more, appear more motivated, and are more attentive in classes which use technology (Kulik, 1994; Schofield, 1995).

The parts of the training include technological skill attainment and development using particular hardware and...
software. Students are instructed in the use of devices from printers to scanners to digital photography. While a number of school districts across the country report that they will be requiring 1-10 hours of technology training for their teachers (Barron and Orwig, 1995), Project Promise students will receive 25-30 hours of direct instruction and hands-on practice. In addition they are expected to infuse technology into their lesson plans. As students achieve mastery of the technological parts they progress toward a new whole. As coaches, the Project Promise staff has the ability to work with preservice teachers on an individual basis to assist them in developing their best performance.

Preservice teachers who have mastered the component parts of technology, and understand the purpose and benefits for using technology in the classroom, can begin to incorporate it as a tool in their classroom. The teacher can more readily adopt a “guide on the side” pedagogical stance and devote more time to individualized instruction. The instructional focus becomes more student-centered, with students often assuming the role of expert (Schofield, Eurich-Fulcer, & Britt, 1994; Sandholz, Ringstaff, & Dwyer, 1990). This frequently leads to collaboration between students as they help one another succeed in using technology (Means and Olson, 1995).

**Teacher-to-Teacher**

The Project Promise teacher training model is designed so that students receive three main “chunks” of direct instruction followed by lengthy and diverse field experiences. During the fall instructional session, students are introduced to technology on the first day of registration. All students, even those with no computer experience, are instructed in a mini-lesson on how to access a site on the World Wide Web. This particular site has an online version of the Kersey Temperament Sorter, which Project Promise students are required to complete. The School of Education at Colorado State University houses a computer lab with 20 Macintosh and more than 30 IBM computers. Our 20 students can complete their first assignment with relative ease. This initial success often assuages the fears of those students with no computer experience.

During this early fall session, Project Promise students will engage in eight hours of technology training. Included is instruction in the basics of internet usage: e-mail, newsgroups, listservs, and accessing the World Wide Web. This initial training is intended to enable students to locate and retrieve resources to supplement pedagogical and content area knowledge. This is primarily a Teacher to Teacher phase of the instruction. Students learn how the internet can be beneficial to professional development and content area enrichment.

In a four-part process, Project Promise students are introduced to ways in which they can access information from around the world. First, they set up an e-mail account at the University. This allows them to communicate with one another and with the staff more conveniently. Next, students are introduced to newsgroups where teachers share ideas and concerns. As preservice teachers, they have more questions than they have answers. The newsgroups become an additional source of information about the complexities and realities of teaching. Then students learn about listservs which specialize in K-12 teaching. Here, they can delve into a deeper conversation about particular issues. Finally, students discover the wonders of the Web. The number of web sites which are devoted to education has seen a steady growth. To reduce the time spent following hypertext links, students learn how to use search engines for locating specific information. In addition, a Project Promise resource page has been created for their use (http://promise.cahs.colostate.edu/Project/Promise.html)

This entire fall session of technology instruction is designed to heighten awareness of the immensity of resources available to teachers. This allows preservice teachers to streamline schedules. Preservice teachers’ concerns about content knowledge and classroom management seem to take priority over reflective practice and creative lesson designing. In addition to instruction and practice using information technology, students learn how to use software for managing the classroom. This includes software for keeping track of grades, attendance, seating assignments, and lesson plans. We have found that when preservice teachers learn to take advantage of the resources available through technology they have more time to devote to their pedagogical development.

**Teacher-to-Student**

After the first instructional session, which lasts for seven weeks, the Project Promise students begin an 11-week field experience. During that time they meet one evening a week for seminars. Technology is taught in four of the seminar sessions which lasts for two hours each. The technology seminars consist of instruction and practice in the basics of computer and peripheral device usage. This includes: word processing, spreadsheets, HyperCard®, and the use of scanners, digital photo equipment, video/audio capture, computer-to-TV hookup as well as LCD projection panels.

During this phase, preservice teachers implement the use of technology (parts) into their lesson plans as they continue their student teaching assignment (whole). This creates a Teacher to Student paradigm. At this developmental juncture, preservice teachers use technology as elements of their lessons; particularly for mini-presentations or for content enhancement. Their students are introduced to the integrated use of technology to supplement classroom instruction. In addition, preservice teachers begin to introduce their students to the Internet. Some secondary schools with which Project Promise works have
computer labs with direct internet access. Our teachers can then set their students up with e-mail accounts. They can use the training they have received as a model for introducing their students to the Web.

Student-to-Student
Upon completing 11 weeks of student teaching, Project Promise students return to the classroom for a three-week January inter-session. During this time they participate in an intensive, six-hour weekend workshop to learn the mechanics of presentation software. Students learn how to design and format slides in PowerPoint® and cards in HyperStudio®. They spend time learning how to import video, clip-art and sound from web sites to use in their presentations. This lets the teacher model the use of presentation software as they instruct. The primary purpose for this instruction is so that Project Promise teachers will be able to guide their students in developing individual or group presentations. This orientation is Student-to-Student. The secondary student will organize and construct a presentation for an assignment in class. The teacher, who has now achieved proficiency with the software, can effectively guide the students in the development of their projects.

After the January inter-session, the students embark on another field experience. Upon the completion of nine weeks of student teaching, the Project Promise students return for their final instructional session. During this time they will receive an additional four hours of training in technology. This final training consists of Web site development and HTML instruction. Students author their own home pages and post them on the Project Promise file server. Students’ technological proficiency is assessed authentically through student-designed projects. They are required to demonstrate evidence of their competency, including the direct observation of a lesson in which they implement technology.

Looking to the Future
The Project Promise Program has been training teachers for eight years with an experimental model. The model remains fluid and continually strives to incorporate best practices in preparing teachers. This is the second year that Project Promise has included a rigorous and comprehensive technology training component in its preparation of teachers. To date, the whole-part-whole model for training in technology has been highly successful. Project Promise students are career change professionals with an average age of 29. Many come to the program with a little computer experience. As a result of the training they receive, Project Promise preservice teachers often are more knowledgeable in technology than their cooperating teachers in the field experience. Former students report that this training enhanced their marketability in the job search process (20 of our 21 graduates of the class of 1996 have teaching positions, one has opted to pursue graduate school). While we have only recently begun this practice we believe it has the potential to become a model for training teachers for a technological future.

Acknowledgement
Project Promise was recently featured as an Alternative with promise in the September, 1996 Report of the National Commission on Teaching & America’s Future, “What Matters Most: Teaching for America’s Future.”

Today teachers are beginning their careers in a highly technological world. Computers have become necessary tools in every aspect of their lives, including teaching and learning. School boards expect computer competency as an entry skill for new teachers, and still teacher educators have been slow to recognize their responsibilities in the preservice preparation of these teachers (Harrington, 1993; Hunt, 1995; Resta, 1993). The present paper describes an innovative project in which special education faculty integrated computer technology into a preservice resource teacher education program.

While there is a growing body of literature on the issue of infusing technology into preservice teacher education, papers by Fulton (1993), Norvack & Berger (1991) and Resta (1993) are particularly germane. In her keynote address at the STATE conference in California, Fulton (1993) provided both a retrospective and a perspective on the increasing role of computer technology in education. From her experience in the Office of Technology Assessment, Congress of the United States, she summarized a number of studies which showed that while most teachers wanted to use the technology, they were either not using it very much, or were using it in relatively narrow applications. Above all, she noted that new teachers coming from schools and colleges of education were not entering new teaching jobs ready to teach with technology. In concluding her paper she noted that the next major issue on the educational agenda was how to bring about “a marriage between teachers and technology”, that is, how to prepare teachers to integrate computer technology into their teaching.

The state of Michigan had earlier established a task force to study ways of integrating computer technology into the preservice preparation of teachers (Norvack & Berger, 1991). State education officials and school boards were also concerned that new teachers were not well prepared to use computer technology. The Michigan Task Force suggested that much more be done to integrate technology into teacher education during initial preservice preparation. Specifically, the Task Force recommended that teacher educators: a) model teaching with computers, b) make sure that teachers-in-training are taught to use the computer in teaching, and c) that teachers-in-training be able to show proficiency in the use of computers during field practica.

Resta (1993) reviewed some of the barriers colleges of education experience in trying to infuse computer technology into preservice teacher preparation. He then listed the 13 computer competencies which the International Society for Technology in Education said newly graduated teachers should have. These competencies include some associated with using the computer as an aid to instruction and others related to using the computer as a personal planning and productivity tool. Finally, he reviewed new and emerging models for infusing computer technology into teacher preparation programs.

These three papers supported the ways in which special education faculty at the University of Saskatchewan responded to student requests for the inclusion of more course content on the use of computers in resource teacher preparation. Since we prepare our resource teachers in a collaborative model, faculty reviewed published computer programs in search of software to support the collaborative roles of resource teachers. We were particularly interested in a software package which could be used—according to the Michigan Task Force recommendations—in preservice teacher education and subsequently as a long-term tool for practicing resource teachers. Not having found any such software, we obtained an innovative project grant and, over a five year period, conceptualized, programmed, and field-tested “CoPlanner”. CoPlanner is an open software system, which can be readily adapted to any local resource teacher education program. Its strength is in the fact that it is equally effective in preservice resource teacher education.
and in subsequent use as a support for collaborative teamwork in schools. After three years of using CoPlanner in our own program, we have found that our students do indeed learn to use the computer effectively through preservice education, as the Michigan Task Force had predicted (Haines, Sanche & Robertson, 1993; Sanche, Haines & Robertson, 1994).

What is CoPlanner?

CoPlanner is the first software system specifically designed to mediate the efforts of collaborative teams working with students with special needs. These teams—which today frequently include the students with special needs and their parents, as well as classroom teachers, resource teachers, and other support staff—strive to maintain effective, on-going communication as they plan with the students. Also, they try to be thorough and systematic as they create a single, shared, accessible plan for each student. CoPlanner has built-in features to help the team: (a) achieve consensus on the needs of the student, (b) create a detailed personal program plan, (c) implement the plan and monitor the student’s progress, (d) maintain confidentiality of student information while providing ready access for all team members, (e) facilitate effective on-going communication among all team members, and (f) save team members time and energy in planning, record keeping, and reporting.

There is usually a team of two or more support staff, including the resource teacher, serving most students with special needs. CoPlanner empowers these teams to work collaboratively and to communicate effectively as they collaborate. Team members can use CoPlanner to send e-mail messages, they can share documents from the student’s file, or indeed they can transfer the student’s complete file confidentially and instantly. An initial collection of useful assessment and teaching tools is provided with CoPlanner. Teams can add their favorite tools to the initial collection.

The following are the CoPlanner features which support collaborative planning and service delivery:

• Program Planning Worksheets. At the core of CoPlanner are preformatted, two-dimensional, electronic worksheets which facilitate collaborative team planning for a student with special needs. These worksheets are configured according to a generic intervention model, with guiding questions to focus the support team on relevant information for planning.

• Forms Tool. An integrated Forms Tool allows a team to place frequently used forms on-line, as templates, which can be copied and used in hard copy or on computer. This CoPlanner feature allows a team to create its own forms, or to use existing preformatted forms.

• A Communications Tool. A user-friendly co-mail system allows all team members to maintain on-going communication, share information, or send a student’s whole file to other team members.

• A Security System. A two-level password system provides both document and file security. Even though a file might be accessible to a team, some documents in the file can be retained as confidential.

Resource Teacher Preparation in Saskatchewan

Resource teacher preparation at the University of Saskatchewan is completed as a 30 semester hour post graduate diploma in special education. To be accepted into the program, students must have completed a four-year general B. Ed. program, have been certified as regular classroom teachers, and have successfully taught in regular classrooms for at least a year. Eight of the ten three-semester hour courses are mandatory, while the remaining two courses can be used to obtain more depth in specific areas of exceptionality. The required courses are built around a computer-based core of four three-credit unit courses on assessment, resource teaching, and service delivery. The fourth course is an integrated field practicum.

During the Fall term, when the first three courses are taught, the students are introduced to CoPlanner, and become proficient in its use in assessment, instructional planning and service delivery. Pairs of students are assigned to established resource teaching programs, where they work collaboratively with the resource teacher(s) and regular staff. In these field practica settings, preservice resource teachers do their work collaboratively using CoPlanner as a support. Faculty can critique instructional plans in advance, review student reflective statements after teaching, receive and mark reports, and submit comments and grades to students confidentially. When they have completed their preservice preparation programs, these teachers can then take CoPlanner with them into their first resource teaching positions, where they can use it effectively as a collaborative and personal productivity tool.

Integrating CoPlanner into Resource Teacher Preparation

Every resource teacher-in-training has a unique learning curve with CoPlanner. Some are introduced to the program having had limited prior computer use, while others are already quite proficient in using the computer for word processing and for student games, drill, and practice. According to the Michigan Task Force, however, teachers in training should see computer use modeled by their professors, and these students should also be required to use the computer in their field practica.

During the first month of teaching, at the beginning of the resource teacher education program, faculty introduce the concept of CoPlanner and model the software. Students then have opportunities to “explore” the software in the dedicated computer laboratory. From the very beginning, students are encouraged to do their class assignments on
CoPlanner and to submit them electronically or on diskette for grading. For example, students are asked to review current literature on some aspect of assessment or teaching of students with specific disabilities. They then use CoPlanner to create assessment or teaching tools, based on the literature. There are many benefits from this assignment; students must do research in the current literature, and they do create relevant and useful tools. What is more important is that in the process they learn a great deal about specific features of CoPlanner, and about the use of the computer in instructional planning. By the end of the Fall university term, the resource teachers-in-training have logged many hours on the computer. They have also used most of the other features of CoPlanner for assignments during the term.

When these students go out to do their integrated field practica, they are already quite proficient at using CoPlanner. Their experience with the software intensifies, because now they use CoPlanner as it was intended—for collaborative planning with a fellow student, an experienced resource teacher and any others involved with the students with disabilities in the schools. During the field practicum, a student will establish a number of case files on CoPlanner, create or use assessment and teaching tools, prepare and submit progress reports, collaborate with university faculty by sharing intervention plans, and submit field work for evaluation. By the time the term is over, most students are quite competent in using CoPlanner as a teacher tool.

Conclusion

The original impetus to integrate computer technology into the preservice preparation of resource teachers at the University of Saskatchewan came from our students. Faculty are grateful for the student initiative which began the development process for CoPlanner. We suspect our resource teachers-in-training were focused on learning to use the computer as a means of teaching rather than as a teacher productivity tool. Serendipity and innovation led to the conceptualization and creation of CoPlanner, a more powerful tool than they had contemplated. Indeed, CoPlanner empowers teams to collaborate in ways not possible in the past. It has the potential to greatly enhance the ways we plan with and serve students with special needs.

Utilizing the Concerns-Based Adoption Model To Facilitate Systemic Change

Debra J. Dirksen
University of Northern Colorado

Major Donald Tharp
United States Air Force Academy & University of Northern Colorado

Technology plays an integral role in American life. Technological tools have become essential for the effective operation of businesses and as a primary means for people to acquire information. The technological age has increased the demand for well trained, highly educated personnel. Education has long been attracted to technology's promise and potential. The hope is that computing and instructional technologies will yield new levels of educational productivity and excitement for the learner.

The American educational system has a responsibility to prepare students to live and work in this technological age. As K-12 instructional technologies expenditures rise over $2 billion (Green & Eastman, 1994), some worry that training teachers may be an afterthought. For technology to have an impact on education, more than access to equipment is required. Educators need to learn to effectively use these new instructional tools. The integration of technology needs to be a systemic change effort.

There are significant pressures to prepare new teachers to effectively use technology (National Council for Accreditation of Teacher Education, 1993). Some have called for systemic restructuring of our educational system so that it can better meet current and future educational needs. The ultimate goal for many educators is to seamlessly integrate technology in the classrooms so it becomes an integral part of the educational environment.

To prepare preservice teachers to work in a technologically rich environment and become part of a systemic change effort, ways to infuse effective uses of instructional technologies into teacher preparation programs must be developed. However, little evidence exists to show that computers and information technologies have become an integral part of the classroom (Denk, Martin & Sarangarm, 1993). The promise that technology would aid student learning, nurture professionalism and allow teachers to become facilitators of learning, instead of providers of knowledge, has yet to be realized in most educational settings.

LeBaron and Bragg (1994) state that current preservice teachers graduate with skills similar to those of teachers who graduated thirty years ago. With few exceptions, instructional technologies are typically presented to preservice teachers in a manner which fails to model the seamless integration of technology into the classroom (Lampert & Ball, 1990; LeBaron & Bragg, 1994). For instructional technology to truly become integrated within the school classroom and achieve a systemic restructuring of education, appropriate integration of these technologies must be defined, modeled, and mentored for the preservice teacher. The systemic integration of technology requires time and carefully planned strategies to facilitate the adoption process.

Systemic Change

Systemic change can be facilitated by promoting a mindset that includes strategies or methods that are used to understand education (Jenlink, Reigeluth, Carr, & Nelson, 1996). Systemic change recognizes the interrelationships and interdependencies among the parts of the educational system, with a consequence that desired changes in one part of the system are accompanied by changes in other parts that are necessary to support those desired changes" (Jenlink, et al., 1996, p. 22). The premise presented in this paper is that preservice teacher education, by following these guidelines, promote and support systemic change efforts.

The purpose of this study was to use the Concerns-Based Adoption Model (CBAM) to evaluate a systemic change effort which promotes the integration of technology abilities of entry level teachers (teachers moving from the preservice learning environment to positions as first-year teachers). This study involved identifying preservice teachers concerns about integrating technology into the classroom and their ability to integrate technology with their instruction.
Methodology

Subjects
Subjects were 27 preservice teachers in urban public schools along the Colorado Front Range. The student teaching program is designed to mentor the development of effective teaching strategies and the use of technology in the classroom by preservice teachers. The program utilizes an on-site cooperating teacher and a consultant from the university to mentor the student teacher. The mentor's work is supplemented by bi-monthly seminars which the student teachers attended during the semester. Further, the university consultant visits the student teacher a minimum of six times during the semester and evaluates the student's teaching during a minimum of four of those visits. A standardized form is used to evaluate the student's performance and is designed to provide the student with constructive feedback, both positive and negative.

Concerns-Based Adoption Model (CBAM)

The Concerns-Based Adoption Model (CBAM) was used to evaluate the participants' concerns and level of use of technology within the classroom. CBAM was developed by the staff members of the Research and Development Center for Teacher Education at the University of Texas. They recognized that educators involved with change were having the same types of concerns about innovations that Fuller (1970) had identified in her studies relevant to teaching. The concerns that arose were not limited solely to teaching but related to concerns which developed during the adoption of any educational innovation (Hall & Hord, 1987).

CBAM sets forth several assumptions and assertions based upon the implementation of innovations in colleges and school settings. They established the following perspective for observing the change process (Hall & Hord, 1987):

1. Change is a process, not an event, and it takes time to institute change;
2. Individuals must be the focus if change is to be facilitated and institutions will not change until their members change;
3. The change process is an extremely personal experience and how it is perceived by the individual will strongly influence the outcome;
4. Individuals progress through various stages regarding their emotions and capabilities relating to the innovation;
5. The availability of a client-centered diagnostic/prescriptive model can enhance the individual's facilitation during staff development; and
6. People responsible for the change process must work in an adaptive and systematic way where progress needs to be monitored constantly.

CBAM addresses three assumptions: the individual's concerns about the innovation, the particular manner in which the innovation is delivered or implemented, and the adaptation of the innovation to the individual through three diagnostic dimensions. The Stages of Concern (SoC) measure addresses the intensity of the feelings and perceptions that the individual adopting the technology is expressing. The Levels of Use (LoU) measure addresses behaviors related to how the individual uses the technology. Finally, Innovation Configuration Maps (ICMs) require the development of word maps that describe the operational components of an innovation and how each can be adapted, re-invented, or in some cases mutated (Dirksen & Tharp, 1996). In the following sections, the SoC and LoU dimensions of the diagnostic measures will be described in greater detail. The ICM dimension was not used in the present study.

Stages of Concern. According to Hall and Hord (1987) the process of change can be more successful if the 'concerns' of the individual, as identified in CBAM, are considered. The concept of concerns is defined as: "The composite representation of the feelings, preoccupation, and consideration given to a particular issue or task" (Hall, George, & Rutherford, 1979, p. 5). The SoC Questionnaire provides a quantitative measure of the intensities of the seven Stages of Concern dimensions (Hall & Hord, 1987):

0. Awareness—concern or involvement with the innovation.
1. Informational—gaining more information about the innovation such as general characteristics, effects, and requirements for use.
2. Personal—how the innovation relates to the individual (i.e., role, decision making, consideration of potential conflicts).
3. Management—the mechanics of using or integrating the innovation.
4. Consequence—the effect of the innovation on students.
5. Collaboration—coordinating efforts in using the innovation with others.
6. Refocusing— the exploration of other ways to utilize the innovation or improve upon the innovation.

The SoC Questionnaire contains 35 items representing the seven stages. Respondents are asked to rate each item on a scale of zero (not true of me now) through seven (very true of me now). Peak or predominant Stages of Concern, and the relative intensity of the other concern stages, are plotted from the percentile scores (Hall & Hord, 1987).

A Stages of Concern profile graphically represents the relative intensities of each concern toward an innovation in each of the seven Stages of Concern. The profile pattern, taking note of the highest peaks, characterizes the concerns of a nonuser, inexperienced user, experienced user, or a renewing user. The shape of the concerns profile typically...
changes as the user moves through the change process, shifting from an emphasis on self-concerns to task to impact concerns.

During the course of this study, SoC Questionnaires were administered to participating student teachers on three separate occasions. The questionnaires focused on the student teacher's concerns about integrating technology in the classroom. Questionnaires were administered during the student teacher's regularly scheduled seminars. The first questionnaire was used to establish a set of baseline data; the remaining two questionnaires were used to determine how their concerns changed during the course of their student teaching experience.

Levels of Use. Levels of Use provides a key ingredient for understanding and describing the implementation process of an innovation. Data collected from LoU interviews can provide useful insights about staff development, evaluation, planning and facilitation for leaders and change facilitators. According to Hall and Hord (1987), Levels of Use focuses on the behaviors that are or are not taking place in relation to the innovation. The Levels of Use include three nonuser descriptions:

0. Nonuse—little or no knowledge of the innovation.
I. Orientation—acquiring information about the innovation.
II. Preparation—preparing to use the innovation and five user descriptions (Hall & Loucks, 1976):

III. Mechanical—focused on the mechanical day-to-day aspects of using the innovation.
IVA. Routine—comfortable with the innovation with little preparation and not planning to change how the innovation is used.
IVB. Refinement—working to improve their personal use of the innovation.
V. Integration—is working with colleagues in a collaborative effort to use the innovation.
VI. Renewal—reevaluating the innovation seeking to make major modifications to the innovation.

Typically a person will move in sequence from Level of Use 0, Nonuse, to Level of Use IVA, Routine; assuming that the innovation is appropriate, the leader and other change facilitators fulfill their roles, and time is provided.

In this study, an LoU Interview was conducted with each student teacher at the conclusion of their student teaching experience to determine their Level of Use upon exit from the program. The student teacher's Level of Use will, in part, determine their ability to integrate technology within the classroom as part of a greater systemic change.

Data Analysis

A percentile score was determined for each of the seven stages in the SoC questionnaire. Participant's scores formed a profile that was examined qualitatively. The LoU Interviews were scored using a rubric created by Hall and his associates at the University of Texas. The rubric provides a behavioral description of each LoU relevant to:
(a) knowledge, (b) acquiring information, (c) sharing, (d) assessing, (e) planning, (f) status reporting, and (g) performing. The data obtained from individual student teachers were compiled and comparisons made between student scores. Trends were identified and outliers explored in greater depth.

Results

Stages of Concern

For students entering the student teaching experience, their Self concerns (awareness, informational, and personal) were high. Task and Impact concerns were less evident. Previous research, indicates that this should be expected. “Concerns at this point have to do with feelings of potential inadequacy, self-doubts about the knowledge required, or uncertainty about the situation they are about to face. Typical statements reflecting these types of concerns are: ‘I wonder if I know enough to teach them.’ ‘Will I be able to control them?’” (Hall & Hord, 1987, p. 57).

The results of the second SoC indicated higher Task concerns (management). This instrument was administered midway through the semester. As student teachers transition into the role of teacher, concerns regarding: logistics, classroom management, and preparation are expected to increase (Hall & Hord, 1987). As students begin to observe the new role of the student teacher, they place added demands on the student teacher's time and on their ability to manage the classroom.

As the student teachers progressed through their student teaching experience, Impact concerns (consequence, collaboration and refocusing) increased in intensity. “Ultimately, teachers can become predominately concerned about how their teaching is affecting students and about how they can improve themselves as teachers” (Hall & Hord, 1987, p. 57). At the conclusion of the experience their overall concerns regarding instructional technology were intensified.

Levels of Use

Upon exiting their student teaching experience, the student teachers' LoUs ranged from Level I through Level IVA. The percentage of nonusers was 20%, while the users were 80%. However, the heaviest grouping of users were Level III, Mechanical, at 54%. The remaining student teachers were at Routine LoU. Only 26% of the entry level teachers are prepared to integrate technology within the classroom.

Discussion

The first use of an innovation tends to be disjointed and erratic: Most new users cling to the user's guide and concentrate on the day-to-day uses more than considering long term uses. Hall and Hord (1987) indicate that individuals typically remain at the mechanical level for an
extended period of time. As the user becomes experienced, they move into Level of Use IVA, Routine. Once a user reaches a Routine Level of Use, they typically fall into a comfortable pattern for using the innovation. As users move toward the higher Levels of Use (IVB Refinement, V Integration, and VI Renewal), adaptations are intended to improve the effectiveness and positive outcomes of using the innovation (Hall & Hord, 1987). The user’s focus is on increasing effects with students.

Systemic integration of technology depends upon the faculty and staff receiving training and guidance if the vision is to become reality. This is a process that should begin with student teaching and extend through the first few years of actual teaching. Many preservice teachers leave college using the skills they have learned at a mechanical level of use. This level of use is easily deteriorated (Hall & Hord, 1987). Mechanical level users fall back on their most comfortable methods which are not always productive. To ensure that novices progress beyond a mechanical level of use so that they can participate in a systemic change effort involving the integration of technology within the classroom, a procedure for mentoring them in the continued use of instructional technologies should be instituted. In this program, student teachers progressed through the Stages of Concern as expected. During the mentoring process the concerns of the student teacher must be addressed to help them adopt the innovation.

Teacher preparation programs must model the integration of instructional technologies within effective instructional practices that will prepare preservice teachers to facilitate classrooms which are rich, informational, computer-mediated environments (Bandura, 1986; Fullan, 1993). Research on educational change strongly supports the notion that innovations will not be implemented in schools simply because the change makes sense and meets specified needs (Fullan, 1991). Modeling promotes adoption by socially instructing people about new ways of thinking and behaving as they demonstrate the innovation.

**Summary**

The adoption of instructional technologies and the movement through the change process requires time and appropriate intervention strategies to be successful. This study has presented a perspective for the integration of technology within the classroom through a systemic change process. One means of achieving this is through modeling and mentoring technology integration within the teacher preparation program. The components of CBAM can be used to bring about systemic change in education by evaluating progress in the change process. The concern-based approach requires the understanding that a school does not change until each individual changes throughout the whole system (Hall & Hord, 1987). Concerns and use data, along with the mentoring of preservice educators, can provide a foundation for a ground-up approach to effect systemic change in education.

Project Infusion, funded by the U.S. Department of Education's Fund for Innovation in Education, sought to address the teacher training needs created by Hurricane Andrew in 1992 and proposed a training model that had the capability of directly influencing the training of personnel in instructional technology at the elementary school level across the entire school district.

Submission of the grant application was made by the Educational Computing and Technology department of the Adrian Dominican School of Education at Barry University, in collaboration with Dade County Public Schools (DCPS) in Miami, Florida.

The purpose of this project was to develop, implement, and evaluate a model for providing district-wide teacher training in the use and integration of instructional technology to achieve curricular goals that are competency based and designed to be world class standards.

Barry University proposed a training-of-trainers model to conduct system-wide teacher training to help teachers utilize and integrate available state-of-the-art technology in the teaching of math, science, social studies, language arts and English as a second language. The seminal works by Joyce (1990) and Joyce and Showers on effective inservice education (1983, 1988) and Joyce, Showers, and Rolheiser-Bennett (1987) served to guide the development of the Infusion training model.

The key components of the Infusion model included:

- best practice in teacher training/professional development;
- levels of training: university, school based, and parent;
- competitive recruitment of teachers to be trained;
- intensive, graduate level training of project teachers;
- administrative involvement at all levels of project;
- mentoring and follow-up of trained teachers responsible for training personnel at their school sites.

Each project year, a team of two elementary school teachers per school were competitively selected from applications from Dade County Public Schools and interested private schools. Using grant monies, selected teachers received tuition remission at Barry University for 6 graduate credit hours in Educational Computing and Technology which they could apply toward 1) state recertification requirements and/or 2) a master's, specialist, or doctoral degree in Educational Computing and Technology at Barry.

The first course was ECT 680, Integrating Technology in the Elementary Classroom, a three-credit course that included a comprehensive examination of instructional technology, learning theory and research in the field, competency-based curriculum and technology, models of teaching and learning with technology, and integration of instructional technology across the elementary curriculum. Instruction for each of the sessions was provided by the project director, who is a faculty member from the Educational Computing and Technology department at Barry University, and the teacher on special assignment from Dade County Public Schools.

The second three-credit course, ECT 690 Teachers, Training, and Technology, was designed to be a practicum during which project teachers 1) developed, with their principals and/or school management teams, teacher inservices at their school sites; 2) carried out training with Level II teachers at their schools in collaboration with Barry University staff; 3) implemented their personal technology infusion plan and evaluated its effectiveness; and 4) collaborated with teachers at their school sites to develop classroom infusion plans and parent training activities.

The Project Infusion trainers were supervised and mentored by project staff during the practicum course in a type of "clinical" follow-up as they conducted inservice training at their respective schools for their colleagues.

Project Infusion's design and implementation has been described in previous articles (LeBlanc, 1995, 1996) and in the final evaluation report, all of which can be accessed from the Infusion web site (www.barry.edu/adsoe/infusion.html). The purpose of this paper will be to describe the results of the project and to discuss the lessons learned from a teacher trainers' perspective that could translate into best practice in teacher education in technology.
Project Results

During the three year period, 248 teachers representing 125 elementary schools completed both courses in Project Infusion. Ninety-six public schools, 1 Indian School, and 28 private schools were involved in the project. Fifty-seven percent of these schools were Chapter I schools. Two hundred eighteen (87%) of the Infusion teachers were female, and 32 (13%) were males. Most of the participants were classroom teachers, and 12 were administrators. Participants came from a variety of teaching assignments, including self-contained elementary teachers, middle school sixth grade teachers, teachers from special programs such as exceptional student education and alternative education, computer lab teachers and coordinators, bilingual/ESOL teachers, and resource teachers.

A total of 1,905 Level II teachers were trained by Infusion teachers at their schools with an average of 14 teachers at each school site and a range of 1 to 88 teachers. Infusion teachers provided a total of 1,542 contact hours of training, with the average being 11 hours and the range being 1 to 75. (The numbers of hours at school sites is reported as only the hours for completion of 690. In most cases, additional training, mentoring, and follow up at the schools were provided by the Infusion teachers, but were not included in the summary of total hours.)

Because of its documented impact, Project Infusion was one of nine projects statewide identified as an Exemplary Initiative in Math, Science, and Technology Related Education in Florida's College and Universities by the Florida Department of Education's Post Secondary Education Planning Commission during the second year of the grant.

At the end of the third year of the project, a survey was developed by the project director and project evaluator and sent to all but 40 of the most recent Infusion participants. This survey was designed to 1) obtain a measure of instructional technology usage by Level I teachers before and after participation in Project Infusion, and 2) probe the impact of the project on the individual, the teachers, and on students. The range of time that had passed after participation in the first course for Project Infusion was from 6 months to 2 years. The return rate for the survey was 64% (134 respondents out of 208 sent).

Tests of dependent samples were used to compare the numbers of Infusion teachers using various technologies at least once a month prior to and after participation in Project Infusion. The results of these comparisons are displayed in the table which follows.

These results point to increased use over time of a variety of technologies to which the teachers were exposed during Project Infusion. Impact of the project was measured by the survey in the areas of impact on the individual participant's teaching, on the teachers at each school, and on the students at the school. The results of this portion of the survey are presented in Table 2.

</table>
The results of the analyses of the survey can be summarized as follows:

1) there were significant increases in the use of and in the variety of technologies used by teachers after participation in Project Infusion;
2) Infusion teachers reported the project as having a great impact on their comfort level using technology, the use of technology in their classrooms, and their ability to integrate technology in their instruction;
3) Infusion teachers reported that the project had a moderate impact on the teachers at their schools in terms of comfort, classroom use, and integration of technology;
4) teachers reported moderate impact on student learning in all subject areas except social studies, which showed minimal impact.

We believe that the project’s impact will continue to grow as access to technology increases at the schools and as teachers’ personal and instructional use of technology continues to develop over time. Other documented measures of Project Infusion’s impact include:

• 19% reported that they moved to a different school or took a new job assignment as a direct result of participation in Project Infusion.
• 17% received honors and awards directly related to the infusion of technology including 4 nominations and 1 award for the district’s Technology Teacher of the Year.
• 30% joined the Dade County Chapter of Florida Association for Computer Educators (FACE) and currently, three of the officers of that organization are Project Infusion participants.
• 30% indicated that they had participated in additional technology-related training since completing Project Infusion, not including those who entered degree-seeking programs at Barry
• 14% authored articles about technology integration, presented at professional conferences, and served on technology advisory committees.
• 37 Infusion teachers participated in grant writing for technology, with a total of $2,301,731 awarded from state or private monies.
• 20% entered the Masters, Specialist’s, or doctoral programs in instructional technology at Barry as a direct result of their positive experiences in Infusion.

In short, we believe that Project Infusion has been very successful in achieving its goals of district-wide infusion of technology across the elementary curriculum and in building the district’s capacity to support instructional technology.

Critical Success Factors

The following factors have been identified by the project director and the project evaluator as being critical to the successful implementation of this staff development model.

At the university level:
• outstanding, hard working project staff and excellent managerial processes;
• appropriate training facilities, equipment, courseware, and technical support;
• administrative and academic computing support at the university;
• competitive recruitment of teachers;
• team teaching;
• telementoring;
• school site observations;
• curriculum and delivery that models the sorts of behaviors expected from the trainers when they integrate technology in their classrooms;
• robust, challenging curriculum which emphasized the reasons for integrating technology vs. how to integrate technology;
• reflection on the day’s activities via journal writing.

At the school sites:
• access to technology;
• administrative support;
• training incentives: money, time, equipment, courseware;
• voluntary participation;
• careful needs assessment and analysis of the school’s capacity to fill those needs;
• careful planning of workshops;
• enthusiastic and patient trainers who can think quickly;
• workshop content which acted as great “hooks” to technology;
• hands on learning;
• partnerships, both trainers and trainees;
• strong trouble-shooting skills;
• time for reflection/closure;
• realistic and fun tasks;
• involvement of Infusion staff;
• inclusion of parents, students, and administrators in workshops;
• employment of strategies to create a critical mass of trained teachers at schools.

At the district level:
• cooperative employment of teacher on special assignment;
• free access to DCPS school mail in order to provide consistent communication between Infusion teachers and project staff;
• announcements of opportunities for additional funding of technology-based projects through state-funded technology incentive grants, Chapter 6 funds, and other funding sources.
Although the majority of Infusion training sessions were overwhelmingly successful, the project director observed some common problems at school sites worth mentioning:

- need for technical support and/or trouble shooting capabilities;
- trainers tried to cover too much in too short a period of time;
- trainers provided too much lecture/talking before hands-on time;
- teachers ran out of time, leaving no time for closure;
- lack of articulation of training with overall technology plan;
- too many people in the session;
- assuming the people knew more or less than they did and not allowing for individual differences during instruction;
- inappropriate beginnings and endings of sessions;
- lack of alternative plans b and c.

**Replication Issues**

The Infusion model for teacher development in the use of instructional technology can be replicated at other universities fairly easily with a few important caveats which follow.

At the University level:

- the university and department must recognize the value of this type of model and support it by means of course load reductions, especially for mentoring and school based observations, both of which are very time consuming;
- the university should have a level of computer-based technologies and courseware sufficient to support instruction which is innovative and enlightening. However, these technologies need not be available for each student in order to be effective. Students can rotate through technology learning stations just as they might in their own schools;
- the university’s academic computing division must support the program, particularly in the areas of email/telecommunications, help desk response, and technical support in the teaching labs;
- the registrar’s office must cooperate with the program to ensure the smooth operation of a program like this one where teachers are finishing their practica at times which do not coincide with regular grading periods.

At the School level:

- access to instructional technology is imperative, even if the access is not optimal in terms of numbers and types of technologies available;
- administrative support for teachers who want to integrate technology in their teaching is vital;
- incentives and continuing professional development activities should be provided for teachers who actively infuse technology into their instruction;
- appropriate technical support is vital to the success of any school based technology integration plan.
- teachers must have a vision of where their school might go with technology and be willing to seek means of supporting that vision.

**Dissemination Plans**

The results of Project Infusion will be disseminated in a variety of ways. Currently the project has its own WWW server which anyone can use to access teacher-developed training materials, school action plans, course syllabi, and other materials developed by project staff. A group of Infusion “tech-perts” are linked to the web site and are available for advice and support to other teachers via email. In addition, ECT 680 and 690 will be offered by the project director as distance education courses in the spring of 1997 to any interested teachers in order to further broaden the impact of the Infusion model. Video footage of several project teachers using technology has been edited by the project director and will be used as part of a weekly instructional TV program called “Techie Tuesdays” in order to model and share with a district-wide audience the exciting things teachers are doing with technology as a teaching and learning tool.

**Conclusions**

Using the training of trainers model, 68% of all of the public and private elementary schools in Dade County were trained during a three-year period, with two people at each school having had graduate course work in the integration of instructional technology across the elementary curriculum. These teachers have already directly impacted more than 5,900 students. In addition, 1,905 teachers and administrators were trained at the school sites by Infusion teachers. These teachers will in turn affect approximately 45,000 students each year. We believe that this model has proven to be a highly cost effective method of providing high quality teacher training in state-of-the-art instructional technology and that the benefits of this infusion of technology training will continue for many years to come.

We also conclude that university based teacher development is the most cost effective means of promoting professional development and growth in instructional technology for a number of reasons:

- university courses provide more long-term instruction and follow up than typical school-based inservices using existing faculty or consultants;
- university courses tend to last longer than most teacher inservice courses, providing more time for practical application and assimilation of information into the teacher’s existing instructional paradigm;
graduate instructional technology course work tends to focus on the reasons for using technology—the “why?” questions—rather than focusing on the “how?” questions most often seen at school based teacher inservices;

• exposure to new and emerging technologies along with innovative strategies for integrating those technologies at the university tends to “raise the sights” of teachers to see what is possible and desirable, while school based inservice tends to emphasize what exists and how to use it;

• bringing teachers together from different schools generates enthusiasm and motivates teachers to try new things at their schools, rather than to focus on the barriers to the integration of technology at their particular school.

Acknowledgements

PROJECT INFUSION was funded by the Secretary’s Fund for Innovation in Education, U.S. Department of Education. Project funding amounts to $594,500 for three years. This level of funding represents 54% of the total cost of the project, with Barry University contributing the remaining 46% of the cost of the project.

With the advent of multimedia technologies, today’s teachers have opportunities that were hardly dreamed of 20 years ago. The ability to easily access video, sound, animation, still pictures, and text from one single control and to quickly choose between them or even to use more than one at a time, allows the teacher and the students to bring greater drama and reality into the classroom.

Just as with any powerful tool, it is only as good as the skill of the artisan directing its power. In order for any tool to be useful in the classroom, the teacher must know how to wield it appropriately. Multimedia is no different. It will only affect the quality of learning in any class to the degree that the teacher can use it effectively. Merely showing a movie to students will not ensure that they have learned anything. The teacher must know how to prepare the students so they know what they are watching, why they are watching it, and how it will affect their lives.

In the Spring of 1995, US West awarded a grant to a consortium of North Dakota State University (NDSU) and Valley City State University (VCSU), Center for Innovation in Instruction (C.I.I.), and 46 public school districts. The grant provided funding to produce training and called for a collaborative effort between the universities, the C.I.I. and the school districts. The purpose of the grant was to help teachers bring the power of multimedia into their classrooms and to build collaborative relationships between universities, K/12 schools and technology experts.

That summer a development team was brought together to begin the process. The team consisted of members from the universities, the C.I.I., and several of the school districts. The development tool chosen was Systematic Curriculum Instructional Development (SCID) from the Center on Education and Training for Employment, The Ohio State University (Hoskisson, Stammen, Nelson, 1996).

In the Spring of 1996, with the skills of public school teachers, district technology directors, computer scientists, instructional designers, and university methods teachers the first phase of the grant was finished (Nelson & Sologuk, 1996; Stammen, 1996). The team had produced the paper version of the training that would then be turned into a multimedia CD-ROM and be made available on the World Wide Web (WWW).

From Paper to CD-ROM: Making the Transition

Because the grant called for a collaborative effort, the team chosen to make the transition from print to CD-ROM retained the same diverse character as the original development team. The members included a professor of computer science, a director of a campus multimedia center, a sixth grade teacher, a school district technology coordinator/elementary teacher, an instructional designer, the assistant director and a training coordinator from the C.I.I., a graduate assistant, the assistant superintendent of a parochial school, and a campus web master.

Problems

The transition team leaders met early in May of 1996 to review the existing material and plan for the first full team meeting. The leaders quickly discovered that no one had a good overall picture of the materials developed. Up to that time, no one had taken all the material and checked it for thoroughness and completeness. Therefore, a review of all of the modules was conducted. One review looked for redundancy among the seven modules. Another review checked the thoroughness of the treatment in each module. The seven original modules, referred to as guides, were: (a) Acquire Basic Computer Skills, (b) Improve Curriculum with Multimedia, (c) Deliver Instruction with Multimedia, (d) Utilize Support Services, (e) Enhance Teacher Communication with Multimedia, (f) Promote Multimedia in the Classroom, and (g) Pursue Professional Development Related to Multimedia.

As the team leaders examined the print version and pursued their planning, it became apparent that there were several problems that needed to be solved in order to make a successful transition from print to CD-ROM. The problems were inherent in the process of turning a linear print project into an interactive CD-ROM and coordinating
the work of a geographically dispersed team with varied backgrounds and experience.

The reviews pointed out several areas that needed work. The concerns could be grouped into two main categories: concerns about the design of the material itself and problems in coordinating and working with such a diverse team.

Concerns about Design. There was considerable overlap between some of the modules. Much of the material was extraneous or even unnecessary. Some of it was nice to know but was not appropriate for the main body of instruction.

The reviews also showed that there was not much interactivity. Because of the nature of the planning tool used in the first phase, the modules were well-designed for print but not for interactive media like CD-ROM and the WWW. Most of the development team members had little or no experience in developing a dynamic medium like multimedia. It was difficult for them to go beyond the design tool and think in terms of interaction between learner and learning material.

Problems in Working with a Diverse Team. Geographically there were difficulties, also. Initially four of the ten team members lived and worked up to 60 miles away from the rest of the members. Before the transition was over a fifth member had moved to North Carolina.

Along with geographical dispersion, team members had other jobs and responsibilities. Four were taking graduate courses as well as working. Finding time when people could meet and then getting everyone there proved to be a tremendous task.

The Final Dilemma. The final dilemma was the choice of authoring system for producing the CD-ROM. The tools that were considered were HyperStudio, HTML, and Director. The main consideration in selecting the possibilities was cross-platform compatibility. Only a few members of the team had any experience with multimedia authoring systems. One member of the team had written and produced a CD-ROM using Director. One other member had experience with Director. Two other members had some experience with authoring tools. Choosing a tool that was cross-platform capable and that all the team members could learn quickly was the task.

Solutions

The transition team met together for the first time on May 28, 1996. For the next two days they worked on defining the process that they would use to produce the CD-ROM and WWW versions.

Design. During this meeting the team coordinator proposed that the original seven guides be changed to: (a) Preparing, (b) Planning, (c) Producing, (d) Presenting, and (e) Promoting.

He then showed how all the original guides could be rearranged to fit into these five new guides and at the same time eliminate the redundancy in the originals. This proposal was based on the planning discussions of the team leaders prior to the full team meeting. The new arrangement was accepted by the full team. With only five guides and the redundancy reduced, it was much easier to maintain an overall picture of the material. It was also easier to check for thoroughness because the various concept treatments were consolidated.

Initially, it seemed that the lack of interactivity would be more difficult to solve. However, as the transition team proceeded they found that, though there were checklists and some questions in the paper form, the learner was actively involved in many hands-on projects. For example, in the Preparing guide aimed at computer novices, the learner was not just reading material and answering questions, but was busily engaged in physically setting up a computer and learning how to turn it on and run it. Later, in the Producing guide, the learner actually produces a multimedia project.

What the team did discover was that the guides did not take advantage of multimedia in the learning process. The whole project could be printed and used without any technology. Therefore the team decided to collect samples of multimedia projects created by classroom teachers. In addition, they embedded an example into the guides that would be developed as the learner progressed through the material. This would enable the guides to actually model what they are teaching. There is still a year of development time left and the team will continue to look for ways to improve the learning experience using multimedia.

The nice-to-know material was placed in an appendix. The team felt it was too good to just throw out, and, while not needed for the instruction, it was helpful and related material.

Diversity. As the team discussed the problems of working together with such great diversity, they realized that they would be more successful if they:

- organized smaller specialized teams that could meet together more easily than a large team could;
- prepared a timeline to follow;
- took advantage of the Higher Education Computer Network (HECN, the North Dakota University System computer network) and SENDIT (the North Dakota public school computer network) for communicating between meetings and sending in work; and
- agreed on a set of design protocols to ensure a more consistent construction and appearance of the material.

Although these decisions did not solve all the problems of coordinating the team, they provided enough of a solution that the work was able to proceed relatively smoothly that summer. Most of the work followed the timeline closely. Everything went well until it was time to put everything on the Web site. Despite our design protocols
and frequent communication, the final guides were quite inconsistent in some areas and many small problems surfaced. It took the web master two months to clean everything up and get it ready for review by the grant administrator and the final editing phase.

Dilemma

In retrospect, choosing a development tool was perhaps one of the easier decisions that was made. Since the intent was to not only have a CD-ROM available for schools to use but to make all the guides accessible on the WWW, HTML was selected. Director, though capable of producing for the web, was too difficult for the team to learn in the time allowed. HyperStudio would be easier to learn than Director, but the team decided to go directly to HTML and save any "middle men." The transition team was not familiar with HTML so two training sessions were held to give them enough knowledge to get started. They used an HTML editor and Claris Home Page for creating the pages.

The Project's Value and Lessons Learned

Despite the pitfalls and the arduous efforts to negotiate all the twists, turns, hills and blind curves of such a collaborative project, all those involved felt that it was worth the sweat and pain. Why was it worthwhile and what was gained that couldn't have been achieved using a smaller and more experienced design team? The answer is simple: relationships and commitment.

One of the most important results of the grant is that there now exists an active, working K-12/university relationship that is much broader than anything that existed before. The members of the various teams represented more than five different districts, two universities, and a statewide public school technology support center. Add to these the remaining 41 school districts and the extent of the relationship begins to spread across the state.

Another valuable outcome of the collaboration is that there is now a commitment from 46 school districts to train their teachers in the use of multimedia. The superintendents all wrote letters of commitment saying that they would support the grant efforts. Selected teachers will be trained using the material and equipment provided by the grant. These teachers, in turn, will train other teachers in their respective schools. If all goes well, the effect will ripple out from these initial trainers throughout the entire school district until all the teachers who so choose will be trained to integrate multimedia into their classrooms.

The commitment from the superintendents was shown from the beginning of the project. Those members of the development team and transition team who worked in the public schools were given time and encouragement from their principals and superintendents to participate in the project. Their principals found substitutes for them as needed to work on the grant.

Conclusion

One purpose of the teacher guides is to help inservice and preservice teachers learn to use one of the most powerful tools that teachers have ever had. Perhaps the only influence in the classroom that is more powerful is the teacher herself. A quality teacher with a dynamic and versatile tool like computer-driven multimedia can work wonders in a child's life. It is the hope of those involved in the grant that the guides will help make the power of multimedia a reality in the classroom.

The second purpose, building a collaborative relationship, has been accomplished as witnessed by the number of different entities involved in the work and which will benefit from the guides. The relationship has been made. It remains to be seen how well it can be maintained.

1078 Technology Diffusion — 1075
As a school district's technology planning, often done by committees with members representing different interests, combines a variety of stockholders' views. Through discourse, the committee constructs a meaning for technology. The result, for the planners, is a paradigmatic truth which is credible, authoritative, evokes a loyalty to that vision, and is complete with roles, values, assumptions, and logic. In this way, school district technology plans serve as symbolic discourse, representing official ideology about technology and, in so doing, about teachers' and students' roles. However, if all implementers of technology did not participate in constructing the plan, or if it is not explained completely, they may not have the same values, assumptions and logic regarding why technology is needed and the role it is to play in the classroom. While planning committee members consult the technology plan to make meaning, to prioritize implementation activities and to judge proper and improper uses of technology, others who did not write the plan, but who are involved in technology implementation may use other (often unstated) criteria to make decisions. This differential interpretation can result in a "collision of visions" with all sides convinced of the sanctity of their actions.

This practitioner-researched, two-year case study of one large, suburban school district utilizes Bruce Lincoln's conceptualization of taxonomy and myth (1989) to analyze the district's technology planning and implementation efforts. The findings illustrate how the official discourse of the technology plan was used to promote one pole of the technology taxonomy that evolved during these two years. Opposition to this view came both from the other pole in the taxonomy—a vision of technology use that was nearly opposite the vision expressed in the official plan. The subsequent struggle by planners to establish the official vision for technology as dominant in this organization illuminates the struggles and confusion many school districts face as they attempt to realize the promise behind educational technology visionaries' rhetoric.

Methodology

This case study explored various district stockholders' views of the use of technology in education. I utilized a case study design to study the technology planning and implementation in context. Data was collected over a two year period through multiple sources: observations, informal interviews, and on-site documents.

Participant observation was my data-gathering mode throughout the study. Sometimes I served more as a participant, such as when a member of technology advisory committee and fulfilling the role of the technology staff developer for the district; this allowed me "insider" access to both technology talk and critical site documents. Insider technology talk I was privy to included informal technology strategy discussions and meetings, and the thoughts and musings of the administrators charged to plan and implement technology. Insider access to site documents included technology committee minutes, and other internal documents such as focus group data and drafts and revisions of documents that would become the official district rhetoric on technology.

At other times I was more of an observer to decision making regarding technology planning and implementation. This included when I acted as a consultant to technology teams from individual school sites and when technology planning and implementation decisions were made by district administrators "above" me in the hierarchy and without my input.

Data was coded for themes and analyzed at several points throughout the two years. Symbolic Interactionism informed my data collection and analysis. In Symbolic Interactionism Blumer describes interpretation as a "process of handling meanings" (1969, p. 5). Thinking of interpretation as an active, mental engagement with the surroundings underlies the Symbolic Interactionism premise that what people do is related to what they think they're doing, what others think they're doing, and what they think of other's opinion of what they're doing. In Symbolic Interactionism, to understand the behavior of
people in the presence of an object, we must understand the
symbolic meaning they give to it and how they created that
meaning. This underscores the importance of how the
technology plan’s official discourse reads and which pole of
the technology taxonomy is dominant as influential on how
computers are encountered and used by teachers in this
school district.

The Evolution of a Technology
Taxonomy

In order to coordinate and make more efficient technol-
ogy purchases for the district’s 27 schools, the Superinten-
dent started a technology planning committee in the spring
of 1993. The committee, with membership representative
of the various district stakeholder groups, met twice a
month during the 1993-94 school year and arranged
district staff and community member focus groups on
technology, conducted site visits to school districts with
recent technology implementations, reviewed technology
literature such as other district’s technology plans, and then
wrote the district’s plan.

Analysis of the technology plan and focus group data,
yielded two quite different ways of thinking about why to
place technology in schools and the role it should play
There. I have named the two categories “Technology, Then
Uses” and “Uses, Then Technology” to emphasize their
contrasting objectives, values, and logic. During technology
planning in this district these two categories gradually
evolved into a taxonomy, a binary arrangement the poles or
categories of which express hierarchically the ways of
thinking about a subject. In Discourse and the Construc-
tion of Society, Lincoln (1989) describes taxonomies as
epistemological instruments: “a means of gathering,
sorting, and processing knowledge about the external
world” (p.136). He goes on to explain that taxonomies
allow us to organize the experiences and ideas of our world,
as we put concepts into our taxonomy categories, it allows
us to categorize not only our experiences and information
but ourselves, others, and their ideas and views.

Interestingly, both categories have similar assumptions
about technology underpinning their categories’ objectives.
One assumption is that schools should have technology and
teachers and students must learn how to use it. There is
nearly universal agreement among community members
and educators in this district that students and their
teachers must become technologically literate. A second
assumption is that technology should serve as a helpful tool
for educators and students in doing their work. Again,
nearly universally, all parties agree that technology would
help students and teachers do their work. However, even
though all parties worked from these assumptions, two
major categories of thought developed with different
objectives. These objectives are the basis for the binary
oppositions of the technology taxonomy.

Technology, Then Uses

This category represents the majority of opinions
expressed during the focus groups. These views were
expressed by the group members who represented students,
licensed and non-licensed staff, and community, as well as
the district’s administrative cabinet (the Superintendent
and his five directors). In this category getting equipment,
getting trained in its use and having technical support for
the equipment’s use is the main concern. Uses for the
equipment focused on day-to-day work including accessing,
handling, and coordinating data so that records and
communication could be transmitted easily all over the
district.

For the Technology, Then Uses category, technology is
a tool that helps teachers do their work. Technology allows
faster access to data and provides a tool for working with
the data more easily and with greater sophistication. The
value of networking a school and providing teacher
workstations and grading software is that it allows teachers
the opportunity to automatically calculate students scores,
send them to a main server, and allow the office to compile
report cards, all without paper.

The focus group responses indicated that the members
of the Technology, Then Uses pole valued the equipment as
most important, getting connected to data as their next
most important value, and training in computer uses as
third. Responses indicated that with the technology in
place, administrators and staff would then determine uses
for it by themselves and their students. The logical basis of
this category is that software and hardware can be a time-
saver for doing work and clearly, administrators, teachers
and learners have a considerable amount of work to do. In
addition, there is recognition that beyond school, everyone
has computers and students need to know how to use them
to survive.

Uses, Then Technology

The other category, or pole, of the technology taxonomy
sums up appropriate uses of technology identified in the
official district technology plan. This official document
represents what I call the Uses, Then Technology category.
The technology plan mentions the hardware and technical
support that the focus groups addressed and added to nearly
every statement “for curriculum and instruction” or “for
teaching and learning.” These added phrases about why
equipment would be purchased and what training would be
needed creates a rationale for the technology plan that
members of the focus group did not articulate. The Uses,
Then Technology category members recommended
placement of technology in classrooms only after a school
site had defined specific educational objectives that made
use of the technological capabilities.

For the Uses, Then Technology category, technology
helps teachers, students, and administrators do their work,
but it is new and different educational work—work that without technology would be impossible to do. For example students can: use the Internet to conduct research and publish their findings on Web pages, construct databases and use Boolean logic to search for relationships in the data and test hypotheses, and use e-mail to share and compare knowledge with students in other countries. The technology should provide the necessary tools to assist teachers to teach in an interdisciplinary manner, transform students into compilers and users of information, aid more authentic assessments, encourage higher levels of thought and creativity, and allow individualization of instruction.

The Uses, Then Technology category promotes technology as a tool with capabilities that will help achieve instructional outcomes beyond what schools currently are doing. Changing current educational practice is a primary concern. Another critical factor in this category is training staff in the use of technology. If technology use is not internalized, it can not be a part of a teacher's instructional thought. The logical basis of the Uses, Then Technology category is that educators will first redefine what their work is, and then technology will allow initiatives that, before access to technology, seemed impossible to implement. For this category, technology use only makes sense when it is directed by specific curricular and instructional goals.

Lincoln's work points out that it is the dominant group that can claim they are the "good" side of the taxonomy and that the other side (its binary opposite) is "bad." In so doing the dominant group can appear as if it is classifying along innate lines and make it difficult for the other group to gain a hearing. In this way taxonomies can construct social order. But which pole of this taxonomy is dominant? Clearly, the Technology, Then Uses category had number-dominance, the focus groups provided a view that expressed the conventional wisdom in the district about technology. The Uses, Then Technology category had voice-dominance in that the official technology plan for the district reflected their ideology. However, this dominance existed mainly on paper. As the technology planning efforts of this district turned towards developing a budget for the technology plan and implementing it, the struggle began.

The Struggle for Ideological Dominance

When the school board unanimously endorsed the plan in the Fall of 1994, funding the plan became the next step in the process. Because of their emphasis on access to information and communicating knowledge, the technology planning committee ranked infrastructure wiring, local area networks and a wide area network as top priorities and recommended funding in these areas to the Cabinet. However, the Cabinet (the superintendent and his five directors) created the budget that was actually presented to the school board. The authority to set the agenda for funding, in effect, gave them control over technology implementation. Cabinet members who did not identify with the constructivist orientation of the plan used other criteria regarding what technology should do and be for in the classroom and thus had different implementation priorities.

For example, the director of elementary education supported the use of technology for learning skills and factual information through individualized learning systems. Consequently, her top priority for funding was to purchase this software and equipment for computer labs in all of the elementary schools. This view was in opposition to the constructivist orientation of the official plan but the district in which she had previously worked had utilized individualized learning systems and she wanted to replicate their use in this district. She actively opposed the installation of networks which she deemed unnecessary because they would direct money away from purchases of computers for in her schools. She pressured the technology committee to reconsider their prioritization, demanded an ad hoc "brainstorming" committee be formed to offer opinions on priorities for implementation, and indicated to the chair of the technology committee that she felt the committee had been "brainwashed" into supporting networks.

To other cabinet members what really mattered was the technology itself; acquiring hardware was the main goal. They focused on the hardware and network configurations in the plan. Technical issues like processor speeds, megabytes of RAM and hard drive space, video cards, network connections, hubs, routers, LCD display panels, scanners, and overall numbers of computers was the focus for these cabinet members as they talked about implementing technology.

After addressing funding issues for two months, the cabinet revealed their three-year budgeting plan at a school board meeting—where it was approved. Their budget was expressed strictly in terms of dollar amounts to be spent and the type of hardware allowed for purchase. Infrastructure wiring was funded and there was a per pupil dollar amount for computers (referred to as learning/work stations for instructional access by both students and staff). The secondary Director also funded the local area networks whereas the elementary Director divided the local area network installation in elementary schools into a three year project, finishing one third of the schools each year for three years.

While this budget did reflect the letter of the technology plan by funding wiring, networks, and computers, it did not reflect the spirit of the plan—the district technology plan's rationale was not referenced. Furthermore, secondary and elementary Directors allocated money directly to building principals who were only required to present their building's plan to the relevant director to receive approval for expenditures. This resulted in a wide variety of site-
based plans. Some school level plans had a rationale for technology use similar to the district technology plan, others merely listed the hardware they wished to purchase, and others planned for the use of individualized learning systems.

Following the release of the budget, the Superintendent created a technology advisory committee to advise district administrators and develop guidelines and plans for various aspects of technology implementation. According to the committees charge, this was to include monitoring implementation of the plan, creating selection criteria for hardware and software, reviewing all district technology purchases and tracking all planning components. The chair for this committee was the top administrator for technology services in the district. She had been Chair of the technology committee and all of the personnel with technology duties as part of their job description reported to her (i.e., repair, technical support, network management, staff development). She was also responsible for setting the standards for hardware purchases and coordinating the network installations, and received the phone calls when technology coordination or implementation problems occurred. However, she did not have any budgetary control for implementation.

Technology Plans as Official Discourse

Educational technology visionaries agree that a common view of the educational purpose of technology is the most important requisite for successful implementation. (Collins, 1991, Means, Olson & Singh, 1995, Newman, 1992, Sheingold, 1991) Although originally charged with effective and efficient coordination of technology purchases, the advisory committee’s emphasis clearly shifted to address issues of curriculum and focus that accentuated a constructivist view of learning. This view developed over the course of a year by committee members who developed a clear vision for the role of technology in the classroom. They returned to the vision expressed in the original technology plan, to “Empower learners through technology by providing all students and staff with access to information through voice, video, and data technologies for the purpose of processing and communicating information and ideas, and constructing knowledge.” This group went beyond including an educational rationale to justify all purchases and suggested that technology be used to support instructional reform.

In this way the committee created a paradigmatic truth about the role technology should play in schools. It should create increased access to information, allow teachers to serve as facilitators for students to use information to construct knowledge, and serve as the tool with which students communicate their findings and insights. The technology plan represented the official story of how to use technology. This vision for technology is not unique to these planners. Most visionary technology rhetoric, including the literature that the technology committee read while planning, promotes using technology as a tool in a constructivist learning environment (Metropolitan Educational Research Consortium, 1993).

The Making of a Myth

Lincoln (1989) describes such narratives as myths. His definition of myths demands that the stories possess both authority and credibility. In this way his definition of myth is more akin to what others might call a model, blueprint, or charter rather than the fairy-tale-like connotation of the word myth. He explains that by evoking a paradigmatic understanding of the way things ought to be, a myth can serve as a “coding device in which important information is conveyed, on the basis of which actors can then construct society. It is also a discursive act through which actors evoke the sentiments out of which society is actively constructed” (1989, p. 25, emphasis in the original). The technology plan served as an official myth that the technology advisory committee referenced as the “correct” way to use technology; the plan directed the educators of the district to consider specific uses of technology first, then the technology.

Lincoln also explains how politics can form around different myths. Which myths are told, by whom, and with which groups they are received and evoke a response makes visible the social borders present in organizations such as school districts. In this way the telling of myths create feelings of affinity and estrangement between individuals and groups as the myths evoke or rebut sentiments. Lincoln goes on to describe that the ability of a new myth to influence an organization and its power distributions is in the degree to which it can gain a hearing, be persuasive, and evoke sentiment.

Implications for Implementation

In this district the official discourse/myth of technology use represented one pole of the technology taxonomy that evolved. The analysis of this pole’s struggle for dominance provides insight into directing technology implementation—a high priority for many school districts across the nation. The district utilized their standard protocol of creating a committee with representative membership and charging it with several roles including developing a vision, planning, guiding, and implementing. However, the budget for technology implementation was held at a higher level of the district hierarchy and allocated directly to the building level. This influenced which pole of the taxonomy was able to gain a hearing and as a result there have been goals funded which deviated from the official technology plan.

At the end of the first year of implementation there are aspects of both technology visions in. The infrastructure wiring for the networks is done, local area networks are
complete in the buildings scheduled for them and the wide
area network, which will bring Internet access, is in
progress (Technology, Then Uses category members are
eager for a direct Internet connection). Individualized
learning systems are in the district schools with Title I
allocations as the Title I Coordinator was pressured to fund
the hardware, software, and technical support for this
project. The secondary subject areas worked with the
curriculum and media specialists during the curriculum
planning cycle to select software. In the elementary
schools, the software is chosen by individuals or grade level
teams in an individual school. As implementation contin-
ues, it appears that implementations of technology depend
on which of the competing taxonomy poles an individual
references.

Conclusion

The words on the paper of a technology plan matter far
less that the imagining, constructing, and myth and
meaning-making that occurs between those involved in
creating the plan. Technology planning treated as myth-
making can create a set of values and logic for technology
use that has the potential to transform education. The
impact of such a myth, Lincoln cautions, is limited to the
ability of the myth to gain a hearing and evoke sentiment.
If there are other conflicting accounts of how technology
ought to be used circulating, including the ubiquitous
Technology Then Uses account, a technology taxonomy
forms. If the creators of this myth are not the implementers
of the technology plan, or are subordinate to the controllers
of funds and decision-making, a “collision of visions” is
likely to result. Which pole gains dominance is likely to
determine technology use. When a particular goal is
desired, the technology myth, the authoritative, credible,
paradigmatic understanding of the way technology will be
used in the district, must be repeated often throughout the
implementation.

In the past decade, the number of computers in schools across the nation has increased dramatically. By 1994, 98% of American schools had one or more computers for instructional use in contrast to fewer than 20% of the nation's schools with at least one computer in 1981. This increase equates to approximately 5.5 million computers in schools across the country. (Mehlinger, 1996). The infusion of computers into educational settings has an enormous potential to impact the teaching and learning process when this technology become an integral part of classroom instruction. Unfortunately, the existence of larger numbers of computers on the nation's school campuses does not mean that students have daily (and as needed) access to these computers nor does it ensure that classroom teachers are comfortable and competent in integrating computers into the daily instructional process. The most common pattern of computer location is in laboratory settings with 20 or more computers which serve each classroom on a once weekly basis. Computers in elementary schools and in increasing numbers of secondary schools are used to teach basic skills and for remedial instruction. (Center for Excellence in Education, 1995).

Campuses which have computers distributed in classrooms, whether as stand-alone or networked units, tend to differ widely in the extent to which teachers and their students use computers as tools for instruction and personal productivity. This difference has been obvious to university, community, and school district personnel who have been in regular contact with the four campuses that are public school partners in the Lower Valley Center for Professional Development and Technology (LVCPDT). Funds awarded to the LVCPDT were used to provide computers for 12 classroom teachers at each of the four campuses when the program was initiated in 1994. From this even start, site-based-decision committees recommended use of additional campus funds for the purchase of more computers and other hardware to provide more teachers and students with classroom computers.

Each campus also had the services of a technology facilitator paid by grant funds who provided twice-monthly training in the use of technology and on-site assistance to teachers in response to their requests. By the end of the second year of funding, teachers and students at one campus demonstrated substantially greater, and more sophisticated, utilization and integration of technology across all grade levels. These observations led us to question what elements had contributed to create the obvious level of technological literacy among these teachers and students. Our questioning led us to a review of the literature and an analysis of the contributing factors that fostered the varied ways in which teachers and students used computers in the teaching/learning process.

Critical Leadership Attributes

Knowledge about technology and leadership attributes are critical components in ensuring the integration of technology across the grades. Campus administrators are the key to encouraging and supporting faculty in the development of computer literacy and the use of technology as a tool for instruction and student learning. By the late 1980s the importance of administrator knowledge and support was identified as a key variable in implementing educational technologies in the classroom (Mecklenburger, 1989). The role of the principal as an instructional leader and role model is critical for any campus desiring to change paradigms of instruction to embrace technology in formats other than computer-assisted instruction in isolated laboratory settings. Components of facilitative administrator behavior include acquiring a basic knowledge of hardware, software, and telecommunications; promoting site-based involvement in the development and implementation of technology plans; identifying and overcoming the human, fiscal and technical barriers to successful implementation programs; and providing on-going leadership for campus technology-related activities.

Campus Process and Outcomes

At the campus level, a deliberate process was adopted by the school administrative team (principal and instruc-
tional facilitator) to encourage teachers to transform traditional instructional programs into technology-enriched programs with the seamless integration of technology across the curriculum.

In order to meet the technology needs of all students and teachers, the campus administrators felt that there should be a system of checks and balances to assure that all computer hardware and software were being used effectively. Accordingly, the campus established a protocol for weekly technology "checks." This was based on the belief that "what is important gets monitored (or checked) and what gets monitored gets done." Major components of the monitoring plan put into place included: ongoing needs/satisfaction assessment, collaborative policy-making and goal-setting, training and support, administrative involvement and "modeling," fiscal commitment, recognition and sharing, and accountability.

Ongoing Needs/Satisfaction Assessment
Faculty, professional staff, and paraprofessionals responded to technology surveys at the beginning, midyear and the end of year to adjust training to their requests for technology training and additional equipment and software needs. Staff members also are encouraged to make recommendations that are used to make necessary adjustments during the year. By responding to teachers' needs and desires, training is tailor-made to fit the priorities of its recipients. The majority of the training is done by the CPDT technology coordinator, campus-administrators, campus computer lab managers, and district technology specialists. However, administrators and faculty frequently attend special training sessions or conferences where they receive additional specialized training. This specialized training is then shared with the rest of the campus so that all staff have the benefit of the new knowledge and skills.

Collaborative Policy-Making and Goal-Setting
The Campus Improvement Plan developed by the Campus Performance Objectives Committee (CPOC) and approved by all of the staff, gave technology implementation high priority. Thus, all technology integration activities have campus-wide support. The CPOC recommended that teachers submit technology samples on a weekly basis and that lesson plans reflect the integration of technology into instruction and student projects. The committee also set guidelines for when samples were due, what to include, and how they were to be shared with other teachers.

Training and Support
Every staff member (including paraprofessionals and office staff) is required to attend at least 10 hours of in-house or outside training in the area of technology. Training includes computer hardware, file management, the electronic gradebook, and grade/position appropriate software. All teachers have Texas Educational Network Telecommunications (TENET) accounts that allows them access to both the state information network and to Internet. Teachers have all received TENET training and are currently receiving training in using Netscape and the World Wide Web. All teachers also participated in training in using ClarisWorks, MS PowerPoint, Kids Desk, KidPix2, Grolier's/Compton's CD-ROM encyclopedia, and equipment such as scanners and Quicktake cameras.

Training for teachers at specific grade levels has also included software utilization such as Wiggleworks, Kidworks, Hyperstudio, Using a Spreadsheet, Thinkin' Things, and Inspiration. Finally, a core team of teachers has been trained in using the compressed digital interactive video equipment available on the campus. Teachers and their students regularly conduct video conferences with teachers and students in other schools to share information and learn from and about each other. Last spring, kindergarten students prepared and presented a video conference to eighth grade students in San Benito in which they described their science experiments and explained their findings.

Administrative Involvement and "Modeling"
The principal and instructional facilitator take advantage of every opportunity to become more familiar with, and knowledgeable about, computer hardware, software, distance learning equipment, software, computer applications in instruction and emerging trends. This means that they can serve as "resident experts" for their staff. Certainly, their knowledge helps to give them credibility among the members of the school community. However, the critical element that makes all of the difference is that they don't just know about technology, they are competent users of technology. The principal developed a very professional PowerPoint presentation last fall to show parents the campus performance profile at a district-required "campus report card night." Using a notebook computer and an LCD panel in the school cafeteria, the principal and a team of teachers presented a series of 25 PowerPoint slides to more than 200 parents.

The principal and instructional facilitator as well as the computer lab managers are all willing, and able, to troubleshoot when a teacher has a problem with hardware or software. Teachers do not need to wait for an outside technician to come in to help them or demonstrate how technology works. All communications with the school community and central office is done using various computer software. In fact, technology is so integrated into campus administrative and instructional activities that its use has become nearly effortless.

Fiscal Commitment
Every classroom has from one to three computers accessible to teachers and students with a wide variety of software that enables children to use the computer as a tool for expressing their ideas, for creating meaningful products
and for developing personal portfolios. Money is budgeted each year to meet the growing demands for upgrading hardware and adding needed software. Through flexible scheduling, teachers and paraprofessionals are able to participate in technology training during the school day several times a year. Funds are also budgeted to ensure that campus educators can attend technology conferences to learn more about effective use of computers in classroom settings.

**Recognition and Sharing**

Teachers and students are encouraged to share their technology knowledge and products with each other. Two very effective, and nearly effortless, vehicles for sharing are the Samples of Success (SOS) Wall and the bi-weekly newsletter for parents. The centrally located SOS Wall offers a new display each week of technology samples from each grade level in the various subject areas. Not only do teachers display computer-generated examples of effective lessons or materials, but students are also involved in the selection of the technology samples that will represent their room. They choose their best samples to be displayed on the SOS Wall.

Another means for giving recognition for the use of technology is in the scanned pictures and samples of student work that are included in the parents’ newsletter. These newsletters reflect children’s activities and often also include scanned pictures of students at work, or pictures taken with the Quicktake Camera. Teachers and administrators also have been asked to give inservice training to educators at other campuses or have had papers accepted for presentations at regional, state, or national conferences. This recognition serves to encourage teachers to keep learning and growing.

**Accountability**

The very obvious expectation that all teachers will develop competence in using technology is no doubt an important factor that has contributed to the extent of technology integration that is evident on campus. Each staff member keeps a verification form outlining the training they have completed throughout the school year. These data become important indicators when the principal completes the statewide Texas Teacher Appraisal System evaluation forms for each teacher. Technology training and classroom technology utilization are reflected in both the classroom instruction and professional development sections of the appraisal instrument.

**Summary**

The effective integration of technology into schools depends on the vision and leadership of the campus principal. Successful programs are those in which the principal has put into place expectations, motivators, rewards, and support components. Teacher reluctance and apprehension over the everyday use of computers and the resultant changes in classroom organization, management and instruction can be allayed when there is a climate of support from the top.

Teacher education faculty are continually challenged to keep up with the latest technological developments and applications in the schools as well as to design and implement training programs that prepare undergraduate and graduate level students to be effective technology users (Niederhauser, 1996; McKenzie & Clay, 1995; Strudler, Quinn, McKinney, & Jones, 1995; West, 1994). To succeed in this undertaking information is needed on the current status of technology in K-12 schools in order to adequately prepare pre and inservice teachers at the college and university levels.

Undergraduate and graduate instructional technology course revision decisions often are based on formal and informal data generated by students enrolled in technology classes and/or the collective opinions of teacher trainers in the technology area. Relatively little interaction appears to be taking place between technology educators in higher education institutions and technology personnel in the schools, who daily see teachers and students more or less effectively utilizing technology.

This exploratory technology study focused on collecting technology related data from selected technology leaders in the schools to add to the existing technology revision database. It was believed that the additional information would be more representative of the current technology training needs of practitioners and their students.

**Methodology**

The research team collected exploratory technology data through the design and distribution of a questionnaire to all the technology trainers and media specialists in two selected school systems (one city system, one county system) in northwest Georgia (N=19). A second step, currently underway, involves the use of follow-up interviews with the same group of respondents to collect additional and more in-depth data.

Survey recipients were asked to provide demographic data on themselves and to respond to eleven research questions dealing with current technology use in the schools and technology-related problems.

The specific questions were:

1. What are the top three types of technology equipment most frequently used in your school by teachers?
2. What are the top three types of technology equipment most frequently used in your school by students?
3. What are the top three types of technology software programs most frequently used in your school by teachers?
4. What are the top three types of technology software programs most frequently used in your school by students?
5. What types of computer programs are the most frequently used in the teaching/learning process?
6. What types of CD-ROM programs are the most frequently used in the teaching/learning process?
7. What types of technology skills do your incoming teachers need to be better trained in upon entry into your school system to be better prepared to meet the students' technology needs?
8. What types of software programs do your incoming teachers need to be familiarized with to better integrate the programs into the curriculum?
9. What are the most commonly occurring types of technology problems in the school that you must deal with?
10. What types of technology training do you need to better deal with your school technology problems? and
11. How do you update yourself to stay abreast of the latest technological developments?
Analysis

Frequency counts were compiled for the demographic data and the results were rank ordered from the highest to lowest frequencies. A content analysis was performed by two of the researchers on the responses to the eleven open-ended technology research questions.

Findings

Twelve of the nineteen surveys were returned, a 63.2% return rate. The majority of the respondents were female (66.6%), from the high school level (66.6%), had 1-5 years actual teaching experience in their position (33.3%), served as a media specialist (50%), and had either a M.Ed. (25%) or Ed.S. degree (25%).

The types of technology hardware used most frequently by teachers in rank order were computers (N=9), videotape recorders (N=8), overhead projectors (N=6), and televisions (N=3). Student use of technology was found to be similar to that used by instructors. The types of technology hardware students were reported to use included computers (N=11), videotape recorders (N=4), and videodisc players (N=2). Other types of technology used by students which were cited once included the Georgia Statewide Academic and Medical System (GSAMS), television, scanner, and Dukane filmstrip projectors.

The technology software programs that respondents reported teachers used most frequently were WordPerfect (N=4), Microsoft Works (N=4), Lotus 1-2-3 (N=3), Grolier's Encyclopedia (N=2), and PrintShop Deluxe (N=2). Other software products that were mentioned by single respondents were Learning Logic, Edunetics, Infotrac CD-ROM, Proquest CD-ROM, ClarisWorks, Gradebook, Newsbank, Electronic Card Catalog, and Microsoft Word.

Student utilization of software programs was reported to be relatively similar to that used by teachers. The top programs used by students were WordPerfect (N=4), Lotus 1-2-3 (N=4), keyboarding programs (N=3), Microsoft Works (N=3), Children's Writing Center (N=3), Mental Edge (N=2), Georgia Career Information Systems (N=2), and Grolier's Encyclopedia (N=2). Other software that was mentioned once included dBase, Printshop Deluxe, Writing to Write, SAT software, Linkway, Math Blaster, Surpass, and Tom Jr.

When respondents were asked to identify the types of computer programs used most frequently in the teaching/learning process, five responses received two or more mentions: various word processing programs (N=8, Word Perfect being mentioned specifically), databases (N=5, specifically dBase), keyboarding (N=3), spreadsheets (N=2, specifically Lotus 1-2-3), and electronic periodical indexes (N=2, specifically Infotrac and Proquest). Other programs that were mentioned once included integrated software programs (Microsoft Works), graphics software (Printshop Deluxe), desktop publishing, Edunetics, multimedia, and various CD-ROMs.

The CD-ROM programs that were found to be used most frequently were Grolier's Encyclopedia (N=6), Newbank (N=3), Broderbund Living Books (N=2), World Book Encyclopedia (N=2), and Proquest (N=2). Other CD-ROMs that were cited once included the Ebsco Magazine Index, Microsoft Dinosaurs, Putt-Putt, Sing-a-long Songs, Discovering Authors, Animals, Infotrac, Time magazine, and Tom Jr.

When asked to indicate the types of technology skills in which incoming novice teachers need better training, three responses emerged. These included basic computer skills, Internet skills, and keyboarding skills (N=3).

Specific software programs that respondents indicated incoming teachers should be familiar with included Microsoft Works (N=5), presentation software such as PowerPoint (N=3), Microsoft Word (N=2), Children's Writing Center (N=2), Printshop Deluxe (N=2), and multimedia such as Hyperstudio (N=2). Other software applications mentioned once included networking, desktop publishing, Internet, web page development, Writing to Write, Math Blaster, Carmen San Diego, Caryol Art, Excel, and touch typing for beginners.

A variety of technology problems were reported to occur in the selected schools. The most commonly cited difficulties involved hardware malfunctions. These included computer downtime that resulted from network crashes (N=4) and individual computer problems such as disappearing icons and printer errors (N=4). Other technology problems encountered by multiple respondents included obsolete computer hardware (N=2), insufficient computer support (N=2), school personnel with inadequate computer skills (N=2), and student apathy (N=2). Singularly reported problems were school failure to upgrade CD-ROM programs and insufficient funds to purchase memory upgrades and ancillary computer equipment such as cables and replacement mice.

The types of technology training that respondents stated they needed to better handle their school's technology related problems were diverse. The most frequently reported needs included computer networking (N=3), more familiarity with the IBM platform (N=3), how to install new software (N=2), and technology grant writing (N=2). General information on the use of ICLAS, CNA, Web page development, and exposure to new software were needs mentioned by singular respondents.

Media and technology personnel reported a myriad of ways in which they updated their skills. The top two practices cited were attending workshops and/or instructional classes dealing with new and emerging types of technology (N=11), and reading technology and media magazines (N=8). Other training strategies that were identified included networking with other technology
people (N=4), taking the necessary time to learn and practice new programs (N=3), reading selected technology manuals (N=2), and watching television when technology information was presented (N=2).

Conclusions and Future Directions

This exploratory research was effective in finding out some of the technology practices and problems of practitioners and students. It confirmed that computers are the most frequently used technology in the targeted school systems by both teachers and students. It also suggested that productivity tools such as word processing, databases, and spreadsheets are still the predominant applications used by teachers and students. In addition, the study reinforced the importance of adequate computer training in basic skills and advanced applications for new and veteran teachers, and indicated that sufficient funding and personnel support for computer maintenance is still a problem for some.

However, several new needs and problems for computer users and technology managers were identified. Specifically, the need for Internet training for novice and veteran teachers surfaced, and the impact of computer networking in schools was introduced. The study indicates that some school personnel need network training to be able to solve problems schools experience due to network failures. It also pointed to the importance of having advanced training and workshops available for media and technology personnel, since the overwhelming majority of the respondents indicated that this was how they kept up with new developments in the field.

The current research effort is being augmented by follow-up interviews with the technology/media personnel who participated in the study. Future plans include expanding the research to include surveys and interviews with additional P-12 schools throughout the state, as well as with media and technology faculty and trainers in the College of Education, particularly those working in Early Childhood, Middle Grades and Secondary Education. Broadening the research to include these populations will help identify gaps between needs in the field and existing technology training (both credit courses and staff development workshops) provided to pre and inservice teachers enrolled in College of Education technology offerings.

The dynamic state of technology in the nineties necessitates a constant review and redesign of instructional technology education and training. The results of this study, and follow-up studies, will be used to help restructure the technology experiences offered to undergraduate and graduate students in the College of Education. This will insure that pre and inservice teachers, media specialists, and technology trainers will gain the skills and knowledge required to work effectively in today's technology-rich classrooms.

In addition, the research findings will be used to design technology staff development offerings for all faculty in the College of Education. Basic technology training sessions have been offered to College faculty for several years. However, as technology is infused into the College of Education curriculum, appropriate use of contemporary technology must be modeled by the entire faculty. This means that staff development must provide College faculty the broad range of skills required to enable them to use current technology effectively in their own classrooms — and to assure that their classrooms provide the kinds of technology experiences that students can expect to encounter in the field.

Universities across North America are hurriedly adopting high technology. The push is to develop competent and confident high technology users and the fear that pushes this movement is the fear of being left behind other institutions who similarly seek to be on the cutting edge of these new and promising technologies. Political machines similarly urge educational institutions under their jurisdiction to ‘get with the program’ — to innovate and hence to remain relevant to a fast paced, changing technological society. This paper is an attempt to look at one aspect of the much larger technological phenomenon sweeping the world. We look at what is happening to technologies in the public schools. For purposes of comparison we will look at two forms of technology: Low technology consisting of all forms prior to the introduction of microcomputers; and high technology consisting of microcomputer-augmented support in any form.

Related Literature

The Japan Audio-Visual Association conducts surveys regularly at three year intervals. Their latest national survey was completed in 1992 (Japan Audio-Visual Association, 1993). This is one of the only efforts found in the literature to keep track of what is happening to audiovisual resources. Elsewhere the interest seems to have been almost completely extinguished. Seidman (1986) surveyed Fort Worth classroom teachers about their use of media. He found that teachers as a whole seldom use media but the simpler the medium is to use the more likely it will be used by teachers. Similarly, Carter and Wedman (1984) reported that teachers were more likely to use media if they were easy to use or alternatively simple and inexpensive to produce. Aside from these surveys there has been very limited formal attention to the status of audiovisual media in the post-computer era.

The Survey

The core of this paper is based on an original survey entitled Technology in Alberta Schools designed to find out what was happening to the older technologies, herein addressed as low technologies, as a result of the diffusion of microcomputer technologies in the school. The survey was sent out to schools in Spring 1995 and the results were compiled in June 1995. This survey was based on a 1993 Alberta government survey entitled Microcomputers in Alberta Schools—1993 Survey. The 1993 survey looked exclusively at the microcomputer presence in the schools so the survey addressed in this paper sought to fill the gap by finding out about the current status of the other forms of technology present in the schools.

The survey consisted of five parts. Part I identified the responding school’s enrollment, grade levels taught, staff data, and other statistics. Part II looked at the existing inventory of low technology, its location in the school or school district and the expectations about acquiring new inventory over the next budget year. Part III looked at the usage patterns by school staff and asked for estimates of use compared to two years ago. Part IV asked respondents to compare the extent of use of low-tech media with high-tech media. Finally, Part V asked about teachers’ perceived needs in professional development in relation to both hi-tech and low-tech resources. Comment sections were included for each subcategory of questions. These comment boxes were used to express clarification of the answers given or to add information not addressed by the questions.

A stratified random sampling technique was used to send surveys to a sample of 500 Alberta schools out of a possible 1664 of the province’s tax supported schools. The surveys were sent out to the three categories of schools (K-6 Elementary Schools; Grades 7-9 Junior High Schools; and Grades10-12 Secondary Schools). Of the 500 surveys sent out 203 were returned making a return rate of 40.6%.

In order to collect the opinion from a school a single representative spokesperson was sought. An earlier American survey, the National Survey and Assessment of Instructional Materials conducted in 1974 recommended that the best respondent for this type of survey would be the school principal or the school librarian. Therefore, the survey was addressed to the school principal and in the
accompanying letter the principal was asked to complete
the form or to give it to the person who would most likely
be able to respond to questions about the use of resources
on a day-to-day basis in the school such as the school
librarian. Each school, however, had only one spokesper-
son who answered the questions on the survey on behalf of
all the teachers in that school.

Since the statistics from each of the three categories of
schools were quite similar the data were collapsed for the
purposes of analysis. The reporting, therefore, is representa-
tive of Alberta schools, generally, and not from a single
level of school in the system. The basic question being
addressed is “What was happening to the older technolo-
gies in the school?” Implicit in this question was a series of
other questions: “How were older technologies affected by
the introduction of new technologies?” “Was there evidence
of a transition from low tech to high tech in the public
school system?” and even “Were the audiovisual media
dead?”

Survey Findings

The data generated from the eleven-page questionnaire
were extensive but with respect to the central question there
are three generalizations coming out of the survey.
1. Low-tech media are still used as teaching resources on a
regular basis by large numbers of teachers.
2. Teachers perceive low tech educational media to be in a
state of declining use over what it was two years ago in
the schools.
3. The influx of high-tech media is perceived as a separate
issue from the perceived decline of low-tech media use
in the schools.

The first two of these generalizations are not a surprise
to people who are in touch with teachers in schools. The
third generalization, however, deviates from what would be
expected at least on the surface. Let us look at each of these
generalizations in turn.

Teachers Still use Low-Tech Media Regularly.

Figure 1 represents the perceived usage patterns for six of
the more common low-tech media formats. Of course there
are media-specific differences in evidence but the general
trend shows regular use of these media in teaching and
learning. Looking further into the data we see that teachers
who have been regular users of the low-tech media
continue to be regular users. Video as a resource continues
to be a very popular choice by teachers. There are indica-
tions in the survey data that video is gaining popularity in
teaching as a production tool even though many schools do
not have adequate video equipment for locally produced
videotapes. The use of overhead transparencies, similarly,
enjoys a fairly strong position as a teaching resource. The
place of slides, filmstrips, and films is much weaker than
the newer media of audiotapes, overhead transparencies,
and videos.

When comparing the usage of low-tech media and
high-tech media, the similarity is remarkable. Findings
indicate that both forms of technology are used either
frequently or regularly in the implementation of the school
program.

Figure 1. Perceived Frequency of Media

There are also some differences in this comparison
chart. The frequency of use of computer technology is
perceived to be somewhat higher than for the traditional
technologies and the division lines between the different
categories of use are much sharper for the high-tech media
than for low-tech media; but on the whole, it must be
admitted that both forms of technology are recognized as
respectable players on the resource team.

These same findings were corroborated by different
questions in the survey. The usage patterns for both forms
of technology are correspondingly similar. Not evident in
Figure 2, but coming from other sources, there is a larger
complement of teachers who do not use or very seldom use
computer technology than there is for teachers who fit in the equivalent category for the low-tech media.

Teachers Perceive Low-Tech Media to be in a State of Decline. As shown in Figure 3, the older media of slides, filmstrips and films are perceived to be in a state of declining use by about 60% to 70% of the schools responding to the survey. The opaque projector, however, still holds its own as a tracing tool in the school's resource repertoire.

![Figure 3. Perceived 'Declining Use' Patterns.](image)

Based on your personal perceptions would you say that the introduction of computer technology in the schools has resulted in a corresponding decline in the use of the more traditional media?

![Figure 4. Perceived Effect of New Technology on Old Technology.](image)

Discussion

Change without transition is not characteristic of change in the schools. The schools are conservative and tend to resist sudden or dramatic change. Elements in today's schools remain very similar to the way they were in schools in the 1800s. In many ways this is a positive comment. It represents a form of stability or even security. Essentially the purpose of the school has not changed. The school still exists to enable our youth to be able to cope effectively with society: with work; with relationships; with leisure; and with life. In examining the change that is occurring with respect to the new technologies we need to be reminded of the basic purposes that our educational system has. Admittedly, these purposes differ somewhat depending upon your philosophical orientation whether that is essentialist, progressivist, or constructivist or some combination of these three. However, in general terms they share a commonality of preparing our children for adulthood and to achieve fulfillment in their expression of humanity.

The new technology has a sense of urgency attached to it. As well there is the implicit mandate that to not endorse it without reservation means the person is out of touch, out of date, or simply not with the program. There is a bandwagon effect in the adoption of the new technologies which accelerates its penetration and closes down an attitude of critical inquiry. Along with the new technologies we need to accept enormous costs and the fact that much of the technology is out of date before it is mass produced. Everyone at every level needs to be involved in the development stage of the technology.

Based on the results of the survey and our observations as low-tech specialists in education we want to make one strong point. We believe that educational technologists need to respect the heritage in the technologies. There is much to be learned from the work of people in the older technologies. If the two technologies are viewed as unrelated to one another then we cannot use the experience of earlier research and study to inform the direction and contribution of the new technologies to learning. The pattern of research in high tech appears to be concerned with defining the unique and facilitating characteristics of microcomputer-augmented instruction or with comparative studies of computer instruction versus traditional instruction (Ryan, 1991; Wang, 1993; Snowman, 1995). This type of research characterized the early developments in audiovisual technology but research strategies became more specific as the field realized that the questions asked were too general to contribute in a meaningful way to any useful theory about how learning outcomes were affected.

We need to encourage a "true transition" from older media to newer media. A true transition would involve activity in the middle zone between the two technologies:
overhead transparencies prepared using computer software; analog video footage incorporated into desktop video presentations or used in conjunction with computer presentations. Teacher training institutions need to take the stance of proceeding more deliberately in the diffusion of high-tech media into their programs. There is a level of high-tech functioning that could be classified as staple including the use of word processing, spreadsheets and record keeping software, and presentation software. At the staple level development of the software is largely completed. New versions bring refinements but they are incorporated within a fairly well defined and stable structure.

There is a second level of application which has strong relevance but standards, if they exist, are more loosely defined and changes from one version to another in the software are often giant leaps by comparison to similar activity in the staple area. This level includes Internee production, and much of the activity in the manipulation of graphic images and sound. A considerable investment in development needs to occur for applications at this level to be ready for use as classroom resources. Activity in this arena needs to be more selective than at Level One. Level Two needs to be thought of as exploratory and experimental and not everyone needs to do it immediately. Finally, there are applications on the horizon which go beyond many of the applications currently conceived by educators. This Level Three activity is the type of activity that many technologists should read about.

Of extreme importance is for technologists to get in touch with their roots. This not only means looking at the value and need for resources in the first place, but also to look at what has happened with older forms of technology. We need to look at where we are going from the shoulders of giants and consider high tech to be part of the evolving educational technology rather than as a quantum leap away from previous technologies.

IT INTO EDUCATION: A CHANGE EFFORT WORTH PURSUING?

Peter Twining
The Open University

It is almost a cliche to say that the only constant thing in the world is change; but like most cliches it is predominantly true. Certainly within the world of education change is the norm. Fullan (1996, p. 420) points out that one of the main problems in education at the present time is overload due to "the continuous stream of planned and unplanned changes that affects schools." Elsewhere Fullan and Stiegelbauer (1991) point out that it is not possible to pursue all the available change efforts and suggests that it would be more productive to "work at fewer innovations, but do them better" (p. 104). Thus we need to be able to decide which of the range of competing changes are worth pursuing.

Three key questions which should help this decision process are:
Q1. Is the quality of the change high?
Q2. How great are the costs involved?
Q3. Is the change effort likely to be successful?

In considering these questions it must be remembered that any change effort involves not only the substance of the change (the innovation) but also the process of change (how the innovation will be implemented and institutionalized); to paraphrase Gilbert (1996), you need a vision (the substance) and a path to reach your vision (the process).

Question 1: Is The Quality Of The Change High?

There is, implicit within much of current thinking, an assumption that change is 'a good thing'; change is progress. This seems to stem from the belief that not changing is a bad thing (which may well be the case in many contexts). However the two statements do not follow on from each other in a logical sequence; just because a lack of change is bad does not mean that all change is good. The quality of a change will depend on your values and perspectives on the purposes of education, but it is important to remember that "change is not necessarily improvement." (Cuban, 1988, p. 341).

In order to identify the quality of a possible change one needs to be clear about what it entails; one needs to have a clear vision of what the change will mean. This is problematic; even if you think you are clear in your own mind about the change effort there is a great deal of evidence that suggests that the very process of implementation leads to modification of the intended change (Berman, 1981; Miles, 1993). For example one might start out with the intention of enhancing children's use of IT by increasing the number of computers available and providing staff training in how to operate the equipment. During the process of implementation it may become clear that the training need is not in how to operate the software but in how to manage children's use of IT in the normal classroom context. In addition the 'real meaning' of the change often does not become clear until it has been operationalized (Fullan & Stiegelbauer, 1991, p. 92). In other words, it is often difficult to see the true impact that a change will have until you start to implement it. For example the most significant impact of increasing the number of computers in classrooms may be to alter power relationships between staff and children, but this may well not become apparent until the equipment is in use.

As can be seen from the examples above the criteria for judging the quality of a change should include consideration of the intended outcomes as well as possible side-effects. Clark, Lotto and Astuto (1984) have identified that a focus on learning is one of the attributes which characterizes excellence in America's best run schools and given that learning should be the key function of education it needs to be emphasized given that "there is no automatic educational value in mere exposure to computers" (Maddux, 1993, p. 14).

Question 2: What Costs Are Involved?

When thinking about the costs of a change one needs to consider not only the costs of pursuing the change but also the costs of not pursuing it. For example if legislation were passed which stated that every child was entitled to benefit from using IT and must be taught how to do so then the costs of not incorporating IT into your teaching would be high; not to do so would entail breaking the law with all the associated consequences.

At least three different types of costs need to be considered: (a) resource costs, (b) people costs, and (c) opportunity costs. Resource costs include such things as technology diffusion...
salaries and the cost of staff development as well as the cost of equipment and the like. People costs refer to the costs individuals have to pay in terms of stress, change of status, emotional upheaval and so forth. Opportunity costs are the costs which one incurs as a result of not being able to pursue other activities because you have committed yourself to this one.

**Question 3: Is The Change Effort Likely To Be Successful?**

In order to determine whether or not a change effort is likely to be successful you need to: (a) Define success; (b) work out how complex the changed is (the number of obstacles to overcome); and (c) determine the forces operating on the change.

**Defining Success**

Huberman (1973) identified one key criteria as durability, the continued survival of the innovation. This presupposes that you know what the change was going to look like in advance which, as has already been stated, is often not the case.

Even if we accept that the process of change will modify the originally intended change, each change must have characteristics which have to be preserved if that change is to be thought of as successful; those characteristics will vary from change effort to change effort but (none the less) should be identifiable. If, for example, one were considering introducing Integrated Learning Systems (ILS) then one criterion might be the extent to which children’s mathematical skills increased. The reason for the increase might be unexpected, such as the teacher being able to target teaching more accurately as a result of the feedback from the ILS, but this would not detract from the success of the change if an increase had occurred.

Many authors view one key criterion for success as the degree to which the change effort has increased the systems (individual’s, school’s, etc.) ability to change in the future e.g. (Huberman, 1973; Miles, 1993). Indeed Fullan & Stiegelbauer (1991) suggest that “changing the culture of institutions is the real agenda, not implementing single innovations.” (p. 107)

Thus, though it may be the case “that different definitions of success are necessary under different circumstances,” (Berman, 1981, p. 264) every definition of success should include criteria relating to the enhancement of the culture for change and the institutionalization of identifiable key aspects of the change itself.

**The Complexity Of The Change Effort**

The complexity of a change depends upon its scope, degree and divisibility.

**Scope.** The scope of a change effort refers to the number of people that it will involve. Thus the scope is small if only a small number of people are involved. As the scope increases so does the complexity, not only because of the increasing number of different perspectives on the change effort, but also because of the increasing complexity of the interactions of those people.

**Degree.** The degree of change refers to the extent to which individuals (and the systems which they make up) have to change. Huberman (1973) identified two dimensions that make up the degree of change, the first relating to how much change is required and the second to the kind of change. Fullan (1986) identified three aspects which contribute to the degree of change which effectively combine Huberman’s two dimensions. Fullan’s three aspects of change are: (a) use of new or revised materials; (b) use of new skills; and behavior; (c) changes in beliefs and understanding.

His view that significant educational change must include the latter two fits well with Cuban’s (1988) definitions of degrees of change:

First-order changes, then, try to make what already exists more efficient and more effective, without disturbing the basic organizational features, without substantially altering the ways in which adults and children perform their roles. ...Second-order changes seek to alter the fundamental ways in which organizations are put together... Second-order changes introduce new goals, structures, and roles that transform familiar ways of doing things into new ways of solving persistent problems. (p. 342)

As the degree of change alters from first to second order the complexity increases. Indeed Cuban (1988) identifies that to bring about second order change “basic social and political changes would need to occur outside of schools” (p. 344); the degree of change thus affects the scope of the change as well as impacting on its complexity directly.

**Divisibility.** The extent to which a change effort is divisible also affects its complexity. Divisibility can be applied to both the scope and degree of change: the greater the degree to which a change effort can be broken down into components which can be implemented progressively, the less complex it is to implement. In effect it becomes a cumulative series of less complex changes. Similarly the greater the possibility of increasing the change effort’s scope progressively over time, the less complex it is. Davis, Kirkman, Tearle, Taylor, and Wright (1996) suggests that “an appropriate strategy is to focus effort and resources on one area or department, thus establishing local expertise which will sustain the innovations when the focus moves on to another department” (p. 14).

Common sense tells us that the more complex the change the less likely it is to succeed, but the research evidence suggests that the situation is not so clear cut. Fullan and Stiegelbauer (1991, p. 71) point out that more complex innovations result in greater change but also have
a greater danger of failure; Miles (1993) goes further than this and states that "it’s been repeatedly found that more substantial change efforts addressing multiple problems are more likely to succeed than small-scale, easily trivialized innovations" (p. 215).

The Balance Of Forces

Fullan and Stiegelbauer (1991) state that you need both pressure and support in order to bring about planned change; “Pressure without support leads to resistance and alienation; support without pressure leads to drift or waste of resources.” (p. 91). The implication here is that pressure and support are different kinds of things; pressure is portrayed as directional and ephemeral whilst support is undirected and concrete. This analysis seems flawed because pressure and support can both be ephemeral and/or concrete. For example, providing a teacher with ‘training’ (concrete) in the use of computers in her classroom or with encouragement (ephemeral) to use computers in her classroom may both be seen as pressure or support depending upon that teacher’s views about computer use.

Thus pressure and support are in fact different perceptions of the same thing; each can be thought of as being a ‘force’ which ‘pushes’ you in a particular direction. Something is perceived as pressure when it is ‘pushing’ you in a direction which you are not actively moving in yourself or may be moving away from. Something is perceived as support when it ‘pushes’ or facilitates you moving a direction that you want to move in. As with forces in physics pressure and support can vary in strength, direction, duration and in the ways in which they manifest themselves.

In any change effort there are a large number of such ‘forces’ (pressures and supports), some of which are directed towards the change effort and some against. Pressures and supports that are directed towards the change effort I shall call ‘enablers.’ Those that are against the change effort I shall call ‘resisters.’ The ‘net force’ is the strength of pressures and supports (in the direction of the change effort) remaining after the resistors have been neutralized by the enablers. (Enablers - Resisters = ‘Net force’)

For a change effort to succeed the ‘net force’ must be of a sufficient strength to fulfill the needs created by the complexity of the change effort; i.e., it must be sufficient to overcome the ‘resistance’. Having a strong enough ‘net force’ is a necessary but not sufficient condition; adequate duration of the ‘net force’ and appropriate manifestation (observable conditions) are also needed.

Change takes a long time; significant first order changes take a minimum 2 to 3 years and second order changes take much longer (Fullan & Stiegelbauer, 1991, p. 106). Thus, while the strength of the net force that is required will not be the same at each point in time, it is necessary for there to be a sufficient ‘net force’ in favor of the change until it has succeeded.

The ways in which the forces manifest themselves are also crucial. These can include concrete forms (e.g., resources which may include time, access to training and/or expertise, equipment) and ephemeral forms (e.g., expectations such as group norms; directives which include orders, mandates and legislation; encouragement or advice). Different manifestations of forces perform different roles and are necessary at different points in the change process.

In order to determine the likely net force, its duration and manifestation you need to consider where each of the different enablers and resisters are emanating from, their level of commitment, degree of influence and style.

For each individual force the level of commitment can be determined by exploring why the force is operating: a form of cost/benefit analysis. A clear focus here should be on whether the ‘motivations’ of the force are internal or external: internal motivations (e.g., beliefs and convictions) tend to be more durable than external ones (e.g., political pressure).

The degree of influence a force has depends on where it emanates from. For example a teacher in her classroom has a high degree of influence over how her classroom operates but a low degree of influence over government legislation on education. The idea of leadership, which is identified in the literature as being a crucial aspect of any change effort (Blumenfeld, Hirschbul & Rubaiy, 1979; Clark, Lotto & Astuto, 1984; Fullan & Stiegelbauer, 1991; OFSTED, 1995; Rhodes & Cox, 1990), is important at least in part because of the degree of influence that leaders can exert. The greater the degree of influence that an individual has, the greater the strength of force that they can bring to bear. Likewise the greater the degree of influence, the greater the ability to increase the effectiveness of the manifestation of the force. For example a Government minister has a greater ability to affect the level of funding of a scheme than does a classroom teacher.

The style of the source of the force is also crucial because it determines how the force is manifested. A key component here is the ability of the source of the force to determine the most appropriate manifestations of that force at any point in time. This is dependent on their sensitivity to the needs and subjective realities of others as well as to their models of the change process. These models determine the strategies that are likely to be employed in implementing the change effort.

Chin and Benne (1976) identified that the change strategies which prevail in the literature can be placed into three categories. These categories are: (a) Empirical-rational, (b) Normative-re-educative, and (c) Power-Coercive.

Empirical-rational change is seen as a rational process in which the innovation will be adopted once those
Normative-re-educative change is seen as a learning (reeducative) process involving altering sociocultural norms which entails “changes in attitudes, values, skills, and significant relationships, not just changes in knowledge, information, or intellectual rationales for action and practice.” (p. 23) Normative-re-educative change strategies “emphasize norms of openness of communication, trust between persons, lowering of status barriers between parts of the system, and mutuality between parts as necessary conditions of the reeducative process” (p. 37).

Power-Coercive involves a process of compliance of those with less power to the plans, directions, and leadership of those with greater power” (p. 23). Any change effort which ignores the normative-reeducative strategies is unlikely to succeed because effective implementation “seems to be characterized by mutual adaptation at the user level and by the staff’s clarification of the innovation’s goals and required role behaviors” (Berman, 1981, p. 273) or to phrase it more succinctly: “any significant innovation, if it is to result in change, requires individual implementers to work out their own meaning” (Fullan & Stiegelbauer, 1991, p. 105).

**Conclusion**

The answers to the three key questions which are presented above will tend to be fuzzy as opposed to a clear-cut. This is because they depend on knowledge of a vast range of factors and this knowledge is often subjective (i.e. depends on one’s perspective), unavailable and/or too multitudinous and complex to comprehend (Fullan & Stiegelbauer, 1991). Considering these questions does help to clarify whether a particular change effort is worth pursuing.

Whether an individual decides a particular change effort is worth pursuing will depend not only on the answers to these three key questions but also on the degree to which they are prepared to take risks. Figure 1 below provides a decision tree which suggests how a cautious person might respond to a potential change on the basis of the answers to the three key questions.

![Decision Tree](image)

**Figure 1. A Decision Tree Showing How One Might React to a Potential Change Effort on the Basis of the Answers to the Three Key Questions.**

Ultimately the selection of which change(s) to pursue is a complex decision, but “in the final analysis, either we have to give up and admit that effective educational change is impossible, or we have to take our best knowledge and attempt to improve our efforts” (Fullan & Stiegelbauer, 1991, p. 102). The questions presented here provide a starting point for doing just that.

FOUR JOURNEYS WITH TECHNOLOGY: GETTING SOMETHING WE DIDN'T PLAN FOR

Laurie Bowers  
Rocky Elementary School

Kathy Budd  
Rocky Elementary School

Kathleen Rodriquez  
Rocky Elementary School

Katy Campbell  
University of Alberta

C hange theory proposes many models for successful development and implementation of new educational practices (Fullen & Steigelbauer, 1991). While acknowledgment is given to involving teachers as active participants for successful innovation and planning (Fullen & Steigelbauer, 1991; van den Akker & Plomp, 1992) we have also come to realize that changes can cultivate new ways of seeing ourselves as teachers and learners. We as teachers may implement and/or affect changes, but, how do these changes alter our personal/professional landscape? Moving into new territories with technology has offered us an opening for enrichment of this landscape.

Recent work at our school in opening up possibilities for our children has launched a philosophical conversation. Technology has become not only a tool by which our students may pursue new learning possibilities but also a vehicle by which we, as educators, are alerted to our basic personal beliefs and fears about our work. It is also a means by which we pursue new ways of seeing ourselves as learners/teachers and compose new stories of collaboration with each other and our students. Each staff member has followed his or her own path, yet many shared dreams have emerged. Anderson (1995), Kazlauskas (1995), and Schuttloflel (1995) have offered possibilities and models for successful implementation of technology. We would like to offer these stories of implementation of technology at our school as portraits of personal and professional growth within a collaborative learning environment.

This paper includes highlights of the history of technology implementation at our school. In particular, four of us have met to discuss our own journeys: one as a special education support teacher (Kathy), another as a grade two teacher (Kathleen), a third as an instructional design consultant with the University of Alberta (Katy), and, finally, a school administrator (Laurie). Each of us has a different story of how technology has become part of our professional lives. Our current school context is the thread that connects us. Through our stories, we hope to share insight into the complexities of life in schools, particularly as it relates to our personal/professional growth with technology.

Kathy’s Story

In the past decade it seems that we have been bombarded with new technology tools and programs. The media hype and the excitement that technology innovations have caused in the outside world have made us very anxious to get involved and try out these ideas with our students. While I can see the usefulness of these tools, I continue to ask questions about the change in my pedagogy that technology demands.

Do computers save us time and effort at school? Definitely not—at least at the beginning stages of implementation. In fact, quite the opposite is true. I have spent hours learning, experimenting, failing, and trying different programs and tools. However, once I have successfully used a program and integrated it into my planning and my students’ days, it is hard to imagine teaching without it.

The most significant change in my job has come from my own use of technology. It seems that the computer has crept into every aspect of my teaching from test management and student records to worksheets and activities. I have learned to use a very limited amount of what we have available and keep looking for time to learn, practice and experiment with other tools.

I think that using computers depends largely on your comfort level around the machine. The only way to increase that comfort level is to use it and the only way to use it is to find the time to try. Yet, unless we trust that this will someday make life easier or that technology is important to our students’ learning and to our teaching, we will not allow ourselves the time to be the learner.

Technology Diffusion — 1095
When I first started using computers I thought this would be the answer to the massive amount of record keeping that goes with my job. I started to painfully record, on floppy disk, all of my objectives and units from my special education curriculum. Needless to say, this was like the never ending story. Long before I ever found the time to finish my project, the technology had changed to the point that I could no longer use the disks that I had created. Although this was a time consuming endeavor, it was also a wonderful learning experience and greatly increased my comfort level with computers. However, it makes me very cautious about what we are spending our time and money on at our school. I also spend more time thinking and debating the value of programs or new innovations.

Kathleen’s Story

I grew up in a home where the rapid growth of technology was not very apparent. It wasn’t until I entered university in 1975 that my mother finally put away her old wringer washing machine and bought an automatic washer. A microwave followed in the late 1980s, and only in the last few years has a VCR invaded my mother’s home. There are still no signs of a dishwasher, and computers and computer language is as foreign in her home as an exotic language would be.

As a child growing up in this setting, I, mistakenly, determined that technology must be quite dangerous, and something to be avoided. After all, my mother was a teacher, and if it was a good thing, I felt sure that she would be making use of it. Only years later, looking back, have I come to the realization that finances were the real reason that technology was so slow in entering our home. I took this misconception with me as I began my teacher training at the university. While some technology was available to students in the library, I never made use of it.

Eight years ago, technology was introduced into the school where I teach. Classrooms received computers and heavy inservice training followed. The computer was to be used mainly as a way to strengthen students’ skills through games. I dislike educational games, and so I now had two aversions to technology. I saw it as a danger based on my early experiences and as another medium for playing games. This use of computers at the school has since changed. Computers are now used primarily as tools for writing stories and reports, and more recently, for conducting research.

Luck was with me, I thought, as I was in a position teaching music and physical education and neither course involved computers. I hoped that no one would notice my absence from the inservice activities. On those nights I ran from the school as quickly as possible, trying to mingle with parents who had come to pick up their children.

Shortly after this year of computer introduction, I was assigned a grade two classroom complete with a computer, and a stack of disks. For a few months, the computer sat shrouded in the corner. Then, finally, I decided that the students should be able to use it for drill and review, and I learned the basics from other staff members. To anyone looking in, I would have appeared comfortable with technology. However, other than turning the computer on and off, I still had no connection with it.

In terms of my use of technology, those were difficult years. I had come to realize that I had incorrectly assessed technology as a child. However, it still frightened me. At the same time, I felt like the rest of the staff had climbed on to a locomotive, and I had elected to stay behind at the train station. I began to doubt my abilities and felt that I had very little to offer the teaching profession. I was not connected to my more technologically sophisticated peers.

A year ago, Katy, an instructional design consultant from the University of Alberta came to our school to provide inservice for us in technology. At the beginning of the day, I felt as if we had been transported to another planet. While the new technology that Katy showed us overwhelmed many teachers who were comfortable with the technology in place at our school, it left me speechless.

Katy showed us how to use the Internet and e-mail. Even though we had some problems using the Internet that day, I became intrigued with the communication possibilities. As we are situated in a small rural area, it is often impossible to make connections with people who can broaden and intensify our learning. Katy was offering us a door to the entire world. Within weeks, I was closeting myself daily with the Internet. Teaching became alive as my grade two class and I researched animals and countries for classroom projects. I used e-mail with a passion.

I began to take my students to the lab for very basic keyboarding. As they absorbed my enthusiasm, they became relaxed and comfortable with technology. Some of the weakest students have flourished, finding great success in our lab, where we are all on a fascinating journey of discovery.

For myself and my students, technology is building a bridge across the distance of rural living to people all over the world. Like chefs creating new meals, we are creating new connections, becoming open to new ways of learning. Our circle of communication grows daily. Personally, I feel recharged as I once again assume the role of both teacher and learner, moving toward the next century with enthusiasm and anticipation.

Katy’s Story

I was invited to enter the process of school-based technology planning in the way that I have always come to the practice of educational technology - through personal relationships. Relationships are the social context in which I design and in which I am able to best explore, and share the experience of technology in my work. I do this through conversation.
I had first worked with Laurie, the principal of Rocky Elementary, on a videodisc project in teacher education. The project was run by a professor in Elementary Education and Laurie was his graduate student assistant. I was the instructional designer. Through the conversation-based process of design Laurie and I created a social space in which the design process became a process of sharing teaching and personal experience. We became friends and, through that relationship, colleagues and design partners. Laurie knew, and had helped me write, my story of becoming a multimedia instructional designer.

Like so many of us who call ourselves Instructional Designers, I have an experiential base to my practice which only later (and only sometimes) seeks validation through formal training and credentials. Personally, I seek authorization to do what I do - to be, in effect, the expert - through the tacit agreement of my work partners. I enter into their worlds and make my own understanding of technology accessible through discussions about experiences with teaching and technology. I chose a technology model because I had an instructional need best solved by technology-enabled instructional strategies. I did not fall in love with technology as an entity, that came later. I know that teachers, and university professors, will only use technology when they need it to solve a problem.

I was invited to an inservice at Rocky Elementary as an Internet expert. Far from being impatient with the resistance to embrace a mostly ubiquitous technology because “what if the network goes down in the middle of the lesson”, or becoming defensive about the reliability of 1996 technology, I told the story of my own confrontations, as the technology expert, with constantly failing technology. I entered into the world of the classroom teacher who cannot afford to problem-solve a failed Internet connection for even five minutes with a class of restless 7-year-olds, and worked with the assumption that technology will fail, and how we can recover from that. In the afternoon, I was invited to model my practiced serenity in the face of technological havoc as the school network went down and stayed down all during my hands-on workshop. And I’m told that in so doing I brought the teachers, feeling immensely relieved, into my world of sometimes uneasy alliance with technology for teaching.

Laurie’s Story

In 1994, I thought I knew about technology, or, at least some of the possibilities that technology could offer our students. I had embraced it as part of my own classroom teaching since 1980 and had been very active in professional development related to technology. My journey at Rocky Elementary since 1994 has taken me to places I could never have imagined. I have been a privileged observer and participant in a wonderful journey of discovery as I have watched new relationships evolve through dialogue and debate about technology. These relationships have been the foundation for support as teachers have wrestled with the frustration and excitement that technology can bring. Conversations continue spontaneously in the hallways during and after school, at inservices, in our meetings for our technology plan (involving para-professional staff and parents), and now in our writing about our experiences. For us, planning for, and utilizing technology has become another starting point for reflection.

When I came to the school as the principal in 1994, I arrived at a place where many teachers were using computers in exciting ways in their classrooms. For others, computers remained under covers, unused in a corner of the classroom. How could these teachers begin to see themselves as part of the dialogue about teaching and learning with technological tools? In their resistance, I sensed their feeling of being left out and apprehensive about the time that technology could demand of them while at the same time being reluctant to open the doors to new possibilities. Computers had been a mandated part of life for grades four and five teachers for several years with support provided by a teacher (Karen) who was given release time (20%) for technology. I looked for cracks in the doors and tried to provide as many places and spaces as possible for dialogue about changes.

Many doors opened through the broadening of our technology planning process. Whereas Karen had done the majority of the planning until 1995, an increase in the decision making authority of teachers through site-based decision making enlarged the circle. Our staff realized that having the authority to determine where and how our budget would be spent also required careful thought and planning. Our first meeting of the “Step-Forward” committee, held in the fall of 1995, had 17 volunteers in attendance (professional staff, support staff, and a parent representative). This committee was originally formed to address changes that we wanted to see in our library, however, we soon realized that it would become our school plan as it related to technology. I found myself as an observer rather than an active participant. A synergy evolved that allowed me to step back and enjoy watching the direction that the group was heading in. The enthusiasm and energy of each member generated exciting discussions about what we should be doing with our technology and how teachers and students would get the support they needed. A plan evolved whereby our new computer purchases would replace the old ones in our grade one classrooms, followed by the twos, and up to the higher grades as we could afford it. We talked about supporting ourselves with professional development and sent eight teachers to a local conference on technology. The group traveled together to the conference and indicated that a highlight was the two hour drive home at the end of the day. The sessions had cultivated new ways of seeing
technology for many and the conversations in the van were buzzing with excitement. Shortly afterwards, I watched many covers come off of computers in the corners of classrooms.

An inservice in the spring opened up new conversations as I invited Katy to work with us in our exploration with the Internet. Having worked with her on several other projects, I knew that she would bring another perspective from the University while at the same time understanding the frustrations that we were facing in the classroom. A prerequisite for the workshop was that all staff members were asked to send an e-mail to Katy and we set up written instructions in the corner of our lab so that staff could complete the task according to their schedules. Those who were comfortable helped first-time users and several overcame the hurdle of delving into the Internet through one session with Katy. Now it is not uncommon to find teachers at school late Friday evenings, receiving and sending e-mails to new connections they have made all over the world.

Our Step-Forward committee continues to meet on a regular basis. In making our school plans last spring, and based on the recommendation from the committee, teachers unanimously voted to give up a half hour preparation period each in order to release an additional half-time position for technology support. With creative budgeting and utilization of our old computers, we have two labs and two technology support teachers. Our grades one, two, and three students can now explore computers in our second lab and exciting new conversations are opening up between young children as they help each other log on, find icons, and weave their way through programs. This has also facilitated exciting new team-teaching opportunities with Kathy as our second technology support teacher. Karen and Kathy have set aside Tuesdays (an hour after school) for drop-in professional development activities related to technology and each session is full.

This journey continues to be two steps forward and one back as we live with the elation and frustrations that technology can bring. However, it has also become one for forging new working relationships with each other and professionals outside of our school. In sharing our struggles with each other we are able to find safe, supportive spaces in which to continue the debate about how best to meet our students’ needs.

**Possibilities**

We, as educators, need to continue to feel success in various aspects of our lives. In this way, we are able to experience the success and excitement of learning that we want each of our students to have. Technology in our school is offering educators the chance to experience this excitement. We have a variety of technological encounters available to teachers and, as we have made requirements manageable, teachers need not feel threatened by the enormity of learning to teach with technology. Rather, we all have the opportunity to experience being student and teacher as, together, we work our way along the technological highway.

Two questions arise from our personal/professional journeys with technology: first, is it the nature of technology itself that engages us in dialogue thereby facilitating collaboration? Technology demands dialogue since we are all beginners in many ways. At the same time, there are many threads of continuity, for although it is a new medium, technology does not dismiss the importance of relationships in our work. If anything, it offers new possibilities for broadening collaborative relationships.

Second, is our staff already on the road to new ways of being teachers and learners with technology acting as a catalyst? We would suggest that our growth may be based on a combination of the two; our staff has the opportunity and is open to engage in reflective conversations about our practice. Technology offers many new landscapes for this dialogue and collaboration.

NOTEBOOK COMPUTERS FOR ALL FACULTY AND STUDENTS AT VCSU

Joe Tykwinski
Valley City State University

Gary Thompson
Valley City State University

Larry Grooters
Valley City State University

In 1990 the North Dakota State Board of Higher Education gave Valley City State University a mission. It was decided that VCSU should be the State University System's leader in the application of instructional technology. In August 1996 this 1,100-student institution leaped into the 21st century as the first notebook computer university in the state and one of just two universities nationwide that provide notebook computers for all students.

The desire for a technology-intensive learning environment surfaced on the VCSU campus a number of years ago. Beginning in 1989 faculty and staff started meeting and discussing the changes needed to prepare the institution for expanded use of technology in an environment of limited resources. The institutional Mission Statement was revised and included the following wording to reflect a new direction for the institution as approved by the North Dakota State Board of Higher Education:

Faculty and staff are striving to develop a unique culture of innovation and commitment to continuous improvements in teaching and learning. In this spirit of Total Quality, it is assumed that every student is capable of high achievement. Pursuit of knowledge at VCSU is a dynamic, never ending process founded on a belief that the rapid emergence of technology as an intellectual, cultural, and economic force requires new types of relationships with other human beings and significant changes in societal institutions.

It soon became apparent that new and more formal planning was needed to insure that the campus obtained and maintained an adequate technology infrastructure to support the learning environment. A formal technology plan was prepared on the VCSU campus in May 1995 that called for implementation of a notebook computer campus by Fall 1996. This decision was not an easy decision for faculty, staff or students. Some faculty said it would not work and many students were opposed to the idea altogether. The administration, student senate, and many of the faculty leaders felt that implementing the technology plan would benefit the institution and its graduates.

Valley City State University's teaching and learning environment has been transformed in a dramatic way. In August 1996, every full-time student at VCSU was issued an IBM 701CS computer. The computer features a 486 75MHz microprocessor, 720 MB hard disk drive, 12 MB of RAM, a color monitor, modem and an Ethernet card. This model has a unique expanding keyboard that results in one of the smallest, lightest notebook computers on the market. The computers feature the same software as the faculty computers: Windows 95, Microsoft Office Professional, Novell Groupwise and Netware Client, F-PROT virus protection software and a World Wide Web browser.

Faculty at Valley City State University have been using IBM 365CSD notebook computers since February 1996. Weekly training sessions specific to the software loaded on the computer were provided by our Center for Innovation in Instruction. Our University has also obtained a 1.7 million Title III grant that provided training for 10 faculty and 14 students in the use of multimedia development software that will be used in creating CD-ROM portfolios. The original 10 faculty and 14 students have become mentors for an equivalent number of faculty and students the next semester, until all faculty and students have been trained.

The Alumni Association at VCSU also provided funds for faculty development that were used to purchase 46 hours of videotape training covering all the Microsoft Software included with the notebooks. The videotapes can be checked out of the library. Faculty were also provided with training sessions two weeks prior to the opening of the school term. Most faculty members attended these sessions that provided direct instruction in the use of the software and network resources. Many faculty are now using the WWW and have developed Homepages for their courses. This level of training will continue as VCSU's Bush grant for faculty development has been renewed for $180,000 over a three year period.
Seventeen classrooms on the VCSU campus have been renovated to "multimedia" classrooms. These classrooms feature student tables with electrical connections and 12 of the classrooms have tables with both electrical and network connections. Most classrooms have 36 inch wide tables where students sit across from each other to facilitate group work. Some of the classrooms have 18 inch wide tables where students all face the front of the room. All of the classrooms feature projection televisions that can display computer and video information.

Technology support personnel were restructured and realigned. Academic and administrative support personnel were combined and all information technology support personnel now report to the Vice President for Academic Affairs.

Nearly one million dollars was devoted to renovating and expanding the LAN (local area network). Conduit was trenched between buildings to house the fiber optic cable for the ATM backbone. All existing servers, routers, and switches were replaced in anticipation of the notebook computers and the daily academic application of network resources.

Faculty have taken advantage of the technology available to them and the majority are integrating it into their classrooms on a daily basis. Faculty and students are using computers to develop multimedia presentations, communicate with each other, prepare reports, and conduct research through the Internet. Students graduating in the next four years will also leave campus with a professional resume/portfolio on a CD-ROM.

Traditionally, there have been boundaries in universities based on content taught, department designations, or other classifications. These separations may have been brought about by a perceived need to protect one's department, college, or own area of expertise from being appropriated by another unit of the university. In many cases, much of this isolation has been sponsored and perpetuated by administrators rather than faculty.

Technology has been a good example of how common sense gets lost in the isolation shuffle. The very use of the word "technology" is confusing as it has become an umbrella term to define not only the hardware and software itself, but also the means to an end.

The old saying that a piano player does not need to know how to build a piano is appropriate for describing the two roads that technology is traveling, for we need to train both technology developers and users. Certain departments, usually computer science and other mathematics-based fields such as engineering, seem to have had a monopoly on technology. Our contention is that while this approach is necessary, in its isolation, it is a small piece of a larger entity. The applications of technology to all content areas is the real validation for technology to exist at all.

Faculty attitudes are yet another problem that needs to be factored into the effective use of technology across collegial/departmental lines. In the short period of the digital revolution, we have found faculty who have adopted the use of technology to expand the knowledge base and the effectiveness of delivery systems in their content areas. We have also found faculty who fight the technology as though it were academic blasphemy. Technology knowledge requires an effort and time commitment which many people refuse to make. This has often left the early users in non-technology departments with little financial or other incentive support. When funds did become sparingly available, the technology was distributed as minimally needed with little, if any, university-wide planning to make the use of technology fit into any coherent model or plan.

But that was in the beginning, a mere five or six years ago. Today, still without a cohesive plan, the use of the computer, and the type of computer found on faculty desks have become a symbol of status. In some cases, advanced users have barely enough technology to accomplish their goals—in others, minimal technology users have the most powerful word processors on the planet. The distribution is based on a mixture of chaos and status rather than need.

Three years ago, a number of professors at Governors State University who were heavy technology users, but tired of fighting for their needs in isolation, got together to see if there was another way to generate both heightened interest into what technology could afford educators and alternative funding for its promotion. This group came into existence as part of a university-wide effort to develop a new mission statement. Thus was born the Center for Technology and Information (CTI), an organization to promote and support the use of technology on all levels. The CTI is a voluntary organization comprised of faculty, administrators, advanced students, and support systems from throughout the university community. The CTI organizational structure is simple - no matter where you are in the hierarchy of the university, in a CTI meeting you are an associate director. To become an associate director, you simply have to attend meetings. The group meets weekly with about 30 people in attendance on a regular basis from a pool of approximately 70 members contributing throughout the year. This has created a positive proactive environment which has eliminated or at least minimized "turf wars." Faculty members from Computer Science, Business, Education, Health Professions, the Sciences, the Fine Arts, and the Humanities all work together.

Funding sources are many. Seed money for projects begins with a modest $25,000 stipend from the university to be used to secure additional resources or to fill in operational gaps. The CTI actively pursues manufacturers and developers, not for gifts, but for partnerships. While most manufacturers have considerable resource and development efforts, the ability to take a new product and place it for application development into the hands of so diversified a group as a university faculty, has led to many new applications of their products. In return, the manufac-
Turers continue to support the efforts with state-of-the-art equipment. The equipment is not turned over to the university, but remains on the manufacturer's inventory and is then removed or exchanged as long as the partnership proves useful to both parties. Project teams are formed from within CTI based on interest - the teams usually coming from a number of different academic disciplines. To this day, funding and projects have never been put to a vote, but have come about as a result of healthy discussion and eventual consensus. While it was never intended to be a policy-making body, the university recognizes the CTI as a think tank and has asked them to establish budgetary protocols, equipment purchasing guidelines, and to establish a short list of supported software and to establish interconnective networks.

The CTI must keep a balance between protecting and promoting the high end users and establishing interest and training for the general faculty. These two purposes stretch the physical abilities of CTI and its members. While its successes have been many, it functions only out of a base of mutual respect and collaborative spirit.

The establishment of CTI has allowed faculty members from all departments to borrow any of the equipment purchased by CTI. This policy has made it possible to efficiently share resources between units. Traditionally, this would have been impossible because of "turf" and ownership issues. Colleges or departments no longer have to duplicate expensive or single-use equipment purchases in order to make them available to faculty. In this era of limited budgets, an organization like CTI can help the university to remain on the cutting edge by sharing hardware and software across units without overspending or duplicating efforts. Based on our success with collaborative planning and technology use, we believe that a similar structure could work within other universities, and even at the high school level.

Today's schools are charged with the formidable task of educating students to meet the needs of the job market of the 21st century. Our students will be expected to perform jobs in the future that have not been created or even conceived of today. In preparing students to meet this challenge, schools must change from institutions that graduate students with a standard set of skills to ones that produce future citizens who can manage resources and use information for problem solving and decision making. These are the skills that will help our students become lifelong learners who are actively involved in their own educational process.

In order to meet the needs of our students the role of the teacher must change from gatekeeper of knowledge to facilitator and manager of the learning environment. The role of the student must shift from passive learners to self-directed learners who set priorities and achievable goals and assume responsibility for reaching their goals. The Internet is one tool that will enable education to make this shift. It will enable students to engage in self-directed learning experiences and activities that encourage self-expression, cooperative learning and interaction with their immediate environment as well as the outside world.

The Internet is a timely tool for educators who are reforming education. If we believe information is the bedrock of knowledge, understanding, and power, then universal access to worldwide databases and up-to-the-minute, global information and people-to-people networking is crucial to providing students with educational challenges. (McLain & DiStefano, 1995, p. iii)

While many teachers recognize the value of technology and the use of the Internet, the question remains, “How do I use the Internet in my classroom?” The purpose of this paper is to answer that question.

Incorporating the Internet in your Lesson Plans

Teachers are often most comfortable when they begin using the Internet by incorporating it into existing lesson plans. Since not all lesson plans are easily adaptable for use with the Internet, teachers must consider carefully which plans to use. The following are some guidelines to use when choosing lesson plans to use with the Internet (Source: “Make Your Lesson ‘Net’ Worthy,” 1995, pp. 1-2):

1. Research on a particular topic such as life in space, Gothic literature, or irrigation
2. Comparing and contrasting information
3. Information gathering from human sources such as other students or experts
4. A multicultural or global aspect, such as foreign language
5. Critical thinking and analysis
6. Researching and writing a report
7. Using graphics and art
8. Collecting and analyzing data and building a database
9. Conducting a survey via questionnaire
10. Making a final presentation
11. Working in teams

To ensure that the Internet is an appropriate tool to use with a lesson plan, teachers must do some research to see if information is available on the topic which the students can use to meet the objective of the lesson plan. It is important that teachers have a variety of sites they want the students to explore and that they have thoroughly explored the sites themselves. This way teachers are aware of good, valuable sites that would benefit the students as well as sites that would be dead ends or inappropriate links before sending the class on the online assignment. However, teachers must not limit the scope of student research. Often the best sites for future lessons are those discovered by the student after they have accessed the sites suggested by the teacher.

The Internet is an excellent reference tool, but is only one of many resources available to the student. When incorporating the Internet into lesson plans, teachers can also use printed materials available in the media center. Integrating the new technology of the Internet with print and other resources can create a powerful learning environment for students.

To ensure that the Internet incorporated lesson plan meets the goals of lesson teachers can have a fellow teacher look over the lesson plan. This can be done online. Teachers can post their Internet lessons on newsgroups.
such as K12.chat.teacher and ask for feedback on the lesson. Once the teacher is comfortable that the lesson plan will meet the goals of the lesson and any problems with logistics have been worked out, it is time to give the lesson plan a classroom trial. Like all lesson plans, the lesson may not work perfectly the first time. Internet lesson plans may need minor adjustments to make it work better next time. However, if the goals of the lesson were met by the lesson plan, it was a success and in learning Internet search skills students have gained a tool they can use for life.

For the teacher who wishes to use the Internet, but is not sure he/she has the skills necessary to integrate this new technology into existing lesson plans, the Internet is a gold mine of hands-on, step-by-step methods for integrating the Internet into the curriculum. Teacher can use the Internet to access sites that list lesson plans in every curriculum area along with research links to complete the lesson. Some such sites include:
1. The Hub (http://hub.terc.edu/)
2. Teacher’s Edition Online (http://www.southwind.net/~lishiney/index.html)
3. Scholastic (http://www.scholastic.com)
4. Web66 (http://www.web66.coled.umn.edu/)

The Internet for Research and Publishing

The Internet is the ultimate source for research. Using the Internet, we can teach students to search for, retrieve, collect and exchange information. More importantly, they will learn to analyze, write about, and then publish information on any imaginable topic. Using the Internet, the student can stay on top of international news, track and discover developing trends, gather, analyze and synthesize data and information from around the world in real time, parlaying that into career-enhancing knowledge (McLain & DiStefano, 1995, p. viii).

Students can use the Internet to research answers to real-life, problem-solving situations. They can then produce text-based publications, videos, and multimedia presentations that reflect originality and build self-esteem and interpersonal skills. When students are involved in authentic research, learning content becomes a part of the process rather than the end goal; they must master the content in order to solve the problem at hand. Students actually go out into the real world and learn to solve real-world problems.

Completed research projects can then be published to the Internet. The relevance of lessons are seen by students who realize that their work is of value to others in their community and around the world as they get feedback from others reading and observing their work on the Internet. Not only is self-esteem developed in students as they see their work published, but a real life skill is learned — the production of an end product that is used by others.

Another publishing opportunity on the Internet is the creation of school homepages. According to Web66 (host to many school sites) over 2,500 schools from 43 countries registered pages with Web66. Many schools have a school homepage and also provide opportunities for teachers and students to publish individual homepages. “By weaving their own informative, innovative Web pages, students move beyond passive learning and become global publishers.” (“Create Your Own Internet Project,” 1995-1996).

School and individual homepages offer much to the Internet community including: student poetry, scientific research results, school news, sports and club activities, description of the school’s community, introduction of school’s faculty, reports on field trips, and links to useful Web sites. The language of the web is HTML, or Hypertext Markup Language. It is simple to learn and can be developed using any word processing program or using specialized HTML editors such as HotDog Web Editor, WebMaster, WebEdit, and Web Wizard.

Before teachers allow students to begin publishing to the Internet they must be sure that students know the rules of publishing to the Internet. First, students must respect the copyrights of other Internet publishers. Because the Internet is an open environment and information can be easily copied from it, students may be tempted to simply take the work of another and claim it as their own. Teachers must research what the copyright laws are concerning Internet documents and graphics and ensure that students respect these rules. Student should also be made aware of how to cite electronic media, thus giving credit to the original author.

In the real world, students everywhere learn rules to make life easier and kinder. Because the Internet is relatively blind to the identity of the user and because that blindness makes rudeness very tempting at time, all users of the Internet adhere to a basic set of manners. This set of manners is commonly known as netiquette. Teachers should have a netiquette policy controlling the behavior of students on the Internet. Most policies forbid: putting unlawful materials (such as pirated software) on the system; the use of abusive language or behavior on the Internet; posting racially inappropriate comments; transmitting messages or programs designed to slow down or incapacitate a computer or network; and the use of the Internet for publication or retrieval of pornography. Any student who fails to adhere to the rule of Netiquette can and should lose Internet privileges (Williams, 1995).

Joining an Online Project

Online projects require students to use the Internet’s navigation and communication tools to get involved in data exchange, team writing projects, virtual explorations, and
even global grocery shopping. These Internet projects generate student excitement and expand learning potential. A large number of projects on the Internet today are teacher-created projects and can be powerful, valuable learning experiences for students. There are five different types of Internet projects students can join:

1. **Online correspondence:** Involves setting up keypal (e-mail penpal) connections between your students and their "wired" peers and subject matter experts.
2. **Information gathering:** Requires students to reach goals or solve problems using the Internet as one of their research tools.
3. **Competitions:** Information-gathering projects through which students must search the Net to answer questions or solve problems.
4. **Interactive writing:** Includes joint writing activities in which one class starts a short story, passes it along to another class, writes another chapter, and so on.
5. **Online conferencing:** Requires students to use Online chat rooms or audio (NetPhone) or video conferencing (CU-SeeMe) software.

Teachers can access information about projects that their classes can join at the following sites (Source: "Internet Integration 101," 1996, p. 4):

1. Academy One (http://www.nptn.org/cyber.serv/AOneP/academy_one/project.index.html)
2. Global SchoolNet Foundation (http://www.gsn.org)
3. Hilites (http://archieves.gsn.org/hilites/)
4. IECC-Projects (http://www.stolaf.edu/network/iecc/iecc-projects.html)

There are twelve steps for creating a successful Internet Project (Source: Williams, 1995, pg. 226-227):

1. Think about your goals for the lesson. What do you want to accomplish?
2. Consider whether the Internet is the best way to accomplish your goals.
3. Identify and analyze the Internet resources that your students may use. Do they need access to e-mail? FTP? Tools for downloading, unpacking, and decoding files?
4. Check your hardware and software, including your telephone connections, before class begins.
5. List the steps necessary for success. Follow the KISS rule and establish a step-by-step procedure if that's the way your particular group learns best. The Internet is huge. Your students can, and probably will, get lost there more than once.
6. Set parameters for time. You need to consider not only how long completing the project may take, but also how much lead time you need to give your fellow teachers or collaborators on the Net.
7. Build in opportunities for feedback. When are students on target, and when are they just surfing aimlessly around the Net? How do you let them know where they stand?
8. Think about the final product. What should the final report, document, or outcome look like? What constitutes success? How will you grade it: rubrics, an analysis of printed documents, evaluating reflective writing in journals?
9. Identify how and when students should, can, or must use their fellow students, teachers, parents, and so on as resources.
10. Think about your role. How closely do you need to supervise the students? Should you answer questions?
11. Try it yourself. The potential for chaos/disaster/bizarre stuff is high on the Internet. Try the project yourself first.
12. Make time to look back and debrief. You'll find that there's more than one way to accomplish nearly every task in the Internet. Leave it to the students to startle you with new ways to link information and to locate new resources you'd never imagined.

A few of the ways the Internet can be used as a classroom tool were discussed in this paper. However, if a teacher decides to use the Internet he/she must plan carefully for the online experience. While planning an online experience is not dramatically different from planning regular lessons, careful consideration must be given to ensure that the lesson does not end in a technological disaster. Using the Internet can be a successful experience for teachers and students alike, if proper time has been spent on the planning stage.

Telecommunications: Graduate, Inservice, and Faculty Use

Section Editors:
Gertrude (Trudy) Abramson, Nova Southeastern University
Sharon S. Brown, Nova Southeastern University

Telecommunications in education, a.k.a. distance learning, means many different things to learners and institutions. The common thread is that the learner receives instruction in some way other than face-to-face in a classroom. This section of the Annual is devoted to post-baccalaureate learners: graduate students, teachers, and faculty. Last year, there were nine articles in the section; this year there are twenty-one. There would be more but some of the presenters were unable to meet the publication deadline. Last year, the only contribution beyond the 50 states came from the University of British Columbia (Canada). Within these pages find articles from countries as distant as Italy, New Zealand, and Norway.

Some Recent-Past History
In May 1995, I chaired a conference, Technology Education in the Use of Technology-Based Learning Systems, sponsored by the Society for Applied Learning Technology (SALT) and the American Association for Colleges for Teacher Education (AACTE). Speakers included representatives from the AACTE, the Association of American Colleges and Universities (AACU), the National Association for Equal Opportunity in Higher Education (NAFEO), the Council of Chief State School Officers (CCSSO), the Office of Technology Assessment (OTA), the Office of Science and Technology Policy, and the U.S. Department of Education (DOE). Everyone recognized the pressing need to integrate technology into the learning process, the need for adequate teacher-training and preparation time, and the need to use online technologies to bring the world into the classroom and the classroom into the world. At the same time, everyone agreed that, looking at the broad spectrum of K-12 education in America, very little had been done to date. In addition to the national organizations listed above, speakers included representatives of universities where educational technologies were viable parts of the pre- and inservice learning process and vendors who are working to create materials that compensate for underprepared teachers. The university speakers represented the University of Northern Iowa, Nova Southeastern University (FL), University of South Florida, National-Louis University (IL) and University of Virginia.

State of the Art?
The proposals for inclusion in this section were submitted in October 1996, only seventeen months after the SALT meeting and one year after last year’s SITE submission date. Change is occurring at speeds we have never before witnessed. Whether it is the proliferation of the World Wide Web (WWW), with its ability to transmit images as well as text, the growing popularity of web browsers on home computers that is spurring education to follow, or the support of the Clinton administration in bringing telecommunications technologies to the schools, it appears that online communications in adult learning have arrived!

It is our collective job as teacher educators to make the delivery mechanisms effective and efficient tools that improve the teaching and learning processes. The papers in this section bear careful study. Each examines the “elephant” from another perspective; each contributes subject matter for discussion and reflection.

To contradict a point made above, articles are grouped by geographic locations and are referred to in terms of their universities or sponsoring organizations. The authors are listed within the papers. As the host country, we begin with our global guests. Within the United States, there is a single west coast entry, four from the mid-west, five from
the central Atlantic states, six from Texas, and two from Florida. Is it premature to celebrate widespread telecommunication adoption in post-baccalaureate education?

**Distant Shores.** Stord/Haugesund College and Agder College, both in Norway, are developing a paradigm called ODL, Open and Distance Learning, in which the emphasis is on open access of learning material through electronic networks and the collaborative efforts among higher learning institutions. University of Waikato, New Zealand, runs an Internet service for 200 local teachers through its School of Education. The article describes inservice tools that focus upon incorporating Internet tools into regular classroom teaching.

The Institute for Educational and Training Technologies (Italian National Research Council) reports on the initial use of the Internet in the classroom by school districts. Reports on a process of moving to online delivery of teacher education and describes a teacher education activity aimed at making teachers aware of the educational potential of the new powerful information and communication technologies.

**West Coast.** The University of Southern California is the home site of ISLA, Information System for Los Angeles, a digital research archive of local materials in multiple information formats for research, teaching, and public access. ISLA’s applications as learning and inservice tools are described.

**Mid-West.** Iowa State University offers a description of a masters program for high school mathematics teachers delivered over a state-wide, fiber optics network. Indiana University at South Bend uses the Internet, particularly the WWW, primarily as a library resource within undergraduate and graduate education courses.

At Emporia State University (Kansas), a researcher looks at the ways that the Internet is reshaping the teaching and learning process from a variety of perspectives in on-site learning environments. At Illinois State University, a professor examines ways to support constructivist activities through the use of the Internet by pre- and inservice teachers in K-12 classrooms. Examples of modeling constructivist approaches in teacher education are presented.

**Central Atlantic.** University of North Carolina at Wilmington is experimenting with a WWW "remote classroom" for state-mandated inservice professional development. Bloomsburg University (Pennsylvania) reports on the initial use of the Internet in the classroom by elementary and secondary public school teachers. These teachers had all taken an intensive Internet course at the University prior to adoption of the technology in their classrooms.

From South Carolina, collaboration between the Citadel and Low Country Children’s Center, has resulted in online resources to help teachers identify and report child abuse and neglect. Several websites are listed and discussed. School-University collaboration exists between the University of North Carolina at Wilmington, New Hanover High School (NC), North Dakota State University, and the Center for Innovation in Instruction (ND). This work addresses opportunities and issues related to the use of the Internet and WWW as an emerging channel for the delivery of pre- and inservice teacher professional development.

The University of Delaware and the University of Agriculture in Nitra, Slovakia, embarked upon a cooperative, distance education experiment. The web was used to deliver course materials and to collect student assignments.

**Texas.** From Southwest Texas State University comes a description of a cooperative approach used in the development of a WWW group project. The project was a required assignment in a course in Advanced Instructional Technology, in a graduate program in Curriculum and Instruction. Our Lady of the Lake University has a new program that prepares classroom teachers to teach information processing in K-12 settings. Completion of the program meets the eligibility requirements for a state technology endorsement.

Texas A&M University at Commerce has identified some issues involved in preparing teachers to utilize Internet resources. This paper addresses the issues and describes ways in which education faculty can collaborate with discipline faculty to provide role models for their students. Midwestern State University views the Internet as a global classroom and learning center and presents an approach to induce teachers to pursue the Internet as a source of instructional resources.

Texas A&M University at Commerce discusses the evolution of an online graduate course for teachers. The rapid evolution of technology is paired with the sculpting of the course based upon reflection and student feedback. Rice University has two and four week intensive summer training models that empower teachers to take advantage of information technologies. Two projects and lessons learned from development are presented.

**Florida.** Nova Southeastern University presents impressions and recommendations of professors and doctoral students with online classroom experiences. From the University of South Florida come samples of web-based instructional materials for higher education. The applications described are a teacher’s guide to the Holocaust and a teacher’s guide to school networks.

Gertrude (Trudy) Abramson is Professor, Computing Technology in Education, at the School of Computer and Information Sciences, Nova Southeastern University, Fort Lauderdale, FL 33315. Voice: 954-423-1211. E-mail: abramson@scis.nova.edu

Sharon S. Brown is Faculty Assistant at SCIS, Nova Southeastern University, Fort Lauderdale, FL 33315.
In 1996, it was declared the European year for life long learning, stating the fact that there is an increasing demand in all walks of life for updating and refreshing existing knowledge and skills in order to keep abreast with professional and social requirements. With significant revisions of methods as well as content of professions, with tight working schedules and continuous challenges posed by new tasks and requirements, most professionals tend to postpone the extra effort required to embark on traditional continued education or inservice training programmes.

New information and communication technology (ICT) has for a couple of decades posed increasing challenges to the working force. A few adventurers and enthusiasts, on their own or by initiative from their employers, threw themselves into the technical whirlpool in the early 80s. Gradually they were mastering different operating systems, obscure user interfaces and arbitrary pieces of software available for their purposes. Improved user friendliness as well as escalating capacity/price ratio and popularisation of the technology have all contributed to an increasing application of ICT at all levels.

The combination of life long learning and ICT naturally leads to programmes for provision of inservice training through the use of computers and electronic networks. Both trans-European and different national initiatives have been launched in order to exploit the possibilities incorporated in the new technology. Several projects are in progress, gathering experience and developing new methodologies to suit both course providers and learners. The electronic learning environment may be a challenge to the traditional auditorium, classroom and hotel based seminars.

Cooperation between course providing institutions seems to be a fruitful track for saving efforts and resources. Through different projects in the field of ICT-based Open and Distance Learning (ODL), one has found that partners in production of learning material benefit a lot from exchange of electronic lessons, examples, programmes, etc. They tend to save on development costs, administrative systems and infrastructure, and at the same time increase the quality of final products and offers to target groups.

Future Role of Professionals

Life in the information and knowledge society puts new demands on professional roles and performances. Not only does the technology itself change the characteristics of traditional work, it also shifts the required skills for certain operations into completely different levels of understanding or detailed knowledge. In one direction, the visible results of efficient working in a store is changed from that of manually noting and adding numbers to that of pressing the correct buttons on a calculator or cash register - or moving the bar codes past a photo cell or similar device. On the other hand, the engineer does not need the same drawing skills as before when constructing a house or a ship, but must control the drawing facilities of a computer, requiring a higher level of understanding and insight into practical consequences of certain decisions.

In teaching, as well as in company training programmes, the role of the presenter or trainer is gradually changing from that of being a knowledge provider and a source of solutions to all problems, into being a guide or adviser for learners to find and choose from the information and instructional material available. In a society where information, and our access to it, is growing exponentially, it is becoming increasingly important to assist learners in acquiring skills to handle information. An important part of this is to develop a critical and reflective way of sorting, discriminating and interpreting the information provided. They must also be able to turn the acquired information into knowledge and understanding of their immediate surroundings and the challenges facing them.
IT and Telecommunication

Particular requirements are related to new technology as part of new professional roles. ICT is not only used as a tool and a source of information, it is also in its own right an important part of workmanship and required skills of future citizens. It is well accepted that a clerk expecting to work in the future must know how to apply word processing, and that an accountant will be obsolete if he does not know computer based accounting systems. Maybe it will also be expected that a journalist or a history teacher must know how to search in databases for interesting extensions to his lessons, eg., the present situation in the Middle East. But do we realise that it is equally important for a social science/biology teacher or an environmental adviser to manage system dynamics and simulation models in order to understand or communicate the challenges of local or global pollution?

Telecommunication seems to play an increasingly important role in future society. Capacity, bandwidth and speed of transfer of large amounts of digitised data, including sound and graphics, is covering greater parts of the world every month. From being a separate technology, it is now accelerating its integration into the computer and other information technologies, changing the PC from a stand-alone device into a small node in a world wide network of information. Large databases are included in the same network and professionals of all kinds are meeting in the virtual space to discuss their problems and points of interest.

Open and Distance Learning (ODL) as a Tool to Cope with New Demands

The ever increasing demand for updated skills and knowledge in different fields makes it impossible to cover it all through traditional education or training systems. Companies and public institutions have long traditions in arranging courses in-house or at hotels, etc. when new skills or principles are to be introduced into their activities. No credits or formal qualifications were attached to most of these courses. It was part of the inservice training offered by the employer and a requirement to be updated on the task to be performed.

An alternative for raising the qualifications of the staff was to let a selected few attend formal education programmes, acquiring new degrees or diplomas. Expenses related to such programmes could be born by the employer, by the professional her/himself or as a joint agreement between the two parties. Costs could be considerable for study programmes running over several years in order to obtain a degree, even in cases where the education or training was provided outside regular working hours.

Distance education has long been a practical way of taking courses and obtaining qualifications. Specialised institutions like correspondence schools and open universities have provided thousands and millions of citizens with interesting offers of initial and further education. In the age of new ICT it is natural to apply the technology for distribution of learning material. As a consequence of this, the importance of distance in the learning process is changing. It is now becoming more essential to talk about open learning, possibly combined with learning at a distance into open and distance learning, ODL.

The definition of ODL varies according to organisation, structure and possibilities. In this paper we will limit ourselves to the interpretation, where the openness is particularly directed to the open access of learning material through electronic networks. The distance of the students is not of the same importance to us; they may well be regular students inside the institution, staff members or individuals in another part of Europe. The important principle is that university courses, learning material as well as exercises and examinations, are available to the learners in their part of the world. With certain restrictions the services should also be available to them when it is required, i.e. asynchronous distribution and availability is the general rule.

Further and in-career training through ODL therefore makes it more easily available, costs and regulated working hours can be saved and the traditional universities and colleges may be opened to the public for life long learning programmes. The effort for traditional universities to change some of their traditional mass lectures and demonstrations into transferable, ICT-based learning material, is quite a scary exercise. It may not even be possible or desirable in many cases, in particular subjects or topics. The latter is certainly the case for some of the special aspects, e.g., in training of nurses or in teacher education, where important values can hardly be detached from the human touch. There are, however, lots of topics and courses related to teacher and nurses training that may successfully be offered through ICT based ODL, where positive results have already been observed.

Challenges to Institutions

The enormous efforts and resources needed for providing ODL material to new target groups of learners simply requires that parallel work and development of products should be avoided. All partners will benefit from cooperation instead of competition, exchange of material instead of protection, specialisation of competence instead of covering all fields at every institution, sharing of duties instead of providing double work. In particular the learners will benefit from the products and facilities resulting from such cooperation.

There must be regulations and rules to play by, however. Models for cooperation between academic institutions for the purpose of ODL have been tried out in several European projects, providing valuable experience...
that serve as a basis for revision of models and development of new ways for providing ODL to the optimal benefit of both students, staff and the institutions. Most valuable results and experiences have been acquired when both academic institutions and receiving organisations have been working together in the planning and development of ODL courses and material. Examples of such activities will be provided in the following sections.

**Institutional Cooperation**

Cooperation between academic institutions seems to be an educational policy, nationally as well as internationally, including the establishment of a educational cooperative network between centres of higher education and research. Several countries throughout Europe state in their White papers or other political documents principles and guidelines for cooperation and sharing of expertise between educational institutions. As an example of how cooperation between institutions and exchange of experience are stressed, the European Commission’s Socrates programme has **partnership between educational institutions** as one of their criteria to allocate funding to projects.

Enterprises throughout the world claim that there is a huge need for updating of personnel skills. To meet this need we already see a growing tendency of real cooperation between enterprises and the formal educational system in order to update their employees. Normally the employer has the responsibility for updating their staff, but by now we more often see a combination of updating the staff by offering them formal qualifications. Development of necessary curriculum to obtain formal qualification is based on cooperation or enterprises between the companies and the formal educational system, where the companies play a central role in describing the needs and also are the ones to find or provide the know how.

Introduction of electronic networks, e.g. Internet, increases the functionality and facilitates practical activities among cooperating institutions. Both academic staff, learners and the outside learning society are supposed to benefit from diverse specialisation and expertise, sharing of duties between institutions.

Together, the collaborating institutions may be able to provide a greater variety of studies to their learners than any one of the institutions can manage on its own. Collaboration should emphasise the importance of being able to utilise the various profiles, specialities and professional expertise of the different institutions and enterprises. This should increase both the width and depth of the learning environment.

One example of how institutional cooperation has been practised is the way the Norway-net with IT for Open Learning (NITOL) project has organised their work. Four academic institutions in Norway have successfully practised their own model of cooperation since 1994. Much of the success in this pilot project is probably based on longstanding relations and trust between the key personnel involved. The major goals of the project were to:

- gain experience and develop methods for ICT based, open, flexible and distance learning at university level;
- facilitate cooperative research and development between geographically separated academic units and personnel.

In order to approach these goals, partners had to:

- establish an open network making education within Norway-net available to students and other groups and individual participants from business, schools, administration, etc.;
- gain experience on distribution of educational materials through electronic networks;
- test the use of electronic conferences and mail systems as the basis for group work and cooperative learning;
- develop an extensive, dynamic and creative electronic learning environment based on local and wide area electronic networks.

**Organising NITOL**

Despite the close relations and friendship between the active partner representatives in the project, a formal organisation had to be established in order to be prepared for disagreements or conflicts that might arise over economy, responsibility for students, networks, software, academic property, etc. To meet this requirement two formal contracts were established, one general agreement of cooperation between the four institutions, signed by the heads, and one particular NITOL contract signed by the project representatives from each institution.

The signed contracts are mostly dormant. In a few cases they have turned out to be very useful as reference and guidelines for disputes that arose. The project agreement is mainly in line with the project groups’ feeling of common sense, while the institutional contract is an important document especially when institutional authorities forget their commitments to NITOL.

Technical support and standards have proved to be important issues for an ODL project based on ICT. This always turns out to be a touchy issue between experts. Among the “experts” in such a project are tens of teachers and hundreds of students - who all have their own, well founded preferences for software and communication systems. On the other hand, there are also hundreds of “non-experts” or novices who need to be given simple solutions that fill their present needs. Among the latter group are also some of the course providers. It is therefore of utmost importance that the project group is able to make firm decisions, stick to the solutions given, and that there are able and committed people to support the technical system decided upon. As new technology develops and becomes available - outside the project - a careful balance
must be found between existing, stable solutions and introduction of new, improved facilities for the project services. Responsibility for these technical decisions lies with the project group, while implementation and support is placed with one of the partners.

**Objects of Collaborative Activities**

**Course Material**

Together, the collaborating institutions are able to provide a greater variety of studies to their students than any one of the institutions can provide on its own. The collaboration emphasises the importance of being able to utilise the various academic profiles, specialities and professional expertise the different institutions stand for. The colleges are able to enhance their curricula at both undergraduate and graduate levels, thus providing their students with a greater variety of subjects than can be offered at any one institution alone. In addition, quite a few students want a more flexible programme that allows them to study at the time and pace of their own choice, with fewer restrictions on attendance and place of study. Collaboration around flexible and open learning makes this possible.

Because of the variety of professional profiles at the cooperating institutions, close collaboration strengthens the whole teaching and research environment at each institution. Experience shows that through electronic communication it is possible to work together in a close and efficient manner in a “virtual” environment of cooperation. This has already been established between the NITOL institutions, and is spreading throughout the rest of the IT environment. This is a system that effectively establishes and utilises contacts across the boundaries of institutions, regions and countries. Course material is developed along three different paths or models for institutional cooperation:

- **The Open Access Model.** This is one of several models within the NITOL. This was the first one tested, where each institution offered some of their traditional courses, revised or redeveloped for electronic transmission to their own students as well as to outsiders.

  The beneficiaries of this model were mainly the students, having easier access and more courses to choose between. The institutions and the professors gained experience in dealing with distant students and the colleagues’ ways of presenting learning material. This golden opportunity, to look at how colleagues presented and designed their teaching material, was a fringe benefit.

- **The Composite Model.** This model is applied when the institutions compose larger courses by joining two or more smaller modules developed at different institutions. The result could be a tailored study for special purposes or just an extension of a small course, which a single institution is not able to develop alone, due to restrictions on time, staff, expertise, etc. This model seems to have its strength especially when colleges/institutions are small or medium sized, where resources and the variety of the staffs’ expertise is limited.

- **Joint Venture Model.** This is a model where the main idea is continuous, real collaboration between professional groups to develop course work (See Figure 3). This means that two or more institutions within the network join forces in developing open, flexible learning materials in the form of lessons. One or more lessons forms a module, and the final course consists of several modules. Mature students and professionals jointly contribute to the understanding and learning of a topic or subject. This is not utopia we are suggesting here, it is already a reality in the joint venture model. As an extension of the model, a virtual, joint...
venture learning society on the network does not seem far away.

A first evaluation of collaboration, assessing the intentions and the models described, identifies characteristics like inspiration both to students and professors, improvement in the quality as well as an increase in quantity of the courses offered. All parties involved seem to be satisfied and inspired to further efforts for open and flexible learning.

![Figure 3. The Joint Venture Model.](image)

**Mutual Services.** An important issue in the partnership agreement is the mutual recognition of credits, courses and modules between the partners involved. Students may thus choose modules and courses from a larger menu, combining it into more varied and specially tailored lines of study. It is, however, still up to the institution that issues the certificate to recognise the final combination of subjects and courses.

External funding has played a central role in the early stages of NITOL. Applications and proposals for funding have turned out to be more positively viewed in cases where a collaborative organisation has already been established. The NITOL partners have therefore in several cases joined forces in the process of application, and afterwards shared the benefits obtained through decisions by the project group. The basic principle is sharing of funds acquired in equal parts. Often the group agrees to reserve particular sums for special services, e.g., technical support, printing of catalogues, administration, etc., and then shares the remaining sum equally.

**Marketing.** Instead of competing over the same target groups with parallel courses in related fields, the NITOL group has consequently, from the start, issued a common course catalogue for all the courses provided by the group. Even though the courses are provided by individual staff members at separate institutions, and marked this way in the catalogue, there are great advantages in joint market-ing. Distribution of information becomes easier, potential students get a better overview, and large scale customers, like the Navy, can find a more varied offering for their members.

After only two years, the NITOL concept already has more meaning to a lot of people interested in ODL than the name of each of the partner institutions. At the same time, each institution benefits from belonging to this group.

**Visions**

The models for ODL through telecommunication, taking advantage of the institutional cooperation described above, may open up for simpler access and higher flexibility for all kinds of professionals to obtain inservice and further education, as well as taking new formal degrees, without leaving their regular work/duties or their families. With the growing familiarity of Internet, telecommunication and similar facilities in homes and work places, the time may soon be ripe for higher education modules to be available when and where the learner finds need or desire for it. This will compose an important aspect in the policy and possible success of lifelong learning.

Harald Haugen, Associate Professor at the Department of Education Studies and Science, and Deputy Principal at Stord/Haugesund College, N-5414 Rommetveit, Norway. Voice: +47 53 49 13 76, Fax: +47 53 49 14 01. E-mail: harald.haugen@hsh.no

Bodil Ask, Assistant Professor at the Department of Engineering, Agder College, N-4890 Grimstad, Norway. Voice: +47 37 25 31 31, Fax: +47 37 25 30 01. E-mail: bodil.ask@hia.no
Constructing an Interactive, Online, Social Studies Tutorial on Internet Use

Gray Clayton
University of Waikato, New Zealand

Since 1994, the School of Education at the University of Waikato in Hamilton, New Zealand, has been running an Internet Service for 200 local teachers. The service is called WeNet - Waikato Education Network (URL: http://www2.waikato.ac.nz:81/education/WeNET/WeNEThome/). WeNet provides SLIP access for a range of primary and secondary school teachers, and, as part of the service, undertakes research projects in Internet use and provides workshops and services based on the outcomes of that research.

Past projects have included The International Water Project in 1992 (Campbell, Christensen, Clayton & Knezek, 1993) and The Air Project in 1993 (Campbell, et al, 1994). These projects explored ways in which e-mail contacts between teachers and students might enhance classroom programmes. WeNet grew from the success of these projects, and the desire to move beyond e-mail and incorporate the results of the research into a complete range of curriculum teaching.

The Project

In 1996, funding was obtained for developing a resource to help teachers incorporate Internet tools into their regular curricular programmes. The aim was to establish programmes which saw Internet tools as more than topics of study. The proposal was that an inservice course be developed which drew on previous projects to help teachers incorporate Internet tools, not only into their daily classroom programme, but actually into the whole range of curriculum subjects.

Design

In choosing the topic and the design for the inservice course, it was decided to canvas WeNet teachers. The 200 WeNet teachers constitute a group that now has at least two years experience in SLIP access to a range of Internet tools. Regular workshops are held on using the tools (Making the Most of Eudora, Netscape, Search Engines, etc.) as well as workshops on a range of issues (Acceptable Use Policies, Classroom Organisation for Single-Computer Use, etc.). The Helpdesk facility works with WeNet teachers on a regular basis. Regular bulletins and news issues are provided. Based on this exposure and support, it was reasoned that WeNet teachers would be a good source of guidance for designing the inservice course. A sample of 30 teachers was contacted in a telephone survey and seven additional teachers were interviewed in-person. These seven were teachers who had come to the attention of WeNet staff as being particularly interested in the service and as demonstrating a high level of usage.

The results of these surveys altered the preconceived plan, which had been to produce a workshop on accessing the Internet and learning to use the basic e-mail and browser tools. Teachers reported that they were able to manage these tasks with the help that ISP's provide, with assistance from colleagues and technical support at the school. The assistance that was most often requested was help in incorporating Internet tools into regular curriculum teaching.

It was decided to mount a series of workshops on WeNet as web-based courses. Each course would demonstrate an individual curriculum area and would guide teachers through issues and procedures that would help them incorporate Internet resources into their teaching in an efficient and effective way. It was decided to start with a course on social studies teaching because previous research had provided most experience of Internet use in that curriculum area (Barr, 1994).

Issues

In designing the course, specific teaching objectives were established as well as some criteria for outcomes that would not be sought. For example, it was reasoned that the inservice clientele for the course would not require guidance in teaching or in delivering the social studies curriculum; it was decided that the course would cater to New Zealand teachers, and not provide pathways for teachers who might access the web pages from abroad in order to utilise the course in their own national curriculum.

After taking this course, teachers will:
have interacted with course material to develop their own cognitive model of the principles and practice for utilising Information Technology (IT) tools in Social Studies curriculum teaching;

- have satisfied their curiosity about structural mechanisms and procedures for utilising IT tools in social studies curriculum teaching;

- have had the opportunity to discuss developing ideas with course tutors and with course members;

- have planned and developed a successful social studies unit which utilises IT tools;

- have reflected on, analysed and restated in a cogent form, their ideas, understandings and experiences in utilising IT tools within social studies curriculum teaching;

- feel empowered to adopt a mentor or tutor's role for future courses.

It was considered important that the course attempt to be interactive. The reasoning was that "Active Learning" should be a good goal and that "Net Surfing" could sometimes be seen as an exercise in flitting among quantities of "Good Stuff" without commitment. (In New Zealand a popular retort to salespersons in retail stores who approach shoppers with the intent of persuading them to buy, is "Just browsing, thanks.") To this end it was decided to require enrollment and to require active responses from course members.

Social contact between course members was deemed important. Staff at the School of Education frequently comment on a preference for face-to-face teaching rather than teaching by distance modes because of their perception of the importance of social interaction among the group of learners. The metaphor for the interface design was specifically chosen to suggest a familiarity with face-to-face courses and in-person site visits. A chat section as well as e-mail contact was devised, and a procedure implemented which enrolled course participants into groups that were identified to members, so that they could share their experiences with the course with each other another.

Course credit was considered. While designing the course materials and resources so that teachers are free to explore those features which they feel are important, it was recognised that it might be reasonable to formally recognise the achievements of participants who succeed in developing their knowledge, understanding and practice to a certain extent. A course that is designed to require the participant to identify and be responsible for accessing the information that is of greatest benefit to that individual is potentially a very valuable experience for that individual. Such a course is also open to very cursory participation. Assessment and accreditation are issues that required some careful thought. A two-tiered approach is currently being investigated. It is possible to pass through the sections of the course without asking for credit, in which case no attempt is made to evaluate the work of the course member. Teachers who do request credit are asked to provide a document outlining the results of their reflections and to provide a theoretical position to support these. The record of their participation is then passed to a course mentor, together with their document, and is assessed. Feedback is given and successful candidates are offered a position as mentor or course tutor for future groups.

The development and extension of the course was considered. An obvious factor relating to the initial course is that it depicts one class taking one topic. Accepting the aim of providing course participants with the vicarious experience of participating in a class, it would obviously be of benefit to provide a range of classes and topics so that participants can choose ones that are of personal interest. Using an approach similar to Group Hypermedia, described, for example, by Acker (1990) in which users collaborate in a common workspace and build information structures through co-use (Stevens, 1989; Akscyn, McCracken, & Yoder, 1988), it was proposed that new tutors and mentors might bring with them resources from their own experience with the course and add them to the resources originally provided.

Production

The production process proceeded in a number of trial-and-revision stages. In order to provide the vicarious experience of "sitting in" with a class undertaking a unit, it was necessary to arrange for a class and teacher to allow the recording of a social studies unit. Having achieved this, it was important to record, in as much detail as possible, the events of the unit's planning, preparation and implementation. Audio and video recordings were made, photographs taken, participant observer's notes were recorded and samples of the children's work were collected for scanning and photographing. The unit was taught during two weeks; prior planning, subsequent reporting and feedback added a further three weeks.

In reconstructing the unit for the course, original recordings were repeated in many cases in order to obtain clear audio and photographic records. Using the original recordings as guides, reminding the children of the events they had previously experienced and explaining the need to repeat those events, it was possible to record remarkably close approximations of the original reality in ways that produced informative pictures and sounds. At this stage it was also possible to make recordings for parts of the course that had not been foreseen, such as an audio description of the class by the teacher (when a visitor enters a teacher's class to observe their programme, the teacher will usually describe the class to the visitor) and an audio discussion of her objectives (a written record had been collected, but a less formal, conversational explana-
tion was deemed to be also in keeping with the metaphor being used.)

**Piloting**

Piloting began during the design phase. During the early part of the production phase, an approach was used that involved laying out the structure of the course in diagrammatic form, in relation to the structure of the unit planning and lesson implementation of the class being recorded. During the whole production stage, the model (first its design and structure; later the design together with examples of the resources) was demonstrated for feedback. The audience included staff teaching pre- and inservice courses in curriculum social studies, preservice students, and academic staff, students and researchers involved in educational technology and web-based course design. Suggestions and comments were acted on throughout the production phase. Once a pilot version of the course was completed, it was provided in an off-line form to four teachers identified as being experienced in utilising IT tools in social studies teaching. These teachers were asked to work through the course as a group, accessing the course material from files on their personal computers but communicating with each other and with the project organiser by e-mail. They were asked to record full comments on any issues they felt needed addressing.

**Future Development**

The course is currently available through the WeNet Teachers Page (http://www2.waikato.ac.nz:81/education/WeNET/teachers/teachers.html). It is proposed to monitor its use and to canvas feedback to allow for its development. It is proposed to produce courses in other curriculum areas and utilising classes in a range of age groups. It is planned to monitor course participants with a view to clarifying, and hopefully resolving, the issues outlined above.

**Conclusion**

Social Studies On The Web has generated a large amount of interest for the people involved in its production and trial. It has raised issues worthy of further investigation and has provided impetus for careful thought and exploration of those issues. It was not spurred by an interest in utilising new technological tools, but has utilised leading edge technologies for their intrinsic value to the project.

Early responses indicate that there might be considerable interest in the production of future courses in a similar mould. Valuable outcomes can be seen for social studies teaching; for teaching in all other curriculum areas; for the educational use of Information Technologies and for the purposeful use of educational technologies in producing useful, teacher-centred courses in classroom applications of theoretical positions.

**Telecommunications: Graduate, Inservice & Faculty Use** — 1115

**1118**
At the Italian National Research Council - Institute for Educational and Training Technologies - we have designed a Virtual Class that implements an online cooperative learning environment. In the context of this project, we have carried out a teacher education course aimed at making teachers aware of the educational potential of the Information and Communication technologies.

After a brief overview of the project, we describe the course and highlight modalities, difficulties and results of the experience. Specifically, we focus on the advantages of an online phase of the training activity, during which teachers have planned the Virtual Class activities; this phase has proved extremely useful to allow teachers to fully appreciate and understand potentialities and functions of the telematic tools.

We have adopted the Bulletin Board System (BBS) technology to develop both the online learning environment and the online teachers' training phase; BBS's with graphic interface have proved efficient in fulfilling the communication needs of the learning/teaching process. Rapid developments in interactive communication technologies are quickly leading towards a new model for our society - at least in the developed regions of the world - which will be based on the Information Society principles.

Since it is a very deep social transformation, the educational system must play an essential role in developing this modification process: only schools can effectively lead - through specific curricula and by adopting technology for teaching/learning processes - to a full transition to the Information Society. The educational system must promote and sustain the innovative vision of the Information Society, by introducing - as early as possible in the child's scholastic life - pedagogical activities based on the new interactive electronic communications.

Furthermore, the Information Society is based on the same communication technologies which represent huge potential for education. As a consequence, during the past few years, it has been easy to imagine an educational system that - by adopting these technologies and suiting them to its own educational needs - would be able to play the educator role for the incoming Information Society.

However, this process might be delayed because of a teacher's incorrect approach to the new technologies. Actually, underlying the idea of a school as a promoter of the Information Society is the teacher's awareness that computers are learning tools and not merely objects to be studied. It is not easy to get teachers to develop this awareness, mainly because of the way computer science has been historically introduced in the educational system.

That was the time when the concepts which are basic to a view of the computer as a real and effective didactic resource - Multimedia, Hypermedia, Telematics, and so on - were not yet mature, both from a hardware and from a software point of view. Therefore, the computer was regarded as a technical (but not didactic) laboratory tool, and it was introduced as a subject of class curricula: the purpose of its introduction was to teach students how to use it, rather than to exploit the computer as a real learning tool.

Because of this view of the computer, only those teachers who were interested in the technical and programming aspects of computers (generally speaking, teachers of technical disciplines) became familiar with computers. Most of the other teachers were not really interested in the computer, since it could not be used as a tool to support their activities. To make things worse, the non-graphic
interface of the first computers, and an initial skepticism towards the new devices, discouraged the adoption to computers.

During the following years, since the applications aimed at developing cognitive and meta-cognitive abilities (such as self-learning systems based on the hypertext paradigm, or telematic applications for cooperative learning) started being introduced into the learning process, most of the teachers have been still feeling the initial view of computers; consequently, it is extremely important make teachers aware of the new role of computers as didactic support resources.

In our Institute, we have designed and carried out, as tutors, a teacher education activity, aimed at making teachers aware of the educational potential of the new powerful information and communication technologies. In particular, this is to help them use the new technologies in the context of a Virtual Class designed to implement an online cooperative learning environment.

This paper aims to point out the difficulties encountered in training teachers who are often tied to traditional teaching methods and work in logistically unfavourable situations, and to point out the key elements in the training process, which have produced satisfactory results. Finally, it should be noted that we report on an Italian experience in a socioeconomic context which is very similar to many developed countries that are going to develop an educational system projected into the Information Society.

The Online Cooperative Learning Environment

The online cooperative learning environment we have designed is aimed at analysing the advantages and problems related to the use of telematic tools at school and how Telematics modifies teaching/learning processes.

The learning environment, which in the first year involves four classes (20 students each, aged between 12-13) belonging to two secondary schools in Palermo, is based on Bulletin Board System (BBS) technology with graphic interface. BBS allows users to communicate through several easy-to-use tools (E-mail, chatting, by exchanging messages through conference areas and files through shared areas, and so forth) and modes (synchronous vs. asynchronous), thus enabling different communication styles and strategies, according to the needs of the different educational moments.

The activities inside the developed learning environment have been subdivided into a preliminary stage and three subsequent stages. Through the different moments, the students (grouped according to sociometric criteria) and their teachers have been gradually encouraged to experiment with the telematic communication tools and with different communication paradigms, thus creating a concrete experience of Virtual Class. During the online activities, the groups exchanged ideas on various themes of special sociocultural interest, concerning the different geographical areas they come from, and concentrated on the study of a monument.

As indicated before, the different stages are characterised by different communication models, which have been designed to develop innovative and creative interaction strategies, and to increase the incentive and motivation to learn.

The model of the preliminary stage regards the presentation of students, by a telematic identity card or home page, created according to their fantasy. The aim of this first phase is to allow each student to meet fellows online and to familiarise students with the telematic tools. The second and third stages of the experimentation form the main part of project. Their aim is to lead the groups to learn and to cooperate by using the telematic resources.

In the second stage, remote groups are coupled so that two corresponding groups gather information about the same subject; the first group deals with the general aspects of the subject, while the corresponding remote group analyses a specific case regarding the subject. At the same time, a bi-directional communication flow between couples of corresponding groups takes place on a common argument in a horizontal way, from general aspects to particular ones and vice versa.

The third stage implies a transversal interaction model so that the groups which have studied general aspects cooperate and, in the same way, the groups which have studied particular aspects cooperate between teams. The aim of this stage is to guide students to analyse analogies and differences and to reciprocally integrate all the pieces of information.

During the second and third stages, teachers and tutors assess the participation of each group (and of each member within the group) to the study activities, by evaluating both the production of materials and the amount of interaction with the other groups. According to the results of their observations, teachers and tutors can suitably modify the role of each member within a group and the task distribution among the groups; similarly, they can vary the communication flows, e.g. by proposing new discussion topics, or stimulating the interests of the students into the material produced by groups less active in the online communication.

Finally, the fourth stage implies a free discussion model: all the students are invited to discuss topics, which have been deepened during previous stages by each single group. During this phase, each student can cooperate with and between groups, because all of them can study the results of the research activities of other groups and ask some questions, making their curiosities about specific topics clear and suggesting new reflections. The aim of this stage is to allow the groups to learn the materials produced.
by the remainder of the students, thus giving everyone a complete view of the research work.

**The Teacher Training Course: From Face-to-face to Online Meetings**

The training course described in this paper has fallen within the context of a school lacking in information and communication technologies, and where technology, until the beginning of our experience, had been left out of educational activities. Both the schools involved in the experience had only a few computers, essentially used to familiarise students with the basic elements of a computer.

Results of questionnaires handed out to the teachers before the training course started indicate that, among the teachers attending the course, computer science expertise was very poor and this reflects the general situation in these schools. As a matter of fact, two thirds of the teachers had never used a computer before. This situation caused practical difficulties on the top of the purely methodological problems.

The teacher training has focused on the basic aspects of educational multimedia and telematic technologies, in order to familiarise teachers with the instruments for the definition and the management of online cooperative environments. The course consisted of three phases: in the first and second phases, we have proceeded according to traditional methodologies, with teachers and their trainers meeting in the classroom. The last phase has been aimed at the online planning of the didactic process.

The aim of the first two phases of the course has been principally to provide a general view of the multimedia and telematics concepts by stressing their role as useful technologies within the teaching/learning processes. To be more precise, the first phase has focused on the theoretical aspects of the two concepts; the second one has been based on practices on the use of the computer and, more specifically, of the FirstClass communication software.

As far as the theoretical aspects are concerned, after the definition of the terms Multimedia and Telematics, we have moved on describing their basic features. Then, we have illustrated the major application fields of Multimedia by highlighting the potentialities of multimedia communication for education and by proposing concrete examples of didactic, self-evaluation and self-learning hypermedia and hypertext systems.

As regards Telematics, firstly we have pointed out the key-role of telematic networks in educational contexts; particularly, we have argued how, by means of suitable communication models, telematic networks are able to enhance the extremely important socio-relational component of a learning process. Secondly, we have highlighted the advantages and problems of the two basic network uses (accessing remote resources and synchronous/asynchronous communication), both for teachers and students.

Furthermore, we have dwelled upon the added value of the telematics in different moments of the didactic process (planning, management and teaching/learning activity). Finally, we have stressed the opportunity to use telematics to implement new teaching/learning methodologies, useful to introduce meaningful changes in the way of teaching.

The need to provide teachers with a concrete example of innovative didactic methodology, such as the Virtual Class, has made it possible to clarify the theoretical concepts and describe in detail the different stages and communication models of the designed online learning environment.

The aim of the second phase has been to really guide teachers towards the basic elements of computer, by means of practices, in order to enable them to fully understand and appreciate the several potentialities offered by the FirstClass BBS software.

During the second phase we have guided teachers (organised in small groups) to practice with the different basic functionalities of the telematic tools (which had been previously learned at a theoretical level during the first phase). In order to make teachers really appreciate the features and functionalities of the communication tools, we have simulated interpersonal communication sessions, both in synchronous mode (chatting sessions) and in asynchronous mode (e-mail). In addition, teachers have experienced the enormous potentialities offered by graphic user interfaces.

At the end of these practical activities, the teachers had understood the differences between the functionalities of E-mail, chatting, file exchange mechanism, and so on; however, they had not yet really focused on the different contexts of use of each tool. This result would be reached at the end of the next phase, as reported below.

During the third phase, we have guided teachers to meet us and remote teachers through the BBS, in order to plan the activities of the Virtual Class. Our role, as tutors, has been central to the success of this stage: we have encouraged the use of the BBS to produce, send and exchange all the documents concerning the planning of the activities of the Virtual Class (such as the socio-metric questionnaires used to group the students), and to handle most of the activities concerning the Virtual Class (the distribution of the study activities among the groups, the organisation of guided tours to the studied monuments, the communication paths between couples of groups, the communication mechanisms between students, students and teachers, teachers and tutors and among teachers themselves), as well as to discuss their technical difficulties in using the BBS software itself.

The third phase has proved to be extremely effective, as it has given teachers the opportunity to experiment with the communication technologies and methodologies that make for optimal use. Only in this context have they
learned how to adopt suitable ways of telematics according to the changes in their communicative needs, e.g. when to exchange files, when to communicate via e-mail rather than via conferences, when and how to organise meetings in online chat sessions.

It should be noticed that, at the beginning of the training activity, the teachers showed a strong preference for interactive online discussions vs. asynchronous ones, probably because synchronous communication is the way they are used to communicating in their class. Consequently, teachers tried to use chatting also in situations where that mode was not well-suited. In addition, it has been noticed that the more the teachers acquired the skills to effectively use the BBS tools, the more they found useful and effective to manage their meetings through the BBS, since they could work according to their own space and time constraints. Consequently, they got used to phoning only for urgent problems and questions, and to reducing the physical meetings on particular circumstances. In other words, they really felt the concrete advantages for their activities.

During the whole training period and, above all, during the online stage, other interesting aspects have emerged. Firstly, telematic technologies can really help communication among teachers in specific communicative situations, by avoiding a direct relational component which, sometimes, might generate complex dynamics. Secondly, the use of telematic networks for educational planning has made the teachers realise that traditional curricular activities can be successfully supported by the methodologies provided by the new technology. Consequently, teachers have begun to consider computers as a useful support for the whole educational process. Thirdly, looking ahead, the recording of online discussions, via e-mail or discussion forum, concerning problems on didactic organisation and technical questions, will be the starting point for producing, in a short time, Frequently Asked Questions documents to be published on BBS and Internet. Finally, it should be noticed that communication amongst the actors of the Virtual Class (teachers, students and tutors) has been significantly simplified by using the graphic interface of BBS software like FirstClass which, through immediately comprehensible icons, allows the visualisation on desktop of all the folders corresponding to the carrying out different communication models.

Conclusions

Teacher education is crucial to successful experiences based on the introduction of innovative communication technologies in education. In this context, not only should the training activity make the teachers acquire the technical know-how and skills related to the new tools, but above all it should make them understand the potentialities offered by the new information and communication technologies for educational purposes; in addition, the training activity should point out the changes these technologies impose throughout the learning/teaching process.

In this paper, we have reported on a Virtual Class project, designed to implement an online learning environment, and we have focused on the corresponding teacher training activities we have designed. Among the several activities, we have guided teachers to design and plan the activities of the learning environment directly on line; this has been proved very efficient to enable teachers to realise the real potentialities of the new media, thus going beyond the simple use of new attractive tools.

The concept of computer as a tool for communication and learning has enabled teachers to acquire really innovative ideas about computer science at school. Through the experience described in this paper, we have fostered, in the teachers involved in the project, the change in the concept of computers, from simple objects to be used for communication to effective learning tools.

Acknowledgements

We would like to thank the teachers who have taken part in the project and our colleague Onofrio Di Giuseppe for his precious support in setting up the FirstClass server and for his suggestions for the project.

ISLA (Information System for Los Angeles) is a digital research archive of Los Angeles materials in multiple information formats for the purpose of research, teaching, and public access. Its scope includes the widest variety of information from all historical periods, linked by spatial and temporal coordinates. The primary, long-term goal is to create a system that will enable all kinds of users, including K-12 students, to search and access a rich and diverse range of research materials residing in many different locations. The system seeks to enable an open information-exchange network for all persons seeking to study the metropolis of Los Angeles.

ISLA is developing the specific information system requirements for researching large metropolitan areas in a multi-disciplinary fashion. “Los Angeles” is defined as broadly as possible: by an approximate 60-mile radius around downtown LA. This encompasses about 15 million persons, half the population of California. Large metropolitan areas like Los Angeles are only effectively knowable from many finite vantage points, each merely a small segment of the whole living historical entity. ISLA will maximize access to a critical mass of interdisciplinary data about Los Angeles in multiple formats. This will aid the process of learning about and solving long-term questions and problems facing all large metropolitan regions at the end of the 20th century.

The design of ISLA is a joint creation of researchers and is also an open project, inviting collaboration with area institutions and communities. The specific project defined here is entitled Learning with ISLA: An Exploratory Regional Information System for Classroom Integration of Digital Humanities Materials. This project is funded by the National Endowment for the Humanities (NEH) with the purpose of adapting a powerful interface to the World Wide Web; training pre- and inservice teachers in the use and development of curricular materials from the continuing-growing interdisciplinary resource; and connecting K-12 teachers and students to the digital humanities resources held in a very large, University-based digital archive.

ISLA Functional Overview

ISLA is designed to maximize access to a critical mass of interdisciplinary data about Los Angeles in multiple formats. It involves two components: (1) a library of multidisciplinary digital materials (texts, photographs, quantitative data, and other formats) about the Los Angeles region; and (2) a specific search and retrieval method involving a space/time/full-text/format index.

Materials

The prototype ISLA contained digital spatial data made available from Thomas Bros. Map Company and the Bureau of Engineering of the City of Los Angeles, historical data layers from the 1939 WPA and land use maps, 1945 and 1928 Fairchild aerial photography, and representative photographs. During this project additional items will be added to the growing ISLA digital archive. These include, for example, the first surveyed map of Los Angeles (1849), at least 25 large-format nine-color maps from 1939, English- and Spanish-language newspapers, 2,000 historical photographs, and other materials such as audio-visual media audio, video, film) and demographic data. The University and area archives hold a great wealth of valuable historical photographs about the Los Angeles region. For example, the University alone holds 1.5 million photographs covering the entire period from the 19th through the 20th century. From these collections, materials will be selected to provide classroom use of a critical mass of digitized materials capable of supporting open-ended investigation by students in three focused periods: the Native American, Spanish, and Mexican Periods of California History, the Great Depression, and Contemporary Period. In addition, the project has defined two major thematic areas: Human Geography, Ethnicity, and Neigh-
The interface capitalizes on the space/time/full-text/format indexing to search for and retrieve materials. ISLA allows multiple time and space areas to be defined. In addition, conventional indices of author, title, subject, or other cataloging fields, the attributes of Geographic Information System (GIS) vector layers, the gazetteer, or the full text of documents can be searched via the full-text line at the bottom of the screen display. A full palette of logical operators is available.

But the ISLA design goes beyond these indices by integrating a spatial-temporal element, (historical data layers, e.g., orthophotography, or “registered” scanned maps), into the search and retrieval infrastructure. The intent is to allow users to define their search in a historically-appropriate setting. In effect, users will be able to take a “core sample” of a geographic area, through layers of time. The hypothesis is that intuitive exploration without the barriers of time and space may facilitate conceptual breakthrough and allow creative integrated learning.

A primary objective of the ISLA interface is to promote flexibility and ease of spatial definition. In keeping with this objective, the ISLA interface allows users to define their search using different digital spatial layers such as neighborhoods, streets, orthophotography, zoning, land use, census areas, and parcels. Also, every effort is being made to lend a realistic, lifelike appearance to the map by using satellite imagery at a small-scale, and high resolution orthophotography at a large-scale, and projecting into California State Plane V for display.

It is important to note that no knowledge of these features is necessary for a search definition; the default values allow zoom from the Landsat TM image to current orthocorrected aerial photography with generally appropriate vector overlays. Whatever database is being displayed can be viewed at its full resolution. The highest resolution available at this time is 10.4 inches/pixel.

The ISLA interface will allow users to choose historical base layers upon which to define a search. For example, a student investigating the environment and wanting to research a site across time might be able to pick several dates of orthophotography, roads, or parcels upon which to finely define a search. The interface allows patrons to zoom in from space and/or back in time. The intent is that, in time, users will no longer have to guess from the present concerning the past in defining a search, but will be able to integrate historical definition into their search request. The capacity to show spatial layers at different times allows students and researchers to develop intuitive approaches to search construction without the barriers of time and space.

Since its inception, a primary goal of the ISLA project has been to create a system capable of providing uniform search and retrieval access to a very wide variety of information formats: textual, quantitative, still photographic and graphic, time-based (audio, video, film), and spatial data. Very advanced software systems have been developed for digitally handling all these data formats, but to date, no single interface has been designed that can weave them all together to use primary sources of the historical period. ISLA is particularly suited to assist in the fostering of participation and critical thinking skills, and in the development of information literacy skills.

The view of this project is that one of the keys to the success of technology into the classroom is appropriate teacher training, both in technology use, integration, and classroom teaching approaches. This is accomplished in the project through innovative teacher and technology training for both preservice and inservice teachers. The methodology employed in the teaching of teachers and the design of applications is the instructional technology process. This process supports designs based on solid learning theory and which emphasize evaluation, both formative and summative, as an integral part of design and development. This process emphasizes, regardless of the pedagogy, the role of communications an essential ingredient, communications between teacher and student, and among students. Our specific pedagogy views the role of the teacher as assisting students in constructing their own understanding of the content, based on the use of a rich set of learning materials, e.g., ISLA.

The other key to success is implementing technology into the classroom in approaches that are integrated, interactive, cooperative, and authentic. The design of the student curriculum will be based on the student collaborative-project based model which provides a high degree of interactivity and student exploration. Students will interact with real data and solve problems using their own experiences, learning styles, and culture. The approach also provides learning which has meaning beyond the classroom, and which provides links to students’ own neighborhood communities.

Preservice Use

As part of the USC Teacher Education Program, ISLA will be incorporated into the required teaching credential/master’s degree course entitled Computers and the Curriculum. The purpose of this course is to provide preservice teachers with the necessary computer literacy and experiences with integrating computer technology into the K-12 classroom. At present there is inadequate focus in this course, except in the area of Language Arts, in the Humanities. It is also noted that it appears that existing courses at other institutions also appear to focus more heavily on computer applications in other content areas, namely the Social Studies, Science, and Mathematics.
Preservice students will develop a basic understanding of the ISLA system and of the necessary skills to search and retrieve from ISLA. Based on this foundation and working in cooperative learning groups, they will develop a humanities focused lesson plan for their specific K-12 curriculum interest level. Their lesson plans will be presented to the class for critique and discussion. These developed lessons will be available for in-service teachers to review, evaluation, and modify for possible classroom use. (It should be noted that some of the students in the Computer and the Curriculum are already existing classroom teachers).

Inservice Use

A new version of the USC (University of Southern California) master's degree in Instructional Technology is being offered through the Institute for Technologies and Learning, a joint collaboration of the USC School of Education and the Los Angeles County Office of Education. This degree program is based on a learning-cohort education model which uses a constellation of learning services, major of which is the virtual classroom (electronic network).

A similar pedagogical approach will be undertaken as with preservice students. Those teachers in the program who teach humanities, or components of humanities in their classroom, will develop a basic understanding of the ISLA system and of the necessary skills to search and retrieve from ISLA. Based on this foundation, they will develop humanities-focused curriculum materials for their specific K-12 curriculum level at various layers: the lesson plan, a unit of study, and the thematic unit. All teachers will develop an ISLA-based lesson plan; a portion of these teachers will also develop and implement in their classrooms a broader unit of study which uses the ISLA humanities component. ISLA will also be used to develop several interdisciplinary thematic units, such as A Study of Culture: Southwest Native Americans, and How and Why an Areas Changes as Detected by its Arts.

Additionally, several of these applications will include integration of other existing WWW resources. Through the use of hyperlinks, existing humanities-oriented WEB resources (such as the “4th Grade California History Review” which provides lessons on aspects of California History, and “California’s Natural Resources” which includes some information on cultural diversity) will be linked to the ISLA-based system.

It is also proposed that several of these applications include student-input data. For example, students will explore their neighborhoods and provide unique data (such as current neighborhood photographs and interviews/oral histories of residents) to update the ISLA repository.

Evaluation

A standard methodology is being developed to evaluate the results of using ISLA. Several of the stellar-model (exemplary) ISLA-based curriculum applications will be evaluated in more depth by ISLA-project personnel. Specific examples of techniques to assess the outcomes of using ISLA in the Humanities curriculum could include achievement of specified learner outcomes and behaviors, content achievement, cognitive skill development, attitudinal assessment, amount of time-on-task, curricular improvement, teaching improvement, etc. It is also expected that an educational doctoral dissertation(s) will be focused on the evaluation of the use of ISLA.

Acknowledgments

The ISLA project gratefully acknowledges the generous support of the National Endowment for the Humanities, the RCL Foundation, the Lucy Batson Doheny Endowment, the USC Office of the University Provost, the Southern California Studies Center, and the USC University Library.

The ISLA project also gratefully acknowledges the generous support of the following institutions, firms, and individuals for the provision of data, software, and other resources: The City of Los Angeles, Bureau of Engineering, the Environmental Research Systems Institute (ESRI), the Southern California Association of Governments, the Map and Imagery Library of University of California at Santa Barbara, Thomas Brothers Map Company, PCI Inc., SPOT Image Corporation, the Department of Geology at Whittier College, and The Henry E. Huntington Library.

A UNIVERSITY DEGREE PROGRAM USING AN INTERACTIVE FIBER OPTICS NETWORK

Janet Sharp
Iowa State University

Bill Rudolph
Iowa State University

The use of fiber optics distance education to link various locations in Iowa is possible due to the Iowa Communications Network (ICN). This network is the telecommunications system installed by the state of Iowa to handle its telephone, data, and video/audio transmission needs. The ICN uses over 3000 miles of two-way, full motion, interactive fiber optic cable, supplemented by the Instructional Television Fixed Service. The network connects the three state universities, 15 community colleges, and Iowa Public Television. In addition, there is one site in each of Iowa's 99 counties with connections to various libraries, hospitals, and postal services. By the year 2000, 600 ICN sites are projected. Currently, at Iowa State University, there are nine on-campus ICN classrooms.

Iowa State University offers a unique graduate program, the Master of School Mathematics (MSM), intended for inservice high school mathematics teachers. This graduate degree is built upon three themes:
- the enhancement of knowledge of geometry, calculus, and discrete mathematics,
- the importance of problem solving in learning and teaching mathematics, and
- the use of computing technology in learning and teaching mathematics.

The course work includes geometry, topics in discrete optimization, intermediate calculus, a seminar on current literature in mathematics education, a statistics course, electives and a written creative component, totaling 36 semester credits. Completion of the MSM program fulfills the Iowa Masters Teachers Certificate. The program is structured so that all or most course-work can be completed in three summers.

Evaluations of the MSM program have generally been positive. However, we felt that the ICN provided an opportunity to reach mathematics teachers in remote, rural regions of the state who might otherwise not have the opportunity to leave their communities to obtain a higher degree. Although Iowa State University is located in very nearly the geographic center of Iowa, teachers in the western half of Iowa must travel two or three hours one-way to attend classes at Iowa State University, their closest in-state option. Moreover, there is no other master's degree program like the MSM in the state of Iowa so we felt we could draw mathematics teachers from the eastern half of the state as well.

The MSM program together with Iowa State University Extended Education jointly developed a survey to indicate interest in taking courses leading to the MSM degree. During the spring 1994 semester, this survey was administered to all secondary school (7-12) mathematics teachers in the state of Iowa. One hundred sixty mathematics teachers returned the survey indicating they were "very interested" and an additional 200 mathematics teachers indicated they were "interested" and wanted to know more about the requirements of the program. These results encouraged us to pursue the matter of putting the MSM program "online."

By the middle of summer 1994, the MSM program had been approved for the ICN by the Iowa Coordinating Council for Post-High School education. In the fall of 1994, an ICN prototype course was offered on campus with no remote sites. During the spring 1995 semester, a continuation of that course was successfully offered on the ICN. Then, in the summer of 1995, we offered the regular intermediate calculus and discrete mathematics courses over the ICN. After these inaugural ICN course offerings were enthusiastically received by the students in the program, we moved to a totally-ICN program. The response to this change was incredibly positive; enrollment in the MSM program increased 50%. We are delighted that we chose to offer the entire MSM program over the ICN to better meet the needs of our students.

Literature

During the 1995-96 academic year, the instructors of the MSM courses worked diligently to learn about effective and successful teaching via distance education. In terms of pedagogy, lecturing for long periods of time

[1126]
is unacceptable (Beers, 1996; Baker, 1993; Schoenfelder, 1993; Zbiek & Foletta, 1995). The use of cooperative group work with students at a given site (Beers, 1996) or at combined sites (Zbiek & Foletta, 1995) could also facilitate student interaction. Bialac & Morse (1995) found that students at the remote sites would sometimes sit back and watch as the students at the origination site answered questions. However, many researchers (including Bialac & Morse) reported methods to maintain meaningful interactions with students through e-mail (Zbiek & Foletta, 1995) or through conscientious eye-contact by the instructor (Schoenfelder, 1993). Baker (1993) also found instructors to be more successful when they took the time to learn student names immediately in order to call on them. In order to accomplish such solutions, Beers (1996) indicated that large class sizes, such as his class size of 50, were not workable and should not be attempted.

By spending some of the opening class period teaching students to run equipment (Bialac & Morse, 1995), all students become more comfortable with the microphones, camera, and the other technology such as facsimile machines (LeBaron, 1994). In fact, Beers, (1996) indicates that each site will somehow appoint a member of the class to be the “de facto technician for that site” (p. 680). Most experienced distance educators have had success teaching the course by traveling to each of the remote sites at least once (e.g. Beers, 1996; and Bialac & Morse 1995). Preparation of all materials in advance (e.g. Baker, 1993; Beers, 1996) is vital to successful classroom interactions and information sharing. After studying the findings of such researchers, we felt prepared to deliver our first ICN course.

Results

During the summer of 1996, Iowa State University offered the mathematics education course and the statistics course over the ICN. In the mathematics education class there were five remote sites along with the Iowa State University classroom site for a total of 25 students. The authors of this paper team-taught the mathematics education seminar course. Although we felt our experiences supported much of the literature, we also discovered three primary results.

First, even though remote-site students sometimes appeared to be off-task, we were delighted to learn that they were not off-task. Rather, they have learned an effective use for their previously developed “TV-Mental- ity,” which helps them to focus on their monitor when an important occurrence happened. This was actually a different situation to which the instructors had to become accustomed. Particularly with graduate students, we were each used to all eyes being focused on us so that we could verify that our students had heard and understood our every word. Another minor finding related to this idea was the breaking of our unfortunate habit of looking at the monitors showing remote-site students or at the real-live students at our site, rather than at the camera. With practice, we corrected this problem.

Second, we successfully used a set of two end-of-the-semester evaluations (See Appendix A). The first evaluation focused on the system, equipment, and distance education in general and the other evaluation centered on the course and the instructors of the course. Prior research (Beers, 1996) consistently indicated that students would deliver a poor evaluation of the course and hence, instructor, when, in fact, it was the equipment that had failed in some capacity.

Third, we were fortunate to have had the help of an efficient assistant during the planning and delivery of the course. Her skill at handling a multitude of time-consuming details, such as mailing TI-92 calculators and algebra tiles to the various sites helped the class move smoothly. As teachers, we were able to concentrate on the teaching of the course and not on the housekeeping details. She also helped us to handle the technology of the origination teaching station. It is essential to have an assistant to help with the planning and delivery of the course. This assistant gathers information, acts as a liaison with students, takes care of mailings and photocopying, and takes care of the mundane tasks which often impinge on an instructor’s time.

Recommendations

In addition to verifying many of the previous researchers’ solutions to possible discouraging situations, (e.g., being certain to plan ahead, writing text items in 28-point or larger, and not using a lecture-style of teaching), we also discovered a few simple tricks for effectively teaching through distance education:

1) A highly successful strategy for eliciting student responses was to put the camera on that classroom and wait. Admittedly, each of our sites had a relatively small number of students. In fact, we found the success of this strategy to be inversely proportional to the number of students at the site. Once the site housed 5 or more students, it was less effective. This is an interesting adjustment to “wait time.”

2) As instructors, we learned not to wear clothing that sported stripes, plaids, or large prints.

3) On the first day of class, we collected the e-mail addresses of all students and created a listserv that afternoon. The mathematics department employs a technology person whose job includes such activity. One of the most effective uses of this listserv came into play whenever we ran out of time. When a distance education course runs out of time, all transmissions are ceased. Consequently, students learned to check their e-mail for final comments from classmates or instructors.

1127
4) The class was scheduled for one hour each day. However, we were able to successfully solicit funds from our Dean's office to increase daily transmission for thirty minutes to have "office hours." The students were able to use those 30 minutes to ask questions of the instructors, to discuss professional topics with fellow classmates, and generally to bond with one another. Therefore, our class was one hour long, but we had the cameras on for one and one-half hours.

5) In accordance with suggestions from previous researchers, midway through the course, we planned a picnic for a Saturday afternoon. This served two purposes. First, as instructors, we provided an opportunity to visit face-to-face with all of our students. Second, we had initiated a class project that could be completed only when all students' work was combined. The picnic offered the opportunity to complete the class project.

During class prior to the picnic, the instructor asked the two students from Bettendorf whether or not they would attend. This site is well over 3 hours from the picnic site. Neither student from that site attended. When the instructor indicated that they would be excused because they were so far away, they countered with a reality check. "That's funny, we think it's you who are so far away." This reminded the instructors to be sensitive to the feeling of isolation that students encounter through distance education. We were careful not to make such comments in the future.

6) One of the most successful ways to ensure that all students are involved in the distance education course from the first moment is to use a roll call developed with the help of such software packages as PowerPoint®. This form of attendance gathering was created by two Iowa State University Professors: Ricardo Salvador and Michael Simonson. Within the first week of class students at all sites were required to create a PowerPoint slide with their name and containing a photograph, phone number, e-mail address, school where teaching, and other interesting facts. By the end of the first week, the finished product on a floppy disk was sent to the instructors who developed a PowerPoint roll presentation for the class. As we scrolled through these slides each day we asked a question, or other days the students would merely indicate "presence" or "absence." This was an excellent way to learn student names immediately.

Most students had no experience with PowerPoint prior to our class and were apprehensive about whether they could find and use it. However, it was a readily available software package which our students, regardless of location, were able to find and use. A few students were not able to access a scanner and either sent pictures to us for scanning or used the available graphics in PowerPoint.

7) Remote site students seem unable to appropriately decipher some non-verbal communication. Consequently, we felt that in the future, the pace of material coverage needs to be reduced. It is simply impossible to cover the same amount of material when so much of the communication process is lost or debilitated. These thoughts were supported by the evaluations we received at the end of the semester.

8) Student access at remote sites to relevant articles in the literature would appear to be a problem, especially in graduate courses. However, this was not the case. Prior to the course articles were identified, approval for reproduction of these articles was obtained, and then the articles were scanned onto a CD using a CD writer. Students were sent these CD's along with other class materials prior to the first day of class. All students had access to CD readers and were able to make hard copies of articles as desired.

9) Several students had to travel to other regions of Iowa for personal matters on occasion throughout the summer session. They were able to attend classes at other remote sites without missing class which was an unanticipated benefit.

10) Outside resources were used successfully during the class. For example, a classroom teacher having considerable experience with the TI 92 calculator spent a class period with us when this topic was discussed. A remote site close to where the teacher lived was used by the teacher - one not normally used but readily available for this activity.

11) Evaluation of students revolved around group presentations and a portfolio final. No formal pencil and paper examinations were given.

12) Several cooperative groups consisting of members from different sites worked very well. These students were able to use the ICN during "office hours" and group times. Other technology such as e-mail, listservers and facsimile transmission aided interaction.

13) One site had only one student and no official technology staff person. The student became very proficient with the technology at that site. He learned to let himself into the room, turn on the equipment, and set up all cameras. Nevertheless, we felt each site should have a minimum of two students in the event of technology problems and to aid in the student interactions and discussions.

14) Our experience suggests a maximum of five remote sites and the originate site. Three or four remote sites would be better. It is difficult to successfully manage and ensure a good educational experience for students when more sites are used.
In general, our experiences with the course were quite successful. As an accessible opportunity for professional development among high school mathematics teachers, this type of course offering will provide the teachers with unparalleled opportunities for furthering their education.

INTEGRATING THE INTERNET INTO THE UNIVERSITY CURRICULUM

E. Marcia Sheridan
Indiana University South Bend

Fred Herschede
Indiana University South Bend

The rapid adoption of Internet browsers, easy access and utilization of the Internet is significantly changing how we deliver instruction at all levels. As desktop computers changed our lives, so has the Internet changed the way we learn and teach. This paper will address how the Internet, particularly the World Wide Web (WWW), has been integrated into both undergraduate and graduate Education courses, and a MBA Economics course.

The WWW as an Education Teaching and Learning Tool

With the introduction of user friendly Internet browsers, teachers and students can readily enter the Internet universe of information. However, the ease of entry can soon turn to frustration if students cannot find their way around or locate relevant information. The new Web user is often confused and experiences disorientation regarding spatial relationships on the Internet, where things really "are," gets "lost in space," and is unable to find his or her way back to a reference point. There is a real need to help students conceptualize the relationships on the Internet, where things begin and end, and how they are linked together. They need to understand how the Internet is structured, where links are connected, the structure of a homepage, and how to utilize efficient search and retrieval techniques - how to find what they are looking for. These issues will be discussed in the context of several course homepages used by the authors.

Integrating Technology into Teacher Education Courses

The first thing university faculty must understand in integrating technology into their courses is what students know and how they can use it. Undergraduate Education students generally have more familiarity with E-mail and the Internet than Graduate Education students. Having grown up with video games, they are much less apprehensive than graduate students in exploring the technology. However, we have found their familiarity to be superficial regarding the Internet. They have seen it, but cannot really utilize it effectively. Graduate Education students, except for the technical coordinators in the schools, generally have never sent E-mail or even seen the Internet. A few of them border on being "technophobic," and need much support in exploring the technology. In both undergraduate and graduate Education courses, we have worked to guide students to the understanding that e-mail and the Internet are no longer just part of instructional technology and computer education classes. This way of communicating and learning needs to be integrated into all subject areas and at all levels of teaching. Our philosophy is that the university must model this integration with our students so that they have sufficient time and practice to move from guided to independent practice and utilization.

In both undergraduate and graduate Education classes taught by this instructor, all students were required to send one e-mail to the instructor. While this was a steep learning curve for just one e-mail, formative evaluation from graduate students support continued use of this requirement. Student questions indicated they needed help understanding where messages go, how they are accessed, and that they actually came back if they were not received by recipients.

Course Hotlink Websites

All students were introduced to Netscape, the browser used in our networked student computer labs. Graduate students who had less knowledge of the Internet, as compared to undergraduates, watched a 40 minute instructional video and spent a total of 3 hours in a computer lab receiving hands on instruction in sending e-mail and using Netscape. All students were given information on mini-classes offering further instruction conducted by our computer services staff. Lab assistants were also available in all student labs. Both undergraduate and graduate students were introduced to the course syllabi on the Internet, shown how to access the IUSB Library Homepage, do ERIC searches, and do interlibrary loan requests by computer. They were also introduced to specific course hotlink pages developed by the instructor to assist them in finding websites that would help them in looking for teaching and research materials which related to specific course assignments. The following organizational chart, Figure 1, Marcia Sheridan's Website for Education Materials (http://sun.iusb.edu/~msherida/), demonstrates the two hotlink websites developed for the Education students in two different courses. One is
oriented towards general reading materials useful for middle and secondary education teachers of all subjects; the other is devoted to the topics students study in a course on Education and Social Issues.

Figure 1. Marcia Sheridan's Website for Education Materials.

While we have seen some K-12 facilities in our area with excellent technology available for students, much of it is underutilized. Future and practicing teachers must learn to utilize technology or the money devoted to it will be poorly spent. Preservice and inservice teachers in university classes need to learn how to use the Internet as a research tool, as a resource for planning and accessing lesson plans in various content areas, as well as locating Internet sites which can be used with elementary, middle and secondary students if teachers are ever to integrate the Internet into their teaching. They can learn these if teacher educators integrate this new form of learning into university curricula as an integral part of instruction. Teachers are busy people, and unless a school corporation has an active professional development program which provides time for this practice, the kids in the school will remain the most adept users of the technology. At a minimum the goal should be to help future and practicing teachers reach the same level as some of the best K-12 students. When they are both at the edge of the technology, they will be learning together as new developments occur. But teacher educators need to be there as risk-takers and models of how this happens.

Course Syllabus Website

The entire Education course syllabi for three courses were placed on the Internet, and students received hard copies as well as had time in a computer lab accessing them through Netscape. The following organizational chart, Figure 2. Marcia Sheridan's Website for Education and Social Issues (http://sun1.iusb.edu/~msherida/h520co-1.html), illustrates one syllabus homepage used for a graduate course on Education and Social Issues.

Figure 2: Marcia Sheridan's Website for Education and Social Issues.

When incorporating a homepage as an integral part of an instructor’s course, the instructor must teach the homepage as a new study skill. A course homepage can deliver material developed by an instructor, course related materials developed by others, links to relevant associated materials on the Internet, as well as previous student work. The instructor must be sensitive to the problems that the students are likely to encounter on the Internet and offer techniques for solving these difficulties: getting lost, time delays, not finding what you are looking for, and wasting a lot of time surfing. Students need to realize that the WWW is constantly changing: sites appear, disappear, and move.
Furthermore, the use of the WWW does not mean that libraries are no longer necessary, but that perhaps libraries and librarians will be playing a different role in the electronic future. Also students need to understand just what is and is not there, at least yet. And, lastly, copyright issues are just as important on the Web as they are in the libraries: we need to discover new ways to reimburse authors and creators of new knowledge who want to be paid for their knowledge.

While graduate students were given the latitude of utilizing the Internet in their research papers or not, some embraced the technology more than others. Quite a few, as did the undergraduates, made efforts to connect their home computers by modem to the university or to subscribe to online services for e-mail and the Internet. Undergraduates were required to utilize material from the Internet in their lesson plans and units. Cooperative learning groups assisted this process as those who were more knowledgeable assisted others. Two of the five cooperative learning groups in the undergraduate Middle/Secondary Reading Methods class asked to be allowed to develop homepages instead of an instructional unit utilizing Internet materials. These students have become comfortable with the Internet and its applications. They are bringing their expertise into other courses and, in doing so, are bringing an influence on other professors to become more familiar with the Internet and how students are using it.

Delivering Course Content Over the WWW

A different use of the WWW is to deliver a majority of course materials and content developed and produced by the instructor for his or her class. Examples and experiences from an MBA Economics course that uses a homepage to deliver lecture notes, chapter handouts, quantitative problems and solutions, and research materials will illustrate this approach.

A502, Managerial Price Theory is an MBA Economics course which applies economic theory to business situations. As prerequisites, the students are to have an understanding of introductory economic theory, statistics, and mathematics. The objective of the course is to apply economics to managerial business decisions. The students come from a wide range of backgrounds: about 40% have an engineering undergraduate degree and work full-time in a technical job, about 40% have a business degree and work full-time for a service or manufacturing firm, and the rest generally have a liberal arts degree and often work in the nonprofit sector. Furthermore, a portion of the students are international students. The international students are usually the only ones who are full-time students. Unfortunately, given these diverse backgrounds and the fact that many have been out of college for quite a few years, much time during past semesters was spent reviewing economic theory and statistics as well as working on hypothetical problems, with insufficient time left for real world applications.

Organization of Course Homepage

Recent technological developments have allowed the instructor to resolve the dilemma of content versus application in the A502 class. The class now uses the WWW and collaborative learning techniques to improve student learning and research. All of the economic content has been previously presented in class via lecturing and hypothetical problem solving has been put on a homepage (http://sun1.iusb.edu/~fhersche/a502.html). This includes lecture notes with hotlinks to external economic and business sources, hypothetical problems that in earlier semesters had been worked on during class, practice problems, homework problem sets, and answer keys for all these problems. Supplementary materials such as handouts, grades, and previous examinations, have been also put on the homepage. The homepage has hotlinks to specialized economic search engines, economic resources, freeware, and grades. The following organizational chart, Figure 3. A502, Managerial Price Theory, demonstrates the organization of the A502 homepage.

Impact of a Course Homepage on Teaching and Learning

The primary impact of the course homepage is that the instructor has dramatically changed the organization of class time as well as the focus of learning because the dilemma of content coverage vs. application has been alleviated. In the past, in order to develop mastery of the economic theory and the use of this theory to solve problems, the instructor spent class time lecturing and working out hypothetical problems and having the students individually work out hypothetical problems. Thus, there was a very limited amount of time applying the economic concepts to the everyday work experiences of the students. Currently, however, lecture material is offered on the homepage and there are numerous hypothetical problems with solutions as well. Quantitative, hypothetical problems are still assigned as homework, and they remain the central focal point of the examinations.

Class time is now almost entirely oriented toward student-centered learning. Each class period of two-and-one-half hours is devoted to one chapter. Each chapter is divided roughly into thirds. For each third the instructor...
spends about five minutes highlighting the main points of the respective section of the textbook. This brief review is supplemented with a detailed chapter outline which links each important concept to the relevant class handouts, homework assignments, and in-class problems. Next, the students participate in teams in a problem solving exercise. For purposes of in-class work and the major research project, the students are divided into three to four person teams that are carefully selected for a wide range of experiences. The teams are handed an in-class discussion problem composed of three parts. Part A states the major concepts of that part of the chapter and the students are to see that all team members are familiar with each concept. Part B asks the team members to collectively work on a quantitative, hypothetical problem that requires them to apply the concepts of Part A. Part C, the core of each exercise, then asks the team members to discuss the economic concepts in light of their actual work experiences. Given the diverse background of the team members, generally more than one person in each team can draw on his or her work experience. The in-class discussion insights are then shared among the teams and the instructor. During this stage the primary focus is on Part C, the sharing of real world experiences. Since the solutions to the problems are on the homepage, little time is spent on this activity.

The second major benefit of the homepage is that it allows the instructor to supplement lecture material with links to real world applications and data on the Web. In this sense, by assigning the students to read not only the lecture notes but also the links on the lecture note sites, subject matter content becomes alive and much richer than if it was presented merely as a classroom recitation. If course, the richness of the learning varies by chapter at this point since applied economic and business materials are much more available for certain topics than for others.

The third and not insignificant advantage of the homepage, especially given the nature of the university’s MBA students, is the convenience to the students and instructor of having material on a website. The MBA students tend to travel fairly often for business (it’s not unusual to have 10-15% absent any one week), and so in the past much time and effort was devoted to faxing materials to the absent students. This has been entirely eliminated as a result of posting all course materials on the homepage. A related aspect of the course is that the instructor strongly encourages the students to use e-mail to communicate with the instructor. Given the dispersion of the students over northcentral Indiana and southcentral Michigan, the frequency of business travel, and the already widespread use of business/personal e-mail among the MBA students - communicating over the Internet has dramatically increased the amount of contact between the instructor and the students, in the neighborhood of fivefold.

Student Evaluation of Using the Internet

Although measuring some of the benefits of using the Internet in this course is difficult to measure (such as the students becoming familiar with an important technology and gaining experience with collaborative problem solving), there are some indications that the use of the homepage has had a positive impact on learning. The just described innovations have been in place for two semesters, and compared to examination results of prior semesters, students’ performance on quantitative homework problems and examinations indicate that students who use the homepage and collaborative learning, even without class lectures, perform just as well as students in earlier semesters. There are no significant differences in grade results. Also, the student evaluation of the use of the homepage indicates that the homepage has significantly improved their learning. The results of the Fall, 1996, student evaluation reported that: (a) 11% accessed the A502 homepage 0-4 times per month, 83% accessed the homepage 5-10 times per month, and 6% accessed 20 or more times per month; (b) in terms of the homepage’s “usefulness … in terms of your learning the material for A502,” 56% rated it “very helpful,” 39% rated it as “helpful,” and 5% rated it as “of little value.”

Conclusion

The simplicity with which Netscape and other browsers have made easy entry into the Internet masks the important point that there is a wide gulf between surfing and learning. As university educators we need to guide our students in efficiently and effectively finding information for their projects and lessons. Proper modeling of accessing the Internet through a well designed course homepage is an important first step in this process. Using the web to find materials for research projects, lesson plans, and class related learning is another critical step on the path to enhancing student learning. The course homepages described in this paper can serve as possible first examples in using the web to enhance learning and teaching.

K-12 Teacher Use of the Internet: A Research Report

Cynthia Anast Seguin
Emporia State University

This dissertation research involved a review of Internet sites and resources, a survey, and individual teacher interviews regarding the challenges, problems, and successes of online technology used for teaching and related professional activities. The teachers selected for this study used the Internet frequently and for diverse applications. They and their students reached beyond the physical classroom boundaries to become linked via voice, video, graphic, and text communications to other classrooms or sites in the same school, city, or nation, as well as to other countries. Their classroom windows were open to the world. They used the information highway to reach beyond simple information gathering to collaborative online learning and activities that used higher-order thinking skills.

The Problem

As classrooms connect to the information highway, "the world" becomes more available and traditional curriculum and instruction practices change. While access to the information highway continues to increase, a minority of classrooms are connected. There is also a difference between connectivity and skillful integration of telecommunications into curriculum. Effective integration of educational online activities has not been extensively researched. Thus, school districts faced with limited resources, time, and personnel need additional information so that curriculum and technology are designed and implemented wisely. The need to examine the successes and problems experienced by teachers who are frequent telecommunications users, an area of limited formal documentation, led to the design of this research project.

Objectives of the Study

Five questions served as a basis for this investigation:
1. How are teachers using the information highway for instruction and for related professional activities?
2. Is student thinking and learning being enhanced?
3. Has this technology been a catalyst for changed educational practices?
4. What obstacles have teachers encountered that served as barriers to usage?
5. What do teachers perceive to be the future direction of curriculum design and instruction which includes the information highway?

Review of the Literature

The partnership of educational reform and technology in shaping new frameworks for curriculum and instruction was examined. Armstrong (1994), Eisner (1994), and Gardner (1991, 1993), considered educational reformers, advocate multidimensional, sensory learning that is beginning to be found in Web sites, CD-ROM software, and commercially prepared curriculum that some teachers are using. Researchers (Bonington, 1995; Dede, 1992; Schrage, 1990) have indicated that hypermedia structures may even develop more user metacognition than linear text, such as found in textbooks, because these structures demand continuous choices and navigation from learners. The Web mimics the structure of human long-term memory development as its many linkages provide networks and bridges for transforming fragmented databases of information into richly detailed worlds of usable knowledge. Dede (1992) also observed that students using the Web might not be frustrated by cognitive overload, because they navigate imbedded content at their own pace, which aids in assimilation and manipulation of ideas.

Dede (1992), Shapiro (1995), and Trotter (1993), indicated that multimedia also has the potential to bring a greater variety of materials to students and to address multiple learning styles because of the self-directed discovery learning format. Dede (1992) explained that virtual reality technology is currently complex and expensive, with limited Internet sites, but enhanced learning may be possible. He warned, however, of potentially troubling effects of undetectable technological manipulation of human experience so that it is difficult for anyone to determine authenticity.

Another negative aspect of telecommunications use is the gender gap that Hughes (1994) noted for Web users—94% were male, with 56% of them between the ages of 21 and 30. He also stated that K-12 students were only a minority of Internet users. If indeed, the future belongs to those who can access and apply information, with those who cannot being left behind (Johansen & Swigart, 1994;
Naisbitt & Aburdene, 1990; Toffler, 1990), inequities in usage, whether based on gender or economics, are significant. Toffler noted that the American workforce has struggled with a shift to an information-based economy, and Naisbitt and Aburdene warned of the difficulties in absorbing the large amounts of information that whiz by people daily.

With this global information age, according to Reinhardt (1995), the Secretary's Commission on Achieving Necessary Skills (SCANS) report (1992), and Sizer (1992), business, government, and educators alike are suggesting the need for a different type of education. This puts pressure on students to be more flexible, better educated, technologically sophisticated, and skilled in interpersonal communications. Similarly, educators are challenged to address these needs, yet often without addressing finances. The review of the literature revealed a movement to blend educational reform and technology to prepare students for a changing global information age that is shaping new frameworks for learning.

Procedures Used

For this qualitative study, findings from a survey and scripted interviews were presented as case studies of three elementary and three secondary teachers from several urban and suburban areas of the United States. Interview transcripts were checked by these teachers to insure data accuracy. Educational web sites and Internet listservs were also monitored to provide triangulation during the study. Peer examination was employed as findings emerged to verify interpretations with technical experts. The researcher's biases were also disclosed (experience in using technology). The survey and interview instruments were pilot tested and revised before mass distribution.

The population from which the sample for this survey and interviews was chosen was purposely selected from K-12 schools who have access to the highway and were documented as frequent Internet users at the beginning of the 1994-1995 school year at a Web site listed in Ellsworth (1994). The survey instrument regarding online classroom activities was mailed to each individual in the sample. The returned surveys were analyzed to find three K-8 and three 9-12 teachers from a variety of urban and suburban areas who used the information highway most frequently and in the most diverse, sophisticated ways. These teachers were individually interviewed using a scripted instrument of 28 closed- and open-ended questions plus 9 items regarding school and teacher demographics, with additional probing questions added as needed.

Results of the Study

An analysis of patterns began to emerge first from the results of the survey, and then expanded as individual teachers were interviewed.

The Survey

This database, consisting of twenty-six completed surveys, revealed information about teacher experience with the information highway, education, access, and background information. The majority of the educators responding indicated that they were frequent users (at least once a day) of the information highway for basic activities such as e-mail and listservs. Survey respondents included nine elementary teachers, sixteen secondary, and one with K-12 responsibilities. The subject areas most frequently taught by responding secondary teachers were science, math, and computer technology. An equal number of males and females responded. Respondents represented eleven different states from the east and west coasts and the midwest. The majority of schools were urban and suburban; only four were rural. Over half the teachers had Internet access from their classrooms and homes. The teachers had similar proportions of length of experience—about half were beginners and half had experience ranging from five to twenty-five years. Fifteen had at least one or more master's degrees and five had doctoral degrees.

Teachers reported student use of the Internet as early as kindergarten. Nearly all teachers used the Web for professional activities, but seven had never used it in the classroom. Twenty-one reported that they had telecommunications access from home, and fourteen had access from their classrooms. Twelve teachers had multi-station labs, ranging from five to 40 computers. The survey indicated that the classroom activities these teachers planned utilized the Internet for cooperative and individual learning. The activities also included accessing information resources, communicating with subject-matter experts and peers, visiting online museums and virtual reality sites, and participating in data-gathering projects. The majority of the respondents indicated that they used the Web at least once a week, although seven respondents never used it in their classroom. Ten schools had developed a site on the Web. Few teachers, however, reported classroom use of virtual reality sites.

The respondents indicated successful experiences with the Internet. For example, all of the teachers felt that the Internet created opportunities for educational improvement and enhanced student motivation. Teachers were most positive about Internet-related improvements in student achievement, social and emotional skills, and the ability to learn how to learn. A majority of teachers felt that the Internet helped students develop workplace-related skills. Responses were mixed when it came to deciding whether the Internet had led to information overload or addictive behavior. In terms of student assessment practices, less than half had used any type of alternative assessments.

With regard to using the Internet for teaching, the vast majority reported that it had changed the way they taught. All of the teachers also noted that the Internet had en-
hanced communications with colleagues. Responses were mixed regarding the opportunity it provided for teachers to be freer to work with individuals. The majority of teachers noted that the Internet helped them access and share curriculum and find other education-related resources. Teachers were split as to whether or not their experiences had been frustrating as a whole.

The Interviews

The six selected interviewees had all used the Web for classroom and personal professional activities. Four taught at schools that created their own home pages on the Web, and information from these Web sites as well as the interview was included in the findings.

Types of Activities Reported. The teachers noted that online activities were successful with students of all ability levels, from at-risk through gifted. Many activities were structured to integrate the technology and the subject matter and take advantage of local community resources. Both local area networks and the Internet were used in some schools, so being “online” had multiple connotations. Collaborative activities were reported within the same classroom, with higher-grade classrooms in the same building, as well as with classrooms around the globe. All of the teachers used some type of authentic, responding, online audience for their students to share their ideas, creative writing, and products, as well as to collaborate. Teachers also noted that they and their colleagues sometimes learned more about the Internet from students. Indeed, students in some schools accompanied their teachers to conferences and community events to participate collaboratively in formal presentations regarding online activities.

Some teachers reported that their students also enjoyed preparing lists of their favorite Internet sites, and even compiled Web statistics. Students visited online museums, participated in global gathering of online data about issues or scientific experiments. Others went on online scavenger hunts designed to improve geographical and multicultural literacy. One secondary teacher even had her students volunteer to help other teachers prepare online-enhanced lesson plans. Some individual students and some classes had created Web pages to share their activities, personal information, or the local culture. Online discussions often included querying subject-matter experts, such as the “Ask Dr. Math” forum. Many of those activities evolved into longer-term mentorships. Secondary students also mentored with university students at campuses they wished to attend upon graduation.

Impact on Teaching and Learning. The Internet changed the way teachers taught and students learned in many positive ways. For example, students worked on projects that involved learning about the importance of peaceful conflict resolution as an alternative to violence and shared their feelings via their school’s Web site. Teachers also noted that students exposed to a world outside their own classroom saw the importance of education in changing lives for the better and the power of individuals to make a positive difference in a community. Teachers praised the ability of the Internet to help both students and teachers get out from behind their classroom walls literally and figuratively.

Teachers also reported increased motivation, communication skills, and writing skills. They noted students were increasing their ability to solve problems and question—“learning how to learn” and think critically. Overwhelmingly, students enjoyed online experiences, increased motivation and on-task commitment, as well as creativity. With teacher guidance, students engaged in metacognitive reflection. Students also learned without regard to the ethnicity, race, age, special needs, socioeconomic class, etc. of their online partners. Indeed, teachers reported that students grew in their knowledge and understanding of other cultures and improved social skills and esteem.

Students with language backgrounds other than English, as well as students studying another language, also enjoyed opportunities to converse online with speakers and learners of that language. High school students often became so skilled with online activities that local employers hired them. The teachers also grew professionally as they increased their technology and curriculum development skills. They reported that they began to guide learners in ways very different from previous traditional teaching. They helped students learn actively (the constructivist model) rather than passively, and some started to assess learning in new ways. These teachers knew that they and their students were becoming catalysts for educational and even global changes.

Professional Activities of Teachers. Teachers reported receiving assistance from local universities and school districts to learn the Internet. Several used the networking found in listserv’s to connect with like-minded colleagues and to solve problems. They also used the Internet to locate lesson plans and teaching resources quickly and inexpensively. Some complimented their national professional organizations for showing leadership in addressing online classroom activities in their publications and at conferences.

Obstacles. Teachers consistently reported time-consuming, on-going efforts to implement classroom activities connected with online learning. While some teachers were recognized and praised by their districts and/or national groups for their extraordinary efforts pioneering this technology in their schools, a few noted lack of constructive support, even resistance or hostility to change, from administration and colleagues. Several felt their districts could do a much better job of providing training...
for both beginning and advanced users of online technology.

Equitable access to technology was a major concern of all teachers interviewed, both in their own districts as well as nationally. Frequent frustrations with equipment, both hardware and software, led to time lost in learning and planning. The main theme in terms of "inadequacies" consistently revolved around teacher time and money issues. Additionally, teachers complained about not having the computing tools to match their ideas and the enthusiasm of the students—both were often ready for more than was presently within their reach. There was very much a feeling of "we could do more if only...". While these were very real individual concerns, the teachers also noted that this was an important challenge for America in terms of melting the divide between technology-rich and technology-poor schools.

Another obstacle teachers reported was that the physical limitations of their classrooms or computer labs had prevented better integration and use of the information highway. For younger students, lack of keyboarding skills was sometimes a reported drawback, but they could point and click with a mouse. Acceptable use issues challenged some interviewees. Teachers took individual responsibility to discuss netiquette issues with students and following through, when necessary, to remove online privileges of those students who did not respect acceptable use policies and expected courtesies. Some teachers expressed personal or community concern regarding access of inappropriate materials on the Internet. However, one teacher felt strongly that educators needed to help guide students to develop their own sense of what might be appropriate or inappropriate access, rather than risk censoring anything on the Internet or restricting access. When reflecting upon the obstacles and challenges that they had faced, however, all of these teachers felt the inconveniences experienced did not overshadow the joys and positive results of online learning for them or their students.

Implications

This research indicated that the information highway is allowing students and teachers worldwide to bring vast resources and people into their classrooms and use them positively. To make this a reality for all students, access for every classroom in America in the very nearest future should be a high priority at local, state, and national levels. The experiences of teachers in this study indicate a need for greater progress in funding, technical assistance, training, conference attendance, released time for curriculum development, and other types of support—all still unsatisfactory conditions in too many districts.

Teachers in this investigation indicated that they found that the information highway served as a catalyst for changes in their curriculum design and instructional models. The Internet is thus providing a framework that is beginning to reflect the goals of education reform. Indeed, Internet use may be one of the fastest ways to accomplish these goals. Students as well as teachers are becoming powerful agents of change, collaborators, and explorers of content areas. A mass distribution of Internet technology may help to bring greater empowerment and hope to forgotten inner-city schools and children of lower socio-economic class by expanding opportunities to learn and increase motivation. Schools with inadequate libraries and outdated textbooks might instantly have better resources. Children from homes without adequate study resources and parental guidance might benefit from online materials and mentors. A well-educated citizenry is crucial for any democracy to survive, and the information highway might be that catalyst to move us closer to that goal and away from slippage towards a third-world status of under-educated, under-employed citizens. Perhaps the greatest investment in its future that America might make would be to give every school child and teacher a portable computer, from kindergarten through university levels.

Whether this ever becomes a reality, teachers using the information highway today must encourage students to use this technology in positive ways. Sadly, growing reports of online criminal activity and hate messages raise the issue of character education as yet another partnership with technology instruction. Online activities afford excellent opportunities to introduce components of peace and multicultural education into classrooms around the world, and present opportunities to empower students to feel personally responsible for and capable of doing good works, as teachers in this study have reported.

To use online activities most effectively, teachers will also need to watch for possible network addicted students (some examples reported in this study), and provide direct instruction regarding the difference between online facts, opinion, and propaganda, as well as the ethics of original work versus copying off of the network. Also, as technology sophistication grows, students and teachers alike may have difficulty distinguishing between "real" and "phony" online photographs and documents. Virtual reality technology may allow new learning opportunities previously unavailable because of physical danger from hazardous materials, curriculum complexity, or geographic limitations. These types of issues are emerging and changing our notion of how we teach in a high-tech world.

In addition to new notions of literacy skills, curriculum in general will have to be revamped in other ways. For example, one of the elementary teachers interviewed mentioned that she had a secondary-level colleague upset because her fourth-graders were learning at the same level of complexity as high school students. This was threatening to the secondary teacher who feared that when these fourth-graders reached her classroom, there would be
nothing left for her to teach. Thus, this research indicated a possible downward shift in curriculum that could have a major effect at the secondary level in a few years.

Advance planning and retraining will be required if the needs of students like those fourth-graders are to continue to be met. This downward shift may be uncomfortable for teachers, yet it raises a vision of successful learning experiences at earlier ages and in ways not imagined previously. With more students using the Internet in kindergarten, the population that reaches high school nine years later may be more sophisticated learners than any previous generation. Perhaps they will be students who have become quite expert at learning how to learn anything desired whenever and wherever they wish. Teachers must prepare for these changes, and one area where additional leaders may emerge is from professional subject matter associations that have or need to establish and promote national networking, online curriculum sharing, and peer support systems. Additionally, related student organizations in subject matter areas might also play an important collaborative partnership in the implementation of telecommunications.

The African proverb, “It takes a whole village to educate one child,” may also apply to the online global village. As classroom walls disappear with the windows to the world that the Internet offers, collaborative lifelong learning may know no boundaries. Bertrand Russell said: “The first step in wisdom as well as in morality is to open the windows as wide as possible.” To achieve these goals, educators must be skilled Internet users and developers of curriculum that partners the best of educational reform models and the most sophisticated use of online technology. They must insure student opportunities to move beyond online information retrieval to gain in wisdom and morality in the spirit of “we’re all in this together.”

Dede and Griest allege that technology can facilitate school reform if it is used to support new models of teaching and learning (O’Neil, 1995; Griest, 1996). The social constructivist approach with Internet as a scaffold can provide this new model for reform. This paper presents a literature review as a foundation for the development of this new model.

Ways to support constructivist activities through the use of Internet by preservice teachers and inservice teachers in the K-12 classroom are examined. The principles of constructivism are presented first. The four general ways in which Internet can be used to support a constructivist classroom are presented next. The paper concludes with examples of modeling constructivist approaches using technology in teacher education.

The University of Colorado at Denver, School of Education maintains good Web sites with links to information about constructivism in education (http://www.cudenver.edu/~mryder/itc_data/constructivism.htm) and information about teaching and learning on the Internet (http://www.cudenver.edu/~mryder/itc_data/net_teach.htm).

Defining Constructivist Learning

Roblyer, Edwards, and Havriluk (1997) in their new text for technology education identify the following characteristics of constructivist learning:

- Authentic problem solving activities
- Wide variety and format of resource of materials
- Collaborative work groups
- Emphasis on the process of problem solving rather than the product
- Authentic assessments with qualitative methods such as portfolios

A constructivist classroom provides students with an information rich environment where they can actively manipulate and synthesize information to construct their own knowledge (O’Neil, 1995; Ryder & Wilson, 1996; White, 1996). As a result of this new environment, the role of the teacher changes from an information provider to a facilitator of learning (Nicaise & Barnes, 1996). Authentic learning experiences are provided through collaboration within the classroom community, the local community, and the global community. Active learning through the manipulation of information and interaction with others on Internet anchors learning to genuine tasks in situated contexts (Ryder & Wilson, 1996).

Internet Activities for Constructivist Learning

The constructivist model is supported by four general categories of activities that integrate Internet into the classroom. Harris (1994) divided educational telecommunication activities into the following three categories: interpersonal exchanges, information gathering, and problem solving projects. Harris’ three categories have been adapted for this paper and a fourth category, content generation, has been added as Web publication has become easier and more accessible. These four categories address the characteristics of constructivist learning set forth in this paper. The categories are as follows: computer mediated communications (CMC), resource retrieval, collaborative projects, and content generation. Each of these categories is explained with K-12 examples as illustrations.

CMC in education usually means communication through e-mail, listservs, or newsgroups. Students can discuss real problems and gather information from other students and experts in relevant areas. CMC may be enhanced to include desktop conferencing using digital video over the Internet with CU-SeeMe software. Students at Rocky Run Middle School in Chantilly, Virginia, and students from three schools in New Zealand used CU-SeeMe to access health information prepared by two medical doctors from the University of Otago (Todd, 1996). Students first used e-mail to become acquainted and teachers used e-mail to plan student activities. Another CU-SeeMe activity between the schools was the production of a news show at each site that featured fashion, movie reviews, sports, weather, and local, state and national news. These students were engaging in collabora-
tive authentic problem solving activities. Assessment was based on an authentic activity.

The second category is retrieving resources from the Internet. The number of text objects on the World Wide Web has increased from several thousand to several million during the past two years (Ryder & Wilson, 1996). Access to information is the first step in knowledge construction. Internet provides a multitude of information on a wide variety of topics and in many formats. Gleaning useful information from the plethora of available information requires advanced searching skills. Students need guidance learning effective use search engines and search trees and in how to refine searches to reduce the number of hits (Brehm, 1996). Once relevant information is located, the validity of the source must be evaluated. Kathleen Schrock maintains a Web page with links to guidelines for the evaluation of Internet information (http://www.capecod.net/Wixon/eval.htm). Harris (1995) reports on a student research project using the Internet and describes a 13-step process for interpretation and application of information.

The third general category of constructivist Internet activities is collaborative projects. An authentic problem is proposed on the Internet. Classrooms sign up to participate by gathering data or information from that site. When all the data are gathered, they are analyzed by the students and hypothesis or problems are confirmed, modified, or rejected based on the data. The results and conclusions are evaluated by the participants (Brehm, 1993). Educational projects encourage collaboration and community development both on site and at a distance. Emphasis is on the process of problem solving with the process and the conclusion providing information for reflection. Assessment is embedded in the project and can be monitored through the decisions made during the project. Brehm (1993) describes the "Most Livable Places" project in which students from sites around the world suggested factors that make a place livable. After a discussion of the factors, students at the host site developed a survey for ranking each site on livability. Sixteen sites around the world rated their site according to the survey. A lively online discussion followed the survey summary. Students debated the criteria used by individual sites to determine the ratings and whether or not rural sites were fairly rated since they had very few fast food restaurants and rock concerts. Data was collected on pre- and post-test questionnaires and from classroom observations. The two middle school classes participating in the "Places" project ranked significantly higher in problem solving ability and had more time on task than the four other middle school classes. Four control classes in the same school district studied similar information but did not participate in the telecommunications project.

Students can generate content for the Internet by publishing in electronic magazines, posting a web page, or posting a summary of information such as an interview with an expert (D'Iganazio, 1996; Nicaise & Barnes, 1996). Students create content in areas that they have selected and publish for a real audience. Ryder and Wilson (1996) suggest that students create Frequently Ask Questions (FAQ) web sites on topics of interest such as snow boarding or roller blading. D'Iganazio (1996) suggests publication on an intranet, a small private network for a school. Students reap the benefits of publishing pictures and information with personal identification for a real audience within their school but without the risk of making their identification accessible to strangers.

State of Technology in Teacher Education

Even though teachers value the use of technology in education, they do not feel that teacher preparation programs adequately prepare them to use technology in the classroom (O'Neil, 1995; Topp, 1996; White, 1996). The U.S. Congress, Office of Technology Assessment (OTA, 1995) study found that most teachers who do use technology use it in traditional ways. Dede (O'Neil, 1995) predicts that if schools do not effectively use technologies, a decade from now many students will join the growing trend of independent schooling and the voucher system. Public schools will educate only a few of the most difficult and poorest students. Teacher education programs need to integrate technology if they are going to continue to attract students and meet NCATE standards (Barksdale, 1996).

For preservice teachers to utilize the rich resources of Internet during field experiences and as new teachers, they must be adequately prepared in technology and must see technology integration modeled during methods classes. About 50% of teacher education programs require students to take a technology class and another 35% offer an optional class (Topp, 1996). The 50% that do not require a separate class report that they integrate technology instruction into methods classes. Over 85% of the recent graduates that he surveyed (n=135) who did not take a technology class rated their preparation in technology as inadequate or very inadequate. Roblyer (1994) suggests that while technology integration into methods classes is the ultimate goal, he found that successful integration is infrequently achieved.

Over two-thirds of Topp’s respondents rated the importance of an educational computing class as "should be required." Another 26.7% selected "very important." Ninety-two percent of White’s (1996) survey of 387 preservice teachers rated technology integration as "definitely important in teacher education."

The OTA study (1995) reports the training that teachers do receive often focuses on the mechanics of operating computers rather than on the classroom uses of technology.
An example of this approach is the practice of giving students Internet accounts in college but not teaching them to use Internet to search for resources (Barksdale, 1996).

The OTA study (1995) also reports that 66% of teacher education faculty members reported some anxiety about working with information technology and that those faculty were likely to communicate this anxiety to their students. Professors, preservice teachers, and teachers need working models of technology infused constructivist classrooms (Nicaise & Barnes, 1996). The results of two recent surveys (Topp, 1995; White, 1996) call for more modeling of computer use in preservice education methods classes. White suggests modeling by using technology to teach and by having students apply technology in class projects and field experiences. Cotty (1996) concludes that teacher educators must find ways to model constructivist activities so that their preservice teachers will incorporate active learning into their teaching. The remainder of this paper focuses on how teacher educators can model the constructivist approach through the use of Internet in classes.

Modeling Internet Activities for Constructivist Learning

Nicaise and Barnes (1996) used technology to assist students as they employed constructivist methods to develop a geometry curriculum in a mathematics methods class. Groups of their students engaged in collaborative activities which illustrate three of the four categories of Internet use. Examples of relative and reproducible activities from other methods classes are included under each category. This is not an exhaustive literature search but rather selected examples of how constructivist activities using Internet are modeled in education methods classes.

During the mathematics methods class, some students used an online address book of U.S. Teachers to initiate communication with practicing teachers (Nicaise & Barnes, 1996). One such connection was with a mathematics teacher in Hawaii who shared examples of constructivist tasks and assessment from his classroom. This is an example of the use of CMC to connect with online experts in an authentic problem solving activity.

Another study involved 11 English student teachers and two professors (Thomas, Clift, & Sugimoto, 1996). Two university classes were also delivered on site. Each student received a laptop computer with an internal modem to use for the semester. As part of these two classes, students were required to submit assignments online. Each week they submitted responses to required articles, one question per chapter, lesson plans, and classroom journals. These students reported using Internet primarily because it was required for the class.

Sixteen elementary students and five professors from Appalachian State University participated in a year long telecommunication project. During the first semester, one-half of each day was spent in a university class and half in a K-12 classroom. The second semester 10 weeks were spent student teaching in the same K-12 classroom. Students were required to send two e-mail messages per week. General education topics such as describing the reading or language arts program in their classroom emerged as the focus of a significant number of messages. These researchers found that professional conversation occurred spontaneously through e-mail. They conclude that this conversation has the potential to strengthen and vitalize teacher preparation (Schlagal, Trathen, & Barton, 1996).

Technology can provide the infrastructure to support teachers who use collaborative and constructive learning. The teacher no longer has to know all of the information but instead needs to know the process to access information (O’Neill, 1995). Retrieving resources from the Internet allows students to spend more time on higher level reflective thinking and less time gathering and organizing information (Nicaise & Barnes, 1996).

Merideth and Williams (1996) first teach an introductory lesson using search engines and setting bookmarks. Then their language arts methods students use search engines to locate and bookmark at least four resources that can be incorporated into a lesson plan. Students construct meaning by evaluating the information through sorting, sifting, and saving only what is important. They directly cut the pertinent information from the Web site and paste it into a database. The finished lesson plans incorporating web information are published on the web. Nicaise and Barnes (1996) have their students find and retrieve geometry lesson plans which are then evaluated for classroom use.

Collaborative projects using telecommunications became popular about ten years ago on the FrEdMail network. That network, now the Global SchoolNet Foundation (www.gsn.org), continues to facilitate problem solving projects and continues a highlight listing of excellent projects.

The book, James and the Giant Peach, provided authentic context for a collaborative project between a fourth grade class and an elementary methods class at Otterbein College in Ohio. The college students posed weekly discussion questions focusing on James’ travails. Elementary students evaluated activities from the college students’ proposed lesson plans. Fourth grade students provided feedback about the ease of understanding, reading level, and appropriateness of the lesson plans. Thus, assessment for the college students was incorporated into the lesson plan development (Barksdale, 1996).
Cotty (1996) in a capstone class, School and Society, had students design and analyze a cooperative distance learning project for fifth grade students. They communicated with classroom teachers for feedback while designing the project. During the class students maintained portfolios which included ideas, feelings, insights as well as a record of information exchanges, data valuation, and feedback from peer partners at various stages of project completion. She suggests that distance learning in her classroom supported the constructivist paradigm by actively engaging the students in constructing their own knowledge including the incorporation of input from distant sources. Inclusion of distance learning made the content personally relevant and encouraged self-regulated learning.

Publishing Web pages has become popular in teacher education as well as in other areas. Data is not yet available on the benefits of publication versus the time involved learning to write HTML code or to use an editor. As programs such as Adobe PageMill for the Macintosh and Microsoft Front Page for Windows computers become more sophisticated and more common in the schools, web publication is likely to blossom.

Classes of several teacher educators included in this paper posted completed projects to Web sites. Students from the Geometry methods class created a web site to publish the math curriculum that they had developed for others to use as a resource. Nicaise and Barnes (1996) see this project as an authentic activity for a real audience. As such, they conclude that the ownership of knowledge is returned from the teachers back to the students. They also suggest that a significant amount of teacher time was spent monitoring students by demonstrating resources and posing questions. Teachers learned new assessment procedures and embedded assessment into activities throughout the semester.

As direct Internet access becomes widely available in K-12 classrooms, students have access to information rich environments which support knowledge construction. For new teachers to use technology, they must see it modeled in college classrooms. This paper has presented a theoretical structure for the connection between constructivism, technology, and teacher education. It concludes with examples of teacher educators who are currently modeling constructivist Internet activities in the teacher education classroom.

JUST-IN-TIME PROFESSIONAL DEVELOPMENT USING THE WORLD WIDE WEB

Paul G. Shotsberger
University of North Carolina at Wilmington

Teachers in North Carolina are required to participate in inservice professional development as a part of a five-year licensure renewal cycle. This training normally takes the form of workshops conducted at a central site over the course of several days or even several weeks, typically during the summer months. Drawbacks to this type of staff development include the time and money required for travel to the workshop site; the artificiality of professional development done in isolation of the classroom, wherein teachers must wait until the school year begins again to apply their learning; the logistical problems of attempting to support teacher change once teachers have returned to their schools; and the difficulty inherent in trying to keep teacher training current in a discipline such as mathematics education where knowledge and practice are rapidly evolving.

This paper discusses a World Wide Web site being piloted for teacher training to address the above shortcomings. Using this technology, just-in-time professional development and support is available to teachers at their home or school during the school year, and the online training and resource materials can be updated on a continual basis to maintain teacher awareness of current trends. Further, sufficient interactivity can be built into the system so that teachers feel that they are a part of a community of educators despite potentially being the only workshop participant at their school.

Background

Brush, Knapczyk, and Hubbard (1993) identified some important aspects of distance performance support systems intended for use with practicing teachers:

...a support system for distance instruction would need to aid in the delivery of the content of the training, to provide a mechanism for interaction between instructors and students, to offer options for feedback about assignments and projects, and to give the program staff alternatives for evaluating the training and maintaining quality control over activities. (p. 39)

Schrum (1996) elaborates on the need for balance in a telecommunications environment, noting that “Freedom to explore and investigate individually is important, but some structured activities and minimal weekly requirements are also essential” (p. 422). As Mandviwalla and Olfman (1994) suggest, users should also have the capability to meet synchronously or asynchronously, as appropriate, and the tools for carrying out these interactions should be contained in a single system.

The Mathematical Sciences Department at the University of North Carolina at Wilmington (UNCW) is currently piloting a World Wide Web site called INSTRUCT, which stands for Implementing the NCTM School Teaching Recommendations Using Collaborative Telecommunications (http://instruct.cms.uncwil.edu). INSTRUCT is intended to assist high school mathematics instructors in implementing the National Council of Teachers of Mathematics Professional Standards for Teaching Mathematics (NCTM, 1991) while providing them with the opportunity for reflection through dialogue with colleagues (Novick, 1996). INSTRUCT’s design integrates hypermedia training materials with aspects of groupware, or software intended to support group interaction, to expand its use beyond being simply a storehouse of instructional material.

INSTRUCT’s Design

Following is a listing of the options available through INSTRUCT with a description of their function:

Check Here for the Latest News

This option gives training coordinators a means of making announcements of online meetings and other events which do not necessarily require responses from trainees.

A Hypermedia Version of Standards for Teaching Mathematics (NCTM, 1991)

This choice links users to a Web page with the following menu items: Worthwhile mathematical tasks,
Teacher's role in discourse, Tools for enhancing discourse, Student's role in discourse, Analysis of teaching and learning, and Learning environments. Each of these items link to Web pages which employ multimedia to provide the user with an introduction to the NCTM Standards for Teaching Mathematics using authentic classroom activities and materials.

Each sub-menu page contains its own Check for Understanding form for users to fill out and submit to training coordinators in order to assess mastery of the standard. Assignment of licensure renewal credit is in part dependent on successful responses to questions about the standards and on teacher reports about their implementation of classroom activities intended to reflect the standards.

Online Educational Resources

Choosing this menu item takes the user to a table of links for education-related sites on the World Wide Web. Sites are grouped by category, such as Geometry and Chaos, History of Mathematics, Lesson Planning, National Agencies and Information Sources, Statistical Data Sources, and Technology Resources. Additionally, this page provides direct links to the North Carolina Department of Public Instruction and K-12 Schools online.

Attend a Meeting

Choosing this menu item launches "Netscape Chat," connecting users to the Internet Relay Chat server located at UNCW. As indicated above, trainees are given assignments to carry out in their own math classes in order to promote teacher active participation in and application of INSTRUCT training. An intentional by-product of these assignments is to encourage the need for sustained interaction and collaboration among participants and coordinators (Honey & McMillan, 1994). The meeting option provides a means for teachers both to brainstorm and to reflect together on implementing the standards in their classes, and for INSTRUCT training coordinators to provide additional professional development materials and support to users. Participation in these meetings is another requirement for receiving licensure renewal credit.

Join in a Discussion

This option connects users to a threaded hypermail message board (WWWBoard) allowing them to communicate asynchronously with other INSTRUCT users at their own convenience. The format benefits teachers by involving them in more long-term discussions about issues raised in the NCTM Standards, by providing just-in-time support for implementing instructional changes in their classes, by facilitating the sharing of news and other items of interest between colleagues, and by affording users continual access to previous communications via discussion histories.

Send a Message

This choice provides Internet mail access for communicating privately with a training coordinator.

Pilot Project

During fall semester 1996, four mathematics teachers from two counties in southeastern North Carolina have been involved in an INSTRUCT pilot project using their home computers. The project has been granted licensure renewal credit by the state Mathematics and Science Education Network in recognition of the time participants will be spending online using INSTRUCT. Each teacher received face-to-face training during summer 1996 in navigating the Web, publishing Web pages, and communicating synchronously using "Netscape Chat." As a part of their training, teachers meet online before and after the implementation of each standard in their classes. Following the final meeting for a standard, teachers are required to complete a Check for Understanding form summarizing their comprehension of and experience with the standard.

The teachers have been enthusiastic about sharing teaching ideas during online meetings and have been equally diligent about reading and responding to messages posted in the discussion area. Records being kept as a part of the project include messages posted in the discussion area, transcripts of online meetings, and submissions from the Check for Understanding forms and the pre- and post-tests of Professional Standards knowledge. Initial results from the project provide a preliminary notion of the ways in which teachers benefit from just-in-time professional development using the World Wide Web:

1. Consistent Opportunities for Reflection and Sharing with Colleagues. Cohen, McLaughlin, and Talbert (1993) noted that "The only way we change our teaching is to talk to people who are also changing" (p. 93). For each standard, teachers have the opportunity to be engaged in two online meetings, one to discuss the hypermedia material and brainstorm ideas before implementation, one to reflect on implementation attempts and future applications. Additionally, teachers have unlimited access to each other through both the message board and e-mail. The asynchronous format allows for more prolonged and thoughtful exchange of ideas, as can be seen in the following excerpt from a discussion thread on the use of calculators:

Teacher 1: What I said about hating the fact that students had been allowed to use fraction calculators is that even my Adv Alg 2 students have no idea whatsoever the concept of fractions. I kid you not that 70% of them could not tell me how to change 1 into 4ths and almost none of them could tell me how to divide the no. 2 by 3/2. They are completely oblivious as to how fractions work. They even struggle with canceling when multiply-
ing fractions as they never had to worry about canceling with the calculators.

Teacher 2: Yes, [Teacher 1] is correct. Fractions and the basic concepts are a weak link even in the 7th grade. They come to me lamenting about long division and fractions. Is the Explorer (fraction calculator) to blame? Maybe, in part...I suspect teachers are using those calculators for quick and easy answers, and students have gotten sluggish in their mental math...

Teacher 1: My main concern is that if kids don’t understand the basics it is hard for them to interpret what the graphing calculator is telling them and gosh knows they can’t tell if their answer is reasonable!

INSTRUCT appears to be promoting the formation and maintenance of a virtual community through its blending of synchronous and asynchronous communications tools, which when combined with online professional development materials and resources for lesson planning provide teachers with a rich, safe and self-sustaining environment for implementing changes in instructional practice.

2. Shortened Cycle for Training, Implementation and Evaluation of New Practices. The problem of attenuation of training between workshop and implementation is a constant cause for concern in traditional professional development (Guskey, 1986). A key aspect of professional development on the Web is the natural capability for conducting training during the school year, thereby giving teachers a realistic chance to plan classroom implementations that might be attempted the next day or the next week, instead of the next month. Further, with the ability to reflect on successes and failures with colleagues each week, it is more likely that implementation attempts will be sustained and not just one-time efforts. A project teacher noted in her Check for Understanding form that “INSTRUCT has become an essential element of my classroom planning. I have visited the resources and every week put something in my lessons that I want to try.”

3. Teacher Empowerment through Direct Access to Information. Information access is, of course, one of the powerful elements of the World Wide Web generally. For teachers, this access is even more critical because of the oft-times isolated world in which they find themselves. The following online meeting transcript segment provides some notion of how the Web can make a difference in instruction:

Teacher 1: I did a technology problem this week to find the correlation between team batting avg and earned runs avg to games won. We used data from American League. Pretty cool with the World Series going on.

Facilitator: what year was the data from?
Teacher 1: Unfortunately 1988 was what was in the book....
Teacher 2: How about current data from ESPNet?
Facilitator: Actually, that’s not a bad idea.

The difference between 1988 and 1996 represents half a lifetime for high school students. Thus, the ability to use more current data in math classes can foster an increased sense among students of math’s relevancy in their lives. The facilitator provided Teacher 1 with the Web address of ESPNet Sportszone, which contained 1996 statistics for both the American and National League baseball teams. This exchange ultimately resulted in a new INSTRUCT multimedia vignette on statistical analysis of data and determining lines of best-fit.

Some limitations to Web-based professional development have also been discovered in the course of the pilot project. Successful web-based instruction depends on the presence of self-directed learning (Shotsberger, in press), though it should be noted that self-direction in distance education is a function not only of the individual learner, but also the instructional facilitator and the sponsoring institution (Eastmond, 1995). Since teachers must essentially carry out an independent study of INSTRUCT’s hypermedia materials, it is evident that those involved in this type of professional development need to be self-starters who desire to improve their classroom practices. Similarly, teachers must have a base of experience from which to evaluate and discuss ideas for classroom implementation. Pilot project teachers ranged in experience from two to 19 years of classroom teaching, with a mean of nearly 11 years. This type of technology would be of limited utility for the new teacher who possesses neither the time nor the maturity to take full advantage of the variety of resources offered.

A Model of Web-based Professional Development

Guskey (1986) has posited a model of teacher change resulting from face-to-face professional development. It is essentially a linear model wherein staff development impacts teacher classroom practice, which in turn influences student learning outcomes, finally resulting in changes in teacher beliefs. The present author has adapted the Guskey model to describe the unique characteristics of just-in-time professional development using the World Wide Web (Figure 1). This new model represents an initial attempt to represent and thereby better understand the complex dynamics of Web-based professional development and is intended specifically to serve as a guide for implementation of INSTRUCT on a wider scale.

The new model diverges from Guskey’s in two fundamental ways. First, it takes into account the shorter cycle of training, implementation and evaluation of new practices, as noted above, by allowing for changes in
teacher beliefs to affect future staff development efforts. Thus the new model is cyclical rather than linear. Second, an attempt has been made to display the effect that each of INSTRUCT’s options has on the overall professional development cycle. Note especially that some elements of training carried out using the Web, such as Asynchronous Discussions, can both affect and be affected by various components of the cycle. The model will likely be modified and elaborated based on future applications of INSTRUCT with different user populations.

Future Plans

Brush et al. (1993) observed that for their performance support system, “...the formation of cohort groups of teachers was important not only to operate the program efficiently but also to produce ongoing benefits to the teachers after they have completed the program” (p. 40). Pilot project teachers agreed that they would benefit from continued use of INSTRUCT’s resources throughout the remainder of the 1996-1997 school year. Teachers plan to meet online approximately every two weeks to report on their progress. INSTRUCT’s hypermedia training materials and links to web resources will continue to be expanded to provide teachers with fresh ideas and perspectives.

The Mathematical Sciences Department at UNCW has been awarded a Dwight D. Eisenhower Professional Development Program grant for expanding the use of INSTRUCT in southeastern North Carolina. During spring semester 1997, a total of 21 high school teachers will be recruited from public and private high schools in three counties surrounding UNCW. The UNCW Science and Mathematics Education Center will coordinate a four-day, 24 contact hour summer program that will meet during summer 1997. This face-to-face portion of the project will emphasize participants becoming comfortable with navigating the World Wide Web and using both synchronous and asynchronous communications tools. Two high school mathematics teachers from the fall 1996 pilot project have been selected to act as lead-teachers for 1997. The 21 teachers from the summer sessions will continue their participation in the project by using INSTRUCT during fall semester 1997. During the distance training phase, participants devote a minimum of five hours online for each of the six standards, for a total of 54 contact hours devoted to the project.

Summary

INSTRUCT employs the capabilities of the web to provide math teachers with just-in-time professional development. INSTRUCT’s features include a hypermedia version of the Standards for Teaching Mathematics (NCTM, 1991), links to online educational resources, an asynchronous discussion area, and the capability to meet synchronously using “Netscape Chat.” Results of a semester-long pilot project involving four teachers using their home computers provided an idea of benefits associated with web-based professional development: consistent opportunities for reflection and sharing; shortened training cycle, implementation and evaluation; and teacher empowerment through direct access to information. A tentative model of just-in-time professional development using the World Wide Web was introduced representing the complex dynamics of this learning environment and guiding the expanded implementation of INSTRUCT.

1146
CONSIDERATIONS IN IMPLEMENTING AN INTERNET COURSE FOR TEACHERS

Raymond S. Pastore
Bloomsburg University

In the Summer of 1996, twenty-seven graduate students enrolled in a course at Bloomsburg University titled “Internet Applications for Educators.” This was an experimental “hands on” computer course in which students explored the World Wide Web and studied the structure, organization, and use of the Internet, Internet tools and their potential. The students used a variety of applications through the use of Netscape including Telnet, FTP, Usenet News, Gopher, Internet Relay Chat, WAIS, and Intranet. Each graduate student constructed a personal Web page and made a personal “hotlist” of web sites. Students also studied the use of multimedia, video, and phone conferencing on the World Wide Web. Final projects, including web sites and hotlists, were mastered on a CD-ROM for distribution to class members. A web page was constructed to link all home pages of class members and to maintain future contacts with the teachers after they returned to the classroom. The students used Internet for Educators (1995) as a text and The Educator’s Internet Companion (1995) as a reference.

Questions

Since this was an experimental course, it was designed to consider the following questions:

1. Is a separate course on Internet necessary for teacher training or should Internet be taught through integration into other graduate courses?
2. What content should be taught in an Internet course for teachers?
3. How can teachers avoid Internet information overload and use Internet as a classroom resource?
4. How should teachers have their students use Internet?
5. What are the problems associated with student use of Internet?
6. How can teachers and students use Internet with limited access to computers and computer labs?
7. How can teachers use personal web pages to enhance their teaching effectiveness?
8. What are the problems associated with the construction and maintenance of web pages?

Procedures

Individual interviews were conducted with the Internet course students during late fall by the course instructor to determine their classroom use of Internet. Seventeen of the 27 students who had completed the summer Internet course were teaching full-time in an elementary or secondary school. They were asked to respond to the following questions:

1. Do you use Internet as a resource for yourself? If yes, please describe.
2. Do you use Internet as a resource for your students? If yes, please describe.
3. Do you have access to Internet in the school? If yes, please describe.
4. Do your students have access to Internet at school? If yes, answer the following questions:
   A. How many computers are available with Internet access?
   B. What types of activities are Internet used for during lessons?
   C. Does your school have special software for blocking specific web sites?
5. Do you have access to Internet at home? If yes, how often do you use Internet for school-related activities.
6. Do you use a personal web page for school activities? If yes, please describe.
7. Following is a list of topics from the summer Internet course. Please indicate if you used any of these areas during the last several months and indicate how you used them:
   Internet Basics
   Multimedia on the Web
   Telnet
   File Transfer Protocol(FTP)
   Gopher
   Usenet Newsgroups
   Keypals
   WAIS
   Listserv
   Technology Planning
   Intranet
   Web Page
   Freenet
   Instructional Design
   Internet Relay Chat (IRC)
8. What recommendations would you make for future Internet courses? Describe what topics should remain in the course and suggest new topics that should be added.

Results

Problems
Most of the teachers reported limited or no access to Internet in their schools. The availability of equipment and lack of support was a common problem. Many of the schools were planning to implement Internet access during the school year. Six teachers had Internet at home. None of the teachers had updated their class web page from the Internet course.

Classroom Use of Internet
Nine of the teachers reported the use of Internet as a personal resource for the classroom. Two of these teachers joined professional newsgroups and six used e-mail. Several teachers were taking leadership and initiative to implement Internet into their schools. Two teachers reported that their classes regularly visited a single Internet computer station in another part of the building. One teacher reported limited access to Internet for her entire class. She visited a classroom lab on three occasions to introduce the students to Internet basics. A follow-up survey will be conducted in the spring as schools begin to connect with Internet.

Recommendations
Following is a list of recommendations in consideration of Internet courses for teachers:
1. Due to the enormous amount of information, a separate course should be offered to teachers on Internet.
2. The content of the course should include the topics outlined in this report and should also consider new areas of Internet development.
3. Web page construction and use of multimedia and video on the Internet should be considered in an advanced course.
4. The focus of the introductory course should be to address the issues associated with Internet use in the schools. These issues are:
   - limited access to Internet for both students and teachers.
   - student access to uncensored information.
   - Internet training & support for teachers.
   - use of Internet with one computer, several computers, or an entire lab.
   - meaningful activities beyond Internet navigation which promote student learning, problem solving, and critical thinking.
   - using the unique characteristics of Web Sites which provide current and spontaneous information.

Summary
Although many faculty members do not embrace technology (Cummings, 1996), the teachers who completed the Internet course were beginning to use and explore the Internet in the classroom. However, the lack of access to Internet and Internet support is obviously a problem as schools begin to implement Internet technology into their curriculums. In addition to equipment, teachers need continued inservice training and collaboration with other educators to optimize the potential of Internet technology.

CHILD MALTREATMENT: TRAINING EDUCATORS WITH INTERNET RESOURCES

Michael J. Berson  
The Citadel
Ilene R. Berson  
Lowcountry Children’s Center

Educators in school settings serve as a critical first line of defense in assisting with the identification and prevention of child sexual abuse. Due to the extensive interaction between teachers and students during the school day, educators have an important opportunity to observe children, establish a reasonable level of suspicion, and report suspected incidents. However, teachers typically do not feel equipped to address their evolving role in safeguarding the emotional and physical well-being of children. Moreover, confusion over appropriate responses to victimized children has resulted in a pervasive failure of significant adults to protect children and ensure their safety.

This paper addresses the tremendous gap which exists between teacher training and the increasing demand for support of victimized children. Although there is a legal mandate for educators to report abuse and neglect, most teacher education programs make only a cursory mention of child maltreatment. Once in school settings, the majority of teachers are given no additional inservice training on this issue. If assisting vulnerable children is a priority for educational systems, then action must be taken to create a pool of educators with the skills to identify and respond to child abuse. Similarly, administrators need to develop their awareness of the legal and ethical issues associated with reporting maltreatment, including the psychological stress involved in the decision to report suspected abuse.

In order to bridge this rift, the investigators have explored the use of on-line resources for child maltreatment as a means to increase educators’ awareness and understanding of child abuse and neglect. As mandated reporters of child abuse, educators may access references and interactive materials on the Internet while they improve their skills for identifying, reporting, and responding to suspected child maltreatment. The Internet allows teachers to link with on-line forums for professionals, gain information on relevant conferences and trainings, and access professional bulletin boards on child abuse issues.

Child Abuse Rates: A National Crisis

While reported incidents of child victimization continue to grow, accurate statistics on the prevalence of the problem remain elusive (Russell, 1983), and estimates regarding the scope of the problem vary. The National Center on Child Abuse and Neglect (1981) reports that barriers to identifying and reporting sexual abuse will continue to hamper the collection of precise data on the actual incidence and prevalence of child victimization. Early figures of the under-reporting of child sexual abuse estimate that only 20% of cases reach professional attention (Finkelhor, 1984). Barriers exist due to historical, sociocultural, and familial impediments to the child protection process.

The Third National Incidence Study of Child Abuse and Neglect (Sedlak & Broadhurst, 1996) reported that an estimated 2,815,600 children have been abused and neglected in the United States. Prevalence estimates range between 19% (Finkelhor, 1984) and 38% (Russell, 1983) of female children under age 18 have had sexual abuse experiences and approximately 9% (Finkelhor, 1979; 1984) of male children have been sexually victimized. As a guideline for educators to comprehend the pervasiveness of this issue Crenshaw, Crenshaw, and Lichtenberg (1995) estimated that during a three year period, teachers service between 60 to 400 children. “Even if just 1 in 10 students is being abused—a conservative estimate—most teachers would teach between 6 and 30 abused children over a 2-year period” (Crenshaw, Crenshaw, & Lichtenberg, 1995, p. 1110). Based on these figures, within a 2-year span each classroom teacher should be confronted with at least one suspicion of abuse which necessitates mandatory reporting.

The Role of the School

Schools represent an important system involved in safeguarding the well-being of children, and often are the first intervening system to interact with the victimized child, assess an incident, report suspected abuse, and provide supportive services for the child. All 50 states have reporting laws which identify school teachers and administrators as mandated reporters of child abuse to child protective service agencies. Despite this legal responsibility, educators typically remain unclear about applicable
laws and reporting procedures. Even when teachers are aware of their mandatory obligations, they are significantly less likely to report sexual abuse than other education professionals (Crenshaw, Crenshaw, & Lichtenberg, 1995).

An integral role may be played by educators in this process; however, teachers lack confidence in their range of knowledge of abuse and their ability to provide appropriate intervention services to victimized children. Consequently, as society struggles to address the rising tide of incidents of child abuse, educators often find themselves inadequately prepared to confront the growing number of victims in the classroom.

**Linking Educators to On-Line Resources**

This training initiative focuses on introducing issues of child abuse to teachers. The purpose of this endeavor is to promote a clear understanding that educators, who may be among the first professionals to interact with a child during and following their victimization, should (a) serve as informed resources, by being knowledgeable about child abuse; (b) respond appropriately to the disclosure of abuse, including accessing crisis intervention for the child; (c) react appropriately to emotional and behavioral indicators of sexual abuse in the classroom setting; and (d) report suspected abuse to the proper authorities as required by mandated reporting laws.

By accessing Internet resources, teachers may be engaged in an exploration of child abuse and the role of the educator in supporting the victimized child. Through this training model, participants may explore mandatory reporting laws and ethical standards, discuss when and how to seek outside assistance in order to address issues related to victimized children, develop skills as liaisons between the school and community to create environments in which children may feel protected and supported, and discuss the impact of child victimization on academic and socio-emotional functioning, including common myths.

Based on the premise that child maltreatment can only be effectively addressed through a multidisciplinary decision making approach, educators are introduced to the use of the Internet as a means to participate as a member of a larger team of professionals and community members who are committed to stemming the tide of abuse. This is facilitated by exploring key Internet offerings on child victimization as well as their application to teacher education courses. Specifically, students are given the opportunity to access networks which distribute a substantial collection of policy information and research on child maltreatment. This expanded technology is then utilized to foster educators' interaction with professionals on child abuse and neglect. Through these linkages teachers may evolve a greater understanding of their roles and responsibilities in addressing child maltreatment and become part of the community of caring, informed professionals who are meeting the needs of vulnerable children.

**Child Abuse Resources on the Internet**

In order to mediate the risk of perpetuating myths and misinformation which are so prevalent in the field, the identification of relevant sites is a vital first step in the process of accurately informing educators regarding child maltreatment. Since the Internet is a dynamic and evolving medium, descriptions of sites quickly become outdated as information is continually updated and revised. Moreover, since numerous Web-sites are not refereed, it is important to direct teachers to links which are associated with major, reputable organizations and institutions which are promoting awareness of child abuse and neglect.

The authors have developed a recommended sequence of instruction using Internet resources to facilitate educators' understanding of salient issues. The epidemic of child victimization is emphasized through the *Executive Summary of the Third National Incidence Study of Child Abuse and Neglect* which is available at the NCCAN Site. The study results reflect a prevalence estimate of 2,815,600 children who have been abused or neglected in the United States. Further data on the crisis of violence against children is accessed via The Virtual Hospital Web-Site link to the U.S. Department of Health and Human Services report *A Nation's Shame: Fatal Child Abuse and Neglect in the United States: Executive Summary*. This information provides the background for the impact of this problem on children and establishes a context for the necessity of informing educators about their role and responsibility in identifying and responding to child abuse.

Once the problem of abuse is identified, teachers are introduced to guidelines on identification, reporting, intervention, and prevention. *Child Abuse: A Guide for Mandatory Reporters* which is available through The Virtual Hospital Web-Site provides educators with specific information on indicators of abuse, abuse categories, reporting law and procedure, issues of confidentiality, and the process of addressing the needs of a victimized child. Teachers also are directed to the NCCAN Clearinghouse Catalog where information on ordering free resources, including a user manual series with training guides for educators, can be accessed. Topics covered include why educators should be concerned with child maltreatment; how to recognize and report child maltreatment; what happens when a report is made; and how to implement prevention strategies.

NCCAN also offers specialized services to allow teachers to explore their own state statutes. As educators reflect on their state law and district guidelines, *Child Abuse: A Handbook for School Staff*, which is part of the Frontenac County Board of Education's Web site, serves as a guide for developing procedural information and resources on child abuse which is disclosed to or suspected by school personnel.
The following is a list highlighting a few informational sites which educators may access for information on child abuse and neglect.

**Child Abuse on the Virtual Hospital.**

URL: http://vh.radiology.uiowa.edu/Providers/ChildAbuse/CAHomepg.html

The Virtual Hospital was created by the University of Iowa through a grant of the National Library of Medicine. Patients, healthcare providers, and others can access medical departments, multimedia textbooks, and connections to other relevant sites. Approximately 250,000 contacts are made to this web site per week.

Within the Virtual Hospital is a child abuse home page that provides references and interactive materials designed to increase awareness and understanding of child abuse and neglect. This site was developed with the cooperation of the Iowa Child Protective Training Academy (CPTA), a multiuniversity collaboration that provides extensive training for child protective service investigators. Sources of information such as *Child Abuse: A Guide for Mandatory Reporters* and a multimedia textbook entitled *A Nation’s Shame: Fatal Child Abuse and Neglect in the United States*, are available with the entire text on the Web at this URL. Additionally, this site connects to most significant child abuse Web operations, including the National Committee to Prevent Child Abuse (NCPCA), the American Professional Society on the Abuse of Children (APSAC), the National Clearinghouse on Child Abuse and Neglect, the National Center on Child Abuse and Neglect, the National Resource Center on Child Sexual Abuse, the National Child’s Advocacy Center, and the Department of Health and Human Services.

The link to the American Professional Society on the Abuse of Children (APSAC) includes an introduction to the organization, information on APSAC publications, task forces, legislative relations, state chapters, and other APSAC activities. Additionally, registration forms for colloquiums can be accessed for printing.

**Child Abuse Prevention Network**

URL: http://child.cornell.edu

This site is an initiative of the Family Life Development Center at Cornell University. The network is dedicated to enhancing Internet resources for the prevention of child abuse and neglect, and reducing the negative conditions in the family and the community that lead to child maltreatment. The Child Abuse Prevention network has been awarded a 3-Star Rating by the Mental Health Network. Through the site, key resources identified as being of assistance to professionals addressing child maltreatment are described with suggested bookmarks in the area of child abuse prevention. Top web sites can be accessed, including APSAC; *Child Maltreatment* (APSAC’s professional journal); National Data Archive on Child Abuse and Neglect (NDACAN), an extensive child abuse research database; LifeNET, an alliance for building a network designed to support all professions concerned with prevention of child abuse and other forms of child endangerment; Children’s House, a resource being built to address program and research issues that affect the well-being of children; CD-Mom, a site of information for parents to make family life less stressful and more positive; child abuse listservs to keep track of intervention, treatment, and research within the field; and child abuse newsgroups which provide support for victims and perpetrators.

**National Data Archive on Child Abuse and Neglect**

URL: http://www.ndacan.cornell.edu or via Child Abuse on the Virtual Hospital (http://vh.radiology.uiowa.edu/Providers/ChildAbuse/CAHomepg.html) or via Family Life Development Center (http://child.cornell.edu/fldc.home.html)

This data bank is housed at Cornell University and is used to facilitate the secondary analysis of research data relevant to the study of child abuse and neglect. It serves as the major repository for key studies funded by the National Center on Child Abuse and Neglect (NCCAN). A listserv for child maltreatment researchers also originates at this site.

**Kempe National Center on the Prevention and Treatment of Child Abuse and Neglect**

URL: http://electricstores.com/kempe/default.htm

The Kempe Center has provided leadership in child abuse awareness, education, and the development of innovative programs. Its web site provides information on the history of the organization, Answers to Frequently Asked Questions by Parents and Other Consumers on Responses to Child Abuse, and information on Kempe programs.

**Higher Education Center Against Violence and Abuse**

URL: http://www.umn.edu/mincava

This web site provides a wealth of information on publishers, journals, books, and handbooks which can be accessed on-line. Especially salient for educators is the link to *Child Abuse: A Handbook for School Staff* which is part of the Frontenac County Board of Education’s Web site. This resource provides explicit guidelines for handling abuse cases within the school setting. Additionally, a site for *Voices for Children*, a non-profit book project on Child Abuse, provides access to true stories from the case files of a child abuse attorney.

**National Clearinghouse on Child Abuse and Neglect Information (NCCAN)**

URL: http://www.calib.com/nccanch/
This resource provides information on the prevention, identification, and treatment of child abuse and neglect. This site describes the latest materials from the Clearinghouse, including manuals, research reviews, studies, and reports. Information also may be accessed on up-dated statistics, child welfare, child abuse and neglect prevention, and state statutes. Additionally, this site allows links to the Clearinghouse Documents and Prevention Programs Databases. More than 22,000 records on child abuse and neglect can be searched and information on effective community-based prevention programs from around the United States can be found.

Conclusion
The pervasiveness of child abuse necessitates appropriate training of educators to fulfill their legal and ethical responsibilities in detecting, treating, and preventing child abuse and neglect. Moreover, school personnel are in a unique position to serve as advocates for children which may be an imperative function, especially when a parent is not either emotionally or physically capable of serving in this capacity.

Although educators are vital to the intervention effort, they do not function in isolation. Child abuse is a community issue which requires collaboration between community members and agencies. The Internet helps facilitate linkages between professionals by providing a forum for the exchange of essential information and innovative ideas.

In order to address the needs of victimized children, teacher education programs have an opportunity to create meaningful training experiences by reaching out to Internet resources for information. This initiative highlights the sharing of information among diverse professional groups with the common mission of promoting the positive growth and development of children. By joining forces with other agencies which advocate for young people, teachers may play a critical role in reaffirming the value of children.

New Hanover High School

Ronald Stammen
North Dakota State University

Ronald Vetter
University of North Carolina at Wilmington

Marilyn Nelson
Center for Innovation in Instruction

This paper addresses opportunities and issues related to the use of the Internet and World Wide Web as an emerging channel for the delivery of preservice and inservice teacher professional development. The benefits and risks of using the Web as an educational delivery vehicle are explored from the perspective of two systems specifically being developed to address the needs of practicing teachers. The authors are involved with two Web-based projects that are using the Internet as a development platform to carry out teacher professional development at a distance. An overview of each of these projects, and future prospects for Web-based teacher professional development, are briefly described in this paper.

UNCW INSTRUCT Project

The Mathematical Sciences Department at the University of North Carolina at Wilmington (UNCW) is currently piloting a World Wide Web site called INSTRUCT, which stands for Implementing the NCTM School Teaching Recommendations Using Collaborative Telecommunications (http://instruct.cms.uncwil.edu). INSTRUCT is designed to introduce high school mathematics instructors to the National Council of Teachers of Mathematics Professional standards for teaching mathematics (NCTM, 1991). INSTRUCT's design integrates aspects of groupware, or software intended to support group interaction, to expand its use beyond being simply a storehouse of instructional material. INSTRUCT provides teachers with hypermedia training materials, links to online educational resources, as well as the capability for users to communicate both synchronously and asynchronously, as appropriate.

During fall semester 1996, four mathematics teachers from two counties in southeastern North Carolina have been involved in the INSTRUCT pilot project using their home computers. The project has been granted licensure renewal credit by the state Mathematics and Science Education Network in recognition of the time participants will be spending online using INSTRUCT. Each teacher received face-to-face training during summer 1996 in navigating the Web, publishing Web pages, and communicating synchronously using a text-based chat tool.

During the pilot project, trainees work on six professional standards, including meeting online before and after the implementation of each standard in their classes and completing a Check for Understanding form summarizing their comprehension of and experience with the standard. Records kept as a part of the project include messages posted in the discussion area, transcripts of online meetings, and submissions from the Check for Understanding forms and the pre-and post-tests of Professional Standards knowledge.

INSTRUCT's initial results are very promising. INSTRUCT appears to be capable of promoting the formation and maintenance of a virtual community through its blending of synchronous and asynchronous communications tools, which when combined with online professional development materials and resources for lesson planning, provide teachers with a rich, safe and self-sustaining environment for implementing changes in instructional practice. During 1997, use of INSTRUCT has been expanded to include twenty-one teachers from southeastern North Carolina whose training is funded through a Dwight D. Eisenhower Professional Development Program grant.

NDSU/US WEST Multimedia Project

With financial support from a US WEST Foundation grant awarded to North Dakota State University's (NDSU) School of Education/Tri-College University's Educational
Administration program, a consortium of universities and school districts are developing a multimedia training program for teachers. The project, "Collaboratively Created Multimedia Modules for Teachers" (http://www.ndsu.nodak.edu/~stammen/uswest), is developing and implementing a series of Web-based multimedia modules to assist K-12 teachers and university teacher educators to integrate multimedia education and training into their day-to-day teaching activities.

The primary objective of the NDSU/US WEST project is to develop competency-based training modules for preservice and inservice education through a systematic curriculum and instructional development process. The SCID (Systematic Curriculum Instructional Development) model for curriculum development from the Center for Education and Training for Employment (CETE) at The Ohio State University in Columbus, Ohio, was chosen for this purpose. The SCID process involved selecting a group of experts with varied backgrounds (computer technicians, multimedia specialists, curriculum developers, classroom teachers, teacher educators, students, administrators, and practitioners), and asking them to collaboratively describe and develop the tasks needed for successfully using multimedia in the classroom. During summer 1995, a group of 24 people were trained by the Ohio State CETE personnel to develop a series of learning guides for a competency-based curriculum in using multimedia in the classroom. This group identified the following seven duties during this process:

1) Acquire Basic Computer Skills
2) Improve Curriculum with Multimedia
3) Deliver Instruction with Multimedia
4) Utilize Support Services
5) Improve Teacher Communication with Multimedia
6) Promote Multimedia in the Classroom
7) Pursue Professional Development

The modules (duties), which are comprised of learning guides (related tasks), have become the competency-based curriculum package.

During summer 1996, technical designers proceeded to put the learning guides into electronic form (i.e., code them in the hypertext markup language) for access via the World Wide Web. Allowing access to these learning guides over the Internet was seen as an important step. Although many of North Dakota's teachers are geographically isolated, they are connected to the global Internet. Thus, turning the learning guides into Web-based documents made it possible to have them accessed and used at a distance.

Currently, we are in the training and implementation phase of this project. This phase activates the training plan, its evaluation, and documents learner achievement. Our initial program evaluation is still underway and the project's impact on the learning environment in North Dakota's schools and universities remains to be seen. Evaluations from the SCID training sessions have assured us that the project has already motivated and enlightened approximately thirty educational professionals. Approximately twenty-four K-12 school districts have agreed to participate in this project. We expect that, as the project reaches these districts, hundreds of teachers will be affected by this project.

**Future Prospects for Web-based Professional Development**

We believe the experiences and lessons learned from the Web-based teacher professional development projects described in this paper can be successfully applied to other educational systems as well. Already today, the explosive growth of the Internet is having a dramatic effect on the way teachers and educators view professional development. We are seeing many ways in which multimedia systems can be used to enhance education at a distance (Stammen, 1995). Remote and collaborative teacher education is just one of the many applications for this emerging technology.

Teachers are embracing the World Wide Web in increasing numbers. The network and software technologies needed for carrying out effective group and collaborative work applications over the Internet will continue to mature and evolve in the next few years, but there are also many remaining challenges. For example, it is still not well understood how the roles of instructor and learner change as professional development is carried out at a distance (Shotsberger, in press). Although the potential for multimedia training systems in teacher education is great, we must still address social concerns in order to build successful systems. It is also imperative that systems designed for teacher use do not become so sophisticated that they are rendered unusable on the hardware typically available to educators (Shotsberger, 1996). This limitation will likely persist in the near-term and needs to be given serious consideration by Web site developers.

TEACHING GIS VIA THE WORLD WIDE WEB: A DISTANCE EDUCATION EXPERIMENT

Over the past three years the University of Delaware and the University of Agriculture ("VSP" in Slovak) in Nitra, Slovakia, have exchanged faculty and graduate students in various management disciplines. This program, funded by a grant from the US Information Agency, established an Institute of Business Development and Management (IBDM) at the College of Economics and Management at VSP. A primary objective of the IBDM program was to "support interdisciplinary empirical analyses of local/regional resources and their development." This objective "grew out of the recognition that a holistic approach is needed to assist in the restructuring of the Slovak economy" (IBDM, 1995.). The IBDM program also financed the purchase of computers and other instructional materials for VSP.

Several faculty members visiting Delaware from VSP were introduced to research in Geographic Information Systems (GIS) at the University of Delaware's Spatial Analysis Lab, and later requested that I teach a short course in GIS at VSP under the auspices of the IBDM program. During the summer of 1996 I prepared a GIS lab design and a short-course curriculum for VSP. In October 1996, I spent three weeks in Nitra establishing a computer lab for GIS and initiating an experimental GIS training program under the sponsorship of this project.

A GIS supports geo-referencing, display and analysis of various types of geographic data derived from digitized maps, global positioning systems, airphotos and/or satellite imagery. GIS technologies are used to model a wide variety of natural and human-generated spatial processes, including drainage and erosion problems, habitat requirements of particular species, transport mechanisms and fates of environmental pollutants, land use changes, etc. The power of a GIS lies in its ability to combine and analyze spatial relationships in data from diverse sources.

GIS technologies are of particular interest in Slovakia, since the country's emergence from communism in 1989 has led to widespread privatization of land resources. Slovakia also faces significant environmental problems, including toxic waste problems from communist-era industrial sources, contamination of aquifers and waterways from agricultural chemicals and fertilizers, increasing traffic congestion and air pollution from both factories and automobiles. The country is still developing the institutional framework to deal with these problems, and has urgent need for GIS technologies to ensure that new environmental protection policies are efficiently designed and targeted. The purpose of this project was to establish a core capability in GIS at VSP from scratch.

GIS technologies are typically expensive and difficult to learn. The typical GIS lab requires a start-up investment of at least $50,000 for computer hardware, software, data acquisition, technical training, in addition to employee salaries. Depending on the complexity of the problems to be analyzed and the availability of local GIS data, it may take anywhere from three months to two years for the lab to reach a satisfactory level of productivity.

Unfortunately, VSP itself has almost no money for computer workstations, expensive commercial GIS software or GIS data acquisition, and the IBDM program budget could only provide minimal funding for this project. While the IBDM program could have funded me for additional time in Nitra, I could only spend three weeks away from Delaware. Thus the principal challenges were (1) to build a functional GIS lab and develop a basic set of local GIS data at minimal cost, (2) teach GIS skills to a core group of students over three weeks, emphasizing the transferability of those skills to other students, and (3) establish a distance-learning program to support the continuing development of GIS capabilities in Nitra after the termination of the Delaware/VSP project in November, 1996.

The basic objective of this project was to create self-sustaining GIS research and teaching capabilities at VSP. The project targeted an initial group of students who began training in October. This class was intended to produce a core group of GIS users who will eventually train other students in the GIS lab using local Web training materials.
and who can revise these Web materials as VSP’s GIS capabilities continue to develop.

**GIS Lab Configuration**

The GIS laboratory was developed around a 120 MHz Pentium PC reconfigured as a UNIX server. This server runs GRASS 4.1.3, a UNIX-based public-domain GIS developed by the Construction Engineering Research Lab, US Army Corps of Engineers. Like many GIS’s, GRASS handles both raster and vector data structures. A raster data structure represents sets of geographic features as values in numeric arrays representing regularly-spaced points in a grid covering a geographic area. A raster structure is most appropriate for modeling continuous surfaces or storing scanned image files. A vector data structure represents geographic features by sets of coordinates defining each feature’s shape or outline. Vector data are easier to plot on conventional hardcopy devices. GRASS is a fairly comprehensive collection of raster manipulation functions, raster analytics, image processing tools, vector functions and raster-vector-point conversion utilities.

The server’s operating system is Linux (Slackware 3.0 release), a shareware UNIX operating system for personal computers, including full X-window functionality via Xfree86 (8-bit color) and various shareware X utilities, and full network functionality. Networked PC’s can access the server using any standard X emulation software. Two unused X-terminals were located and networked to the server. VSP provided the Pentium microcomputer as well as the spare cabling and X-terminals. The Delaware/VSP project purchased extra RAM and an additional 1.6 GB hard disk for the server locally for less than $400. The server’s IP address is 193.87.98.7, with the registered name gis.uniag.sk. Unlike most GIS labs, the VSP GIS lab setup does not include any hardcopy output device. This reflects both budget limitations as well as an emphasis on GIS for spatial analysis rather than cartographic production. Although the lab is indirectly networked to a standard black-and-white laser printer, College policy restricts student access to this printer in order to minimize costs of paper and toner. The College network has no color printer. Consequently, students are encouraged to prepare their GIS work for presentation on the World Wide Web rather than on paper. This offers several advantages over hardcopy: students are not charged for paper and toner; they can prepare presentations more quickly, combining text with in-line color maps; and submission of work via the Web avoids costs and delays of mailing work from Slovakia to the US. The student Web pages are now served from a separate Linux server in the College (pefstud.uniag.sk) accessible through the main GIS WWW page at VSP, sun.uniag.sk/mackenzie/public.html/. To maintain its computational efficiency, the GIS server itself does not double as a Web server.

The lab setup benefited from extensive volunteer assistance provided by interested VSP faculty members and students. An undergraduate with extensive (self-taught) knowledge of Linux oversaw the configuration of the server. The College’s computer systems administrator took charge of the network connectivity and X-terminal configuration. Pre-compiled GRASS software and various GIS data in native GRASS format were brought from Delaware on CD-ROMs and installed directly onto the server. The complete lab setup required five days and approximately 100 work hours.

**Data Sources**

The critical element in any GIS is data. The official CERL distribution of GRASS includes a fairly extensive GIS data set for two 7.5-minute quads around Spearfish, South Dakota, US, including digital elevation models (elevation data at regular grid sampling intervals), geology, soil, vegetation, streams, roads, etc. This data set reflects the wide range of public data available for the continental US, and is very useful for teaching principles of spatial logic and map algebra. Unfortunately, the available GIS data for Slovakia are extremely limited.

The IBDM program funded the purchase of two sets of satellite imagery for southwest Slovakia where Bratislava (the capital), Nitra and most of the country’s prime farmland are located. For a base map, I acquired georeferenced August 1986 Landsat Thematic Mapper satellite imagery from USGS’s EROS Data Center. These data are comprised of 7 spectral band files—3 visible light bands and 3 near/mid-infrared bands at 30-meter pixel resolution and one thermal infrared band at 120-meter pixel resolution. These data were resampled by EROS to UTM coordinates (World Geodetic Survey 1984 datum) using well-defined ground control points. Total cost of these data was $425. The geo-referenced Landsat TM imagery are currently being used to create a series of digital vegetation and land-use maps. They also support geo-referencing of other GIS layers.

The project also acquired raw July 1994 SPOT multispectral imagery for a 65 x 65 KM region to the southeast of Nitra. The 3-band SPOT image data (near infrared, visible red and green bands) underwent initial processing in Delaware, and then ftp’ed to Nitra and geo-referenced to UTM coordinates using reference points from the Landsat imagery. Total cost of the SPOT data was $975.

Additional GIS data include 30-arc-second digital elevation model (DEM) data for Europe, developed by EROS in lat-long coordinates, and distributed by EROS from edcftp.cr.usgs.gov. For congruence with the satellite imagery, these data were resampled to UTM coordinates. The DEM data are readily analyzed to create terrain slope and aspect maps, as well as 3-dimensional terrain models.
These data also support delineation of watershed divides, calculation of overland drainage volumes and inferred drainage channels, analyses of erodability, etc.

These GIS data resources were intended to increase both the local relevance and the functional value of the course. The fully processed standard sample data from the US allowed students to experiment with GRASS's various analytic functions. The raw local data let students learn the fundamentals of GIS data development—radiometric and geometric correction of raw imagery, image processing and classification, terrain modeling, etc. In reality, most GIS professionals spend far more time on data development than data analysis.

One fifth-year student at VSP is using the 1986 Landsat TM imagery and 1994 SPOT multispectral imagery to support thesis research into recent cropland fragmentation patterns in southwest Slovakia. Most of this fragmentation is associated with privatization of Slovakia’s collective farms since 1989. Among other things, this research can help identify the effects of ongoing privatization of agricultural land on water quality.

Course Syllabus and Software

VSP students attended 14 2-hour class sessions combining lecture, demonstration and hands-on lab exercises over three weeks. The classes included introductory sessions on the UNIX operating system, GIS data structures, and projection systems (all taught while the lab was being set up); GIS display techniques; map logic; raster manipulation and analysis functions; on-screen digitizing; satellite imagery acquisition, processing and classification (using the imagery of Slovakia); and HTML basics for student project presentations via the World Wide Web.

Students are required to complete at least two of four assigned projects which run the gamut of GIS operations. The first project involves determination of optimal habitat areas for an endangered species which prefers proximity to agricultural land on water quality. The second project involves calculation of rock overlay to be blasted out by a mining operation, and combines buffer and logic functions with volumetric analysis and simple AWK programming. The third project involves creation of a raster digital elevation model from vector hypsography (elevation contour line) data, and introduces data import, vector-raster conversions, surface interpolation, and terrain analysis and visualization. A demonstration of these techniques using DEM data for Slovakia is posted on the GIS Web site at VSP. The fourth project involves development of a land-use/land cover map from raw satellite imagery. It introduces image enhancement, color compositing, geometric correction, texture analysis, cluster analysis and maximum likelihood classification techniques. This project uses the satellite imagery acquired for southwest Slovakia.

The syllabus and project assignments reflect my own research interests in natural resource management, and my uses of GIS as a spatial analysis tool rather than a cartographic production tool. My objectives are to teach students to “think spatially,” i.e., to conceptualize dynamic spatial processes. This approach differs in several ways from GIS instructional programs emphasizing vocational training in a specific GIS software. This is reflected in the choice of GRASS as the GIS software used in the course. GRASS is not a commercial GIS package. It lacks some of the vector capabilities of a high-end commercial package such Arc/INFO, and lacks some of the image processing capabilities of a high-end commercial image-processing package such as ERDAS. GRASS also lacks a visually attractive graphical user interface.

But the advantages of GRASS are substantial. First, both the C source code and compiled binaries for various UNIX platforms are freely available (via ftp from the Construction Engineering Research Labs, US Army Corps of Engineers, at moon.cec.army.mil or from European mirror sites), and it is well supported by an active online news group (grassu). Second, it uses open (non-proprietary) data structures for storing geographic features, which makes GRASS highly programmable. Third, GRASS is extremely robust software: it is actually comprised of several hundred independent modules which exploit a common set of global environment variables defined at the start of a GRASS work session. Failure of one module does not compromise any other module. Fourth, GRASS is fully transparent to the UNIX shell and thus works with any other installed utilities (sed, AWK, Perl, Xview, Image Alchemy, xanim) and is programmable with standard shell programming. GRASS teaches general expertise in UNIX programming and system administration—skills which are useful throughout the UNIX world. There is no need for students to learn any special macro language. Finally, at least compared to other GIS software, GRASS has a reasonably smooth learning curve, and, once familiarized with GRASS and the GIS operations it supports, students can learn other GIS’s very rapidly.

While most GIS problems are treated as two-dimensional (static and planimetric), my approach encourages students to experiment with three- (2D through time or synoptic 3D) and four-dimensional (3D through time) modeling. The first hands-on lab session introduces GRASS’s 3D terrain visualization capabilities. The shell programming examples include scripts to simulate down-gradient flow processes, create terrain fly-over animations, etc.
World Wide Web Course Materials

The class sessions were complemented by World Wide Web course materials condensed from similar materials used in the University of Delaware's graduate-level spatial analysis course. A fairly complete set of the source materials, developed over the past two years, is available from bluehen.ags.udel.edu/spatlab/ or www.udel.edu/johnmack/frec682/. These materials are still being adapted for VSP students using local data and applications. Updated materials are prepared in Delaware and ftp'ed to the server in Nitra. Remote editing of links from existing Web materials in Nitra is done with the vi editor, and is slow. Draft English versions of the Nitra Web materials are currently available from sun.uniag.sk/mackenzie/public.html/, but will be moved shortly. Additional funding is now being sought to pay for local maintenance of the GIS lab's Web site in Nitra, and for eventual translation of the class materials into Slovak.

The design of the GIS Web site at VSP is simple. The home page links to (1) the course syllabus page, which links to instructor e-mail, project assignment pages and pages providing detailed treatment of each course topic; (2) a student projects page, with links to each student's own GIS home page and individual project pages; (3) a local resource page cataloging local GIS data resources, satellite images and 3D terrain models from the GIS server; and (4) an external resource page, linking to other GIS sites around the world, including GIS data distribution sites.

The initial group of students is now submitting their own projects for grading via the Web. Since GIS presentations are typically graphics-intensive, the Web is well-suited to presentation of them, and provides an adequate substitute for hardcopy. As mentioned previously, students have no easy access to any hardcopy device. Since conventional mail service between Slovakia and the US can be slow, the Web also provides relatively efficient communication between Nitra and Delaware. Connections between Delaware and Slovakia are often slow during peak load periods, but are reasonably fast during evening hours in the US. Since students are very aware that their Web submissions can be viewed by anyone, they typically take considerable care to assure the quality of their work.

From Delaware, I maintain regular e-mail contact with students in Nitra. Students contact me for technical help with their projects, and notify me when their Web submissions are ready for grading.

Conclusions

Although this project is still underway, it has already had some apparent successes. Two students out of an initial group of 12 have already completed the course requirements and are pursuing further research interests in GIS. One of these has assumed local system administration responsibilities for the GIS server, and provides local help with the GIS software. Both of these students are planning to start graduate study in the US next year. Six other students are making good progress on their class projects, and should be completing the course over the next few months. Four students have unofficially dropped out of the class, citing frustration with UNIX, the complexity of GRASS software and the difficulty of the projects.

This success rate more or less mirrors the success rates of students in my graduate spatial analysis course at Delaware: a handful in each class become GIS fanatics, and a significant minority fail to complete the course. As noted above, my basic objective is to teach students to "think spatially," and students evidently have varying aptitudes for this. Student expertise with UNIX at the start of my courses also varies widely. My general observation is that students who become GIS fanatics do not necessarily have strong computer backgrounds, but they are typically enthusiastic about spatial logic problems and are quick to perceive spatial patterns in data. The students who fail typically have weak knowledge of UNIX, and often articulate frustration with spatial logic problems.

In conclusion, the GIS lab design for VSP succeeded in minimizing setup costs while providing very adequate GIS and image processing functionality. The lab setup depended on significant local expertise, and would probably have failed without it. The GIS data resources are already supporting preliminary research efforts, including thesis research on fragmentation of farmland in southwest Slovakia due to privatization of the economy. The accelerated class has produced at least two GIS enthusiasts who will be active promoters of GIS at VSP for as long as they remain there, and the Dean of the College of Engineering and Landscape Design is now a strong supporter of continued GIS development at VSP.

Development of GIS capabilities at VSP now appears to be self-sustaining. The GIS Web materials and e-mail communication between VSP and Delaware provided project continuity at a critical phase after my departure from Slovakia. Control of VSP's GIS Web materials is now being turned over to local system administrators, and these materials will keep evolving as VSP's teaching and research in GIS continue to develop.

The purpose of this paper is to describe the method and discuss the results of a World Wide Web (WWW) group development project. The project was a cooperative group effort and was a required assignment of an Advanced Instructional Technology course at Southwest Texas State University.

The course titled Advanced Instructional Technology is a graduate course in the Department of Curriculum and Instruction. It is offered twice a year (Spring and Summer) and the enrollment is approximately 15 to 20 students. The students are a mixture from the Curriculum and Instruction department and the Developmental and Adult Education department, both in the School of Education. Although traditionally an instructional design course, the main project has slowly evolved to use technology as the delivery method. Prior to the summer term, students had produced print based projects as well as HyperCard or HyperStudio projects.

In the Summer of 1995 (and again in the Spring of 1996), I decided to teach the creation of World Wide Web pages to the students so that they might create WWW sites for their project. I decided to teach the WWW page creation for several reasons:

1. Hot topic - Everywhere you look in the papers, magazines, and television, WWW is discussed and site addresses are given. One of the largest demands we have in the lab is the use of the web and how to search for information. Many of our graduate students have expressed interest in learning web page construction to use in their classrooms at schools or in the departments in which they work.

2. Instructional design (ID) skills - By creating a web site, I felt the students could put many of the instructional design principles to use, such as a thorough analysis of the users, task analysis, planning, revision, and evaluation. I feel the ID part of the course is an integral part of the designing of any project.

3. Computer skills - In addition to using ID skills, students would also learn many computer skills such as scanning, graphic programs, converting files, word processing, page layout, and Web page programs (HTML).

4. Real life situation - One of the main benefits of this approach was the ability to put students in a real life situation. In the real world instructional designers must work in groups with content specialists, graphic designers, and programmers to create a product. The students had to work for a client. The client was interviewed and consulted frequently by the groups for guidance and approval in each step of the design.

5. Needed projects - Another large factor in the decision was the fact that the web sites were needed and clients were readily available. The School of Education has its own web server and the Dean has encouraged all programs to have web pages. Thus, there is a high demand for people to work on the sites and I knew the projects would be put to immediate use.

6. Cooperative learning - It was important to me that we have group projects and I was eager to try "jigsawing" within the groups (Slavin, 1990). In the summer especially, group projects seemed to be the best way to accomplish a goal in a short period of time (four weeks).

The cooperative group learning method used for this project is referred to as Jigsaw II by Slavin (1990). In this modified version of Jigsaw II, teams are formed and each member of the team is given a unique assignment in which they are to become an expert. Students from the different teams with same assignments meet in "expert groups" to receive training, discuss, and work on learning their job. The experts then return to their teams and teach their teammates about the topic they have learned. The success of the whole group depends on the motivation of the students to learn in their expert groups so that the whole team can do well. The key to Jigsawing is the interdependence of the team members; the team depends on every teammate to provide training and information that every member of the team needs to succeed. The various assignments for this project are discussed in Week 3 below.
Teaching the Course

Weeks 1 and 2

During the first week and a half of the course (eight meetings), we discussed the chapters in the Dick and Carey (1996) book "The Systematic Design of Instruction." These discussions on the chapters would last about one half of the class period. The other half of the period, students were taught how to use the World Wide Web. Specifically, how to search for sites, find clip art, and to study sites which were graphically pleasing and content rich. We also spent several days learning the basics of HTML (HyperText Markup Language) so students would understand what a web page design program such as PageMill™ produces as output. Meanwhile, I was finalizing the clients for the projects.

The last several meetings of week two, the students were presented with the three project proposals. Students then divided into three teams according to interest in the topic. After the teams were chosen, the students further divided themselves into a specific job/title (expert groups).

Week 3

With teams and assignments given, the students were now ready to start learning their duties. The duties in each team were divided as follows:

- **Project Director.** Works at scheduling, assigns tasks, calls group meetings and meetings with client. On the average, the teams met with the clients four times.
- **Programmer.** Learns how to use PageMill™ to assemble text, graphics and links on the page. Since time was very limited in the summer, I tried to enlist persons with extremely good technology skills as the programmers.
- **Graphic Artist.** Designs, selects, and scans graphics for pages. A large part of their training involved learning how to scan and clean up images as well as converting the PICT files into GIF files for the web.
- **Content Specialist.** Collects content information and word processing of data. These persons spent an incredible amount of time hunting down word processed files already in existence as well as creating new ones.
- **Project Designer.** Keeps all documentation of project and is responsible for overall design of project, an extremely important job as information could be passed on to the next person who might maintain or update the site.
- **Other.** Any other job needed (example: contact book publishers for releases or publishers for permission to use copyrighted text, pictures, or graphics)

During the first two days of week three, I met with each expert group. For example, I met with all the graphic artists and made sure they knew how to operate the scanner and were aware of where the clip art files and graphic programs were located. By the middle of week three, the teams had formulated interview questions and were ready to meet with their clients (see below for sample of interview questions). After meeting with their clients, the teams rouged out the web site and met with clients again later in the week. Once the plans were approved, the site was ready for construction.

Sample of interview questions. The following questions are a sample of the questions students asked when interviewing their clients:

- **What is the purpose of the Web page? Is it to inform, entertain, or convey an attitude or feeling?**
- **Who is your audience? What would the age, education level, and interest level of your prospective viewers be?**
- **What benefits would a person receive from visiting the Web site? Why would they wish to return?**
- **What kind of information would be presented at the site? Consider graphics, photos, documents, and links to other sites.**
- **How would you like the site to look? Bright and colorful or conservative and formal? Any special color preferences for text, backgrounds, etc.? Does the organization have a logo?**
- **Which is more important: 1) quick loading time of the page or 2) visually appealing but slower?**
- **How much information is already word processed and ready to use?**

Week 4

To say week four was busy would be an understatement. All groups were simultaneously working on graphics, layout, and word processing and assembling the site as they went along. Some sites had to be scaled back due to the time factor, but the most progressed nicely. The vital importance of jigsawing became apparent during this week. Each group member was responsible for advising all the other members about how their jobs were being performed.

At the end of the week, the projects were finished and presented to clients. If the projects met with approval, they were immediately posted on the server so the whole class could view them.

Results and Discussion

I feel the project was a success. All three clients were extremely happy with the web site and the three sites that were developed are still in use. One web project was for the Adult and Developmental Education Department at SWT, the second web project for Thomas Rivera Mexican-American Book Award, and the third a page for the School of Education Teacher Fellows program.

The students were pleased with their accomplishments. Most students felt they had learned a skill they could use again at their schools or businesses and had learned much about instructional design and using the World Wide Web. However, I feel some suggestions for implementing this plan should be considered:
1. Be sure to leave time for “jigsawing” to take place. The Summer schedule was so rushed many students did not get enough time learning the other roles. For example, many students felt they could have used much more practice in the role as programmer to learn how to make links and import text as well as graphics.

2. Make sure each person understands their role within the group. Confusion could result if duties overlap or duties are left out. Monitor very closely the various group dynamics and don’t be afraid to step in to help the group reach decisions and clear up assignment problems. Rather than being territorial about their duties, some members were perhaps too deferential.

3. Don’t put too much power in the hands of any one member. Even the project director did not have the authority to make a major decision but only to call a meeting to decide.

4. Try to match the clients with the group. One client wanted a very conservative instructional site while the other was open for a more modern graphic approach. I made an effort at the beginning of the team assignment process to make sure the students were given a general overview of what each client had in mind for a web site. The decision on the type of site was dependent on the type of information presented as well as the client’s wishes.

5. Make sure clients are willing to spend time with the groups so groups will know what the clients want. One group wanted to replace the existing site (which they thought boring) with their own pages but the client resisted. The group was given a link on the original pages to present the content in their design.

6. Agree beforehand who will maintain the site once it is posted. This underscores the need for extensive documentation by the group so someone else can find the files to make updates.

7. Site organization is a must. All of the web pages of a site should go in one folder or directory. Contained within this folder should be a folder for all of the graphics for your site. If you don’t follow this organizational scheme, total chaos will result on your web server. Others who post pages and graphics on the server with the same name can easily erase your work. Insist on organization!

PREPARING TEACHERS TO USE TELECOMMUNICATIONS AS AN EDUCATIONAL TOOL

Denise Staudt
Our Lady of the Lake University
Hugh Fox
Our Lady of the Lake University

Communication technologies are powerful, motivating tools that can actively engage students in thinking and learning. By making the journey onto the Internet, teachers and students can break down the walls of classrooms and open up new worlds and unlimited information. Technology and telecommunications activities carefully integrated into curricula areas provide students opportunities to develop the process skills, content area knowledge, literacy skills, and technology skills necessary for effective, lifelong learning. To realize technology and telecommunication's full potential, classroom teachers must be prepared to use technology and telecommunications as an educational tool.

Electronic networks are unparalleled teaching tools, making research findings, educational materials, experts, and original sources available to any teacher and any student. Interpretation, discovery and experimentation in the academic areas can be enormously quickened and expanded by electronic networks. Networks can facilitate scholarly collaboration, lowering barriers posed by geography and specialization. Web pages (searchable documents written in Hypertext Makeup Language), are becoming an even increasing means of providing information through this online effort. Not only is it important for teachers to be able to locate online information, but also to contribute to the knowledge available via the Internet (American Council of Learned Societies, 1994).

Significant changes in teaching and learning must accompany the integration of technology and telecommunications activities into teaching. It is one thing for a teacher to be able to navigate the Internet to find information, and quite another to incorporate technology and telecommunication into classroom activities in a meaningful way. Using technology and telecommunications for instructional purposes has major implications for practicing teachers as well as students preparing to be teachers. Perhaps the most serious challenge for educators today is how to prepare technology-literate teachers to face the classrooms of today and the future. One possible solution to help meet this challenge is for universities to prepare preservice teachers and practicing teachers to use the technologies of the 21st century (Darling-Hammond, 1994).

The need for technology in education is well documented in the literature (Byrum & Cashman, 1993; Fox & Thompson, 1994; Levin & Waugh, 1995). Most universities preparing teachers have addressed this need and restructured their undergraduate teacher preparation programs to include the training of preservice teachers in technology. However, it is apparent that there is also a need for universities to offer innovative education programs to train practicing teachers to integrate technology and telecommunications into the schools. While many practicing teachers have access to the latest technology in their classrooms, they are often lost when it comes to integrating the technology and telecommunications activities into their teaching. There is little doubt that placing technology in classrooms calls for fundamental changes in teaching practices on the part of teachers. Perhaps the most serious challenge to teacher educators is to retrain innovative teachers to face the technology-rich classrooms in schools.

Despite the apparent awareness of the importance of technology in education, progress toward the integration of telecommunications into teaching has been very slow. The Office of Technology Assessment (OTA, 1995) identified the following as barriers to technology integration: 1) lack of teacher training, 2) inservice programs that focus on the mechanics of individual computer use rather than on designing instructional strategies that were enhanced by technology, and 3) teacher education programs that were not turning out graduates who could incorporate technology as a teaching tool in any meaningful way.

Building on findings from research literature, Our Lady of the Lake University's Education faculty have developed a unique program which trains teachers to create an innovative learning environment in their classrooms while integrating leading-edge technology and telecommunications activities. Through a cohort approach, teachers enrolled in this program earn a Master of Education in Curriculum and Instruction with an emphasis in Instructional Technology. This program strives to meet the literacy and technology needs of practicing teachers and to help overcome the barriers of technology integration in schools.
Goals of the Program

The primary goal of this new program is the preparation of professionals in the area of instructional technology. This exciting program avoids the current teacher training shortcomings through staff development and will produce a cadre of highly qualified, highly motivated teachers. Narrowly, this program will prepare professionals to teach information processing in K-12 settings. All participants completing the program will be eligible to apply for the Information Processing Technology Level Two endorsement for state certification. The program is also designed to be appropriate for teachers at all levels, including media specialists, computer educators, instructional technologists, curriculum developers, and classroom teachers. The academic objectives of this new program include:

1. Graduates will be able to teach information processing in the school setting.
2. Graduates will be able to create, design, and evaluate technology-based delivery systems of instruction.
3. Graduates will be able to use computer programming for instructional purposes.

Program Description

The Master of Education program was designed to complement this mission of the Education Department at Our Lady of the Lake University: “Programs within the Education Department at Our Lake University are designed to prepare professional educators to understand and meet the educational needs of a diverse student population and to function in a global society which requires all students to be life long learners. The programs provide opportunities for participants to gain the skills and vision to be leaders in schools faced with challenges of the 21st century.” This new master’s program complements the mission of the Education Department in all of the four areas mentioned.

After many months of discussing the needs of schools with current teachers, the education faculty designed the new curriculum for the new master’s program. While maintaining the integrity of the Master of Education in Curriculum degree, the new Master of Education in Curriculum and Instruction with an emphasis in instructional technology was designed to meet the current technology and telecommunications needs identified in the schools. Of central concern to the education faculty who developed the curriculum for this 36 hour program was the training of teachers to use technology as a catalyst for changing schools in ways that better support the integration of technology and telecommunications into the curriculum. Competencies that the teachers will develop include:

1. background information concerning information processing technologies and its use in education,
2. operational skills and familiarity with current information processing tools,
3. methodology for instruction in concepts and skills of information processing,
4. modern programming with experience in at least two languages,
5. technology-based delivery and management of instruction,
6. understanding of how the Internet works,
7. teaching of effective “surfing” on the Internet for instructional purposes, and
8. skills to create and design instructional software using a computer language.

All teachers enrolled in the program will complete the following professional education courses: Multicultural Foundations of Education, Research: Methods and Procedures, Applied Learning and Development, Individual Differences, Curriculum Development, Classroom Management and Classroom Assessment.

All teachers enrolled in the program will complete the following courses in instructional technology: Computers and Education, Teaching Computer Literacy, Computer Programming for Instructional Purposes, Instructional Media.

If the potential benefits of the information revolution are to be realized, teacher educators will need to make vital contributions. With the dramatic advances in educational technology and the increasing availability of telecommunications, all teacher training programs will need to prepare their teachers for the new technologies that are transforming our world, both inside and outside the classroom. Children presently in elementary schools will need new skills to be the information workers of the 21st century. Clearly, Our Lady of the Lake University’s new Master of Education program is a first step in addressing these needs.

Telecommunications: Graduate, Inservice & Faculty Use — 1161
The Internet has become an essential part of today's world—in education as well as in business, industry, arts, and sciences. Teachers and faculty from elementary schools to universities are using the Internet more and more to provide students with skills that will prepare them to access and use global resources of information, both in school and in their future careers. In order for teachers to effectively assist their students in understanding the use of the Internet, they themselves must be familiar with the Internet and must feel comfortable using the different Internet services available. This paper addresses some of the issues involved in preparing teachers to utilize Internet resources, and describes how education faculty can work with and learn from faculty in various disciplines to provide role models for their students.

The Internet and Education

According to Graphic, Visualization, and Usability Center's (GVU) Fifth WWW User Survey (1996), almost 30% of the millions of World Wide Web users have educational occupations. Instructors use the Internet to provide students with syllabi, lecture notes, presentations, and assignments designed to supplement the in-class experience, and in some cases, to replace it (Shotsberger, 1996). Other instructors use e-mail to communicate more efficiently with students, and to encourage collaboration and interaction among the students. Still others rely on the Internet as a powerful resource for finding current information that can be used in student assignments and research projects. While many educators have learned to utilize the Internet for instructional purposes, there are still numerous faculty members at colleges and universities who face barriers to using the Internet, including their own perceptions of the benefits (or lack of benefits) to students, the availability of necessary equipment, and their own lack of skills (Rutherford & Grana, 1995; Spotts & Bowman, 1993).

Education faculty are faced with the challenge of helping preservice and in-service teachers become comfortable with the Internet so that they will be able to integrate Internet activities into their teaching. However, according to Rutherford and Grana (1995), “Some faculty may resist [new teaching methods] because, never having had instruction in how to teach, they teach only as they themselves were taught (which for many means exclusively lecturing)” (p. 82). If some teachers “teach only as they themselves were taught,” then we must overcome existing barriers to Internet utilization and learn to integrate Internet activities into our courses so that we will provide role models for our students to follow.

One member of an online discussion group dealing with issues related to educational uses of information technology made the following suggestion as part of her dissertation: “...an individual’s decision to adopt a particular innovation is a function of available RESOURCES, the PERCEIVED VALUE the individual ascribes to the innovation, and whether the individual engages in COMMUNICATION WITH OTHER ADOPTERS” (Gilbert, 1995, p. 43). If this theory holds true, then in order to help education faculty further their use of the Internet as a supplement to teaching, we must address the issues of Internet access, the perceived value of integrating the Internet into existing courses, and the communication among faculty in all disciplines who are using the Internet.

Internet access varies across institutions, cities, and countries and is not directly addressed in this paper. However, we would encourage individual institutions that are striving to increase the utilization and benefits of using the Internet on campus to make this issue a priority.

The importance of the second issue, dealing with the perceived value of using the Internet, was affirmed in a study conducted at Western Michigan University (Spotts & Bowman, 1993). One of the primary conclusions of the study was that “…perhaps the single most important factor influencing university faculty’s use of technology is their need to be certain that the technology will contribute to improved student learning” (p. 203). One method of identifying whether or not the use of the Internet contributes to improved student learning is to solicit feedback from educators who have already tested Internet integration. In this paper, we present some responses from a
variety of university faculty who were asked whether or not using the Internet benefited their students.

The third issue, communication among faculty using the Internet, is a primary emphasis in this paper. Since future educators come from different disciplines and take courses from departments other than education, it is important to look at how faculty in various departments are incorporating the use of the Internet into their classes, and how they are encouraging or even requiring their students to learn essential Internet skills. Education faculty, as well as other faculty, can benefit greatly by discovering how the Internet is applied in other courses. By becoming aware of the types of Internet activities used in other departments, we will be able to build upon those experiences and incorporate them into our own education curriculum.

Models of Internet Use at One University

We conducted a survey at a regional state university during the Fall semester of 1996 to help determine how faculty from various disciplines were using the Internet to supplement their teaching. The questionnaire included requests for demographic data, questions about how the faculty members were using the Internet, and questions about how they were requiring, or at least encouraging, their students to use the Internet. The form also contained room for respondents to give feedback regarding perceived benefits of incorporating the Internet into their teaching, problems that they or their students had encountered along with solutions for overcoming these problems, and general comments about integrating the Internet into education.

The following discussion presents information gathered from participants in the study. Since the survey was completely voluntary, the results are not meant to be indicative of the entire university, or even of a specific college. The term "instructor" is frequently used to indicate a member of faculty regardless of whether or not that person is a Professor, Associate Professor, Assistant Professor, Instructor, Lecturer, or Adjunct.

The Overall Picture

The questionnaires were distributed to 366 full-time and part-time faculty in the three distinct colleges at the university (listed in Table 1). Seventy-eight completed forms were returned for an overall response rate of 21%. The response rates for the three colleges as well as for the university are shown in Table 1.

When looking at the response rates of full-time versus part-time faculty, we see that 25% of the full-time faculty returned the questionnaires while only 10% of the part-time faculty participated in the survey.

Nearly one-third (32%) of the faculty responding to the survey claimed more than 10 years of prior computer experience, while only 6% had worked with computers for less than a year. Most of the respondents indicated that they used the Internet in some form to help them with their work. Nearly all (90%) of the respondents indicated that they could access the Internet from their offices, while 36% had access to the Internet from both their offices and their homes. Of those with Internet access, the majority used e-mail and the World Wide Web. Table 2 shows the rankings of the Internet services used by the faculty with Internet access, while Table 3 lists some of the reasons they used those services.

While most of the faculty had access to the Internet and were using it personally, less than one-third (32%) of the faculty required work from their students that involved the use of the Internet. More than half (54%) of the faculty encouraged their students to use the Internet without necessarily requiring that they do so. E-mail was the service required the most, while the web was the service encouraged the most. Table 4 lists the services required and/or encouraged by faculty, while Table 5 indicates reasons students use these services.

Survey respondents listed many benefits to incorporating the Internet into teaching, including the ability to quickly access current and relevant material, the availability of a broad range of materials, exposure to ideas and developments around the world, the learning of skills necessary in a technological world, and greatly improved communication between instructors and students. Reasons given for not requiring Internet use included the belief that not all students had access to the Internet and that the faculty member’s own skills were not adequate. For example, one respondent stated that “…our limited facilities cause me to limit how much Internet participation I require,” and another expressed that “I would use the Internet for various activities if I had the skills.” In addition, not all instructors perceive much benefit from using the Internet in specific classes, such as the instructor who wrote that “benefits are minimal because material is often unreliable or, at least, requires verification.”

Several problems concerning Internet usage were described by survey respondents. Two problems that were frequently mentioned were the students’ lack of computer skills and the difficulty of accessing the Internet. These problems were summarized in this comment: “Many students are not computer literate enough to use the Internet. Many do not have access; that is, they do not have computers available at a time or place that makes it possible for them to use the Internet.” Other problems included the lack of ability to determine quality of material, how to cite sources from the Internet, instability of campus network, lack of time to learn and to manage Internet activities, and lack of training and support for faculty.

Some of the respondents suggested ways of dealing with these problems. For example, one person recognized the need for better skills and stated, “I plan to further develop my skills, and then make greater use of the Internet in classes in subsequent years.” Another expressed the need for “SPECIFIC training activities” for faculty. On the issue of Internet access, one respondent commented that “getting Internet access available in classrooms should really encourage instructors to use it.” Another wrote, “I would like more money spent on computers for student use, better coordination/information about/between labs, more support for faculty developing courses around the Internet. Students also ask for more expanded lab hours!”

College of Arts and Sciences

The College of Arts and Sciences is the largest at the university, consisting of Agricultural Sciences, Art, Biological Sciences, Chemistry, Communication and Theatre, Computer Science, Earth Sciences, History, Journalism and Printing, Literature and Languages, Mathematics, Music, Physics, Political Science, and Sociology. One-fifth of the Arts and Sciences faculty (34 full-time and three part-time) participated in the survey (see Table 1).

Every respondent in this group had at least one year of prior computer experience, with 46% claiming more than 10 years of experience. All of the respondents indicated familiarity with word processing, while most indicated that they also had experience with e-mail and the web. Eighty-nine percent had access to the Internet and e-mail, 81% indicated that they used the web, and less than half used other Internet services. One respondent maintained a web site for a professional organization, while another used the Internet for accessing supercomputer centers in other locations.

Over one-fourth (27%) of the Arts and Sciences respondents required their students to use the Internet, while more than one-half (51%) encouraged Internet use. They required or encouraged the use of the web the most, followed by e-mail, then by FTP, telnet, gopher, Usenet, and web page development. Their students used the Internet primarily to find materials for research projects, and secondarily to communicate with the instructors. Students also used the Internet to access materials for classes, keep up with current events in their fields, and communicate with other students.

One English professor explained how students used Internet resources in a graduate course:

I made my students search the Web for information about children’s literature, I made them go to some specific Web sites, and I made them download two
books: The Wizard of Oz and Alice in Wonderland. The students use the etexts in their research.

A radio and television instructor also identified specific student activities by stating that students "view FCC and FTC materials" as well as "mass media web sites." This instructor found that the major benefits of using these Internet resources included "familiarization with data sources and familiarization with data current in law and media." Two other instructors commented on the convenience of e-mail. According to one respondent, "students must use e-mail to submit work, communicate with me and others in the class." A computer science instructor wrote, "I don't give specific Internet assignments to students, but I do expect them to have e-mail accounts so that I can communicate with them or they with me. Many of them do send me e-mail questions or comments."

Several faculty members commented on the usefulness of the Internet in terms of providing resources for students. Some instructors mentioned that they provided information to their students on accessing and citing Internet sources along with discussions related to potential problems with determining quality and trustworthiness of material. One respondent commented on the problem of reliability and verification of Internet sources, stating that "slowly, it seems to be improving. Perhaps hope is out there: www.hope.com?"

**College of Business and Technology**

The College of Business and Technology is the smallest of the three colleges, and includes Accounting, Economics and Finance, General Business and Systems Management, Industrial and Engineering Technology, and Marketing and Management. Twenty-nine percent of the Business and Technology faculty (11 full-time and three part-time) responded to the survey (see Table 1).

As might be expected with business and technology professionals, this group of faculty appeared to be more experienced with computers than the faculty in the other two colleges. Half of the respondents from this group claimed more than 10 years of prior computer experience, including word processing, spreadsheets, databases, presentations, e-mail, and the web. All but one person had access to the Internet from the office and participated in e-mail, while 79% also used the web. Over one-fourth of the faculty used gopher, telnet, web page development, and FTP.

Forty-three percent of the business and technology respondents required their students to use some aspect of the Internet, while 64% at least encouraged the use of the Internet. One faculty member commented on the convenience of using e-mail: "They can send me a message and I can respond at any time." Others explained that the material on the Internet is "more current than that found in journals and MUCH more current than books" and that the Internet provides "fast access to a wide range of material, access to professionals in the field and professional association publications." Other faculty members indicated that they wanted their "students to be in touch with the world" and to benefit from greatly improved "communications from instructor to student and among students."

Some of the faculty provided specific examples of how they had integrated the Internet into their courses. One economics instructor asked students to "search out economic data, download it and then produce a graph." Students in this course also maintained a file of current economic indicators obtained from the Internet and used the Internet for performing basic research. The instructor indicated that, with the help of the Internet, students had "access to data and research" and "access to me."

Another general business instructor maintained a server that provided a local intranet in one of the computer labs.

The instructor explained,

Students are required to prepare a home page on the CBT lab intranet. A total of eight article reviews for each student are posted to the server and linked to the student's home page. The home page must also contain an e-mail link.

The instructor further explained that by using the intranet, "additional course material can be posted at any time, reducing handouts. Also, students learn skills in demand by industry."

**College of Education**

The College of Education includes the departments of Counseling, Educational Administration, Elementary Education, Health and Physical Education, Psychology and Special Education, and Secondary and Higher Education. The response rate for this college was 19%, which was the lowest of the three colleges (see Table 1). Respondents included 25 full-time faculty and two part-time faculty.

Education faculty appeared to be the least experienced with computers in general, with only 30% claiming more than 10 years of experience, and 11% indicating that they had worked with computers for less than a year. The faculty from this college had much more experience with word processing, e-mail, and the web than with any other type of computing.

All but three respondents had access to the Internet. Eighty-five percent of the faculty utilized e-mail services, 63% used the web, and 33% used gopher. Less than one-third used other Internet services. When asked the purpose of using the Internet services, one respondent wrote: "This is new for me. I am exploring (primarily)."

Thirty percent of the reported education courses required students to participate in Internet activities at least 20% of the time, which is more than what was reported for the other two colleges. One-third of the respondents...
required their students to use e-mail, the web, telnet, FTP, or web page development, while 52% encouraged the use of various Internet services.

Several faculty members described Internet activities assigned in their courses. One instructor assigned e-mail journals, had students demonstrate use of technology in their portfolios, and asked students to document the use of technology in teaching. Another instructor "had a class that used only Internet material for presentations" because the Internet "provides opportunity for very up-to-date material." Still another instructor had students "look for materials for teaching fields and write lesson plans integrating Internet activities into lessons" and "look for multicultural resources for presentations and use in the schools." Other instructors assigned research and group projects utilizing the Internet for long distance communication and collaboration, and had their students join a class listserv mailing list for class discussions.

One instructor, who was teaching one on-line course via the Internet and included the Internet as an integral part of all courses, described various activities involving students. Students “create web pages of resources for their schools, etc. throughout classes.” The instructor set up a listserv mailing list “for each class to use for communication” and encouraged the use of “e-mail for working on joint projects.” This instructor also set up a “web site for each class — for me to put information for students and for them to display their work (pages).”

Some of the respondents indicated that they planned to increase their use of the Internet. One wrote, “I plan to use e-mail as a required portion of my course next semester,” and another added, “I am in the process of developing more usage for my classes.” Another instructor stated, “I am teaching one on-line course. I include the Internet as an integral part of all others. I emphasize appropriate use — not just what’s there. I am designing a spring course to be half on-line and half face-to-face. I am planning a fall course that will incorporate the Internet and on-line components, supplemented by traditional distance education.

Summary

The Business and Technology faculty were the most experienced with computers, and they required their students to use the Internet more than the other faculty required its use. Though the Education faculty were the least experienced with computers, they were more involved than the Arts and Sciences faculty in the integration of the Internet into their courses. Arts and Sciences faculty appeared to require mostly research-oriented activities with the Internet, while faculty from the other colleges also emphasized the use of e-mail to improve communications among faculty and students. Faculty from all three colleges indicated a desire to continue improving their own Internet skills and to provide better access for their students so that they could all benefit from the resources and communication available through the Internet.

Conclusions

Faculty from all disciplines are working towards better utilization of the Internet in education. By examining how faculty are using the Internet and by becoming aware of different ideas, benefits, problems, and solutions, we can learn from each other and help one another to achieve this goal. The Internet will continue to grow, and education faculty must continue to be the kind of role models that their students need to follow in order to effectively use the Internet in their teaching careers.

The general public, and teachers in particular, are inundated with information about the Internet, the World Wide Web, and various other components of telecommunications. Unfortunately, the reaction by many schools, teachers, and departments of teacher education is to try to teach many of these components as content to students and teachers. There are at least two reasons why this approach is a mistake: (1) the software, methods, and content used will be antiquated by the time these students get into the work force, and (2) knowing "about" something does not in any way ensure that the individual can use the information. A more productive approach would involve an integration of telecommunications activities and skills that would supplement and enrich rather than supplant and replace the current curriculum and instructional activities in your classroom.

Although you and your students may need specific telecommunications skills before either of you can expect to be successful in integrating telecommunications into your curriculum, that does not mean that these skills should be the primary focus of instruction. Rather, students can learn and practice with the basic skills they need for an activity just prior to (just-in-time training) or along with their actual use in the curriculum. By initially viewing the Internet as a global classroom and learning center, teachers and students can begin using these resources immediately to enrich lessons. This approach to the resources available on the Internet has the advantage of using the known or familiar to approach the unknown, and increases the chances that teachers will pursue their exploration of the Internet as a source of instructional resources. One way to approach these resources is to view the Internet as a source of:

- Lessons and Lesson Plans
- Classroom and Curriculum Activities and Resources
- Content Area Resources
- Online Libraries, Museums, Field Trips, Tutorials, and Periodicals
- Assessment and Evaluation Resources
- Teacher Support and Information

Dyrli and Kinnaman (1996, p. 70) suggested the following approach to getting started:

- Review current curriculum and adapt learning experiences as online activities. Evaluate the content (concepts, principles) and the processes (observing, inferring, predicting, measuring, communicating) of current instructional units and determine what might be supplemented with online activities, experiences, or other resources. Examples might include using online research tools, visiting online locations for specific purposes, participating in collaborative projects with other students in various places around the world, or communicating online with experts.
- Join an education electronic list, discussion group, or newsgroup to ask for resource suggestions, locate online resources, seek keypals, and initiate your own cooperative activities.
- Visit education resource locations and explore the available offerings. Find an efficient and effective way, such as the use of bookmarks, to keep URL's and descriptions of the sites of most interest to you and your students. One way is to develop a database with fields for the name of the site, the URL, and a brief description of what is available at the site.
- Use Internet guides and search tools to locate curriculum and content materials and opportunities.
- Gradually move to more extensive projects and curriculum units.

My purpose in this presentation is to provide you with a perspective so that you can begin planning appropriate use of telecommunications resources in your classroom immediately. Following are examples (Land & Turner, 1997) of how you might supplement instruction with resources available on the Internet and with technology.

Have I Heard This Story Before?

Subject: Language Arts
Goal: To study common story themes such as Cinderella and compare variations of those stories.
Applications:
- word processing- Have students write their own modern-day Cinderella (or other) story.

Telecommunications: Graduate, Inservice & Faculty Use — 1167

BEST COPY AVAILABLE
page layout- Have students write a newsletter article as it might appear in a local paper or newsmagazine describing differences in the same storyline.

database- Prepare a database of as many variations of the Cinderella story as students can find with information on how they differ.

telecommunications- Have students communicate by e-mail with other students in other countries about variations of the Cinderella or other common fairy tales.

Anyone For a Piece of Pi (Math)?

Subject: Mathematics

Goal: To explore the characteristics and applications of pi.

Applications:

- word processing- One state purportedly considered passing a law that set the value of pi to 3 to make it easier for students to use. Have students write a one page reaction to this suggestion.

- page layout- Prepare a newsletter “selling” the virtues of pi as though it had just been discovered.

- spreadsheet- Have students discover pi either by giving them the circumference and radius of several circles or spheres, or have them measure the objects, and calculate the relationship between the circumference and the radius squared by dividing circumference by radius squared. Have students calculate the value of pi from 1 to 15 decimal places (the limits of ClarisWorks). Have them look for any apparent patterns.

Watch Out For the Curves!

Subject: Mathematics

Goal: To explore various kinds of geometric curves.

Applications:

- graphics- Retrieve from the Internet site provided or chart with a spreadsheet.

- slide show- Prepare a slide show or presentation with the graphics in the student-prepared database.

- page layout- Class prepares a group newsletter describing something about their three or four favorite curves.

- database- Database of as many curves as there are students in class.

- spreadsheet- Enter formulas for and experiment with various curves and prepare graphs.

Comments: See file Curves database in the Tools folder (Ch_09) for a database slide show idea. You must use a special technique to place the graphics in the database.

National Center for Genome Resources site (http://www.ncgr.org/)

The influence of telecommunications on education will not be as dramatic as some suggest, but will be more dramatic than others hope. Telecommunications will have an impact on schooling because it is an outside-of-the-schools force that is pervasive in our society, whether it be in business, in the military, in higher education, or in industry. It will also have a dramatic impact upon our culture. For instance, compare the current references to the Internet that you see or hear about in magazines, books, newspapers, television, radio, and movies to as recently as 1994. There is a revolution occurring in the telecommunications industry; education can’t avoid this revolution even if it wanted to.

The traditional curriculum is typically not connected directly to the lives of most students, can become outdated quickly, and is seldom individualized. Conversely, telecommunications brings immediacy and individualization to the curriculum; up-to-date materials including articles, databases, maps, reports, surveys, diagrams, film clips, photographs, and sound bites; and has the potential to transform the curriculum (Dyril & Kinnaman, 1996, p. 65).

1168 — Technology and Teacher Education Annual — 1997
For many of us, the Internet is revolutionizing the way we live, relax, work, learn, and/or teach. Computer conferencing, e-mail, World Wide Web, Internet—these are just some of the terms that are heard more and more both in and out of today’s classrooms. This paper describes how teachers enrolled in graduate courses are entering this exciting online world, and acquiring skills and knowledge that they then use to enhance their teaching and professional activities, and to help others learn to integrate these new resources into the educational arena.

We truly are living in a global society, where students from a small rural school district can visit schools and classes on the other side of the world without even leaving their classrooms; where we can travel worldwide while sitting in our homes and offices; and where increasing numbers of employers are looking for persons with Internet experience and expertise. E-mail is changing the way we communicate, as individuals are able to correspond with more immediacy than by traditional mail, with lower costs than by phone, and with greater access to people and opinions via discussion lists. The World Wide Web brings pictures, sound, and limitless information to us wherever our computers are located. Internet Service Providers abound, and many students come from homes where the Internet is as common as the telephone or television. In fact, some of these students may have more skills and knowledge about online activities than their teachers.

The Challenge

The challenge, then, to teacher education programs is multifaceted: to prepare preservice and inservice teachers to use online communications and Internet tools as resources, to provide opportunities for these teachers to learn to integrate online activities into their classrooms, to help educators acquire skills and knowledge with which to prepare their students to participate in these online activities, to encourage educators to participate online by communicating with other educators and by sharing their materials on web pages, and to model appropriate online activities and behavior. How universities approach these challenges is varied, from denial, to Internet units in computer courses, to supplementary activities in traditional courses, to integration of online activities into content areas, to courses offered totally (or primarily) online. Additional challenges in each of these areas include availability of appropriate technologies, faculty with skills and knowledge to incorporate Internet activities into their lessons, and the widely varying computer and Internet knowledge and skills of students of all ages. How do we, as teacher education faculty, help our departments address these challenges?

The Literature

Literature describing the theory and practice of integrating online activities into instruction is growing rapidly. E-mail has been discussed from a variety of perspectives, from that of a teaching supplement (Poling, 1994) to an instructional strategy (Lowry, Koneman, Osman-Jouchoux, & Wilson, 1994). In an article with the appropriate title “Revolution@Alma Mater.edu” (1996), it is suggested that e-mail “enables students and faculty to communicate conveniently at any time of the day or night—even if the faculty member is traveling or the student is at a remote campus or another off-campus location” (p. 41). Partee (1996), though, emphasized the fact that online activities provide more:

Not simply an alternative to personal interaction of instructor and student, communication technology can serve as an extension of traditional classroom instruction. A computer network can enhance the three major activities of all teachers: to counsel students individually, to deliver general information (a lecture), and to encourage class discussion. (p. 79)

Considering more than e-mail, he also advocates the use of newsgroups for discussion, and of the Web to distribute class materials. Examples of the latter may be found at the World Lecture Hall (http://www.utexas.edu/world/lecture/), where visitors are told, “[t]he World Lecture Hall (WLH) contains links to pages created by faculty worldwide who are using the Web to deliver class...
materials. For example, you will find course syllabi, assignments, lecture notes, exams, class calendars, multimedia textbooks, etc. Print publications and online sites promoting online educational activities are appearing with a regularity that emphasizes the expanding nature of Internet integration into higher (and other) education.

**Meeting the Challenges**

Colleges of Education are taking note of the emergence of the Internet, and are employing a variety of approaches to meet the challenges of preparing preservice and inservice teachers to use the rapidly expanding resources with which we are surrounded. A basic step is to find faculty knowledgeable about, and willing to teach about and with the Internet, often beginning with e-mail. With at least one such faculty member in place, a suggested method employs a dual approach: modeling online course activity, and using a train-the-trainer approach. This is especially effective in graduate educational technology courses, where the students (who are teachers in various school districts) become excited about online resources and share that excitement with university faculty in their other courses, and also with the other teachers in their districts. As their enthusiasm and growing skills are observed, they often find themselves conducting inservice sessions in their local school districts and/or other areas.

**Beginning Online**

For the past several years, teachers taking graduate educational computing courses at a regional state university have participated in online activities as part of their class assignments, and some have taken an online course that has evolved as has the technology. It all began five years ago, when students were strongly urged to obtain and use e-mail accounts (available free for all students on the university network, and for $5 to teachers on the statewide network), and to use those accounts to communicate with their instructor and classmates. Few students participated, though, probably because of the ‘unfriendly’ university VM computer system, and the lack of access to computers with modems.

During the summer of 1993, graduate students enrolled in Microcomputer Educational Applications were required to obtain and use e-mail for some class assignments and for basic communication outside of class hours. It became evident from the beginning that having available appropriate assistance was a must, especially with the university system. As one student said,

Hello, I found my way to the library and am on the computer e-mail. I only had to ask for help twice. The lab person does not understand that I am a beginner. He kept telling me things I did not need to know and not telling me what I needed to know. Maybe I will survive this.

Two years later we finally had Internet access in the lab where our students worked on assignments, and where the lab assistants were graduate ETEC students whose duties included tutorial assistance, along with the more traditional lab duties. Just knowing that there was help available, seemed to build confidence as students learned to maneuver through the ever-expanding variety of Internet tools and activities.

Students used e-mail to submit reflections on articles they had read, and this was especially challenging since students were just learning the online system. A main thrust, though, was to get the students to communicate, so messages like the following (saying an assignment would be coming) were not infrequent.

I will respond to the article later after I have had a chance to read it more thoroughly. I did want you to know that I have finally learned enough about e-mail to at least read my mail and respond to you.

As students became more comfortable with their newfound communications skills, they sought more, sending requests to both instructor and other students. (Students were required to send a specified number of messages each week, and to get credit they had to send a copy to the instructor, enabling her to monitor activities, addressing potential difficulties as appropriate. The monitoring is a must, and continues to this day in all courses.) One student wrote:

I wanted to forward something to you that I sent to Mike but I don’t know how. Can you respond to me with the proper instructions? Thanks!

Another sent the following comment to a classmate: Wouldn’t it be lovely to have time to play with all this stuff at our leisure?

Still another offered to share his skills with the class: I know how to upload files to ACADEMIC accounts. I will demonstrate it sometime this week if you want. Thanks.

And then there was the student who expressed the feelings of many:

I hope that you-all are having a lovely day. I don’t know if any of you received this message but if you did I’m Excited!

After two weeks of class, the student who had sent the message after getting help in the library, sent the following (referring to the community college where she was on faculty):

[Our college] does not have an Internet connection. I am going to talk to my Dean about getting us online some way. We do have a local bulletin board with e-mail. If I cannot get on anything else I am going to have my students go on this.
Students communicate with each other, reacting to what they had heard in our class and in others. For example, this same student wrote to a classmate:

The book about children’s learning styles and computer use looks like a good idea. Some of our community college students need this kind of learning environment. I would like to see the book and see what it says.

As students became more comfortable communicating online, they created distribution lists in their online address books, and the amount of mail increased drastically. In response to a comment about the increasing incoming mail, one student sent the following message to the class:

Overload is possible through the e-mail system; however, I would rather be overloaded with the opportunity to respond than to have never had the chance to begin with. Keep sending those messages my way.

Another student did not feel as positive about the use of e-mail, and her comments reveal an internal dialog:

I was going to say no, graduate students should not have to learn e-mail. My reasoning was going to be if you are in a field which wouldn’t utilize e-mail, then you would only learn it for a grade in the class and promptly forget most of what you learned. But I couldn’t think of any professional fields where the opportunity to use electronic mail might not exist. So I suppose graduate students should learn it.

During the last two weeks of class, an interesting dialog occurred online, when several students discussed the possibility of having a course taught online the following semester. (By this time, messages written to other students often included comments directed to the instructor. As still happens, this may appear to be a check to see if the instructor is actually reading the messages, but sometimes it’s an indirect request for assistance.) The students were not successful in their campaign for an online course at that time, but many of them signed up for and participated in a course that was piloted as a traditional course (with required online activities) during Fall, 1993, but has been taught online ever since.

Actually, this summer experience with e-mail as a course requirement laid the foundation, for both instructor and students, for future online courses, as well as for incorporating online activities into non-online courses. Lessons learned included the need for (a) tutorial support, which improved when we had Internet access in our lab; (b) a user-friendly system, which the university VM system was not, but later we moved to the UNIX machines, where students felt more successful with less frustration; (c) requiring specific online messages, and monitoring, via copies sent to the instructor; and (d) encouraging discussion and reflection, to help students realize and verbalize their evolving ideas, as with the student’s statement about the importance of e-mail. A potential problem is that of having some students dominate online, flooding everyone’s mailbox with e-mail. Three students became quite active, and it was necessary to have private discussions to redirect some of their activities to help others and to not appear overwhelmingly (in response to students who were dismayed with the amount of mail they were receiving). These students are now all active Internet users, and have difficulty remembering what life was like without online access.

**Going Online**

During the fall of 1993, *Computer Research Applications* was first taught, and it became the Internet Course. Although it was not taught online that first time (as the students had requested that summer) it has been each year since then. Although students were required to be online to complete assignments, only six computers in the lab were connected to the university network, and thus the Internet. (There were other labs that had more Internet connectivity, but were unavailable to entire classes of students; students sometimes used these if they were on campus outside class time.) The six computers on which students could access the Internet were slow, and the VM system that many students were using was still not user-friendly. As one of the students who had also been in the previous class, and who is now using e-mail and teaching his students to use the Internet, said:

I understand your approach to this. E-mail is extremely useful when the system is not overloaded. It is difficult for a new learner when expected responses are so excruciatingly slow that you assume you’ve done it wrong.

As was true in the previous class, some students were subscribed to TENET, the state educational network, on which all accounts were UNIX-based, and Pine was the mail program. Comments from a student who had just received TENET account and who had not been in the previous class illustrates one of the fundamental differences in outlook:

Dr. E- I’ve been faithfully logging on each day. Each time, I get a little braver and explore more and more options. Yesterday I got on the Gopher and searched the national network for Internet subscribers that I might know. None of them were on the Internet. I plan to use the Internet to find a periodical for the upcoming ETEC 625 assignment. I’m trying to get more familiar with this networking thing!! (It’s (sic) hard to teach an old dog new tricks, but once he learns them— it’s for good!!)

A week later, the same student wrote:

I plan to use the Internet to find a periodical for the upcoming ETEC 625 assignment. I’m trying to get more familiar with this networking thing!! (It’s (sic) hard to teach an old dog new tricks, but once he learns them— it’s for good!!)

A week later, the same student wrote:
Dr. E- I'm getting more comfortable with e-mail as we move along. I really look forward to checking it to see if anyone wrote.

Another student on TENET had a concern about the lack of personal contact that accompanied e-mail. She said:

I have mixed feelings about corresponding over computers because I am a people person and like to see who I am talking to. I learn a lot about a person from his/her body english (sic) also, (and I know this is weird) but I see an aura around people and it tells me a lot about them as far as personality anyway. So therefore I guess I prefer real life conversations. But this does have it's (sic) purpose. See you tomorrow night.

Discussions of netiquette and appropriate communications methods, as well as ways of conveying feelings online resulted from this comment, and students began using (and creating) emoticons. This issue has been brought up in each succeeding semester— from the students who missed the face-to-face interaction, to a student who would not participate on the class list because of a comment she had received that she felt had been insensitive.

Students telnetted to libraries, gophered to varied sites, and subscribed to lists, to name but a few of their activities. E-mail was still a prime activity, and was made somewhat easier as students began to change their accounts from the VM to the university's UNIX machines. This was actually a breakthrough because all students could then use Pine for mail and could use similar procedures for both gopher and telnet access. All of us learned the value of having a similar type of access for all students. Frustration was reduced, and voluntary use increased.

Unfortunately, lessons learned are not always lessons followed, and explosion of Internet Service Providers has led to more types of Internet access than we could have ever anticipated. However, for about two years, we had the advantage of most students using UNIX systems, and this greatly facilitated the incorporation of online activities into coursework. Other lessons learned that semester and that are still reflected in our current courses include the importance of: (a) developing a sense of community to alleviate the sense of isolation students may feel; (b) using a flexible mail program to keep and organize course-related mail; and (c) knowing what software and hardware students are using, to facilitate troubleshooting, and to be able to refer students to others with the same set-up.

Two additional lessons learned resulted from two events (same student for each) that came to light in the computer lab. Shortly before class one day, the quiet lab atmosphere was shattered by a shriek, as a student cata-

pulted out of her chair. She had recently read The Cuckoo's Egg (Stoll, 1990), had e-mailed the author to share her comments with him, and on this day a reply arrived! The excitement and its effect on class attitudes and activities was a lesson to us all, as it reinforced the importance of sharing our excitement as a means of motivating our students and colleagues at all levels. The second lesson, learned from the same student's activities, was the potential problem of a full mail-box. One of the class assignments required students to subscribe to lists, and this student chose to subscribe to the Star-Trek list. After being away from the computer for a few days, she found that she was unable to send mail because of the amount of mail that had come from the list. As quickly as she attempted to delete mail, more arrived. She stopped the flow by unsubscribing to the list, but this mishap actually resulted in three lessons for everyone: (a) do not stay on lists which generate more mail that can be handled; (b) do not go out of town without setting lists to nomail; and (c) be sure to exercise the proper mail-handling techniques to minimize the possibility of exceeding the allotted disk space for mail.

Teaching Online

In the Fall of 1994, while other courses continued to incorporate e-mail and other Internet activities, Computer Research Applications became an online course—presented completely online except for three face-to-face meetings—and has continued that way each fall. Other courses are incorporating the Internet as essential components, and a question has arisen about whether a course must be one or the other — online or in class. Is there the magic number for face-to-face meetings? Are any needed? What about having five, or eight? What about combining a variety of types of course delivery methods — in-class, Internet, and 2-way interactive video? Upcoming semesters will try out these ideas, but for now, the emphasis is on lessons that will promote more effective educational experiences for both students and instructors participating in online courses delivered via e-mail and the Internet.

The world appears to often forget the early implementation of technologies, not realizing how much these early efforts have taught us, and how lessons learned remain valid and may often be generalized. Numerous changes have required constant revision of course content and treatment: students' knowledge levels have increased for some, but not for others, increasing the disparity between the two extremes; type of access has diversified, from VM to UNIX through direct connect, making it necessary to offer multiple instructions and still not always meeting all needs, because of other connectivity issues; Internet tools/activities have expanded, and instructions for use may differ based on the type of access; and management techniques for e-mail and the web are needed by all.
The lessons learned that first year have been invaluable, and additional lessons have been added to the list on a regular basis. During Fall 1995, Internet access in the lab increased, with full capabilities (including Netscape) available on twenty 486 computers. This has helped with the tutorial assistance aspect, and some students come to the lab to seek advice from the lab assistants (who are not allowed to touch the keyboards when helping students), although they do not come to campus for classes. The time when all students had the same type of access (when everyone was on UNIX) has passed, and confusion again complicates the access issue, as many students are subscribing to a variety of Internet Service Providers, not all of which offer the same services. The university now offers PPP access to all students and faculty, which means that all students who are within local dialing distance can use Netscape and other client Internet software. The difficulty comes when students need to set up their home computers, and each situation seems to have its eccentricities. So with progress (Netscape) comes potential difficulty, but once it's working, students quickly discover that getting online is definitely worth it. One student brought me an article titled “Superintendents in Cyberspace” (1995) that she was taking to share with her school—she hoped it would give people at her school ideas.

Graduate students in these classes have become a part of a new breed of educators who use the resources available online, and then create their own contributions that are now available for others to use. A Curriculum Resource Guide (Espinoza, 1996) and a Research Resource Guide (Espinoza, 1996) are among the products that they have published on the web, and they are using to support the education of today’s students.

Summary

The Internet has opened up vast resources to support the education of both today’s students of all ages and those who just want to continue learning. Teacher education programs can take the lead in providing preservice and current teachers with skills that will help them find, evaluate, and use these resources, but only if the programs are provided with the appropriate technology, support, and training for both faculty and students. We have come a long way since that first course when it was recommended that students get e-mail accounts, but few did. Lessons learned by both the instructor and students will form the foundation for future classes and learning opportunities. We will remember the importance of training, of community, of reflection, and of avoiding a full mailbox. Most important, though, is to remember that lessons learned and heeded lead to growth, which leads to lessons learned, and so forth. While writing this, a message arrived from a student in the Fall 1996 online Computer Research Applications course—he, too, had been thinking about lessons learned, and was submitting his list of ten to the class list. Lessons learned provide the foundation upon which teaching and learning with technology rests.

Technology Training Model for Inservice Teachers to Integrate Information Technologies

Siva Kumari
Rice University

Information technologies are increasingly being used by teachers in educating students in the K-12 arena as evidenced by the wealth of information exchange in areas of pedagogy, curriculum, resources, policy and teaching philosophies among teachers on the Internet. Teachers themselves are reporting increased use of the Internet in their classrooms in professional publications (Quinlan, 1996, Carlson, 1996, Edinger, 1994, McGlenn, 1995, Graves, 1995, Somers, 1995). In the past, adoption of technology into the daily practices of teaching and learning has been relatively slow; in stark contrast, information technologies are being adopted and actively embraced at an unprecedented rate by teachers and students, causing quite a revolution in the field of K-12 education. These technologies, with easy-to-use interfaces, allow teachers and students to access, consume and contribute to a wealth of relevant information, communicate with peers, collaborate with colleagues worldwide and break away from the previously isolating and physically contained experience of a classroom. These technologies empower the teacher to create a “global classroom,” a virtual educational setting that electronically transcends traditional boundaries. Teachers now have a treasure chest of information tools, experiences and resources with which to reinvigorate the educational process for themselves and their students. They can now use contemporary resources and technologies and engage the students in the learning process by making them active partners.

The President’s initiatives, Challenge Grants from the NSF and the revolution caused by the Internet are providing the much needed impetus for large scale technology implementation into schools. National and local initiatives are calling for the infusion of information technologies into the classroom by offering funding opportunities and reduced costs specifically for connecting schools, libraries and public institutions. The immediate challenge to school districts, once connected, will be to train teachers, in a short period of time, to effectively use these technologies. Placing technology into schools without emphasizing associated changes in methodology and curriculum, is a futile venture that will not propel schools into the 21st century but freeze them in current practices. Inservice staff development programs need to be comprehensive, immersive and effective to cause the social and knowledge changes needed to produce creative adoption of information technologies in the schools of tomorrow.

Iterative Design Process

This paper will discuss a two and four week immersive summer training model that has been developed through an iterative design process to empower teachers to take advantage of information technologies. The model has been effectively used to train teachers to become savvy users of the Internet and demonstrate the integration of these technologies into everyday teaching activities. Teachers were trained to be informed consumers and inventive producers of learning experiences on the Internet. Surveys indicate high satisfaction with the content and the intensiveness of the training model.

Training models need to reduce the learning curve by creating immersive environments for computing and emphasizing the application and retention of skills gained in training. These issues, that are of increasing importance as more school districts move toward integration of information technologies, will be the primary focus of the paper. The training model discussed in this paper was initially implemented in the GirITECH project described below and then further compressed through an iterative design process for implementation in the OWLink project. Specific training documents and schedules are available online.

GirITECH Project
www.crpc.rice.edu/CRPC/Women/GirITECH

Funded by the NSF, in 1994, this project provided the initial need for a training model to train twenty Mathematics and Science teachers, to integrate the Internet into their classrooms, in a four week program. Teachers were provided with personal laptop computers, space on a UNIX
server and access to the Internet. Most teachers returned to classrooms where their computer was the only one available for students. Three of these teachers have since implemented the 1995 GIRITECH project, the following year.

Project OWLink

www.rice.edu/armadillo/OWlink

The OWLink project is a tele-distance project that links teachers and students from five diverse schools in the Texas area in project oriented work with each other and with Rice University staff and faculty. A revised version of the training program used in GIRITECH was implemented in the OWLink project in the summer of 1995 with thirteen Mathematics and English teachers from the Houston area. Teachers return to their schools and use the advanced computing facilities of the OWLink rooms which are equipped with twelve high-end multimedia computers, fiber-optic based teledistance equipment and high bandwidth Internet connections where teachers implement the processes of teaching with technology on a daily basis.

The Training Philosophy

More often than not, technology training emphasizes and concentrates on discrete skill development, vastly ignoring application or practices that enable users to gain an understanding of the relation between the training and use in the classroom. Kinnaman (1993) advocates new avenues in teacher training: "Teachers don't need to be 'trained.' They need activities that engage them with the process of teaching- activities that encourage them to explore, create and reflect upon the benefits and limitations of teaching with technology" (pp. 258). Training is often usually in the form of providing information that may or may not have relevance to the end user. In contrast to traditional training programs, this program was conceived with the intention of making the training highly meaningful and personalized to the individual teacher. This paper describes critical components of the model used to train teachers and encourage implementation of skills in meaningful end-products that can be readily implemented in the classroom. The intent is to enable teachers to consciously think beyond adopting the new skills to simplify, automate or duplicate current teaching practices and instead to rethink, re-envision teaching and learning in light of the new skills and produce original learning activities that showcase these qualities. Gorry (1996) challenges teachers and schools to rethink current practices:

- Schools and universities need to view information technology both as an aid to current practice and as a new conception of the world - to balance concern for today's business with invention of the future. In its expressive use of technology, the system-after-next complements planning with envisioning-trying to see, not from the present to the future, but from the future to the present. Without envisioning, information technology in schools and universities will only rigidify the past.

This philosophical orientation succinctly exemplifies the spirit of the training programs described here and has greatly influenced the training model. Emphasizing the learning process and the end-products rather than the discrete skills and shrouding the training in an environment of experimentation and innovation has resulted in teachers successfully producing interesting learning activities that are customized for the Web and engage students in the production of knowledge rather than mere consumption of information.

Technological competency

A nationwide survey conducted by Electronic Learning in conjunction with its sister publication Instructor and Middle Years discovered the following: 66% of the respondents said they gave straight workshops on specific software titles or hardware, rather than on how to use the technology as a tool to expand curriculum. (Siegel, 1995).

In stark contrast to the results described above, this model uses the skill training as simply a means by which the teacher can integrate Information Technologies into teaching and learning. Teachers are given direct instruction in specific skills required to become savvy users of the Internet. They are taught the skills necessary to navigate the Internet, understand its functioning and the user interface. They are taught effective and efficient search techniques and encounter issues regarding relevancy of resources and validity of information. They are taught the use of other Internet related tools: ftp, telnet, e-mail, UNIX space maintenance and HTML (Hyper Text Markup Language). Every step of the way, however, teachers are allowed ample opportunities to practice their skills in meaningful activities that will assist them in accomplishing the larger goals: a project that shows evidence of the teacher having rethought a lesson in light of these technologies.

Progressively, the skill level is increased, mastery of one set of skills leads to an introduction of the next set of skills. This progression is derived through an Instructional Systems Design model: deriving objectives for the training, the delineation of content, creation of activities for practice, reward system for learning and evaluation.

Technological Empowerment

Using UNIX accounts sponsored through Rice University, teachers create and maintain WWW pages retaining control over their data, the ability to maintain, modify and to add to their products, which gives them an immense sense of responsibility in their learning, ownership of their productions and motivation to continue to engage in follow-up activities. Teachers maintain their WWW pages.

Telecommunications: Graduate, Inservice & Faculty Use — 1175

1178
and lesson plans in their accounts and these are reported to be very appealing activities. The instantaneous ability to publish to a worldwide audience has an energizing effect on the response to training and the ensuing motivation to learn new skills.

Collegiality and Collaboration

Key to liberating the teacher from the physical confines of the classroom and encouraging a sense of collegiality and collaboration are an introduction to the principles, nature, roles and responsibilities of electronic collaboration. Teachers are introduced to newsgroups, listservs and other means by which they can collaborate and communicate with colleagues near and far. They are encouraged to think of themselves as both initiators and participants of collaborative online projects. They are introduced to online resources and the means of connecting and contributing to them.

Professional Development

Teachers in the training program are brought into a professional environment within which they are challenged to think of new ways of teaching and learning with information technologies. Through a multi-dimensional and multi-modal approach, teachers are introduced to professional literature from practitioners, from revolutionary thinkers in the field of education and information technology, and from experts in pedagogy. They are asked to conduct group discussion of articles and state opinions. Frank discussions of the pros and cons of teaching with technology provide a venue for teachers to vent fears, participate in a learning and experimenting community and elevates the group to a higher level of thinking within which to formulate their opinions and situate their experimentation. These communal discussions allow the teachers across disciplines to communicate problems and practices unique to their content, understand other subject areas, modify practices to suit their peers' needs and more importantly, modify student activities to encourage conceptual connections across the different disciplines.

Reflective Practices

Teachers are asked to maintain journals of their thoughts during the training. Taking time out during intensive training to reflect on the process allows the teacher to be aware of the change processes, modify and focus on the end goals of the training. The reflection also helps the teacher to take advantage of the increased technological competence and make necessary pedagogical shifts.

Constructivistic Projects

White (1987) talks about the changing world of technology and its implications for curriculum and the need to rethink curriculum.

The technologies should be viewed as the instruments for change that they are, but we as educators should be thinking more about their impact on learning and society.

Education,...K-12,...would require us to rethink the heart of education itself. Instead, education is treating the technologies as just another triad of textbook, teacher and test.

In my view, these changes we are undergoing are so significant for how we learn, how we remember, and how we form judgments that I believe education needs to develop a curriculum designed to educate for these changes. (p.41).

Teachers are given the freedom to create their own meaning or construct their products while implementing the skills they learned. It is clearly communicated that the trainer's role is to provide the training but that creative implementation of skills is their responsibility. The end products that resulted reside on the World Wide Web (WWW). Created in 1994, some of these lesson plans have been widely publicized as models on the Web since there was very little teacher created material online at the time to emulate or improve upon.

An analysis of these lesson plans reveals that a varied set of teaching philosophies are applied when creating online lessons(Kumari, 1996). Each of these lesson plans, though, make excellent uses of the Web. Some require the student to mine the Web, gather relevant data and present the analysis to peers. Yet others require students to make calculations using the data gathered from the Web and suggest the most productive uses of resources. Some require students and teachers to use information processing skills in creative ways to learn new concepts or relearn old concepts with new interdisciplinary connections.

Paradigm Shift

Teachers express excitement when given the opportunity to be collaborators, and pioneer the creation of online curriculum. The short term training program brings a sense of fulfillment and accomplishment. Having the ability to learn, implement and work at home with their computing to practice seem to help enormously. Teachers seem to undergo a change in thought processes; they view teaching with the Internet as a collaborative learning adventure that they undertake with their students. Technologically empowered teachers are invigorated with new ideas about teaching with technology and excited about the endless opportunities that the Internet and tele-distance present for teaching and learning environments.

Drawbacks in Practice

After undergoing intensive training in the summer and having ample time to reflect, create and practice, teachers...
return to schools with intensive workloads and little time for training or the implementation of new skills. Remedies to this major impediment, a barrier to successful retention, implementation and extension of skills, have been suggested to school principals. Providing teachers with time during school to participate in training and continue the maintenance of practices created in the summer will increase the chances for implementation and skill retention. Experimenting with technology and advocating the use of technology takes time, and the administrators need to make changes and create reward structures for teachers pioneering within their schools. Teachers also need to be given opportunities to showcase their technological skills within the school by being provided with scheduled times where they make presentations to the other staff.

Conclusion

Teachers were taught not only how to use the web but to contribute back to it. Teachers were shown how to author for the web, integrate graphics, create links and produce content for the Web. To do so, however, teachers themselves must be intimately familiar with the technology; they need time to understand the medium and experiment. They need immediate feedback and the chance to implement. Simultaneously, they need to be introduced to complementing and new philosophical orientations. Providing articles for the teachers to read incorporates collegiality and stimulates philosophical discussions, making this a learning and experimenting community. Feedback from other teachers and the WWW audience provide additional incentives. Most teachers find the web by in and of itself to be an exciting medium with which to teach and learn.

Students need to be able to be information literate in the 21st century, and these teachers are leading the way. They are conscious of their responsibilities to other members of the teaching community on the Internet and form an operational and practicing group within which to exchange ideas, collaborate and experiment, conduct mediated conversations with stimulating discussions and exchange of ideas and notions. They critique each others lesson plans, suggest new ideas, look for inter-disciplinary ties and sustain experimentation. This brings a sense of collaboration and collegiality to the training process.

The teacher-to-student aspect of course delivery is readily facilitated with a number of electronic communications tools that will be described in this article. The student-to-student aspect of graduate learning, something we deem essential to professional growth, becomes a challenge for students whose “classroom” exists within their computers. Learning to master new and challenging environments with unreliable hardware, operating systems, and software can be tedious and frustrating; people need peers to provide encouragement, laughter, and advice.

Introduction by Gertrude (Trudy) Abramson

For many years, I have taught courses in authoring systems and courseware design and development to teachers at Universities in face-to-face classes, once a week for 150 minutes. The general format was to begin by allowing students to “vent their spleens” for about 5 minutes and then present a 15 minutes mini-lecture; classes typically ended with 20 minutes of questions, reflections and discussion. The remaining 110 minutes were spent in hands-on exploration in small groups. For the most part, students felt very positive about the shared, “guided discovery” process.

At the School of Computer and Information Sciences (SCIS), Nova Southeastern University (NSU), doctoral distance education requires students to come to campus for an intensive week, or two weekends, of classes each term. After that, each student works independently, at home, and all further instruction and communication is electronic. At the discretion of the professor, assignments may be submitted electronically or through the U.S. mail. Successful functioning of our virtual campus depends on an effective SCIS - network including the WWW, the Electronic Library, and the campus bookstore. Of course, our remote students must have state-of-the-art multimedia computers, fast modems, and software required by their coursework.

This panel addresses a variety of issues in graduate and inservice courses that rely largely on distance education for instructional delivery. Many of us gathered here are grappling with the problem of retaining the best of traditional classroom learning using the tools that permit synchronous, asynchronous and remote communications. At the same time, we are developing new paradigms for learning that meet the needs of technology-based society. The panelists are colleagues and doctoral students in the Doctoral Computing Technology in Education (DCTE) program. Here, we discuss successes, failures, and new, largely untested, emerging solutions. Several of our panelists have sent remarks for reader edification.

Online Tools at SCIS by George Fornshell

The graduate education process at SCIS makes use of asynchronous online electronic mail, general topic online bulletin boards, and multi-thread online bulletin boards for course and peer group communication and instruction. A structured Electronic ClassRoom (ECR) enables more formal communication in real time. New WWW form-based tools using Common Gateway Interfaces (CGI-scripting) allow professors and students to gather data related to self-assessment and provide automated responses.

Electronic mail (e-mail) is the heart of online education. This tool is used to convey ideas, to exchange questions-and-answers, to spark and guide research, and to provide
The use of electronic bulletin boards (BBS) provide a forum for a more widespread audience. While it becomes a little more intimidating for some students than the use of e-mail since the messages are read by the entire class, the social distance makes it easier than using the telephone or speaking up in class. A bbs is an efficient and easy way to post information for everyone to see and it ties up fewer computer resources than would sending mass, individual e-mail messages.

The students in the classroom become more real to one another as they contribute ideas and comments that allow other students to formulate pictures of them as people. Common interests are noted and communication is initiated. The BBS helps lessen the isolation and helps sense feel they are not alone, that others are going through the same hardships, problems, enlightenment, etc. It also helps prevent duplication of responses by faculty members since, once a question is answered, it is posted for everyone to read.

I believe that most graduate students welcome the opportunity for “non-graded intellectual growth.” The sharing that occurs through online communications is an invaluable and necessary part of graduate school. The informality that appears to be a part of the online culture may stimulate communications that emulate grad school hallway and late night discussions, but add the benefits of having the ideas maintained in an archive and allowing asynchronous input from people who were not at the initial discussion.

**Rationale for Obtaining a Doctoral Degree through Distance Education by Robert Lipton**

The DCTE program allows me to be gainfully employed and involved in a quality education program simultaneously. Requiring physical residency in an age of e-mail, web-page access, fax, telephone, and postal mail seems passe. Two distance factors are essential: professors who can deliver quality coursework electronically and a well-equipped electronic library that provides rapid service. SCIS’s Cluster format requires four on-campus weekends each year. These intensive meetings enable easy-access to faculty and administrative staff and allow student interaction and the formation of peer support bonds. I have made friends through this program as I have not done since my undergraduate live-on-campus days.

The instructional format, although quite rigorous, allows a degree of autonomy that is conducive to my lifestyle. In addition to my heavy duty schedule at the district level, I am adjunct faculty at Penn State and have family responsibilities. The professors in my program provide the appropriate guidance and understanding that has made it possible for me to balance my life and to perform well as a professional, a father-and-husband, and as a doctoral student.
Electronic Learning at SCIS by Margaret Marston

The electronic library (EL) service at NSU is very valuable as I pursue my doctoral studies. It provides access to many databases that are otherwise very difficult to locate and use. For example, through EL research, I have found standardized tests to use in my research class. I accessed ERIC, FastTrak, and WorldCat from my home computer. Many resources that I use are not available on a commercial Internet server. NSU uses Lynx through Unix, a menu-based environment that allows fast retrieval of information.

Interpersonal communication works well using e-mail. Some professors send mini-lessons online, others have online web pages. These pages may contain assignments, discussion forums, links to relevant databases, and/or lecture notes. Grades are transmitted online with the electronic student (ES) system. Depending on the professor and the nature of the assignments, work is submitted online or through the postal system. The Cluster meetings are invaluable as they help students and professors to form bonds that personalize the electronic communications.

Learning Communications in the Age of Technology by Mitchell Pratt

Communication, or the flow of information between teachers and students, is a hallmark of the educational process. Today's technology facilitates the process. Thornburg, in Betts (1994), states that we "are seeing tools of the Communications Age starting to change the face of the Information Age" (p.20). Our professors at SCIS communicate with us electronically without regard to time or distance. Negroponte (1995) points out that we are evolving in our communication from atoms to bits; that is, we are becoming a society where we communicate increasingly with digital technology rather than paper.

Because time and distance are no longer factors in interpersonal communication, the look-and-feel of higher education is changing accordingly. We, at SCIS, are working largely in a distance but highly-personalized environment. New and emerging online tools will continue to impact and improve distance learning communications.

A Distance Student Becomes A Distance Teacher by Crystal Sandigo

I took my first distance learning class, the subject of which was the Internet, at the University of South Florida at Tampa, with media specialists in Dade County in 1992.

At that time, I learned the joys of using Veronica to search gopher space and the ready access made possible by the Virtual Reference Desk. The first and last classes were on-campus and all other communication was e-mail-based. This allowed me to devote my time to classwork rather than invest it in travel. The DCTE program makes it possible for me to work full-time while I pursue my degree. Every course I take is job-related in some way, has sharpened my technology skills and has made me more employable. The project courses have inspired me to undertake many technology projects that I have presented at conferences where I show teachers and media specialists how to merge new technologies into their curricula.

I am preparing to offer my own distance learning course, "The World Wide Web for Educators," which I developed using Netscape and e-mail and is based on a program that I developed for my courseware course given by Drs. Abramson and Fornshell. Following are elements I plan to integrate into my course:

- There will be a first meeting to introduce the students to one another and to me, and a final meeting to hand in and demo final projects.
- E-mail addresses for all class participants will be distributed for online peer support.
- A bulletin board will be set up on the university server for message posting, requests for help, and comments.
- Assignments may be uploaded for submission.
- Messages will be sent to students in advance of assignment deadlines.
- Performance will be assessed through a project to be shown to the group at the last meeting of the course.

DESIGN AND DEVELOPMENT OF TEACHER EDUCATION MATERIALS ON THE WEB

Ann E. Barron
University of South Florida

This paper focuses on the design and development of Web-based instructional materials for teacher education. The Teacher's Guide to the Holocaust and the Teacher's Guide to School Networks were developed at the Florida Center for Instructional Technology, and they are available for teacher education programs throughout the world. Design and implementation features of these programs are outlined as examples of the effectiveness of disseminating instruction via the World Wide Web.

Advantages of Web-based Delivery

The World Wide Web offers many advantages for the delivery of teacher education materials. No other medium can offer such broad, inexpensive delivery as the World Wide Web. Delivering instruction through the World Wide Web is much more economical than traditional delivery methods because you do not have to purchase diskettes and there are no postal delivery charges. In addition, if instruction is disseminated via the Web, it can be updated continuously simply by revising the files stored on the computer server.

Another benefit of delivering instruction on the Web is the cross-platform capability. In other words, when the text, graphics, audio, and video files for the project are placed on a Web server, they can be accessed by Macintosh, MS-DOS, and UNIX computers. This compatibility eliminates the need to develop two or three versions of the same program for different computer platforms.

Another advantage of disseminating teacher education materials on the Web is that they can contain links to other resources. This allows the integration of a tremendous amount of information from other sites that are appropriate to the content area. For example, the Teacher's Guide to the Holocaust contains active links to the National Holocaust Memorial Museum and the Cybrary; the Teacher's Guide to School Networks provides links to other network-related sites such as Novell.

The Teacher's Guide to the Holocaust

The Teacher's Guide to the Holocaust is a Web-based instructional program that was designed by students in the Instructional Technology program at the University of South Florida to meet the Florida mandate for Holocaust education in K-12. Graphic artists, editors, and programmers were provided by the Florida Center for Instructional Technology to produce the program.

The Teacher's Guide to the Holocaust approaches the humanitarian issues of the Holocaust through a multimedia, interdisciplinary approach and provides a clear, concise, and accurate account of the Holocaust. The program is divided into six main sections: People, Timeline, The Arts, Society, Teacher Resources, and Classroom Activities (see Figure 1).

Figure 1. Main Menu for Teacher's Guide to the Holocaust

People

The People section exhibits the behaviorist categories of people in time of war. In this section, the focus is not only on victims, but also on bystanders, perpetrators and collaborators. On a more positive note, People also celebrates the resisters and rescuers of the Holocaust, with a special dedication to the Righteous Gentiles who placed their lives in danger to save Jewish people from destruction. The Survivor section includes numerous firsthand
stories of survivors and personalizes the Holocaust by making connections between the historical aspects of the Holocaust and actual people.

Timeline

The Timeline section presents the story of the Holocaust chronologically along a detailed timeline of history. This section focuses on The Rise of the Nazi Power, Hitler’s Final Solution, the Rescue and Liberation of Nazi death camps, and the Nuremberg Trials. Topics are supported with QuickTime movies from the National Archives (such as a movie of Hitler at the 1939 Olympics), historical photographs of Europe at war, and copies of transcripts and documents from the Nuremberg Trials. This section is designed to serve as a concise point of reference for teachers. Links are included to other Web sites for those teachers who want to further investigate the Holocaust from a historical perspective.

The Arts

The Arts section demonstrates that despite the Nazi’s attempts at dehumanization, victims and survivors of the Holocaust held onto the parts of themselves that made them most human. This section is a gallery of the Arts—literature, photography, fine arts, music, drama, and film. In Music, teachers and students have the ability to hear traditional Jewish music and songs written during the Holocaust in both the camps and ghettos. Drama includes the works of playwrights, Ronald Vierling and Alina Kentoff—materials that teachers can incorporate into their study of the Holocaust. The Fine Arts section contains the works of David O’Iere, a surviving artist of the Holocaust. Permission to use sixteen of David O’Iere’s paintings for this project has been obtained through a copyright release statement signed by O’Iere’s son and the manager of the O’Iere paintings.

Society

The Society section focuses on the interaction of people and places — Society. The history of anti-Semitism provides teachers with background information about Jewish persecution. This section describes Poland, Germany, and other parts of Europe that were directly affected by or involved in the Holocaust. Anticipated links in this area include a virtual tour of Dachau concentration camp, and the journal writings of several young adults from the Patch American High School in Germany who recently visited the Dachau museum and wrote about their experiences.

Teacher Resources

The Teacher Resources section provides teachers with a bank of reference materials, including annotated bibliographies for books, articles in the ERIC database (Educational Resources Information Center), related web Sites, and software programs that might enrich both teachers’ and students’ learning experiences when investigating the Holocaust. The section also lists various Holocaust Memorials and Museums in the United States and provide detailed descriptions of the resources available at each center. Teachers may contact these museums to obtain more information or materials to include in their curriculum.

Classroom Activities

The Classroom Activities section presents a series of lesson plans and integrated units that may be used across the disciplines. Arranged according to Gardner’s Multiple Intelligence Theory, the Activities Section is divided into categories of students’ individual strengths, such as Musical, Bodily/Kinesthetic, Intrapersonal, Linguistic, etc. Each lesson describes the learning objective, appropriate grade level, materials needed, and procedure. Moreover, this section contains “Submit an Activity” and “Send us your Comments” segments, where teachers may send their own lesson plans or submit suggestions for revisions of the lesson plans in the database. All lesson plans are edited and evaluated by experts in the field prior to being added to the Classroom Activities section.

The Teacher’s Guide to School Networks

The Teacher’s Guide to School Networks is designed to provide basic information about local area networks for teachers, administrators, and media specialists. Through text, graphics, and hyperlinks, teachers can learn the terminology and basic concepts of installing and maintaining a local area network. Topics in the program include: hardware, software, protocols, topology, and cables.

Figure 2. Imagemap in Hardware section.

Hardware

The Hardware section includes information and diagrams about file servers, workstations, network
interface cards, concentrators, repeaters, bridges, and routers. A summary section is included that uses HTML frames to allow the user to click on an imagemap and review information about various aspects of a network (see Figure 2).

**Software**

The Software section includes advantages and disadvantages of various network operating systems, including peer-to-peer and client/server. Links are included to other Web sites that offer more information on AppleShare, LANtastic, Microsoft Windows for Workgroups, Windows NT, and Novell Netware.

**Cables**

The Cabling section includes diagrams and information about unshielded twisted pair, shielded twisted pair, coaxial cable, fiber optic cable, and wireless transmissions. Guidelines for installing cables are also included.

**Topology**

The Topology section focuses on the physical topology alternatives for networks. Advantages, disadvantages, and diagrams are presented for linear bus, star, star-wired ring, and tree topologies. A table is included that summarizes the topologies and correlates information about common cables and protocols.

**Protocols**

The Protocol section includes information about the most common protocols used in school networks, including Ethernet, LocalTalk, Token Ring, and FDDI. A summary chart is included that correlates the protocols with speed, cables, and possible physical topologies.

**Game**

A Jeopardy style game is included in the Teacher's Guide to School Networks that allow users to review the information in the program. Using a Perl script, the game keeps score of the user's answers and reveals pieces of a puzzle if the questions are answered correctly.

**Issues in the Design and Development of Web-based Instruction**

Numerous issues arose in the design and development of these Web-based courses. Each graphic had to be carefully evaluated to determine if it was relevant to the program and whether or not it justified the transfer time. A "rule-of-thumb" guideline was to attempt to keep each page to less than 50K. Because of this constraint, special efforts were taken to compress the graphics as much as possible or to use thumbnail graphics with links to another page. Copyright issues with graphics were carefully researched; substantial time and effort were required to obtain the proper clearances.

Navigation issues, such as links, image maps, headers, and footers, had to be designed and tested with the target audience. Whenever possible, icons were added to make it clear to the users whether they were branching to a glossary, internal link, or external link. Text was rewritten and edited continuously to ensure that it was accurate and presented in a logical manner.

Creating content for delivery on the Web is an extremely time-consuming task. The rewards, however, can be worth the effort. Within days of the release of these programs, feedback arrived from all over the world, complementing the efforts and requesting permission to use the programs in teacher education courses and inservice programs.

*Telecommunications: Graduate, Inservice & Faculty Use — 1183*
Telecommunications: Preservice Applications

Section Editor:
Sue Espinoza, Texas A&M University-Commerce

The online world is rapidly becoming a part of everyday life, with references to e-mail and web addresses all around us. As growing numbers of homes and schools acquire the resources needed for access to the Internet, more and more students of all ages are coming into our classrooms with at least an introductory knowledge of how to use e-mail, the web, and other Internet tools. Telecommunications is no longer a rarity in the schools — the number of schools with no Internet access in place, or in the planning or wishing stages, is diminishing. Access, though, is not enough. Training must be provided, and this is where it is essential for Colleges of Education to step forward. The papers in this section illustrate a variety of approaches to this task.

Many teacher education programs have been responding to this challenge by developing ways to integrate telecommunications activities into the teacher preparation curriculum. George Davis and Rhonda Ficek, of Moorhead State University, describe one example of how they have redesigned the introductory education course so that "students will use technology to access a significant amount of the information used in these courses." Davis and Ficek describe how students use e-mail, the web, listserves, and newsgroups as essential components, while investigating the major course topics and completing projects. Students also have online access to course mentors — area principals and teachers available to answer questions from these preservice teachers.

Telementoring is recognized as an effective means of providing support for preservice teachers, as shown in the next two papers. In the first, Henry Dobson describes the Great Lakes Collaborative Telementoring Project, which "relies on computer-mediated learning supported by technology, and provides a mechanism for dialoging and sharing pedagogical practices constructed from experiences from the real-world." The online environment provides time- and distance-independent learning situations, with an emphasis on real-time learning in the area of elementary mathematics. In the second paper, Kathleen Weiss describes a telementoring project implemented in her reading class at the University of Houston, where preservice teachers were matched with content area mentors. Weiss also used a listserv to help link classmates, and found that students used it to continue discussions from the classroom.

Technology is no longer restricted to computer (or technology) classes — the Dobson and Weiss papers are but two examples. Carol Long, Mary Ito Dennison, and Sue Reehm describe a project in a Special Education course — Characteristics of Students with Mild Disabilities. Graduate and undergraduate students learn to use the Internet by locating, gathering, organizing content while refining and building upon the previously created web pages. The course emphasis is on the content, rather than the technology. Rick Seaman provides another example of Internet activities in content areas. He describes five activities carried out by preservice mathematics education teachers at the University of Regina. His students participate in a variety of activities at different levels, from observing through creating, to presenting their projects at a mathematics conference. Seaman's paper concludes with a group reflection statement, prepared by the preservice teachers, about their experiences.

Leslee Francis-Pelton and Ted Riecken describe the integration of telecommunications activities into four different courses. In social studies, the Camelot Project united preservice teachers and middle school students in an online activity to learn about the Middle Ages. Students

1184 — Technology and Teacher Education Annual — 1997
assumed e-mail aliases as they participated in an online historical narrative. Francis-Pelton and Riecken also describe the use of telecommunications “as a tool to manage three courses for preservice math majors—a technology course, a mathematics methods course, and a mathematics content course.” They compare the intent, the extent, and the results of the use of technology (e-mail, listservs, web use, and web construction) in each of these courses. In all classes, communication between teachers and students was increased by the use of e-mail.

Cynthia Hutchinson and Jerry Gardner describe the use of e-mail to “establish and maintain communication between student teachers and university professors.” Students submit a variety of reports, as well as their reflection journals online, and faculty are able to respond immediately, as needed. The goal is for these students to continue using timely communication throughout their educational careers after this start.

Hutchinson, along with Gay Staats, Marjorie Adamczyk, Christine Scheer, Rebecca Boggs, and Darrae Norling, describes a partnership between a college of education and a K-5 school, who were joint recipients of an Apple Partners in Education Grant. University students participated in a field experience, where they worked with the elementary students to create web pages. Jackie Stokes describes a different type of collaboration between preservice teachers and elementary students. Most of the interaction takes place via e-mail, as students focus on the information processing that occurs while creating presentations, as well as on metacognitive aspects related to the task. The school buddies concept was used to pair students from the two different institutions, and the buddies communicated with each other about class assignments.

Another type of communication involves the use of listservs or newsgroups. Both of these allow for communication from one person to many, rather than the one-to-one relationship of the more traditional personal e-mail. The next two papers describe student use of listservs and newsgroups. Susan Powers and Karen Dutt-Doner used a newsgroup for communication with one class, and used a listserv for the same class the following semester. They saved all messages from both semesters, categorized and analyzed them, and report on the numbers and types of messages from each semester. The same five themes were evident each semester, although the emphasis differed. Mark Roddy also describes the use of a mailing list—he found eight broad areas of use. He illustrates the use of the list by providing examples of messages from one particular thread of conversation initiated by a student teacher. Roddy suggests that this method of communication is one way “to reconnect the theory held by the larger academic community to the particulars of the daily experience in the classroom.”

Sandy Jean Hicks and Betty Young explain a unique approach to providing Internet training—a series of summer NetShop workshops. They describe the structure of the NetShops and the instruction, and present an analysis of pre- and post- surveys, to illustrate the concept. Unlike the other papers in this section, this was not conducted as part of a university course, although it was possible to get university credit for participation.

The final paper in this section is also unique. Sandra Atkins and Jacqueline Peck describe a project that, as in other papers, utilized e-mail as a communication mode. However, the communication was between preservice teachers at universities in two different states “to provide opportunities for preservice teachers to examine their own views of teaching diverse populations.” Atkins and Peck have used examples of student e-mail to illustrate some of the understandings and knowledge gained by students at each location.

In his paper, Mark Roddy stated that “the electronic mailing list constitutes a powerful tool in the service of teacher education.” We might generalize that statement to include the variety of online telecommunications resources, from e-mail to the web, and everything in between — the papers in this section support that concept.

Sue Espinoza is an Assistant Professor in the Department of Secondary and Higher Education, College of Education, Texas A&M University-Commerce, Commerce, TX 75429. Voice: 903-886-5500. E-mail: Sue_Espinoza@tamu-commerce.edu
Moorhead State University's teacher education program, like many other programs, is working to incorporate technology into the preparation of its education majors. MSU has decided that the best way to do this is to redesign existing courses in teacher education is such a way that students will use technology to access a significant amount of the information used in these courses.

Introduction to Education is a three semester hour required course taken by all education majors as their first course in teacher education and has been so redesigned by the authors. The outcomes of the course are to:

- explore the profession of elementary and secondary teaching as practiced in the United States.
- understand the current re-invention of elementary and secondary education in the United States.
- gain an in-depth understanding of the Minnesota Graduation Standards currently being implemented K-12 statewide.
- begin to think like an elementary or secondary teacher.

A one semester hour (40 contact hours) field experience is a co-requirement of this course.

The four major assignments of the course take the students from a historical review of the U.S. industrial model school as an integral part of the industrial age to the current age of information which requires a new educational paradigm. Students explore this new educational paradigm as it has been defined by the national standards documents and the Minnesota Graduation Standards. Students also explore the growing diversity of learners in K-12 classrooms through a study of student exceptionalities. The course’s final assignment requires students to examine several best practice examples of this new educational paradigm and contrast it with the current practice found in many U.S. K-12 classrooms today.

Teachers designing instruction based on the national and state standards recognize student exceptionalities as a key determinant of appropriate instruction and understand that all students process information as they construct their own knowledge of concepts taught. In the classrooms of these teachers, the use of technology as a way to access a wide range of information is a natural fit. In these classrooms students actively seek out information while the teacher functions as more of an instructional manager than a main source of information. The textbook is replaced as the other main source of information in favor of more primary sources of information including, but not limited to, those sources accessed by technology.

These concepts are not just talked about during Introduction to Education. The course is designed to deliver instruction based upon the use of primary texts, library sources, and information on the Internet combined with the 40 hours of field experience. All of this has replaced teacher lectures and a traditional textbook as main sources of information. In this manner the course gives teacher education majors experience using technology in the process of achieving the course outcomes, instead of having them just talk about how to use technology in instruction.

Redesigning the Course

The redesigning of the Introduction to Education course involved constructing the online environment, selecting appropriate support technologies, and finding relevant online materials for course content. The desired instructional content and outcomes were the primary guiding principle throughout. The temptation to include many of the latest technology tools was avoided in the interests of remaining committed to the goals set out for delivery of this course.

The online environment was constructed to provide access to the course syllabus, assignments, related readings, online information sources, and course mentors (practicing teachers and principals). In addition to the typical content on the course syllabus, links to e-mail addresses were provided for both instructors to facilitate student/teacher interaction. The mentor page contains pictures of the principals and teachers from area schools who agreed to answer questions from the preservice teachers in this course. Links to their biographical information and e-mail addresses were provided to encourage
communication with experts in the teaching field. The assignments contained links to relevant online materials along with suggested traditional readings.

Selection of appropriate support technologies was more difficult. Our vision for the course suggested the following possibilities:

- Electronic mail to facilitate student/student and student/teacher interaction
- Graphical web browser to provide access to online materials in both textual and graphical format
- Presentation software for use during group presentations to the class
- Groupware for collaborative group work on a single electronic document
- Listserv/newsgroups/web conferencing software to enhance communication between all members of the class

Electronic mail using the UNIX-based Pine software was one of the easier components to establish, since all students are encouraged to request an e-mail account as soon as they enter the university setting. Nearly all of the student labs on campus provide access to a graphical web browser (in most cases, it is Netscape). In addition, most student labs also provide access to PowerPoint as a presentation tool for preparing slides and transparencies. However, finding affordable tools for document sharing was not an easy task. After exploring the possibilities in Microsoft Word (which were complex and undependable in our lab setup) and discovering the expense of site licensing for other commercial groupware products, the decision was made to encourage collaboration on the group's research paper using electronic mail for the present. Finally, listservs and related technologies were examined to enhance communication between all class members. Web conferencing software seemed to be the best fit for the course objectives, since messages are threaded by topic, as opposed to a class listserv setting. No conferencing software existed on the campus web server, but a departmental web server running Microsoft's Front Page was suggested, and permission was secured to use that web server for this aspect of the course.

Current Course Operation

Introduction to Education is team taught by Drs. Davis and Ficek. Dr. Davis is the teacher educator for the course and leads instruction on the educational content (theory and practice) for the course. Dr. Ficek provides instruction in the skills required to use the web browser, electronic mail, presentation software, and web conferencing software. She also supervised the design of the course homepage and its maintenance.

The course has 40 students organized into ten four-person cooperative learning groups. Each group is responsible for three major papers and one multimedia presentation during the semester. Individual assignments are also required. The use of the Internet in this course includes regular e-mail among team members and course instructors. E-mail is both initiated by the student and sent in response to specific assignments made by the instructors. A news group is also maintained for the course.

All instruction pertaining to the use of software is conducted in a computer lab setting to provide all students with hands-on training. Several periods of instruction were devoted to the use of e-mail to send basic messages as well as attached documents. Students were introduced to a graphical web browser (Netscape) and were given a set of educational sites to visit. Instruction in organization of electronic findings using bookmarks with folders was followed by an assignment requiring students to organize their bookmarks into several pre-defined categories. In addition, online search strategies were explored.

The course then turned to more educational content as the students investigated the four major course topics. Each topic's assignment called for students, working as teams, to collect information on the topic by using the MSU library (searches are conducted using the university's computer PALS system), several articles on reserve, one of the course's required primary texts and several web sites. As the students progressed through the course, the number of information sources provided by the instructors declined and student teams were required to find their own information sources using the Internet and the MSU library.

During the latter part of the semester, instruction in the use of presentation software (using PowerPoint) is provided. The final team project is a multimedia presentation by each group for the entire class.

Future Course Enhancements

Now that the course has been offered in the redesigned format, several enhancements are planned for the next offering. The web conferencing environment will be integrated into all four group assignments. This will allow students to more effectively interact with their cooperative learning group outside of class. This should address student concerns about finding time to meet together as a group outside of class. Similarly, group assignments will be modified to make better use of the online mentors. This will give students the opportunity to interact with experts in the field when face-to-face interaction is not feasible.

Along these lines, encouraging students to become active in existing national online discussions pertaining to instructional issues, such as KidSphere, is an important goal. Many such discussion groups (listservs) are readily available, and an assignment is planned which will require students to participate in at least one listserv related to education.

Groupware is becoming more prevalent and affordable. As these products mature, the course will utilize this software to enhance online collaboration on research.
papers. Since four group members will provide input on
the content of the papers, this software will make the job of
the "senior editor" much easier, since contributors can
annotate their suggested changes before actual incorpora-
tion into the document.

Additional web materials such as group pictures with e-
mail addresses will be added to the course web environ-
ment. This online environment provides a rich opportunity
to create a non-static set of materials which can be
continually updated and enhanced.

Evaluating the Innovation

Since we are carrying out an instructional innovation
(using the Internet to find information), we are monitoring
our effectiveness in preparing students to succeed by using
two instruments. At the beginning of the semester, a
technology skills survey was distributed to each student.
The information collected in this survey was used to tailor
the technology instruction for the group, based on their
past experiences with the various technologies.

The second instrument we are using is the Concerns
Based Adoption Model (CBAM) Stages of Concern
Questionnaire (Hall, George, & Rutherford, 1986). This
instrument is given twice, before and after instruction, and
is designed to measure the relative intensity of seven types
of concerns people exhibit when faced with adopting an
innovation. By determining the relative intensity of each
type of concern for each student we are better able to
adjust our instruction to address the higher intensity
concerns of our students and therefore insure a greater
level of student success.

1188 — Technology and Teacher Education Annual — 1997
TELEMENTORING: TRAINING PRESERVICE TEACHERS IN THE NEXT MILLENNIUM

Henry D. Dobson
Bloomsburg University of Pennsylvania

Changes in computer technology are changing the way future teachers are being trained. The advances in information technology have significantly affected the way future educators will experience the process of becoming effective teachers. Teacher educators now possess the ability to become intellectual coaches, engaging their protégés as active learners through the use of computer-mediated communication, diverse databases of academic resources, and online/real-time telecommunication dialog. This new generation of preservice teachers is able to connect with learning projects related to real-life experiences in different educational environments. They are able to share similar and not so similar experiences with mentors, peers, and educational specialists. This new process is not text-bound in a college classroom filled with columns and rows of students, but is a dynamic medium interwoven with a collaboration of professionals at all levels.

Collaboration

The Great Lakes Collaborative (GLC) Telementoring Project was developed to improve the effectiveness of training preservice teachers, especially in the area of elementary mathematics. It involves a collaboration of those individuals who have significant impacts on teacher education: the preservice teachers, teacher educators or educational specialists, and the in-service or cooperating teachers. This telementoring project relies on computer-mediated learning supported by technology and provides a mechanism for dialoguing and sharing pedagogical practices constructed from experiences from the real-world. These practices can be shared, discussed, and evaluated at different times and at different locations. This scenario is entirely different from the traditional teacher training classrooms of textbook experiences, where everyone receives the same information at the same time and in the same place. With the telementoring project, preservice teachers are able to dialog with one or more teacher educators who act as consultants, or with other in-service or preservice teachers.

The GLC Telementoring Project is a distance-independent learning situation for preservice teachers. It can be on-site, in an elementary classroom, or in the living quarters of the preservice teacher. This type of learning is definitely time-independent and can be conducted in real-time or at different times. The technology supports dialog with or among teacher educators, other preservice teachers, inservice cooperating teachers, and educational specialists. This communication mode can be conducted with individuals or as a group using the conferencing software. It provides an effective way of addressing the individual needs of the preservice teachers. Computer-mediated, multi-modal communication is predominantly written communication and requires all participants to engage in the process if it is to be successful in training a new generation of preservice teachers. This type of format requires increased levels of maturity and motivation, as well as the ability to work independently on classroom projects. These developed or acquired attributes of time-independent learning are benchmarks of an effective teacher.

Real-Time Learning

The GLC Telementoring Project provides real-time learning that is independent of time, place, and distance. It uses online chat mode with real-time discussion groups promoting conferencing on special topics related to pedagogical skills or subject matter content areas. This type of learning must be coordinated with participants so that the preservice teachers can interact with other preservice teachers, educational specialists, and cooperating teachers.

Preservice teachers can benefit from the independent learning mode of the GLC Telementoring Project. They can work alone, using the academic resources available from the GLC Explorer Database of Academic Resources in Mathematics and Science. These academic resources include curriculum materials, appropriate software, and videos in tape and laser disc formats. In addition, the Explorer Database contains unit and lesson plans in
mathematics and science. These lessons have been reviewed by experts in the field and are rated to be effective, correct in content and matched with various curricula and instructional levels. The teacher educator's role in this mode is one of being a human resource when needed to support the acquisition of pedagogical skills or comprehension of math or science concepts. Also, the teacher educator functions as an educational counselor, supporting, nurturing, and guiding the preservice teachers into successful careers as professional educators.

Life-Long Learners

The GLC Telementoring Project is well-suited to the development of the professional educator, an educator who will always be a life-long learner. An educator of the 21st century is one who will use technology to create a community of learners, not bound by textbooks, distance, time, or professional status.

Henry D. Dobson is a Professor of Computer Technology in the School of Professional Studies, Department of Curriculum and Foundations, Bloomsburg University of Pennsylvania, Bloomsburg, PA 17815. Voice: 717-389-4024.
E-mail: hdobson@bloomu.edu
After surveying the literature on information technology and teacher education, Willis and Mehlinger (1996), concluded that “preservice teachers know very little about effective use of technology in education” (p. 978). Furthermore, teacher education is indicted for “not preparing educators to work in a technology enriched classroom” (p. 978). According to the Office of Technology Assessment [OTA] (1995), graduates of teacher education programs in the United States do not think of using technology as a “teaching tool.” Even though students are taking computer literacy courses for teacher certification, they are not incorporating computers into their lessons when they become certified as teachers (OTA, 1995).

Technology in Teacher Education Programs

It is not enough for students to take a computer literacy course. Integration of technology must be modeled by the faculty in the college of education (OTA, 1995). The problem lies in the fact that present day faculty did not receive training in technology. This gap in training is part of the cause of technology not being modeled in teacher education programs (OTA).

Furthermore, technology needs to be incorporated into content area methods courses (Fullan, 1991; Novak, 1991; OTA, 1995). An introductory approach would be for students to communicate with content area professors by e-mail or on a listserv set up for the specific class.

Telecommunications

Findings from the 1995 Survey of Advance Telecommunications in U.S. Public Schools, K-12 (National Center for Education Statistics, 1996), reveal that 50% of U.S. public schools now have Internet capabilities, compared to 35% of the schools a year ago. Because there is an influx of telecommunications abilities in our schools, our preservice teachers need to know how to incorporate this into their teaching curriculum. Telecommunications is an easy first step for collaboration of faculty and students (Bishop-Clark & Huston, 1993).

Telecommunications Projects

An example of an on-going telecommunications project involves biology students at the University of Illinois (Levin, Levin, & Boehmer, 1994). Freshman biology students are involved in a model called teaching apprenticeship. Students are apprenticed by a community of educators through e-mail.

The Internet-based Electronic Emissary Project (Jones & Harris, 1995) is still another example of an on-going telecommunications project. It matches teachers with subject matter experts. One of the benefits of this program is the promotion of collaborative learning.

Telementoring: Preservice to Inservice Teachers

The modeling of these and other electronic projects that fill the literature has influenced this author to venture out on her own. Preservice teachers from the author’s Reading in the Content Area methods class were chosen for this research project. As previously mentioned, the literature supports modeling of the integration of technology in methods courses.

Mentor teachers from all over the USA and Australia volunteered by way of an educational listserv. The mentors had a plethora of teaching experience. Many of the mentors hold master’s degrees and have their own web pages. One mentor has recently published an article about her own online experience in the classroom.

The preservice teachers, prior to being matched with content area mentors, were administered the Computer Attitude Measure (Kay, 1989). The measure consists of Likert type questions in the behavioral, affective, and cognitive areas. The survey can easily be completed in fifteen minutes.

Next, the instructor modeled the creation and sending of a short e-mail message for the preservice teachers. At that time, a computer technologist was not available. For some students, this demonstration was enough. However,
not all students owned a home computer. It depended on their class schedules as far as how often they were able to check their e-mail messages. One of my students suggested that in future that a few minutes out of class time be allotted to check and send e-mail messages. This might be a practical suggestion worth pursuing.

Preservice teachers that felt a kinship with their mentors remarked: "We have the same philosophy of teaching, we are so alike in our thinking, we are passionate about teaching."

The preservice teachers that developed a nurturing bond with their mentors were able to be open to suggestions from these mentors.

Even though some students were reticent in the beginning about having an e-mail mentor, most of the students felt it was a beneficial project by the end of the semester. Many of the students plan to continue to communicate with their e-mail mentor. The students especially look forward to communicating with their mentor when they are involved with student teaching.

**Implications for Future Research**

This research project was an initial attempt of a college of education methods instructor to model the integration of technology. The rationale was based on a review of the literature. This is just one way to model technology in teacher education programs. More in depth research needs to be conducted in the area of technology in methods courses. This semester our class has only scratched the surface. It is a first start.

To enhance learning and the acquisition of technological skills, preservice teachers at Winona State University enrolled in a Special Education course have been involved in an ongoing project. The project encompasses the development and revision of interactive web pages connecting content, recent research, and local, state, national and online resources pertaining to learning disabilities and mental retardation (Long, Dennison, & Reehm, 1996).

The Project

Winter quarter of 1996, students taking the Characteristics of Students with Mild Disabilities course created 15 web pages which were linked to the Department of Special Education home page. The pages provided definitions for the two disability categories and reflected national and state interpretations. Lists of common characteristics of children with learning disabilities and children with mild mental retardation, a bibliography of recent research, and resources for locating further information and assistance were published.

The class was organized so that graduate students enrolled in the course were leaders for undergraduates team members. The graduate students were evenly distributed among the teams and were instructed in HTML and web page design. The responsibility of the graduate students was to program the pages and to supervise the undergraduate students who researched information for page content. In subsequent quarters, students enrolled in the course have revised and added to the web pages using the same organizational structure.

As the project has evolved, the role of the students has changed. The first class that participated in the project had the primary goal of publishing on the World Wide Web, and a great deal of effort was put into programming as opposed to focusing on content. Later classes have had the advantage of being in the position to refine and build upon what already exists. Now the emphasis is on evaluating and critiquing what has been published, revising, reorganizing, and providing additional material.

To date, the students have made several major changes. For example, the research bibliography was annotated, expanded and categorized. Student generated definitions for learning disabilities and mental retardation were included along with formal definitions and e-mail addresses and web sites were linked to agencies listed in the resource directories.

Project Evaluation

Evaluation of the project has been conducted in three parts each quarter. First a pretest was administered to determine attitudes toward technology and perceived Internet competence. Second, the same survey was given as a section of a posttest at the end of the quarter and, third, the posttest also contained a portion asking the students to compare their knowledge gained from this project to projects in other classes.

In comparing the results of the pretest questions, the students have consistently reported the following personal perceptions. They considered it very important for teachers to know how to use a computer, acknowledged the need for computers to be used in every classroom, and reported they were comfortable working with computers.

Analysis has found significant increases in the students' knowledge levels for locating information on the Internet—using Netscape, gopher, telnet, listservs, e-mail, and FAQs; defining search engines, URLs, and home page; and publishing home pages. None of this information has related to skills directly taught during the course. The students learned how to use the Internet by locating information on the web and gathering and organizing the information to create and expand the web pages (Long, Dennison, & Reehm, 1996).

Upon completing the web pages, the students have reported they felt the project was worthwhile with graduates rating it more so than undergraduates. The students have rated their learning greater from this project in the areas of content knowledge and working as a team, than projects in other classes. Students thought the project was superior in several ways to projects assigned for other classes but that it required more effort, more time, and more organizational skills on their part. An overwhelming majority indicated they would like to do a similar project.
for another class with all of the graduate students wanting
to do so.

WEB SITES AND TEACHING WITH THE INTERNET FOR PRESERVICE TEACHERS

Rick Seaman
University of Regina

This paper describes how preservice mathematics education teachers at the University of Regina became familiar with the Internet during their pre-internship year. The preservice teachers participated in a math project that required use of the Internet, became involved in a web site, developed their own mathematics Internet projects, presented their projects at a mathematics conference, and reflected upon their mathematics Internet project.

The web site chosen was Math Central, which became an Internet site in September 1995 and is maintained by faculty and students in mathematics and mathematics education at the University of Regina in Regina, Saskatchewan, Canada (http://MathCentral.uregina.ca). Math Central is a place for teachers to share resources, have mathematical questions answered, and carry on a dialogue amongst themselves. The site is presently administered by Drs. Denis Hanson, Vi Maeers and Harley Weston. The description of activities in which the preservice teachers were involved will include a more complete description of Math Central.

Activity One: Involvement in and Development of a Mathematics Internet Project

For one of the activities, the preservice teachers set up potential mathematics Internet projects for their internship. To gain a better understanding of this process, the preservice teachers were informed at the beginning of September, about a high school mathematics Internet project found on a listserv, and were asked if they were interested in becoming involved. They agreed to participate and, at the conclusion of the project, to describe their feelings about being part of such a project. The project entailed responding to a survey prepared by high school students in an eastern United States high school. The responses, gathered by e-mail, would help the high school students learn the survey research process, including sampling designs, questionnaire design, data collection, and data analysis. The high school students would then determine whether any two groups of participating students differed significantly in their responses to the survey. Some of the countries that responded to the survey were Hong Kong, Canada, United Kingdom, Mexico, Australia, Germany, and Spain.

Since many diverse countries responded to the survey, it was possible that several questions in the survey might be misinterpreted due to differences in culture. As a pilot, the teachers of participating schools were asked to review the survey’s questions and suggest changes before the actual administration of the survey. Even though the preservice teachers were high school graduates, they were allowed to participate in the survey that was constructed for 14 to 18 year old students. By the end of September the survey had been piloted and final changes made to its questions. Some of the questions requested respondent information about language(s) spoken, how many people were resided with, how many hours per week were spent watching television (doing homework), age of the respondent, and gender. Participants were asked to e-mail the completed forms to the high school students by mid-October. On October 23 we received the raw data concerning other participating groups and a thank you for helping out with the project. We were told the high school students were presently analyzing the data and were to complete a report by October 28.

Looking back at their involvement in the Internet project, there was an appreciation of all the work the high school students had gone through. However, the preservice teachers concluded that it is valuable to show the final results of projects that people have participated in, not merely provide raw data. They also decided that such a survey could have its origins and analysis in mathematics but also have an impact on other subjects such as Health, Social Studies, History, and Geography. The preservice teachers were beginning to understand what it takes to develop a mathematics Internet project properly. It was now time for them to develop their own mathematics Internet projects.

The preservice teachers divided themselves into three groups of either five or six people. The first group consid-
erred sports team web pages on the Internet because they are plentiful and easily accessible. These pages were found to contain the past and present statistics for teams and players. Using the information on these pages helped demonstrate the applicability of mathematics in some of the areas that students enjoy, but which are not ordinarily considered as areas involving mathematics. An objective was to have students learn different ways to represent and statistically analyze the data of a particular team, in addition to working on problems dealing with proportional reasoning. Their project concluded with some questions that students might be asked and a list of other possible sites.

The second group developed their version of how they would run a survey on the Internet. They would have a group of students pick a topic from a given list (e.g., school, family, personal, geography etc.) and then brainstorm for possible survey questions. A ceiling on the number of questions that could be asked within each topic would then be decided upon. They would then find schools that were willing to participate through web sites, listservs, etc. Data collected would be prominently displayed in their classroom and their students would be involved in collecting and disseminating the results to the participating schools. To facilitate this process the students would use various statistical methods to represent and analyze the results much like the survey in which they had been involved. In contrast, they would get the comparisons out to each participating school as soon as possible, so that a discussion of the results using e-mail could follow. The objective was to have other subjects such as Health, Social Studies, History and Geography become involved in what was initially only a mathematics topic.

Group Three's project involved developing a list and description of sites on the Internet that might benefit teachers, students, and parents concerning mathematics. Addresses and brief summaries of some sites were included along with downloaded examples. They also included a sample lesson so that the reader could see how an Internet site might be included in a lesson plan.

Activity One was an ongoing project from September to November. During this time period the preservice teachers were also familiarizing themselves with other Internet resources, in particular, Math Central.

Activity Two: Joining and Involvement in a Web Site

The site chosen in which to become involved was Math Central. Other sites could also have been chosen but this site was selected because it was located at the University of Regina. Math Central has a discussion forum for teachers of mathematics (Teacher Talk), a question and answer area for students and teachers (Quandaries and Queries), and a sharing place for mathematics resources (Resource Room). In September the preservice teachers subscribed to Teacher Talk and began their interaction with the web site.

The preservice teachers received e-mail daily from Teacher Talk while preparing questions to be submitted to Quandaries and Queries for discussion on Teacher Talk. Some of the questions asked dealt with the memorization of formulae, use of calculators in the classroom, assessing group work, the value of grade 12 calculus, Internet math lessons, and how to teach the composition of functions. They received replies, from all over the world, that were enriched with teachers' experiences and research. One preservice teacher was able to make contact with a teacher in the field that resulted in the two of them planning to set up a project between their classes in the fall during the preservice teacher's internship. Another response caused a preservice teacher's position to 'soften' on the use of calculators in the classroom. Some would have liked to have had more responses to their queries, and as a result joined other listservs to get more responses. Overall, the preservice teachers found the experience worthwhile and found new ideas that would help them during their internship. They also said they would use this service again.

Activity Three: Contributing to the Resource Room

Math Central has a place where mathematics educators can share resources—the Resource Room. The preservice teachers were to send to the Resource Room three ideas (one from each group) concerning the teaching of mathematics. The contributions made were a game to help in the teaching of adding and subtracting integers, ideas for teaching the Pythagorean Theorem, and a short comment concerning the Babylonian number system. These contributions will be placed into the appropriate educational level and curriculum strand at Math Central.

Activity Four: Identification and Critique of Mathematics Sites

Each group of preservice teachers was asked to identify and critique three sites that would help them during their internship. Each student identified specific locations, and each group came to a consensus on which three they felt would be the best. The sites chosen offered the preservice teachers resources, sources of problems, ways to apply mathematics, data sources for math projects, lesson plans, and a site that helps new teachers make the transition to their new profession. The initial screen of each site was downloaded to assist in the identification and selection process of the sites by each group.
Activity Five: Presentation of Internet Projects at a Mathematics Conference

At the end of October, the preservice teachers were given an hour and a half to present their mathematics Internet Projects at a K-12 mathematics conference that included math educators from all over the province of Saskatchewan. The preservice teachers not only discussed what they were doing, but also talked to teachers ‘in the halls’ about what use they were making of the Internet. Although their presentations went fairly well, they had high expectations and would have liked to have seen a better turnout. However, they felt it was an excellent experience and enjoyed talking with those teachers who had the Internet in their classroom. Overall, the experience of being at their first mathematics conference was an educational one—from their presentation to others’ presentations and from the workshops to the displays.

Preservice Teachers’ Reflections

The preservice teachers submitted a group reflection concerning their mathematics Internet project experiences. The following is their statement.

This project was not only an educational experience but also a practical exercise that we will be able to use in the future when we are teaching. Through this project, we became familiar with the Internet and learned how to use it to our advantage. At the beginning of the project, many of us were not comfortable with using the Internet but this project took away the fear of technology. The Internet gave us ideas on lesson planning, evaluation, making adaptations, and projects for the students. We also discovered that the Internet is not only a place for resources but it also serves as a means of communicating through e-mail and listservs. These allow teachers from all over the world to share their ideas. The Internet seems to ‘shrink’ the world.

This project also taught us the importance of working with other people. Group work involves cooperation and management skills. It is important that as future teachers we recognize how important it is to work effectively in groups. Students need to be exposed to group work and teachers also must learn how to work together. People have a lot to learn by working with each other.

Even though there are many advantages to working with the Internet, there are also disadvantages. We thought that it was hard to find original things to do with the Internet. Sometimes working with the Internet is a time consuming experience because you have to sort through a lot of ‘garbage’ before you find something worthwhile. It is important that as teachers we are aware of the ‘garbage’. It is important that we are able to judge whether or not the information we are receiving is accurate and reliable.

Overall, this project was a real eye opener for all of us. It showed us the power of technology and how to make use of it in our classrooms. It is important that we became familiar with the Internet because it is going to be a big part of everyone’s lives in the future. By learning how to use the Internet in educational settings, we have taken a step ahead of current teachers who have limited computer experience. We can now use our knowledge of this new technology to teach them and bring them up to speed with the world of technology.

Rick Seaman is a Professor of Mathematics Education, Faculty of Education, University of Regina, Regina, SK Canada S4S 0A2. Voice: 306-585-4510. E-mail: rick.seaman@uregina.ca
The Internet is the most rapidly expanding means of mass communication in the world today. As of 1995, there were over seven million computers on the Internet and a new network was being connected every 30 minutes (Cerf, 1995). With an almost 100% annual growth rate, these figures should now be double those amounts. Over half of this growth is in countries outside the United States, making the Internet a veritable library of worldwide resources.

The rapid rise of popularity and accessibility of Internet resources has implications for education and the training of teachers. As more schools become connected to the Internet, schools need teachers with Internet skills among their repertoire of computer skills. Although many universities now require students to complete a course on using computer technology as part of their teacher education programs, most such courses do not provide enough time to cover the scope of technology use in the classroom (Bruder, 1989). Students are often given only a limited exposure to the resources and possible classroom uses of the Internet, as it is only one topic out of many.

Studies over the last seven years have consistently indicated that less than one-third of students leaving teacher education programs felt adequately prepared to teach using computers (Fulton, 1989; Handler, 1993; Scrogan, 1992). Barker (1994) noted that teachers show great enthusiasm for using computers, but often find it difficult to integrate technology into the curriculum. Preservice teachers rating the importance of a variety of computer skills rated as highest those skills with which they were most familiar and confident in usage (Francis-Pelton & Pelton, 1996).

If we wish teachers to use the resources of the Internet in their classes, we need to provide experiences beyond short segments of a technology course. Internet usage should be woven throughout the teachers’ education program in such a way that they gain confidence, skill in Internet usage, and models of how the Internet can be used to enhance education. This paper will highlight two projects that used telecommunications in preservice teacher education settings as a tool for learning rather than as the subject to be learned.

The Camelot Project: Interactive Electronic Storying

The Camelot Project was a joint school-university initiative in which preservice teachers and middle school students used e-mail to learn about the Middle Ages. The project was conceived by Dr. Ted Riecken of the Faculty of Education at the University of Victoria and Jordan Timney, Vice-Principal of Bayside Middle School in Brentwood Bay, British Columbia, and was implemented in the 1994-95 school year. Sixteen preservice teachers enrolled in a senior level social studies methodology class used e-mail to work with a group of 15 middle school students to create two virtual communities which then engaged in a dramatic role play about life in medieval times. Built upon Egan’s (1989, 1990) theories about teaching as storytelling and the role of imagination in learning, the Camelot Project explored the potential of electronic mail as a vehicle for engaging students in interactive learning about social studies topics. Project students at the university and the middle school each assumed an e-mail alias and sent messages back and forth between their virtual communities to develop a living and interactive historical narrative which explored different aspects of life in the Middle Ages. Topics that students explored included treachery and intrigue in medieval politics, the role of women in medieval society and the tension between pagan and emerging Christian belief systems in the Middle Ages.

Structuring the Interactions

The original vision for the project was to create a kind of multi-user domain (MUD) using a beta version of an e-mail package being developed by the British Columbia Ministry of Education. The software, known as OnRamp, was designed for use in a Macintosh environment and supported the inclusion of sounds and graphics along with e-mail messages. A sophisticated drag and drop addressing...
system made the system very easy for students and novice users to use. We discovered very early in the life of the project that we would not be able to achieve our intention of guiding the middle school students’ learning about the Middle Ages through involving them in a carefully crafted storyline. We discovered there is a strong incompatibility between predetermined educational outcomes and the kind of free-flowing dialogue and plot twists that characterize a living interactive story created via group interaction. With more than 30 individuals involved in the interactive dialogue, the task of maintaining a coherent storyline proved to be impossible. The combinations and permutations of different individuals sending messages back and forth was so great that it proved impossible to manage the overall plot that was to give structure to the interaction. What we opted for instead, was to put students at each setting into groups of four or five with each set of paired groupings having their own storyline and themes. Thus, each group of four or five students from the middle school interacted with a similarly sized group at the university.

**Developing Students’ Historical Understanding**

From a social studies perspective, one of the goals of the project was to help the middle school students develop what social studies researchers refer to as “historical understanding” (Downey & Levstik, 1989). Such an understanding involves recognizing that people living in time periods other than our own, usually had a different set of material resources, values, customs and beliefs than those which characterize our own time period. For example, the following segment of e-mail correspondence between Jordan Tinney, in his role as King Arthur, and a middle school student who was involved in the project, reflects a distinct lack of historical understanding on the part of the student.

**King Arthur**: (Jordan Tinney)

Welcome to the Middle Ages. A time of Kings and a time of wizards.... I am King Arthur and I welcome you to the Court of Camelot. You have each been selected from a large group of people to join me in my court, and as such you will be given a room in my castle. I would like you to decide what you would like placed in your room and I will have the servants attend to your every need.

**Student reply**

In my room I want to have a bed, a bookshelf, a Power PC like yours, a matter transporter pad, a replicator, a trap door that is in front of the door, and an electronic steel door with voice password. [Electronic mail, Bayside Middle School, November, 1994]

As indicated in the student’s reply there is a clear lack of understanding about what life was like in the Middle Ages. Some of the devices the student requests are from our own historical era and others, such as a matter transporter pad, do not even exist except in the realm of science fiction. Over the course of the project, the middle school students appeared to develop a richer and deeper understanding of what life may have been like in the Middle Ages.

**The Development of Voice**

A significant, but unintended outcome of the project was the way the interactive electronic storying allowed some of the middle school students to express themselves in a manner not usually available to them in a regular classroom setting. When, at the end of the project, the two groups removed their aliases and revealed who they “really” were, it turned out that the keenest middle school participants were girls who were normally very quiet and reserved in class settings. This finding is significant because although computer technologies are still perceived to be more of a male domain, in this case, the technologies appeared to enhance and increase the educational involvement of a number of normally very reserved adolescent girls. What was especially startling about this discovery was the depth and sentiment of the involvement of the young female participants from the middle school. One of them, masked from gender based preconceptions through her genderless alias of “The Labyrinth” made particularly powerful contributions to her group’s interactive story. The following excerpt, although presented out of context, shows the creativity and depth of involvement that the project elicited from one of the girls.

**Dearest Vivien,**

If you seek haven you may come to my castle to the east of Camelot... Journey to the top of the mountain and speak my name three times. I will appear and take you to my castle. I have offered Eleanor and Piedmont the same offer, and if you know of any others who need a safe haven, speak to me. You must trust them completely before you offer them haven. I will be away for the next ten days on a mission which I will tell you about when I return. I sincerely hope that nothing fatal happens to Camelot or UVicshire, for I know many have seen visions and felt the evil coming upon us. Lord Dudley is angry and mightier than he appears.

If life is so dear or peace so sweet, is it to be purchased at the price of chains and slavery? Forbid it, Almighty God! I know not what course others may take; but as for me, give me liberty or give me death.

**Signed Labyrinth** [Electronic mail, Bayside Middle School, March 1995]
That this e-mail based project was able to allow for the involvement of the girls in this manner points to some interesting research directions for those who study the gendered dimensions of computing. Pipher's (1995) recent work on the drop in self-esteem experienced by adolescent girls points to the importance of voice and self expression for teenaged girls. Whether the use of computer technologies and e-mail exchanges such as the one described here can promote positive self image for adolescent females is an important research question that needs further investigation.

What Was Learned From The Camelot Project

The Camelot Project provided evidence of the strong potential that electronic exchanges have for teaching and learning. Over the duration of the project, the middle school students' responses indicated a growth in understanding of the subject area even though content was explored through imaginary and fictional settings. As a medium for involving students in their learning, electronic mail appeared to offer a number of girls opportunities to express themselves in a manner not normally available to them in regular classroom interactions.

Managing Courses Through Telecommunications

Telecommunications was used as a tool to manage three different courses for preservice mathematics teachers - a technology course, a mathematics methods course, and a mathematics content course. Although very different in focus, each course had a World Wide Web home page which included a course syllabus, readings, assignments, and links to Internet resources useful for that particular course. Use of these resources varied widely due to the varying nature of the courses and the extent to which technology was a course focus.

The Technology Course

The technology course began with a three week instructional segment on the use of the Internet, e-mail, and web page construction using the Hypertext Markup Language (HTML). By the end of their first week in the course students were required to send an e-mail message to someone and to reply to any message they received. They were also to choose a listserv of interest to them, sign up, and participate in it.

Students' first major assignment was an on-going assignment involving construction and regular updates of their own home page, which was then linked to the course home page. Students were required to include appropriate links of their choice to a variety of educational resources in predefined categories. Required resources included:

- a source for lesson plans useful in teaching their subjects
- a source for shareware/freeware which could be downloaded
- a resource such as a database or graphics
- their favorite search engine
- an electronic journal that would be a useful resource for them as teachers
- a company/products
- information available through the Internet that could be used in a class project or problem solving activity.

Home pages could be further personalized by including color and graphics and any additional links of interest to the student.

All students were expected to participate at least weekly in a course newsgroup accessible from the course home page. The first assignment for the newsgroup was to sign in and introduce themselves to others. In subsequent weeks students were expected to comment on reading assignments or respond to questions posted for discussion purposes. A log was kept of all postings to the newsgroups.

Course readings were links from a readings page to appropriate articles or resources selected to coordinate with the current topic. Some were links to resources at other locations throughout the world, while others were links to pages assembled by the course instructor.

Assignments were also managed via the Internet. Descriptions and grading criteria were given on an assignments page. Assignments consisted of preparing classroom activities utilizing the following applications:

- Spreadsheet or database
- Geometer's Sketchpad
- A graphics package of their choice
- HyperCard
- A symbol manipulator, graphing utility, or graphing calculator.

Assignments were sent to the instructor as e-mail attachments. Feedback from the teacher was also sent to the students as an e-mail message.

The Mathematics Methods Course

The mathematics methods course began, like the technology course, with an instructional segment on use of the Internet. However, as technology was not the focus of this course, only one week of instruction was given on use of the Internet and HTML. All but one student entering the course were already using e-mail, so no class time was devoted to this topic.

As with the technology course, the first major assignment was constructing a personal home page, with updates throughout the semester to add links and resources to the page. Required resources were the same as those required in the technology course. Again, all home pages were linked to the class home page and readings consisted of both links to teacher generated pages and other resources on the World Wide Web.

By contrast, class communication for this course was conducted via a class mailing list. There was no direct requirement to participate in discussions through the class.
list, but students could use this list as a convenient way of disseminating information to other students in the class.

Assignments for the course were described on the course home page and primarily involved developing teaching materials for use in the practicum the following semester. No assignment other than the construction of a personal home page directly required students to use technology. All students were required to share the materials they had developed with other students. Many chose to do this using technology. Students' most frequent use of the course mailing list was for this purpose. Feedback for any assignments submitted electronically to the instructor was by personal e-mail messages to the student.

The Geometry Course
The mathematics course was a traditional third year geometry course, focusing on axioms, proofs and geometric relationships. Instruction focused on the mathematical content. No direct instruction on the Internet was provided, but course materials and related resources were provided through a course home page. The software program, Geometer's Sketchpad, was frequently used for both instruction and student assignments.

E-mail accounts were provided to enable students to submit assignments completed with Geometer’s Sketchpad electronically. A course mailing list was also available, but was used very little by the students. Most telecommunications use was limited to submission of assignments or asking questions of the instructor.

Findings Related to the Three Groups
In course end surveys, students rated exposure to the Internet, e-mail, and making personal home pages among the most useful topics in the technology course and the math methods course. Not only did computer use increase for course related work, but students also reported an average of five hours/week of computer use unrelated to the courses. The geometry course, by contrast, made little mention of the Internet as playing an important role in the course. Although the students did appreciate the benefits of technology, they focused on the mathematical content rather than the technology tools of the course.

All three groups appreciated the ability to communicate and update course materials on the WWW. The ease of editing and changing web pages allowed announcements, modifications, or additions to be made as needed. Record keeping and management of assignments was enhanced as all e-mail messages and attachments were automatically logged and saved. Comments could be easily typed in an e-mail message while marking the assignments and the length and detail of the feedback to students increased.

Drawbacks to electronic transmission of assignments were also noticed. In the technology and geometry courses, attachments worked very well, as students were completing assignments using a common software package. However, in the math methods course students were mainly using word processing to complete assignments. Assignments were not submitted in a standard format using a standard package, and often there were difficulties retrieving and reading the assignments. Students frequently had to resubmit assignments as text files. This limited the ability to include graphics, formatting, and other enhancements. Some students chose to resubmit assignments by printing them out. If assignments are to be submitted electronically, guidelines need to be established early to define acceptable formats for submission to avoid student frustration.

E-mail increased teacher-student communication in all three courses. Many students took the opportunity to write the instructor to ask questions, comment on the assignments or courses in general. The Usenet group was less effective for mass communication than the mailing lists, as most students participated only as a class requirement and did not take the time to read comments posted by others in the class. Mailing lists were preferred by students, as they could check their e-mail from home without needing to use a browser.

Using the Internet to manage a course allows students to learn valuable skills through experience. Confidence increases because skills are continually reinforced, and they transfer more easily to other tasks. As the Internet continues to grow, more resources will be available and teachers and students alike can benefit from improved access to more current resources and the flexibility and efficiency offered by the Internet.

At the University of Central Florida a group of faculty members was frustrated by the limited number of contacts we typically had with each student teacher. The reasons for this included budgetary restrictions on travel to each school site, the number of students supervised, and the time available for supervision. A review of literature suggested that there might be a solution to our frustration right at our fingertips - when seated at our computers, that is. Electronic mail could be used to establish and maintain communication between student teachers and university professors (Casey, 1994; Casey & Vogt, 1994; Hoover, 1994; Lowe, 1993; Thompson & Hamilton, 1991).

To facilitate the transition of student teachers to experienced professionals, Teacher Net (Casey, 1994) in California and Dial-a-Teacher (Lowe, 1993) in Texas were implemented. Both were computer networks that used electronic mail (e-mail) to provide contact and support between student teachers and education professors. This idea of a 911 for student teachers was very appealing to professors seeking ways to improve student teacher morale and confidence (Lowe, 1993).

In the fall semester of 1996 a group of junior and senior student teachers at The University of Central Florida was asked to use the university-wide e-mail system, called Pegasus, to keep in contact with the college coordinators who would supervise their internships. The University had just begun a more active use of its e-mail system, striving to have a "paperless" system of communication. The faculty involved were all familiar users of the system, having been introduced to e-mail and its uses through professional development activities. The students, however, were at various levels of familiarity with e-mail.

How Email is Used

Every student teacher has a variety of reports and an application to complete prior to and during the internship period. In this pilot project these reports were e-mailed to the college coordinator. For example, first day reports, daily schedules, first impression papers and the reflection journal/continuous log were e-mailed regularly to the college coordinator. These documents could be saved, printed, and responded to immediately. The college coordinator no longer had to wait for the next visit to the site school to review these documents.

Reflection Journals/Continuous Logs

The use of e-mail has been most successful with the reflection journal/continuous log. Previously, some of the journal/log entries seemed to be written the night before the due date. The reflections often lacked depth or true feeling. Now, the college coordinator receives weekly, and in some cases daily, e-mail messages which reflect greater credibility and opportune reactions. A response to the reflections can be given immediately. Responses could include strategies for improvement, ideas for content enhancement, or approaches to classroom management.

Communication with Supervising Teachers

College coordinators could also use e-mail to communicate with the supervising teachers. Prior to accepting a student teacher, supervising teachers are required by the state of Florida to complete clinical supervision training. This shared responsibility gives the college coordinator more time to work with the school on curriculum development, technology implementation, or other projects. E-mail was a very efficient way to keep in touch during the...
supervision process and to share information related to the other projects. Some of the e-mail communication included a listing of possible Internet sites and announcements of university workshops and presentations.

What We Are Learning

We have learned that there are advantages and disadvantages to using e-mail with student teachers. The advantages of using e-mail for journals and other forms of communication are numerous. Both students and college coordinators attest to the ease over the traditional forms of telephone and regular mail. The junior year student teachers are usually on campus only two or three days per week so students feel it is easier to contact the college coordinator using e-mail. When college coordinators are available, their schedules do not usually coincide with the student teacher’s for personal consultation. With teaching loads being two to four classes at the university, office hours are usually at times when student teachers are in the public schools.

When student teachers were surveyed, they made the following comments about the advantages of using e-mail:

I don’t have to worry about how I’m going to get it (journal) to you since I’m not on campus very much. I like the fact that I HAVE to get used to using the Internet. Now I’m more willing to use e-mail to communicate with friends at other schools.

It is neat to talk about a problem on a given day and to have suggestions from you concerning an alternate approach to fixing classroom management or a particular teaching strategy.

It is good for me to organize my thoughts using Microsoft Works, use the spell-checker, and then copy/paste it to e-mail.

The disadvantages seem to be mostly centered around the problem of computer accessibility. The following are comments made about the disadvantages:

I have to remember to check my e-mail which I am not used to doing yet.

I don’t have the time to write about everything I do everyday I intern.

E-mail is always busy when I try to connect from my home computer.

Sometimes it’s hard to get online from off campus.

It’s a drag waiting in line to use a computer lab on campus.

A computer lab for interns only would be nice and make it more easily usable.

Conclusion

A professional teacher communicates in a timely manner with students, colleagues, and administration. As a result of this pilot project, it is our hope that these student teachers will consider clear, timely communication a top priority. This will enable them to comply with all deadlines for information exchange with the university during their student teaching and, it is hoped, that there will be some carry-over into their future careers.

While we have found both advantages and disadvantages to our use of e-mail, we need to improve the system in the following ways:

1. Provide a clear list of expectations concerning the e-mail process for the student teachers at the beginning of the internship (See E-mail Procedures for Internship I)
2. Provide a listing of alternative computer labs to enable the student teachers to solve the problem of accessibility
3. Distribute additional questionnaires to determine the suitability of the project both during and after the internship is completed
4. Expand the use of e-mail for communication between the college coordinators and the cooperating teachers
5. Encourage student teachers to use e-mail to communicate with other student teachers.

Using e-mail during student teaching allowed for success for all concerned. Problems with classroom management, lesson plans, subject matter, and teaching strategies could be addressed in a timely manner which resulted in the student teacher’s progression at a much faster and substantial rate. We look forward to a new semester with the improvements suggested.

Appendix: E-mail Procedures for Internship I

A professional teacher reflects upon/evaluates the lesson content, his/her delivery of instruction and the students’ responses, and revise/improves lessons as necessary. Student teachers will reflect on and discuss with their supervisors the effectiveness of their lessons, their presentation, and the student responses. They will then revise written lessons accordingly, and re-teach the lesson, if possible.

1. Communication with Mr. Gardner, Dr. Kassner and Dr. Scott-Kassner is an important part of your success in assuming the role of a professional. If you do not have access to a computer, problem solve so that you can use one at least twice a week (all public schools have computers).

2. E-mail addresses: jgardner@pegasus.cc.ucf.edu and kassnerk@aol.com

3. Phone numbers: Gardner 823-2864 (w) 629-8228 (h) and Kassner 823-6493 (w) 426-7134 (h)
4. You can copy word processing documents and paste into your e-mail.
5. Keep all hard copies for your portfolio.
6. Daily reflections should include lesson plans and reflections of how the class progressed. If you are reflecting on an observation, include an outline of the lesson and your evaluation of the teaching/learning process.
7. You will be asked to submit your schedule and data during the semester. You will be evaluated on how well you adhere to administrative/communication detail.
8. Format for e-mail is as follows: Student X, at School X, Week X, Day X.
9. Obtain the listing of other student teacher's e-mail addresses and communicate regularly. You will probably find that you are having similar concerns.
10. E-mails must be received at least weekly by the college coordinator.

1206 — Technology and Teacher Education Annual — 1997
The popularity of the Internet is exploding. The World Wide Web has literally opened the world to computer users with access to the Internet (Winner, 1995). The proverbial playing field is finally leveling off as K-12 students across the nation are gaining access to resources available on the Web.

Educators from around the state of Florida have attended workshops on “Creating Your Own Web Page” at the Center for Multimedia Research and Training which is operated by the Florida Department of Education and housed at the University of Central Florida. K-12 educators are customizing Web documents for classroom use (Quinlan, 1996). College and university faculty are creating Web documents to enhance their unique course requirements. In 1995, 600 four-year colleges in the United States had Web pages on the Internet (DeLoughry, 1995). Today the listing of faculty and students at the University of Central Florida alone who have Web pages is quickly approaching that number.

This paper will describe how the students in the College of Education at The University of Central Florida partnered with students at Altamonte Elementary, a K-5 school in Seminole County, Florida, to experience firsthand the role technology can play in school reform and to gain a global perspective through web publishing.

**Background**

The partnership between the elementary school and the college of education came about as the result of an Apple Partners in Education Grant, PIE-2, awarded in 1995. The grant was one of ten awarded to teacher training institutions and K-12 schools to enable educators to develop and implement innovative projects that incorporate Apple technology. Each site received a variety of technologies including the Power Macintosh LC 5200’s, Newton Message Pads, QuickTake cameras, color scanners and limited free time on eWorld, Apple’s online service. A variety of software was also donated. A team of five representatives from both sites joined educators from each of the ten partnerships at an Apple-hosted two week professional development retreat in California. Teams tackled issues ranging from using computers as tools to support restructuring efforts to modeling ways to integrate technology into student-centered learning experiences.

**Elementary School Partner**

During the 1995-96 school year, the elementary school began implementing a major restructuring of their K-5 program to prepare all students to become successful adults, while realizing the necessity of meeting the developmental ability levels of a culturally diverse population. Learning communities were created. One community, called the Vision Center, was comprised of 120 third, fourth and fifth grade students combined in multi-age classes to create a “school within a school.” The students rotated among four teachers who specialized in math, science, language arts, and technology. One classroom became a technology lab with sixteen LC 5200’s provided by the PIE-2 grant. During the first year, several major technology projects were completed including an interactive map of the central Florida area and electronic field trips across the United States.

Wanting to incorporate technology into all areas of the curriculum, the hardware was reconfigured during the second year of the grant. Four computers were placed in each classroom and the 120 students were divided into two groups of 60 multi-age students. Each group of third, fourth and fifth grade students rotated between two teachers each day; one teacher for math and science and a second teacher for language arts and social studies.

**University Partner**

The college of education had been making a concerted effort to incorporate technology into all of its classes since a stand-alone technology course was dropped from the undergraduate program in the early 1990’s. The hardware received from the Apple PIE-2 grant was placed in a Curriculum Materials Center, then moved to a computer lab for college of education students. In the first general
methods class, Teaching Strategies I, students are introduced to E-mail, the Internet, a grade management program and HyperStudio.

During the 1995-96 school year students in a Teaching Strategies I class which met weekly on the elementary school campus, participated in a field experience in the Vision Center helping to create the interactive map and the electronic field trips. The joint project for the second year of the grant is the creation of a home page.

Training and Software

The classroom teachers and the university students were provided with training to use Claris Home Page, a software program which allows the user to develop customized web pages without having to learn Hypertext Markup Language (HTML). A site license was donated by the Claris Corporation to the university for training purposes.

The Process

Each university student was teamed with four intermediate students, a Dream Team, to help create the home page for the elementary school. The Dream Teams met throughout the semester to research Internet sites, to critique previously created HyperStudio stacks for inclusion on the home page, to storyboard ideas, and to help create the home page. In addition, each university student was required to create a personal home page as a course requirement.

Goals of the Experience

A major goal of the partnership between the College of Education and the Vision Center of helping students and teachers collaborate on technology projects is being realized. Teachers, professors, university students, and elementary students are sharing the roles of learner and coach. The motto “each one teach one” is lived day by day.

A second goal of the project was to introduce the university and elementary students to the Internet in a meaningful way and to have them experience how Web sites are created. Each Dream Team learned how to plan, design, build and publish its own Web site. The Web pages are colorful and exciting, and contain valuable information. Publishing allowed the Dream Teams to put their ideas and interests in front of a global audience. The students’ awareness of this became dramatically real during a class when the Vision Center students were participating in peer editing of some HyperStudio stacks to include on the home page. When the author of the stack being edited was asked if she wished to make the suggested correction, she responded, “Absolutely, if the whole world is going to see it!” The Dream Teams learned that Web pages can be a bridge to new interests and new friends. The friends may be at a neighboring school or around the world.

1211
USING TELECOMMUNICATIONS TO AID REFLECTION IN PRESERVICE ELEMENTARY TEACHER EDUCATION

Jackie Stokes
Queensland University of Technology

The increased use of computers in schools has brought about new possibilities and new problems for teachers. Access to greater amounts of information, much of it electronically published, means that it is important for teachers to develop students' literacy skills. The skills of defining, locating, selecting, organizing and presenting information creatively can be facilitated by a range of presentation software. Various software packages have different capabilities which allow students to incorporate different media for expressing their understandings of the relationships between parts of the concepts they are exploring. As part of a unit of work investigating software for the curriculum, students at Queensland University of Technology (QUT) create a slideshow in KidPix to explore how this presentation software can be used to enhance student information processing skills in the elementary classroom. During this time they deconstruct slideshows created by primary students, and then correspond with them by e-mail, outlining their creation of a similar slideshow. The culmination of this interaction is the sending of the tertiary students' slideshows to the elementary students.

There is much literature about the role of teacher education in preparing students for the use of information technology in elementary classrooms (Downes, 1993; Handler, 1993; Oliver, 1994a; Wild, 1995). At QUT this has been addressed in the newly structured Bachelor of Education (Primary) course by the introduction of two units to develop skills and understandings of the uses of computers in the classroom, and in society in general. The foundations unit considers global issues involving technological progress and societal change whilst developing students' skills in the use of information technology. The second unit, which introduces students to software for the curriculum, is based around three 4-week modules. Students are then called on to reflect on the value of these 4-week modules in implementing the goals and objectives of the Department of Education, Queensland, (1995) Guidelines for the Use of Computers in Learning.

Creative Publishing with KidPix Studio

The Creative Publishing module is partially designed to introduce the students to the Macintosh operating system. Whilst approximately half of the computers in use in elementary classrooms in Queensland are Macintosh the majority of student laboratory work at QUT is on Windows machines. Although the two hardware platforms are becoming increasingly similar it is felt important that students be required to operate in both before they leave the university. The activity chosen for this experience is the creation of a slideshow in KidPix Studio which is significantly easier, at QUT, on Macintosh computers. However, the main focus of the activity is not on the technical aspects of working within the Macintosh environment, but on the information processing that the students go through in the construction of their presentation and the metacognitive aspects of planning, monitoring, evaluation and reflection.

It has been proposed that one reason that beginning teachers do not use computers in their classrooms is the lack of role models presented to them during their course.
The third week tutorial deals with adding sound, both in the form of sound files from the KidPix Studio CD and voice-overs. Students are expected to complete their slideshows for presentation at the next tutorial.

In the tutorial in week four students are to load one slide and discuss a design problem that they encountered and how they overcame this problem. In the workshop session students load their slideshows, run them continuously and evaluate the slideshows of their classmates.

Reflection

Reflection is an essential part of effective learning and teaching. It has been built into this module in a number of ways. Students reflect on their information processing when they discuss how decisions were made in their pair whilst writing to their school buddies. They reflect on design decisions and problem solving when they present to their peers in their oral. As part of their assessment, their reflection journal is to discuss how decision making took place within their pair, the value of the interaction with the school students, and how the use of KidPix Studio software enhanced information processing. They are also required to demonstrate how their experiences aided an understanding of the three readings (Pacey, 1993; Sallay & Naftel, 1996; Taylor & Stuhlmann, 1995) that formed the background for this module.

Further to this students are to show how activities such as they have undertaken in the creative publishing module can be used to implement the goals and objectives as outlined in the Guidelines document in the first section of their fourth assignment. This assignment is a synthesis of the lecture program, the tutorials and computer workshops, and the set readings.

Results

As with any undergraduate unit, the rate of success was varied. Although a strict timetable of activities was prescribed in the student handbook, this involved student interaction outside of class time. The short timespan of the activity meant that students had to establish these meeting times in their first week. Whilst it was possible to achieve well without adhering to the suggested timeframe, this meant that the experience was not as enjoyable as it could have been. For instance, students did not take opportunity to play—to investigate the capabilities of the software—in the first week. This learning to operate in the environment is an essential part of the learning strategy in engaging with any new software environment. These comments are taken from the student reflection documents accompanying their creative publishing slideshows.

Timeframe

A three week timeframe for the completion of a slideshow causes some problems. This is especially true when students do not sufficiently plan in their first week.

Structure of the Creative Publishing Module

The 4-week modules consist of an hour demonstration and an hour computer workshop each week. The demonstration is facilitated by use of a video projector. Students are required to spend up to nine additional hours per week on further activities associated with this unit. In the first week tutorial students are introduced to the software, the concept of a slideshow and examples of an effective animation and an ineffective animation. Students discuss the features of two elementary student slideshows in terms of the clarity of the purpose, the message conveyed, and the effectiveness of the animation sequence. Students build on this knowledge in their computer workshop session by deconstructing an elementary student’s slideshow using the same criteria by which their own will be assessed. After this the students are encouraged to play with both the KidPix and Moopies sections of the software.

This week is vital to successful time management of the project. Student pairs are to plan their slideshow together outside of class time. They need to work out which aspect of their topic can be presented in a slideshow format, what the purpose of the slideshow will be, and what message the slideshow will convey. They also need to decide what aspect of their presentation is best suited to an animation. Once these decisions are made they are then to e-mail their elementary school buddies telling them of the processes that they have been through and how the decisions were made. They are also to comment (favorably) on their buddy’s slideshow.

The second week tutorial is a demonstration of scanning images, image manipulation and animation techniques. Those students who are prepared, can create their animation in the computer workshop time. However, true to form, many pairs have not completed their planning at this stage. During the second week all slides and the animation sequence are to be completed.
However we did not have time to play. In the second week we were expected to dive straight in and create our animation.

**Attitude**

As with all things the attitude of the individual students had an enormous impact on how they enjoyed their experiences.

My partner came to grips with operating KidPix but I just sat there wondering when this whole KidPix experience would be over.

**Interaction with School Buddies**

The interaction with the school buddies cannot be too highly overrated. Having the elementary students' texts to deconstruct in the first week enabled the tertiary students to see the standard of work that is possible by elementary students of the age capable of completing the unit of work that is planned for the tertiary students. Having e-mail contact with these students was an added bonus. The quality of the exchange was not great. The tertiary students expected long replies to their initial responses but the logistics of including the contact within the elementary school when the use of *KidPix Studio* was no longer the main focus of the curriculum was difficult, as was getting elementary students to type long messages!

However, the tertiary students made three main comments about the interaction. First, they said that when they first deconstructed the student slideshows they were quite critical of them. (This criticism was confined to their comments about the interaction. First, they said that when expected long replies to their initial responses but the quality of the exchange was not great. The tertiary students contact with these students was an added bonus. The quality of the exchange was not great. The tertiary students expected long replies to their initial responses but the logistics of including the contact within the elementary school when the use of *KidPix Studio* was no longer the main focus of the curriculum was difficult, as was getting elementary students to type long messages!

Second, students said that the fact that they had a real audience to present to had spurred them on to produce more effective work than they would have purely for a piece of university assessment. Their understandings of the effective aspects of their buddies' slideshows and the fact that the buddies were going to view their work were constantly thought of by the students as they created their work. Third, students said that they were conscious of the younger students as they constructed the slideshow and composed their e-mail messages. It helped them to focus on the task.

At the time of this writing, the reflection documents that the students provided with their slideshows were limited in their acknowledgment of the ability of software such as *KidPix Studio* to enhance the information processing skills of students. Their evaluation comments related to Pacey's (1993) remarks on the use of different media as being applicable for ‘the video age child.’ However, explicit examples of how they made decisions to use different media in their slideshows as examples of this process were infrequent. One of the few pairs of students to discuss this, commented on the age of the students with whom they were corresponding and the aspects of those students’ slideshow that they had found most effective. They therefore decided to use visual aspects as the main focus of their slideshow with

**Building on Previous Knowledge**

Many aspects of this unit have built on the skills and knowledge developed in the foundations unit. An understanding of file format has been extended by the use of the scanner and graphics manipulation software. The necessity of naming disks and keeping track of files-in-process-of-creation and files-in-final-format and the necessity of making backups also builds on skills developed in the foundation module. The naming of disks has added significance when working in the Macintosh environment as students are quick to discover! Skills in the use of e-mail was extended in the communication with the elementary school students.

One disappointing feature was the lack of transfer of the need to reference from the foundations unit to the curriculum unit. This was a major skill and understanding, underpinning the work that the students undertook in the foundation unit. However very few students saw the need to reference the images that they scanned or to provide a reference list at the end of their slideshow. This will need to be incorporated into the teaching of the module in future.

**Learning From Peers**

Although the skills needed to construct a slideshow are demonstrated to the students and written in a manual for them, the translation of these modes into the construction of the slideshow often leads to errors of understanding. Students commented that having a partner with whom to work through problems was valuable as was the camaraderie that developed in the computer laboratory as the students worked together in their own time. Errors that often occurred were students trying to incorporate sound into their animations, trying to include wrongly formatted Moopies into a slideshow, trying to incorporate large graphics into a slide and the constant swapping of untitled disks!!

**Information Processing and *KidPix Studio***

The reflection documents that the students provided with their slideshows were limited in their acknowledgment of the ability of software such as *KidPix Studio* to enhance the information processing skills of students. Their evaluation comments related to Pacey’s (1993) remarks on the use of different media as being applicable for ‘the video age child.’ However, explicit examples of how they made decisions to use different media in their slideshows as examples of this process were infrequent. One of the few pairs of students to discuss this, commented on the age of the students with whom they were corresponding and the aspects of those students’ slideshow that they had found most effective. They therefore decided to use visual aspects as the main focus of their slideshow with
voice-overs, rather than written information, to deliver their message.

It was pleasing to note that students were able to interpret the experiences that they had in the creative publishing module in terms of the Department of Education, Queensland, (1995) *Guidelines for the Use of Computers in Learning*. Students were able to identify when activities that they had undertaken aided in learning about computers (e.g. in the adoption of file management strategies - Students will develop skills in information management, Department of Education, Queensland, p. 7) and when they were learning with computers as with the selection of appropriate material and use of language to convey their message to their identified audience (Students will use computers for a range of purposes, to communicate (using text, sound, images, numbers and combinations of these - Department of Education, Queensland, p. 6).

**Conclusions**

The reactions of the students to the creative publishing module have not all been favorable. Those students who prefer to read and regurgitate are challenged to adopt another learning style. Although the skills necessary for the completion of the slideshow are demonstrated to them, their application of these skills requires a great deal of self-directed learning to occur. The quality of the slideshows varied but all student slideshows have demonstrated student mastery of both KidPix Studio and the Macintosh platform, and some outstanding work has been achieved. In terms of addressing the metacognitive underpinnings of this unit, student reflection documents have revealed that the writing for three audiences, the discussion in pairs and the discussion with peers and elementary students, have all aided in their ability to monitor and evaluate their work and understandings. Students have demonstrated that they have understood how KidPix Studio can be used to support the elementary curriculum in an integrated curriculum approach.

**Acknowledgments**

The author wishes to acknowledge the co-operation of the staff and students at Roseville Public School, Sydney, NSW whose interaction added much to the dimensions of this project. In particular, thanks go to Adrienne Sallay, technology co-ordinator, for her brainstorming of the project and e-mail interaction, and to Rochelle Naftel, teacher librarian, for hours of loading student slideshows and the videotaping of student reactions.

ENHANCING THE PRESERVICE TEACHER EXPERIENCE THROUGH ELECTRONIC DISCUSSIONS

Susan M. Powers
Indiana State University
Karen M. Dutt-Doner
Indiana State University

As an experiment, an electronic newsgroup was introduced to three sections of a sophomore-level elementary education course during the Spring semester of 1996. The goal of the newsgroup was simply to introduce these students to different forms of information technology. Within two weeks, it became apparent that the newsgroup was fulfilling the above need of alternative communication. With student permission, the researchers began to save the messages for future content analysis. By the end of the semester, 66 students had made 856 postings and replies on the newsgroup. Five major themes emerged from the over 800 messages posted. Students used the newsgroup as a means to support each other either during stressful points in the semester, or with just general words of encouragement. This was a means to share teaching information and ideas — students would post ideas they gathered from other teachers, professional journals, or the Internet. The newsgroup was also used a great deal by students to reflect on their field experience in the elementary schools and to receive feedback from peers about performance in the field. Students also reported that they felt the newsgroup was a safe place to discuss controversial issues related to education. Finally, the students willingly used the newsgroup to discuss issues related to the class itself; issues such as the merit of various homework assignments or the timing of field experiences were openly discussed even though it was known that the instructor was a participant on the newsgroup.

With over 800 messages posted by the end of the semester, the researchers were pleased that the newsgroup had been so successful for a majority of the students. However, several issues remained to be resolved. First, not all students participated at all or to a great degree in the newsgroup. Their reasons ranged from a lack of interest to technical difficulties in using the newsgroup. In order to combat both issues, the decision was made to switch the newsgroup over to a listserv format for the following semester. The students reported being more comfortable with the use of their e-mail, thereby eliminating many of the technical difficulties. Additionally, with the listserv messages appearing directly in front of the students via e-mail, those students with a potential lack of interest might have their interest piqued when a message appears in front of them.

Second, and perhaps more important, it was unknown if the level of participation on the newsgroup was simply an aberration. The researchers wanted to know how to replicate, if not improve, the level of participation in the electronic discussion. Experience with other courses demonstrated a definite lack of interest on the part of the majority of students to participate. By determining the elements that made this listserv successful, the researchers might be able to develop a formula to ensure success on an ongoing basis in future elementary education courses, as well as throughout the school.

A listserv was instituted during the Fall, 1996 semester. By the end of that semester, approximately 680 messages had been posted by 56 individuals. Individual messages were again content-analyzed, as well as the reflections of the instructor over the course of the two semesters. The same five themes were again apparent. However, this group of students placed different emphases on these categories, as will be discussed below.

Themes
The same five themes emerged for each semester the electronic discussion was implemented. What is interesting for this study is not the particular themes themselves, but rather the differences in the way the issues were addressed by the two different cohorts of students.

Peer Support and Encouragement
In the first semester, a large number of the messages (approximately 18%) focused on students supporting each other in some form or fashion. The students using the listserv during Fall, 1996 posted far fewer messages that could be designated as peer support and encouragement.
(less than 8%), but when these messages appeared, they contained the same subthemes. There were a number of ways students utilized the newsgroup to ask for support and give support. First, students used the newsgroup as a way of communicating with classmates and professors to get answers to questions about course requirements, the National Teacher Exam, other courses and degree requirements. The newsgroup meant they did not have to wait until the next time class met to get needed answers. Related to degree requirements one student asked the following:

I was interested in getting a reading endorsement, but my counselor advised me against it. She said people are having a real hard time getting the classes that are required for it. I would really like to pursue this endorsement, do you have any hope?

Another student responded to this query with information as to why s/he was seeking the reading endorsement.

Second, students used the newsgroup as a way of sharing concerns, fears, and feelings in an effort to gain affirmation. One student put the following message on the newsgroup:

... a woman came and spoke to (one of my) classes from the career center today. She talked about some of the openings she was receiving from school districts...But then she started talking about alternate careers you could do with an Elementary Education degree. Now maybe I am wrong, but when I decided I wanted to be an elementary teacher I did it because it is a field I could get more than monetary rewards from. I thought this was quite strange because if we come to college for a particular degree, shouldn’t we look for jobs pertaining to the degree? ... Listening to her speak today really made me think about looking for a job. What are your opinions on the career center focusing on alternate career choices?

Even though the students may not have solutions to each problem or concern, the students begin to understand that they are not alone in their feelings. In this way, students used the discussion as a way to relieve stress and to support each other during stressful times in the semester. Students found the newsgroup to be a safe place to share their honest feelings. With time, they learned that it was also a place to find common ground. Additionally, the instructor was better able to monitor students’ feelings — some students appeared to be comfortable sharing things on the newsgroup even though they were not willing to share the same feelings with the same people out loud in class. Thus, students are given a forum in which they feel comfortable sharing things they would not otherwise.

Sharing Information with Each Other

Approximately 35% of the messages posted during the Spring of 1996 involved students sharing ideas or information about teaching with each other; an equivalent percentage was posted during the following semester. Students shared information about teaching magazines/books, teaching materials, teaching strategies, and effective teaching tips. Among the most popular topics were special needs children, classroom management issues, teaching tips for your classroom, and web sites of interest. In all cases it became apparent that students were sharing their ideas in order to help each other become better and support the professional development of each other. In some cases students simply used the newsgroup as a way to share information they had read or learned in another class.

Hey everyone! I was searching the Internet the other day and I read a neat idea that we could use in our own classrooms. Many children have trouble with fractions. As the teacher, you could have each student bring in some family pictures or cutouts of a magazine. Have the students examine the pictures and then give them a worksheet that asks some of the following questions: What fraction of the people have brown hair? blonde? red? are wearing striped shirts? jeans? are smiling? The questions can go on and on! You can be creative with them or make them straight forward. I thought this was an interesting and fun way for children to practice fractions. What do you think?

Students utilized the electronic discussion as a means to share ideas, elaborate on each other’s ideas, and integrate ideas into their own teaching philosophy. The students were also able to expand on the information shared in class. Instructors are limited in the amount of information that can be shared during class sessions. The newsgroups allowed for an opportunity to expand the amount of information that can be shared related to course topics. It became clear that students were trying to make sense of what kind of teachers they wanted to be. Even more so, they began to understand that their teaching practices needed to be linked to their beliefs about teaching.

Reflecting on the Field Experience

Approximately 20% of the messages posted to the discussion each semester related to the field experiences students completed in local professional development school sites. The field experience assignments included observation tasks, as well as teaching three lesson plans. Students were assigned to a classroom in pairs and teaching included team as well as individual lessons.

Each semester, students indicate that the field experience is one of the most beneficial. At the same time, it is one of the most anxiety-laden ones for them, too. While there is always time for debriefing and reflecting about the
field experience during class time, there can never really be enough of it.“Sharing of experiences” often happens after the fact instead of immediately following the experience. Many times situations experienced in the field have such an influence on the students that they are eager to share them right away and the electronic discussion provided a vehicle for such immediacy. Some students shared good as well as bad experiences. One student wrote provided a vehicle for such immediacy. Some students share them right away and the electronic discussion such an influence on the students that they are eager to

One of my lessons that I taught started out well but ended in disaster!!! The lesson was on how to count to 10 in Japanese. ... Like I said, it started out good ... Then after we learned the numbers and their symbols I put them into groups of two by distributing cards... After they got into their groups it was all down hill!!! I felt like I had no control at all. After I was done... I started to leave. Joan, the teacher, walked me out and started talking to me. Then I started crying. Joan made me feel so much better. She asked me what I would have done differently and I told her. Her eyes got big and a smile came on her face and she said “you have grown today and because of today you are going to be a better teacher.” I was amazed!! The next day I did another Japan unit and we had to discuss what we had learned so far about Japan. 4 out of the 8 things that they said they had learned were from that one lesson that I thought I had bombed. So even if you mess up a lesson - look at it in a positive way and learn from it.

A student responded in the following: I’m glad to see that I wasn’t the only one who felt the same way you did. I didn’t really think that my lesson was a disaster, but I did feel really uncomfortable when I was explaining to the children the directions to the lesson that I was about to teach. Just when I was about finished, my partner and the teacher were lost on what the children were supposed to do. So, the teacher corrected me and did I feel like the idiot! But after all, what is this field experience suppose to be about anyway! LEARNING FROM YOUR MISTAKES!!! Thanks for sharing your story.

What is so interesting about these messages is that students are willing to share negative experiences and that students responded to each other in very sympathetic, caring ways. Students seem to be more willing to share these types of stories on the newsgroup than in class. Once again, the students are learning to support each other as they learn and make mistakes. The responses allow students to see things with different perspectives.

The key difference between messages posted during the two different semesters related to the depth of discussion that took place. The messages posted above where completed during the Spring, 1996 semester. Students engaged in far more analysis of the teaching and reflection of their next progressive steps. Conversely, messages posted during the Fall semester, 1996 were more cursory and less introspective.

I experience with my teacher at Dixie Bee has been great so far. The only problem I have is the way they departmentalize. I usually observe in the morning. The only problem is Mrs. Hicks is teaching someone else’s classes in the morning. So, I only have limited time with her students. I am trying to make time to observe in the afternoon, so I can become better acquainted with the students. I went to Dixie Bee in the afternoon last Wednesday, and I had the opportunity to help one of the students take a test. When I came back on Thursday, Mrs. Hicks asked him if he had anything to say to me. He told me thank you because he received an ‘A-‘ and shook my hand. I thought that was really polite for a fifth grader.

The students are able to share their frustrations with their field assignments, their enthusiasm for what they get to do, as well as reporting some of their experiences. However, what did not occur was student reflection on their personal performance. They were more apt to report on the performance of those they observed.

Debating Controversial Issues

During the first use of electronic discussion, there were approximately 60 messages on the newsgroup in which the students debated educational issues such as: inclusion, using the Internet to teach, teachers that are too physical with their students, showing videos in your classroom, open classrooms, and home education. This theme became the dominant theme during the second cohort’s use of electronic discussion (slightly less than half of the messages) discussing issues such as: sexual harassment among elementary school children, corporal punishment, abortion, elections, and drinking among school personnel. Many of the debates began by a student having read or heard something and then posting the issue on the newsgroup. For the students during the fall semester, most of the issues were first raised in the popular press. More often than not, students responded back with a variety of perspectives. A small excerpt of the sexual harassment issue follows: Did anybody hear about the six year old boy from Lexington, NC? He kissed a playmate on the cheek and the administration called it sexual harassment! The boy was placed in a type of detention, he was at school all day but didn’t participate. Does anyone else think this is absolutely crazy? A six year old doesn’t even know what sexual harassment is! Kids that age still do not know when to and not to display affection and who they should or
shouldn’t display it to. I think the administration should have taken different tactics. This might go along with our future discussion about discipline with dignity.

One such response was:
I totally agree. A six year old is not going to think that kissing a girl is wrong. They usually get oohs and ahhs from parents and others whenever that happens. I always thought it was cute because usually six year olds think those of the opposite sex are icky.

With this particular issue, students did not disagree with each other, but were able to build on each others’ ideas, debate the issue from a knowledgeable standpoint, and offer multiple perspectives. Other issues, such as election-related topics and the abortion topic elicited more disagreement, although these were not necessarily counter-productive. Even though not all students participated in the debate, they had the opportunity to learn about an educational issue that was never discussed in class. Thus, the learning that takes place during a semester can be extended through discussions on the newsgroup. All students involved in the debate leave with a better understanding of the issue because they have opened up their ideas to discussion.

Discussing the Course

One of the things we learned quickly is that if you empower students with a vehicle of communication, students will use it. We learned that the newsgroup was a safe place where students felt comfortable sharing positive feedback as well as criticisms about the course and how it was progressing. The instructor encouraged students to share their feedback about class sessions, course readings, class assignments, etc. on the newsgroup. Any feedback that could be given as the course was moving along could be helpful in modifying the course. During both semester, students shared at least 7% of messages on the electronic discussion about the course and class sessions. In most cases, students would comment about particularly impacting activities, videos, or class discussions. Other students commented on a simulation assignment the students completed called Creating and Maintaining a Positive Learning Environment.

...it was a great sense of accomplishment to get the simulations done. I learned so much from the simulations. I feel like I am really getting into my major alot more than last semester.... I really had fun working with my group also. Everyone had great ideas which made the project more exciting. I’m glad that we didn’t have to do this project by ourselves, because I think it would have taken me forever to get it done. I feel a lot more confident in what I want to do for the rest of my life after doing this project.

The instructor can have a better sense of the impact of an assignment when students provide feedback. Students also have the opportunity to synthesize what it is they learned from an activity.

There were a number of messages that the students put on the newsgroup to generally evaluate their experience in the course. These messages tended to be on the positive side—we can understand why the students would not want to put their names to negative comments about the course. These comments proved invaluable for the instructor because she could bring an issue posted on the newsgroup to the whole class. Students, in turn, felt their concerns were addressed throughout the semester.

Conclusions

It is clear from our data that an electronic discussion provides a vehicle for teaching and learning that may not be possible to achieve in the classroom setting. The students who actively participated in the discussions flourished and grew through their discussions. However, a major focus of the research was not only to determine how the newsgroup was used, but also to determine how such positive results could be continued and built upon each semester. By switching to a listserv accessed through e-mail from the newsgroup accessed through the World-Wide Web, many of the technical issues were solved for the students. Students during the second semester of use never reported an inability to access the discussion information. However, the hope that by placing the discussion directly in front of them by using e-mail only worked to the degree that the student was an active e-mail user. For example, those students who used e-mail for more than the electronic discussion (i.e. talked to friends, other faculty members, other classmates, etc.) were more apt to check their mail on a regular basis and therefore see the listserv messages. Approximately five to ten e-mail messages accumulated per day on the listserv - manageable if the person checked e-mail multiple times per week. However, for those students who checked their e-mail less than once a week, the resulting backlog of messages could be discouraging. Therefore, although technical issues were resolved, the issue of how to inspire the desire to regularly participate in the listserv still remained.

Second, the sheer number of messages posted from the second cohort was substantially fewer than the first electronic discussion (using the newsgroup), although with about the same number of students participating. Messages in the theme category of controversial issues sparked a great deal of interest and debate among students, more so than the previous semester; however, that could be attributable to the attention paid to most of these issues in the news media. Other themes received less attention, or at
least more cursory attention, most notably discussion about field experiences and peer support/encouragement. Upon reflection, several factors are thought to have possibly contributed to this: first, the instructor had several life experiences which necessitated her absence from the class for periods of time (including marriage and deaths in the family); and second, two of the three class sections never seemed to bond as cohesive groups, perhaps affecting their willingness to discuss issues whether electronically or face-to-face. It is known that these two sections have a large number of off-campus students enrolled and these students have been vocal in their difficulty and inconvenience in accessing e-mail, and therefore the listserv. Further analysis would be needed to determine what other demographic factors might have impacted online discussion, but is beyond the scope of this paper.

In conclusion, the researchers continue to be pleased with the use and potential of electronic discussion as a means to enhance to the experiences of preservice teachers. The electronic discussion provide a window on student thought and discussion that may not be available through more traditional instruction. Removing technical boundaries is apparently helpful, but not enough to encourage enhanced discussions. However, the issue of how to facilitate and ensure that such vital discussion occurs for all, or at least the vast majority of students, remains.

USING THE INTERNET TO UNITE STUDENT TEACHING AND TEACHER EDUCATION

Mark Roddy
Seattle University

In this paper, some of the challenges associated with and criticisms leveled against teacher education are introduced and discussed. Specifically, the perceived disconnection between theory and practice during the student teaching phase of the teacher education program is briefly examined both in the literature and in the specific context of teacher education as it is conducted in the Master in Teaching program at Seattle University. In this program, an electronic mailing list has been employed for the past two years to facilitate communication between students, faculty, and others concerned with the task of teacher education. Assuming a framework of constructivist learning theory, the power of the mailing list to reconnect student teachers with the learning community they have established is investigated. An example of this process, drawn from an archive of messages addressed to the list, is offered. The conclusion is that the mailing list can serve as a useful tool, allowing students to construct their understanding in concert with the larger community of learners in the teacher education program.

The Context

Teaching is a difficult and demanding profession. The process of transforming a concept so that individuals within a diverse group construct understanding that will persist and enable the learner to solve the problems encountered in life, is profoundly complex. Each student arrives at the classroom with a different constellation of abilities, interests, background experiences, and learning needs. Yet teachers are charged with the responsibility for enabling all students to learn. In order to accomplish this they must manage many tasks simultaneously. At the macro level, they must construct a social, academic, and emotional environment where a group of individuals is likely to construct the target understanding. At the micro level, they must take attendance, call parents, help children put on their boots, accommodate frequent interruptions, and deal with short supplies and things that break. Good teachers are extraordinary people. Feiman-Nemser and Buchmann (1987) put it this way: “Teaching, in sum, requires knowledge of subject matter, persons, and pedagogy. It demands principled and strategic thinking about ends, means, and their consequences. Most important, it requires interactive skills and serious commitment to foster student learning” (pp. 256-257).

Learning to teach is no less complicated or demanding than teaching itself. At Seattle University, in the Department of Teacher Education, the conceptual framework that guides the Master in Teaching program states that: “The teacher is an ethical, knowledgeable, and reflective decision-maker who teaches all learners to function effectively in a global and pluralistic society.” The task that is joined each day by this department and more than a thousand others across the country is to enable people with an increasingly diverse set of qualifications, expectations, and experiences, to become teachers.

The program at Seattle University enrolls fifty graduate students in the Fall quarter and fifty more in the Spring. Each group proceeds through the four-quarter program as a very tightly knit cohort. The courses are primarily extensive (12 credit), integrated, and team taught. They include periodic forays into the schools and encourage reflection on the integration of experience and theory in the context of the learning communities that are formed within the cohort. While the program is unique in many ways in terms of its structure and content (see Roddy, 1996), it shares with most other teacher education programs around the country an extended period of student teaching. The student teaching takes place during the third quarter of the program, rather than the fourth, and is followed by a quarter of research and reflection, but it is, in other ways, a typical student teaching assignment.

The Problem

From a constructivist point of view, this period of student teaching is a uniquely powerful opportunity to construct understanding about teaching. Student teachers have richly textured and detailed impressions, built up over at least 16 years of experience, of what happens in schools. Indeed, one of the criticisms leveled against student
teaching is that it is not sufficient to overcome this "apprenticeship of observation" (Lortie, 1975). On the other hand, they have been introduced during the foundations and methods courses (the first two quarters of the program) to a host of ideas about students, learning, teaching, and schools—ideas that may contradict many of their ideas and impressions. Given the array of concepts, generalizations, and models to which student teachers have been exposed, the potential for the construction of meaning as a result of experience, communication, and reflection is great. Ideally, student teachers have built their understanding of the best of what research has to offer concerning effective methods of teaching. They now have an opportunity to try these notions out in a real classroom under the guidance of an experienced teacher. Their motivation to learn about teaching and to succeed in the classroom is high. Yet student teaching is roundly criticized as being ineffectual (e.g., Feiman-Nemser & Buchmann, 1987; Goodlad, 1990; Zeichner, 1981).

Goodlad (1991), in his research on teacher education, points out the separation between the theory developed in the university and the reality student teachers encounter in the schools. Students who have studied cooperative learning, for example, and who are frustrated in their attempts to implement cooperative groups because they may not recognize the proper conditions for the application of this technique, may conclude, unless they are well coached by their cooperating teacher, that cooperative learning does not work and that the theory is wrong. In the relative isolation of the K-12 classroom, deprived of the support of the learning community they have grown accustomed to in the university classroom, they revert to the understanding developed over their years as students—an understanding that is based not on research and models but on idiosyncratic experiences and hunches.

In situations such as this, the only readily available source of experience and assistance in the field setting is the cooperating teacher. As noted, however, by Richardson-Koehler (1988),

...concern has been expressed about their influence. Because cooperating teachers are more oriented toward the practical and particular rather than toward theory and generalizations, student teachers may not learn the more general principles from their experience that would allow them to adjust to different classroom situations (p. 28).

Richardson-Koehler goes on to point out that in her research, a participant observation study of fourteen elementary student teachers, the norms of the school culture related to individualism, egalitarianism, and learning from experience strongly affected the feedback offered to student teachers by their cooperating teachers. She states that student teachers concluded from their experiences that...each classroom and teacher is unique, that each teacher has to rely on trial and error, and that the criterion for success is 'what feels right to the individual teacher'. Thus, the student teachers were not exposed in the schools to a model of learning to teach that relied on rigorous analysis of teaching and collegiality (p. 33).

Other researchers have questioned the efficacy of student teaching that does not incorporate an intentional focus on the quality of the feedback offered to student teachers in the field.

Though many applied skills must ultimately be learned in practice, it is clear that unsupervised on-the-job experience is, in and of itself, insufficient to support teacher learning and teacher effectiveness, as it can lead as frequently to the adoption of regressive and ineffective methods as to the acquisition of appropriate strategies (Darling-Hammond, 1990).

Kennedy (1991) noted that, in general, cooperating teachers, because they are so close to the practical side of teaching, have difficulties relating specific instances to larger, more generative principles. Zeichner's (1981) earlier research drew similar conclusions, noting that by concentrating on how to teach, cooperating teachers often missed the opportunities to consider what to teach and why to teach it. University supervisors are said to be similarly ineffective, for different reasons, at raising the level of the conversation (Richardson-Koehler, 1988).

These are some of the general problems that surround student teaching. In Seattle University's Master in Teaching program, because of the tightly integrated and cohesive nature of the program, individuals become accustomed to the support of the learning community that develops through daily close association and shared challenges. They have employed and consciously followed the constructivist learning cycle again and again through experience, reflection, conversation, and revision of understanding. Once they are out in the field, however, they are no longer supported in this cycle. In the setting that is richest in the important factors that provide essential feedback and clues about the effectiveness of the decisions they make and the understanding they construct, they are largely deprived of the support that could help them formulate solid generalizable understanding.

Part of the Solution

Various researchers have recently described efforts to address this problem and to improve teacher education generally through the use of the Internet (Merseth, 1991; Roddy, 1996; Schlagal, Trathen, & Blanton, 1996; Thomas, Clift, & Sugimoto, 1996). At Seattle University, Master in Teaching students are given computer accounts and e-mail addresses as soon as they enter the program. At present, they are allowed to keep these accounts as they
begin their professional teaching careers. They have nearly full-time access to a computer classroom equipped with 32 Power Macintosh computers, all networked and connected to the Internet and the World Wide Web. At the beginning of the program they are introduced to telecommunications and to the Internet as a tool that can assist them in the teaching process.

Early in the first quarter of the program, they are invited to join a mailing list created for their cohort. The list is often joined by faculty members, support staff, and others concerned with the work and well being of the cohort (e.g., the program placement officer, the program secretary, an AmeriCorps volunteer who alerts students to service learning possibilities, etc.). The list, however, is rarely used to conduct university business. That is, unlike most instances in the literature (e.g., Thomas, Clift, & Sugimoto, 1996), faculty very seldom use the list to conduct course assignments, etc. Students, therefore, use the list in ways that make sense to them and in the rhythms that suit their needs.

The messages that have been addressed to the list have been reviewed, analyzed, and categorized in a preliminary fashion (Roddy, 1996) and are undergoing a more thorough analysis at present. The preliminary analysis, however, indicated eight broad areas of use. Of these, the messages that fit the category, substantive reflections, are of most import in this context. These messages often contain the threads of conversations that arise as a direct result of significant events in the field. Students describe their experiences, their frustrations, their thoughts and their questions. Other students and faculty members read these messages, consider them in light of their own understanding, and offer responses that sometimes serve to shed new light on the general meaning and implications of the events described. An example of a particular thread is given below.

The Whole Language Thread

In the Fall of 1995, students in the integrated 12 credit methods course (second quarter of the program) had been engaged by one of the professors in classroom discussions regarding the use of the “whole language” approach to reading. One of the students had encountered opposition to this approach in one of her field experiences and brought the issue up on the mailing list.

...I’ve heard several people say that whole language means that kids don’t learn phonics. Is that true?

Another student replied:

Interesting. I have been talking with my sister about my niece’s spelling. . . . She’s in 6th grade and she (plus several of her friends) still spells poorly - e.g., prity (pretty), fon (phone). My sister is concerned but teachers have been saying that ‘spelling will come later.’ When is later???? I don’t know if this...
Again, there were a number of replies. The conversation took another turn as a faculty member noted that there was a great deal of negative publicity surrounding public education at the time and urged students to consider a different view. She cited two references.

Finally the literacy instructor who had, in a sense, engendered the entire conversation but who had been out of town subsequently weighed in with a comment that seemed to bring the thread to a close.

"I do not question that it [the brand of direct instruction shown in the 20/20 segment] may be successful with some readers - we all know that any method will work with some children and a combination of methods seems to be most widely successful. However, I was distinctly uncomfortable with the finger-snapping, 'ready, here we go' routinizing of reading instruction. To say that it works where whole language has failed is a tired and simplistic argument. [Name] mistakes whole language for a 'program' when it is merely a philosophy about connecting reading instruction with — gee whiz — Real Reading. Within a whole language framework, I could see the application of direct instruction techniques . . . but the program does a tremendously uninformed disservice by — AGAIN — making it an either/or thing.

In this example we see a problem encountered in the field by a student. The student had a real need (to respond to parents) and was looking for guidance. In this case the guidance developed through the vehicle of the mailing list. The list offered a place to obtain more information, different points of view, related experiences, and reasoned judgments from colleagues and professionals in the field. It is important to note that the nature of the conversation that developed on the mailing list was different from that which might have taken place with a fellow student, a cooperating teacher, or even with a professor in the hallway. This conversation unfolded over almost two weeks. There was time for participants to consider, to reflect, to write, to revise, to read again, and to reformulate their own understanding in ways that would not otherwise have been possible.

**Conclusion**

One of the problems with teacher education as it is typically structured is the profound disconnection between theory and practice during the process of student teaching. Student teachers who have become used to learning through a cycle of experience, reflection, communication with others, and revision of understanding are suddenly on their own, deprived of the support to which they have become accustomed. When faced with an experience that requires action, they turn to their cooperating teacher for advice. In many cases, however, the cooperating teacher is so engrossed in the practical day-to-day art of running that particular classroom that he or she may not make the generalizations that facilitate the construction of a more powerful and generative understanding. The example given in the preceding pages illustrates the potential for an electronic mailing list to be used as a tool to reconnect the theory held by the larger academic community to the particulars of the daily experience in the classroom.

This tool is still rather crude and, at times, cumbersome. Not everyone wants to check e-mail on a daily basis, and the interface with the system is, at best, user neutral. Nevertheless, it is evolving. The World Wide Web page, with its greater visual appeal and ease of use, holds promise as a more friendly and useful means to the same end. Programs are appearing now that allow users to post and peruse messages in a much more intuitive fashion. Even in its present form, however, the electronic mailing list constitutes a powerful tool in the service of teacher education.

The professional world into which preservice teachers will enter will be tremendously influenced by the explosion of information, as well as the ever widening access to, and mindboggling capabilities presented by the Internet. Reformers who are focused on implementing the National Council for the Teaching of Mathematics (1989) Standards in Mathematics and the American Association for the Advancement of Science’s (1993) Benchmarks in Science are effectively using this electronic network to disseminate the many creative mathematics and science education ideas that talented teachers and others are developing across the nation. Schools are scrambling to provide their students with the advantages of travel within the information superhighway which has great potential for equalizing educational opportunities. Though the supply of computers is growing as indicated by a recent estimate of one computer for every 18.9 school children (Market Data Retrieval, 1992), teachers underutilize computers available in their schools (Marcinkiewicz, 1993/94). Additionally, school districts need counsel in how to enhance the use of electronic network resources through purchases of hardware and software. The potential of technology in our schools can only be realized if teachers “are skilled, competent, confident, and innovative in the educational use of computers” (Makrakis, 1991, p. 47). At the very least, school districts should be able to expect that newly prepared teachers will have expertise and practice in using the Internet and involving children in accessing the wealth of information available. However, one of the greatest challenges facing teacher educators is to present preservice teachers with state-of-the-art skills that they can apply, immediately, to their teaching practice. In order to provide for this invaluable experience, there is a need to build the knowledge base of both cooperating teachers and preservice teachers, and to identify immediate applications so that the use of this resource becomes as commonplace as the more traditional sources.

Description of InterNet Academy Project

The InterNet Academy Project was funded by a mini-grant from the SMART Project, an NSF technology training grant for teachers administered by the Rhode Island Department of Education. The total project provided for an InterNet Academy for elementary and secondary preservice teachers from the University of Rhode Island (URI), a school by school (elementary) thumbnail directory of online computers from which teachers could access e-mail and the Internet, and a series of summer NetShops for inservice teachers—particularly those who supervise URI student teachers.

The purpose of the InterNet Academy project was to enrich the computer capabilities of preservice and cooperating teachers, as well as of University supervisors, so that they can utilize electronic network resources in connecting with each other and locating and generating valuable teaching resources on the Internet. In order to accomplish this goal, there was a need to provide training and share information about computer facilities so that implementation could be immediate and school based, no matter where the preservice teachers do their student teaching.

Purpose of Study

The focus of this paper will be on the background, perceptions, and products of the 48 teacher participants from the summer NetShops. Upon acceptance to NetShop sessions, teachers were asked to fill out a Pre-Academy Survey which collected information regarding previous computer/technology experiences, sense of efficacy in computer and Internet usage, personal goals for the course, fears or reservations about computers, and perceived positive aspects of computers in schools. Teachers who took a full 3-session sequence evaluated the NetShop contents and wrote learning summaries which indicated what they gained as well as future implementation plans. Finally, all NetShop graduates were sent a Post-Academy Survey to ascertain personal and professional uses of their newly acquired skills and to determine future training needs. This follow-up was sent four months following the last training session.
NetShops

The InterNet Academy provided five week-long NetShops in the summer of 1996. The NetShops were team led by three elementary teachers trained as leaders by the Teachers in Technology component of the SMART grant. All three of these teachers had been supervising teachers for URI student teachers. The NetShops were conducted in the Macintosh Computer Lab of a local elementary school. Thus, NetShop participants were able to develop their knowledge and skills in an authentic environment which demonstrated the feasibility of realizing the computer and technology rich instruction which was being presented.

The Academy instructors, along with the university project directors, designed the NetShop contents as a series of short courses that could be taken for university credit. NetShop met for 12 hours (four sessions of three hours each). Teachers could take part in all or part of the series. Thus, teachers could join the Academy at their level of expertise and take as many as three consecutive sessions. A description of the NetShops follows:

NetShop 1: Use electronic networks to facilitate conversations on education topics. Online sharing of lesson plans, Internet resources, evaluations and other student/teacher related content. Locate useful teaching/learning resources on the Internet that will enhance student lessons. Learn how to use Netscape.

NetShop 2: Build on topics of NetShop 1. Organize online information in order to make it more useful. Create, organize and use bookmarks.

NetShop 3: Build on topics of previous NetShops. Investigate student and teacher online projects and listservs.

NetShop 4: Learn how to construct a web page.

NetShop 5: Learn how to use technology such as PowerPoint and HyperStudio to enhance presentation of information and provide a new medium for creative student projects.

Participants

Participants were recruited from all schools, statewide, which had URI student teachers. Priority for participation was given to teachers who have mentored student teachers. Of the 48 teachers who participated in the NetShops, 20 had served as cooperating teachers. Only about two-thirds of the participants took the course for university credit, even though the course fees were about $300 less than normal summer school fees for a three credit course. Thus, the course credit was not a great incentive for all teachers. All grade levels—K through 8—were represented, as well as eight resource teachers (e.g., library/media, ESL, Math, Speech). The overwhelming majority of participants were just beginning to use computers and only a few teachers signed up for the advanced applications sessions (NetShops 104 and 105); thus, the beginning sessions were repeated as subgroups during the advanced NetShops. The team teaching approach allowed the flexibility to make these adjustments.

Pre-Academy Survey

Twenty-nine of the 48 participants completed the pre-Academy survey on their use of technology, sense of efficacy in using computers and Internet usage, personal goals for the course, fears or reservations about computers, and perceived positive aspects of using computers in schools.

The questions for this survey were shaped by education literature. Teacher change literature posits that teachers’ beliefs must change in advance of lasting changes in practice (Richardson, 1990). Thus, a survey to tap into teacher beliefs about computers and technology was an important first step in developing the NetShop sessions. In addition, Marcinkiewicz (1993/94) found three variables which predict whether computers will be integrated into classroom use. First, a teacher’s sense of competence with computers leading to a motivation to pursue computer literacy to mastery was a powerful factor. Second, perceived relevance that computers are instrumental to improving instruction is strongly associated with adoption behavior. Third, the teachers’ innovativeness or willingness to change is strongly related to future integration of computers into their teaching and classroom.

Previous Experience

Teachers were asked to indicate whether they used any of a total of 19 technologies such as VCR’s and video cameras, computers and computer programs, and specific Internet and e-mail applications. Teachers’ experience with technology was relatively mixed. A few teachers had very limited experience with even the most commonplace of technologies such as VCR’s and video cameras. Responding teachers either used an IBM (33%) or a Macintosh (67%), but not both. Most of the computer use related to word processing (83%), with much less experience with applications such as graphics (28%) or spreadsheets (21%). Approximately half of the respondents had some experience with e-mail and the Internet. Less than one-third of the participants had experience with Netscape, the Internet access program used in the InterNet Academy.

Efficacy

The Pre-Academy Survey asked teachers to rate themselves on a 3-point scale (no doubt, need help, grave doubts) related to their sense of efficacy in using computer and Internet use. Efficacy is seen as the teachers’ perceived power to produce results or intended effects when using computers or other forms of technology. Generally, teachers were more confident in using computers than in using the Internet. Forty-one percent of the respondents indicated “grave doubts” about their ability to use the Internet, while only six of the respondents had no doubt of their ability in this area. Sixteen of the teachers responding indicated needing some help in using a computer and
seven reported having grave doubts as to their ability to use a computer. Not surprisingly, teachers who reported having no doubts about their ability to use computers or the Internet also had a great deal of experience with different technologies (e.g., VCRs, scanners, computers). Particularly interesting was the fact that some teachers had never used even some very commonplace technologies (e.g., five teachers had never used a VCR and 11 had never operated a video camera!).

**Personal Goals**

Participants were asked what their personal goals for taking the course were. The 29 respondents gave a total of 58 different reasons for taking the NetShops. These responses fell into four general categories: to develop basic skills, to expand skills, to use the Internet to teach and find resources, and to learn advanced applications. About a quarter of the responses related to wanting to start to learn about computers and the Internet. One teacher identified her goal as, “To become comfortable with using computers and to learn all about using the Internet and that I can be up with the times.” Another 26% of the responses related to expanding existing skills and knowledge, “to become a more efficient user of Netscape.” Forty-one percent of the stated goals related to learning to use the Internet to teach and find resources, “I would like to use the Internet to find lesson plans and teacher related materials.” Finally, only 9% of the responses indicated a desire to use advanced applications, “to be able to create a web page and to be able to effectively teach it to students.”

**Fears and Reservations About Computers**

Participants were asked what their greatest fears or reservations about computers were. In all, 33 different items were named in this area. These responses fell into four categories: lack of experience, worry about getting stuck or breaking the computer, concerns about the advisability of using computers, and those without fear. About a third of the concerns related to the teachers’ lack of experience, “My limited knowledge of them and my limited involvement with them, when it seems the rest of the world is all connected with them. Time I jumped on board!” Another third of the responses related to fear of getting stuck or breaking the computer, “I’m afraid I’ll ruin the computer somehow by forgetting to do something, or by doing something wrong.” Said another teacher, “Every time I use the computer, something goes wrong and it ends up taking more time and I don’t get the job done.” Another example of quotes in this area, “getting into a program and not being able to get out.” Some teachers (15% of the responses) took this question to relate to the larger question of whether we should be using computers and technology in classrooms to such a great extent. One teacher stated, “People will think that computers in the classroom will accomplish the impossible; computers are a poor substitute for good teachers and caring parents. Students will have to carefully evaluate all information they access online.” Finally, 12% of the responses indicated no fears or reservations.

**Positive Aspects of Educational Computer Use**

Teachers were asked to indicate, “What are some positive aspects about using computers for educational purposes?” Teachers offered more than one purpose resulting in a total of 60 responses. Reducing the categories was somewhat difficult due to the range of benefits cited. The largest groups (18% each) related to the ability to access an incredible amount of material from diverse sources (e.g., “…you can access current, up-to-date material on a wide variety of subjects”) and the use of computers as tools for teachers (e.g., “professional parent communication”) and children (e.g., “They serve as a wonderful tool in the classroom to support the writing process…”). The next most frequent responses (17% each) cited the potential for enrichment (e.g., “children becoming familiar with their world as a friendly neighbor”) and motivation (e.g., “They are highly motivational…”). Twelve percent of the benefits related to the need to develop computer literacy as a necessary life skill for the 21st Century (e.g., “New educational goals are all geared toward computer literacy…”). Finally, teachers saw the advantages of computers in working with special learning needs of children, (e.g., “Computer programs are available for all types of learners and students’ individual needs are better met.”) Only a couple of teachers said, “You tell me!” Thus, even before taking the NetShops, teachers perceived many different advantages of greater computer use in classrooms.

**NetShop Evaluations and Summaries**

After each NetShop, teachers were asked to evaluate their experience and to indicate how they would use what they learned in the future. NetShops facets were rated on a 5-point Likert scale (e.g., “I=No, Lousy! Boo!” to “5=A hearty yes! Great!”). Evaluations of the InterNet Academy were overwhelmingly positive. Teachers indicated that the objectives were clear, the topics useful and interesting, and the instructors were well prepared and knowledgeable. In the 10 separate categories, the ratings generally averaged between 4.5 and 5.0 out of the 5-point scale. Teachers found comfort in having fellow classroom teachers as instructors and having the workshop located in an elementary school. The instructors were able to relate specific school-based examples of uses of computers, e-mail, and the Internet.

Teachers who participated in the first three NetShops completed learning summaries in which they indicated what they learned and future plans for implementing computer and Internet use in their own classrooms in the coming year. In all, 21 teachers completed this assignment.
What They Learned

In terms of what they learned, there were 56 separate responses which generally fell into two categories: learning to use the computer and manage the specific programs such as Netscape and Eudora (61%), and utilizing the newly developed skills to use listservs and search engines to locate specific instructional information on the web (39%). Among the topics explored were math activities and lessons, information on natural disasters, dinosaur facts, and updates on the Iditarod race in Alaska.

Future Plans

Responses to how teachers planned to use what they learned in the future ranged from simply continuing to use electronic mail for personal use or for gathering information on curriculum topics, to fully developed projects for students using the Internet. Many worked on these projects during their Academy experience and set up bookmarks for themselves and their students to use on specific projects. There were 25 separate responses that can be divided into four categories. Eleven out of the 25 simply said they were going to use the research they conducted via the Internet to develop lessons and classroom activities. Seven planned to have students research topics on the Internet or use e-mail to communicate with others. Five responses indicated they planned to continue to use the Internet to search for teaching ideas and materials, and two teachers wanted to teach others, students and colleagues, some of what they had learned in the NetShops.

Post-Academy Survey

Surveys were sent to all participants of the InterNet Academy in order to ascertain whether the skills acquired during the Academy were utilized for personal and/or professional purposes during the school year. Teachers were asked to describe how the skills were used, and to provide information on further assistance or training required to enhance their Internet skills.

Eighteen participants responded to the survey. Three had purchased computers as a result of their newly developed interest in technology. All had used the knowledge and skills for either a personal or professional purpose. Five teachers had not yet used the Internet at school. Two said they had “just not gotten to it,” and three cited problems with their computer or the lack of a functioning modem or other online connection. With one exception, the other 13 teachers were using their new Internet skills for both personal and professional purposes. In terms of school use, teachers: created school and classroom homepages; investigated shipwrecks, Monarch butterflies, and sea turtles; hooked up with a geography contest and e-mail projects with students from many parts of the United States, Canada, Mexico and New Zealand; collected lesson plans and online math/science projects; set bookmarks for student use on yearly themes; joined lists such as Kidsphere; and started an Internet Club.

Assistance or Training

When asked to provide information as to what further assistance or training would be needed to enhance their Internet skills for either personal or professional purposes, teachers asked for more training on the Internet and on technology (e.g., scanning, creating web pages) in general. One teacher recommended that administrators be required to take the training “...so they would support our requests for computers in the school for faculty use!”. Others reported problems with the ability to access the Internet due to either software or hardware problems (some lost their e-mail account provided by the university at the end of the summer and are having difficulties getting new accounts either through the university or the State).

The statements of the teachers demonstrated a more sophisticated knowledge of computers and technology in that their interests were much more focused than those indicated by their goals listed in the Pre-Academy Survey. The following examples illustrate typical responses,

I would be interested in learning more about the process of searching the Web. The various search engines seem to have different protocols and, as a media specialist, I am particularly interested in successfully locating information. I need to learn how to narrow the search field so that I am not wasting time with a lot of useless hits.

What I need, like most people, is more time. I would like to see how teachers actually use the Internet with their students for lessons, beyond the class first researching themes.

...I think it would be helpful to learn about ways to integrate the computer into the classroom curriculum. What projects are others involved in? How is the computer time managed-both in the lab and with the one in the classroom? How are students (at the elementary level) using the Internet?

Conclusions

Sheingold and Hadley (1990) identified the development of teacher skills in educational computer use as a process requiring time, support and colleagues to work with in order for the technology to become integrated. The Academy provided these elements and clearly those who participated in the NetShops of the InterNet Academy found them useful. Many learned how to find their way around the Web and locate resources that could help them in their personal as well as professional life. Future InterNet Academies would best serve past and future participants by providing introductory NetShops, as was the case during the first InterNet Academy, as well as training that would model for teachers ways in which these
skills could be used in the classroom, and address some of the more practical, management issues. The use of highly trained classroom teachers as instructors and a real elementary computer lab as the setting were critical to the success of this project. By selecting cooperating teachers for the training, we have increased the likelihood of continued connections with the NetShop graduates as they continue their journey toward more effective integration of technology into their classroom and teaching practice.

believe in the near future that letters delivered to your home via mail carriers will be a thing of the past. Instead, checking your e-mail will replace the daily task of going to the mail box, just like I have been doing with my e-pal. I have begun to explore the capabilities of the computer, discovering the powerful ways computers can improve my teaching. The rapid advances of computer technology have opened up user-friendly programs for virtually every imaginable field. Education can benefit from computers by the computer’s ability to bring vast amounts of information to the user, student or teacher. [UCF Preservice Teacher]

We communicate our life experiences by telling stories. These stories reveal who we are and how we view our world. In sharing our stories we often evoke stories from others (Jalongo & Isenberg, 1995). The dialogue begins.

We can investigate the ways in which preservice teachers’ stories reflect the meanings they have given to their experiences using qualitative inquiry (Eisner, 1991) and we can share our findings through qualitative narrative (story). In the following pages we will tell a story of preservice teachers’ perceptions of teaching diverse populations. University of Central Florida (UCF) and Cleveland State University (CSU) preservice teachers shared stories of their respective school experiences via e-mail. Through examining these shared stories, we are able to gain insight into the ways in which these preservice teachers have interpreted their experiences. In addition, we are able to gain insights into the importance of sharing teaching experiences with others in different regions of the country, and into the use of e-mail as a vehicle for critically examining the teaching of diverse populations.

Our Stories

To begin our story, it is important that we first introduce you to the tellers and the “characters.” This provides a context for the voices (Eisner, 1991) through which our stories are told.

Sandy’s Story

I was a native Floridian until I moved to Cleveland, Ohio in 1992. I had never seen snow, had very little knowledge of the urban-suburban structure of the Greater Cleveland area and the various ethnic groups which lived there, and quickly found that it was difficult to tell the story of living and teaching in Florida. I had never really thought about it. I just did it.

I was startled the first time I saw all of the snow boots lined up in the hallways during the first winter storm. At that point I realized how different the school facilities were in the two regions. The Ohio schools are primarily multi-level, enclosed structures. Many of the classrooms in Florida schools have outdoor access. I had not previously thought about the role weather played in architectural considerations for school building designs.

I have now returned to Florida. I find that the words used to describe teaching and schools in Cleveland are not suitable for describing teaching in Florida. In trying to tell my story I find that I have to reflect on the commonalities and differences of the two settings. In doing so I have expanded my view of teaching and learning in various settings. Although we could not physically transport students at UCF to Cleveland, we could have preservice teachers from the two universities share their stories via e-mail.

Jackie’s Story

My story is in sharp contrast to Sandy’s. I have lived in Cleveland all my life. I attended suburban schools, earned my teaching degree at a local liberal arts college, and taught for six years in the same district I had attended. My first experiences in urban schools occurred several years later. I am a professional storyteller, and it was through the sharing of stories—folk stories and personal stories—that I came to know urban students and teachers. Building on these experiences during my doctoral studies, I worked with teachers and students in the Cleveland Public Schools through a long term partnership project.

Although I have not lived in another region, I have experienced Sandy’s awareness of commonalities and
differences in schooling in other ways—suburban and urban settings, public and private schools. I have asked my preservice teachers to reflect on their perceptions of teaching in urban settings, and my curiosity about their perceptions has grown. I viewed Sandy's invitation to participate in an e-mail project involving preservice teachers in our diverse regions as an opportunity for continued exploration into these perceptions. I was particularly eager for my students to exchange stories with preservice teachers in another geographic region.

**The University of Central Florida (UCF) Preservice Teachers**

The UCF participants are enrolled in an elementary mathematics methods course. Thirty-five percent of the participants have been Florida residents from birth. Twenty-six percent have lived in Florida more than fifteen years. Nine percent have lived in Florida more than ten years. The UCF preservice teachers are placed in either an Orange County school or a Seminole County school for their junior internship experience.

The Orange County public school system is the sixth largest school district in Florida. Currently over 60,000 students are enrolled in the 87 elementary schools in the district. The racial/ethnic distribution of the student population is 52.5% Caucasian, 27.9% African American, 16% Hispanic, 3.3% Asian/Pacific Islander, and less than 1% American Indian/Alaska Native. The Seminole County School District is less than half the size of Orange County Schools. There are 29 elementary schools serving over 24,000 students. The field experiences for these preservice teachers provide opportunities to work with multiple grade levels; however, there are few opportunities to work with culturally diverse populations. Many of these students do not have any idea of what it would be like to teach in another region of the country and have misconceptions or no idea of the differences between urban and suburban settings.

**Cleveland State University (CSU) Preservice Teachers**

The Greater Cleveland area is home to approximately 80 ethnic groups, speaking more than 60 languages. There is a distinct east side and west side, each made up of suburbs. Within these suburbs are many thriving ethnic communities (e.g. Old Slavic Village, Little Italy). Each suburb has its own government structure as well as its own school system. In some cases two suburbs join together to form the school system for that area. In addition, there is a definite classification of urban versus suburban school systems.

Preservice teachers attending CSU are required to complete two field experiences in urban schools and two field experiences in suburban schools. The urban placement must be in either the Cleveland Public Schools, East Cleveland Public Schools, or the Catholic Diocese Schools. The Cleveland Public School system consists of 81 elementary schools. Approximately 75% of the students represent minority populations, 80% are in the free lunch program and 70% live in single-parent homes (N. Klein, personal communication, December, 1996). In East Cleveland Schools, 99.4% of the population is African American, 69% of the students live in single-parent homes, and 49% live at or below poverty level (Hampton, Perry, Towns, & Mumford, 1996).

CSU participants are enrolled in an elementary arts course. Ninety-five percent of the CSU participants live in the greater Cleveland area. Fifty percent have grown up in one of the Cleveland suburbs and now travel into the urban center to attend classes at CSU. Prior to the urban field experience many of these preservice teachers have had little experience in the urban schools. They enter this quarter with many preconceived notions of what it would be like to teach in these schools (Stuart & Peck, 1995). Seventy-five percent of the CSU participants have not lived in the south. Consequently, they have misconceptions or no idea of how teaching in a southern metropolitan setting differs from teaching in a midwest suburban or urban setting.

**The Study**

Jordan (1995) suggests that most prospective teachers have limited or no experiences with minority populations. That is, their socialization has been "culturally isolated" (Jordan, 1995). However, through dialogic interaction preservice teachers can critically analyze their beliefs, world views, and assumptions (Harrington & Hathaway, 1995).

This study linked 39 preservice teachers attending a southern metropolitan university (UCF) with preservice teachers attending a midwestern urban university (CSU). By establishing a dialogic interaction between these two groups we sought to provide opportunities for preservice teachers to examine their own views of teaching diverse populations.

**The Method**

Preservice teachers at both locations completed an open-ended questionnaire regarding their perceptions of urban, suburban, and metropolitan settings as well as teaching and learning in these settings. Each preservice teacher at CSU was then given the e-mail address of a UCF e-pal. Each was charged with finding out what it is like to teach at their partner's location. We suggested that they consider discussing the facilities, resources, instructional strategies, and types of student and teacher interactions. However, they were not limited to these topics.

After approximately five weeks, participants were asked to write a paper describing their findings. They were also asked to complete a final questionnaire. On this questionnaire participants were asked to comment on the

---

1282 — Technology and Teacher Education Annual — 1997

1231
experience itself. We asked them to suggest improvements and to comment on whether future elementary education majors should be required to complete a similar activity.

**The Emerging Story**

The preservice teachers’ stories of the experience were analyzed looking for common themes. The following provides a preliminary discussion of four emerging themes from the stories retold by the UCF and CSU preservice teachers: 1) validation of teaching techniques, 2) inability to imagine teaching in an urban setting, 3) impressions of teaching in the urban setting, and 4) changes in perceptions as a result of this experience.

**Validation of Teaching Techniques**

I did find out, however, that the classrooms up there are using an integrated teaching style. That to me is reassuring, we must be doing something right down here if we’re not the only ones doing it. [UCF Preservice Teacher]

Ten of the thirty-two UCF participants were pleased to find out that the instructional strategies being emphasized at UCF are also being used at CSU. Knowing that instructional strategies were being used in more than one region of the country added credibility to what we have been discussing in the university classroom.

CSU students also described similarities in the university classes and the field classrooms.

My e-pal’s classes sound a lot like ours at CSU. She uses math manipulatives for almost every math lesson. Whole language seems to be the strategy used for language arts. [CSU Preservice Teacher]

But it was most affirming for CSU participants to learn that...preservice teachers across the country are learning how to be effective and efficient and are just as dedicated to the futures of their students as those here in Cleveland. [CSU Preservice Teacher]

**It is Unimaginable**

This school is such a foreign concept to me that I am not sure I can truly imagine what it is like. [UCF Preservice Teacher]

UCF participants were surprised by the stories they heard about the facilities and resources available to teachers in the urban setting. They could not imagine teaching at a school without playground equipment, where the doors automatically lock when closed. They realize that safety is an important consideration at all schools. However, they had not considered what it would be like to teach in an area where the doors had to be locked to protect the students and teachers. There is a “bell door” at each school through which visitors may enter the building. This is not a part of the UCF experience. Each individual classroom has a door to the outside in many of the schools at which UCF students are placed. One door can not be designated as the door through which visitors enter the school.

This outdoor access to the classrooms was an unimaginable, or at least unusual, idea for the CSU preservice teachers. CSU participants expressed surprise with exterior hallways, one-story buildings, and hurricane drills. These overlooked differences of daily life stand out when telling a story of teaching in various geographic regions.

**Impressions**

Through his description of an urban setting, I almost feel like I have experienced teaching there myself. [UCF Preservice Teacher]

The most powerful stories told by the CSU participants were about the facilities, teaching techniques, and teacher attitudes. The UCF preservice teachers repeatedly described their surprise and sadness in hearing their e-pals’ stories. They appreciated the wealth of resources available to them in their schools.

I was also surprised by what I learned. As I read the e-mail these last few weeks, I began to be very thankful for the type of school I was assigned for my internship. [UCF Preservice Teacher]

CSU participants appreciated hearing the viewpoints of preservice teachers in another region. They overwhelmingly commented on the increased availability of technology in the southern metropolitan settings. One student in particular was surprised to learn that the southern school...was as well equipped as it is because I expected a poorer region. This must be based upon a preconceived notion I have about Florida. [CSU Preservice Teacher]

This realization of the differences in resources and facilities led to changed views as well as generated strong reactions by the CSU participants. One CSU participant said that she...found herself being jealous of [her e-pal’s] ‘wonderful experience.’ [CSU Preservice Teacher]

**Changing Views**

I had no idea how clueless I was about the different types of school settings. I am so glad that I learned about this before I entered into my teaching career. [UCF Preservice Teacher]

UCF preservice teachers overwhelmingly described a change in their perception of teaching. They had not considered what it was like to teach in other regions of the country. They just had not thought about it. Prior to this experience, some UCF participants thought that teaching was similar in all regions of the country.
From this experience, I have learned that there is no such thing as a standard elementary school. I always thought that elementary schools were pretty similar—the same material was taught, the make-up of students was similar, and the facilities were relatively the same. I found out completely different. [UCF Preservice Teacher]

Although CSU participants also changed their views about teaching in a southern metropolitan setting, they were changed to a greater degree by their own urban experiences. This project gave them an opportunity to reflect on their beliefs. They had to find the words to tell the story of their experience.

Personally, all of the stereotypes I had of an urban school were thrown out. [CSU Preservice Teacher]

**Student Recommendations for the Future**

Twenty-nine of the thirty-seven UCF preservice teachers surveyed stated that this should be a required activity for future elementary education majors. Six respondents stated that this should not be required and two did not comment. Five of the UCF participants who did not recommend doing this activity again were unable to complete the e-mail project. They had difficulty receiving responses from their e-pals. Consequently, they were frustrated with the project and did not feel that other preservice teachers should experience the same frustration. The majority of the CSU respondents also recommended that future language arts students do this assignment.

Although the UCF preservice teachers felt that this was a very worthwhile project they suggested several areas for improvement. First, the UCF students felt that more time should be allotted for the completion of this project. CSU students also made this suggestion. They suggested that the project be assigned early in the semester and continue throughout the semester so that they have more opportunities for the exchange of stories. Although we agree with this suggestion, the time constraint was unavoidable. UCF utilizes a semester system whereas CSU currently utilizes a quarter system. Consequently, CSU students began classes four weeks after the UCF students. The UCF students begin their internship experience the second day of classes. The CSU students begin their field experience four weeks into the quarter. Consequently, the CSU students cannot supply a great deal of information about the urban school setting until the eighth week of the UCF semester.

The UCF students were very concerned about the difficulty in receiving responses to their inquiries. They suggested that a system be established in which student-student interactions via e-mail could be monitored at both locations. One suggestion was to require students to submit a copy of the e-mail exchanges each week to encourage students to dialogue on a regular basis. Similarly, a CSU participant suggested we have assignments due throughout the term to ensure contact is being made. Another CSU participant suggested e-pals could schedule times to read and send messages as a way to make the exchange more intentional.

**Lessons Learned**

Over one-third of the UCF participants specifically commented on the importance of this project in making them more comfortable with using technology. More than half of the UCF participants commented on the importance of learning about teaching in other regions of the country. I had no idea it was so different in other areas of the country. I enjoyed this assignment and learned so much. [UCF Preservice Teacher]

More than half of the CSU participants learned to use and appreciate e-mail. Several even surprised themselves by teaching someone else how to use e-mail! One-fourth commented on the importance of learning about schooling in another region, and they appreciated “talking” online about their preservice teaching experiences with each other.

I learned that the e-pal process is a productive one. I liked it because “it” (the technological process) literally takes you to other parts of the country to find out about the similarities and differences in the pedagogic experience. The e-pal experience hinges on cooperative learning. ... I really like the idea that this process can be used in our own classrooms with our own students. It is almost as good as a field trip to a different region. [CSU Preservice Teacher]

We found that this experience for the UCF and CSU preservice teachers paralleled our own experiences. That is, both UCF and CSU students struggled to tell the story of their respective experiences. This activity forced the participants to make the familiar strange so that they could create and tell a meaningful story. Although we did experience technical difficulties, we both agree that this was an invaluable experience for our students. Our students not only became more familiar with e-mail, they reconsidered their previous notions about teaching.

The World is moving so fast these days that the man who says it can't be done is generally interrupted by someone doing it. —Elbert Hubbard

For many of us in education, we have known about the power of telecommunications for years and we have been trying to spread the word to our students, our colleagues, our administrators and anyone else who would listen. Often times, it seemed as if we were fighting a losing battle as we discussed the value of understanding and using applications such as listservs, newsgroups, and gophers. The reception was not always enthusiastic, but we persevered. In education, especially, we have been the pioneers, the early adopters and the innovators, as we helped shape the vision of a telecommunications-equipped future. But times have now changed. No longer does it look like we are losing ground in our evangelical holy war. On the contrary, we have been more successful than many of us could ever have imagined. Bill Gates is the richest man in the world and anyone who wants a presence on the Internet can have one, a fact that seems to be validated every time we cruise the Web. In fact, we don't even call it the World Wide Web anymore, it's now simply "the Web," and if there are still students, faculty and administrators who don't know what that means, they soon will.

Interestingly, with the acceptance of telecommunications as a legitimate communication medium, our roles as innovators and early adopters have not diminished. As educators, we are still leading the way in finding meaningful examples of how emerging technologies can be used in the design, development, and delivery of instruction. The articles in this section cover a variety of issues related to this idea, how telecommunications technology can be used to support the educational process and the training of students and teachers. Several papers deal with the creation of electronic communities. Others describe products and processes where telecommunications has become an integrated part of the curriculum. Issues related to developing a usable network infrastructure are explored in this section along with methods for dealing with the changing nature of intellectual property and copyright.

The section begins with a paper by Zimmerman and Greene, who describe their work in establishing an electronic community of learners at Appalachian State University. This network connects the university with local public schools and other universities, and allows teachers, students, and university faculty to become full participants in shared pedagogical dialogue and activities. Utilizing such resources as listservs, Web pages, and videoconferencing, the authors detail how experienced educators help public school teachers and preservice teachers learn to use telecommunications by using it along with them. In the next article, Alvarez examines how science students and teachers are using electronic communications to become "communities of thinkers." This collaborative project involves students, teachers and astronomers working together to analyze data and solve problems in astrophysics.

Volpentesta, Greco, Frega, and Pisculli discuss the development of CODEE, a collaborative drawing tool that can be used to support teleworking and teletraining. This exciting tool allows users anywhere in the world to draw on the same canvas. The article provides a detailed overview of the technical specifications of the program, a comparison of similar applications, and an analysis of how this program is being used in a European distance education project. The authors also include strategies that other may find helpful when using such a tool. Cote's paper is centered on the development of SPICE, Standards-Based Products for Interactive Classroom Education. This program was designed by the Colorado Alliance for Science in an attempt to use Web-based materials to support teachers in the use of technology, mathematics, and
they call it, is an innovative way that educators can
without an Internet connection. Microweb technology, as

science education based on the Powers of Ten tradition.
The system, which is designed to allow students to visualize relationships among the various physical and life sciences while perceiving the role that mathematics plays in each of the disciplines, uses Web technology and advanced features such as Java applets and three-dimensional environments based on VRML.

In the area of developing network infrastructures, Chang, Gilbert, and Bao discuss Project Caprina, a campus-wide network-accessible archive of digital images and software applications at the University of Maryland. This innovative project is expanding the way faculty are able to teach their classes and students are able to complete their assignments. With a strong emphasis toward the use of multimedia, this project helps define how technology-based education can be used both in and out of the classroom. Jerman-Blazic presents an in-depth view of how Central and Eastern Europe countries are providing training opportunities for creating network infrastructures following the dissolution of the Soviet Union. The article provides a fascinating look at the efforts of CEEnet, the Central and Eastern European Networking Association which is focusing on academic and research networking in 19 different countries.

Simon and Abbott present an update of WIN (Walden Information Network), an ongoing distance education program at Walden University. The WIN program seeks to develop a fully electronic campus by providing all of Walden's students and faculty members with an electronic connection to each other and to the Internet. The authors report on a study that tracked students who have gone through the program and include comments from students as well as plans for the future. Bedell and Wilker write about a method they use to access Web pages locally without an Internet connection. Microweb technology, as they call it, is an innovative way that educators can simulate actual use of the Web, with the same functionality as the original site. The authors describe both the technical component of their work, and also examine other related issues such as storage of large files, censorship on the Internet, and copyright.

Robin and McNeil also examine the issue of copyright and electronic materials in their article about Archive.edu, a Web site that was developed as an online area where sharable educational resources can easily be found and downloaded. The authors invite other educators to adopt a model of sharing not only curricular resources online but also tutorials and specific examples of how various technologies can be used in the classroom. Erickson presents an overview of digital copyright issues in the Age of the Internet and describes The NetRights Licenslt System. This system allows users of content to easily obtain copyright data and engage in online (and possibly automated) licensing by way of the digital content elements, directly from the context of the document or project in which those elements are being used. The Licenslt system addresses the need for a uniform, timely and persistent means of identifying digital content in the networked environment.

The section concludes with Simon's work on DisNet, a model of a database-centered network environment that specializes in the generation of contextual relationships in a discursive format. A variety of collaborative strategies that emerged during the course of the project are also discussed.

As we continue our efforts to help our students and our colleagues take advantage of the power of telecommunications technology, there is always more work to be done. Each year, greater numbers of students and educators will look to us for ways to use telecommunications technology, from finding funding to developing training to integrating it into the curriculum. The articles presented here can assist us in that task as they provide innovative ideas and specific examples of how telecommunications systems and services are being developed for multiple content areas and implemented in locations around the world.

BUILDING A TECHNOLOGY RICH COMMUNITY OF LEARNERS

Sara Olin Zimmerman
Appalachian State University

Melanie W. Greene
Appalachian State University

With the vast array of technological resources currently available, the question for public schools is not whether to link up to the Internet, but how to link up and how to assist teachers in productive use of telecommunications and networking. Telecommunications can provide teachers with a means for communication and reflective thought and can connect them to a community of learners that reaches beyond the school building. Despite the enormous potential that telecommunications holds for education, it has been estimated that only two to three percent of teachers use this technology (Grabe & Grabe, 1996).

Our decisions about field experience shape an important part of our elementary education program. When we place students in field experiences we want them using telecommunications. It is imperative that teacher preparation programs use these resources as tools for the preparation of reflective practitioners. Pedagogical dialogue is one way that technology can assist in this process. Computer-mediated communication on various listservs reveal that unique and powerful support networks emerge as joint construction of meaning occurs (Schlagal, Trathen, & Blanton, 1996; Laffey, 1995; Levin, Waugh, Brown, & Clift, 1994).

At Appalachian State University (ASU), we have established an electronic community. We have connected our university with local public schools and other universities, creating a network where teachers, students, and university faculty can become full participants in shared pedagogical dialogue and activities. Within this community of learners, we have multi-level and multi-skill membership. Experienced educators collaborate with new teachers, enabling their induction into teaching in a non-threatening atmosphere. Dialogue among participants creates a community where all members, new and experienced, learn as they participate in practice (Lave & Wenger, 1990). We believe that a key role for university faculty in these partnerships is to help public school teachers and preservice teachers learn to use telecommunications by using it along with them. It is through participation in shared activity that learning best occurs (Rogoff, 1994). In this paper, we describe how a university/public school partnership structures telecommunications activities and dialogue to create a community of learners.

Members of the university and public schools created a Learning and Technology Laboratory to serve as the focal point for the application of technologies. A local telecommunications network was established between the university site and five local schools: Blowing Rock, Green Valley, Hardin Park, and Parkway Elementary Schools, and Watauga High School, in the Watauga County School District. With the establishment of the network, university and public school faculty designed a series of activities. A major activity was the application of telecommunications in preparation of elementary school teachers. Several electronic discussion lists were developed to facilitate ongoing discussions among university faculty, teachers, university students and students in public schools. For example, XMODEL was designed for university cadre discussions; XBLOCK was created for faculty and student discussions; XTEACHER promoted a dialogue between university faculty and cooperating teachers; and XSTUDENT was limited to university students to allow exchange ideas on a more personal basis. Other content oriented lists were created for members of university methods courses to discuss issues related to literacy, social studies, and mathematics. During the courses, faculty structured activities to help students connect abstract university classroom knowledge to their public school experiences.

Videoconferencing provides another vehicle for linking the university setting to public schools and for stimulating creative teaching and learning. It is a viable tool for clarifying current topics, issues, and trends in education and allows professors to view and engage in current practices. On one occasion, university faculty and an educational consultant representing a major textbook company participated in a teleconferencing session with teachers reflecting on the strengths and weaknesses of a new published reading program. On another occasion, university students were linked to a fourth grade classroom teacher and technology specialist via teleconferencing and engaged in a discussion on lighthouses and plans for teaching about them.
We have found that our electronic community provides clear advantages for both public schools and our teacher education programs. For the first time we have linked teachers with teachers, so that individual teachers in western North Carolina are no longer isolated. A community of teachers and educators creates a network to share cultural experiences, write to an audience, and make comparisons about teaching, learning, and schools. Teachers are also able to communicate with each other about issues that affect all of them.

Research suggests that traditional methods courses taught in isolation limit reflection and application (Paul et al., 1995) and consequently do not empower a novice to make connections with questions, problems, and contradictions that arise in the classroom. The ongoing community of discourse in teacher education provides opportunities for novice teachers to apply, critique, and think flexibly about their teaching knowledge. As a result, students are able to structure their knowledge base for making decisions about a critical teaching task (Greene & Zimmerman, 1996). In our community of learners model, critical teaching concepts are targeted by the researchers for development and analysis. These concepts are presented at the declarative and procedural levels (Paris, Lipson, & Wixon, 1993) during the methods courses. The conditional knowledge or the understanding of when and why to apply the previous forms of knowledge becomes the focus for the instructional discourse during the field experiences. Structures were designed to ensure all critical concepts were discussed during the year. Examples of two students, one on reading and one on behavior management, linking the abstract declarative and procedural knowledge to concrete teaching is seen in the following passages.

I taught a reading lesson today. I used several strategies that we learned in class. I used an anticipation/reaction guide, a concept map, and a writing strategy. My students liked these strategies and they worked. I sat in on a meeting with my teacher who was being interviewed about her program. I actually understood the questions and could have answered them myself.

I didn’t understand the motivation behind my teacher’s discipline plan, so I began to observe and ask questions. I could tell that she was using some of Glasser’s ideas in her approach. I found her goal was to create an atmosphere where students learn to regulate their own behavior and to try to help their classmates do the same. It is amazing to see kids meet together in a democratic type of environment and set classroom goals. Now that I understand her philosophy, I have much more respect and commitment to her approach.

These examples demonstrate how telecommunications reveal the transformation from prospective teacher to beginning teacher. Students reexamine issues based on direct observation. They develop different perspectives after seeing the value of instructional strategies in practice.

To summarize, with easy access to a network and a social and instructional scaffold for support, an electronic environment within which teachers, students, and university faculty can grow and explore can be created. Factors which are essential for success such as support, leadership, and funding have been included in our plan. The application of technology has not replaced the special teacher/student relationship but has helped redefine and strengthen it. Neither a community of learners nor technology can effortlessly transform education by themselves. A combination of both is necessary to create a powerful opportunity to change the structures of public school education and teachers. For more information on our project, visit our Web site at: http://www.ced.appstate.edu.

COMMUNITIES OF THINKERS: INVESTIGATING INTERACTIVE SCIENTIFIC LITERACY ENVIRONMENTS

Marino C. Alvarez
Tennessee State University

High school teachers and students are not thinking and learning together. They are focusing on learning outcomes rather than the processes necessary to achieve these outcomes. This paper examines conceptual learning, application of electronic discourse and scientific inquiry through an emergent curriculum that uses innovative technology. The focus is on four aspects of a learner-centered scientific literacy environment designed to stimulate curiosity and inquiry: 1) how literacy and scientific inquiry is promoted by exploring the universe using self-directed case-based instruction that incorporates a multi-disciplinary approach; 2) the educational role that primary data from automatic photoelectric telescopes have on teachers and students; 3) how mathematical and scientific competencies are enhanced by engaging students and teachers in "real life" applications. The fourth feature is unique to this project and not currently found within a traditional curriculum: 4) the impact of interactive literacy environments by demonstrating how teachers and students are using electronic communications to become "communities of thinkers."

Much of the science teaching in our secondary classrooms indoctrinates students with pre-existing knowledge. In this context, the student is limited to absorbing the information they receive. Over reliance on a single textbook and materials provided by the publisher makes this type of teaching less meaningful. In these circumstances critical thinking (thinking about thinking in ways to bring about change in one's experience) and imaginative thinking (exploring future possibilities with existing ideas) is given minimal consideration by the teacher and student. The teacher does limited thinking when preparing lessons and assignments because the lessons have been pre-prepared. Students resort to completing prefabricated worksheets and assignments with the least effort and thought. In fact, because of these types of assignments, much of the science vocabulary is reduced to rote memorization with little understanding of the concepts, details, generalizations, or theories involved (Gowin, 1981; Novak, 1990, 1993; Thelen, 1984).

The Explorers of the Universe (http://coe.tnstate.edu/explorers) is a project that combines pedagogy with contemporary scientific exploration of the universe by investigating authentic scientific problems that have significant implications for a global society. This collaborative project involves teachers with their students and astronomers investigating astrophysical problems and analyzing data from state of the art automatic telescopes. Astronomy students in grades 9 through 12 in two high schools, University School of Nashville, Nashville, Tennessee, and Thomas Jefferson High School for Science and Technology, Alexandria, Virginia, participate in this project. Unique aspects of this project are: (1) students analyze data received from automatic photoelectric telescopes monitoring properties of variable stars by computers; (2) they make innovative uses of videodisc and electronic technology to create interactive learning environments. These are designed and carried out by teachers with their students for their use; and, (3) teachers and students are involved in research dealing with "real life" exploratory space investigations.

Self-Directed Case-Based Instruction
The case-based method of teaching and learning allows students to develop their own framework to reason and think about problems and situations related to an area of study (Hunt, 1951). Our students research and develop their own cases as they investigate real problems which differ from those cases that are typically written by others for students (Alvarez, 1993). Their cases involve them in thinking processes as they interact with an array of print and multimedia environments. The school's library resources (e.g., books, articles, video CD's, etc.), the Internet, and persons who have knowledge or resources are consulted. Students are encouraged to think about integrating other subjects into their case (e.g., literature, art, music, social studies, etc.).
As students formulate their cases they focus their thinking processes beyond undirected thinking to more advanced stages including inductive thinking, problem solving, critical and imaginative thinking, and discovery. These types of thinking change their view of learning. Instead of thinking of ways to expediently achieve learning outcomes, these students now focus on ways to achieve meaningful learning. Their energy is redirected to satisfying an intrinsic need to know and understand.

Classroom Environment

The environmental context of the classroom also influences students' written reports. If the report is written for the teacher and classmates it may be written in one form. However, if the environment changes to one that is electronically interactive (i.e., e-mail or papers published on the World Wide Web (WWW)), the format and thought processes may be altered to meet the challenges that may be incurred from faceless and unknown readers (Alvarez, 1996a).

Students use the Web as a tool to conduct research, publish information, and direct e-mail inquiries to specific persons. They use the Web in the same manner as the library. One significant difference is that authors of documents that reside on the Web can be contacted directly through e-mail with questions to help clarify or solicit additional information. The students also publish their papers on the Web which allows anyone with Web access to read and critique the documents. The use of the Web forces students to carefully analyze both the information as well as the source. Not everything on the Web is accurate so they must discriminate and select information. Web usage also increases collaboration between students. They co-publish papers as well as develop links to other related student papers and Web pages.

The textbook in this type of interactive class environment becomes a resource rather than the sole source of science information. This results in increased ability of the students to be more critical of an astronomy text with regards to its organization, readability, and graphic features (Alvarez & Rodriguez, 1995). Many of these science texts contain a high volume of conceptual terms that require meaningful understanding. Because of the conceptual density of these texts, many students resort to memorizing these terms without knowing or understanding what they actually mean within a given context (Thelen, 1984). As a result, much of the science vocabulary is reduced to rote memorization with little understanding of the concepts, details, generalizations, or theories represented. Our students become better acquainted with the concepts and theories in textbooks due to their exposure to and analysis of other readings and resources.

The apparatus consists of small and automatic telescopes, and computer terminals with Internet access. The telescopes these students and teachers access include: (1) the Fairborn Observatory 10-in automatic telescope (APT), and the Vanderbilt/TSU 32-in (APT) at Washington Camp in Southern Arizona equipped with a photoelectric photometer. These remote automatic telescopes are controlled electronically and enable students to place their stars for observation and analysis. The classroom becomes an active place for students to communicate with peers, their teachers, astronomers, and university educators via the Internet.

Enhancing Mathematical, Scientific, and Literacy Competence

Students use their mathematic, scientific, and literacy skills to interpret calculations received from the automatic telescopes, relate the findings to their study of astronomy, read scientific journal articles, write their case reports, make journal entries, construct concept maps, and develop vee diagrams. These processes, used in combination with each other and incorporating other subject disciplines, enable students to link new information to prior knowledge. The interactive nature of the technology, together with the tools that are needed to plan and represent their ideas provide a forum for teachers and students to think and learn together.

These high school students are thinking about additional ways to analyze data received from the remote automatic telescopes. They are rewriting a program developed by one of the astronomers to make it more comprehensible. Together with their teacher, two students at the University School of Nashville have written a manual published as TSU Explorers of the Universe Technical Report. This program written in FORTRAN uses local Windows software to find and analyze periods of variable stars. It was piloted and is being used by students at Thomas Jefferson High School for Science and Technology. Students from these two high schools collaborate on cases with similar variable stars and discuss their progress as they evaluate data received from stars they have placed on these remote automatic telescopes. In addition to exchanging information by electronic communications, these students are interacting visually using CU-SEE-ME software. The project is soon to be expanded to include teachers and students in Stockholm, Sweden, which will add a new educational and cultural dimension to our project.

Concept maps assist students in seeing the relationships of their central and subordinate ideas pertaining to their case investigation (Novak, 1990, 1993; Novak & Gowin, 1984). Concept maps are arranged hierarchically representing the most inclusive ideas first, the less inclusive ones next, and finally the least inclusive ideas. Vee diagrams are used to aid students in understanding the structure of knowledge, and are used in this project by teachers and
students to plan their research (Gowin, 1981). The vee is a heuristic that depicts important epistemological elements involved in the construction of knowledge, or new meaning. A computer based template of the vee diagram was developed to provide students with an efficient way to record and make changes. Concept maps and vee diagrams are tools used by students to regulate and monitor their own thinking. They serve to promote self-analysis and enhance critical thinking by having students think about the ideas and their relationships to each other.

**Thinking and Learning Together**

A community of thinkers is defined as an active group of students and teachers striving to learn more about a discipline by engaging in critical and imaginative thinking (Alvarez, 1996b, 1995). During this inquiry, the teacher thinks about the facts and concepts that students need to understand, supplementary reading materials and artifacts that need to be provided, ways to incorporate other subject disciplines into the inquiry, and selects from an array of teacher-directed/teacher-assisted strategies to facilitate student thought. Likewise, the student becomes an active thinker in the learning process by engaging in the inquiry, relating prior knowledge and world experience both informal and formal; selecting from an array of student learning; and working with the teacher toward extending meaning and understanding of the subject matter.

**Thinking of ways to achieve learning outcomes are not the same as focusing on ways that learning outcomes can be achieved** (Alvarez, 1996b). The former is process oriented; the latter product oriented. A learning outcome focuses on increasing a skill or perfecting solutions (Russell, 1956). In an effort to increase learning efficiency, we focus on the processes of thinking, selecting, eliminating, searching, manipulating, and organizing information. Emphasis is placed on thinking as a process involving a sequence of ideas moving from some beginning thought, through a series of a pattern of relationships, to some goal or resolution. Within our community of thinkers, teachers and students ask questions, seek answers, and reflect on their thoughts and feelings as they engage in action research case-based investigations.

**Emerging Findings**

This project is monitored using Gowin’s (1981) four commonplaces of educating: teaching, learning, curriculum, and governance. Gowin’s theory of educating is a conceptual approach to assessment within which both the cognitive and affective domains are assessed. Case reports and projects are evaluated by the teacher. Concept maps and vee diagrams of the events and objects being studied are assessed by teachers and students. Student maps and vee diagrams are assessed by their teacher and university educator to determine the degree of conceptual understanding of complex relationships using Novak and Gowin’s (1984) procedures for evaluation. Students maintain portfolios of work accomplished and work in progress, for a collaborative assessment of their individual performance and progress along with their teacher (Farr & Tone, 1994). Student journal entries show a high degree of understanding of topics under study. Papers published on the WWW lend further credence to their knowledge and understanding of astronomical concepts. Writing a scientific paper that appears on the home page of their school’s world wide Web affects the student positively. This is substantiated by feedback from a WWW audience. This feedback raises their level of consciousness with this electronic medium and prompts them to be more cognizant of their writing skills. Teacher and student interviews indicate positive feelings and thoughts concerning the instructional learning strategies and events associated with this project.

Also significant are ways in which the teachers and students are making their knowledge known. Several newspapers and journal articles have featured our project. One astronomy teacher, Bill Rodriguez, and several of his students have accompanied this author and presented papers at state, national, and international conferences. They have shown examples of their published papers on the Web and discussed planning and organizing their research using vee diagrams and hierarchical concept maps. We have co-authored articles and papers evolving from our project. This astronomy teacher is presently writing a scientific article, with two of his high school junior students and two TSU astronomers, reporting the results of a significant finding of a variable star that will be published in an astronomy journal.

**Conclusion**

A transformation is taking place within all of us. We (university educators, astronomers, and teachers) are thinking more about our disciplines and how relevant ideas can be shared with one another. Teaching and learning are also undergoing a change from reliance on linear texts to more diversified and challenging paths of inquiry using multimedia learning environments. Thinking about science and learning are becoming more evident by written and electronic communications and conversations occurring between students and teachers, among students themselves, and in dialogues with scientists. Ideas are being discussed and acted upon, meanings are being negotiated and constructed, and all of us are involved in pursuing unanswered questions. Students are learning the subject matter, but of more interest and importance is that they are looking at how they think, learn, and ask questions. They are deliberately choosing to relate new information to what they know and use this newly acquired information to make better and informed decisions.

However, this process takes time and energy and it is a mistake to believe that students accustomed to traditional
teaching and learning will fully embrace this process immediately. As Bill Rodriguez, the astronomy teacher, said: “They [students] need to be 'untaught' to rely mainly on recitation and learning through rote memorization and 're-tooled' into questioners, listeners, and writers.” This “re-tooling” involves caring and knowledgeable teachers who are willing to embark on a new path for their students. An interactive environment in which thinking and learning evolves presents these students with many alternatives to use language to explore multiple possibilities through interactions with a variety of individuals and circumstances. This kind of environment provides a setting that fosters a community of critical and imaginative thinkers.

The development of Collaborative Drawing Systems is a significant research area in the field of Computer Supported Cooperative Work: both in Office Automation and in Educational applications. In our laboratory we have developed a tool for collaborative drawing, called CODEE, with the aim of supporting innovative methodologies for teleworking and teletraining activities. This tool is essentially a multi-user program that allows anyone with a Java-capable browser to draw on the same canvas.

In this paper, we describe the client-server architecture, functionality and implementation solutions for such a tool and provide a comparison with similar prototypes. Moreover, we present an analysis of drawing-space didactical activities that have been performed in the execution of a European teletraining and distance education project and point out some strategies in the use of such a tool.

Emerging Technology

Collaborative drawing (CD) has received much attention from researchers and tool developer in recent years (Peng, 1993). Observational studies of group interaction on a shared drawing space have been led to the discussion of design requirements for CD tools. Many of these design requirements have been embodied in research prototypes and commercial applications: (Bly & Minneman, 1990), (Krueger, 1982), (Paltakis, 1996), (Slesinsky, 1996), (Smith, O’Manley, Scanlon & Tayla, 1989), (Tang & Minneman, 1990).

On the other hand, the World Wide Web has emerged as a popular and powerful infrastructure for group-oriented activities. Thus, it has seemed useful to us to make a CD tool available on the Web which satisfies some of these design requirements.

CODEE is the name of our prototype, and it has been developed at GiudaLab to support distance education and teletraining activities during the execution of EXPERTIZE (Exchange and Promotion of Telematic and Robotic Technologies for vocational training and employment of disabled), a trans-national project to promote high level facilitation and employment of handicapped people in the European Union.

In the following paper we present:
- the basic set of functionality we have implemented in CODEE
- the CODEE architecture and client-server communication protocols
- usage scenarios and a first observational study
- future works about some extension which take into account lessons we have learned during the usage of CODEE.

Tool Functionality

In contrast to other approaches on the Web oriented to support synchronous painting activities on the same canvas (Krueger, 1982), CODEE is a multi-user program for asynchronous drawing on multiple shared canvas each of them can be accessed by an authorized group.

The tool embodies classic functions that can be normally found in most draw programs. In a vertical toolbar on the left of the drawing area, a user can select among five type of objects: rectangle, circles, lines, freehand and text. Rectangles and circles are available in both outlined and filled style. A color palette is available on the same toolbar. Objects can be selected and then deleted, resized or moved on the document. Moreover they can be grouped together in order to enable complex objects manipulations and locked to avoid further modifications.
Multiple documents can be simultaneously present on the client side, a user can select any of them and move/copy objects from one to another. Figure 1 illustrates the client interface.

![Figure 1. The Client Interface.](image)

A file menu provides options to save, load and delete documents. A group oriented password system is provided as a support to collaborative work; actually members of a group share the same drawing space and documents in this space can be accessed only by them. Figure 2 shows the interface for group management.

![Figure 2. Interface For User Group Management.](image)

All documents are grouped in directories and stored on the remote server file system, and can be accessed by any Java compatible browser.

**Architecture and Protocol**

CODEE is based on the client-server paradigm, see Figure 3. The server consists of a Java stand-alone multithreaded application which manages the communication with Java applets clients via sockets.

The server's primary function is the management of a shared work space (basically a dedicated file system) where graphical documents are organized and stored for successive retrievals. A password system protects both individual and group works.

On the user's computer, the tool runs as an applet in any Java compatible Web browser.

The server makes available to a client the following functions:

- list of available files
- load a file
- save a file
- delete a file
- create a new users group
- control user access

**Usage Scenarios**

EXPERTISE (EXchange and Promotion of TElematic and Robotic Technologies for vocational training and employment of the diSablEd) is a trans-national project to promote high level formation and employment of handi-
capped people in the Horizon/Employment Initiative of the European Union. Such a project aims at providing effective tools and innovative methodologies for the vocational training and the employment of the disabled by exploiting most recent results in the area of information and rehabilitation technologies.

![CODEE Architecture](image)

Figure 3. CODEE Architecture.

In our sub-project participants have been split up into groups composed by social assistants and disabled persons in order to better organize and control teletraining activities. Moreover, each group is supported by a tutor and all workgroups are supervised by a teacher.

Tele-training activities are supported by a distributed technology infrastructure which connects a digital lab center to peripheral nodes. Some of these activities consist of specific tasks to be performed by using distributed information tools, CODEE is one of them. In particular, we have considered two possible usage strategies:

- as a medium for asynchronous graphical communications,
- as a tool for collaborative design management.

In the first case, CODEE turned out to be a useful tool for improving communication among group members. In the second case, it made it possible to collaboratively carry out simple drawing exercises in some training modules.

CODEE is available at http://sungiuda.deis.unical.it/java/HTML/Draw/.

**Future Work**

In our ongoing work we are trying to extend CODEE's capabilities. Such extensions deal with (1) the implementation of two different interfaces: one for the trainees and one for the trainer. In fact, the trainer needs a way to control the actions of the trainees and to direct groups composition; (2) the integration of suitable features to enable easier access to people with certain kinds of disabilities; (3) the integration of a mail system to enhance the communication among groups members and to handle the collection and distribution of frequently asked questions (FAQs).

Standards-Based Products for Interactive Classroom Education

Don Cote
Colorado Alliance for Science

SPICE (Standards-Based Products for Interactive Classroom Education) establishes a new paradigm for supporting science and mathematics learning in the classroom. SPICE provides exciting interactive instruction for students, it places powerful knowledge tools into the hands of the teacher (who acts as a guide and co-learner), integrates the instructions with online analyses of performance and assessment histories, and matches the learning to national, state, and local education standards. SPICE is centered on standards-based learning modules developed through collaboration between classroom teachers and institutes of higher education. The modules are maintained on World Wide Web servers and are brought into the classroom through off-the-shelf personal computer systems.

This paper discusses the pressures and experiences that led to the development of the SPICE concept. It provides details on the overall SPICE structure and complimentary elements (instruction, interactive work space, and assessment) of the learning modules. It demonstrates how, the supporting World Wide Web (WWW) technology that link the elements together, provides the stimulating environment for the module’s use. It discusses the SPICE delivery system that brings the modules into the classroom and provides for their execution.

Background

SPICE was developed in response to the emerging Science and Mathematics Education Standards in our communities and the need for matching performance assessment. It attempts to aid classroom teachers who are already juggling a host of demands on the limited time they have with their charges. It is reported that today’s students are not keeping up with their international counterparts in science and math. The reasons are many; some lay the responsibility on teachers who are not well founded in the underlying concepts of math and science. These teachers are reluctant or even unable to adequately guide the students in these areas. Other teachers, both willing and able, are unable to make effective presentations of the complex subjects because of obsolete classroom tools or lack of constructive access to subject matter expertise. Even subject matter experts are challenged to stay abreast of advances due to the explosion of information and the rapid pace of change.

The World Wide Web has become a convenient and productive way for Internet savvy teachers to keep up with the advances and insights in many fields that may affect their curriculum. They have also found the WWW to be an excellent source of lesson plans, activities, and material for their classes. However, the overwhelming volume of resources on the Web and the many blind alleys that one may encounter requires the seeker to have tenacity, search expertise, and a measure of luck. Unfortunately, not all teachers have the expertise nor patience to navigate the Web. The result is that many teachers (and therefore their students) miss out on valuable resources available on the Web.

The Colorado Alliance for Science (CAS) decided to investigate the use of the WWW-based material to assist those teachers who are lacking a firm technology and/or science and math foundation. A few teachers have already mastered the WWW and have located numerous online resources to enrich their classes. The goal was to make this limited experience a universal result. The CAS Education/Technology Center developed Online Activities for Standards in Schools (OASIS) - http://www-co-cas.colorado.edu/oasis - to bring together the myriad of Web science and mathematics material and the Education Model Content Standards. OASIS is a system for locating standards-matched Internet science and math curriculum materials and resources that are directly useful to teachers and students. While there is a great deal of Internet material already available, it is not always obvious how the activities or materials fit into a standards-based classroom. By linking the Colorado State Science and Math Standards with various activities, OASIS simplifies the task of integrating Internet resources into the classroom.

OASIS listings are not comprehensive, but are selections of materials designed to enhance and support current
standards-based education reforms. All the entries or "links" have been reviewed, cataloged, and rated by classroom teachers. The links include "hands-on" work, group activities, student discussions, computer-based activities, general information, and indexes of photos, graphics, or articles. Each link in OASIS is accompanied by a short description of the target site, an activity icon to assist the users to readily identify the types of activities presented, and "usefulness" or quality rating. The access to this collection of online resources is provided through the OASIS Structured Access System. This system will help teachers with minimal Internet capabilities to find useful resources quickly and easily. Online information is accessible by subject matter, grade levels, types of activity and/or Colorado State Standards.

The OASIS experience has shown that while the Web does provide many valuable resources, much of what is out there requires too much work from an individual teacher to be useful in the classroom. The exercise would require a resourcefulness beyond most teachers and sadly, the Web material lacks a ready explanation of how it might be integrated with the curriculum. The great promise of the Web and its supporting technologies is not having the impact on education that they could have. CAS spawned the SPICE approach, recognizing that the pieces, willing teachers, powerful technologies, and subject matter experts were there but the integration was lacking to reach that promise.

The SPICE approach was to form collaboratives of schools, districts, institutes of higher education, and technology partners to bring together the pedagogy, subject matter expertise, real classroom experience, supporting technologists and media specialists. As with OASIS, teachers had to be the backbone of the endeavor. This partnership of inservice teachers and subject matter authorities creates exceptional knowledge tools that support classroom/erudition-based inter-activity in the acquisition of knowledge and skills. It involves higher education in the generation of the guidelines and exercises, and most importantly allows the teacher to manage the learning experience for the students. These teams would develop the SPICE modules.

**SPICE Modules**

The SPICE Modules are constructed around attention grabbing multimedia interactive presentations with embedded instructions and assessment. The technical information contained in each module is dynamic and voluminous. They will be executed by users with a variety of education/system environments. The World Wide Web (WWW) provides a unique platform that best supports these interactions. Maintaining the modules on Web servers enhances their accessibility, provides accountability, supports the broadest suite of multimedia displays (video, audio, virtual reality, digital imagery, graphics, etc.), eases and encourages positive updates, and enforces configuration management. Users access the server resident modules using Web browsers on their Macs/PC's. The SPICE modules are 1) WWW server-based, 2) interactive, 3) content-assessment coupled, and 4) self documenting. They are developed along uniform guidelines providing a consistent look and feel. The layout of each module corresponds to a single display screen architecture.

**Screen Architecture**

The SPICE screen architecture brings instruction, interactive work space, and assessment/feedback together on a single display screen, each in its own individually sizable window (see Figure 1). The screens are received by WWW browsers on the user's machine.

The structure of SPICE modules is designed on a standard screen configuration that integrates Instructions, Interactive Work space, and Assessment/Response. Each component resides in a separate window or "frame." Frames break up a screen or page into several mini-pages all on one screen. The mini-pages are independent. Each frame has its own Uniform Resource Locator (URL) address, so you can click a link in one frame and view the corresponding information in another frame. For example, you might click a topic heading in the Instruction Space and view an image under that heading in the Interactive Work space. Or, you could request a computation from Instructions and view your results in the Work space. The Work space contains the largest amounts of information - text, graphics, even multimedia content.

**Instruction Window**

The Instruction Window is used to provide detailed directions. In the Presentation Mode it supplies step by step instructions, gives the teacher additional information on the subject matter, presents standardized questions, and prompts the teacher to review assessment data. In the
Practice Mode, it outlines the problems, presents material, makes suggestions, and leads students through the multi-threaded exercise based on performance.

**Work Space Window**

The Work Space Window is interactive, linked to the Instruction Window, and accepts participation from the teacher console or from the student hand held PCs. Results of interactions can be integrated with server-based resources and displayed as animations, video loops, graphics, plots, 3D viewing, etc. The Work Space Windows may also be displayed on a separate large screen monitor.

**Assessment/Feedback Window**

During Presentation mode, this window gives the teacher ongoing assessment information, captures student responses, displays the analysis of individual student and group performance, and gives suggestions for follow-up work. During Practice Mode, it displays assistance, provides answers, and encourages the students.

**SPICE Delivery System**

SPICE modules are maintained on Web servers and are provided interactively to the classrooms over the Internet (see Figure 2). In the classroom, they are requested through an Internet browser residing on the teacher console. The browser returns the SPICE screen described above for the module selected. Following the instructions, the teacher leads the class through the activity. The class views the interactive work space on the separate large screen Presentation monitor and interacts through their Hand held Personal Computers (HPC). Based on class performance, student raised lines of inquiry, SPICE suggestion and teacher discretion, the exercise may take a variety of paths through the multi-threaded module.

![Figure 2. SPICE Delivery System.](image)

At various junctures in the exercise, students are requested to participate using their HPC's. The data is collected via infrared links at the teacher's console. The answers are analyzed and presented in the assessment window for the teacher. In this window the teacher can see quickly how individual students are doing and the direction the class is moving. Current assessment data are combined with historical data from other related SPICE modules and standardized test to make recommendation for reconstruction. Specific areas that need additional review or reconstruction are highlighted to strengthen the student proficiencies.

SPICE reconstruction suggestions can range from the recommendation that certain students should have one-on-one interaction with the teacher on a specific point, to a suggestion that a group of students should practice elements or exploration of new concepts of the lesson using supporting SPICE sub-modules. In these sub-modules, instructions are tailored to the student; the work space is local only and the information in the response windows is directed at the student.

**Supporting Technology**

The content and structure of SPICE modules are profoundly enhanced because of the synergy with the exciting supporting technologies. SPICE relies upon the WWW to make modules easily available to users anywhere across the world. Browser capabilities such as frames allow cooperative linking between instructions and display work space. Common Gateway Interface (CGI) and Java make it possible to present the content as an interactive multimedia presentation. The structure of the Web allows dynamic updating of material and central monitoring of module use.

**World Wide Web**

The WWW is primarily an information retrieval service on the Internet, which is designed around a technology called hypertext. It was developed in the early nineties at CERN, the European Particle Physics Laboratory, and is probably the most user-friendly and useful tool available on the Internet today. The Internet has had a variety of information retrieval services since its inception, however, the WWW, or the Web as it is called, is the single most important factor in the explosive growth of the Internet in the last five years.

The SPICE architecture relies upon the browsers features: 1) Multimedia, 2) HyperText Markup Language (HTML), 3) Interactive Content, and 4) Virtual Reality Modeling Language. These basic Web functions access the module content and provide the connectivity between the modules' major segments.

**Frames**

Frames provide excellent instructional opportunities via the Web. They make navigating an Internet site easier, especially one with a lot of information such as a SPICE site. SPICE users can scroll and resize frames. Frames can also remain frozen on the screen, acting as horizontal or vertical ledges. Large amounts of information can be
presented clearly. With frames - which divide SPICE pages into multiple, scrollable regions - information can be presented in a more flexible and useful fashion. As the user navigates the site in “live” frames, the static frame’s sharing the user screen remain fixed, even though adjoining frames redraw.

An Instruction frame can contain links that, when clicked, display results in the adjoining Interactive Work space frame. The side-by-side design allows queries to be posed and answered on the same page or screen, with one frame holding the query form and the other presenting the results. Note: Frames have been submitted to the Internet Engineering Task Force and the WWW Consortium for consideration as Internet standards.

Common Gateway Interface

Within each SPICE frame, the pages come to life with audio, video, 3D viewing and other enhancements to HTML. The pages no longer look flat and static, nor are they constrained to textual environments. Common Gateway Interface (CGI) allows the SPICE server to run programs that generate “dynamic documents,” rather than being restricted to delivering “static documents.” When the user requests a document from a CGI directory, rather than sending the “document” to the user, the server runs the program and sends the output to the user’s screen.

CGI is a standard for interfacing external applications with information servers, such as HTTP or Web servers. A plain HTML document that the Web daemon retrieves is static, which means it exists in a constant state: a text file that doesn’t change. A CGI program, on the other hand, is executed in real-time, so that it can output dynamic information. In SPICE, requests from the user console are routed by a Web daemon on the server to a CGI program. The CGI program passes the requests in real time to an executable that operates on it and integrates it with current performance information. The program also receives the results and displays them to the client. In effect, it generates HTML code on the fly.

JAVA

Another approach used by SPICE to create dynamic pages is the use of Java APPLET’s. A Java™ applet is a program that can be included in an HTML page, much like an image. The SPICE system uses Java-compatible browsers to view SPICE pages. When the page contains a Java applet, the applet’s code is transferred to the SPICE classroom system rather then the server and is executed by the browser. Extensions to the basic applets such as Marimba’s Castanet channels are being investigated to create and maintain persistent data, such as documents and preferences, that can communicate data, such as usage patterns, back to their servers.

Running on a user machine, a Castanet tuner can install new versions of a channel’s files while the current version is running. For maximum efficiency, channels are “differentially” updated: only modified files are sent by transmitters to tuners, and all files are sent in a single TCP connection. Because only a small percentage of a typical file change, updates can be frequent and fast. Castanets maybe used with Hybrid Media to smooth out the communications loading as the Internet bandwidth grows. SPICE modules may combine session sensitive data pulled from the Internet with graphics, animations, video and audio stored that were captured locally during off-line downloads.

Conclusion

SPICE modules will be built on an existing technology that has been demonstrated, and is anticipated to grow. It only requires the wise application of these proven elements to contain and present the expert subject matter. Evaluation of this new paradigm as it applies to school-to-career connections and to the acceptance of education standards will be conducted in 1998.

The TEECH (Teacher Enhancement Electronic Communication Hall) program is a three year National Science Foundation (NSF) funded project aimed at fostering collaboration among leaders of teacher enhancement grants. Its purpose is to encourage communication, collaboration, joint exploration, and pooling of this community's collective resources.

TEECH (http://hub.terc.edu/terc/teech.html) has used Internet technologies to build a body of professional knowledge to inform the online teacher enhancement community. TEECH has employed such techniques as listservs, a library of online resources, and RealAudio. TEECH hosts discussions among Principal Investigators (PIs) on critical issues in teacher enhancement, electronic seminars with experts in the field, and special interest groups on topics such as follow-up after workshops, long-term sustainability of teacher enhancement efforts, and use of video in teacher enhancement.

During the past year we experimented with Internet audio as a tool for teacher enhancement. RealAudio (http://www.realaudio.com/) is an up-and-coming technology used on multiple Internet sites that range from news programs, record companies, and online courses. Internet audio is appealing, novel, and allows for user multi-tasking. It provides real-time streaming of audio information over the Internet and allows us to present discussions, debates and conference presentations asynchronously. It is now being applied as a tool for educational purposes (Figure 1). By having several experts in the teacher enhancement field address issues of concern, we are providing a forum for informed discussion and intellectual debate.

In this demonstration/poster session, we will share how the TEECH project has used Internet technologies to build a body of professional knowledge to inform the online PI community. Our focus is on the project's use of audio technology. The audio is accompanied by full text transcripts, so that people can listen while reading.

Figure 1. Leaders in the Field.
During the past year, we have experimented with three different formats:

- Conference Presentations — This format takes a live conference presentation and makes it permanently available to a wider audience. The user interacts with the Web-based presentation in ways similar to presentation software, with the audio and the presentation slides available at the same time (See Figure 2);

- Online Debates — While debates are usually real-time, an intellectual exchange of ideas doesn’t have to be. By interviewing leaders in the field and asking them a set series of questions, we are able to represent different perspectives on a single question. (Figure 3) Their different thoughts and perspectives can be fuel for thought and future discussions/debate;

- Leaving a Legacy: Sustaining a Project after the Funding Ends

There’s a Web page with instructions for downloading the Real Audio software you’ll need to hear the discussions.

Listen as Bob Tinker (President of The Concord Consortium) and Beverly Hunter (Manager of BBN’s Educational Technology Systems) discuss some of the questions, issues and concerns raised by the participants of the Leaving a Legacy mailing list.

What are some approaches to sustain the work of teacher enhancement projects?

Key ideas include:

- Developing something unique
- Working with systemic reform efforts currently underway within a school or district
- Reaching out to other Teacher Enhancement efforts

Creating linkages between Teacher Enhancement projects
- Institutionalizing the grant
- Using the network
- Treating the teacher as an intellectual contributor

Strategies for discouraging procrastination and lurking
- Advantages of having a support, private community online
- Linda Hurst’s book Learning Networks

Figure 3. Example of an Online Discussion.

- Case Study Discussions — The user is able to hear the presentation of a case study as well as multiple reactions and insights from the audience. (Figure 4) To date, group reactions were recorded at the time of the case study presentation. However, RealAudio provides the
opportunity for people not present at a presentation to comment on it and for users to then hear the presentation and multiple commentaries.

A NISE Conference Case Study
The Workshop Center

There's a Web page with instructions for downloading the RealAudio software you'll need to hear the discussions.

Hubert Dyasi, Director
The Workshop Center
City College of New York

The Case Study began with An Introduction to The Workshop Center (12 min.)
The Introduction included the following:

What is The Workshop Center?
Where is it located?
What is its population?
(3 min.)

What are the professional development needs of The Workshop Center?
(1 min.)

How does The Workshop Center work with teachers?
(5 min.)

What support programs does The Workshop Center use for teachers?
(2 min.)

Some thoughts about teachers as professional developers of other teachers
(1 min.)

Then, Hubert Dyasi answered questions about The Workshop Center.

During the second half of the session, members broke into small groups to discuss the issues raised by the case study. Each group shared a summary of their discussion with the entire group.

Figure 4. Example of a Conference Case Study.

These multiple formats allow us to experiment with Internet audio and bring the voices of leaders to a larger audience. As technology moves to incorporate real video transfer over the Internet, it will be important to reflect upon the lessons learned from audio Internet use. This has the potential to expand the scope of invitational conferences to a broader base of educational leaders.

INTEGRATING MATHEMATICS AND SCIENCE EDUCATION USING THE POWERS OF TEN

James R. Miller
University of Kansas

Adrian L. Melott
University of Kansas

In recent years, we have witnessed an enormous growth in the use of the Internet in general and the World Wide Web (WWW) in particular. More significantly, the modality of use has evolved from simple perusal of hypertext to the use of very sophisticated tools which enable platform-independent interactive distributed processing. This confluence of technological developments has enabled exciting new educational tools which are accessible to anyone with a Web browser and access to the Internet. The fact that these web resources are programmable and hence dynamically configurable means that they can readily be made applicable across an extremely wide range of age levels. The availability of these technological tools at this point in time is fortunate when there is a renewed national commitment to improve the quality of today’s science, mathematics, engineering, and technology education (NSF, 1993).

In this paper, we describe a prototype system that we are building which presents an interactive organizational framework for mathematics and science education based on the Powers of Ten tradition. We believe that use of this system will allow students to visualize relationships among the various physical and life sciences while perceiving the role that mathematics plays in each of the disciplines.

One of the major problems with existing science education is that students study science as if it were comprised of independent and compartmentalized disciplines: biology, chemistry, earth science, space science, etc. They acquire little or no sense that these and other disciplines are highly dependent, and that major concepts cross the boundaries of these domains. It is equally important for students to understand that mathematics is a tool with important applications across all the sciences. Therefore, it has been increasingly recognized in recent years that instruction in mathematics and the sciences must be integrated. This has led to a greater emphasis on team teaching of mathematics and sciences in middle and high schools.

We believe that visualization capabilities based on state-of-the-art graphics technology can be used to bring to life, and thereby significantly aid in teaching, important scientific concepts. We further believe that mathematics and science curricula can be developed in an integrated fashion using a powerful unifying metaphor coupled with compelling interactive visualizations. We begin by justifying the unifying metaphor.

In the broadest sense, science seeks an understanding of the universe in which we live. Our current understanding spans all levels, from the scale of $10^{-16}$ meters at which quarks are bound into a proton in the nucleus of an atom up to the scale of about one billion light years ($10^{26}$ meters) where the large-scale uniformity of the universe becomes visible. Viewed in this way, the scales (i.e., the Powers of Ten) form a “table of contents” for the bulk of our current scientific knowledge. The traditional scientific disciplines — biology, geology, astrophysics — are best understood as overlapping segments of this table of contents.

This scheme for organizing our scientific knowledge was first exemplified in the late 1950’s by a Dutch school teacher named Kees Boeke. He produced a book whose goal was to help students and teachers understand the nature of our universe (Boeke, 1957). Beginning with a girl in a chair, the reader sees a series of pictures ten times bigger (or smaller) on each page. Boeke's images spanned 40 powers of ten scales from $10^{-14}$ to $10^{22}$ meters. This book inspired the production of two movies, the first was produced in the 1950's, the second in the 1970's. These films are still widely used in K-12 science classrooms.

There is an updated book version based on the second movie (Morrison & Morrison, 1982), and a third generation IMAX film has recently been released (Summers, Mihos, Herquist & Bryan, 1996).

Clearly the fact that strong interest in this approach has been sustained for the past four decades is powerful evidence of the importance and value of this pedagogical approach to the organization of scientific knowledge. We wish to extend this approach into an interactive medium by
developing a prototype web-based organizational framework for mathematics and science education. The system we are building will extend far beyond a simple updated version of this visualization. We plan to use the Powers of Ten framework as an index of scientific disciplines from which interactive, engaging hands-on lessons dealing with specific topics and disciplines can be accessed.

The overall goal of our efforts is to provide the necessary infrastructure to support the development of tools promoting educational practices which can be used to integrate and improve the quality of mathematics and science education across the K-12 grade levels. Clearly this is a huge and obviously open-ended effort. For the purposes of our prototype, we are focusing initially on the middle school level and the physical sciences. We will see in a later section how the system architecture will help us deal with the “open-endedness” that arises as we add support for additional subject matter, other grade levels, and even adult learners.

The remainder of the paper is organized as follows: In the next section, we discuss how the system would be used by students and teachers. The following section discusses high-level architectural features, focusing on how the system can be extended indefinitely. Finally we summarize and make some concluding observations.

**System Usage**

As in the book and movie versions, students initially see an image of a person where the size of the image corresponds to a one meter by one meter area. Using the image of a person allows us to zoom into the skin, then into the cells, on into carbon atoms, and so forth, thus allowing us to explore various life science concepts along the way. Starting at the one meter scale ensures that our starting point relates to our everyday experience, hence the student will have an immediate sense of familiarity with the image. There is a system parameter which allows the visualization to start at any scale, but we anticipate that it will be most common to start at the one meter scale.

A sense of how the various scientific disciplines are interrelated will be achieved by seeing that major concepts cross boundaries between the domains. That is, since the sciences are highly dependent, in general, several disciplines will serve to explain what is happening at the current scale. For example, at the cellular scale, both biology and chemistry are relevant in understanding how nutrients get inside cells.

In our view, this tool is best viewed, not as an adjunct to the curriculum but rather as its backbone. As such, the educational possibilities are open-ended. At the level of the human, for example, students can explore in small frames the differences in follicles and visual appearance between straight, wavy, and curly hair when magnified. However, they will also learn that the descent to the molecular level or expansion to the large scales causes these differences to disappear: we live in the same Universe and are composed of the same kinds of molecules.

Upon entering the skin, both a hair follicle and a sweat gland come into view. At this point the student can choose to examine one or the other. Choosing hair can branch the user to examine the types of human hair, lessons on its growth rate, alterations to its chemistry by humans (curl and color), and a physics lesson on light (kinds of light reflection that lead to highlights) and heat (explanation of thermal insulation by air entrapment). Choosing the sweat gland can lead to learning about its role in maintaining body temperature, the fluid and salt balance of the body, and the relationships to subject areas such as physics, chemistry, physiology, and sports, in each of these cases.

A maze of conceptual connections is possible at each level, some more than others. At the level of atoms the basic general structure of an atom will be presented. At the middle school level we will only introduce the elements of the idea of chemical bonding by molecular orbitals, but we insist that pictorial instruction of these basics is an essential. In addition, the uniqueness of the carbon atom and its multiple bonding capability which is so important to life will be mentioned.

Mathematical concepts and methods can be presented at each scale in appropriate scientific contexts as well. For example, integration of functions can be introduced while studying how long it takes an object to fall to the ground. Distance, surface area, and volume computations can be introduced with meaningful visualizations.

For purposes of discussion, we briefly explain the screen layout currently used by the prototype. The primary display is partitioned into five major regions. The largest region is the middle of the screen where the current Power of Ten image will be displayed. The other four regions surround this central image. Above the image is a caption identifying the current Power of Ten scale and a set of buttons which allows the user to zoom up or down through the scales. Along the left and right hand side of the images are buttons for associated operations; those on the left are scale-dependent (e.g., links to explanatory text, exercises, and auxiliary visualizations and simulations), while those on the right are for tasks which are scale-independent (e.g., there is a button which creates a “tear-off” frame containing the current image for purposes of visual comparison with a subsequent image). Along the bottom of the image are buttons which control an animation of the images.

Using these buttons, a student can see a movie version in the center of the screen by having the system continuously zoom up and down through the scales. Various aspects of the animation, such as the delay time in milliseconds between subsequent frames, can be controlled by the user.

At each scale, embedded links along the left side of the image will be used to take the student to appropriate and related resources such as simple raster images (GIF, JPEG,

**Telecommunications: Systems and Services — 1251**
etc.), interactive 3D visualizations defined using the Virtual Reality Modeling Language (Pesce, 1996), interactive programs or simulations, movies, related external web sites, and so forth. For example, when the student is at the scale of a human cell, a video of cell mitosis might be displayed in one window while relevant vocabulary terms are displayed in another. These scale-dependent static and interactive resources will enable students to visualize important phenomena as well as provide them with an environment in which to perform experiments relevant to the current topic.

System Architecture

The core of the system is being based on standard WWW technology. We believe that to be most effective, these materials (as well as additions, corrections, and updates) must be disseminated as widely and efficiently as possible. There simply is no better way to achieve these goals than to use the infrastructure of the WWW.

Specifically, the Hypertext Markup Language (HTML) and standard protocols such as Hyper Text Transfer Protocol (HTTP) are being used for all textual explanations as well as providing the context for the controlling program which is being developed as a Java applet (Arnold & Gosling, 1996). The Virtual Reality Modeling Language (Pesce, 1996) will be used to model and deliver realistic interactive 3D visualizations appropriate to the current scale. VRML is a language designed to support multi-participant interactive simulations across the Web. One defines a structured three-dimensional world with this language, complete with interaction handles and “hyperlinks” to other VRML worlds. These hyperlinks work in a manner analogous to those in standard HTML documents, but here the links are embedded in three-dimensional space, and their selection typically results in a dramatic change in the visual context since the student literally moves to a “different world”. In our case, for example, the student may move from an interactive environment in outer space to an interactive earth-based environment with a simple click on such a link.

Our use of VRML visualizations differs from that of the Powers of Ten image frames themselves in that the VRML scenes are fully interactive three-dimensional environments. By contrast, the flat projections of the Powers of Ten scales provide us only a “table of contents” organizational structure and corresponding navigation mechanism for getting to move to a particular frame in the Powers of Ten sequence.

As is true of many of today’s web resources, we are not developing a single computer program per se, rather an interconnecting set of tools which include such things as hypertext reading material and embedded interactive tools for students to learn in a hands-on fashion. The general infrastructure of the WWW and the Web-related tools reviewed above allows this set of tools to grow continuously, embracing new subjects, thereby appealing to ever-larger segments of the population.

Java and VRML will be indispensable parts of this approach. We are using Java applets (and we may use standalone Java applications) to do the basic zooming through the Powers of Ten images. Java will also be used for many of the auxiliary applications and simulations. VRML scenes will be used for interactive worlds as noted above. We are closely watching the Java-VRML programming interface developments as we anticipate that the ability to create and manipulate VRML from Java based on end user input will make our visualizations and simulations dramatically more powerful.

The use of these web-based tools allow us to deliver this technology in a platform-independent fashion, supporting everything from personal computers to high performance workstations. This platform independence is extremely important since it means that the materials are accessible to students in virtually all public schools. To access the system, one needs only a relatively modest computer and software configuration.

But there is a definite price to be paid for this platform independence. Java achieves its platform independence by being an interpreted language which requires a virtual environment implemented inside of a web browser. Interpreting Java code inside of a web browser entails a significant performance penalty, particularly when the sort of numerical computations that we will require for our associated programs and simulations is involved.

That there is a performance penalty to be paid can hardly be considered a surprise. To be sure, the Java community as a whole is well aware of this problem, and much work is currently being done to develop a technology known as “just-in-time compilation.” The idea is that, as the byte codes for a Java class are downloaded, the just-in-time compiler translates them into machine code for the platform on which the browser is running. If these tools are successful, the performance of Java programs will get much closer to that achievable with actual compiled code.

The Java applet reads configuration information at startup time which allows it to be tailored in various important ways. For example, the base location of the sets of images and the base location of the associated descriptive text are separately specified. This allows different Powers of Ten image sets to be used, thereby making it easier to appeal to learners across a wide range of ages as well as ethnic and cultural backgrounds. In a similar manner, the separate specifications of the base location for the primary descriptive text associated with the image frames makes it easier to tailor descriptions according to age and background as well.

Also included in the configuration information is a description of the set of applications, exercises, and so forth.
available at each scale. Java does not require that all of this information be known at compile time, hence auxiliary Java applets can be added to the system at any time (even while the applet is running!). This capability allows us to provide a mechanism which would permit anyone — a student, for example — to write an applet which could be executed at the appropriate time by the controlling Powers of Ten applet.

Summary

We are developing a prototype, interactive suite of WWW-based tools for producing and controlling the display of images which help students visualize vast scaling concepts. In the prototype, students will see an initial image and will use interactive graphical controls to zoom in or out. A set of mathematics and science lessons and other auxiliary material will always be selectable. The specific materials available will depend upon the scale currently being displayed. For example, one student might be looking at an image whose scale is 10^4 meters while watching a video on molecular structure; another student might be at the image whose scale is 10^{21} meters and be doing a high school mathematics lesson related to distances between galaxies.

As the project progresses, exemplary teachers will assist in identifying problems that advance critical imagery skills that are consistent with emerging standards of the National Science Teachers Association (NSTA) and the National Council of Teachers of Mathematics (NCTM). Ultimately we envision serving students across the K-12 spectrum, college students, and adult lifelong learners, but we are initially targeting our prototype towards middle school students. The prototype (as well as the full system) will require only the most modest of computer hardware: a personal computer and access to the Internet. We recognize that there are significant performance issues to be addressed, however, so we are closely monitoring developments on a number of fronts including the just-in-time compilation tools mentioned earlier. Other possibilities will be to become a “trusted site” which would allow us to avoid a number of performance issues which exist because of security-related concerns.

It is important for students to learn how to learn in an increasingly technological world. Our knowledge of the world changes continuously. Technical books rapidly become obsolete, hence lifelong learning becomes very much a research activity. We believe it is imperative that we teach students not only the important scientific facts and formulas of today, but also the skills they will need to seek new answers and even new questions tomorrow. We believe experience gained by students using a tool such as this will provide an important part of these necessary skills. Links embedded in the pages of our system will point to outside science and math resources, and exercises for students will include problems which require them to scour the Internet for required information. There will generally be no one “right” place to obtain information, and often the teacher assigning the problem may not know exactly where answers are to be found. But this is precisely the nature of research.

Acknowledgments

The ongoing work described here is being performed in DesignLab, a multidisciplinary research laboratory funded in part by NSF Grant CDA-94-01021.

Project Caprina: University of Maryland's Mini-Application-Web (MiAoW)

Cheng-Shien Chang  
University of Maryland

Walter Gilbert  
University of Maryland

Julie Q. Bao  
University of Shippensburg

Project Caprina, the Mini Application Web (MiAoW) at the University of Maryland at College Park, began as a collaboration between the Computer Science Center and the Department of Art History. The Caprina Project has expanded quickly to many other disciplines as innovative faculty have devised uses for computer-based images (1992-1995) and later for application software (1995-the present) in teaching and learning. The campus-wide optical-fiber-based network permits access to Caprina images and Caprina-supported applications from thousands of computers in student labs and faculty offices. Caprina uses a Novell server for image storage and delivery; a limited World-Wide-Web format is also available: http://www.umcp.umd.edu/caprina/home.html. To date, Caprina has been utilized by University Maryland departments and colleges, including Art History, Chinese, Anthropology, Architecture, College of Business and Management, Textile, and College of Education. Caprina-supported applications range from commercial software to various departmental designs in the University.

Goal and Benefits

The initial goal of the Caprina project is to improve education, research, and community service by providing ready access to large collections and a wide variety of digitized high-quality images via the campus optical-fiber-based network. Therefore, the authors define the initial four years of Caprina development as the “Caprina: Image Service Provider (ISP) Era” (Figure 1). Such a concept is very similar to the invention of an “Internet browser” like Netscape Navigator and Microsoft Internet Explorer. Since Caprina was developed based on the Local-Area Network (LAN) architecture, the authors intend to refer to Caprina as an “Intranet browser.”

The beginning stages of the project are already yielding unanticipated benefits. The large number of students in disciplines such as Art History and Architecture has usually precluded their access to departmental slide libraries for review of images seen in class. In turn, instructors have restricted their syllabi. Now faculty are unrestricted in their choices of images since they are all available on the network. Other benefits of the Caprina project are listed below:

Easy Access. Perhaps the most general and far-reaching benefits of network-accessible digital images will come from “armchair” access to large collections of images. Not only will the images be available, but search techniques for finding images will be vastly improved, especially for people who are not content specialists.

Permanence. It is sad to realize that many of the materials which are fundamental to many lines of study are perishable: pottery breaks, audio tapes demagnetize, buildings decompose, and slides fade. While digitized images are only a representation of a real item, they do not fade, melt, dent, rust, scratch, chip or peel.

Rapid Availability. Many disciplines can benefit from the rapid availability of images. An image can be scanned and loaded into a special collection in a few minutes. Astronomers, meteorologists, and geographers can study the latest images from space. Botanists can access recent images of diseased plants. Medical students can view recent surgeries.

Classroom Use. A collection of digitized images can be shown in class directly. It is much easier to return to a previously displayed image with the click of a mouse than to resort to the trial-and-error search of a slide carousel. With an adequate index, an instructor can spontaneously show images to support a temporary diversion from the mainstream of a lecture. In selecting images for presentation in a course, instructors are no longer limited to those which students can independently find copies of for later study.

Access by “Non-traditional” Users. Facilitating the lives of current image users is noble, but expanding the horizons of others is extremely beneficial. The greatest potential of the online access to digitized images is their...
use by people who, for reasons of ignorance or inconvenience, do not currently use them. Already we see secretaries and administrators browsing the collection from sheer curiosity — just because it's there.

Collection Management. Not only can the art gallery and small museums improve the management of their collections by having digitized images of their holdings, the rest of the campus community can benefit from their availability. Imagine having a preview of an art show online.

Figure 1. Caprina Interface During ISP Era.

The Making of Caprina During I.S.P. Era

The Target of Implementation. The Caprina project began in fall, 1992, as a collaboration between the Department of Art History and Archaeology and the Computer Science Center. Art History has a collection of about 250,000 slides. While this collection is well managed and effectively housed, access to it is limited to faculty and some graduate students; there is no way that access by the hundreds of undergraduate art history students could be accommodated either physically or administratively. Therefore, while there were many approaches which could have been taken to digitizing the collections, it appeared that the most pressing need was providing image access to undergraduates.

Hardware Implementation. Since ease of image accessibility was a key design goal, it was decided that the basic delivery mechanism would involve the campus data network. This optical-fiber-based network reaches over 11,000 faceplates on campus with both fiber and 10baseT Ethernet. The basic protocol is TCP/IP but it also passes Novell Netware packets so that any of the 5200+ computers on the network can potentially reach any of the 60+ Novell servers.

The 1000+ computers in the 30+ student computing labs on campus are all attached to the network via a local server. However, the NeXt computers have monochrome monitors and the Apple computers cannot access the Novell servers — they use local AppleTalk servers; therefore, the initial thrust of the project was the use of IBM computers and compatibles. IBM is the dominant computer on campus; most of them have monitors with 1024x768 pixel resolution at 256 colors, which displays a very nice image. Microsoft Windows 3.1 is the standard operating system. (We expect software will be available this year to permit Macintosh computers to fully participate in the Novell networks.)

Software Implementation. Student access to images is via several locally-written programs. One presents the student with the bibliographic citations of the images in the order in which they appeared in class. Clicking on a citation produces the image. Multiple images can be displayed simultaneously. A flash-card program presents students with sets of images in random order.

Storing Images. We currently copy the 768x512-pixel image to the server and reduce its color palette from 16 million to 256-colors. This is only 1/48th of the information in the original image on the Photo-CD but it is adequate for several reasons: 1) this is a good size for viewing on most monitors (the next larger size, 1536x1024 pixels, will not fit on a 1024x768 monitor); 2) the network transfer time of 5 seconds is tolerable; 3) modem color dithering algorithms are so effective that the difference in appearance between an image displayed with 16M colors (24-bit color) and one displayed with 256 colors (8-bit color) is surprisingly very small; and 4) the disk space required on the server is tolerable: about 200KB to 390KB per image in uncompressed bit-mapped format (.BMP).

Accessing and Displaying Images. The search technique (program) is designed specifically for students who are taking classes requiring image study. The first, called MultiSlide, permits a student to simultaneously view as many images from the class list as they desire. The second, QuizSlide, is a flash-card-like self-test program which randomly presents the user with images from a preselected set. Clicking on a button will display the description of the image. Both are Windows-based programs written in Visual Basic.

In MultiSlide, the student selects the desired class by clicking on its name in a list (see Figure 2).
The list of all of the images for the class appear in a scrollable window; it is actually just an ASCII file so it is easy to prepare. The student scrolls through the file and double clicks on the name of the image to be viewed. The image is loaded from across the network and displayed. Multiple images can be displayed at one time although a 1024x768 screen size imposes a practical limit of three or four. The ASCII text file is prepared from the data entered via WordPerfect.

In QuizSlide, the student also selects the desired class by clicking on its name in a list. Next, the name of the set of images to be used in the self-quizz for that class is selected from a list (see Figure 3).

For example, one quiz list could include all of the images in the course, another could be those to be covered on the midterm exam, and another could be the floor plans of all of the buildings studied. Once the list is selected, an image is randomly selected and displayed for identification. Students can confirm their identifications by clicking on a button. (Kozintsev, Stenchikova, Chang & Gilbert, 1996).

**Caprina: The Application Service Provider Era (1996-Current)**

Caprina was realized as an Application Service Provider (ASP) during late 1995, though it has served as an ASP for applications like MultiSlide, QuizSlide and SearchSlide since 1993.

Such transformation (or recognition) has been highly encouraged by the campus community and thus targeted by the Caprina development team. A simple yet strong support to the shift in emphasis from Caprina (ISP) to Caprina (ASP) can be derived from the important role that JAVA plays in the Internet (World Wide Web) community. Similar to the JAVA applet terminology, Caprina (ASP) enables instant application access from a remote application server. Caprina (ASP) to the University of Maryland "educational Intranet" is analogous to JAVA to the worldwide Internet. Caprina (ASP) was also coded as TT Attach '96 during the development stage (see Figure 4).

![Figure 3. QuizSlide Software Interface.](image)

For example, one quiz list could include all of the images in the course, another could be those to be covered on the midterm exam, and another could be the floor plans of all of the buildings studied. Once the list is selected, an image is randomly selected and displayed for identification. Students can confirm their identifications by clicking on a button. (Kozintsev, Stenchikova, Chang & Gilbert, 1996).

**Extensive Acceptance of Caprina as A.S.P.**

The authors research and summarize below the extensive use and acceptance of Caprina as an Application Service Provider:

**GEDS (Department of Government and Politics).**

The Global Event-Data System (GEDS) is designed to provide computer-aided identification, coding and abstracting of daily international and domestic events, as reported primarily in Reuters international newswire service as well as other sources. GEDS project is a part of the Center for International Development and Conflict Management (CIDCM), which is dedicated to analysis of the needs of nations and resolution of their conflicts.

CIDCM provides undergraduate student internships/research assistantships to develop practical research skills in computer-assisted generation and application of international and intra-national event data through GEDS. At the University of Maryland, GEDS is made available through Caprina '96. GEDS was also developed at the University of Maryland with National Science Foundation support as a basis for updating and expanding the major event-data banks, and also as a basis for the prediction of future trends, crises, and conflicts.

**Multimedia Toolbook (Department of English).**

"The Computer and the Text: Multimedia as Critical Expression" is an innovative course offered by Professor Robert Kolker. This course encourages students to create projects in which words, images, sounds, and design interact. The course examines how multimedia computing offers new ways of critical and imaginative expression (Kolker, 1996). Course readings and discussions cover some computer basics and some theories of the text and hypertext.
Hypertext techniques such as linearity, non-linearity, structures, links, hiding, showing, connecting, searching, and guiding are illustrated in class. A software package “Multimedia Toolbook” is used for creating class projects (Kolker, 1995). This project development is scheduled as a between-classes task, therefore, students need to access “Multimedia Toolbook” outside of the classroom through Caprina (ASP).

HyperCourseware (Department of Psychology). HyperCourseware is a model of instructional interaction designed by Professor Kent Norman to facilitate the application of hypermedia and electronic collaboration in the classroom. Objects used for classroom activities, such as the course syllabus, lecture notes, the class roll, etc., are represented in graphic form on the computer network (Norman, 1994).

Many students take advantage of such a unique and powerful creation to prepare and review course materials both inside and outside of the classroom. Since the contents of HyperCourseware are updated frequently by the faculty, the best place to store these materials is a remotely accessible file server. Caprina provides an ideal bridge for students to get connected to the file server to obtain HyperCourseware and related material.

Microsoft Access (College of Journalism). In fall 1993, the College of Journalism opened a new computer lab dedicated to computer-assisted journalism. The inaugural computer-assisted reporting course was taught by Bill Dedman, a former Atlanta Journal/Constitution reporter who won a Pulitzer Prize for documenting mortgage discrimination against blacks. His series remains a model for computer-assisted journalism. The course is now taught by Penny Loeb, a senior editor in charge of database projects at U.S. News & World Report and a leader in this fast-growing field.

Upon completion of the course, students produce an in-depth computer-assisted reporting project. Microsoft Access is the database management application used for the student database projects. Many database files are larger than two MB in size and cannot be carried around by students using regular floppy disks (1.44 MB average). Some students even produce several database files up to 300 MB. Caprina is thus adopted by the class for downloading large-size database files that were conveniently placed by the students on the file server.

Total Quality Management (TQM) Tools. The TQM software was invented jointly by Professor Maryam Alavi and Professor Youngjin Yoo of the College of Business and Management. Most TQM software components were designed to encourage faculty to deliver innovations in course content and teaching methods around total quality principles and team teaching; to foster students with knowledge and experience in total quality; to highlight the opportunities provided by current information technologies by teaching and learning in a state-of-the-art “virtual” classroom. Some TQM software modules such as One-Minute-Paper and Class Directory are made available through the assistance of Caprina. (Stenchikova, Chang & Gilbert, 1994; Yoo, 1994).

The Making of Caprina During A.S.P. Era

The basic building blocks of Caprina (ASP) are the same as Caprina (ISP) except that Caprina (ASP) has become more class-oriented. The technique for providing application and image access to students is to use a remote Novell server to deliver the application/image. All that is stored on the local server in each computer lab is a special program, the application launcher, which: 1) connects to the remote image server, 2) executes the desired programs from the image server, and 3) automatically disconnects from the remote server (but not the local server) when program execution is terminated in any way.

On each individual computer is a Windows icon; when selected, it invokes the application launching program. Therefore, application maintenance is minimal: the icon on each local computer is just part of the standard Windows configuration. The application launching program on the local server is configured with a small, Windows-compatible initialization (.INI) file which identifies the image server; this file changes only if the name of the image/application server changes — infrequently. All of the “real” software, including the main initialization file, resides as a single copy on the image/application server — easy to maintain. For Caprina (ASP), additional coding was appended to Caprina (ISP) to accommodate any special requirements by the applications to be launched. Below are the four unique features being built into the Caprina (ASP)

User Name/Password. Unlike Caprina (ISP), Caprina (ASP) builds in a unique “user name/password” dialog box that requires each user to enter his/her assigned user name and selected password. This method allows Caprina (ASP) to determine the appropriate items listed in GROUP.INI and REMOTE.INI files as illustrated below (see Figure 5).

![Figure 5. User Name/Password Feature for Caprina (ASP).](image-url)
GROUP.INI File. This file is used by Caprina (ASP) to determine the actual home directory of each user (student, TA, faculty or technical support personnel).

Unique Network Drive Letter. Since different classroom applications have different pre-defined drive requirements, Caprina (ASP) automatically connects and build the desired drives. Below is a list of standard drives that are established after Caprina (ASP) connects to the application server:

- M Drive: User Personal Home Directory
- N Drive: Class Share Directory (for class notes and homework)
- K Drive: General Application Directory (mostly used by students)
- H Drive: Student Digital Photo Directory
- S Drive: Special Application Directory (mostly used by faculty and staff)

REMOTE.INI File. This file is used by Caprina (ASP) to determine the displayed title/name, actual location, and physical execution file name of each individual application required by class users (student, TA, faculty or technical support personnel).

Implications for Teacher Education

Perhaps the most important contribution of all of both Caprina (ISP) and Caprina (ASP) is the opportunity to change the lecture process to include more student involvement and collaboration. Currently, a lecture is where the instructor does something to the students. Much better is a setting where the students participate in the process. By having access to the slide library and advanced learning tools, students could prepare special presentations as class assignments; for example, a presentation on Russian mosaics to be given at a local elementary school. Or they could construct a in-depth database report on international trade analysis; or take pictures of rooftop ornaments in a certain part of town, have them scanned and made part of the permanent image collection. This concept, of students actually contributing to the information base locally in the classroom and remotely before/after class, is the leading trend in teacher education.

Trans-European Networks and Their Role in Improving the Education in Countries with Transition Economy: Educating the Educators

Borka Jerman-Blazic
University of Ljubljana, Slovenia

There are many notions that include networks and education. There are networks of people involved in education or special education topics, networks of excellence, networks of institutions, universities or networks of programs or relay centres. These networks are just some of many involved in the educational process. This paper deals with other type of networks - networks of infrastructure that enable the exchange of knowledge and information relevant for the development of an educational revolution in the late part of this century.

Eastern and Central Europe (CEE) has for many years been the shorthand reference for those countries in the political/military and economic sphere of the Soviet Union with the exception of Yugoslavia and the countries that appeared after its dissolution. The political transformation of these countries after the fall of the Berlin Wall made it possible for these countries to enthusiastically embrace the technology that was developing without political and institutional barriers - the new communication networks and the Internet.

These emerging technologies enabled setting up educational and research networks in Eastern and Central Europe. The infrastructure for basic Internet connectivity was built relatively quickly, since it was mainly matter of funding; but the rest was much more demanding. The building of the infrastructure required knowledge, organisation, management and other skills that were not present in these countries. Several initiatives were launched in cooperation with European Union programs and projects to foster the development and bring necessary knowledge, but some actions were initiated by the countries themselves. One of these successful actions was the setting up of the Association of Academic and Research Networks of Central and Eastern European countries. This action was launched three years ago and now the new-born child known as CEEnet is moving successfully towards new challenges and duties.

The basic ideas that governed the setting up of CEEnet, a complementary organisation to the existing Trans-European Association of Academic and Research Networks (TERENA) are presented. CEEnet activities and experiences in organisation of international schools for educating the educators from CEE countries in the field of networking and Internet-related technology are described and the evaluation prepared by the attendees is discussed.

Setting up an Organisation - the Birth of CEEnet

CEEnet was set up in 1994, however, representatives of seven national networking organisations for academic and research networking started discussions on the coordination of the networking activity in Central and Eastern Europe in 1993. Very soon after the first discussion began, a new networking association was created - the Central and Eastern European Networking Association - CEEnet. CEEnet is a legal body registered in Austria. Currently, 19 countries belong to the organisation. Members of CEEnet are national networking organisations focusing on academic and research networking of Central and Eastern Europe. Each country is represented by only one organisation with official authorisation, as follows: INIMA - Albania networking organisation (N.O. in the text that follows); AConet - Austria, N.O; UNIBEL - Belarus N.O; UNICOM - Bulgaria N.O; CARNet - Croatia N.O; CESNet - Czech Republic N.O; EENet - Estonia N.O; ICM - Georgia N.O; HUNGARNet - Hungary N.O; LATNet - Latvia,N.O; LIITNet - Lithuania N.O; MARNet - Macedonia N.O; NIC - Moldova N.O; NASK - Poland N.O; RNC - Romania N.O; FREENet - Russia N.O; SANET - Slovakia N.O; ARNES - Slovenia N.O; and UARNET - Ukraine N.O.

The main objective of CEEnet is to coordinate international aspects primarily of academic and research networking in the region of Central and Eastern Europe. In order to attain this objective, CEEnet:
promotes and encourages technical and organisational co-operation between national networks;
- supports the exchange of operational, directory and technical information;
- protects and serves the interests of CEEnet and its members with respect to other organisations;
- when appropriate, sets up and maintains common services and technical facilities;
- establishes working groups to perform technical activities in line with objectives of CEEnet;
- supports and organises conferences;
- publishes and distributes documents, brochures, periodicals;
- promotes and encourages the development and establishment of appropriate national services;
- prepares and submits proposals to international and European organisations to promote network developments for CEEnet and its members;
- participates in any other activity that supports the goals of CEEnet.

The main body of CEEnet is the CEEnet General Assembly. Regular meetings of the Assembly are held twice each year where all important decisions for the organisation and its work are made. The CEEnet WWW home page can be found at: http://ceenet.nask.org.pl.

Educating the Educators

Identified Needs and Requirements

New information technologies, especially information networks like the Internet, offer enormous possibilities. While it is true that in most of the CEE countries these technologies are not necessarily developed, or are available only for a smaller community, even these restricted possibilities far exceed the existing human and other resources, and are often unnecessarily limited by the conservative or traditional, but in any case, inappropriate organisational and managerial methods applied. In order to overcome these current difficulties, resulting from the well-known inertia, CEEnet tries to consider various means for the promotion of user demand and awareness. Some of them are very well known such as media, training, clubs, demonstrations, schooling, etc.

In order to get potential users interested and initiated, CEEnet recognised that more information should be provided in the following areas:
- available services, databases, tools,
- new possibilities and methods offered by the world-wide network,
- examples of practical use of network services,
- costs of introduction and usage,
- where and how to start.

In preparing the activities, three different levels of awareness were identified among CEEnet organisations. The scientific and academic community is very active in the field of networking. Its efforts are now coordinated and channelled by the national network organisations. Mail services and list servers offered by the Internet are recognised as an obligatory element of research in many centres and institutions. Still there are some differences among various groups of researchers, but the leading ones, especially in the fields of technology, have both experience and skills.

The medium level of awareness can be found in libraries, chambers of commerce and some specialised technology information centres. They can identify the sources of information that are most relevant to them but usually they lack experience and facilities to get access to it. Libraries are exceptionally poor in facilities due to the budget limitations during the last decade.

The lowest level of awareness is presented by local administration, sometimes even by central institutions, and small and medium sized enterprises (SMEs in the text that follows). The reasons are different. Administration in many CEE countries is poorly equipped with network facilities and personal knowledge on working with the network services is almost nonexistent. Moreover, administrative procedures usually come from the past and do not require networking as a means of collecting information. SMEs in CEE are involved now in problems that are more basic and vital for them, so they do not fully recognise all of the possible gains of networking. They tend to consider more active participation in a network information system as a very distant option for them. In terms of an unstable market and serious transformation difficulties, they are not aware of the relevance and importance of their participation in the Internet and related networks.

Various groups of current and potential users of information within the international networks are very different in terms of facilities, experience and knowledge about networking. Many organisations do not recognise networking as a valuable tool or as a means of support for their activities. Even experience with computers is sometimes not adequate for use of the network services. Unfortunately, the administration, which is in many cases also a decision maker, does not sufficiently recognise new possibilities brought by the information networks and the Internet. The administration is also poorly equipped with network facilities - the majority of Internet users come from academies, universities and research institutes with the most advanced groups of users coming from the scientific and research community. The CEEnet idea was to use these relatively advanced users as information disseminators and tutors in training courses organised for other groups. Analysing the situation in all CEEnet countries, the following need for training and education were recognised:
- introductory courses for beginners,
- upgrade courses, tips and tricks for advanced users,
* user support, peer support, self-support,
* up-to-date on-line help, help-desk,
* new methods, good examples and ideas.

After several months of discussion on the CEEnet mailing list, it became obvious that the best way to meet the identified needs for education is to organise international schools where people committed to disseminating the knowledge they will get, will be invited to attend the school. In other words, CEEnet decided to organise schools where the future educators can be trained.

The International Schools and Workshops

The schools were organised in 1995 in Warsaw and in 1996 in Budapest and were attended by more than 100 participants from all CEEnet countries. The schools were funded by Open Society Institute (SOROS Foundation), NATO and some manufacturers who are also sponsors of the school. Every participant was selected by his native organisation and the number of participants per country was determined during the CEEnet Assembly meeting. All lecturers volunteered and were provided by the CEEnet membership organisations. During the summer, the program which was set up in Warsaw was slightly modified with the introduction of several new topics and the order of lectures was revised, based on the consultations with the track leaders. The format of the previous workshop, namely, to have two tracks - one technical and the other services and management oriented, was maintained. Proceedings from the first school that contained all basic tutorials were printed and prepared for this second school. The lectures started on August 25, 1996 and ended a week later, on September 1, 1996. The program consisted of the following topics:

- The History and the Nature of Communications
- The VSAT Links
- Local and Wide Area Networks
- Basic Internet Networking
- The Internet Network Organisation
- Serial Communications
- Network Management
- Internet Sources and Systems
- Connecting Networks
- Network Security
- Local IR Training
- User Support and Training

In addition to the regular lectures and exercises, the schools had two tracks of value added events. The first track consisted of a short presentations called “Sponsor’s Spotlights” with mainly technical content. These sessions were sponsored by Sun Microsystems, Cisco, and NetSat Express. The second track utilized an 'all in one place' workshop organisation, and contained general topic lectures and round table discussion. This special free style of the “Evening Lectures” become the success story of the workshop. Theses lectures were organised each night after dinner and included refreshments. The topics were exciting and thought provoking, and the refreshments along with a relaxed atmosphere made practically every evening a social event. The Evening Lectures covered a variety of topics, including: Virtual Reality, Internet and Society (with a panel discussion), Java and Assorted Flavours, VSAT Communication, the development of Hungarnet - the new ATM network, the Internet in High Schools, Internationalisation of the Internet and Character Sets. The representatives of Bosnia also spoke on the topic Internet in Crises.

The last lecture at the Workshop was devoted to the problems of User Support and Education where a number of attendees presented case studies of the experience in their respective countries.

The school was held in the facilities provided by the Central and Eastern European University Centre (CEU CC) in Budapest. Many of the school's facilities were used for the conference. The instructional facilities included:

- two laboratories with about 50 personal computer stations, five Sun Workstations, one Silicon Graphics, and one Hewlett Packard with Open View Software installed;
- six PCs in the lecturer's room, a UNIX workstation, along with a copying machine, a fax machine, and two telephones;
- three lectures rooms, with two sets of Video-beams and LCD tablets and a direct Internet connection, which could easily be combined into a very large single room;
- eight PC's were available to lecturers in their rooms;
- eight CISCO routers, in addition to the ones that provided communications services to the CEU CC;
- a large number of hubs, terminal servers, modems and transceivers for establishing various network topologies and executing the hands-on exercises;
- a special room for administrative services, and a separate dining hall for the participants.

The entire building was wired with Cat5, while a T1 link provided external Internet connectivity to the outside world.

Evaluation and Feedback

The school ended with an evaluation provided by the attendees. The format and the content of the evaluation form was completely changed from the previous year, and was based both on quantitative grading and verbal answers and comments. The overall grade given to the school was very good. Some of the answers and attendee's opinions are very interesting and the comments from the evaluation process are included below. The questions addressed the lectures as well as social and accommodation issues. The most relevant issues appear below with comments from participants:

Telecommunications: Systems and Services — 1261
A) The learning environment (program, instructors, teaching)

A1) The relevance of the program content with respect to your expectations:
- deeper covering, but very good
- some difficulties because of the differences in the levels of the audience
- no possibility to hear all the lectures
- additional training on OS for people with no experience in UNIX (Linux, BSD)
- on servers, more about content creation rather than technical details
- some of the lectures too easy
- sometimes too overloaded (some lectures should be optional)
- excellent program, occasionally too demanding
- complete program
- more serious than the ISOC (International Internet Society) workshop

A2) The quality of teaching:
- very high level - very good lecturers
- occasionally, better need for explanation
- no TV in the rooms (in order to study)
- better explanations for lab exercises

A3) The instructional facilities (equipment and labs)
- some exercises too elementary
- too little equipment, especially Cisco routers
- more lab time
- little bit more help in labs
- great place
- such good labs should have been more accessible
- longer lab hours and no TV in the rooms
- very good connectivity
- good program

A4) The suitability of distributed materials - the tutorial in the last year proceedings:
- my grade is four, it would be five if the W/shop results in the book as one from the last year
- more detailed examples as supplement
- put some materials on the Web
- more full text on some topics
- even more materials
- it is a good idea to join all the materials in one brochure (like the year before but more complete)
- materials also in a digital form
- hope to put full materials for downloading
- hope to have a full book
- please, additional text
- very good materials, covering the whole range of FAQ (Frequently Asked Questions) arising in my technical work
- the book should be distributed a month before the W/shop
- very good, right on time

A5) How useful were the Evening lectures:
- very useful to have two different viewpoints on VSAT technology
- it is good to learn about the social impact of the Internet
- Internet in Art for the next year
- all new developments
- some of the lectures excellent
- could be used for representations of national networks
- security issues in detail
- to hear more about social and legislative issues
- excellent, although sometimes tiring
- interesting topics and relaxed evenings

A6) Was the Sponsor’s spotlight worthwhile?
- some not very well prepared
- more technical issues and less advertising
- companies like Sun and Cisco must use on-line facilities (video + network) for their presentations and not plastic slides
- next year Microsoft should be sponsor

A7) What should be improved and/or changed in the Program and its execution in the future:
- I think it is very good such is now, it was very well organised
- more labs
- closer connections between lectures and labs
- too much lessons per day
- more solicited program
- more practical information
- additional lectures on multi-casting services
- two kinds of programs: beginners and system administrators
- lectures Vs exercises - 1:2
- more time in lab
- extensions of the lab time
- different venues for system administrators: beginners and advanced ones
- labs need to be organised for different levels of experiences
- more information
- track 2 programme should be more advanced
- may be another track 3
- unlimited access to labs
- CEENet has to have permanent educational programs, not only during the W/shops
- no changes whatsoever, only hope to repeat the same experience

B) The Living Environment (travel, housing, food, social events)

B1) How was your room accommodation:
- enjoyed connectivity in the room
- connectivity + computers in the rooms = great
- never seen that class of dormitory before
B6) From a logistic point of view in the future, I would prefer certain things done in a different manner. For example,
- for prospective future students in advanced info on the Web should be nice
- to have lecture descriptions, one day in advance
- more information, but good organisation otherwise
- the lab policy should be improved, and should be open all day and night
- the lectures should be ordered by previous knowledge and announced so if you already know the basics just skip the lecture
- the training in the lab over particular issues, so that every participant can do a complete lab by himself

C) Additional issues:
C1) Do you think that your country might be a good candidate for CEENet W/shop. Please, explain
C2) In case you have a local W/shop in your country, would you require a help from CEENet to organise it? If so, how could we help you?

Combined comments on C1 and C2:
- yes, good experience CEENet 1 (Poland)
- no technical base for the W/shop (Bulgaria)
- I do not think so, our country has no experience
- yes, but this (Estonia)
- not enough equipment
- yes, if in Yaroslav (YSU) we have developed environment for lectures and labs, and many places for sightseeing and visits
- of course yes because we have very heterogeneous environment and many service providers (Russia)
- Yes, we have fairly developed network
- yes (Bulgaria)
- we actually already discussed some potential places, there are a lot of lecture rooms in Tartu university and the hotels are not too bad, plus the Internet connection (Estonia).
- no, slow link
- no, not yet
- Estonia would be a good candidate - good infrastructure, people to do the logistic (technical) work, local experience to be shared.
- I think so, but depends on the people from CESNet and CEENet
- CEENet might help organised summer student exchanges

What more would you like to tell us?
- I would like to thank you very much for all that you have done for us
- Thank you so much
- Home Page with materials-please organise
- Thanks for organising the whole event-it was worthwhile to organise
- A Web site and the book should come out of this

- If the point of the W/shop was explaining most of the Internet topics and giving systematic view of them, that you did it.
- very professional event
- excellent place with excellent organisation. Congratulations.
- the security of the labs needs some revisions.
- I appreciate very much what you have done. Actually, I believe that the CEENet W/shop is already competitive to ISOC W/shops and has the same efficiency.
- thank you very much
- I liked it. There are things to be improved and I am ready to co-operate
- we are very tired, but we are lucky to get many new ideas for our work at home. Thanks.
- an effort at least as good as the ISOC Workshop, but more demanding and serious
- thank you. Waiting for the book.

Conclusion
After two years of experience in organising the education of the educators, CEEnet learnt that schools of this type are still necessary for the users and future service providers in the CEE region. The evaluation report has also shown that despite the fact that some CEE members have good and well organised infrastructures, such training is beneficial for both the less and more developed. The less developed gain basic information and learn how to set up, run and use a network, while the more developed get in touch with the most advanced technology provided through Sponsors Spotlight events and the evening panels and roundtables. The evaluation of the guests coming from ISOC, NATO, and SOROS were encouraging and stimulating. It was evident that CEEnet and its members managed to addressed the real educational needs in the region.

Acknowledgment
Part of the material presented was taken from the WS report prepared for the GA of CEEnet for the October 1996 meeting by the Workshop leaders: Jacek Gajewski, Poland and Oliver Popov, Macedonia.

HIGH TECH...HIGH TOUCH AT WALDEN'S ELECTRONIC CAMPUS - REVISITED

Marilyn K. Simon
Walden University

Andrew Abbott
Walden University

Walden University (WU), a distance learning doctoral degree program accredited by North Central Association, supports the philosophy that adult learning should be pursued at a pace determined by the student. The rationale for the Walden curriculum is grounded in the beliefs that what is learned should be relevant to students’ needs; that learning demonstrations should be negotiated between the student and the mentor (a relationship that should be one of mutual respect); that knowledge to be acquired should be applied to practice; and that learning how to keep on learning is more important than acquiring facts.

Walden University offers six Ph.D. programs, 1 M.S. program, and Distance/Collaborative/Adult education courses. The students and faculty come from many walks of life including: managers, executives, teachers, health care providers, consultants, and social workers. Although Walden does not have a traditional campus, it does support its students by providing access to the research libraries at Indiana University, Bloomington. A Walden librarian is available on site, and on line, to find and forward the books and publications students need for their research.

The WIN at Walden

To further increase the effectiveness of distance learning, without decreasing human interactions, Walden has developed an electronic campus. In May of 1994, Walden took the primary steps needed to make this electronic campus a reality. This involved providing the entire Walden Community (approximately 1200 students and 129 faculty members) with an electronic connection to each other and to the Internet. This virtual campus has been christened the Walden Information Network (WIN).

The rationale which led to the creation of WIN was based on the belief that:

1. Students should be able to receive training when and where they need it. During asynchronous workshops an instructor need not be present, so the student can select the time which best fits their personal schedule.
2. Students should be able to exit a training session at any point and return when it is convenient.
3. Students should be able to do more collaborative learning and group problem solving with each other and with members of the faculty.
4. There exists a vast range of instruction, and especially gifted lecturers should be able to reach a greater number of students.
5. Universities need to become a true community of scholars and focus more on the content of education.

Many people are concerned that electronically-mediated education will lack the human touch that is essential for true understanding. Although most of these concerns are normal, the experience of those who have participated in computer conferencing, or other interactive media, feel that these fears are unwarranted. In actuality, it appears that the intensity of relationships is often enhanced by the technology.

Translating the dream of an electronic campus into a reality has been fraught with challenges, many of which were not foreseen. Not only are electronic advances being made continuously, but development with respect to the National Information Highway seems to defy predictability. It has been almost three years since WIN has been operational. All students and faculty members have made it on to the I-way.

Dr. Marilyn K. Simon is one of the faculty members who participated in a pilot project to determine the efficacy of WIN. What follows is a descriptive evaluation by Dr. Simon, of WIN over a six month period. During this time, Dr. Simon had 12 advisees who were enrolled as doctoral candidates; 5 were connected (C) and 7 were not yet connected (NC).

Advantages of WIN

The following benefits have been observed by Simon’s advisory group C at Walden University who have been connected to WIN:

1. A high level of faculty/student; student/student and faculty/faculty interaction. Generally WU community members only get the opportunity to interact during
Admission Orientation Workshops (AOWs), Regional Intensive Sessions (RISs), cluster meetings, and summer residential sessions (SS).

2. The ability to have a written record of discussions. Telephone conversations, and conversations in general, can often be misconstrued. When a student receives electronic information from their advisors or other students on WIN, they have the option of printing this message for documentation purposes and for future reference.

3. The asynchronous nature of the dialogues allows time for reflection. Students and faculty can prepare responses to poignant and probing questions. They can then work at times which best suit their needs and learning styles.

4. The anonymity of this media allows for a more free flow of ideas.

5. Being place-independent means that participating on WIN does not disrupt a person’s work or their private and personal lives.

6. There is a more democratic process since there is an equalization of participation between those individuals who are more assertive and those who tend to be more reticent in group discussions.

7. There is a greater sense of a shared Walden culture. Participants interchange information they have ascertained about the events, policies, and procedures at Walden. They look forward to meeting each other at regional meetings.

8. There is a great deal of collaborative learning and group problem solving taking place.

9. There is authentic learning as participants enhance their communication and research skills and broaden their perspectives by considering other points of view.

### Progress with WIN

There is a wide range of time tables that students produce as they advance in the Walden program. Amongst students who have obtained degrees from Walden in the past few years, the mean average stay is between 2.5 and 3.5 years. To determine the progress made by the sample students in this study, the investigator dissected the Walden program into units as follows:

- **1 = PDP (Professional Development Plan)**
- **21 = KAMs (Knowledge Area Modules)**
- **4 Basic KAMS, 3 Advanced KAMS** [demonstrations of Breadth, Depth, Application of knowledge]
- **6 = Dissertation Proposal**
- **9 = Dissertation Completion** [once proposal is accepted]
- **1 = Oral Presentation of completed Dissertation** [no units were awarded to students for the completion of a Learning Agreement].

Of the 12 students in this study, 5 were fully connected to WIN either through the address provided by Walden or through their own internet connections. There was a great variance in the amount of work units produced during this time period between the members of the study. The mean and standard deviation were: \( \mu = 2.25, s = 1.9 \) units, and ranged from 0 to 6 units.

To determine if there was a significant difference in work units produced between those who were on WIN (C) and those who were not (NC), an independent t-test was performed. The mean number of units completed by those not on WIN (NC) was \( \mu = 0.875, s = 1.89 \) whereas the mean value for those on WIN (C) was \( \mu = 4.52, s = 2.5 \). The t-value of 3.743 (p = .0032) was determined. This indicates a statistically significant difference between the two groups with those connected, C, to WIN showing significantly more progress than those who were not, NC.

To determine if there was a statistically significant relationship between a student’s status on WIN and the amount of work units that student produced, the linear correlation coefficient \( r \) was computed. The \( r \) value of 0.82158 (p = .001), indicates that a statistically significant linear relationship between these two variables exists. Having determined that \( r \) is significant, the regression line was determined, and the coefficient of determination, \( r^2 = 0.675 \) was computed. This means that 67.5% of the total variation can be explained by the regression line, and 33.5% of the total variation remains unexplained.

### WIN Student Comments

The following are responses from students who were asked about their experiences on WIN. The length of time, in years, that the student has been enrolled at Walden appears in parenthesis.

PT (0.75)
Keeping in touch by e-mail inspires me and gives me the extra energy to maintain the momentum that is necessary to complete the work that is before me. It is also great to have an answer, most of the time the same day, rather than using snail mail which at times does not make it to the destination in this life time.

KK (1.5)
Being able to be in touch with my advisor and receive a reply within a few hours and at my convenience are by far the most important advantages to me. There are plenty of messages that I save and file and some end up as a hard copy in my papers. On-line communication fits with my busy life-style.

GD (0.5)
E-mail has made my Walden experience very enjoyable, so far, and has given me the direction that was
missing from my previous experience with distance learning.

In conclusion, I would like to share the thoughts of Gary Miller (1995) of DETC NEWS which were picked up online and reflect my own beliefs and opinions about WIN:

The irony of distance learning is that it was intended to allow students to work alone but is now bringing them closer together. Students can participate in education programs from anywhere in the world. These technologies not only allow students to study at an individual pace but to interact with each other, with their teachers, and with the universe of information sources, from databases to international libraries.

Students who have enrolled in Walden after Sept. 1, 1995, are required to demonstrate technological competency by completing a WIN I based learning experience. These entering students are placed in a group facilitated by a specific faculty member. To complete a WIN I seminar the student must:

- Identify, access, and use, technological support services
- Engage in collegial e-mail networking with faculty and colleagues
- Utilize many of the services available on WIN
- Join and contribute to professional listservs
- Access various databases

This presentation will begin with a description of WIN 1 + which is a high tech/ high touch new student orientation program. This will be followed by examples of applications such as: new systems of advising, accessing student records, faculty and student conferences, on-line seminars, corroborative research projects, and how WIN I has enhanced critical thinking skills while augmenting technological knowledge.

This presentation will also describe the pilot project, used to determine the efficacy of WIN. An interactive demonstration that will enable participants to evaluate WIN will follow. Information will then be provided delineating the operational procedures involved with creating an electronic campus, followed by examples of applications such as: new systems of advising, accessing student records, faculty and student conferences, online seminars, corroborative research projects, and enhancement of critical thinking skills will be discussed.

The presenters will discuss their views on telelearning and the implications of technology providing a lifelong learning system. Participants will be invited to share their views and experiences in these areas.

**Conclusion**

Distance learning is no longer a marginal part of higher education; it is an important means of providing access to educational opportunities and resources. Moreover, the dramatic rate of change in information is forcing us to realize that we don't need an "educated" population, but rather that we need to become a nation of learners who combine work and education. Learning must become an active and ongoing process rather than a test of memorization skills based on some acceptable list of core knowledge (Cochenour, Rezabek, & Burton, 1993). WIN was created to support this type of learning. Walden University was created to support this type of scholar-practitioner.

The Walden Community has discovered that when adopting informational technologies, it is critical to involve stakeholders at all levels of the organization. Faculty, however, must be involved in the governance of these systems, and the introduction of telecommunications-based education should be a collaborative effort. A successful process-created team is one weighted toward professionals who can best consider the non-technical questions that are asked (Duning, Van Kekerix, & Zaborowski, 1993). One must place the learners' (customers') needs ahead of organizational convenience and at the center of planning and decision making.

As colleges and universities in the future will no longer control all access to knowledge, we will find ourselves competing for students with other entities such as the telecommunications and entertainment industries. Walden University has embraced this new paradigm and hopes to serve as an exemplar for others seeking similar distance education programs.

Few educators would argue that the World Wide Web is a wonderful tool for energizing the classroom. A recent survey by the National Center for Education Statistics (NCES) indicated that half of the nation’s public schools have at least one computer connected to the Internet (Milone, 1996, p. 1). The ability of students to access information immediately, independently, and with all of its multimedia technology makes Internet access a must for all teachers, administrators and school leaders whose motivation is to prepare students for the world of the 21st century. However, this exciting educational tool is not without its shortcomings. Funding for both hardware and software, network management including downtime, and the ethical ramifications involved in controlling access are just a few of the many issues that teachers and school leaders must address prior to developing and implementing a plan for online telecommunications. Most educators today agree that one of the biggest constraints of this technology is the cost. The expense can be so staggering that to many schools the prospect of an Internet connection is just that, a prospect.

An alternative to the high expenditures associated with Internet access is Microweb technology. A Microweb is a collection of Internet sites that have been copied and downloaded from the World Wide Web. It is, in effect, a locally run Internet, with access to preselected sites that have been chosen and controlled by the faculty. Microwebs have the same functionality as original Web pages which can include graphics, sound, motion and links.

**Simulating the World Wide Web**

Simulation programs have been developed by computer software designers for a number of years. Presently there are a number of software packages available which allow the user to copy entire sites. With the advent of new and emerging hardware, such as an A/V hard drive and a recordable CD-R drive, complete copies of remote Web sites, or “Microwebs”, can be created which simulate a portion of the World Wide Web. Through the use of software programs like Web Whacker, actual Web sites and their links are downloaded and copied (“whacked”) on many levels to create in-depth simulations of the World Wide Web on any single topic or entire content areas. Once downloaded, the site can be stored in a number of different media.

**Task Focused**

Educators are voicing many concerns regarding the granting of student access to the Internet. Some educators fear that when students explore the World Wide Web they gloss over information preferring to hyperlink their way from site to site without really learning anything (Sturm, 1996, p. viii). They become sidetracked by “slick” graphics or even games and pass over the required information when using the Internet. This is an all too common occurrence when the Internet is used directly to teach a lesson or unit of instruction. The capacity for students to “surf” their way out of the designed instruction is all but eliminated when Microweb technology is implemented because it allows the teacher to tailor presentations of specific content for a lesson or unit and choose which Web sites students will utilize. In this way teachers can readily adapt objectives to meet the goals of the curriculum. By downloading an entire Web site and placing it in local storage, focus on a specific task is ensured. The use of Microwebs also guarantees immediate access to the desired sites and subject matter without the frustration of waiting for network connections and delays when the server is busy during peak hours.

**Technology vs. Curriculum**

Does curriculum dictate the requirement for technology or does technology decree the change to curriculum? As educators, we hope that the curriculum distinguishes the requirement for the use of technology in the classroom. More often than not, however, the latest technology is implemented in the classroom with little or no forethought to curriculum design. An online connection alone does not produce educational magic. Educators need to know how to integrate technology into the curriculum and manage online learning experiences effectively (Dyril & Kinnaman, 1995, p.79). The adaptability and flexibility of Microwebs can make the issue of curriculum design for technology a secondary consideration if not a moot point. Microwebs can easily be designed and adapted to fit a particular lesson or
if need be, an entire curriculum. The ability of the faculty to tailor presentations of specific content, therefore satisfying the daily lesson and ultimately meeting the objectives of the curriculum, makes the Microweb an ideal classroom tool from both an educator and administrator perspective.

Networking & Telecommunications

The idea of connecting your school or classroom to the Internet seemed like a practical and sensible insight when it was made back in the early 1990s. The ability to provide students instant access to unfathomable volumes of research materials made this technology a "must" for all schools in order to prepare students to take their place in the twenty-first century. The popular notion, at that time, was to simply run a few extra telephone lines into the school in order to prepare students to take their place in the twenty-first century. The popular notion, at that time, was to simply run a few extra telephone lines into the school and hook them into a couple of computers with external modems and like magic the school would be connected to the world via the Internet. Soon, a sobering reality manifested itself. The actual cost for hardware and software upgrades, Local Area Network topology design, wiring configurations, and maintenance, just to name a few, became apparent. The costs were so staggering to a large number of schools, that the idea of Internet access was shelved until one of two things occurred, either the costs dropped to an acceptable level or until a viable alternative could be found.

The concern over the cost of network access have not dissipated. It is not uncommon for the costs of Internet access to be identified as one of the larger expenditures in the budget of many of today's schools. Currently, the costs of accessing the Internet range from approximately a $1,500 one time start up fee and a recurring annual cost of more than $12,500 for the establishment of a minimal single text based workstation. A more sophisticated and representative multimedia model involving multiple workstations with a one time cost of approximately $260,000 and a reoccurring annual cost of almost $130,000. These rates and costs vary considerably, however, and are much lower in some states due to state-mandated rate reductions for schools and business-school partnerships.

The exorbitant cost associated with school telecommunications can be dramatically reduced with the implementation and integration of Microweb technology. Using a Microweb design, schools can transform their entire network computer topology, consequently reducing the number of lines to the Internet Service Provider (ISP). With the application of a compact disk recordable device (CD-R) and an external AV hard drive for a one time cost of about $2,500, Internet cabling to every classroom is no longer a requirement because the programmed CD can be used in a stand-alone configuration. If, however, the school already operates a Local Area Network (LAN) configuration, the server can be utilized in its present form simply by loading the CD. Access to the Internet itself could still be maintained by the teacher or administrator.

Even if controlling Internet access is not an issue of concern for a particular school, the use of Microwebs can still be of value to both the teacher and administrator. If you have copied a Web site including the hypertext links, you can still access Internet sites simply by choosing the link. As long as there is an operating link to the Internet, the Microweb will function as well as the original Web site, possessing full Internet capability and capacity. If you are using your Microweb and want to access a site that you did not copy, all you need to do is type in the address or select the hypertext link to access at that page on the World Wide Web.

Microweb Storage

Microwebs can be stored using the same storage devices that save other forms of computer data. Internal or external hard drives and Zip drives work well for this purpose. Diskettes can even save the data from Microweb sites. Microwebs do not restrict how the data is saved, however many Web sites, particularly those which have audio clips, video clips or abundant pictures are generally very large sites and thus require a lot of storage space. A technique that has proved very successful is to save the copied sites on an external drive, edit as needed, and then use a CD-R device to permanently imprint them on a CD for future use. As mentioned earlier, this is the preferred technique for either a stand alone configuration or when utilizing a server. Additionally, once a site is downloaded and recorded on a CD it is permanent. If for some reason the Web site is abandoned or discontinued, the site with its links is preserved.

A further advantage of using the CD-ROM as a storage device is the capacity to save data in a duel operating system mode. Most writable CD's have a cross platform capability that allows the data to be written so that both Macintosh and IBM platforms can read the same CD. The advantage of this capability is apparent when working in classrooms and computer labs that possess both types of hardware. Consequently, the practice of purchasing two copies of same software title, one for each type of machine, can be eliminated.

Ethical Issues

A number of ethical issues continue to evolve regarding the use of information available on the Internet. Educators will want to consider the possible implications which these issues reflect when using a Microweb to simulate the World Wide Web.

Censorship

When Microwebs are created, the student is restricted from exploring any other than what has been locally
Microwebs designed to be used in a classroom should reflect the content of the curriculum in much the same way as a textbook or a computer software program, with suitably selected information that is developmentally appropriate. Students should be able to experience the full range of materials available in the content areas being studied. Through the use of Microwebs extraneous material can be eliminated. As a result, the student is able to concentrate and focus on specific information, eliminating the temptation to become sidetracked or go off on a tangent that is irrelevant to the subject being studied. While this may be considered a form of censorship, attention to the broader picture must be addressed.

An appropriate and interesting analogy has been expressed between the Internet and a school field trip (Salpeter, 1997, p. 1). A teacher would not plan a field trip to an inappropriate or irrelevant site or allow students to venture forth on their own without the appropriate supervision. Surfing the Internet permits students to experience the world outside the classroom. However, just as a field trip requires the appropriate planning and supervision by the teacher.

Copyright

With the advent of electronic media, the use of copyrighted material has become an issue which should be considered by educators. Guidelines for the use of materials loaded on the World Wide Web are still being formulated. Teachers should consider when and if Web sites with copyright notifications will be used to create Microwebs that will be permanently stored on CD’s for continuous use in the classroom. A number of Web sites, especially those that include graphics and video are copyrighted. However, currently, provisions have been made to download the information providing the copyright notification is included with the work when it is downloaded. Graphics, especially clip art, that are copyrighted can often be used royalty free or with the permission of the creator.

The copyright symbol (the letter c inside a circle) is the standard for indicating copyright. Since the advent of electronic media, the word “Copyright” can also be used in the United States.

At this point in time, there appears to be a doctrine of implied public access on the World Wide Web. The WWW was created on the basis of being able to attach hypertext links to any other location on the World Wide Web. Consequently, everyone publishing on the WWW is deemed to have given you implied permission to link to their Web pages (O’Mahoney, 1996, p. 4).

Leveling the Playing Field

The issue of computer equity has fanned the flames of passionate debate amongst professional educators within the US and elsewhere. The long-standing contention of the “haves vs. the have nots” continues to be an issue of concern for all of those who teach technology based subjects. How do we as educators determine who will receive the technical instruction of such a limited resource? Introduction of Microweb technology may provide a respite in the debate over technology equity. If implemented Microwebs can dramatically reduce both size and scope of school network topology. The monetary savings gained from network downsizing can be employed to purchase additional hardware, therefore granting greater student access to technology. Microwebs are certainly not the answer to all of the issues and concerns of computer equity, but they do provide a short term resolution.

Microwebs that can be produced and stored permanently have enormous potential. Resources with current and topical information are unlimited for the teachers and students who will occupy the classrooms of the 21st century.

AN ARCHIVE OF SHARABLE EDUCATION RESOURCES ON THE WEB

Bernard Robin
University of Houston

Sara McNeil
University of Houston

This article discusses the development of an electronic archive of sharable resources that can be used by educators to support a variety of instructional activities. The authors and their students at the University of Houston have developed Archive.edu, an educational storehouse of classroom materials on the World Wide Web. This site was created in response to a number of trends that the authors view as having important implications in the area of networked educational resources.

One trend is that new Web sites appear almost daily, and this ever growing list of sites vie for the attention of Web users. Although the proliferation of Web pages adds to the number of matches found by Web search engines, the volume of material makes it difficult and often frustrating for users to locate the information they are seeking. Additionally, there is a rapid rise in the number of commercial Web sites, where copyrighted material is displayed, but users are not allowed to download and use these materials for their own purposes.

Further, the ability of users to download material is becoming faster and easier as the Web matures into a more user-friendly resource. Perhaps most significantly, the Web is now capable of distributing multimedia materials that go beyond just text and graphics. Hypermedia projects developed with software such as PowerPoint, HyperStudio, and Authorware are increasingly being disseminated through the Web. The promise of high-quality audio and video delivery via the Web is also becoming a reality.

Implication for Educators

These trends are having a dramatic effect on the educational community as more K-12 schools, colleges, and universities become connected to the Web. Many educators are wanting to, and in many cases expected to, integrate technology into their classroom instruction. But today’s Web, with all of its potential to deliver educational materials, is frequently a confusing and underutilized resource for teachers and students.

To summarize, the state of the Web today for educators is as follows:

1. There is a comparatively small amount of relevant downloadable courseware, instructional graphics, video clips, and technology tutorials available on the Web for educators.
2. What materials do exist on the Web are often difficult to find, and educators frequently do not have the required navigation and search skills to access them. Perhaps more importantly, many educators simply do not have the time necessary to search for materials that can be used in their classrooms.
3. When educators do find instructionally-relevant materials, many times these materials are copyrighted. The issue of copyright and its implications for educators has become an important component in the development of Web sites as a means for disseminating digital materials and will be examined in greater detail in the next section.

What is Needed

A growing body of research indicates that many educators would like to develop multimedia materials that can be used in their classroom but do not possess the knowledge and skills necessary to do so (U.S. Congress, OTA, 1995). The authors have found that one of the most successful teaching models for developing meaningful multimedia projects has three major components:

- multimedia projects, stacks, files, presentations
- a description of how multimedia is used in the classroom
- step by step instructions for creating similar multimedia projects

In most educational Web sites, one or more of these components may be found. For example, there are numerous good examples of multimedia projects on the Web.
There are also many theoretical models of how multimedia can be used in education. In addition, there are many Web sites that focus on how to use certain software applications to create multimedia projects. However, there are relatively few places where all three components, the project itself, how the project can be used instructionally, and directions for creating new projects, are found together so that the entire development process is documented and may be studied, not in isolation, but as a complete, integrated unit. The Web is an excellent medium for bringing these components together in one location, and this model has served as the foundation for Archive.edu.

One example of this model is Texas Your Texas, a Web site developed by a graduate student at the University of Houston (Berg-Chandler, 1996). This resource was created for use in Texas history classes where students can go for a “historical field trip” close enough to home to be familiar, but too far away to go with a class. The site provides a vehicle for integration of technology into the classroom by extending rather than duplicating the existing social studies curriculum and expands student knowledge and interest about the history of their state, while motivating further student exploration.

Figure One illustrates the three components of the model. The first screen shows an example of the information about various cities in Texas. The second screen presents related resources and ways that this material can be incorporated into classroom instruction. The third screen demonstrates how the Web site was created and includes guidelines for creating a similar site.

**Copyright Issues**

There has been much discussion recently about what is legal and ethical regarding copying and using works created by others, especially, the use of digital material found on the Internet. The ease with which information may be copied from the Web has forced many developers and users to consider the issue of intellectual property, perhaps the first time. Copyright laws for the electronic dissemination of information are still evolving, and most educators are unclear about their rights and responsibilities.

Copyright law, simply stated, means that legally one is not allowed to take someone else’s words, graphics, video, or any other type of media and use it for their own purposes. However, the long-standing tradition of “educational fair use” allowed many educators to feel comfortable using parts of other people’s works for instructional purposes as long as those materials remained within the walls of the classroom. But education today does not always remain within an isolated classroom. Many schools are developing their own Web sites and sharing the work of their students and teachers. A potential copyright infringement problem occurs when, for example, students surf the Web, download graphics or audio clips, insert them into their own work, and redistribute this “borrowed” material on their school or classroom Web site. This situation has forced educators and legal experts to reconsider the issue of what is legal in the world of digital manipulation and electronic publishing.

According to current guidelines, every work that is found on the Internet is copyrighted by its author, whether a declaration of copyright is explicitly stated or not (U.S.
Copyright Office, 1996). Copyright guidelines in the past have even included a “Classroom Exemption,” which covers such things as the display of a work by a teacher or student. Today, however, the copyright situation is murky and filled with uncertainty. The average educator does not know what the law actually states, nor where to go to get answers about how digital information can be used instructionally and shared with others. According to Baer (1996), even unintentional copyright infringement is still a violation and “…the same powerful tools that make your original creations possible are also unsurpassed tools for infringing copyright” (p.163).

Archive.edu will serve as a storehouse of instructional materials on a variety of topics that educators can easily access. But more than just another Web site, Archive.edu is a location where educators will have full permission to download any of the materials. These materials can be used as they are, or customized and incorporated into other instructional projects.

Figure 2. The Main Screen of Archive.edu.

Basic Organization of Archive.edu

The design and development of Archive.edu is based upon interviews with educators and students who have expressed an interest in locating educational materials on the Web and plan to use this resource. The prospective audience for Archive.edu includes preservice and inservice K-12 teachers and technology coordinators, university faculty and students, and others interested in educational materials. The Web site has begun with a series of content areas or “vaults” that include resources for Math, Science, Social Studies, Language Arts, Multicultural Education and Technology, among others.

Within each vault, the following materials are available:

- Instructional Graphics - such as student-created maps, diagrams and charts
- Lesson Plans - such as instructional materials that describe ways to integrate technology
- Audio Clips - such as short interviews with professionals who use technology in their jobs
- Video Clips - such as short motion segments that demonstrate multicultural songs and dances
- Hypermedia Applications - such as a PowerPoint presentation on Graphic Design Principles
- Related Web Sites - such as NASA Web pages containing sharable images from the space program

Figure 3. The Math Vault.

Figure 4. The Instructional Graphics Menu of the Science Vault.
The Technology Resources Vault contains those six choices plus two additional areas: 1) Research, which will include master's theses, doctoral dissertations, research papers, and works in progress, and 2) Tutorials, which might contain a presentation about adding sound to a hypermedia program.

A variety of methods can be employed by educators to successfully develop multimedia materials that are free from copyright restrictions. One such technique involves the use of digitizing student work to create graphic images. Teachers might have their students create their own drawings and paintings and then convert them to digital format. This can be accomplished using scanners, digital cameras, or video camcorders and inexpensive video digitizing cards available for a variety of personal computer platforms.

The work of teachers in Maryland's Montgomery County schools has pioneered this effort to use technology as an integral part of classroom activities and share their experiences with other educators via the Internet. Students in a fourth grade class designed a Web page based on self-portraits that the students created (O'Haver, 1996). Each student then wrote a paragraph describing themselves and explaining the setting of their portrait. A sound clip was also recorded and included on the Web page. This process demonstrates how educators and students can become multimedia developers and integrate customized images into their own hypermedia projects and share them via the Web.

Figure 5. Electronic Self-Portraiture Web Page.

Tutorials, Guides, and Step-by-Step Instructions

Tutorials and instructional guides for developing technology resources will maintain a strong presence on Archive.edu. One of the consistent findings of our interviews with prospective users of the archive indicates that educators would like to have access to materials that will help them become more proficient with educational technologies (Pinell-Joffrion 1996). Instructions for how to integrate technological resources into the classroom was also of interest to potential users.

A variety of research materials will be included in the archive. Doctoral dissertations, Master's theses, and scholarly articles that deal with the use of technology in education will be collected and categorized. In this way, a broad perspective on the use of new media by educators will be available in one common area on the Web.

Submitting Shareable Resources

To make Archive.edu a worthwhile resource, it is hoped that the Web site will also become a place where educators can submit resources that they and their students create and are willing to share with others in the educational community. The authors have begun this process by "seeding" the archive with a number of useful materials that have been developed by faculty, students and teachers from Houston area schools and universities. It is our hope that other educators from around the world agree that this method of sharing instructional materials is beneficial and can further expand the usefulness of the Web as a truly collaborative networked resource. Visitors to the Web site may find guidelines for submitting their materials at: http://www.coe.uh.edu/archive

NEW TECHNOLOGIES FOR DIGITAL COPYRIGHT MANAGEMENT

John S. Erickson
NetRights, LLC

The explosive growth of the Internet as a backbone for creative development and distribution has put the issue of digital copyright into the spotlight. Much of the debate surrounding the copyright protection of digital works has focused on the distribution side of information commerce, calling for technologies that achieve secure delivery and micropayment-based, metered use of content (Murphy, 1996; Cox, Tygar, & Sirbu, 1995). In the context of copyright management these are considered strict-enforcement methods.

The creators, owners and derivative users of digital content have begun to realize that the production side of information commerce is unique, with varied legal, business and technical requirements that may be ill-served or even hindered by strict-enforcement technologies. A new approach called enhanced attribution links multimedia content elements with complete, readily available, secure copyright data and specifically addresses the problems of the production environment (Erickson, 1996). The NetRights LicensIt technology, building on this concept of enhanced attribution, allows users of content to easily obtain copyright data and engage in online (and possibly automated) licensing by way of the digital content elements, directly from the context of the document or project in which those elements are being used. The LicensIt system addresses the need for a uniform, timely and persistent means of identifying digital content in the networked environment.

Industry analysts find this approach interesting "...because it is targeted at content creators occupying the middle ground in the copyright debate" (McKenzie, 1996). While acknowledging that some publishers are looking for "pay-per-view" technologies, a recent report stated that "[m]any others...[we venture to say the majority], are looking for a system that adds flexibility and openness to the traditional rules of exchange, without forcing them to simply abandon their works in cyberspace and hope for the best. LicensIt seems to strike this balance (McKenzie, 1996).

Internet: The Mixed Blessing

The Internet is about connecting people and sharing information. By its nature it has the potential to radically change the way new media is created and distributed. Creators are rapidly adopting the tools they need to develop digital content but have been slow to embrace the Internet as an infrastructure for collaborative development and product distribution. This is rooted in the fact that content owners and creators cannot usefully and persistently identify works in the digital, collaborative, networked environment. Without some assurance that their names, services and processes will remain associated with their work, and without confidence that they retain control of the rights to their work, creators of original digital content have been forced to orphan their work in cyberspace (Dyson, 1995).

Multimedia developers and other derivative users of digital content have a related problem: it is frustrating and expensive to locate, identify and acquire rights to content elements targeted for new productions and it is difficult to match the content requirements of projects with possible content providers. Until the development of the NetRights LicensIt technology, no regular, systematic method has existed for identifying works found on the Internet and obtaining detailed, current information about ownership, creatorship and licensing terms. Before LicensIt no solution existed that combined a means for free and unfettered evaluation of content with a system of persistent attribution and authentication.

Multimedia developers who choose to incorporate content elements created by others in their works are required to obtain authorization from a large number of creators and owners. For every work used there may be a different authorization mechanism in place — for some content direct contact with the creator may be appropriate while others may require them to do business with another rights holder or through a collective agency such as the Copyright Clearance Center (CCC) or the Harry Fox Agency. While this rights acquisition process may be expensive and time consuming, the absence of proper authorization for content elements used in a multimedia work may mean that the entire work may not be sold commercially (Gaster, 1995).
The essential balance that defines rights management in the production environment can be summarized by the following (Gaster, 1995):

- Multimedia products cannot be economically developed unless their producers are able to easily identify the holders of rights and appropriate negotiation and licensing mechanisms for content elements they wish to use.
- Holders of rights for multimedia content have an interest in effective systems for rights acquisition since such systems would increase the dissemination and use of their works.

There remains a paucity of substantive multimedia services directly available on the Internet. The cost of entry into the market for creators of digital content is lower than ever, and the Internet certainly promises low costs of distribution and collaboration. In the electronic marketplace wholly new categories of creators will have the opportunity to compete. But without a means to authentically associate content with providers, the risks for content creators outweigh the potential gains and growth in networked multimedia development will continue to be sluggish.

**Rights Management: Where Are We Today?**

Over the past two years much attention has been drawn to the dangers of copyright infringement on the Internet. Many organizations have produced reports that begin to explore the problems of copyright management on public networks and summarize certain proposed commercial solutions (Ebersole, 1994; Weber, 1995).

Debate raged throughout 1995 and 1996 after the introduction of bills in the US (National Information Infrastructure, 1995) based on the recommendations of the US Commerce Department’s “White Paper,” *Intellectual Property and the National Information Infrastructure* (Information Infrastructure Task Force, 1995). This period saw the launch of the Digital Content Rights Management Group (DCRMG), an inter-industry organization sponsored by the Information Industries Association (IIA) to consider standardization and business issues amongst vendors, customers and adopters of rights management technologies (Information Industries Association, 1995). These events have made it clear that rights management on the Internet is a huge issue, content creators and owners have a wide variety of requirements and ad hoc solutions are not sufficient.

The problem is fundamental: most of today’s ad hoc attribution schemes and emerging document packaging technologies are *end-use solutions* that don’t allow the Internet and a developer’s creativity tools to work in synergy to lighten the rights management burden. Rights clearinghouses (Broadcast Music, Inc. (BMI), American Society of Composers, Authors and Publishers (ASCAP), CCC, and others) offer self-consistent points-of-entry for licensing works, provided those works have been clearly identified and are associated with those clearinghouses. Restricted access and encryption technologies offer a means for controlling access to a work but are not conceived with collaboration and derivative use in mind. Likewise, metering and subscription technologies are directed at end-use or consumer access, solving the distributor’s problem of collecting payment for use without addressing the multimedia developer’s production issues.

Most emerging technical solutions have little to do with collaboration and sharing, instead focusing on keeping information under lock and key. In particular, controlled access and metering approaches do not address the problem of enabling multimedia developers, editors and publishers to use the Internet to reduce the real costs of production: finding and identifying content, competitive and best-in-class contracting for new content, and rights acquisition. *The answer is rooted in the fundamental purpose of attribution:* associating the people behind creative works with their content, wherever it may be found and however it may be used. As technologies for expression evolve, so must our means of attribution; from this was born the concept of enhanced attribution.

**What is Enhanced Attribution?**

Enhanced attribution, the approach introduced by the NetRights LicensIt technology, bridges the gap between the creator and user by facilitating real-time rights transactions and other networked communications. Creators and owners may use the technology for tasks as simple as identifying a work and its creator or as complex and extensive as listing the variety of source works from which a derivative work is composed, all of the creative contributors and their contact information. It also allows the creator to affix a set of *minimum permissions* to a work, specifying activities for which rights transactions are not required (Erickson, 1995). Minimum permissions represent a unique, systematic way to provide for free and fair use.

When creators and owners use LicensIt to register new works, information about the work, minimum permissions and links to communications services may be associated with the work. As works progress through the creative process those attributes will likely change. Some, such as ownership and rights administration data, may only change at the registry (since the work itself has not changed). Modifications of the work or derivative works will typically require new registration.

Any information that an owner or creator may associate with a work is accessible via the content itself. Enhanced attribution typically first becomes evident when a possible infringement occurs. For example, when an attempt is made to copy a work (e.g. dragging and dropping between applications or copying at the operating system level) the
current ownership and copyright information may be displayed immediately. Through the same interface, the user may instantly review ownership details, examine minimum permissions for use and request permission for a specific use by e-mailing the rights administrator or completing an integrated electronic form.

The Licenst interface enables the user to communicate directly with owners or creative talent using their current, preferred means of communication. This interface may be used to negotiate new licensing terms or to establish collaborative development arrangements. Eventually a worldwide network of Licenst registration servers will enable searches for content and providers based on type of work, media, subject matter, or other attributes.

From the perspective of enhanced attribution, properties attached to data are persistent, propagating through the “family tree” of a work. As derivative works are prepared, the attribution records for source works are accumulated and become part of the final attribution for that work. At each stage of the project, licensing status and a complete list of source works is available. Since each record points back to a Licenst Registration Server, rights management and licensing is made easy.

Enhanced attribution focuses on making compliance and related communications effortless, not on making cheating difficult. It is targeted at those honest, hard working multimedia developers and electronic publishers who spend a large percentage of their production costs in an effort to comply with copyright as they produce great works. Enhanced attribution makes ubiquitous on the Internet the ability to authenticate digital content and engage in real-time communications and rights transactions related to that content. With enhanced attribution, every work becomes a launching point for communication and commerce.

**The NetRights Licenst System**

The NetRights Licenst System is an Internet-based application that is built around the Licenst Object and has as its major components the Licenst Creator’s Toolbox and the Licenst Registration Server. Underlying components, including the Licenst ActiveX Control and Shell Extension, enable Licenst Objects to be viewed on target operating systems and from within a variety of applications.

Digital works created today become part of a worldwide content asset library. It is a library with no systemic organization and no clear entry point and is therefore difficult for developers to exploit. The application of enhanced attribution to digital content by way of Licenst’s packaging tools and the registration of works by authorized users on a network of registration servers will facilitate the location, identification, licensing and use of content worldwide. This network-wide collection of registration servers becomes a virtual clearinghouse (Greguras, 1995). Primary access to this worldwide virtual clearinghouse will be through content elements (packaged as Licenst Objects) that appear on web pages, CD-ROMS and through other means of electronic distribution.

**The Licenst Object: A Uniform Package for Digital Content**

In today’s digital network environment, there is no way to uniformly represent content to applications. This means that creativity tools — graphics, sound, video, word processing, and multimedia authoring tools — must be shipped ready to recognize the wide variety of media formats that they may encounter, and in particular those formats that may be included as elements within compound documents, in multimedia presentations or on the Web. This presents a significant problem for both the rendering of the content within a given context and for the storage and representation of the content element’s metadata — the authorship, ownership, licensing, and other useful information associated with that content element. Licenst packaging allows content of all types to present a uniform interface to host applications, relieving those applications from the responsibility of rendering all media types.

There must also be a way for creators and owners of content to uniformly store and later make available for use the volume of metadata that may be critical to that content’s licensing and use downstream. Currently very few media types provide for any form of identification within their respective file formats. Fewer do it in a way that is flexible, allowing the owner to choose what information should be presented and how. And none do it in a way that allows the content element to provide its own interfaces and facilitate communications with its “home” (owner, creator, rights administrator or some other entity), regardless of its context.

**The Licenst Packaging Process**

The NetRights Licenst technology transforms flat content elements into Licenst Objects through a process called packaging. Licenst packaging involves the merging of content, metadata and user interface elements that will be presented to the user through a set of *property pages*. The layout of a property page is customized for the intended audience and expected use of the content.

![Figure 1. Components of the Licenst System.](image)

1276 — Technology and Teacher Education Annual — 1997

BEST COPY AVAILABLE
Typically the owner/creator will choose to attach a small amount of identifying data to the object, with the larger and/or most volatile data being supplied to the object from a remote registration server via the Internet. After their work is packaged as LicensIt Objects, owners and creators can be confident that potential users can always obtain up-to-date ownership, contact, and licensing information about specific content elements.

**Content:**
- Digital image, graphic, video, sound, music

**Template:**
- Property page layouts with controls for email, DB access, web access, and metadata

**Metadata:**
- Static & Dynamic data that will be associated with content (static or dynamic)

**Packaging:**
- Content, template, and metadata merged

**Relationship:**
- Dynamic data stored on Internet-accessible Registration Server

**LicensIt Object**

Figure 2. The LicensIt Packaging Process.

**Customized Layouts with the Template Editor.** The flow from flat digital content to LicensIt Object begins with the use of the LicensIt Template Editor. This tool presents an easy interface for designing sets of properties and property pages that organize the presentation of the object's metadata and buttons that initiate various functions of the object.

The Template Editor enables content owners to create layouts for property pages, placing various viewing and interaction controls on the pages. These controls may include text fields for static and dynamic data that will ultimately be bound to the object or stored on a remote server, labels for clarifying or identifying sections of the property page, buttons for initiating an e-mail or web access action, buttons for retrieving dynamic data from a remote server and other elements including illustrations, logos, or icons. Figure 3 shows an example of a LicensIt property page.

**LicensIt Packaging.** After creating the Property Page Template a user employs one of several versions of the LicensIt Object packaging tools according to their needs: the LicensIt Creator's Toolbox, the Express Packager, or the LicensIt Software Developers Kit (SDK). In each case the user of the packaging tool specifies a source content element (photo, sound, video, text, etc.) and a template to be used in the packaging process. The user then fills in any data required by the template. When all the data is supplied the packager, taking its basic instructions from the template, creates the LicensIt Object, binding static data to the content and automatically storing dynamic data on a designated server in the process.

**Servers for LicensIt Registration & Rights Management**

In the process of packaging an owner creates a registered object by communicating with a LicensIt Registration Server. Alternatively, the owner may prefer to create an unregistered object. In this case static information is bound to the content but there is no record placed on a remote registration server.
The LicensIt Registration Server provides the communications back-end to LicensIt Objects. Usually it is the creator of a Template who establishes relationships between dynamic data required by the LicensIt Object and the registration server. The registration server responds to requests from LicensIt Objects for specific elements of metadata that will be displayed on property pages or other data that may support functions such as e-mail or web site addressing. Requests from LicensIt Objects may also initiate transactions that involve interfacing to legacy business systems or financial transaction systems.

Responses by the registration server may involve queries to existing information and transaction systems. In this role a server may retrieve product information or pricing from a business system so that it can be displayed on a property page; it may receive an incoming payment request and submit it to a third-party payment handling system; or it may supply transaction activity data to an in-house marketing database.

Many institutional content owners will choose to have their existing business information and transaction systems inter-operate with a LicensIt Registration Server. Other customers, however, may opt for an all-LicensIt approach by choosing the LicensIt Rights Administration Server. The Rights Administration Server is a database containing document and business information and transaction rules pertaining to owner’s distributed content, supplying this information to the Registration Server when requested by the LicensIt Object.

The LicensIt ActiveX Control & Shell Extension

Viewing LicensIt Objects, accessing the LicensIt property page interface and initiating other functions from the context of a container document or Web page require that the LicensIt ActiveX Control be installed on the user’s system. Similar actions and other added functions at the shell level require the installation of the LicensIt Shell Extension. Both software components act as extensions to the operating system, ensuring that LicensIt functionality is available from within various applications and not just through an Internet browser.

The LicensIt ActiveX Control and the Shell Extension are compact, self-installing and freely distributed via the Internet. Users who come across LicensIt content but do not have these components installed are automatically prompted by the operating system, at which point certified copies are downloaded, installed and the LicensIt objects are displayed without rebooting.

Summary

The multimedia industry has waited too long for networked rights management solutions. Arguably, the tools and technologies should have evolved as the means for delivering information payloads evolved. Now is the time to provide attribution tools and technologies that support and extend creativity tools.

The value of networked communications will be realized when new media creators can supply new, original content with confidence, when consumers may readily access that work, and when commercial communication can easily take place between owners, creators, and potential consumers. Our belief is that those who deliver the means for enhanced attribution will go the farthest towards supporting this type of commerce.

DisNet (Discursive Networking) is the model of a database-centered environment that specializes in the generation and representation of contextual relations in a project. A contextual component is formalized by a multi-slot object-structure, called a “frame”, which can be defined by the user. This strategy makes contextual relations between objects explicit on several contextual levels and thereby accessible to representational methods, referencing and differentiation. System functions are modularized in order to configure setups for different work situations and to support stand-alone as well as networked operation.

The appeal of the service-characteristics and businesscard-mannerism on the web also encourages old learning concepts (traditional courseware) to be decorated with the nimbus of the new packaging and delivery formats. The booming edutainment aspect of telecommunications is accompanied by the trend to monopolize and devalue notions such as “collaborative learning”. Listening carefully we may find that “learner-orientation” occasionally means that the business plan is learner-oriented, rather than the learning strategy, or material.

On the other hand interesting and promising developments can be observed in the field of Computer Supported Collaborative Learning/Work (CSCL/CSCW) research and many other more or less obviously related fields. Synegetic effects can also be expected from recent developments of network-specific languages and development environments as well as of newer communication models (such as distributed, parallel processing).

Networked Learning

The term Networked Learning is introduced and given preference over others because it centers on learning and specifies the organizing structure (not necessarily the medium, application, or content type) in which it takes place. We tend to causally relate and colloquially identify learning with the teaching strategy, or the delivered material, but learning still is a cognitive process performed by the learner: knowledge is “actively constructed” (Piaget, 1973) in this process, rather then delivered to the learner.

Of course the learning situation (learning environment) has a more or less supportive influence on this process. In particular, environments that encourage and facilitate active involvement in the situation can foster learning because it is experienced directly and more intensively,
because it can relate new experiences to known situations, and because it motivates students to activate their own prior knowledge. The learning situation thereby functions as a scaffolding providing connection points for new contextual relations.

Setting up a collaborative experience (conventional, or networked) requires an educator to make decisions at least with regard to the following aspects:

- participant relation
- learning environment
- project organization and process
- context structure and differentiation

**Participant Relation**

As constructivist learning theories have emerged, common notions about the transferability of knowledge and the traditional roles of the student as a receiver, and the teacher as a mediator of established knowledge tend to become obsolete. From a constructivist viewpoint, knowledge seems to be acquired more efficiently and comprehensively in the social communication and interplay of self-responsible actors.

The functional relations between these actors constitute the infrastructure, and its (re-)definition can be seen as part of the project work. Apparently it is difficult for a teacher to find an appropriate position in this setup. S/he may play the role of a commentator (reflect actions), or moderator (direct the course of the collaboration), a motivator (support individual participants), or an agent provocateur (stimulate response), a translator (integrate different approaches, or work styles), a communicator (solve conflicts), an interface to sources, a provider of materials, or a real participant, with equal rights and duties. The teacher may also stay outside as an observer (not to disturb the collaborators with analyses), or an evaluator (grading), etc.

Note, however, that these types of participation are not reserved solely for the teacher. Students may play all of these roles as well.

**Learning Environment**

Some CSCL systems put a lot of effort into the creation of a realistic virtual space. Although it has some appeal to users (especially when they are not too comfortable with the system usage) this strategy dedicates most of the available representational dimensions to the representation of users and world metaphors. An additional spatio-temporal representation of knowledge structures often results in a mixing of representation metaphors. Our own observations indicate that a collaborative environment is established actually by characteristics of the communication between peers. The environment provided (representational, topical, logical) serves as a scaffolding.

**Project Organization and Process**

Usually a significant portion of project work has to be dedicated to its own organization. Setting up the context of a collaboration is an ongoing process throughout a project; it concerns the establishment of work standards, rules and conventions, the (short/long-term) goals and evaluation criteria, the definition of interfaces between collaborators, the selection of methods and strategies, and many implicit decisions with unforeseeable consequences; these parameters have to be negotiated and (re-)evaluated in praxis. This meta-discourse establishes the "axiomatic" basis of a project and should - especially in a learning project - neither be shortcut by using predefined conventions or treated as external to the project.

**Context Structure and Differentiation**

The structuring of context is influenced by the subject matter as well as by the project setup, the chosen working methods and strategies, and also by the form and logistics of storing and representing material in the project space (e.g. organized threaded-topic, or hypertextual). The granularity of contextual units determines the "interactivity" of a context and it sets, to some degree, the possibilities and limitations on interactions (such as commenting, referencing, differentiating, reusing, rearranging and extending contextual components).

**DisNet, Outline**

Any discourse defines by its discursive rules what can be said and what is reasonable to say (Foucault, 1974). Discursive Networking is a discourse-model based on the idea of organizing (group-)work as a rhizomatic (Deleuze, Guattari, 1980) networking of discursive actions creating a knowledge map, called a "contextual network." Formally a discourse is the interaction with the context it generates (rather than with the peers). To a certain degree the discursive rules are established within the discourse itself, which makes it a recursive, dynamic system: every interaction differentiates the context, and the context determines the differentiating potential of an interaction.

DisNet is the model of a database-centered environment that is specialized for the generation and representation of contextual relations in a discursive, or productive project. A contextual component is formalized and instantiated by a multi-slot object-structure, called a "frame", which can be defined by the user. This strategy makes contextual relations between objects explicit on several contextual levels and thereby accessible to representational methods, referencing and differentiation.

System functions are modularized, in order to configure setups for different work situations and to support stand-alone as well as networked operation. The approach conforms to the basic idea of hypersystems (Delany, Landow, 1990; Kuhlen, 1991; Cordes, Streitz, 1992) in that it allows us to represent context as a linked, nonlinear...
knowledge structure integrating multiple data types. While conventional hypersystems focus on representing and browsing preproduced material DisNet is a generative system. (For a more detailed description of the system and its use, see (Simon, Wohlhart, 1996; Simon, 1996.)

**Object Structure**

While the information-unit (node, card, page, site) in hypersystems usually has a header-body document-structure Disnet uses the frame approach. Besides selecting from obvious slot-types (such as creation-date, author-name, object-title, content, content-type, source, link-type, object-size, status-flags, object-representation, object-behavior, etc.) the user may define slots that make any contextual property explicit that she regards as essential with respect to the requirements and the scope of the project.

Contextual components with frames that share slot-types have a relation in that they are comparable; components which have the same value in corresponding slots belong to a context-class. The relation of the content-slots of objects may be made explicit by determining the link type (Rittel, 1980; Conklin, Begeman, 1989) in the link-slot. Also, another slot may describe the type of speech act (Austin, 1962; Searl, 1969) a component represents in its local context.

**Database Organization**

The core of the system is a database organized as a tuplespace (Carriero, Gelernter, 1988). In particular, it is a distributed, object-oriented tuplespace with a special instruction set. A tuple contains a reference to (a tuple that determines) the frame-type of the object and the corresponding slot-values (which may be references to other tuples). The main methods are matching (template-tuple, slot-value, value-value) and compression (substitution, determination, other frames can be referenced.

The tuplespace model has been chosen to decouple data from an address-based organization and to thereby allow the database to perform internal restructuring. Another reason is that a collaboration in many aspects resembles parallel processing and that a collaborative environment has to provide solutions for similar problems. The tuplespace model is based on the orthogonality between creator and receiver, creation and usage: in the process of a collaboration the relations and function an object may have at a certain time in a certain context change - the way an object is integrated in a context should not preclude its relevance in another context. Object orientation allows us to apply methods without regard to the particular structure of an object. These methods are realized as tasks (such as search, filtering, version management, synchronization, access control, data transfer, representation, etc.) which are controlled by user interfaces.

**Domains of Interaction**

The user-interface is decoupled from the database (Model-View-Controller paradigm). It is modularized, so in fact several modul-families are provided for particular domains of interaction and may be combined at will. The idea is to provide a construction set to allow the user to construct interfaces for special requirements. In the following only two of five currently specified domains of interaction and only essential aspects with regard to the scope of the paper will be described.

JECTOR. JECTOR is the object browser and editor for displaying and editing slot-values of an object; it allows users to browse through a project on the basis of relations between objects and slots. The JECTOR-prototype consists of several fields and two popup menus; one to select a slot from the slot-list, the other to navigate to the same slot in another object. A slot can be assigned to a field. Usual GUI-features such as drag and drop, multimedia capability, context-sensitivity, etc. are provided. When the object that defines a frame ("configuration object") is selected by the JECTOR it allows users to configure the frame (edit the slot-list). The selected slot-name is displayed in the active field and can be edited, the order of slots can be determined, other frames can be referenced.

Several JECTORS (a family) have been designed to suit particular project-settings, or use cases (stand-alone, network-enabled, personal organizer, etc.). The figure below shows a JECTOR as a web-browser. It combines web-related features with that of DisNet. It can be used to script and display HTML-documents in a single application, to excerpt a web-page (field3), or include it into a DisNet-project.

![Figure 1. JECTOR on the Basis of a Web Browser.](http://www.cs.cf.ac.uk/section2_4_1)
STRUCTOR. The STRUCTOR is an interface which graphically represents a project’s object-structure as a knowledge map, or semantic network. The structure can be represented in a 2D-, or 3D space. Objects are represented by graphical images (icons, 3D-objects) that carry a label, are connected by links and that may have behavior. The space can be navigated and objects can be manipulated. Clicking an object opens it in a JECTOR [Simon, 1996].

Object-behavior, Scripting

The system has the potential to actively participate in the collaboration by executing scripted object-behavior; e.g., the positioning of objects in the representation space, or of tuples in the tuplespace is controlled by constraints the system seeks to satisfy. Background-matching uses idle-time for matching slot-values and proposes found matches to the user and thereby supports relating and compressing redundant data/structures. Another feature lets the system form questions on the basis of production rules, using slot-values. The purpose of this feature is to motivate the user to reflect the project-work.

Collaboration Strategies

Several aspects of collaboration that emerged in the course of our project will be described as well as strategies that are supported well by the proposed system. Some teachers in our project thought of collaboration as a supplement of their lectures much in the way textbooks provide questions at the end of a chapter. Assignments could be solved collaboratively. More interesting is the reverse approach: pose the problem to a group and supply specific instruction and references when needed. The teacher may operate from the perspective of a participant, using the same interactional infrastructure, and manage with the same rights and functional possibilities. The student should be able to apply the same operations, or strategies the teacher used.

Another approach involved introducing new concepts on the basis of a learner’s own attempts to solve a problem. New concepts are more easily understood when they relate to problems or questions already conceived. This approach allows users to more specifically adapt the scope and presentation of a new concept to a learner in a non-trivial and personally meaningful way.

Another application of a scaffolding strategy concerns the structuring of the project-space, which can be used to initiate, direct and control the course of the project work. This would not be done, however, to accomplish the traditional goal of having the teacher define precisely what is to be done as well as when and how. Instead it is a way of providing some preliminary structuring of the problem-field by means of questions, projections that provides a beginning point and helps learners define and formalize the problem for themselves.

A special form of collaboration, role-playing, can also be supported. Role-playing is a strategy to delegate partial responsibility to and thereby motivate individual collaborators. It requires users to organize his or her infrastructure and gain special competence; it may increase productivity by specialization (essential for structuring a project); it may improve group dynamics and foster respect for different approaches and integration of different work-styles. Role-playing adds playfulness to the characteristics of collaboration.

In the educational context, it requires special effort to define the roles, their interrelation and interfaces. The moderator-role has been observed to be counter-productive by some, in that it hinders self-organization; it is a good candidate, though, to be distributed among all collaborators so that every one moderates the actions related to his or her special role.

Learning does not only concern the acquisition of first-order knowledge, but also of meta-knowledge, such as determining the core of a statement, analyzing and structuring context, representing contextual relations, or social aspects of a collaboration. The meta-discourse of a project concerns two major aspects: the negotiation of the project organization seen from a general perspective and the discussion of local questions from the perspective of the particular work situation.

Both, the continuous (re-)evaluation of rules, conventions, work methods, strategies, coordination of tasks, interfaces between roles, as well as the continuous monitoring and questioning of the current collaborative interactions significantly supplement the topic-related (first order) actions and should be performed within, and integrated into, the project-space to naturally involve participants in a collaborative process and stimulate a differentiated understanding of this process (first-order- and meta-knowledge cannot be clearly separated, anyway).

The information-delivery approach of conventional teaching emphasizes the delivery of the same content to all members of a group of students, who usually receive the content at the same time. Many multi-user systems used in education also adhere to the postulate that all participants should, at a given site and time, see the same world represented. Assigning priority to this kind of consistency favors a hard-wired, global worldview with the characteristics of a broadcasting medium.

There are cases where global synchronization is appropriate and efficient, but there are many situations where that is not the case. In DisNet, representation is first a private task of the client that can be made subject to diverse manipulations according to a user’s wishes and needs. Of course a collaboration system must be synchronizable, but selectively and on demand. The standard communication between peers can be reduced to the exchange of a Compliance Code that contains informa-
tion about system states and configurations. "Synchronization on Demand" extends this concept in that it suggests that - not only for efficiency reasons - synchronous collaboration (conferencing) should be embedded in an asynchronous environment.

**Summary**

It is well understood that an essential condition for learning is to represent, and make a context accessible on several levels and to allow seamless switching between different types of interactions such as orienting, editing, browsing, and restructuring. DisNet provides domains of interaction on different levels of a project and encourages their modification. The frame-base object-structure has the effect that objects are related to other objects on different levels. This feature supports a Stratification of Context and provides multiple-level operability.

**References**

This section of the Annual has never been large, but it has traditionally dealt with broader conceptual and theoretical issues that have widespread implications. Whether that is good or bad depends on your perspective. Some readers avoid the entire section on the assumption that they are practitioners and theory only gets in the way. Others see theory as the critical heart of education and may read a theory paper far more readily than papers in other sections with “practical” titles.

Actually, none of the eight papers in the 1997 Theory section really fit either of the two extreme characterizations of “theory.” For the most part these papers are about real world issues that are important to most of us. They deal with the point of contact with reality, “where the rubber meets the road” so to speak. But, they do not focus exclusively on the details of a particular problem or issue. Instead, the papers attempt to pull back a bit and take a more conceptual view, or look at an issue from within a particular perspective or theory. We think you will find these papers both worthwhile and useful, regardless of your predilections toward “theory.”

The first paper, by Patsy Clarke and Mari Pete from Durban, South Africa, presents the ubiquitous burger as a metaphor for thinking about educational software evaluation. Their paper is both an example of the use of metaphor and allegory to address significant professional issues, and a thoughtful approach to an important task, thinking about evaluation. This paper looks at evaluation at the level of a single software product. Another paper, by Szabo and Poon, addresses a more specific issue, the use of visuals in computer based instruction and testing.

William Rosener’s paper has no food analogies, but it does address another important issue: technology diffusion in teaching in higher education. Rosener discusses the shift away from lectures as the primary means of instruction in education and the critical role technology can play in supporting alternative approaches to teaching and learning. His main focus, however, is on the reasons why adoption has been less than spectacular thus far. The final section of his paper offers some suggestions for improving the rate of uptake of technology among college faculty.

If Rosener’s paper is about the social technology of diffusion, then the paper by J. Caviedes and colleagues at Phillips Electronics and the University of Pittsburgh is about both the instructional theories of distance education and the technical infrastructure needed to support it. This article addresses two critical areas: 1) the alternative models of delivering instruction at a distance, and 2) an environment created to support group distance learning that includes problem based learning. This article shows clearly how the type of teaching and learning activities planned can influence and guide the creation of the technology support environment needed.

Linking a social or educational theory with a question about technology is also at the heart of the next paper. A British paper, by Loveless, Longman, and McDonnell looks at the match, or lack thereof, between what it means to be literate in a modern, information-intensive society and the type of experiences students receive in schools today. Within this framework they look at the question of what types of teacher training and support are needed if schools prepare students for today’s society. The authors use a project at the University of Brighton to illustrate the points they make. In their paper, Blomeyer and Clemente also point out that the concept of what it means to be literate has changed and the change has significant implications for how we prepare teachers. They look at the issue through the lens of change theories, particularly those of Rogers and Fullan.

The final papers in this section have the same format. They all look at an issue in technology and teacher education from the point of view of a particular theoretical framework. The paper by Rodriguez considers implications of constructivism for teacher technology training.
Hutchinson looks at the implications of Gardner's multiple intelligences for instruction in K-12 education while Sweeder, Bednar, and Ryan consider the implications for teacher education. Finally, Gannon Cook discusses semiotics, particularly the theories of Vygotsky, as a framework for thinking about society. Finally, Sianjina looks at issues in the preparation of school administrators in the area of information technology, and Pari discusses the use of learning tools in Argentinian education.

THE KwaZULU CONCEPT BURGER: A HYPERTEXT CONCEPT MAP OF EDUCATIONAL SOFTWARE EVALUATION

Patsy Clarke
University of Natal,
Durban, South Africa

Mari Pete
Technikon Natal,
Durban, South Africa

The KwaZulu Concept Burger is a co-operative, culinary delight conjured up by Mari Pete, Patsy Clarke and Ari Naidoo. They form a threesome home group of distance learners, reading for a master’s degree in education, specializing in computer-assisted education (CAE). In essence, the “Burger” is a metaphorical representation of the concept, Evaluation of Educational Software, in the form of a hypertext concept map. It is presented in HyperText Markup Language (HTML) format and can be viewed with a World Wide Web (Web) browser on the Web at http://www.und.ac.za/users/clarke/kzb/concept1.htm.

Why Construct a Concept Map of CAE Software Evaluation?

CAE presents potential advantages for South Africa, where an educational priority is to improve learning environments. Advantages include multiple access to learning materials, reduced learning time, instructional consistency and increased motivation (Craig, 1995).

Educators who become engaged in the use of CAE are inevitably involved in evaluation: summative evaluation, conducted during the selection of programs from the existing commercial market; and/or formative evaluation, a cyclical process during the in-house development of software (Hannafin & Peck, 1988). Regardless of the form of evaluation, it is important to make informed decisions based on more than intuition.

It is therefore important to develop a thorough understanding of all aspects that need to be considered during either type of evaluation. To this end, constructing a concept map was considered an effective way of making complex information regarding evaluation theories and techniques more palatable and digestible to learners and educators.

The Medium: Why the World Wide Web?

The three distance learners from Durban work at three different educational institutions in KwaZulu-Natal and study part-time at the University of Pretoria in the province of Gauteng. One reason they opted to exploit the World Wide Web was to facilitate the speedy delivery of the concept map to their lecturer’s desktop on the other side of South Africa, 700 kilometers away.

In addition, the Web has proved to be useful both as a content provider and delivery medium to reach a growing number of “Burger” users beyond the original target. The Web has also made it possible to update the “Burger” regularly in response to feedback from these “Burger” users and the expanding knowledge bases of the authors.

The concept maps that were devised by other students as part of the same project were either in the form of placards or physical three-dimensional models. Although all were valuable representations of how the concepts relate, they were not easy to adapt in response to feedback.

HyperText

HyperText is the default text medium of the Web. Fortuitously, hypertext facilitates the following aspects of constructivist learning theory:

- presentation of multiple perspectives;
- learner control;
- facilitation of non-linear and multi-dimensional traversal of complex subject matter; and,
- linking and making connections between subject components (McManus, 1996; Ross, 1993; Spiro, Feltovich, Jacobson and Coulson, 1991).

Bloom’s taxonomy of the cognitive domain consists of the following six levels: knowledge, comprehension, application, analysis, synthesis and evaluation (Bloom, Engelhart, Furst, Hill, & Krathwohl 1956). Ross (1993) suggests that hypertext could be used as a resource to facilitate the realization of learning objectives belonging to each of these categories. He indicates how various HyperText models correspond to the six levels:
Table 1.
HyperText and Bloom’s Taxonomy of the Cognitive Domain (Ross, 1993)

<table>

<td>Evaluation</td>
<td>Assess, evaluate, judge</td>
<td>Highway</td>
</tr>
</tbody>
</table>

The home group opted for the Network design which corresponds with Synthesis in Bloom’s taxonomy, (see Table 1). Network design presents granules of information in hyper-linked format, allowing learners to discover information in their own order and to synthesize their own understanding. As learners who browse through the HyperText burger may come from different backgrounds and institutions with a variety of implementation needs, it was decided not to impose a definite order of learning, but to let them develop their own schemas through discovery learning.

The Method: Why a Burger?

“Metaphoric and allegorical thinking draw on models to interpret the world and to infer and even create relationships that may not be obvious” (Viau, 1994, p.10). To the authors the layered structure of a burger paralleled the way in which they envisaged the hierarchy of evaluation concepts (see Table 2).

Furthermore, during the period when the designers were constructing the KwaZulu Concept Burger, a hamburger franchise company opened their first branch at the southern tip of Africa. This event made the burger “flavor of the month” and an appropriate metaphor which enabled its designers to express their view of the topic in an accessible way.

Theoretical Underpinnings of the “Burger”

The foundations of the multi-dimensional model suggested in this paper are the pedagogical and user-interface dimensions suggested by Reeves (1994). Reeves’ dimensions provide systematic guidelines which enable educators and trainers to see through software vendors’ marketing ploys in order to establish whether products are educationally sound.

According to Reeves (1994), pedagogical dimensions are those aspects of the design and implementation of CAE that directly affect learning while user-interface dimensions deal with aspects of CAE that ensure the learner can engage in meaningful interactions.
Make a Meal of Your Metaphor

The authors consider that the development of the "Burger" has been effective for their learning as it evolved from a process of negotiating meaning through co-operative learning.

Since the first version of the KwaZulu Concept Burger in February 1996, it has been transformed continuously and become more multi-dimensional as ingredients and condiments have been added in response to feedback from other learners and practitioners.

As suggested by Viau (1994), the effectiveness of the constructivist process has been enhanced by on-going evaluation, challenge, criticism and transformation which has prevented the metaphor from becoming static and losing impact.

This refinement process has facilitated the authors' deepening understanding and internalizing of a wide range of evaluation theories and techniques. The result has been successful transfer of knowledge and application in their practice.

The authors acknowledge the facilitative role of the World Wide Web in this learning process.

References

Desktop visuals are now easily created and accessed in computer-based instruction and increasingly in testing. Research on the use of visuals in instruction is rather extensive, but there is little in the context of computer-based instruction (CBI). There has been little investigation of the effects of visuals in testing on the effectiveness or efficiency of learning outcomes. This experimental study was conducted to assess the effectiveness of using visuals in testing when the instruction employed multimedia forms of instruction.

In a study on visual testing in a non-CBI environment, Szabo, DeMelo & Dwyer (1981) found that students who received both instruction and testing with the same visuals learned more than students who received visual or non-visual instruction and non-visual tests. Szabo & Schlender (1996) found that testing procedures which included animation reduced learning, compared with students who received testing using static visuals. If visuals do not change with time or location, they are said to be static visual displays (SVD). Conversely, if motion or change with time is involved, they are dynamic visual displays (DVD).

We located nine studies on visual testing which examined different levels of achievement; achievement being delineated as identification, terminology and comprehension. Two of these studies (Dwyer & DeMelo, 1984 and Dwyer, 1986) showed visual testing had a significant effect upon all these levels. In the remaining studies, three find effects for identification (only) two for terminology (only) and three for comprehension (only).

Different studies used different operational definitions of visual testing and visual formats, making comparisons across studies somewhat difficult. There were also variations across studies between the number and kind of visuals used during testing and instruction. While the results of non-CBI studies are helpful, the use of CBI adds unique elements to testing in its ability to add dynamic visual displays and allow students to repeat all visuals during testing. The results to date suggest that visual testing presently results in elevated skills of identification, while effects on terminology and comprehension are less clear.

Theories With Relevance to Visual Testing

In 1973, Tulving & Thompson suggested that the presence of identical cues during the instruction/acquisition phase of learning and the testing/retrieval phase results in stronger recognition memory. They called this the encoding specificity hypothesis. Earlier, Glanzer & Clark (1963), at the height of the information-processing theories of image acquisition and storage proposed that all information was transformed and stored as a series of words. In contrast to their verbal loop hypothesis, others suggested that in the case of DVD in instruction, studies which employed a structured behavioristic approach yielded more significant results than studies using a cognitive orientation. If true, would the results hold for visual testing as well? The instructional implications across the theories is not clearly delineated.

Paivio (1986) proposed the existence of two separate cognitive subsystems for representing information, one verbal and one non-verbal. Although separate, these systems can be combined and if information is presented in both visual and verbal formats, stronger learning should result. Paivio refers to this as the dual-coding hypothesis.

Several other theoretical positions with bearings on visual testing have been put forward. One theory argues for the importance of a relationship between acquisition and test situations, observing effects for the similarities. This is referred to as the transfer appropriate principle (Morris, Bransford, & Franks, 1977).

Methodology of the Present Study

A multimedia training lesson for Emergency Medical Responders covered the anatomy and physiology of the pregnant female, stages of labor, and preparation for imminent delivery. This field experiment examined visual
testing effects on identification, terminology and comprehension skills. The 62 subjects were randomly assigned to a visual testing or non-visual testing treatment. The latter consisted of standard tests while the former included static visual displays drawn from the dynamic visual displays used during instruction.

Findings and Discussion

The visual testing group outscored the non-visual test group on the identification subtest but not on the terminology or comprehension subtests. The finding of significant effects on identification and not the others suggests that visual testing in CBI has similar outcomes to non-CBI studies cited earlier. Perhaps identification, a visual task involving discrimination based on distinctive visual features, is enhanced by graphics at the time of retrieval. Several plausible explanatory hypotheses for further research are discussed below.

Years of non-visual testing may have handicapped learners when it comes to the use of visuals, and retraining or re-orientation will be needed. This is suggested by the research done by Szabo and Schlender (1996) in which student performance in visual tests which included animation was lower than in visual tests using only static displays. Just as students require practice and coaching in non-conventional instructional practices, they may need practice in effectively using visuals during testing to be able to retrieve information.

Related to this is the expectation that classroom performance rarely employs visuals or which employs visuals in a supplementary role to the non-verbal, textual mode of testing. Students’ can rely on non-visual cues when being tested academically. A test of this hypothesis would employ the criterion of actual or simulated performance in realistic environments where conventional paper and pencil assessment is not used. Given the performance-oriented nature of emergency medical responders, it is suggested that a further study using performance as the dependent measure be used.

Another possibility is a ceiling effect which limits variability in scoring and thus masks any chance of differences in treatment difficult to be observed. The ceiling effect stems from the high scores required to continue in the program due to a mastery orientation and the meeting of rigorous certification standards, and the high levels of competence needed to preserve human life. It could be argued that students in this study used every strategy available to them to perform well, including visualization and the use of text and visual materials.

The role of overt performance may have a bearing on the situation, where students are able to click and drag, replaying the visual several times, and engage in other overt activities. Perhaps these activities zero in on the identification tasks over the more covert mental tasks associated with acquiring terminology and building comprehension.

Redundancy might also be a factor. Do the non-visual portions of the test communicate or elicit the learning to such an extent that the visuals’ added contribution to learning is minimal? Should we test this by conducting research using tests in which no verbal cues are present? This could be argued on the basis that often an EMR professional must deal with non-verbal patients and have to rely extensively on visual cues.

The nature of comprehension may demand more sophisticated forms of visual representation than possible through the use of static dynamics. Perhaps animation would be a more appropriate and fruitful tool to use to assess comprehension skills levels. Students would have to be taught and practice how to extract desired information from the irrelevant cues which may be present in animations, as well as from static graphics.

What is the relationship between the visuals used during instruction and those used during testing? Does it matter if those sets of visuals are identical, similar, or a subset of one another? Must they be present in equal amounts? This latter case is unlikely given the greater length of time spent in instruction compared with testing, with the opportunity for more exposure to a greater variety of visuals in the former.

Concerning practitioners, should expensive visuals be created for learning and testing when the benefits over simpler visuals is an unknown quantity? Should the publishing houses continue to spend heavily on graphics-oriented programs to the exclusion of graphically oriented exams? For theoreticians, this study provides findings which should be factored in to the development or refinement of any theory related to how the mind captures, represents, and preserves visual and non-visual information.

Information technology presents a critical challenge for colleges and universities. With the rising costs of higher education and the declining quality of graduates, information technology may present a more effective and lower-cost form of instruction (Burke, 1994). This technology has the potential to transfer the mode of instruction in tomorrow’s classrooms. Instead of lectures being the predominant mode of instruction, computers and multimedia presentations could augment or even supplement the lectures and redirect the responsibilities of learning to the student. While few people doubt that information technology can enhance teaching and learning, there seems to be missing a sense of urgency to quickly integrate this technology into the classrooms. This paper will examine why this technology has not been as rapidly adopted into the educational arena as people initially expected and discusses steps which can be taken to successfully promote its adoption.

The phrase “Information Technology” (IT) will be defined throughout this paper as: the use of computers, communication networks (including the World Wide Web, also described herein as Web), and audio-visual equipment to help transform the technology of instruction. The definition of IT varies slightly from one article to the next and is sometimes described using one of the following phrases: academic technology, computer-assisted instruction, computer-based training, educational technology, and instructional technology. In this paper, the term IT encompasses or represents a combination of all of these technologies when used to link teaching with learning.

To better understand the reasons behind information technology’s limited use and how best to promote it, an overview of this technology will be provided. This overview will include a discussion of how best to develop and implement IT and the benefits and costs associated with this technology.

Implementation and Development of Information Technology

Should IT augment or supplement the traditional method of teaching? This answer will vary depending on the subject area being taught. In areas where the subject matter focuses more on value, meaning, and philosophical ideas, IT will only partially be able to substitute for human interaction. In these areas, IT will, at best, be able to augment or enhance a student’s experience; however, in areas which have a high volume of students, standardized curriculum, and factual content, IT will more likely be able to supplement the curriculum and teaching technique. Furthermore, we must continually remind ourselves that technologies such as IT should only be used when they provide new opportunities for students to visualize and understand material.

When creating IT lessons and presentations, it is important to not just computerize or digitize the methods and materials of instruction, but rather investigate how value can be added. To exploit this technology, every attempt must be taken to innovatively reconceptualize new information, not just repackaging old information. For example, by just taking a textbook and making it available on-line is simply repackaging old information. Instead, studies and research should be performed to investigate how textbooks can be reconceptualized so that students are not just memorizing information, but rather are engaged in an activity which promotes a deeper understanding of the subject matter.

Who should develop IT? First and foremost, students must be involved in the development of any IT since they are the real experts on what does and does not work. The students should be able to continuously provide feedback to help separate the methods which are successful from those which are not. Student involvement is essential in the development of effective IT.

Secondly, should universities and colleges or should publishers be developing IT? The research has reported that the best approach to IT development involves some form of strategic alliance with higher education and textbook publishers (Stewart, 95). When universities and
colleges develop IT in collaboration with publishers, the 1) costs tend to be lower, 2) a more open architecture is created, and 3) a more global representation of the subject material is conveyed.

Benefits and Costs

There are many benefits and costs associated with IT that must be considered when evaluating the overall effectiveness of this technology and the reasons for its limited use. Listed below are some important considerations which must be addressed. For each of these issues, both the potential gains and loses will be examined.

Quality of Learning

The scale used to judge any teaching technique must first consider how the quality of learning is affected. A good approach towards teaching will promote a deep understanding of the subject matter, encourage students to comprehend and synthesize information, and help students improve their written, oral, and critical thinking skills. Many studies have found IT to be as good as, or better than, traditional approaches (Alexander, 1995). These studies have shown that information technology:

1. increases motivation;
2. permits self-paced learning;
3. alleviates computer anxiety;
4. provides instant feedback;
5. encourages self-directed incidental learning; and,
6. provides students with greater control over their own learning.

Well-designed IT allows information to be presented in a user-friendly, easy-to-understand, and visually-simulating format by combining graphics, audio, and video. Lessons which incorporate IT can have an enormous advantage in the educational world since research has shown that people, on average, remember less than 20 percent of what they read; but, they will remember up to 80 percent of what they see and hear (RAD, 1995). Hence, information taught using IT should more likely be remembered.

However, a point that is rarely discussed is that the learning gains can almost completely diminish when the same instructor teaches both a course using IT versus their traditional approach (Alexander, 1995). These results indicate that the learning gains are more likely due to the instructional methods used and not because of the technology; therefore, by simply transferring information from one medium to another, it is possible that no improvement will occur in the quality of learning.

Lesson Preparation

One disadvantage of IT, is the high cost associated with curriculum preparation. While a proliferation of commercial companies are developing lessons for some of the general curriculum courses, most instructors prefer to prepare their own lectures. Preparing multimedia lessons can take significantly longer than traditional approaches such as preparing overheads. This is because instructors must not only create and find materials, but they must also learn new software packages and best determine how to use this technology. Understanding this technology and how to use it can be a very time-consuming process in itself. Furthermore, because most instructors are not trained in creating IT, there is no guarantee of its quality.

On the other hand, lesson preparation offers two of the biggest potential gains to IT. These two advantages are economies of scale and mass customization. Economies of scales implies that after a substantial initial or front-end financial investment, the average cost of usage for additional students decreases. Mass customization allows IT multimedia lessons to accommodate differences in the learning styles and abilities of students. At the same time, new software is being developed which makes it easier to create a complex multimedia environment. Adding movies, sound clips, or other powerful audio-visual materials is now easier than ever.

Bonds Between Students and Faculty

Powerful bonds are often created between students and faculty members, especially at the graduate level. These strong relationships and the invaluable advice which stems from them can have a profound influence on a student's professional development. If these bonds fail to exist under information technology, then it must be questioned as to whether a good foundation for teaching can prevail. However, most initial research has shown that even greater bonds can develop under IT, since faculty spend less time disseminating information and more time advising and collaborating (Dwyer, 1993). On the other hand, some of the bonds between students and faculty may be undesirable. For example, an apathetic teacher who teaches out-of-date information from faded notes may be cheating the students of their due.

Limits of Time and Space

One advantage of information technology is that it can help ease the limits of time and space. When using IT in distributed environments, learning becomes easier and students are provided more freedom as to when and where they are able to work. However, for a student who is lacking connectivity or equipment, the limits of time and space are constrained. To these students nothing could seem more portable than a textbook as they study while doing their laundry!

However, textbooks also have their limitations. For example, textbooks can quickly become out-of-date and often fail to integrate meaningful discussions and explanations with the facts; furthermore, having to use a textbook's linear index to lookup information can be a tedious, time-consuming approach.
Complex Material

In the IT environment, many students find note taking a more difficult process. This is mainly due to the great deal of intangible information in the form of sounds and visuals which are incorporated into these presentations. It has been argued, that while photographs provide a great deal of information, much of the visual data is unrelated to what the student needs to grasp (Pence, 1995).

One simple solution to the note taking problem is for faculty to use less complex images or provide students with hard copies of the lectures. However, this perceived shortcoming of IT may really be a strength. It will force tomorrow’s students to learn how to digest complex images.

Hypermedia

Another advantage of information technology is the ability to hyperlink to other information. For example, when IT is developed using the World Wide Web, the Web can serve not only as a delivery medium but also a content provider for enormous quantities of information. Using hyperlinks, complex or difficult phrases and concepts used within a lesson can be linked to definitions, glossaries, biographies, and short essays which describe the phrases and concepts in more detail or from a different perspective. There are also educators who believe that hypermedia improves a student’s ability to handle large amounts of data. Furthermore, from a learning perspective, many writers think that the Web and its hyperlinks closely resembles human cognition (Alexander, 1995). That is, this hypermedia environment of associated links is very similar to how humans store information as a semantic network of links. Consequently, some researchers report that learning can improve when the structure of knowledge (such as that found on the Web) closely represents how humans store information.

A final advantage to hypertext information is the ability to provide interactivity and continuous feedback. Feedback is a key aspect of learning, as it helps learners interpret and understand concepts and ideas by associating actions taken with results obtained. However, researchers argue that a hypermedia environment is really not interactive. Instead, it simply allows the learner to follow predetermined paths chosen by the author. Under this argument, to really provide a true interactive environment, learners must become collaborative authors, creating their own hyperlinks in order to create a really useful learning tool.

Currently there are two major shortcomings of IT developed explicitly for the Web. These shortcomings are: 1) the authoring tools developed for the Web are not as extensive as other multimedia development tools; and 2) it is difficult to limit students’ exploration on the Web. However, both of these problems are actively being addressed.

Bridging the Gap

To successfully integrate information technology into tomorrow’s classrooms, we must first identify the barriers to its adoption and the reasons for its limited use. Once this has been performed, we can consider how to bridge the gap by removing these barriers.

The first step is to understand the reasons for the limited use of IT. Surprisingly, the low rate of adoption is not attributed to faculty discomfort with the technology, nor with faculty belief that IT can enhance the learning process. On the contrary, studies indicate that faculty usage and ownership of information technology is unexpectedly high. Studies have found that 95 percent or more of faculty now regularly use word processing software to support their teaching and research (Geoghegan, 1994). Similarly in the same study, up to 85 percent of faculty agreed that IT can enhance the quality of teaching and learning. Hence, if this is true, then why the slow adoption of information technology? Listed below are some of the reasons of IT’s limited use or barriers to its adoption and solutions educators can take to remove these barriers.

Evaluation of Faculty

Barriers. Faculty are evaluated significantly more based on their research accomplishments than in comparison to their teaching performance. As a result, faculty are often less motivated to improve the quality of their teaching. At the same time, when a faculty’s performance is evaluated, it is often measured by counting contact hours with students instead of their contribution towards student learning. Using this approach, faculty time is measured like that of unskilled labor - using a time clock. Consequently, teaching has been made to appear both easy and undemanding.

Solutions. Faculty must be encouraged to think of productivity in terms of both teaching and research. Incentives must be created to evaluate faculty’s learning accomplishments, similar to the incentives that already exist for research accomplishments. Efforts must also be taken to change the attitude towards teaching to make it look as difficult and demanding as research.

Teaching must be more carefully audited. While most departments carefully evaluate faculty’s research, their teaching and learning performance are seldom audited. Departments must begin to evaluate the teaching skills of their faculty, much like individual professors are evaluated by their students.

Institutional Support and Equipment

Barriers. Many colleges and universities lack a formal plan for integrating computers into the curriculum as well as the financial support for the equipment and facilities this technology requires. Studies have shown that more than 50 percent of all colleges and universities have no formal plan for integrating IT into the classrooms.
(Geoghegan, 1994). Similarly, most institutions are not financially in a position to make the large front-end investments needed to fully exploit information technology’s potential.

At the same time, many IT models have been focused on the “technically literate” rather than on a cross-disciplinary approach. Hence, non-technically oriented disciplines sometimes lack the support services to assist faculty in developing, creating, and using IT.

**Solutions.** A solid commitment from the institution is critical for widespread adoption of IT. This commitment should include: 1) formal plans and policies for integrating computers into the classrooms; 2) financial support to allow the necessary equipment and facilities to be obtained; and, 3) support-services and assistance across disciplines.

**Lack of a Compelling Reason Barriers.** For information technology to really bridge the gap, a compelling reason for institutions to buy must be illustrated. Unfortunately, from this perspective, many of the early prototypes have almost had a negative impact on IT. For example, on the World Wide Web there are currently many sites which claim to provide beautiful examples of instructional technology. One such collection is the World Lecture Hall at http://www.utexas.edu/world/lecture. While a few of the links listed are impressive, a vast majority of the sites merely contain syllabi, textbooks, and articles which have been slapped on-line. These repackaged examples do not allow students to see, understand, and visualize information in ways that were not possible before. In fact, when these pages are browsed using a narrow bandwidth, the time taken to view these pages is much greater and a good deal more frustrating than simply turning pages in a book. Judging from these examples, it is no wonder that the mainstream faculty have not rapidly adopted information technology. To these faculty, the time and effort required to adopt IT is not worth it, if at best, this technology will only barely assist them with their teaching and research tasks.

**Solutions.** To convince the faculty to bridge the gap and incorporate IT, a compelling example must be created that, when viewed, clearly provides recognizable benefits. This application must either 1) perform a currently existing task more effectively or in less time, or 2) perform a task that was previously unsolvable. The added value of the application must exceed the time, money, and effort needed for its development. Such a compelling example could provide the necessary incentive for mainstream faculty to bridge the gap and more actively integrate information technology. However, we must realized that since teaching performance is not closely evaluated, even a slightly compelling example may go unnoticed.

Special thanks to Susan Metros - her comments and suggestions improved this paper considerably.

William Rosener is a Research Associate in the Instructional Technology Center, 2409 Dunford Hall, University of Tennessee, Knoxville, TN 37996. Voice: (423) 974-7912. E-mail: wrosener@utk.edu
Educational innovations are often driven by technology. Examples include electronic classrooms (computers and electronic whiteboards), on-line instruction (asynchronous learning networks), and live, interactive lecturing (interactive television). Pedagogies different from the classical lecture, or broadcast method, are not specifically supported in any of those settings. Furthermore, interactive CD-ROM, another popular technology, generally emulates one-on-one tutoring for individual study only. Figure 1 shows a typical distance education setup for tele-lecturing with interactive student participation. In such environments, student participation is possible over the bi-directional audiovisual channel; however, in lecturing situations, student participation depends on the skills and objectives that the instructors may have.

Problem based learning (PBL) differs from traditional approaches in that it focuses on a problem that is presented in a specific context (Barrows & Tamblyn, 1979). In medical education this context is provided by documents and views, simulating a patient in the classroom. Rather than learning facts by rote, students have to apply their knowledge to work on defining hypotheses about the patient's problems, supporting those hypotheses with observation, facts, and background knowledge, and eventually generating solution approaches. Facts and knowledge are thus put into context and can be turned into medical skills (Schmidt, 1994). In the PBL environment of a medical school, the students typically collaborate on a case in groups of up to twelve students. Guidance in the problem-based learning process is provided by medical teachers who act as learning facilitators. The facilitators help students stay on track, provoke lateral thinking, aid in overcoming mental blocks or dead-ends, and prevent students from pursuing improbable avenues too far (Lajoie and Lesgold, 1989).

PBL has conventionally been supported by paper documents or paper patient simulations. Recently, electronic information technology has been embraced to aid in PBL (Schmidt & Bannon, 1992). Systems have been proposed to tackle various problems posed by the PBL process, such as document handling or visualization. There
are many multi-media systems that had some success at presenting a high-fidelity patient simulation. The transition to electronic content makes it natural to investigate further computer support for asynchronous and synchronous group distance learning. Noticeably, at the forefront of on-line education is the research on Asynchronous Learning Networks (ALN) sponsored by the Sloan Foundation (The Web of Asynchronous Learning Networks, 1996).

Collaboration technologies have addressed the need to share tools and work environments, the need to communicate using multiple media, and the need to provide seamless user interfaces (Hishii & Miyake, 1994). From the work on sharing text editors and supporting business meetings there have been successful product developments, but none specific to collaborative learning (Nunamaker, Denis, Valacich, Vogel, & George, 1991). Although we find that the needs of distance education are similar to those of remote collaborative work, the content, the media, and the tasks are much more sophisticated than those initially addressed by CSCW (e.g. medical diagnosis vs. brainstorming).

![Figure 2. Setup for Remote Facilitation of PBL](image)

We have built an environment for group distance learning which supports PBL with well-matched groupware (CSCW software); see Figure 2. We are interested in matching specific needs such as informal discussion tools and multimedia content sharing, as well as providing a complete environment where teachers can play the role of expert advisors, moderators, lecturers, or content managers, and student peers can play the roles of learners, scribes, reviewers, or teachers. The features we envision for completeness are:

- Multimedia content distribution and sharing with flexible floor control options (e.g. sharing learning and tutoring applications, and distributing updates and reference material);
- Audiovisual communication with options suited to the participant roles;
- Informal discussion tools which allow easy transitions between knowledge creation/input mode and discussion mode, and impose minimal constraints on the material being discussed (e.g. file size, type, source);
- Tools for group monitoring and tracking which are customized to the needs of the facilitator; and,
- Mechanism for session management and control which deals with each session (e.g. agenda, media management) as well as the courses (e.g. syllabus, course logistics).

These features can be implemented in a system composed of teacher and student stations connected to a server over any network with appropriate bandwidth. Although the list above describes individual modules, to be effective, they must be functionally distributed and integrated throughout the system.

![Figure 3. Architecture of a Group Distance Learning System](image)

The architecture of the system is shown in Figure 3. The following sections deal with each of the five main components and the last section provides the closing discussion.

### Content Distribution and Sharing

Electronic content creation is a major bottleneck in computer-supported learning. For collaborative learning the problem is compounded by the need to provide content which is suitable for group work and which lends itself to the creation of positive interdependence among participants.

By choosing PBL as a starting point, we secured the suitability of the content. We have also built upon previous work which has created electronic versions of the classroom content for an asynchronous system known as CALE (Mahling, Sorrows, & Skogseid, 1995). CALE makes PBL cases available over the Web, and students can access the system as a group (sharing a terminal), or individually. CALE was not designed for synchronous use; therefore, like many single user applications, to be used by a group it requires a sharing and a floor control mechanism. That way, one student at a time takes control of the application while others watch and give input.

Depending on the type of multimedia content to be shared, bandwidth and performance become issues. We are currently experimenting with distributed and centralized sharing. Distributed sharing is based on synchronizing...
copies of the content running at each participant's node. Centralized sharing is based on screen replication of a single application running on one node.

Applications which use video and audio are better shared in a distributed manner. Appropriate content update and distribution mechanisms must be available for any type of sharing. Much of the existing content would benefit from flexible sharing which could support synchronization but which could also allow for individual preferences and choices deviating from the original What You See is What I See (WYSIWIS) approach. Problems identified with current sharing methods include platform dependency and lack of flexibility regarding individual preferences and environments.

The World Wide Web (Web) appears to be the scenario with the highest potential for broad delivery of content and for the creation of learning environments (Greenberg and Roseman, 1996). This is supported by the way the most important trends in content and usage have been picked up on the Web. The trends from passive to interactive content, from generic to personalized work environments, from individual to group work, and from static to live multimedia are significant examples.

Newly available Internet set top boxes have potential to be combined with interactive TV for distance learning. This is an economic alternative to the more expensive Web access through multimedia PCs.

**Floor Control**

To interact with a single user application, members of a group must take turns. This is possible through floor control. Round Robin, queuing, and timed-out turns are common methods. The literature on the subject summarizes available protocols as combinations of explicit or implicit floor request and explicit or implicit control granting. For a review on roles and responsibilities in application sharing see (Greenberg, 1990). As we found out, the applicability of those methods needs to be revised for environments in which audio and video communication is also available (i.e. all floor control transactions could be negotiated verbally).

**Audio-Visual Communication**

Audio and video communication is expected to contribute to the creation of a virtual group. We have investigated to what extent analog audio and video can achieve the results of face to face interaction. We have used an open, full-duplex audio channel of high quality to keep everyone in contact. This is the single most important requirement of this part of the system.

The communication which exists in PBL is rich in subtle clues and gesturing. Furthermore, the facilitator needs to read individual reactions in the group context to detect consensus, confusion, or any needs or non-verbal messages from the group. Experienced facilitators can sometimes detect when a student is guessing or confused by the tone of voice, but with video they can do it more successfully.

We have used a setup in which 9-inch or 13-inch monitors provide near real-size images of head and shoulders of each student. The monitors are arranged in a configurable cluster, in a coordinated array combined with the (optionally spatial) sound channel. The facilitator has a self-monitor, and can be seen by the students in either a large monitor for a co-located group, or in small individual monitors. The setup was designed to achieve the best possible eye contact so that the facilitator would not have the feeling of being talking alone in a room full of equipment, as shown in Figure 2.

Although we used the above setup successfully, many challenges remain. One of them is the quality and bandwidth of a digital implementation. Echo cancellation and calibration of the audio proved non-trivial. More advanced features such as creating the illusion of looking at the same or appropriate points, depending on the focus of attention of the students, would greatly reduce the perceived effort by the facilitator.

**Discussion Tools**

During problem solving, when there is uncertainty or disagreement as to what to do next, groups go into a free-format, unstructured discussion mode. The students should be able to bring the discussion subject out of the content area and into the discussion tool and to take the results back as applicable; moreover, importing homework, or work created using tools external to the system into the whiteboard is often necessary.

Many multi-user whiteboards and annotation tools are useful for discussions. Seamless transitions may be tricky, especially if data types and formats other than simple bitmaps need to be handled. The user interface of the content application and the whiteboard must be consistent to minimize user confusion. We have used commercial and public domain whiteboards and also tried sharing graphical editors for annotations. Additional programming effort was required for seamlessness.

**Monitoring and Facilitation Tools**

We have studied PBL facilitation as practiced in the Medical School at the University of Pittsburgh. Using workflow analysis we are currently investigating how to abstract the facilitation and monitoring tasks, and identifying the necessary input data such student feedback, agenda status, audio and floor control activity. As explained before, audio and video help the facilitator to stay in touch with the group and monitor the group. Facilitators need to keep track of students as a group and as individuals. Early observations indicate that the level of perceived effort by the facilitator increases significantly compared to the
classroom situation. Our observations and surveys indicate that the facilitator is fully occupied 100% of the time.

Monitoring and facilitation tools should be designed to take some of the load off the facilitator and bring him or her into the action only when it is necessary (e.g., on demand). This may also open the possibility of facilitating more than one group at the same time.

**Session Management and Control for Collaborative Learning**

In order to create, enter, participate in, and leave a session, users need to have access to information such as scheduled times, participants, resources to be used, and course context. A session status can be defined by three parameters: participants, resources, and tools.

Participants are the end users who are allowed to join the session. Participants can be assigned roles according to certain criteria specified at creation times. A classical example of roles in group learning are facilitator and students. Transient roles such as floor chair and controller (in case the floor control requires them) can also be identified easily at all times.

Resources are abstract entities representing specific activities. Examples of session resources include video communication, audio communication, whiteboards, text editors, Web-sharing mechanisms, and floor control mechanisms. Resources may have a set of attributes which specify the nature of the tool that can be used to provide the resource. Video compression method can be one such attribute associated with a video resource.

Tools are the actual software used to provide the session resources. The reason for specifying tools and resources is that more than one tool can provide a resource thus providing great flexibility. Users may then be able to use their favorite tools as long as they match the resource attributes.

The main functions of a session manager are: session creation and announcement, handling session joining and leaving, inclusion and exclusion of resources, tool attachment and detachment, event notifications to local session tools, and control and status communication across tools and participant nodes. Control privileges are distributed among session owner or creator, facilitator (if different), and students. Session management also deals with work environment persistence (i.e., starting where the group left off) across synchronous and asynchronous sessions.

**Discussion**

In this paper we have presented an approach to collaborative distance learning which will help to increase the options and quality of distance education. The approach consists of choosing a group-oriented pedagogy first, and then building an architecture using properly matched technology. Off-the-shelf groupware does not match the needs of collaborative learning; the two key components, session management and control and group learning monitoring and tracking are not available. However, it is not recommended to develop systems from the ground up, but to re-use existing technologies as much as possible. Most of the effort will be spent in designing and building the unavailable modules and in achieving an effective and seamless integration of the whole system.

In the current stage of our work, we have implemented a prototype and tested it under laboratory conditions to ensure overall functionality. The next step will be a field test in the Medical School at the University of Pittsburgh. Initial surveys indicate high acceptance by the students when working with remote facilitators. However, facilitators reported an increased amount of effort when compared with the classroom facilitation. That situation is explained because the monitoring and facilitation tools are not fully developed yet, and thus the system creates a cognitive overload on the facilitator. Technical requirements for content sharing and audiovisual communication have also been identified but their discussion is beyond the scope of this paper.

Once remote facilitation is achieved, in the setup shown in Figure 2, the following step is to place the students apart. This will require the creation of a virtual environment which can incorporate the features of virtual worlds such as immersiveness, virtual presence, and social dynamics, to support the socio-pedagogical needs of group learning (Roehl, 1996).

On the issue of implementation of practical systems, analog audio and video communication seems to provide the required quality (the other components work well over wide area networks, intranets, or Internet). Interactive TV systems for remote learning are not likely to disappear in the short term. They could be enhanced by adding live sharing of Web content as an additional resource to foster student participation. For PC-bases systems, lower end facilitator and student stations should be designed which use digital audio and video. Further research and development must be done to achieve acceptable quality under reasonable bandwidth conditions.

Niederhauser (1996) described the need for educators to “reassess what it means to be literate in our society”. He proposed a view of an ‘information society’ which demands critical thinking and problem-solving skills of the individual members of society. Training structures in education would need to be reformed and resourced to provide teachers with the opportunity to develop basic technological skills, subject knowledge and collaborative ways of working in order to integrate information technology (IT) in the curriculum. There are similarities between these aims and the description of ‘IT Capability’ in the National Curriculum (NC) in England and Wales (NCC, 1990 A1): - knowledge about IT applications and about IT tools; the skill to use appropriate IT skills effectively; an understanding of the new opportunities IT provides; knowledge of the effects and limitations of IT. The National Curriculum view of information literacy describes the ways in which IT - characterised by the storage, organisation, processing, representation and transmission of data - is expected to enable the learner to identify and access information; organise it for analysis and present outcomes to an audience in an appropriate manner.

Niederhauser’s view of the process of change is essentially a traditional ‘top-down’ model of teacher education, in which the provision of resources and the design of courses to integrate IT skills into the curriculum is supposed to bring about change. In addition, the model he offers has features of technological determinism in which “advancements in electronic technology” drive the ‘information revolution’. The solution seems simple - teach the teachers, and they will then be equipped to help their pupils ride the wave of progress. This seems to be, for example, the view of Anthea Millett, Chief Executive of the Teacher Training Agency in the United Kingdom (UK), who suggests that in order to promote the use of IT by the teaching profession we need to show teachers, “super programs that go to the heart of what they are trying to do and then say to them: ‘Do you like this software? We will show you how to use it.’” (TES, October 18 1996).

This approach is, however, reminiscent of Street’s (1993) description of an autonomous model of literacy in which sets of competences are separate from the situations in which they are used. These capabilities of technical skill, thinking and problem-solving are treated as if they can be learned and taught independently of the cultural context. In contrast with the autonomous model of literacy, Street puts forward the ideological model. This view recognises that literacy is not a generalised, culture-free process, but a set of specific practices embedded in particular social contexts. An ideological model would highlight the culture-specific view of information literacy. We argue that it is this perspective which should guide our understanding of how information literacy arises and develops within society and policy making, within the home and school environments, within classroom activities and within the individual’s experience of a subject and construction of knowledge.

Literacy, numeracy, and information skills are given priority in current educational policy in the UK, reflecting perceptions of the ‘information society’ which are associated with images of economic progress, modernity, intelligence, cultural change and power. (Beynon & Mackay, 1993; Bowers, 1988; Chandler, 1995) Such perceptions, however, are not straightforward and the debates about these images and their relative importance are far from closed. For example, critics of the idea of an ‘information society’ challenge the implicit link that is often made between information processing and knowledge (Roszak, 1994). The image of ‘economic progress’ is used to both attack educational practice and to justify curricular reforms yet the relationship between education and economic well-being is far from clear (Apple, 1996). In the UK context, now that the National Curriculum has been established, pedagogy itself is challenged by those who would limit the control by the classroom teacher concerning methods of teaching and learning (TES, September 19, 1996). Finally, analysts with an interest in discourses of power in the classroom force us to consider the ways in which IT might reinforce and exacerbate social inequalities (Fisher, 1993. Also Bernstein, 1996, provides a relevant analysis of such discourses).
Having acknowledged the wider context in which the use and purpose of IT is perceived, it is important to consider the ways in which IT is taken up and experienced within classrooms and schools. Demands are made of teachers’ pedagogical practices and questions raised about ‘fitness for purpose’ (Alexander, Rose, & Woodhead, 1992) when IT can be used to support a range of learning experiences from individualized instruction to collaborative learning (NCET, 1996, Scrimshaw, 1993). In planning and developing their teaching strategies, teachers need to consider the learning demands of the activities (Galton, 1995) and the role that IT might play in supporting or changing ways of working (Kemmis, Atkins, & Wright, 1977; Crook, 1994).

At the level of particular activities, the features which characterize IT can give insight into the nature of the subject focus itself, changing the experience, construction and representation of knowledge. Mathematical ideas and relationships can be modeled and presented in a variety of ways, from fractal geometry to Fermat’s Theorem. The process of writing and crafting a text, from mark-making and editing to restructuring and publication can be supported and extended. Digital data can be used as a medium to represent, manipulate, and transmit meaning in the visual arts (Loveless, in press; Mitchell, 1994).

In this paper we argue that teachers need to be able to interrogate and challenge the purposes for which IT is being used in classrooms in order to locate the children’s experience in an ideological, cultural, epistemological, and pedagogical context. This is not to be achieved by simple models of in-service or pre-service training which emphasize ‘how-to’ competence but overlook the real and direct ways in which the presence of IT can change the experience of schooling for both teacher and pupil.

A Framework for ‘Good Practice’

Our aim in the discussion of the definitions of information literacy is to raise questions about the purposes for which we use IT in our work; how these ideas translate into ‘good practice’ in the classroom and how we might identify effective teaching. Alexander’s (1996) model of general pedagogy is helpful in addressing the concept of ‘good practice’ and contributing to the debate about the purpose and meaning of our work in teacher education. An important theme is that ‘good practice’ is an aspiration as much as an achievement; about dilemmas more than certainty, compromise rather than consensus.

... good practice, created as it is in the unique setting of the classroom by the ideas and actions of teachers and pupils, can never be singular, fixed or absolute, a specification handed down or imposed from above in the manner charted in the Leeds research... [It] is plural, provisional and dynamic: there are thus as many versions of good practice as there are good teachers striving to attain it (Alexander, 1996, p71).

Alexander’s model consists of five dimensions or ‘considerations’:

1. Value considerations ... beliefs and values shaping views of childhood and the child’s needs, of society and its needs, and of knowledge, which inform a coherent view of what it is to be educated;

2. Empirical considerations ... evidence about the effectiveness of practice: about the capacity of particular teaching strategies to deliver learning in accordance with a coherent view of what it is to be educated;

3. Conceptual considerations ... a comprehensive map of the essential elements of teaching, learning and the curriculum, and of the relationship between them;

4. Political considerations ... expectations and pressures from within the professional hierarchy, and beyond it from parents, community, employers and politicians;

5. Pragmatic considerations ... an awareness of the opportunities and constraints of particular school and classroom settings. (Alexander, 1996, p70).

There are two important points to make about this model. The first is that ‘good practice’ relies on some sort of interaction and balance between all five dimensions. Mere ‘practice’ is a reflection of the political and pragmatic. The second is that the five considerations are not equivalent and there have to be reasons for preferring one course of action over another. Thus, in Alexander’s model, values are central and are expressed in real classroom situations. Empirical considerations are a critical adjunct to matters of value and belief, to enable us to distinguish between the strengths and weaknesses of different classroom strategies. In order for classroom teaching to be effective we must have a notion of what it is to be educated.

This framework can be applied to the use of IT in the classroom. It can be argued that the current situation in schools generally reflects ‘practice’ rather than ‘good practice’. (Watson, 1993, Loveless, 1995). Political considerations lie in the expectations and pressures upon teachers to use IT in response to requirements of the National Curriculum, the demands of parents, and the political policies to promote technology in schools. The pragmatic considerations can be seen in terms of what is manageable with particular resources and classroom constraints and the skills and competency models of initial teacher education.

In order to develop and promote ‘good practice’, there needs to be an exploration of value considerations - the beliefs and values about the role of IT in our society and the ways in which it supports and extends knowledge; empirical considerations of how teachers develop knowl-
edge and understanding in their teaching strategies and conceptual considerations of the claims of IT to support learning and teaching.

**The Teacher Development Project**

The Teacher Development Project at the University of Brighton is addressing these issues in the context of art education and the use of IT in primary education. The project is a collaboration between the University, the Arts Council of England, South East Arts and Lighthouse, the Brighton Media Centre; and was prompted by concern that ‘political’ and ‘pragmatic’ considerations were driving both policy and planning in schools, without full attention being given to the broader context in which children and teachers used IT in the creative visual arts. In Alexander’s terms, IT in the creative visual arts was seen to be stuck at the level of ‘practice’.

The nature of the experiences and knowledge which teachers need to develop are being investigated in three areas:

1. Fieldwork in classrooms to observe and question teachers on their beliefs and theories about teaching, learning, IT and art education;
2. The design of initial teacher education subject and professional courses; and,
3. The development of curriculum materials which reflect the characteristics of the digital medium and the cultural environment in which they will be used.

Value considerations are being addressed by exploring the cultural environment in which IT is used in the visual and performance arts and contributes to the experience of childhood in the age of the computer, film, and TV screen. The development of visual literacy in the twenty-first century is embedded in the contexts discussed above. The characteristics of IT and the unique qualities that it brings to artistic knowledge are highlighted. Digital data is a new medium which enables not only the simulation of more traditional physical processes, such as painting, drawing and photography, but also the construction and communication of visual representations in new ways. Computational tools manipulate, transform and process a set of mathematical values in order to communicate meaning in a visual language. The display and transmission of visual ideas on screen and over networks, rather than in fine prints, opens up new ways of interacting with visual art which alter the relationship between the artist and the viewer of the image. The emphasis on the transforming process and the potential for transmission, rather than capture and printing, as in photography, has been described as ‘electrobricollage’, fragments of information that circulate in the high speed networks now ringing the globe and that can be received, transformed and recombined like DNA to produce new intellectual structures having their own dynamics and values (Mitchell, 1994, p52).

Empirical considerations are being drawn from observable practice in the classroom for students and practicing teachers. The context, content, planning, and management of the use of IT in the visual arts is being evaluated in terms of the requirements of the National Curriculum, the teaching strategies used, the learning outcomes for the children and their understanding of the processes and products of the activities. The teachers’ experience, interests, confidence and needs are also being evaluated in order to develop models of staff development and support. Although Alexander does not apply his framework to the issue of effecting change and development from ‘practice’ to ‘good practice’, we argue that it is through empirical considerations of evidence and evaluation that we can move from an uncritical to a critical pedagogy of IT.

Teachers’ views of the role of IT in supporting learning in art education are influenced by their personal philosophies of the nature of the subject, of children’s learning, of the place of IT in education and society, and of the pedagogical practices which express these theories and beliefs. An important outcome of the research involves conceptual considerations of the relationship between teaching, learning and the curriculum for art education which will then inform the production of support materials which exemplify ‘good practice’.

Again, we present this aspect of the model as problematic, for we are aiming at a moving target; the interaction between what is immediately practical in the classroom, the rapidly changing cultural context in which IT differentially affects pupils’ lives, and the wider horizon of technological possibilities that inform our imagination, gives our conceptual considerations a provisional quality. A framework for ‘good practice’ in the use of IT in art education is complex and difficult to implement. The different aspects of the framework will influence and compromise each other and, as Alexander notes, educational practice is about “dilemma no less than certainty” (Alexander, 1996, p. 68). Our aim is to acknowledge the tensions raised by ‘good practice’. The debate about the nature of ‘information literacy’ must reflect and take account of the challenges and uncertainties of the situations in which children and teachers learn.

As the use of computers has expanded and diffused through K-12 education, there is movement from learning about technology to using technology as a medium through which learning is augmented (Becker, 1990; Beynon & MacKay, 1993; Blomeyer & Clemente, 1996; Blomeyer & Martin, 1991). Teachers are using an ever-increasing variety of technology in every aspect of the curriculum (Becker, 1990; Blomeyer & Clemente, 1996). This trend is causing some in teacher education to question traditional computer literacy and its place in teacher preparation (Harrington, 1993; Novak & Knowles, 1991; Roberts & Ferris, 1994; Todd, 1993; Wetzel, 1993). The purpose of this paper is to recast the existing idea of computer literacy as a technological competency process.

The conception or definition of technological competency process (literacy) that we offer here is exemplified when a teacher education faculty member tries, assesses, adapts, and finally adopts or rejects a new instructional technology (or technology-rich learning environment) in his/her course. His/her decision would ideally be based on the technology’s suitability or fit to the objectives and content of the particular course within the teacher education curriculum. To support this process-oriented conception of technological competency and illustrate the relevance and potential of this concept for strengthening teacher education, we will: (1) explore a process-oriented perspective on curriculum change and innovation, based on the works of Rogers (1983) and Fullan (1991), and (2) present case-based examples using their frameworks as a vehicle for evaluating the descriptive or heuristic potential of technological competency process as a focus for organizing and implementing new interactive technologies in teacher education.

**Diffusion and Institutionalization of Innovations**

E. M. Rogers: Organizational Change and Innovation

Rogers offers a developmental model representing the Stages in the Innovation Process in Organizations. Within this model, the earlier stages or initiation of organizational change cannot be preceded by the latter stages of implementation, including: (a) redefining, (b) clarifying, and (c) routinizing. Individual initiative, including the individual choice to adopt or reject the innovation are critical to success in organizational adoption.

Strategic Planning and Institutionalizing Change.

Strategic planning to support technology in teaching and learning should initiate development of an organizational infrastructure in which instructional technologies can be supported. Typically these plans address the first three stages in Rogers’ model for organizational innovation:

1. **Agenda-setting** involves all the “information gathering, conceptualization and planning” (p. 363) required to assess the perceived needs for instructional technologies within teacher education programs and identify those technologies that may be of potential value in addressing these needs;

2. **Matching problems with solutions** involves fitting specific technologies with organizational and instructional needs. This often involves identifying hardware requirements (including replacement and maintenance schedules) and acquisition and deployment of hardware and software for administrative and instructional use;

3. Because most instructional technologies are complex bundles of inter-related technologies (i.e., hardware, software, operating manuals and training), it is often necessary to redefine or restructure the components of tight technology bundles to fit particular programmatic circumstances and curricular needs;

4. **Clarification** of a new instructional technology is crucial in the organizational innovation process where the new technology first becomes used by faculty and teaching staff in an education program. This stage is particularly important because it is the juncture where adoption decisions by individual faculty and staff are necessary for organizational success; and finally,
5. Routinizing the use of instructional technologies would involve incorporating them into daily instructional activities to the degree that the innovation loses its unique identity within the context of teaching and learning.

Strategic planning for technology integration in curriculum is not adoption and does not constitute curriculum change. It is however a compass that can point to identifying the next stages in the planning process.

Fullan on Enabling Change

Fullan (1991) characterizes and describes the complex process of implementation at the micro level and provides a theoretical framework that can guide curricular integration as faculty members incorporate new technologies (this may take three to five years) into teacher education curriculum.

Fullan offers ten assumptions about change which are a philosophy in action that can enable and guide efforts to integrate technology with teaching and learning. Applied to technology in teaching and learning, they are:
1. The innovation and change as conceived by the originators will be modified by those who implement it;
2. Persons implementing change will come to their own understanding of the innovation over time by using it;
3. Change in practice will result in conflict and disagreement among those implementing the innovation. These experiences can be a sign that things are changing;
4. “People need pressure to change.” (p. 106) Therefore, institutional infrastructures should provide incentives that encourage and support change (e.g., technical assistance, opportunities to talk with other implementors);
5. Incorporating change is an example of “development in use” (p. 106). People grow developmentally as they embrace change, each in his/her own time;
6. There are many reasons why implementation may not occur. “Do not assume that the reason... is out right rejection” (p. 106);
7. Not everyone asked to implement an innovation will change;
8. Plans developed should consider the above assumptions and “knowledge of the change process” (p. 107);
9. Because implementation is a complex process “no amount of knowledge will ever make it totally clear what action should be taken” (p. 107); and,
10. “Assume that changing the culture of institutions is the real agenda, not implementing single innovations” (p. 107).

Illustrating Technological Literacy as Process

Fullan (1991) and Rogers (1983) address change as an ongoing process. Since instructional technologies are continually changing technological competency is demonstrated when individual faculty members assess and adapt appropriate new technologies to the core of the teacher education curriculum or reject technologies that do not fit with either the instructional objectives or learning environment in a particular institutional setting.

The research and practice supporting sample episodes includes a needs assessment concerning technological use in teaching and learning (Blomeyer & Clemente, 1994), a statewide survey concerning technology use in Indiana’s K-12 schools (Clemente & Blomeyer, 1996), and case-based examples constructed from the teaching and program development experiences of the authors.

While teaching graduate level classes on technology in the schools, by listening and sharing our students experiences, the authors have discovered that the technical, human, and procedural hurdles to technology integration that are faced and overcome by educators at all levels of the educational system, are extremely similar. Educators from K-12 schools should not be surprised to discover that many public schools are more advanced with respect to integrating and diffusing technology in curriculum than many teacher education institutions across the country.

Clarification: Increasing technological complexity enables curricular change. According to Rogers, clarification provides a means by which innovations are formatively evaluated based on their impact to the university. It is through this process that problems may become apparent and solutions sought and carried out. A possible example of clarification examines the extension of Internet connectivity to the microcomputer instructional laboratory shared by the Elementary and Secondary Education Departments. The College of Education has a fifteen person Macintosh™ instructional lab primarily scheduled to support undergraduate and graduate courses in elementary and secondary education.

All Macintosh™ microcomputers in the lab were networked. Although the LAN in the instructional lab enabled demonstration and practical application of basic networking concepts, lack of an interconnection between the campus network and the local network made it difficult to show or teach about extending connectivity. One workstation in the lab was connected via the modem port to the university mainframe computer by a simple serial line connection. This workstation was often used to show the use of mainframe resources by using an external LED display device on an overhead projector.

As telecommunications and connectivity beyond the confines of the classroom became an important teaching
and learning issue, the needs were first met by using shared university terminal rooms. The terminal facilities were scheduled for use with classes as needed. There, the students used the university mainframe system to experience (a) the mainframe mail utility to send and receive e-mail, (b) the mainframe Gopher client, (c) WAIS information servers, (d) Usenet News Groups, and (d) the Lynx™ mainframe client to browse the text-only version of the World Wide Web.

Currently the faculty who teach technology classes as part of their instructional load have an unchallenged monopoly over use of the microcomputer lab in the College of Education. Few of the other faculty members who teach the core teacher education courses had asked to schedule the lab. The most common core courses using the microcomputer lab were teaching methods or instructional media classes coming into the lab for one class session on educational uses of instructional software.

As competition between first corners and a predictably larger group of early adopters for access to the microcomputer laboratory in the College of Education might predictably increase, the role of microcomputers and Internet information resources in teacher education curriculum will continue to clarify and expand. Expansion of demand for access will lead to calls for the expansion of existing microcomputer labs in the College of Education; or possibly for installation of 10Base-T ethernet as an instructional resource in College of Education.

Achieving stability for new informational technologies in teacher education will amount to the establishment of an infrastructure to support and aid in the assimilation of new technologies and other curricular innovations. When any new instructional technology or idea clarifies its role in curriculum, it eventually becomes invisible and commonplace.

Illustrating Fullan's' Assumptions: Micro Level Initiatives

As the conception of technological competency process is modified and refined by successive iterations of changes in both new interactive technologies, and in the stated expectations for instructional competencies as articulated by local school officials, instructional practice that brings new uses for interactive technologies into teacher education will continue to evolve. The locus of curricular change in the teacher education program will be the individual classes that comprise the teacher education curriculum.

No Solutions are Absolutely Clear: No Blue-print or Road Map to Change

One of Fullan's (1991) most interesting caveats is his assertion that: "no amount of knowledge will ever make it totally clear what action should be taken." (p. 107). He cites Louis's and Miles' evolutionary planning regarding the inherently chaotic environment surrounding and within school organizations.

No specific plan can last very long, because it will either become outmoded due to changing external pressures or because disagreement over priorities arise within the organization. Yet there is no reason to assume that the best organizational response is to plan passively, relying on incremental decisions. Instead, the organization can cycle back and forth between efforts to gain normative consensus about what is to become, to plan strategies for getting there, and to carry out decentralized incremental experimentation that harnesses the creative energy of all members to the change effort. (Fullan, 1991, pp. 108-109)

An example concerning the use of evolutionary planning is illustrated by considering a possible curricular use of e-mail and-based informational technologies in courses. Of the newly available technology systems that have apparent potential to influence teacher education curriculum, these telecommunications applications have great potential to augment existing instructional practice.

Monitoring the implementation and integration of informational technologies by teacher education faculty is one response that seemingly fits with Louis' and Miles' evolutionary planning model (Fullan, 1991). Collecting and sharing descriptive, case-based accounts documenting faculty members efforts using technology in teacher education would be a possible strategy for reducing unnecessary duplication of implementation strategies within a programmatic context (Blomeyer, 1991; Goodson & Mangan, 1995a).

Necessary Roles for Faculty and Administration: Integrating Technology in Teacher Education

To realize integration of technology in teaching and learning changes in the role of faculty, traditional teacher education curriculum, and leadership priorities are critical. Primarily faculty must model technology integration in teacher education classes. To achieve this, staff development should empower faculty to achieve technology integration in their own classes. The teacher education curriculum must address issues concerning the fit of particular technologies to pedagogy and curriculum within discipline-based courses (content and general methods).

Teacher education programs should identify faculty and staff who already have the training and experience necessary to use new instructional technologies. Technology-competent faculty could work with less experienced faculty to collaborate and diffuse the expertise necessary to realize appropriate technology integration in the teacher education curriculum. These technology resource persons could be supported and rewarded within the academic system of promotion and tenure.
This collaboration between technology and curriculum must be more than simply showing colleagues how to use a new model of computer or how to navigate the World Wide Web. It must include (a) exploring and trying new technologies for possible applications to specific classes, (b) rigorous and objective assessment of the potential these technologies for improving instructional systems, and (c) ultimately collaboration on decisions to use or abandon new technologies as components of particular classes.

The technological competency process that we propose here is a complex process having indefinite and possibly unpredictable outcomes. We propose that teacher education faculty consider a wide range of technological devices and software for possible use in discrete curricular niches within individual discipline-based courses. Harnessing this technological competency process to achieve discipline-based integration of interactive technologies in teacher education is a creative act. We believe that this development in use (Fullan, 1991) will result in unique instructional applications that will fit the intent and local context of teacher education programs.

The sophistication, complexity and risks associated with this proposed conception of technological literacy is much greater than those previously associated with computer literacy. Encouraging the integrated use of instructional technologies in discipline-based teacher education classes requires that we no longer delegate teaching about technology to specialists. Faculty in content and general methods courses must become the models for technology use in the teacher education curriculum.

The simplistic teaching and learning strategies that have characterized computer literacy are unsuitable for integration with content and general methods courses and field-based clinical experience. Our work is the training of teachers. Complex tasks require sophisticated, long-term solutions. Although the suggested path to an appropriate integration of interactive technologies in the comprehensive teacher education curriculum is seemingly long and difficult, it is a solution matching the difficulty and complexity of the task at hand.

Discussion of constructivism is wide-spread in our literature. However, little discussion has occurred regarding the question—what contribution might the constructivist perspective make in the area of technology training for teachers at the preservice or inservice levels? This discussion explores possible answers to that question.

Constructivist Perspectives
Those attempting to gain a meaningful understanding of the implications of constructivism for teaching in any curricular area face a challenge at the start. This is because the literature reflects wide-ranging views. Most agree that constructivism holds that "... we construct our own reality through interpreting our experiences in the world" (Jonassen, 1996, p. 12). However, many authors fail to agree at a fundamental level as to what constructivism encompasses. Existing views hold that constructivism is a theory (Jonassen, 1996), a collection of theories (Driscoll, 1994; Newby, Stepich, Lehman, & Russell, 1996), an instructional model (Roblyer, Edwards, & Havriluk, 1997), and a philosophy grounded in values (Lebow, 1995). Others offer extended discussions aimed at teachers regarding the nature of constructivist approaches in the K-12 classroom (cf. Henderson, 1996; Brooks & Brooks, 1993). These diverse perspectives are useful in providing educators with ideas regarding how constructivism may improve teaching and learning in various fields; however, yet more specific advice relating constructivist approaches to specific subject areas is needed.

Some of the general guidance in the constructivist literature seems applicable in the technology arena. In the remainder of this discussion, I draw upon that literature and my teaching experience to derive some strategies for use in technology courses for preservice and inservice teachers.

Constructivism: A Matter of Balance
While some argue that constructivism has usurped cognitivism (Gredler, 1997), others argue that constructivism and cognitivism complement each other (Henderson, 1996). In this regard, Roblyer, Edwards, & Havriluk (1997) compare directed instructional methods with constructivist ones. They suggest that the two approaches should be merged so as to benefit learners and teachers. Their view is consistent with that of Smith and Ragan (1993). The latter authors, distinguishing between supplantive and generative instructional strategies, also suggest that the decision regarding which approach to employ is "... like a balancing act" (p. 153). A supplantive strategy provides for explicit coverage of the events of instruction. A generative strategy, on the other hand, is less explicit and encourages students to construct individual and unique meaning. Smith and Ragan suggest a balanced approach. They suggest requiring students to exert their mental effort in support of generative learning on the one hand while providing explicit instructional support to avoid information overload in short-term memory on the other.

Experience bears out the importance of striving for a balanced approach in technology courses. In covering a skill such as how to set up a spreadsheet, the instructor can begin with a directed approach. This might involve presenting a demonstration and providing some written guidance as to the steps and concepts involved in the process. Subsequently, students can independently apply preliminary learning by taking on a bigger related challenge, perhaps of their own choosing, such as setting up a gradebook. This allows them to elaborate upon the preliminary instruction and to increase meaningfulness and relevance by developing a spreadsheet they can use in their work or studies.

Focusing on Learners and Their Needs
The constructivist view places the learner at the heart of the instructional enterprise. Just as K-12 teachers are urged to employ a learner-centered approach, so too should university instructors of technology courses (see Rodriguez, 1996). Current instructional design literature further reminds us to involve would-be learners when planning for instruction (Wilson, Teslow, & Osman-Jouchoux, 1995).

Discussing the reinvention of instructional systems development, Davies (1995) suggests that instructional
designers focus on increasing clients' personal productivity. Davies' comments — centered on corporate training applications — seem germane to constructivist instructional approaches with most adult learners. Davies' recommendations include the following:

- Provide instruction that explicitly recognizes learners' needs;
- Make a priority of learning activities even if content coverage suffers; and,
- Focus on action learning whereby learners work on real problems in real time and can measure the results of their efforts.

These recommendations stress the criticality of keeping students engaged through active participation and maintaining students' sense of relevance concerning course activities.

What other steps can a technology instructor take to focus on the learner? Ideas include adjusting course scope and content based upon students' entry skills and providing flexible learning goals based upon students' needs. Experience shows that some students in technology courses lack even basic computer skills. These students should be encouraged; they may be able to be "brought up to speed" via online tutorials or one-on-one assistance provided by peers and the instructor.

**Focusing on the Essence**

Experience suggests that "less is more" in the technology applications arena. Consider the above situation of students trying to learn how to develop a spreadsheet. It does little good to expose students to huge spreadsheets or lengthy procedural guides in introductory instruction. A simpler approach is in order. "Learners of all ages are more engaged by concepts introduced by the teacher and constructed by the learner from whole-to-part . . ." (Brooks & Brooks, 1993, p. 48). The simplicity provides building block upon which students can elaborate as they move toward personally meaningful problem solving. The instructor would thus demonstrate the construction of a simple spreadsheet consisting of perhaps a few data cells and a single computational formula. Grasping the essence, students can then literally construct more complex spreadsheets with the instructor's guidance, thus developing their understanding as they grapple with more complex problems (cf. Driscoll, 1994).

Applying the idea of spaced-practice — that is, revisiting foundational material on a regular basis over time — should support understanding of core course content. For instance, a one-shot demonstration of how to access and use an electronic mail program is not likely to foster true understanding or skill. The instructor should also use learner assessments, perhaps in the form of authentic tasks, to verify understanding of a given concept or procedure as the course progresses.

**Social Negotiation**

Driscoll (1994) points out that learning under the constructivist view is a communal activity. The idea of social negotiation has to do with learners making meaning through personal interaction and discussion with each other as they attempt to solve a given problem. Social negotiation and related meaning making among students require more than traditional cooperative learning approaches. Collaboration supersedes cooperation in that it requires students to reflect upon their actions and to share insights and solutions among the group (cf. Henderson, 1996; Driscoll, 1994). Students benefit through the increased power of "pooled minds" and the opportunity to understand each others' perspectives.

As with other constructivist strategies, balance is in order. Young adults in technology courses need time to develop skills on an individual basis. At the same time, they often enjoy providing informal assistance to each other. Culminating group projects can be worthwhile if the challenge at hand lends itself to a collaborative effort where tasks can be subdivided among the group. Examples here might include group projects to develop a series of related pages for the World Wide Web or to develop a series of multimedia lessons. Collaborative projects are useful because they promote social negotiation while reflecting what it is like to work as a part of the team in the real world.

**Nurturing Reflexivity**

A final strategy for technology instruction concerns reflexivity — learners' awareness of their role in constructing knowledge. Driscoll (1994) sees reflexivity as akin to metacognition while pointing out that the notion of reflexivity implies more than awareness of one's thinking and learning processes:

With reflexivity, a critical attitude exists in learners, an attitude that prompts them to be aware of how and what structures create meaning. With this awareness comes the ability to invent and explore new structures or interpretive contexts. In other words, when learners come to realize how a particular set of assumptions or world view shapes their knowledge, they are free to explore what may result from an alternate set of assumptions or a different world view (p. 370).

In related discussion, Lebow (1995) suggests that learners be encouraged to explore their errors. The goal of such activity is to strengthen the learner's ability to apply and manipulate knowledge while working on authentic tasks.

Experience does suggest that students should be aware of their learning process and the causes of their errors. If, for instance, a beginning student is unable to save a file to
a floppy disk, showing the student how to do it may not promote true understanding. To acquire the skill, the student must choose to reflect upon the problem, understand that the floppy disk must be specified as the destination for saving the file, execute the procedure, and then practice it. The instructor's role becomes one of engaging the student via questioning and prompting so that the student assumes responsibility for acting to solve the problem. Reflection and action, then, support construction of new knowledge.

Final Thoughts

I was somewhat chagrined while forming the panel associated with this paper to find that some university instructors are at a loss to articulate constructivist elements of their teaching efforts. I heard comments like, "I'm not an expert on constructivism — ask someone else," and "I have no idea how what we do with students could be considered constructivist!" These comments may be attributable to the difficulty we all seem to face in trying to derive concrete constructivist strategies from the somewhat scattered and still developing related literature. There also seems to be a paucity of related research.

In the end, much of what might be called constructivist strategies are ideas that good instructors employ as a matter of course. The present discussion was an attempt to explicitly link ideas about constructivism with ideas about how to best instruct adults about technology. Of prime importance, constructivists hold, is the need to move away from a view of instruction as an information transmission enterprise. Instead, we may now choose to view instruction as an opportunity for instructors and learners to work together to generate and construct new meanings and knowledge with the individual learner placed at the heart of the effort.

Theory — 1311
In his 1983 book, *Frames of Mind: The Theory of Multiple Intelligences*, Howard Gardner proposed the theory that there are multiple ways or "intelligences" by which people acquire knowledge (Gardner, 1983). When this theory was introduced, Gardner defined seven intelligences: linguistic, logical-mathematical, intrapersonal, spatial, musical, bodily-kinesthetic, and interpersonal. He has recently added an eighth intelligence, naturalist, to the list (Gardner, 1995). It continues to be his assumption that these separate intelligences develop at different times and in different ways in different individuals and that learners may have a preferred intelligence.

Many educators share Gardner's belief. Thomas Armstrong and David Lazear have written extensively describing how Gardner's theory can be applied to K-12 schools (Armstrong, 1987; Lazear, 1991). Sue Teele, Director of Education Extension at the University of California in Riverside, and Dr. David Thornburg of the Thornburg Center for Personal Development in Palo Alto, are co-founders of the Renaissance Project. The Renaissance Project is a research project aimed at helping students improve their potential to learn by addressing all of the intelligences (Davis, 1991). Sue Teele, Director of Education Extension at the University of California in Riverside, and Dr. David Thornburg of the Thornburg Center for Personal Development in Palo Alto, are co-founders of the Renaissance Project. The Renaissance Project is a research project aimed at helping students improve their potential to learn by addressing all of the intelligences (Davis, 1991). Sue Teele, Director of Education Extension at the University of California in Riverside, and Dr. David Thornburg of the Thornburg Center for Personal Development in Palo Alto, are co-founders of the Renaissance Project. The Renaissance Project is a research project aimed at helping students improve their potential to learn by addressing all of the intelligences (Davis, 1991).

Despite the amount of research and writing done since Gardner's theory was first proposed, many K-12 educators continue to plan instruction which typically only addresses the first three intelligences - linguistic, logical-mathematical and interpersonal. Believing that school doesn't have to be the way we remember it, a workshop was offered called Making Critical Connections: Bringing Gardner's Multiple Intelligences and Multimedia Together to Bring Out the Best in your Students. This paper will describe the workshop and discuss ways that technology can be utilized to activate the various intelligences.

**Origination of Workshop**

A one day workshop, Making Critical Connections, was offered through the UCF/DOE Multimedia Training, Research and Development Center (MTRDC) to teachers in the state of Florida in October, 1995 and June, 1996. The MTRDC is housed on the campus of the University of Central Florida in Orlando and was established to support school improvement efforts related to technology in Florida's public schools. It is funded by a grant from the Florida Department of Education, Bureau of Educational Technology and is made possible by the continued support of many business partners, Florida schools and school districts.

Faculty members in the College of Education at the University of Central Florida were encouraged to offer workshops relating technology to their particular subject areas. I was encouraged to create this workshop since I was teaching a course on how to help students develop their higher order thinking skills in our undergraduate teacher education program. I invited an intermediate multi-age teacher to work with me, as well as the Director of Faculty Technology Development for UCF College of Education.

**Workshop Activities**

The workshop had to be multi-sensory and fun. It opened with a brain teaser (Logical-Mathematical) to demonstrate each participant's preferred learning style. Participants sang and danced (Musical) about higher order thinking skills with a parody to Hot Hot Hot by Buster Poindexter. They participated in hands-on lessons with laser disc players, scanners, CD-ROM players and drawing tablets (Bodily-Kinesthetic). They explored the Internet alone (Intrapersonal) using a World Wide Web browser and they viewed a presentation on multiple intelligences (Spatial) using presentation software. They created their own multimedia interdisciplinary student projects in teams (Interpersonal) using authoring software. At the close of the workshop all participants returned to their schools with a notebook of materials (Linguistic) to use and share with others at their school sites.
Workshop Materials
Every participant was given a notebook of handouts which included a variety of references for future use. The notebook included:
• a template for designing multi-modal lessons;
• a listing of classroom activities to activate each intelligence;
• a multiple intelligences summary sheet;
• a weekly checklist for multiple intelligences;
• a listing of multimedia tools which can be used to activate each intelligence; and,
• an authoring software preview disk.

Connecting Technology to Multiple Intelligences
The truly exciting aspect of the workshop was the exploration of the multimedia tools which are available in most Florida schools that can be used to activate each intelligence. The following is a listing of each intelligence and the tools which can awaken, amplify, or teach each intelligence. This list was developed by the Florida Diagnostic and Learning Resource System (FDLRS). FDLRS/TECH operates as a Specialized Center in the Florida Diagnostic and Learning Resources System Network through General Revenue funds administered by Brevard County, Florida. FDLRS/East serves Brevard and Volusia Counties and is funded by EHA VI-B and State General Revenue.

Students with a High Degree of Linguistic Intelligence
think in words;
learn by listening, reading, and verbalizing;
benefit from discussion;
enjoy writing;
like word games;
like books, records and tapes;
like tape recorders, typewriters, word processors, label-makers, and printing sets;
have a good memory for verse, lyrics or trivia; and,
enjoy outings to such places as libraries, bookstores, and newspaper bureaus.

Students with Linguistic Intelligence May Benefit From:
word processors;
prompted writing programs;
label-making software;
crossword puzzle generators;
programs with speech output;
word game programs;
programs which require them to read and answer questions; and,
programs which ask them to create poetry, and other literary forms of expression.

Students with a High Degree of Logical-Mathematical Intelligence
think conceptually;
reason things out logically and clearly;
look for abstract patterns and relationships;
enjoy computing arithmetic problems in their heads;
like brain teasers, logical puzzles, and strategy games;
like to use computers;
like to experiment and test things out;
enjoy science kits;
like to classify and categorize; and,
enjoy outings to science museums, computer fairs and electronics exhibitions.

Students with Logical-Mathematical Intelligence May Benefit From:
database programs;
spreadsheet programs;
problem-solving software;
programs that teach reading in a logical way such as word patterns;
simulations which allow them to experiment with problems and observe results;
computer programming software; and,
strategy game formats.

Students with a High Degree of Spatial Intelligence
think in images and pictures;
like mazes and jigsaw puzzles;
like to draw and design things;
like to build models;
like films, slides, videos, diagrams, maps and charts; and,
enjoy outings to science museums, architectural landmarks, and planetariums.

Students with Spatial Intelligence May Benefit From:
draw and paint programs;
graphic production software;
reading programs with visual clues, i.e., a rebus method or color coding;
programs which require them to solve mazes or puzzles;
programs which require them to create a picture and then write about it;
programs which allow them to see information as maps, charts, or diagrams; and,
hypermedia.

Students with a High Degree of Musical Intelligence
think in tones;
learn through rhythm and melody;
play a musical instrument;
remember melodies of songs;
may need music to study;
notice nonverbal sounds in the environment;
learn things more easily if sung, tapped out, or whistled;
can use metronomes, percussion instruments as aids for learning rote material; and, enjoy concerts and musicals.

**Students with Musical Intelligence May Benefit From:**
- programs that combine stories with songs;
- reading programs which associate letters/sounds with music;
- programs which use music as a reward;
- programs which allow them to create their own songs;
- programs designed to teach music concepts and skills; hypermedia; and,
- programs which add music to their computer presentations.

**Students with a High Degree of Bodily-Kinesthetic Intelligence**
- process knowledge through bodily sensations;
- communicate through gestures;
- move, twitch, tap or fidget while sitting in a chair;
- learn by touching, manipulating, and moving;
- like role playing, creative movement, and any physical activity;
- demonstrate skill in crafts such as woodworking or sewing;
- enjoy fixing machines, building models, and hands-on art activities; and,
- enjoy outings such as sporting events, swimming, hiking trails.

**Students with Bodily-Kinesthetic Intelligence May Benefit From:**
- software requiring alternate input such as joystick, mouse, touch window;
- keyboarding/word processing programs;
- instructional games, especially arcade format with fire buttons;
- graphic programs that produce blueprints for making 3-D models;
- science and math programs with accompanying manipulatives and probes;
- driver education programs;
- software which includes animated graphics; and,
- programs which allow them to move objects around on the screen.

**Students with a High Degree of Interpersonal Intelligence**
- understand and care about people;
- have a lot of friends;
- like to socialize;
- learn more easily by relating and cooperating;
- enjoy playing group games;
- are good at teaching other children;
- like to be involved in clubs, committees, after-school programs; and,
- enjoy outings of any kind when allowed to socialize.

**Students with Interpersonal Intelligence May Benefit From:**
- telecommunication programs;
- programs which address social issues;
- programs which include group participation or decision-making;
- games which require two or more players;
- programs with a simulation or adventure format;
- any program that turns learning into a social activity; and,
- guidance programs.

**Students with a High Degree of Intrapersonal Intelligence**
- display a sense of independence;
- like to be alone;
- seem to be self-motivating;
- learn more easily with independent study, self-paced instruction;
- prefer individualized projects and games;
- need their own quiet space;
- enjoy such things as the solitude of their rooms, and long quiet walks; and,
- enjoy movies and books about heroes.

**Students with Intrapersonal Intelligence May Benefit From:**
- tutorial software;
- programs which are self-paced;
- instructional games in which the opponent is the computer;
- programs which encourage self-awareness or build self-improvement skills;
- any program which allows them to work independently; and,
- researching on the Internet.

**Students with a High Degree of Naturalist Intelligence**
- observe nature and make sense of it;
- enjoy learning about ecology and the environment;
- think about the problems of society, the shrinking world, the future of the planet;
- care about the hole in the ozone layer, and the destruction of the food chain;
- fight to protect wildlife and the rain forest;
- enjoy cooperative learning activities; and,
- volunteer to be in charge of the class recycling project.

**Students with Naturalist Intelligence May Benefit From:**
- simulation programs which ask them to solve environmental problems;
- programs involving social issues;
- Internet locations dealing with outdoor education and global education; and,
- programs related to consumer education.

**Can This Really Make A Difference?**

The true success of the workshop, Making Critical Connections, can only be measured when participants return to their classrooms and apply the ideas they experienced. It is hoped that these K-12 educators will approach important skills and concepts in eight different ways - linguistic, logical-mathematical, spatial, musical, bodily-kinesthetic, interpersonal, intrapersonal, and naturalist. An important lesson shared will be applied when these
teachers select technology for their classrooms. They were
encouraged to examine not only the skills a particular
computer program develops, but the intelligences through
which it operates as well.

After the teams of participants presented their
authoring program projects at the end of the workshop,
they were asked to chart the five most important learnings
of the day. I close with these five suggestions on how to
optimize learning opportunities through technology for all
students:

- select software which offers a variety of approaches
  and formats;
- select software which gives students the opportunity to
  learn critical curriculum skills and concepts through
  their learning strengths;
- provide activities related to software programs which
  engage a variety of intelligences;
- assist students in identifying their learning styles; and,
- help students learn to select software which helps them
  use their learning strengths to insure success.

Theory — 1315
There stood a log cabin made of earth and wood,  
Where lived a country boy name of Johnnie B. Goode...  
He never ever learned to read or write so well,  
But he could play the guitar like ringing a bell.  
— Chuck Berry

Johnnie B. Goode, an American child of the 1950s, was a mediocre student. One might assume that because his linguistic intelligence was not his area of strength, he was somewhat limited in showing his teachers what he had learned. His teachers may never have given him the opportunity to show his knowledge through his area of genuine strength, his musical intelligence. If his teachers had, they would have recognized his intelligence, adjusted their instruction, and possibly motivated him to “read and write” better.

Today’s Johnnie, an American child of the 1990s, should not have to face the same problems as the 1950s Johnnie because many educators, and even parents, have broadened their views of what constitutes intelligence. Intelligence is no longer traced to verbal and nonverbal categories, but instead is understood as being reflected in various modes of expression and behavior (Gardner, 1983; Gardner, 1991; Gardner, 1993; Sternberg, 1990); furthermore, information is now available to assist teachers with addressing multiple intelligence in the classroom (Bennett, Tipton & Bennett, 1996; Campbell, Campbell & Dickinson, 1996; Gardner, 1995; Mc Clasky, 1995; Smagorinsky, 1995), and even popular literature references ways for parents to be aware of and tap into their children’s intelligences (Blumenthal, 1996).

Despite the seemingly widespread dissemination of these less restrictive views of intelligence, questions arise as to how well classroom teachers understand and truly use multiple intelligences as a guide to classroom practice. As with the initial appearance of any innovation in educational theory and/or practice, multiple intelligence theory might be dismissed by some teachers as a fad or viewed as a threat to their personally held beliefs about learning which were nurtured in preservice education programs.

Assumptions and Purposes

We believe that knowledge can be represented in different modes, and that students process knowledge in a variety of ways. One way we actualize this developmental perspective is through Gardner’s multiple intelligence (MI) theory. As teacher educators we subscribe to the proposition that Gardner’s multiple intelligence theory is a form of idea technology as described by Hooper & Rieber (1995). Idea technologies, unlike tangible product technologies such as computer hardware and software, are systematic, intangible theories that guide a process. Examples include cooperative learning, problem-based learning, and simulations as well as many others. MI Theory, as an idea, undergirds our instructional and assessment decisions as we teach our undergraduate preservice education students at La Salle University in Philadelphia, Pennsylvania. We believe that inter- and intrapersonal, spatial, musical, and kinesthetic intelligences are true intelligences like their more traditionally accepted mathematical/logical and linguistic counterparts. They are not merely talents or aptitudes (Armstrong, 1994).

In addition, we hold that product technologies are natural complements to MI theory because they enable learners to access and apply their natural learning styles or preferences more readily, which Armstrong (1994) suggests emanates from one or more of their personal intelligences. Thus, by conjoining MI theory with a variety of product technologies, we believe that we are more likely to engage our students and assist them in comprehending course content.

The purpose of this action research (Kindsvatter, Wilen, & Ishler, 1992) is to hold a mirror to our own
practices regarding the manner in which we operationalize our beliefs about MI theory. In addition, we raise questions regarding the appropriateness and effectiveness of infusing both MI theory and product technologies in so-called “non-technology” teacher education courses. The following two questions guided our investigation:

- In what ways, if any, has Multiple Intelligence theory, an idea technology which we espouse, informed our everyday classroom practice in teaching non-technology teacher preparation courses?
- To what extent do the product technologies we incorporate into our classroom practice interact with Multiple Intelligence theory?
- Ultimately, through this examination, we hope to improve the teaching and learning taking place in our courses.

**Procedures**

During the 1996 Fall semester, we collected data from our three respective undergraduate courses — Educational Psychology, Foundations of Education, and Developmental Reading. The Educational Psychology course, intended for second year education majors, is open to non-education majors; whereas, the Foundation of Education and Developmental Reading courses intended for third year students typically enroll education majors who do student teaching within the year. Each course enrolls twenty-five to thirty students in a fifteen-week semester. Classes are held twice per week, one one-hour, and one two-hour period.

Although our individual format for data collection varied, each of us, for each class session, classified the entry strategies we employed. Unlike traditional entries that focus upon attention-getting, review, or preview techniques (Kindsvatter, 1992), Gardner (1993) describes five specific entry points which “help the teacher introduce new materials in ways...that...can be easily grasped by a range of students...so they have the chance to develop...multiple perspectives...” (p. 203). It is in the context of Gardner’s view that we classified our entries. Next, we inferred, through careful reviews of lesson plans and post-instructional analyses, the types of intelligences we addressed. Finally, we noted the type and frequency of product technologies we incorporated into our instruction. From our logs and notations we subsequently refined and formalized a Multiple Intelligence & Technology Checklist (see Figure 1) which helped us develop a more systematic and comprehensive overview of the instructional technologies that we used.

Data collected was analyzed by examining the frequency and distribution of responses — first for each researcher, and then for the aggregate group — listed for the three categories contained in the Multiple Intelligence & Technology Checklist. Where appropriate, we debated individual interpretations of classifications until agreement was established.

Results

In Table 1, five entry points, or modes of addressing a concept, are identified (Gardner, 1993). Collectively, we used narrational entries — that is, story or historical approaches to topics, most frequently (25%). This was followed closely by foundational entries (24%) which examine philosophical or terminological aspects of concepts; logical/quantitative entries (22%) which emphasize numerical or deductive reasoning; and experiential entries (20%) which employ hands-on approaches. The least frequently used type of entry was esthetic (8%) which highlights artistic, sensory, or surface features of concepts.

Linguistic intelligence (26%) was the most frequently inferred use of MI-idea technology (see Table 2). This was followed by mathematical/logical (20%), interpersonal (19%), intrapersonal (18%), and spatial (12%) intelligences. There was a precipitous drop in the reported incidence of addressing bodily-kinesthetic (3%) and musical intelligences (less than 1%).

The most frequently used category of product technology (46%) was non-projected media which included the use of handouts, the chalkboard, comic strips, realia, flashcards, puppets, books, dolls, etc. (See Table 3). The projected visuals category (29%) ranked second with the overhead projector being the predominant hardware that was used, supplemented with the occasional use of a 16 millimeter film projector. There was a pronounced drop in the remaining three categories: computers/multimedia (13%), video (10%), and audio (2%).

Discussion

Entries and Idea Technology: Doorways to Learning

Gardner’s (1993) concept of different types of entry points provided us with a way to examine how our instruction provided conceptual gateways for our students. We had anticipated our across-the-board use of narrational, experiential and foundational entries; however, we were surprised by the relatively low citation of use of the esthetic entry. We discovered that one of the authors used the esthetic entry significantly more often than the other two. Teaching the Educational Psychology survey course, he found that the students were not sufficiently engaged with the material. Over the years he has developed a repertoire of esthetic entries designed to foster and increase interest and motivation. For example, when introducing the concept of psychoanalysis the instructor began his class by asking his students, “Who can remember and share with us what they dreamt last night?” The other two instructors who teach upper division courses for the majors used this entry less frequently and on a more limited basis, for example, one just used comic strips and newspaper ads which elicited strong learner responses.

Assuming that our entry classifications were accurate, we inferred which of the seven intelligences were being promoted either by the initial lesson entry or transitional entries within the class session. The higher incidences of addressing linguistic, interpersonal, and intrapersonal intelligences confirmed what we encounter in an academic context, namely — the university. Language is a wonderfully efficient tool that we, as teachers, rely upon to convey abstract information, probe the depths of our students’ understanding, and share insights about that understanding with others within finite amounts of precious classroom time.

Interestingly, we were heartened by the relative frequency of our addressing mathematical/logical intelligence. This higher incidence proceeded from our understanding that this form of intelligence was not limited to pure numerical quantification, but included opportunities for analytic reasoning as well. Instructor use of concept
maps, such as top down, hierarchical branch tree diagrams, proved to be one such entry tool used to promote deductive and comparison-contrast reasoning. Visual in nature, concept maps also provided “doorways” for spatially oriented learners.

Overall, we were not surprised by our lack of attention to bodily/kinesthetic and musical intelligences. Although we had realized individually that we did not address these intelligences, seeing the combined frequencies in print really jolted us into recognizing that we may not have provided a sufficient number of pathways for students who might have benefited from learning opportunities using these intelligences. Possibly, if we had implemented more esthetic entries, we might have been able to address these students’ needs more effectively.

Product Technologies

Our preponderance of the use of non-projected technologies did not strike us as extraordinary. Curiously, we discovered that two of us did not even tally some of the non-projected technologies; for example, chalkboard and handout usage. Two of the authors discounted these tools because they were not readily perceived as forms of product technology. Hooper and Reiber (1995) might argue the reason for this lack of awareness is because chalkboard and handout usage has been so well integrated into their instruction that these two authors took such media for granted. Ironically, without these forms of product technology, they would have found it difficult to be as effective.

Computer use was cited more frequently than we thought due to one author’s sole use of presentation development software. Upon reflection, it was discovered that this was due to her renewed enthusiasm upon resumption of full-time teaching and access to a multimedia-ready classroom. In contrast, one author did not use the computer due to general lack of familiarity and expertise, while the other author, who possesses considerable expertise, did not have convenient access to the electronic technology.

Recognizing video as a convenient, user-friendly product technology, we were somewhat intrigued by its relatively infrequent use. Again, one author used video frequently in his Educational Psychology course to motivate as well as to instruct. In the Developmental Reading course, video was used strictly to demonstrate procedures; whereas, in the Foundations of Education course, video was used to present models of schooling that were then analyzed. Audio, also readily available, remained the least frequently used product technology and its use was limited to demonstrate linguistic issues or present dialogue, never music.

Idea and Product Technologies Conjoined

We believe that the varied entry points employed throughout the semester afforded us opportunities to address most but not all of the multiple intelligences to which we espouse. Obviously, we will need to review our individual lesson entries and actions to see how, when, where and if we should adjust our current practices to provide more consistent gateways to target bodily/kinesthetic and musical intelligences. To what extent did product technologies provide us with these perceived MI Theory “hits”? A review of the types of technology used underscored how specific product technology fused with MI Theory as an idea technology. It also identified gaps.

Multimedia presentations, video, projected and non-projected visuals helped to provide entries for students with linguistic, logical-mathematical, and spatial intelligences. Video case study presentations and demonstrations also resonated with those students who possessed strong interpersonal and intrapersonal intelligences. Non-projected visuals and materials may have assisted learners with spatial and bodily/kinesthetic intelligences. Unfortunately, our audio products addressed linguistic perspectives rather than music. Johnnie B. Goode would probably fare no better in one of our courses than he did in the 1950’s hit song.

Implications

We were propelled into this investigation during the hazy, lazy days of summer 1996 by irreverent questions posed by one member: “Do we really believe in this MI stuff, or do we just teach it because it’s something our students need to know? If we do buy into it, how do we really practice these beliefs?” What started as an informal discussion sparked a full fledged investigation into what we think we know about MI Theory, how we operationalize it and how it complements the developmental theory that is the hallmark of our education department’s programs. We all agreed that we were disciples. But what did that really mean? Again, what started out as a review of our current practices to see whether or not we actually employed elements of MI theory in our courses has turned into the mythical Hydra.

Each time we thought we finally understood an MI Theory concept and its relationship to our actual beliefs and practices, another more startling or disturbing question would rear its head to mock our understanding. Rather than just answer our two proposed questions, we found that we raised a myriad of new ones.

Our study prompted us to recognize the overlapping nature of Gardner’s seven intelligences. We came to appreciate that these are not discrete, self-contained entities but parts of an interwoven tapestry. This fusion and cross-nurturing of the intelligences can best be understood as a synergistic fusion reflecting a Vygotskian infrastructure, wherein one intelligence has the potential for promoting another. A prime example of this fusion was when one author in teaching educational philosophies.
simulated “Ryan’s Coffee House” wherein students informally argued the merits of various philosophies underpinning school policies and operations. Here, a student’s interpersonal intelligence acted as a catalyst in priming both linguistic and bodily/kinesthetic intelligences to argue the benefits of a particular position which ultimately led to a fuller understanding of how educational philosophies function.

Teacher educators need to go beyond cursory explanations of Gardner’s seven intelligences. Our experiences this fall reaffirmed our assumptions that we must not only explain what is meant by multiple intelligences and overtly model how they can inform planning and instruction, but also demonstrate —even in “non-technology” preparation courses — how, by incorporating a broader use of product technologies, we can increase the likelihood of reaching the next generation of Johnnie B. Goode.

SEMIOTICS AS A SOCIO-CULTURAL TOOL FOR A "SOUNDBYTE AND SOFTWARE" SOCIETY

Ruth Gannon Cook
University of Houston

Winston Churchill once said “The empires of the future will be the empires of the mind” (Toffler, 1990, p. 1). Ironically, philosophers and psychologists have made similar observations over the centuries, but their words have often remained buried in the discourses of their respective disciplines. The thawing of relations with the former Soviet Union has unearthed the works of psychologist Lev Vygotsky. Vygotsky’s observations were unique because he crossed over professional disciplines of psychology, philosophy, and sociology to explore a key component of the mind, consciousness via the mind’s activity functions. He did so using the tools of those activities: symbols (Davydov and Radzikhovskii, 1985). Vygotsky’s research has presented opportunities to approach individual mental processes as determined by one’s historically developed activity, both on a physical level, through labor, and on a mental level, through the use of “psychological tools” (Wertsch, 1985).

In this study, I reviewed the translated research of Lev Vygotsky and compared his use of the term “psychological tools” with research in the areas of metaphors and semiotics to see if metaphors and semiotics could be considered “psychological tools.” If so, could these semiotic “psychological tools” be included in media soundbytes and in computer software design to mediate consciousness? Since my research interests reside in the area of instructional technology, my intention was to explore psychological theories, like those of Vygotsky, to see how instructional technologists might use these theories to design innovative technology programs that could have positive and dynamic effects on learning activity.

Vygotsky’s Legacy

The body of research initiated by Vygotsky offered the basis for a culturally grounded theory of cognition, with common units of analysis that could even transcend the limitations of professional and political boundaries. His concept of “mediated tools” linked culture to the functions of consciousness (Wertsch, 1985). His theory of the “zone of proximal development” (Vygotsky, 1978) provided a foundational underpinning to constructivist philosophy and to the field of education. It also offered insight that would later become beneficial in instructional technology because that “zone” has evolved beyond the “zone” of proximal human development to what is now “virtual” infinity. Vygotsky also shed light on the need for the expansion of the field of socio-cultural studies so that social and cultural influences could be viewed across professional, as well as national, boundaries.

The traditional dictionary meaning assigned to the word “tool” is “anything, which, held in the hand, assists a person to do manual or non-manual work. (New Lexicon Webster’s Dictionary of the English Language, 1989).” Vygotsky used the word “tool” in a similar context, assigning it meaning in relation to work. But Vygotsky’s “tools” consisted of metaphors, symbols, and semiotic representations of communication, like auditory/vocal and visual expressions; body talk (kinesthetics); touch (proxemics); and prostheses (extensions of limbs); and, while Vygotsky was very precise in his use of verbiage and definitions, by his definition, “tools” would include current technological instruments (Wertsch, 1985.)

Metaphors

Metaphors are figures of speech which attribute a similar quality or name to something which is not literally applicable to it (Webster, 1989). By reasoning through metaphors, anchoring of information can occur that facilitates understanding of new ideas (Gallini, Seaman, & Terry, 1995). Metaphors are verbal, so the stories told as metaphors, along with speech patterns and method of story delivery, all play a part in the successful understanding of the metaphor. Metaphors conjure up images and emotions, i.e., bittersweet thoughts of love from the metaphor of the lemon tree that, while beautiful, bears sour fruit. Making sense of metaphors can vary, even within the same social group, depending upon the culture of both the narrator and the listeners (Gee, 1990). Vico pointed to the metaphor as...
the crucial factor in the development of language. Even B.F. Skinner felt that metaphors had a strong impact on society and included them in his overall theory of verbal behavior (Verene, 1993; Danesi, 1993). Vygotsky used a metaphor to illustrate his philosophy of knowledge: the metaphor of two vines: the vines of cultural, environmental knowledge; and the vines of disciplined, authoritative knowledge. The child's spontaneous concepts, one vine, grows upward as language and experience develop; instruction and scientific concepts cause the second vine to grow downward, with abstraction moving to a more concrete level (Fernlund, 1995).

"Metaphoric Language Programming (MLP)" was a term initiated in the early 1950's when Karl Buhler began collecting data on how subjects paraphrased proverbs (Buhler, 1990). The results of these early studies encouraged a plethora of additional studies supporting hypotheses that metaphors were not alternatives to literal language, they were already embedded in iconic thought. MLP research explored "frozen metaphors," metaphors that had been absorbed into daily language; bodily reaction responses to metaphors; and the processing of image schemata. Studies of the era also looked at the impact of metaphors and the implications of how humans respond to metaphors. These types of studies began to pose that metaphors involved iconic thinking, filled conceptual gaps; and could become absorbed into society, taking on a literal quality as a part of that culture. The metaphor has become acknowledged as a tool that utilized creative language to provide a universal conceptualization of basic human tendencies (Danesi, 1993; Verene, 1993). A metaphor can shift prevailing public attitude with its persuasiveness (Turbayne, 1962).

**Semiotics**

Semiotics is the study of patterned human communication behavior, including auditory/vocabulary, facial expressions, body talk, touch (proxemics), signs, and symbols (Webster, 1989). As socio-cultural tools, the signs and symbols of semiotics take on enriched meaning, affecting the functions of human consciousness as well as their environment. Ultimately, everyday language and discourse come under the scrutiny of this discipline since it becomes a metalinguistic descriptor of ordinary communication (Dant, 1991). Ordinary language identifies and uses written material and verbiage to communicate and express meaning. It also uses these "tools" to construct meaning and, in some psychological schools of thought, i.e., the structuralist school of thought, analyzes these tools in order to study the social context of language.

Levi-Strauss took this analysis one step further, incorporating more intimate terminology. He stated that "terms are elements of meaning...however they acquire meaning only if they are integrated into systems" (Levi-Strauss, 1970). He posited that if forms are recognized as the same for both ancient and modern minds, as the study of the symbolic functions indicates, the unconscious structure underlying customs and institutions need to be studied to "obtain a principle of valid interpretation" generically applicable across cultures (Dant, 1991). There are proponents of semiotics who pursue the meaning of culture on a deeper, metalinguistic level. On the opposing side, there are also semioticians who ignore "insignificant" semiotics of every day life that are laden with meaning and social and political significance (Dant, 1991). These "insignificant" phonema often contain inspired rich meanings that fill in the gaps of information and help define cultural, and, in particular, socio-cultural, trends.

**Signs and Symbols**

A "Sign" is defined as "a mark or gesture which conveys an idea or meaning; something having symbolic character; a mark or gesture adopted as a method of recognition" (Webster, 1989). Vygotsky defined the sign as "the basic unit of communication" (Turner, 1993, p.121). A sign is divided into two components: the signifier (the narrator) and the signified (the receiver). Much of the conveyance of the signifier will be affected by whether the sign already has a symbolic connotation, for example a sign of a dove or a peace symbol will generally receive a positive, or at least neutral, response. Conversely, a swastika or skull will generally receive a negative response since there are already existing negative connotations for those signs (Turner, 1993).

Vygotsky termed "signs" one of the "psychological tools" used in mediating with consciousness. He elaborated examples of signs as language, counting systems, algebraic symbols, writing, diagrams, maps, conventional signs, etc. He stressed the importance of signs, noting that "the analysis of sign meaning is 'the only adequate method for analyzing human consciousness'" (Wertsch, 1985).

Vygotsky identified two primary sign symbolisms: the first kind denoting actions or objects, i.e., pencil dots on a paper used to denote running; the second kind denoting written signs, i.e., an "F" for failure, or a "green light" to symbolize permission to proceed. "Understanding of written language is first effected through spoken language, but...(later) disappears as the intermediate link. Written language becomes direct symbolism perceived the same way as spoken language" (Turner, 1993). Symbols are important, Vygotsky held, because of their use as "instrumentalist tools for the creation of meaning" (Wertsch, 1985, p.232). This opinion is contrary to many contemporary views of language, which hold that language is the tool from which meaning is derived and constructed (Wertsch, 1985; Davyev & Radzikovskii, 1985). Vygotsky also held that meaning was not a result of language; instead, he felt the revolutionary activity of meaning-making was the precondition for language-making (Newman & Holzman, 1993). Symbols can also
disrupt meaning. Ironically creativity, particularly of children, can precipitate new symbols and, ultimately revolutionary, cultural changes. "It is the revolutionary activity of children — their meaning-making, their 'disruption' of the societal organization of signs and symbols — and sounds — that makes their adaptation to societal organization possible (Newman & Holzman, 1993)."

A deeper meaning of symbols can capture the essential features and structures of modeled activities. Some contemporary psychologists have adopted the retentive and exponential qualities of symbols and integrated those properties into behavioral activity. This activity has been called "symbolic transformation" because it uses the resilient aspects of symbols to encode desired modeled behaviors and affect transformative behavior. Moreover, these modeled activities can be transformed into images and verbal symbols to serve as "guides for subsequent action" (Bandera, 1994).

Technology and Culture

Much of the current research on technology has been influenced by the writings and research of Marshall McLuhan (McLuhan, 1976) who felt that, ultimately, the medium is the messenger of information for society. Ultimately, the medium itself becomes the message...of the shift it has processed through society and the evolution of that society into a new culture. "This insight contains an element of truth easily grasped by anyone: most simply, just that the radio is different from the book, and one senses the difference in the experience of either" (Neill, 1993). In a mere hundred years, radio and electronic media changed the world and all of the cultures of that world into a new culture. McLuhan also held that communication was a form of social action best studied as a process of creating and managing social reality, rather than just a technique for describing it. McLuhan believed cognition was patterned after language, and language was a form of action, therefore that action, in communication of language, influenced cognition. Traditional communication had focused on the transmission of objective, external, information from "experts", scholars, educators, journalists, to the "non-experts"; in doing so, focused on source-using, not constructing, behavior. Technology altered culture by changing the way things were done and the way information was communicated. McLuhan noted: "the use made of it (radio) and of speakers, like Hitler, had been noted...the extraordinary success of Hitler in Germany, (was) won by a faculty of speech" (Neill, 1993, p.86). Hitler's speeches affected his own society enough to spread a war of hate that ultimately impacted the entire world. McLuhan supported the psychological view that the dominant medium of communication fundamentally effected changes in the human psyche, and in social and political acts. He noted that Newton's Optics established a correspondence between inner and outer worlds, between the forms and textures of the world and the faculties of perception and intellection, which has affected the practice of every poet and painter since his time (Neill, 1993).

McLuhan also believed, however, technology was changing more quickly than the mind, which could only process "x" bytes of information. In time the technology would far outpace the mind, which would short circuit the mind with the overload. He suggested pacing the technology as a way to side-step this overload, or face the consequences of a "future shock" (McLuhan, 1976; Toffler, 1970).

Metaphors in Media and Technology

"Life is like a box of chocolates, you never know what you're gonna get...(Forrest Gump, Zemekis, 1995)." Metaphors become more graphic when combined with several sense "tracks." In the "Forrest Gump" example, the metaphor for chocolates, combined with the sound "score" (a term describing the auditory tracking technique in film as well as the traditional written rendition of written musical notes), and a visual picture of "Forrest" holding the box of chocolates, all provide a multi-sensory metaphor. "The series of events in a film (or television show) all enact the same metaphor (Whittock, 1990)." Recurrent metaphorical patterning is multi-dimensional, being repeated not only in the script theme, but in the symbolic references, the elements of lighting, like that of film noir, which reflects a cold fearful world of shadows, and repetitive haunting strains of the music score (1990, p. 35).

Today's journalist uses words, signs, and symbols to convey sounds, images, and contents. "The journalist, not the candidate or other 'newsmaker,' is the primary communicator (Del Rio & Alvarez, 1995)." The exigencies of field reporting in conflicts like the Vietnam War, and later the Middle East Conflict necessitated short reports of events, the style of which continued afterwards as the "preferred mode" of news, along with other types of reporting and entertaining. The media "soundbyte" has particular relevance because it is designed to elicit an emotional response in twenty seconds (Brown, 1992, p.522). Each segment is scripted, footage made, editing done, and the final edited message culled to be conveyed in twenty seconds. Because this type of short programming is less expensive to produce and allows interruptions for advertising, it has grown to become the preferred delivery style in all media, including "The Internet" (Wertsch, 1995).

Computer metaphors often use some of the same metaphors as movies and television. "The mind is a computer" is a popular foundational metaphor in the computer language. The general description, "writing is software" would be another example of a metaphor.
Patterning metaphors, similar to media, exist as well in software, with the names of the software indicating their contents, and their contents, in turn, reflecting symbolic references, “Scripts” (programs), and graphics that repeat the general theme of the software design. The titles basically describe what the programs do, and each program reflects its metaphor. Even games are now played in “virtual reality.”

**Socio-cultural Influences of Soundbytes and Software: A Discussion**

Vygotsky foresaw a need to approach psychology to accommodate the dynamics of a rapidly changing culture. He believed that “...a cultural content emerges in which the development of cultural systems results in decisions (that) become a kind of symbolic action...we can legitimately consider these new psychological designs based in the cultural operators to be ‘cultural theories of mind’” (Del Rio & Alvarez, 1995, p. 232).

Space and time no longer exist in the same linear way as in the past. Globally, people watch CNN (Cable New Network), e-mail each other while listening to music on their digital audio systems, they look up information on their electronic encyclopedias, get stock market quotes on the World Wide Web, and fall asleep to videotaped movies. To McLuhan, modernity is repositioning time from linear chronology, due, largely, to the influence of electronic media. Time, as a linear descriptor of events, is being replaced by a “home page” of simultaneously presented information which can come from the past, the present, or predict the future. With the Internet, and ever newer technology, “the unceasing relocation of information in time and space (has changed)...the co-ordinates of time and space have vanished” (Stevenson, 1995). This “simultaneous” relocation of information into a “communal mosaic” (p. 122) is generating a more internationally based public sphere that exchanges information across the boundaries of hierarchies, of nations, and will, ultimately, create a new global culture.

If socio-cultural influences exist in a dynamic relationship between integration and historicism, as research cited in this study suggests, then “soundbytes and software” may become a future legacy of contemporary culture. It is my opinion that Vygotsky was correct, that consciousness must be observed and measured through its functions of activities in interaction with culture. The “functions and activities” (Vygotsky, 1978) of our culture must include more studies on the psychological effects of electronic media, including software, not just in measurement of how much data or material is presented, or how fast it is processed; rather, the studies should be conducted across the multiple domains of science, academia, commerce, and everyday life. Without finding a way to “surf” through the oceans of information bombarding mankind, it is difficult to get a “big picture” of long-term socio-cultural effects. In addition, “soundbytes” and software could be evaluated through collaborative research across academic disciplines. This would enable psychologists, philosophers, sociologists, as well as instructional designers, to get a perspective of how consciousness will adapt using technological “mediation tools.” Ultimately, cross-academic and cross-cultural studies would help provide reflective data on the impact of technological innovation and electronic media upon both culture and society.

THEMATIC APPROACHES TO DEVELOPING TECHNOLOGICAL MANAGEMENT SKILLS OF EDUCATIONAL ADMINISTRATORS

Rayton Rex Sianjina
Northeast Louisiana University

Computers and computer applications have become a necessary component of almost every occupation—business, government, entertainment, sports, medicine, education, telecommunication, etc. As a result, students need to be exposed to computers and computer applications throughout elementary, junior high, high school, college and/or university to become better prepared for real-world experiences.

During the past ten to fifteen years, computer technology has been gradually integrated into the regular classrooms. Some teachers have eagerly implemented this technology into their teaching techniques and curriculum. However, Clark (1992) found that more than 70% of educational administrators surveyed in the state of California felt unprepared in computer technology. Handler (1993), on the other hand, found that approximately 90% of “educational administrator programs offer some opportunity for computer training” (p. 147) for their preservice school administrators. According to McKeown (1992), an individual who is computer literate has “an understanding of what a computer can and cannot do and ability to make the computer do what is desired” (p. 14). Although many university programs are offering computer training, a large number of school administrators are of the belief that they need more knowledge. If computers are indeed an important technological tool for school administrators, clearly more must be done to prepare them to be confident in their use.

This article addresses three concerns: (1) administrative purposes for which microcomputers can be used by school administrators; (2) microcomputer training that is available to school administrators and can be offered in educational administration programs; and (3) educational administration institutions’ future role for providing adequate and meaningful computer courses for present and future administrators.

While it is well established that much emphasis has been given to the use of computers in the classroom in the form of Computer Assisted Instruction (CAI) and Computer Managed Instruction (CMI), more emphasis should be given to providing meaningful computing skills to school administrators. Educational administrators face many challenges in U. S. schools. With increasing demands placed upon educational administrators, it is essential to determine both the quality and effectiveness of programs being offered to individuals in pursuit of becoming successful educational administrators. It is, therefore, imperative that educational administration programs, which now provide limited generic computer instruction courses as electives, should continue to evaluate and enhance their computer training programs for prospective administrators.

Administrative Use of Educational Technology

Although many school districts have been influenced by the introduction and use of microcomputers with the classroom teachers, school administrators have not yet fully recognized their potential utilization for administrative tasks. Many school administrators are either unaware or are skeptical of the possible benefits offered by microcomputers, while others are unwilling to capitalize on this technology. Additionally, many educational administration programs seem to have neglected the provision of courses that are solely designed for school administrators.

Olson (1985) contends that two schools of thought exist with respect to the use of computer technology, both of which have implications for training programs. According to Alson (1985), “one school of thought views that the computer is a tool; the other that the computer is a means of creating or innovating” (p. 11). Shalvelson and Salomon (1985) further contend that computers should be considered from both perspectives.

If used as a tool, computer training should be application-based (Lockheed & Mandinach, 1986). The time-consuming, routine and realistic tasks which consume the administrator’s day, as well as the more sophisticated tasks like resource allocation, could be handled by appropriate software. Training would require a certain level of knowledge, such as learning to use the elements of basic
computer software. These might include acquiring a certain level of competency or computer literacy and learning certain skills such as how to develop and use templates, as well as procedural skills.

Such application-based computer training should foster high cognitive skills, by encouraging the generalizing of these skills and fostering a positive attitude toward change and self-improvement. Moreover, Olson (1985) attests that by learning to communicate with the computer, one becomes more literate, merely through the process of making one's meanings explicit. The computer can be used not only as a tool, but also as a tool for the utilization of various types of simulations.

**Need for Formal Training**

The second school of thought considers computer technology as an opportunity for educational administrators to “blend school effectiveness, leadership, and management development into a program of revitalization” (Mojokowski, 1985, p. 45). Rather than just automating, the leaders should be asking “what if...” questions, using the computer for simulations and solving problems.

This school of thought recognizes the entrepreneurial role (Mintzberg, 1975) of the manager, that is, the educational administrator. It might be difficult, however, to determine what type of professional development activities would be appropriate to encourage administrators to become more creative, innovative, and risk-takers. According to Alson (1985), “they should become reasonably competent with computer software in order to manipulate the software to suit their own programmatic needs” (p. 12). Alson further contends that administrators must acquire a positive attitude toward change in general and a confidence that they and their staff can create a future of their own choosing. Regardless of the process, of importance is that educational managers use computers to accomplish the range of tasks for which they are responsible, not only routine and maintenance tasks, but also solving problems and completing the unique tasks that come their way.

Regarding the first concern, the administrative uses of microcomputers are classified in various ways. One general plan uses five categories of administrative applications:

1. **School Facilities** - Software used for this purpose performs the function of an electronic filing system adopted to the task of cataloging equipment and other fixed assets, inventory, textbooks, and other items. Each software package contains predefined items of data to be kept on each item in the electronic file. Filing, sorting, searching for, and reporting of inventory are tasks that data management components of integrated systems perform well.

2. **School Finance** - These tasks, which often involve rows, columns, and tables of numbers, that can be performed efficiently with an electronic spreadsheet. Applying the design of the task to the spreadsheet will require learning and may be time consuming, but the ultimate time savings and improved efficiency will be worth it.

3. **Student Affairs** - A student record system will store and retrieve basic information concerning each student. Commonly found items of data include student’s name, gender, ethnic group, student identification number, age and birth date, parent’s or guardian’s names and addresses. A well-designed student record system will permit one to access students by using any of a number of criteria or variables. The payoff for storing student data on a microcomputer is the speed, and convenience, and accuracy of retrieving information from the system.

4. **School Personnel** - This software primarily performs the tasks of filing, sorting, searching, and reporting. Such data as educational training, certification areas, certification expiration dates, inservice education activities, as well as personal data, are easily retrievable.

5. **General Applications** - A word processing software is an example of a general purpose program. Word processing software makes it possible for a small administrative center, such as a school office, to produce professional correspondence documents. In producing documents using word processing software, school administrators can utilize graphic software to add such features as bars, lines and pie charts. Other types of graphics software will help to improve reports, brochures, newsletters, and other applications through a variety of performed designs.

Despite all the advantages of using computer technology to aid educational administrators as listed above, the literature notes that few principals are using the technology (Corbett, 1982; Sturdivant, 1986; Sununu, 1986). Corbett (1982) provides some specific reasons why educational administrators, as a group, do not seem to be making extensive use of this technology. Those reasons given are: a) computer hardware and software are too expensive, especially for poor school districts; b) lack of personnel with necessary expertise; and c) lack of proper university training. Sununu (1986) noted that few school districts developed policies on how they planned to use the technology, yet this aspect is fundamental to the change process.

Regarding the second concern of this paper, microcomputer technology is ideal for students entering the principalship or other entry-level positions for administration. A microcomputer technology class is necessary so that beginning principals can become computer literate and
able to personally use microcomputers for administrative tasks. If these students do not possess such level of knowledge and skill, they should be provided with the opportunity to acquire the expertise through educational administration training institutions. These institutions would then build on this competency by teaching administrative uses of computer technology and introducing students to specialized management software.

Educational administration training institutions must incorporate instructional courses specifically designed for school administrative use. Recently prepared administrators tend to use microcomputers to a greater degree than incumbents who received their preparation in administration prior to the advent of microcomputers.

**Future Role of Educational Administration Institutions**

Finally, it is the responsibility of educational administration institutions to provide more intense courses specifically designed and geared toward meeting administrative microcomputer uses and to provide meaningful inservice computer workshops that are specifically designed for school administrators. As the number of professors in the training institutions who use microcomputers increases, a greater emphasis on microcomputer use in educational administration programs should be emphasized. At present, it seems microcomputer instruction in most educational administration institutions is offered as an elective for most students and most of these courses do not provide sufficient depth to give students the competency to use the microcomputers for administrative purposes.

According to current available literature and personal observations and experiences, there are relatively few school principals who are personally using microcomputers for administrative purposes. The number of software applications available for administrative tasks is equal to, if not greater than, that of classroom computing or instructional management. If the claims of computer technology as a tool for administrators are valid, then much work remains to be done to better prepare school principals and others to be more comfortable and competent with the use of the computers.

In the immediate future, educational administration programs should continue to evaluate and enhance their instruction pertaining to the administrative use of microcomputers. What part of the instruction that should be provided in computer courses and what part should be in conjunction with existing administration courses should be determined by educational administration training institutions. Of course, educational administration faculties must also continue to grow in their own understanding of microcomputers so that they are able to offer meaningful instruction. Students in principalship programs cannot ignore the need to take computer technology courses that are specifically designed to meet their administrative needs. In addition, educational training institutions should develop and improve courses that are specifically geared toward meeting the needs of the students in school administration programs to keep up with the ever growing technology. College professors in these training institutions should also personally continue to grow in their computer technological knowledge so that they can model computer use and mentor their students in becoming technologically able to administer.

HYPERTEXT, HYPERMEDIA, AND NETS AS TOOLS FOR LEARNING: THE CASE OF ARGENTINA

Patricia A. Pari
University of Rosario

First we will try to give a perspective of Argentina facing the challenge of technologies in multiple environments: economic globalization, education and Mercosur. In our opinion, this political moment implies certain decision taking that are strategical for the country's future. Although we will not present a deep view of globalization (our topic is technology and education) we can't deny the effects of this process into local economy, affecting the rates of unemployment and the access and continuity of children in the school system.

Latin America in general is going through the same problems because of the implementation of the same policies, so is urgent to construct new categories and paradigms to research and transform this reality. There are regional similarities beyond this, such as the need of articulating efforts in economy, marketing, communication and education represented by MERCOSUR: a political frame that resembles the concept of NET, and the education nets themselves such as TelAr (Argentine School Network) and RIU (Argentine Universities Net). As we can see in Columbia's Home page, the "Institute for Learning Technologies is guided by an understanding that, by and large, the defining characteristics of the modern school precipitate from the implementation constraints of the information technology that enabled and supports them. As we enter a time when networked digital technologies are fast becoming the prevailing technologies for communication and for information retrieval, processing and creation, the Institute seeks to identify new ways to realize various pedagogical principles - ways that are enabled by this shift in dominant technologies. The educational principles and practices the Institute advocates have historically found expression in diverse philosophical contexts, and they have implications for the whole of the educational enterprise - for schools' size, schools' physical structures, schools' temporal structures, teachers' roles, curriculum, methods of curriculum design and development, teacher training, and so on. My interest in Canada is focused in this country's experiences in New Technologies, specially in Montreal in McGill's Faculty of Education, Department of Curriculum and Instruction, AMEQ, and Columbia University who have long ago become aware of the need of dealing with new technologies. Since 1990 it is noticeable the increasing interest in this matter in all areas involved in Canadian education.

Canada is developing projects such as SchoolNet, TeleLearning Network of Centers of Excellence and the National Network for Learning which are useful for us to research due to the need of apply successful innovations in Argentine's education. This points constitutes the basis of my project.

Argentine School System

Argentine School System can be defined with a single word: CRISIS. As oriental philosophy settles, a crisis can make a person or an institution remove what has to be given away, and search what has to be improve. The taking of decisions in institutions and in the government seem to be decisive factors in this process. From 1930 Argentina's educational system suffered the combination and application of different paradigms due to the political changes which drifted between democracy and authoritarianism. From positivism, rationalism, conservatism, theories of development, to the few but important experiences of the "New School" based in democratic topics and a special perspective of child ' construction of knowledge, Argentina's Education became a mosaic in which it is combined parts of all paradigms. The paradox is based in that this heterogeneous thoughts produced an homogeneous way to teach inside classroom, where the institution appears mostly as a bureaucratic place, designed vertically. Curricular designs are not assented to by the actors of the Education Scene, so relationships between professor and student trend to be traditional in the sense of centre (the knowledge) and preripheria (the non knowledge). An unidirectional situation which the context is left out. Another problem is the lack of organized postgraduate studies and formation for teachers of all levels, plus the low salaries which make a break to proper formation and constitute a cause for curricular splitting. The other cause happens to be unequal access to hardware and software.
The world of communication have changed into networked digital technologies that fastly become prevailing, this fact is well known in Argentine’s educative system, which focus this topic, mainly, in the incorporation of computers workshop. During our observation in 1994 and 1995 within a Project of Investigation and Development in Technology and Education we could see that computers, beyond its presence at school, represent an objective approach to the future, but are sub-used in this potential because of the mixed policies we explained before. Almost every secondary school in Argentina has “the machines” but at the same time are immersed in an asynchrony. Either the access to merely the techniques or the lack of suitable epistemological views make a point of inflection in investigation. In our opinion it is urgent to research: a) the construction of knowledge mediated by hypertext and nets. b) the reconfiguration of subjectivity and scholar roles c) the construction of suitable school tools for students into a new labor market. d) the experiences in other countries such as USA and Canada.

Nevertheless, there are in Argentina valuable pedagogical experiences with technologies, but without a common frame that make these experiences useful for other people. Neither the uses of hypertext, hypermedia nor Internet is used, up to now, as a profitable resource in the construction of knowledge, but each principal, director or teacher is concerned about them. We could indentify worries in acquiring proper formation in the uses of this technologies. The New Federal Law of Education No 24195 gives technologies a central place in curriculas, both as a subject and as a transversal permeation into the contents of educative structure. In spite of the fact of the progressive application of the law, we could detect some gaps between teachers and students facing the reality of having to deal with new technologies with out a solid theoretical and practical background. The Law encourages the rational, organized, planned and creative use of the material resources in order to prepare students for the needs of a changing labor market. So it is defined that teachers formation must be a priority. The ideas of competence, optimum quality, efficiency are strongly remarked. Perhaps this point could be another paradox, because the Law declares this goals as priority but cant offer guaranties in the assignation of budget to support these changes.

The concept of hypertext is defined by Theodore Nelson in the 60‘ as a non sequential text, a text that devises, and let the reader make his own choice in the route of his reading. Hypertext can be enjoyed in an interactive screen. It is a serial of text units linked by connections that allow the reader to make different roads. It lies on the concept of hypermedia, or multimedia in which information, animation, sound, graphics, text, movies, video and audio can be combined in an interactive way, by an active user. The non sequential structure of hypertext is based in the possibilities of connecting “lexias” through electronic connections (links). Moulthrop says that any way of narration requires from us the possibility of going back to the net of the text: it tries to capture us in its inexorable energy. In the case of electronic writing this desire of the narrative, can be satisfied in ways unpracticables in the traditional matter. The cognoscitive model proposed by hypertext links the concept of social meaning construction, in opposition to that concept that conceive knowledge like atoms each person has to bind in an imaginary necklace. Hypertext performs communicative function that encourages the creation of other texts for the human comprehension. We propose to search and construct another way of production and appropriation of knowledge. David Bolter observes that hypertext incarnate the poststructuralist idea of open text. Something that is unnatural in written text becomes natural in the electronic media, and in a short time, it won’t be necessary to explain it, because it will be shown.

1.1. The Potential of Communication Technologies for Inquiry and Investigation at School.

Inquiry and investigation are the most important aspect of learning. However, its difficult for teachers and student to carry along these activities. Hypermedia technology (hypertext and multimedia), as regards both hardware and software, is arising a great interest in the use of applications for education. Researchers, teachers and students may place themselves as mere users navigating through an already developed application, or as generators of their own applications. We think that we should adopt hypermedia methodologies and teach our students, on the one hand, how to navigate, across the ocean of information, and, on the other hand, how to build up expert outlines. Bearing this in mind, our proposal shall be a knowledge-based integrated representation system for creation and re-creation of expert knowledge scripts for multimedia applications.

1.2 Changes in Interaction Models, Subjectivity and Communication: Reconfiguring Teachers’ and Students’ Roles.

Paul Virilio outlined the speed of communication as the most important characteristic of our relationship within nowadays technological context (3). Audiovisual speed is in Virilio’s thought the one who makes a reflex revolution, as it lies on images. A change in memory is being held by images and speed: today we are increasingly accustomed to ocular memory rather than to the old mental representations. Representation capability, though, is an important skill students must not avoid, as it is one of the main
characteristics of human being, but we must say there is a changing of shape in the nature if human representation as we pass from a text to an hipermediated culture. Textbooks have been central in traditional school, with theirs units, chapters. They were unable to allow an unexpected path, the implicit assumption were that the role of teachers were to teach, and the role of students were to study. But nowadays digital culture, has reached our students earlier than us, so, they instinctively know very much about images, due to their exposure to them, since they were babies. Later, the personal computer makes another gap between adolescents and adults. As Virilio adds, children are accustomed to an audiovisual speed we can’t stand for too long. As regards roles, Hypermedia Technologies seem to agree with Cloutier’s communication model “EMIREC”. In this frame, the teacher is viewed not as the ruler of the game, but as a partner who eases the work by giving the right resources. Teachers are at the same time, learners. Vertical institution’s designs becomes horizontal, so students stop hearing in a passive way and become an strategist. Teacher and students can in this frame, become a team. The roles of teachers in these essential schools are reconfigured just as much as the curricular structures are. Whereas, in the comprehensive school, staff members have highly expertise specific duties, in the essential school each and all have a collaborative responsibility for the whole. What’s more, as the raw materials of the curriculum increasingly become electronic ones accessed via digital networks, the range of skills required of teachers is broadening rapidly. All this change points to a need to rethinking the processes of professional development for educators. The work that constitutes their profession is changing and so must their training. The Institute is currently conducting work in this area as well, investigating ways to align the findings and the prescriptions of various standards organizations with new needs that flow from what is enabled by the implementation of networked digital technologies in the context of the essential school.

2. Learning and Knowledge: Epistemological Outlooks.

The main theories of learning are basically represented by behaviorism, constructivism and cognitivism. It’s necessary to make a deep analysis about the concepts of individual, society and learning in each one, trying to lace them with epistemological views such as open and close systems, auto-organized systems and theories about the end of total paradigms.

3. The Virtual School Community: The Cases of Schoolnet, Telelearning Network of Centres of Excellence, the National Network for Learning and Columbia’s Projects 3.1. The Virtual School

Community in Argentina: TELAR AND RIU

These will be the main topics focused in the research. Electronics technology these days allows us to build virtually any kind of communication device that one might wish. One special characteristic of the 90s is the increased number and variety of new communication technologies that are becoming available. Further, and more important, is the nature of how these new media function in society and the theories which tries to build categories to explain the relationships in the “virtual community”. We find that there are many paradigms to explain the changes in human relationships in the era of telematics. Elizabeth Lane Lawley assumed that most studies of computer-mediated communication have focused on conceptions of the technology as a tool, rather than as a constructed environment. This is not surprising, given that the bulk of research about computing in general has taken this tool-oriented approach. Pierre Bourdieu’s work in the sociology of culture has been widely quoted in recent years in the fields of anthropology, sociology, philosophy, and communication. Computer-mediated communication as the process of sending messages—primarily, but not limited to text messages—through the direct use by participants of computers and communication networks. In our opinion, these concepts can be useful in the field of Technologies and Education. In his recent book “The Virtual Community” (1993), Howard Rheingold lays out the aspects of computer-mediated communication over bulletin boards and other computer conferencing networks (including, but not limited to, the Internet) that have led him to consider that medium as constituting communities, and beyond that, culture. Rheingold says “Most people who get their news from conventional media have been unaware of the wildly varied assortment of new cultures that have evolved in the world’s computer networks over the past ten years.” Media technologies provide us - as McLuhan said- with “a window to the world,” and as a result we know more about distant events than we could ever experience directly. We can be part of the virtual community and make it profitable for education. Argentina has started few but very important projects of networking we’d like to improve. TELAR net is a Local Area Network (LAN) settled in Puerto Madryn. In 1993 the national Ministry of Culture and Education and the I EARN WORLD NETWORK Argentina (International Net of Resources and Communication) gave TELAR the opportunity of contact other nets in more than 25 countries. Argentina has not very log became aware of the possibility of promoting new educational policies which go beyond the traditional uses of new technologies. RIU (University Interconnection Net) tends to establish the link of every argentine university. Its funded by the Secretaria de Politica Universitaria and the Banco Internacional de Reconstrucción y Fomento. The University of Rosario has recently started to build a local net
which will link all academics units. The projects TEL AR and RIU mark several goals achievements to begin a generation of students who can deal with the converging computing and telecommunications

AIMS: - To get in touch with USA’s and Canadian projects such as SchoolNet, TeleLearning Network of Centers of Excellence, the National Network for Learning and Columbia’s University Programmers: - To exchange Argentinian experiences of hypertext and hypermedia technologies as a pedagogical tool, such as TelAr (Argentine School Network) and RIU (Argentine Universities Net). - To attend to lectures, courses and seminars on that matter, if possible. - To begin collaborative research on the field of hypermedia and net education between any of these institutions

Impact of the Collaborative Search
Work Contribution to Scientific
Knowledge Advance and Significance
to Human Resources Formation

Related to the Course - A cooperative research like I propose will be profitable for university teachers coming from several colleges (Social Communication, Psychology, Educational Sciences, Anthropology and others) and researchers interested in collaborative research with USA's and Canadian experiences in this matter. - High School teachers eagerly claims for proper formation to dealing with technology. Workshops can be offered for them. - Primary school teachers could also get advantage from this course, as in Argentina, Computer Workshops have long ago being functioning. - This can moreover encourage interdisciplinary investigations.

Significance to Social and Economic Development

Quantitative and qualitative diagnosis of Argentina and Canadian education centred in communication technologies will be useful for public and non public institutions.

Patricia A. Pari is the titular professor of communication technologies at the University of Rosario, Argentina.
E-mail: ppari@fcpolit.unr.edu.ar
Though teachers of young children have typically been among the first among educators to implement innovation in their classrooms, they have been among the last to embrace computer technology for personal and professional use. The roots of this hesitancy to use technology originate from a number of possible sources. First, the writings of Piaget which have influenced the field of early childhood significantly focused teachers on children’s use of physical objects in classrooms (Ginsberg & Opper, 1988). One of the signs of a good preschool continues to be the existence and hands-on use of many colorful manipulatives in child-directed centers. Secondly, uses of the computer in mainline early childhood journals often caution the reader on how not to use the computer (Elkind, 1986) instead of focusing on opportunities for growth using the computer. Third, many people’s image of the computer as a sophisticated machine which needs sophisticated users does not fit primary school children. Finally, it is argued that young children cannot properly care for or use the potential of such an expensive machine.

Since young children are often not expected to use technology, the teachers themselves don’t have much exposure to the machines. As a consequence, this lack of familiarity with technology retards teachers’ use of computers for their professional growth. In some preschool or primary classrooms computers remain unused or children simply run a program without much attention from the teacher. In other schools, computers are only used in computer laboratories where there is typically little integration of topics of study in the classroom with topics of study using the computer.

The authors of the papers in this section have taken on many of the above challenges in their search for using technology for teachers of young children. I have grouped discussion of the papers in this section of the annual into three parts that may help organize a range of issues teacher educators are involved in. The first section focuses on general issues in the use of technology especially those opportunities and problems originating from teachers. The second section centers on the use of technology to learn professionally about early childhood education including the description of the integrated role technology plays in two teacher education programs for young children. Teacher’s use of software in their classrooms points out many needs for teacher development in the third section. Finally, in view of the research that exists in this section on teacher education in early childhood using technology, directions for future research are suggested.

**General Issues of Teacher Use of Technology for Young Children**

Chang, Rossini, and Pan comment on a number of issues concerning teacher education and early childhood including using appropriate software, use of the World Wide Web, and the use of difference between structured and more open-ended software. Also, they help us focus with a summary of advantages computers have in the early childhood classroom. This paper finds e-mail to be a source of information on techniques of using technology.

The second paper in this section deals with a range of issues of teacher education of early childhood and the use of technology that takes more of a teacher perspective. In a survey of teachers at a wonderful new model early childhood lab school in Corpus Cristi, Texas, Rodriguez confirms many of our suspicions about teacher’s needs for software, support, and information regarding integration of use of technology into their goals for children and for their own professional development.

**Uses of Technology to Provide Professional Information to Teachers**

The next group of three papers deals more directly with the subject of teacher use of technology for professional learning. Bohn & Rhodes discuss a study they performed analyzing student use of a computer program and an accompanying laserdisc of child development. They found a variety of differences of teacher education students’ use and lack of use of technology outside of class and discuss...
the motivational differences that may lead to more student use of technology resources. One of the most interesting findings described how integration of the content conveyed by the technology was a vital factor in making sure students use the technology. It seems that importance of the perceived payoff for the extra effort students put in to use of technology can never be overemphasized.

The next two papers take a more programmatic view of the use of technology to educate teachers of young children. In both programs, one at Southern Georgia and the other in Queensland, Australia, the projects attempt to solve enduring dilemmas of teacher education by allowing campus-based students to view early childhood classrooms in the field. There is a sense of immediacy and meaning students feel when they ground theory into real classroom practice they are interacting with in schools.

With a new grant from the Georgia University System System’s Office of Information and Instructional Technology, Downs & Rakestraw describe a fully integrated distance learning program in which graduate students as classroom teachers welcome campus-based undergraduate students in to their classrooms to view “real life” classroom via two way interactive video. At the Queensland University of Technology, Yelland, Grishaber, Stokes & Masters describe the learning of preservice and inservice students connected with four separate classes at Queensland University of Technology in Australia. Using audiographics, class members to have remote access to classroom situations. Other early childhood university classes address important issues of familiarity and becoming critical about software.

Software Issues in Teacher Education

A number of papers discuss software and it’s relationship to the teaching and learning of young children. Since much of the software is written for the home market, the purposes of the software and the pressures of marketing that surround them make them questionable resources for teachers. DeVoogd & Kritt discuss the importance of teacher guidance and examination of the interaction between children and software. This paper looks at specific examples of how software does not achieve the purpose they were designed to teach.

Snider & Gerstner examine groups of kindergarten students using structured software, open-ended software and a control group; they found that children using open-ended software scored higher on tests of verbal creativity measures. What’s more interesting is how students who learned cooperative techniques using structured software also achieved high creativity scores. This would seem to indicate the importance of establishing social routines and procedures in the classroom promoting cooperation instead of promoting classroom routines and practices which keep students from sharing with each other.

Bornas, Servera, Llabrés and Mata have built on their past work (Bornas, Servera & Llabrés, 1996) developing models for handwriting to develop software that provides children with the ability to learn from models of mathematical processes. They argue that much of the difficulty and failure in schools results from poor modeling and lack of student access to interactive modeling. Their software, VISPRO.Calcul, provides dynamic modeling to students and frequent modeling for students. Their program improves on the teacher’s limited ability to be available for students and on the static models provided by printed materials.

When teachers have trouble finding good software or it is too expensive, they can construct their own. Teachers creating learning centers, printed media, and pictorial media is a tradition in early childhood. Gore and Broussard begin a discussion of research on teacher’s creation of new media using the computer and its effects on students. They found positive effects for a teacher-made program on the topic of patterning were found only in the top half of the class, and not for the bottom half. Was the finding partly a result of the developmental level of children and their inability to understand the level of abstraction represented by the computer? This is certainly a fascinating topic that returns us to the heart of questions about the developmental appropriateness of computers for young children.

Future Areas of Study

When I get home I usually ask my third grade daughter what she read in school that day. Sadly, I often find that she doesn’t read at all but watches videos. Perhaps the school my daughter attends is different from most, but I would venture to guess that videos are playing an increasingly large role in the classroom education of young children and yet none of the papers in this group focused on the use of television as a topic for educating young children. Although there is a small body of research in the area of the use of television and videos for the education young children in schools, there is less in the area of teacher education and television watching. How do we help teachers use video to promote our goals in education? Are there ways teachers can build on the knowledge base of the 25-35 hours of television watching preschoolers do weekly (Clements & Nastasi, 1992)? How can teachers learn to work with parents to make that television watching more effective? What are the understandings of beginning early childhood teachers who create and view video as a method to improve practice? These are areas of study that may prove to be appropriate topics for study in future years.

There is also much to be done in other areas of technology and teacher education. Since many of the papers above describe programs using technology for the education of teachers of young children just newly started, we shall look forward to hearing the progress of these
programs. The interesting studies introduced in this annual at Queensland University of Australia, Southern Georgia will certainly have follow-up studies that focus on different aspects of educating teachers of young children using distance learning and forms of technology. Teacher’s understanding, use, and development of software and its appropriateness for young children is an area many authors have touched on, but also an area which needs a great deal more examination.

Although there is still a great deal of work yet to be done, progress has been made outlining areas of study for the teacher education of young children. Progress has also been made in terms of designing teacher education programs that can be studied and replicated in different contexts. Perhaps there is also a need to explore what makes early childhood teachers special and different from other classroom teachers and teaching contexts.

As a section in the SITE annual, we are only a few years old. There are so many possibilities, it seems as though we are just beginning. And like so many of the children and teachers we work with, there is a sense of optimism, joy in the future, and promise. May we all enjoy our exciting beginnings!

Glenn DeVoogd focuses research on teacher education of innovations in early childhood education with a particular interest in the roles technology and cultural diversity play in literacy instruction. Glenn is an Assistant Professor at the University of Houston in the Department of Curriculum and Instruction, CUM 5872, Houston, TX 77204-5872 Voice: (713) 480-5675, fax: (713) 743-4990. E-mail: gdevoogd@uh.edu
Chin (1984) predicted that all the children in preschools would have access to computers by 1989. However, the growth rate of computers in early childhood classrooms seemed very slow by 1991 when approximately 25 percent of early childhood programs had children using computers (Haugland & Wright, in press). Though the high cost of software and hardware contributed lack of use, lack of staff development, and administrative support have also hindered the implementation of technology in classrooms as well. The use of the computer in an early childhood classroom remains limited and controversial. Although there is a growing trend in early childhood classroom to invest in technology as a means to facilitate teaching and learning, many issues remain unclear to early childhood educators and deserve a careful examination.

One of the major concerns about using computers in early childhood education is whether computers can fit in the early childhood practice and facilitate young children’s learning. Some researchers have found that using computers with young children was developmentally appropriate. Other early childhood educators, such as Elkind (1987) claim that computers need to be used as teaching machines—offering drill-and-practice activities—because a child’s cognitive development cannot rely on some open-ended software programs.

Teachers’ readiness in using computers has posed another serious concern. Teachers’ attitudes about computers and about using computers to teach young children vary widely. Some of them feel excited about computers, while others feel intimidated (Hoot, 1994), thinking that they themselves do not know how to use the computer, not to mention how to teach young children how to use the computer to learn. Other related issues include what software is appropriate, how young children can start learning with a computer, and how software should be integrated into the early childhood curriculum. Since there is plenty of educational software on the market, some early childhood educators feel at a loss when considering practical issues of what software to use and how to use it, and how to assess the effectiveness of computer activities in the early childhood classroom. Finally, the crucial issue centers on the developmentally appropriate practice (DAP) of using computers in the early childhood classroom. Although there are many exciting and successful examples of using computers to inspire young children to think and to learn, there are also some teachers using computers simply as a reward for completing teacher-required schoolwork. From our frequent supervisory visits to the schools, we know that some teachers even consider the computer time their “break” time.

The purpose of this paper is to provide some insights to these concerns. The information presented here is based on case studies and other current research, position paper published in journals, classroom observations from our work in preservice teacher education, and on-line (ECENET-L@POSTOFFICE.CSO.UIUC.EDU) listserv discussions with early childhood teachers and educators.

Find Appropriate Software

Children are very likely to learn more or better when working with appropriate computer software. As Wright & Shade (1994) put it, “the effectiveness of computer learning depends critically on the quality of the software” (p.33). Although there are many software titles available on the market and the quality of these titles improved over the years, still, finding appropriate software is a difficult task.

By 1994, 75-80% of software on the market is still drill-oriented (Morgan & Shade, 1994). The other 20-25% encompasses some excellent open-ended, discovery-oriented programs. According to the curriculum guidelines that National Association for Education of Young Children (NAEYC) stipulated in 1991, the use of drill-and-practice software is inappropriate because it limits young children’s thinking. Such programs exert centralized control over
young children’s development and emphasize memorization providing them with few opportunities to interact with people and objects around them (Haugland & Wright, in press). The use of structured software (such as drill-and-practice), therefore, should be minimized.

To help children acquire knowledge effectively, it is the teacher’s responsibility to select appropriate software. One preschool teacher in our area, for example, selected the Kid Pix program, a children’s paint program for her children. After three months’ use of the program, the teacher found that her children’s confidence and competence had been greatly increased. A program of this type is open-ended, similar to the blocks that teach children shapes, sizes, angles and balance through active exploration (Haugland & Wright, in press).

As with any curriculum resource for young children, teachers should have a proper developmental approach to choosing software for young children (Haugland & Wright, in press). Teachers need to know how to separate the software wheat from software chaff as stated by Dublin, Pressman, Barnett, & Woldman (1994). Dublin et al. found that after taking the cost factor into consideration, one needs to look for “consistency between the software and your own instructional strategies of choice” (p. 61), for software that can provoke students’ thoughtful action, that furnishes feedback for incorrect answers, that provides variables that children can control, and that “can adjust to different students at different levels of ability, intellectual, or computer skills” (p. 61). Other researchers added that appropriate software also can offer opportunities for children to solve problems while interacting with computers and can promote cooperative learning (Dublin, et al, 1994; Haugland & Wright, in press; Wright & Shade, 1994).

Haugland and Shade developed a software scale to identify software that is developmentally appropriate for young children in 1995 (Haugland & Wright, in press). Having common threads that run through the NAEYC guidelines, this Developmental Scale contains many crucial criteria that may contribute to the successful selection of proper software, including age appropriateness, control by the child, clear instructions, expanding complexity, independence, non-violence, process orientation, use of real world model, technical features, transformations, multiple languages, universal focus, mixed gender and role equity, and respect for people of diverse cultures, differing ages and abilities, and diverse family styles.

With more programs for young children’s cognitive growth on the market, sometimes it is not an easy job for a teacher to choose appropriate software, especially when the teacher is overwhelmingly surrounded by pages and pages of commercial advertising.

**Freedom of Exploration vs. The Teacher’s Assistance**

Most people agree that computers can function as powerful tools to help young children learn better. However, there appears to be controversy concerning the teachers’ role when young children use the computer about whether children should be left alone to explore on their own at the computer or the teacher ought to assist them at the computer.

Some people argue that children need to be provided with great freedom and the teacher should leave children alone at the computer. In this way, children are given a sense of control—a sense of autonomy, competence and enjoyment. Hoot (1994) states that the major advantages of having children work at the computer alone include 1) they are in sole control of the interaction; 2) working on their own enables them to interpret immediate feedback; and 3) there is less pressure on the children. Moreover, children perform best when they have a chance to interact with a responsive system that provides feedback and encourages further investigation (Wright & Shade, 1994).

A teacher from Kuwait commented in the Internet Listserv discussion that he found his students aged 3-5 were very good at budgeting their time on the computer without too much help from him. A teacher from the States agreed with that comment by expressing that she allotted great freedom to her children when they explored the computer by themselves, and this worked very well. Both teachers came to the same understanding that if their children were not provided with such freedom, they would feel frightened or anxious for not being able to locate or find correct answers or to press correct keys and commands they were required to master. The freedom to explore the computer allows children to develop a positive attitude toward computers at a young age that may result in being willing to learn more complex uses of the computer at an older age.

Moreover, in some early childhood classrooms, young children were placed to use computers without intensive adult attention. Many teachers are occupied by many routines and events such as attending to individual needs. Only when teachers have taken care of most other routines and events will they come to observe young children at the computers. They then sit with children and ask questions like “Where does this go?” “How did you find that?” “What are you supposed to do here?”

When some children encounter problems or become stuck, their teachers tend to direct them to seek solutions or help from other children. The teachers provide help only when no children can solve the problem. They claim that children can thus develop necessary skills by acting as resource persons for one another, by communicating effectively, and by problem solving via inquiry.
However, leaving children totally free to explore computers may result in negative effects. For example, young children in many classrooms, from our observations, were left unattended, wondering what to do on the computer, or trying something that does not make any sense to them. They become bored and frustrated very soon. This kind of computer experience is fruitless and can do more harm than good to young children. Actually, if used properly, good software can greatly enhance young children's learning. Some timely adult guidance can also help children consolidate their learning experience with computers.

A Head Start teacher suggested in the Internet discussion that teachers should consider the children's familiarity with available software, the level of difficulty which the software provides and the individual's computer knowledge and skills before making the decision if he or she should offer help. This teacher suggests that teachers be with children while they explore at the computer so that teachers can observe children's reaction to a program and offer appropriate feedback.

How Young Can a Child Play at the Computer?

A question was posted to ECENET-L soliciting individual cases of young children using computers. From the cases reported, the youngest age working at the computer is six months old. The baby started with the programs like Babykeys and Ian's Game. Most children start to play with the computer at the age of 3-4 (Dublin, et al., 1994; Haugland & Wright, in press; Hoot, 1994; Wright & Shade, 1994).

Because most younger children do not possess good literacy skills, they cannot communicate effectively with others in writing. Some people believe that it is more appropriate to engage young children in some concrete activities such as playing with blocks, dramatic play, using manipulative, etc., rather than computers. Still, there are other points of views. For example, Buckleitner (1996) states:

Most experts recommend that children wait until at least age 2 1/2 before sitting down at a computer; it's at about this age that kids begin to develop the hand-eye coordination necessary to use a mouse. Parents should plan to spend a lot of laptime with youngsters during this time. By the age of four, children can sit still long enough to benefit from more computer activities on their own. (p. 28)

Apparently, some early childhood educators consider computers an appropriate tool for older children, but not for young children who should spend time playing in playing centers.

Internet and Young Children

The Internet has provided an exciting platform for children to explore. The following are some examples of using the Internet with young children. One parent shared her experience that with her four year-old daughter, they together surfed the World Wide Web driven by the girl's interests and explored a lot about the Disney site and other sites that contain images of her favorite books and movie characters. They learned a great deal about how Disney put together Pocahontas, the person behind the voice, etc. Furthermore, the parent and the child also used e-mail to communicate with their relatives, especially the child's cousins and grandparents who live across the country. The girl got the concept that her mail could be replied to the next day by her relatives. Some teachers, as another example, organize a pen pal system for young children to communicate with each other by sending electronic mail on the Internet.

Advantages of Using Computers in the Early Childhood Classroom

The computer is commonly regarded as a "productive tool" and as a medium to enrich teaching and learning. With other tools (especially varied play experiences), computers may be devoted to more productive pursuits and have a potential to further develop young minds (Hoot, 1994). The advantages of computers in the early childhood classroom are as in the following:

- Computers can provide great opportunities to inspire young children to learn (Dublin, et al., 1984). The computer helps develop children's cognition. For example, children are able to use computers to compose their own stories with the Storybook Weaver and Kid Works. When computers are used appropriately with discovery software and teacher guidance, children can be encouraged to develop their freedom and creative thinking (Clements, 1994).

- Computers can capture young children's interest and stimulate their imagination and creativity. Teachers can provide interesting information by using computer programs that introduce new topics, stimulate discussion and debate, and launch a lesson that can encourage children to continuously do the relevant activities on the computer (Dublin, et al., 1986).

- Computers can enable children to learn from each other, i.e., cooperative learning. Children prefer working with one or two partners rather than working alone (Clements, Nastasi, & Swaminathan, 1993; Rhee & Chavagnar, 1991). Students tend to perform better in settings that foster cooperation than in those that foster competition. They can also learn to share information, to contribute ideas, and to respect each other when using computers. Thus, they are able to develop a high
level of communication and cooperation skill, problem-solving skills in a collaborative manner, and higher order thinking skills (Clements, 1994).

* Computers can satisfy individual students’ needs. Some young students are more mature than others. Computers can help children master concepts at their own pace. Individual students may choose to repeat a certain task several times until they feel comfortable about the intended tasks.
* Computers can be used as effective tools for teachers to communicate with parents. Some teachers collect all the printouts that are done by all their students and date them. The dated students’ works record their progress across a period of time in school.

**Suggestions**

Although the debate about the use of computers in children’s constructive acquisition of knowledge is still underway, many early childhood educators agree that computers can help enrich children’s learning if the approaches to using computers are appropriate (Alloway, 1994; Clements & Nastasi, 1993; Guddemi & Fite, 1991; Haugland & Wright, in press; Hoot, 1994; Shade, Nilda, Lipinski, Watson, 1986; Wright, Shade, Thouvenelle, & Davidson, 1989). Having discussed the use of computers in early childhood classrooms, we make two suggestions for concerned educators in the early childhood field:
* Find appropriate software: The most appropriate software fits your instructional strategies and goals, provokes and stimulates students’ thinking, furnishes appropriate feedback, provides a sense of control and develops students’ autonomy, and encourages collaborative learning.
* Provide developmentally appropriate guidance whenever needed: Make an effort to pay attention to the children at the computer, to observe and listen to them in order to provide appropriate help and enhance their constructive learning.

The area of children learning with the computer needs to be researched further in order to develop a better understanding of how computers can be appropriately conducive to children’s cognitive development and their growth in other aspects as well.

EARLY CHILDHOOD DEVELOPMENT AND TECHNOLOGY: A CASE STUDY

Stephen Rodriguez
Texas A & M University—Corpus Christi

The recent opening of the Early Childhood Development Center (ECDC) at Texas A & M University-Corpus Christi (TAMU-CC) affords a unique opportunity to investigate how young children and their teachers use technology in the classroom. The purposes of this discussion, then, are to briefly review related literature and to present some preliminary findings about how teachers have begun engaging students in technology-based activities. Related problems and opportunities that the teachers reported will also be discussed.

The Context

Opened in August, 1996, the ECDC houses a public school of the Corpus Christi Independent School District which presently serves 88 students drawn from throughout the district. Students currently include three year old through first grade students. Current students will proceed to second and third grades in the next two years: a new group of three year olds will enter each year, as well.

The school features a dual-language approach, offering instruction in both Spanish and English. Counselors, nurses, and academic diagnosticians are also an integral part of the ECDC staff. By design, sixty-five percent of the students are of low socioeconomic status as defined by their eligibility for the federal free or reduced-price meal program.

The ECDC staff has targeted use of technology and five other curricular themes as follows:
- creativity;
- academic excellence;
- cultural heritages;
- life skills;
- multi-language communication.

These themes provide a rich array of curricular foci within which to embed technology applications. Each classroom houses eleven current Macintosh computers with hard drives. All computers are tied in to the University’s network which provides Internet access.

Young Children and Technology

Developmentally appropriate practice (DAP) stands as a hallmark of early childhood education. This orientation is built on the idea that children learn best through active, hands-on learning (Santrock & Yussen, 1992). The DAP orientation further holds that both children’s social and cognitive development should be addressed. DAP, in essence, “... is education based on the knowledge of the typical development of children within an age span (age appropriateness) as well as the uniqueness of the child (individual appropriateness)” (Santrock & Yussen, 1992, p. 482). The National Association for the Education of Young Children (1991) offers specific recommendations for strategies deemed developmentally appropriate in early childhood education.

Gardner’s multiple intelligences provide another useful guiding framework. Gardner (1993) suggests that children’s capacities are diverse and include abilities in the following areas: logical-mathematical, linguistic, musical, spatial, bodily-kinesthetic, interpersonal, and intrapersonal. Such a multi-faceted view of children reminds us that children possess a range of capabilities. The microcomputer can provide diverse multimodal experiences to address and develop an individual student’s unique capacities (Wright, 1994). Wright suggests that the multiple intelligences framework can sharpen our insights into the ways that children interact with computers.

Wright has also identified a number of areas that can be pursued by children on a computer with appropriate software. These include the following:
- telling stories;
- making art;
- designing things;
- writing stories with pictures;
- understanding the mechanics of a computer system;
- thinking logically;
- building microworlds.

These general types of activities require appropriate hardware and software and teacher planning and support. They provide an interesting starting point for using computers as more than a means of delivering commercial instruction, which is desirable.

A final outlook on the role of computers in early childhood education is also noteworthy. Under this view,
Teachers’ Uses of Technology and Related Needs

In an effort to identify teachers’ perceptions regarding uses of technology and related needs, the author held two group interviews. The four participating teachers, currently instructing three year old through first grade students, also completed a questionnaire. Following is a summary of major findings.

Uses of Technology

Teachers predominantly use the computers as a means of delivering commercial CD-ROM programs, especially “living books” such as Just Grandma and Me (Broderbund, 1990). The titles were included in an early childhood software bundle available from Apple Computer. Other reported activities included using KidPix (1989) and a bilingual writing program. On the whole, teachers indicated that students use computers at designated times during the day instead of in an ongoing manner throughout the school day.

When asked which kinds of computer-based activities students find most appealing, teachers indicated that children enjoy opportunities to explore and to be creative. Other appealing qualities included software that is highly interactive and that allows students to develop a tangible product as with the program KidPix.

Teachers’ Technology Skills and Related Needs

Involved teachers were asked to rate their current computer skills. This is a crucial issue because teachers must be capable computer users if they are to guide students in technology applications. The majority indicated need to learn more about using the World Wide Web to obtain instructional resources. The majority also expressed desire to learn more about electronic mail. Other areas of interest included strategies for integrating computer activities into the curriculum and use of HyperStudio (1995).

Success Factors and Related Needs

The teachers were also asked to report factors and needs which affect their ability to successfully use technology with the children. Responses were diverse. Two teachers indicated a need for additional technical support. The majority indicated the need for new software, as students are losing interest in the current software collection since they’ve used it extensively to this point.

Other concerns the teachers identified include the following:

- need for more knowledge of technology integration strategies for young children
- need for support group for the teachers in the area of technology applications
- need for in-class assistants to guide students in use of computers

The teachers’ perceptions will guide the author in designing a series of professional development opportunities that will focus on addressing the apparent needs.

Conclusions and Future Directions

Given that the ECDC has only been in operation for a short time, teachers are doing an excellent job of engaging students in meaningful uses of technology. However, teachers have expressed some clear needs which must be addressed if they and their students are to continue to progress in applying technology in developmentally appropriate ways and toward useful ends. This discussion, truly a work in progress, has reported on some key concepts in the literature and on teachers’ perceptions of their current progress. As such, this effort provides issues for discussion, direction for future staff development activities, and a start down the long and winding road toward fuller integration of technology in TAMU-CC’s Early Childhood Development Center.

FACTORS ASSOCIATED WITH PRESERVICE TEACHERS' USE OF INTERACTIVE MEDIA

Anita Perna Bohn  
Illinois State University

Dent M. Rhodes  
Illinois State University

Research into interactive media for preparing preservice elementary teacher education majors has traditionally been concerned with program design features and content acquisition by students. For example, Bitter (1994) describes how interactive multimedia can be used in training elementary mathematics teachers; Vitale and Romance (1992) report on its use in an elementary science methods course. Carlson and Falk (1990-91) discuss the results of a study on concept learning through interactive video and present a model for using the videodisc in teacher education. Bosworth and Welsh (1993) describe an interactive multimedia primer on group process skills. Peters and O’Brien (1996) report on an example of multimedia development carried out by preservice teachers themselves.

In each case, these studies make the directed use of multimedia by preservice teachers an integral facet of the research design. If preservice teachers did not use the technology, there could obviously be no research on how they used it. As part of an analysis of interactive multimedia learning environments for teacher education, Ladewski (1996) does include the larger learning context within which the multimedia system operates. However, each of the four environments considered in the analysis assumes students will participate and contains specific tasks in which they will engage.

In contrast, this study is an investigation into factors that appear to govern student use of an interactive multimedia instructional program when students can choose not to participate fully and tasks are not specified. Although program design may influence student reactions to program content and features, non-program factors, namely instructor emphasis and student orientation toward preprofessional teacher preparation, seem to be more significant determiners of usage in the institutional context under study.

Interactive Program

The interactive multimedia program in this study, “Early Childhood Growth and Development”, has been designed for elementary teacher education majors in a child growth and development course in the Department of Curriculum and Instruction at Illinois State University. The program utilizes film footage from an existing linear video disc available as a contractual supplement to the standard human development text. The 30 minute video was originally part of a public broadcasting series that illustrated development throughout the life-span. The videodisc on early childhood development has been “repurposed” for interactive instructional purposes with permission of the text-book publisher. The multimedia workstation is a “dual monitor” system that consists of a personal computer and its monitor, a laserdisc player and a separate video monitor.

The emphasis in the program is on observing child behavior, reflecting on what is observed, and comparing the results of the observation with material from the course text. The program has 94 separate “pages” or screens, with videos related to general child development issues and on specific developments in six stages from 5 months to 3 years. The program incorporates features that are widely accepted in the design of interactive multimedia for adult learners, such as, meaningful application of content; choice of alternative learning sequences; optional information segments; and informational feedback.

There are 18 separate video segments that may be replayed or paused from the computer keyboard with controls that duplicate functions of a conventional VCR or laserdisc player. There are 9 “advance organizer” pages previewing what is to follow; 9 “choice pages” in which the user can choose how to proceed; and 20 “self-assessment” multiple-choice questions that users can choose to answer and receive feedback on any or all responses selected. Hypertext buttons provide additional information if desired and the program is “personalized” in that users are addressed by their first names throughout.

The program has been designed so that students can complete it about 40 minutes. They need not do all the segments in one sitting and can spend as much additional time as they wish. During the 40 minutes, students are able...
to do some video replay, select more than one answer on the more difficult self-assessment questions and choose to see optional hypertext information. The length of time each students takes to complete the program is recorded, as are choice of segment type and viewing sequence, hypertext selection, control of video disc player, and response(s) to self-assessment questions. Usage data are available to instructors upon request. The work station is located in the media resource center of the library and the program is available to students during library hours.

**Procedures**

This interactive multimedia program was first implemented in the Spring semester, 1995, in 4 sections of the child growth and development course with two instructors and approximately 100 students. Participants were primarily elementary education majors with some from special education and a very few general students. Students were tested on program content by one of the instructors and usage was checked by both. Student response questionnaires indicated high overall satisfaction with program features and also pointed out some technical difficulties that were subsequently remedied.

In fall semester, 1995, the program was made available to 9 sections of the course (about 260 students) taught by 6 instructors. An analysis of the tracking data revealed considerable differences in students usage, especially among sections taught by different instructors. Students differed by course section with respect to amount of time engaged in the program, in number of program sections completed, alternative answers selected, and video segments replayed. Virtually all students from some sections used the program; only a few from other sections did so, though the opportunity was available to them.

It was difficult to believe that these differences in student usage were primarily a function of program design. In order to determine if the result from fall 1995, were anomalous, the program was again implemented with 8 sections and 5 instructors (about 230 students) in Spring, 1996. The same results were evident, i.e., wide variations among the amount and type of student usage in sections taught by different instructors.

These differences were the subject of specific inquiry during the fall semester 1996. Nine sections of the course were taught by five instructors with 276 students enrolled. One of the instructors held a tenure-line position; the others were part-time instructors or graduate teaching assistants. The departmental undergraduate program coordinator "strongly suggested" that the interactive video program be incorporated into each instructor’s course syllabus, and it was made so. Students had the opportunity to use the program for 15 weeks of a 16 week semester, though the content was most applicable in the first four weeks of the course. The five instructors were interviewed to determine the nature of their assignments related to the program, any instructions given students on how to proceed through it, and the extent to which students were held accountable for knowledge of program content.

All instructors “required” that students use the program, but the nature of the requirement differed for each instructor. Instructor A told students she would “check the printout” to determine if they had “successfully” completed the program; completion was worth 3% of a student’s total grade. Instructor B said she would determine if a student had finished the program and take that into consideration as part of the student’s total “participation” grade. Instructor C “assigned” the program and said she would provide some “points” toward the final grade for students who evaluated it as a learning device. Instructor D told her two sections she would check to see how much time a student spent on the program, and include that in the participation grade for the course. Instructor E indicated she would determine if all questions in the program were answered and emphasized the relationship of program content to the text material on which students were tested. None of the instructors gave any directions for using the program or mentioned specific features such as hypertext or video controls.

**Results**

Table 1. shows for each instructor the number of students in sections taught, percentage of those students using the program, average and median usage time, and percentage of students using the program who also took advantage of hypertext information-buttons or video replay.

</tbody>
</table>

The results are quite similar to those from the previous two semesters: considerable variation among usage by students with different instructors. Although the program was "required," no more than two-thirds of the students in any of seven sections of the course had used it after 15 weeks. Only a few more than one-third of the students in the two sections taught by Instructor A used the program as contrasted with more than 90% of those in Instructor E’s section. Instructor E’s students also spent, on the average, 10 minutes longer with the program than students from Instructor A’s sections.
In the absence of specific directions from the instructors, including Instructor E, students did not make extensive use of optional hypertext information sources even if these sources illustrated and elaborated portions of their course text. In none of the sections did half of those students using the program take advantage of the hypertext information and video replay capabilities.

The results confirmed what was suspected: the principal factor associated with student use of the interactive multimedia program was the type of emphasis given to the program by their instructor. Instructor A incorporated program usage directly into her course grading scale, but gave it minimal importance. Instructor C also minimized the importance of the program content for her students. For instructors B and D, program usage was to be included as a rather indefinite element in the students' participation grades, though Instructor D had said that she would check on how much time her students spent with the program. Only in the section taught by Instructor E, where the importance of the program was emphasized and content related to unit tests, did more than 90% of the students use the program. She did not, however, give any special importance to the hypertext information and video control capabilities; her students did not use those features to any greater extent than did students in other sections.

**Discussion**

It is clear that the preservice teachers in this study used the interactive multimedia program primarily because their instructor was prepared to enforce, in some way, the requirement to do so. Why is it that many students did not take full advantage of this relatively new instructional technology, regardless of the course requirements an instructor might have? It is not because they had grown blase about the instructional mode, as “Early Childhood Growth and Development” is the first and only interactive multimedia program used in the undergraduate teacher education sequence. There are at least five possible interrelated reasons, all candidates for testing through further inquiry.

The most plausible reason in the institutional context under study is that students did not take advantage of the opportunity afforded by the technology because they view themselves not as preservice teachers but as college students. These students may be said to have a “collegian” instead of a “pre-professional” orientation to their course work. In their role as collegians, teacher education students do not take the educational initiative when they are not given specific directions about how to use the program and what is expected of them. If the interactive multimedia program does not have a high priority with their instructor, it will not have a high priority with them.

These students apparently do not see themselves as preprofessionals with responsibilities beyond those established in the course syllabus by their instructors. It may be, as Fuller and Bown (1975) pointed out some two decades ago, teacher education students can relate easily and realistically to the student role but can identify with teacher role only in fantasy. Kagan (1992) concludes from a review of research on professional growth that preservice teachers' self-images are largely a product of their prior experiences as students, and that conventional teacher education course work has little effect in changing these perceptions.

A second and related possible reason is that student interpret the content of the interactive media program as declarative knowledge rather than procedural knowledge. Although the interactive program is designed to enhance students' observation skills, in the absence of input from the instructors, a student could interpret the program as simply adding more information to the store already contained in the course text. According to Winitsky and Kauchak (1995), a fundamental issue in learning to teach is the translation of declarative knowledge to procedural knowledge. Without instructor assistance or direction, teacher education students with a collegian orientation would see no reason to attempt such a translation.

A third reason for lack of participation may be the students' perceptions that content in teacher education courses is irrelevant to a teacher's actual work in a school. In a study of preservice social studies teachers, Ross (1987) found that respondents perceived teacher education course work as "artificial" and separated from the reality of the classroom. Kagan (1992) also argues that course work in child growth and development will not provide the kind of knowledge that preservice teachers will internalize. Although the interactive media program documents visually the growth and development of real children in real families, the use of such technology may still be perceived by students as essentially artificial and unrealistic.

Fourth, many students in the institutional context under study may consider teaching to be simply a job that they will work at for a limited period of time, or as something to fall back on (Darling-Hammond, 1990). In a study of preservice teachers, Serow (1994) found that some 55% of the teacher education majors in his study regarded teaching as something other than a personal "calling", to use his term. Serow's sample over-represents secondary majors, but his findings may be relevant to the situation at hand. If prospective teachers view teaching as merely a temporary occupation rather than a life-long personal vocation, then they will have little motivation to go beyond course requirements if not forced to do so.

Finally, teacher education majors in the institutional context under study may have come to believe that the locus of control (Rotter, 1966) over their success in obtaining a teaching credential is external. After all, the
formal courses they take and clinical experiences in which they participate are specified for them in great detail. Their grades will be determined by instructors whom they can not choose and who have no standardized evaluative criteria. In their coursework, as in their plans of study, they are not in control. They believe that their success as preservice teachers resides with their instructors, not in themselves.

Why then did not more participate as they were apparently “required” to do? One could speculate that because the course instructors were virtually directed to include the multimedia program in their syllabi, perhaps students were able to detect that using the program was not related to their success in the course: instructors did not actually care if they participated or not. If the instructors were merely complying with external directions, why should preservice teachers exercise internal locus of control? It may be that both instructors and students perceive that the locus of control over their success as faculty and preservice teachers in the institutional setting under study is not explicitly internal.

Without more information about the individual and collective orientation of students to their preprofessional study, it is difficult to know how to proceed with more effective implementation of the interactive multimedia program on child growth and development. Efforts along the lines suggested by Manning and Payne (1989) in developing cognitive self-direction on the part of preservice teachers, and by Dart and Clarke (1991) in helping teacher education students become better learners, appear to be warranted.

In addition, multimedia programs can be produced with features that emphasize how a teacher’s professional decisions impact consequences in schools. There are such programs for professionals in health care settings (Byers & Rhodes, 1996) and the designs could be adapted to teacher education. One program of this type has been developed by Overbaugh (1994; 1995). He describes a sophisticated interactive video classroom management simulation program. Preservice teachers are able to analyze common classroom problems, select solutions incorporating basic management principles, view the results, and determine the efficacy of the solutions chosen. The preservice teachers in his study did exhibit professional growth in their orientation toward teacher responsibilities.

Though classroom management skills loom large in the minds of preservice teachers, there are other important components in teacher preparation. Interactive media simulations with teaching and learning scenarios could help instructors and students benefit from the significant impact that multimedia can have in preparing teachers. These program would have designs that clearly focus on a preprofessional orientation and give the preservice teacher a “proactive” role (Rhodes & Azbell, 1985). For example, teacher education students would be able to observe, determine, and reflect on the consequences of correctly assessing a child’s level of cognitive development in lesson planning. If such programs exist, descriptions and accompanying research studies are not readily accessible in the professional literature.

In summary, we can say at the least that implementing instructional technology in the form of interactive multimedia in an undergraduate teacher education program is not simply a matter of content relevance, program quality, simplicity of use, timely availability, and institutional support. The quality of the interactive instructional design, specific design features, and program accessibility do not appear to have been major factors governing student usage for students in this study.

For reasons yet to be determined, the traditional factor of instructor emphasis is the key factor determining student usage in the institutional setting as described. The matter of instructor emphasis is apparently related, in some undetermined fashion, to the students’ orientation(s) toward preprofessional study. To make effective use of instructional technology in the future, we will have to rethink our protocols for integrating interactive multimedia into the undergraduate teacher education curriculum, and consider once again the problem of how to convince students that they have a responsibility for their own learning.

Often technology can be used in ways to address enduring dilemmas in teacher education. Below we describe a future project which will uses technology to: (1) provide campus based undergraduate students with real examples and problems of education from real classrooms; (2) provide teachers in different places access to a graduate education they may not otherwise have access to without the use of distance learning technology; and (3) use various forms of technology as tools for learning.

**Description of the Project**

This project is the result of a grant from the Georgia University System’s Office of Information and Instructional Technology (OIIT) to support innovative approaches to implement technology into the curriculum. The purpose of this project is to incorporate technology in a unique way that will team students in a graduate level education course with students in an undergraduate pre-service course. The graduate and undergraduate students will team in the implementation of technology into the pre-kindergarten through fifth grade social studies curriculum.

During the winter 1997 quarter, graduate students enrolled in the Early Childhood Education (P-5) program at Georgia Southern University, who will take the course titled Problems in Social Studies (EC 851), will participate in the first phase of the project. The course will be redesigned to incorporate all aspects of the proposed technology implementation project. The course will be offered over the Georgia Statewide Academic Medical System (GSAMS) which is a statewide distance learning system established by the Georgia Public Service Commission. The GSAMS system is currently used at all levels of education in Georgia to provide distance learning opportunities through the state.

The second phase of the project will occur during the Spring 1997 quarter in the course titled Early Childhood Social Studies (EC 453). The graduate students who were enrolled in EC 851 during the winter 1997 quarter will be asked to participate in the second phase of the project by collaborating with the undergraduate students in EC 453 activities during the spring term. In addition, other master teachers (identified in advance by the project director) who have access to GSAMS distance learning facilities in their school buildings will be asked to team with the preservice undergraduate students enrolled in EC 453.

**Description of the Courses**

Problems in Social Studies (EC 851) is a graduate course designed for Early Childhood Education teachers as an in-depth study of the social studies curriculum. It is offered primarily as a course for people seeking the Educational Specialist degree. The goal of this graduate course is to develop the teachers' expertise in the area of social studies curriculum planning at the pre-kindergarten through fifth grade level, to increase knowledge of social studies content and methodology, and to develop their abilities to research and acquire information related to their teaching.

Early Childhood Social Studies is an undergraduate methods course designed to prepare students for teaching social studies at preschool through the fifth grade levels. Students are expected to become knowledgeable of the content of early childhood social studies, and are expected to demonstrate competence of appropriate teaching methods, materials, and organizational techniques.

**Reason for Course Selection**

There is a need to provide greater integration of technology into teacher preparation programs. The technology is available, but university faculty generally do not have the time and resources required to investigate effective ways to integrate technology and redesign teacher education methods courses. Public schools in the state of Georgia also have the technology, but again have not had the time or resources to implement its integration adequately. Inservice teachers, teacher educators, and preservice teachers need to address the issue of integrating technology into instruction. A social studies methods course and a graduate course seem ideal for orchestrating a
“full circle” effort to investigate ways to integrate the technology and to demonstrate and share with each other in the process.

The social studies content area is ideal for investigating and experiencing the integration of new technology. Technology will allow effective and flexible modes of communication between teachers, students, and educational sites through the use of electronic mail. Access to the Internet will provide extensive research capabilities and information retrieval for use in instructional planning and teaching activities. The opportunity to interact with teachers and students in classrooms throughout the state, and even the world, and to obtain information about other people and places will enhance multicultural awareness and cultural studies, a major goal of social studies instruction. The distance learning technology is available throughout the state of Georgia providing (a) greater access for teacher education in public school classrooms and (b) greater access for public school students to the world outside their classrooms. The use of the GSAMS system to connect the college classroom with various prekindergarten through fifth grade classrooms will benefit teacher preparation and bring innovative teaching practices using technology into the early childhood classrooms. The Georgia Southern University College of Education and the school systems throughout Georgia have available computer technologies, laserdisc technologies, and instructional software that are demonstrated but are not often used to capacity through full integration into instruction. These resources are typically high-quality and should be used to provide individualized instruction and to motivate in-depth learning. These technologies will be integrated into instruction, thereby sharing these resources between all of the distance learning sites.

Technology can improve the delivery of these two courses by providing avenues for professional interaction, modeling, and field experiences through a live connection with elementary school classrooms in action. Technology also supports the delivery of information related to the curriculum content through the software, CD ROM, and laser disk resources. In addition, the integrated use of technology helps develop competence in technology/computer skills, and instructional planning for integrating technology into learning experiences that teachers need today.

**Integration of Technology into the Graduate Course Design**

The redesign of Problems in Social Studies (EC 851) will incorporate extensive integration of technology in all aspects of the course. The course delivery will utilize distance learning to model a primary source of information delivery. Students will be located at one of three sites in southeast Georgia. Each site is located at an academic location and contains monitors, cameras, and microphones in a classroom environment. The GSAMS distance learning system incorporates two-way interactive compressed video. The voice-activated system allows all members of a class to hear and see the individual who is speaking. Participants in the Problems in Social Studies course will observe a variety of teaching strategies that maximize the distance learning environment including various presentation techniques, demonstration schemes, and interactive group activities. Students will also be required to actively participate in the course which will assist them in becoming familiar and comfortable with the distance learning system. This is an essential aspect due to the fact that distance learning is a technology that is available to all school systems in Georgia. The distance learning system can provide valuable resources to teachers trying to expand their social studies curriculum.

Social studies computer software and video disks will be incorporated to demonstrate integration of various media into the social studies curriculum. This project allocated funds for increasing the social studies content software and equipment available to participating teachers. The intent of expanding the technology collection is twofold. First, some of the software and equipment will be utilized in the course structure. This will include demonstrating some media to make teachers aware of the variety of materials that are available to support the social studies curriculum. Some of the software will be integrated into the course structure as an integral part of the course content. Students will be asked to participate in course activities that are supported by the content of the software.

A second aspect of the computer and laser disk technologies identified in this project will be to send the media into the classrooms of the course participants. The additional software and equipment purchased with the grant funds will be available for the students in EC 851 to use on an experimental basis in their classrooms. These teachers will be expected to select software and laser disks that match their curriculum and implement the materials into their classroom structure. Teachers will borrow the software and new equipment from the College of Education Instructional Resource Center for the purpose of previewing, utilizing, and evaluating the content of the media. The media will then be returned to the Instructional Resource Center so that it will be available for other class participants to utilize. Through this process, the teachers will have an opportunity to observe the application of new technologies and implement the technologies into their own classrooms without the barrier of funding.

Telecommunications will play an integral role in the redesign of Problems in Social Studies. Students enrolled in EC 851 will use e-mail to communicate with each other, the instructor, other early childhood teachers, and individuals and organizations that could support the course.
objectives. The participating teachers will use the Internet as a resource to support social studies content and teaching strategies. The students will use the Internet to research topics related to various aspects of the early childhood social studies curriculum. The students will use the Internet as a resource to locate materials and lesson plans designed for the prekindergarten through fifth grade social studies curriculum. Students will locate bulletin boards and other sites that offer interaction among P-5 educators. In addition, students will learn how to incorporate the Internet into their classroom as a meaningful resource for the social studies curriculum. Participants will demonstrate competence in the knowledge of available technology and its integration into social studies instruction. By teaching this course through distance learning, incorporating e-mail/Internet activities, and computer technologies as an integral part of the course, meaningful applications of technology will be modeled as an integral part of the course design.

Integration of Technology into the Undergraduate Course Design

The teachers who participated in EC 851 will be asked to use the distance learning system to model effective planning and teaching in “real life” classroom situations for the undergraduate students. These lessons will be taught to prekindergarten through fifth grade students in a distance learning classroom. The undergraduate students in EC 453 will observe these lessons in the distance learning classrooms on the Georgia Southern campus without having to leave the university campus. This will allow the undergraduates to observe several different classrooms throughout the region. The distance learning system eliminates the barriers that course schedules and travel time ordinarily present. This will give the preservice teachers the opportunity to observe a variety of grade levels and provide interaction with elementary students in a content-focused learning situation through planned observation of classrooms throughout the southeast Georgia region. In return, the preservice teachers will be expected to demonstrate components of social studies lessons over the distance learning system to various prekindergarten through fifth grade classrooms in the region. The teachers and the undergraduate students will participate in panel discussions on course-related topics for the class over the distance learning system. This will give the undergraduate students interaction with practicing teachers regarding course-related topics and issues and modeling of technology utilization and the integration of technology in social studies instruction in the college and elementary school learning environments.

Telecommunications will be used extensively as a resource for the undergraduate participants. Students in EC 453 will be expected to use e-mail to communicate with the course instructor, with their mentor teachers, and with other students in the course. The students will be required to utilize information from the Internet as a resource for information that can be used in the social studies content. This would include researching selected social studies topics over the Internet and evaluating the information to determine validity and reliability of the content. The students will also utilize the Internet to locate resources that can be included in instructional activities in the prekindergarten through fifth grade social studies curriculum. This will include providing students with World Wide Web addresses where they can locate lesson plans and teaching activities related to the social studies curriculum.

Teaming Graduate and Undergraduate Students

A key component to this course development project is the interrelation of graduate and undergraduate students, connecting master teachers with preservice teachers. During the Spring 1997 quarter, the project will connect undergraduate students in EC 453 with students from EC 851 and their elementary classes throughout the region. Teachers who participated in EC 851 during the Winter 1997 term will be asked to collaborate in the undergraduate course activities.

Project Evaluation

This project includes several evaluation strategies. Course evaluations will occur at the end of winter and spring 1997 terms. Graduate and undergraduate students will be asked to evaluate the course content and instruction. An attitudinal survey of the participating pre-
kindergarten through fifth grade students will also be conducted and used in the evaluation process. At the end of spring term, team members will assess the courses, the project in general and make recommendations for improvements and idea/activity extensions. They will also develop a list of suggestions and inferences on how these course designs could transfer to other methods and graduate teacher education courses.

Evaluation of student learning will be conducted formatively and summatively using performance-based assessments. Participants will demonstrate (a) knowledge of the technologies presented and used in the course, (b) competence in instructional strategies that provide for the integration of technology to meet students' needs individually and collectively, and (c) competence in using the technology for instructional purposes. Students will be evaluated on how well they can use technology to communicate and retrieve information in order to enhance the interactive learning environment. Students will also be evaluated on how well they can relate the available technology with the goals of the prekindergarten through fifth grade social studies curriculum.

Summary

This project involves the redesign and development of two Early Childhood Education courses, EC 453—Early Childhood Social Studies and EC 851—Problems in Social Studies, as distance learning courses that will incorporate e-mail communications, Internet activities, and the integration of computer technology into classroom instruction using a variety of software and laser disc technologies. The development of the two related courses, one undergraduate and one graduate teacher education course, both dealing with the social studies content area, will be the first to attempt full integration of the technology and provide instruction in a non-traditional and innovative manner. A key component to the course development project is the interrelation of graduate and undergraduate, connecting master teachers with preservice teachers. The two courses were designed to provide extensive interaction between classroom teachers (graduate teacher education students), their elementary students, and the undergraduate/graduate course instructor, and the preservice students.

This project is the result of a grant from the Georgia University System's Office of Information and Instructional Technology (OITT).
CURRENT LITERATURE SUGGESTS THAT TEACHER EDUCATION INSTITUTIONS ARE FAILING TO PROVIDE COURSES THAT EQUIP STUDENTS WITH THE SKILLS TO INCORPORATE THE USE OF INFORMATION TECHNOLOGY INTO THEIR TEACHING (DOWNES, 1993; HANDLER, 1993; OLIVER, 1994). THE BODY OF THIS LITERATURE ALSO PROPOSES THAT THERE IS NO TRANSFER OF INFORMATION TECHNOLOGY SKILLS FROM PERSONAL COMPUTING CONTEXTS TO THE CLASSROOM USE OF THESE SKILLS (DUNN & RIDGeway, 1991; WILD 1995). THIS PAPER DISCUSSES HOW THE DEFICITS EXPOSED IN THESE STUDIES ARE BEING ADDRESSED IN THE EDUCATION OF EARLY CHILDHOOD PROFESSIONALS AT QUEENSLAND UNIVERSITY OF TECHNOLOGY (QUT). FOUR EXAMPLES OF AREAS WHERE TECHNOLOGY HAS BEEN INTEGRATED INTO THE STRUCTURE OF THE COURSE ARE EXPLORED; A FOUNDATION ELECTIVE, A CORE UNIT IN MATHEMATICS EDUCATION, AN ELECTIVE UNIT ENTITLED TECHNOLOGY AND THE YOUNG CHILD, AND THE UTILIZATION OF AUDILOGraphic TECHNOLOGY IN GRADUATE UNITS.

WILD (1995) PROPOSES THE FOLLOWING PRINCIPLES FOR TEACHER TRAINING COURSES TO ENCOURAGE BEGINNING TEACHERS TO INCORPORATE THE USE OF TECHNOLOGY INTO THEIR TEACHING:

- INTEGRATED LESSON PLANNING;
- THE VALUE OF INCIDENTAL LEARNING;
- TIME FOR STUDENTS TO INTERACT IN A NUMBER OF DIFFERENT SOFTWARE ENVIRONMENTS;
- MODELING OF DESIRED PRACTICE BY COURSE LEADERS;
- A MAXIMUM OF HANDS-ON TIME;
- GROUP WORK TO ENCOURAGE VERBALIZATION;
- GENERALIZATION TO OTHER LEARNING CONTEXTS;
- THE CONTENT OF PROGRAMS TO BE FOCUSED NARROWLY;
- STUDENTS BE ALLOWED TO DEVELOP A SENSE OF OWNERSHIP;
- OPPORTUNITIES FOR REFLECTION BE PROVIDED;
- AND THE USE OF CONTENT-FREE SOFTWARE TO CREATE COURSEWARE THAT IS DIRECTLY TRANSFERABLE TO THE CLASSROOM CONTEXT.

MANY OF THESE FACTORS ARE IN KEEPING WITH AN INTERACTIONIST APPROACH TO TEACHING AND LEARNING (LAURILLARD, 1993) AND ARE INCORPORATED INTO THE CONTEXTS WE WILL DESCRIBE IN THIS PAPER.

A FOUNDATION UNIT IN INFORMATION TECHNOLOGY FOR PRESERVICE TEACHERS

WITHIN THE NEWLY STRUCTURED BACHELOR OF EDUCATION (EARLY CHILDHOOD) AT QUT, STUDENTS CAN SELECT FROM A NUMBER OF FOUNDATION UNITS, OF WHICH INFORMATION TECHNOLOGY IS ONE OF EIGHT. THE FOUNDATION UNIT GIVES STUDENTS GLOBAL UNDERSTANDINGS OF THE IMPACT OF INFORMATION TECHNOLOGY ON SOCIETY AND IN DOING SO ALLOWS THEM TO DEVELOP THEIR PERSONAL COMPUTING SKILLS. THESE SKILLS ARE DESIGNED TO LAY THE FOUNDATION FOR THEIR PROFESSIONAL LIFE. A SECOND INFORMATION TECHNOLOGY UNIT INVOLVES THE STUDENTS IN A SEQUENCE OF INTERACTIONS WITH SOFTWARE CURRENTLY BEING USED IN PRIMARY CLASSROOMS, TAKEN FROM A CURRICULUM DELIVERY PERSPECTIVE.

A MAJOR FOCUS OF THE UNIT CONCERNS AREAS OF CHANGE WITHIN SOCIETY Brought ABOUT BY RAPID TECHNOLOGICAL DEVELOPMENT AND DISCUSSIONS ABOUT THE IMPACT THAT THESE CHANGES MAY HAVE ON EDUCATION. THE AREAS IDENTIFIED ARE: THE CHANGING FACE OF PUBLISHING; TELECOMMUNICATIONS; ACCESS; INFORMATION LITERACY; AND, ETHICAL ISSUES PERTAINING TO TECHNOLOGY.

THROUGHOUT THE READINGS, STUDENTS ARE MADE AWARE OF THE METAPHORS, SIMILES AND ANALOGIES THAT AUTHORS USE TO DISCUSS ISSUES CONCERNING TECHNOLOGICAL CHANGE. IN THEIR FIRST PIECE OF ASSESSMENT STUDENTS ARE ENCOURAGED TO ENGAGE IN PERSONAL MEANING MAKING BY STATING AND DEVELOPING A PERSONAL METAPHOR FOR TECHNOLOGY.

THE IMPORTANCE OF MODELING HAS BEEN NOTED IN SEVERAL STUDIES AND WE HAVE ENDEavored TO PROMOTE ITS APPLICATION IN THE DESIGN OF TEACHING AND LEARNING EXPERIENCES IN THE COURSE. BOTH TECHNOLOGY UNITS HAVE THEIR OWN WORLD WIDE WEB (WEB) SITES WHERE LECTURE NOTES CAN BE ACCESSED AND LINKS ARE MAINTAINED TO OTHER AREAS OF PERTINENT INFORMATION.
on the Web. In tutorial sessions the use of video projectors allows demonstrations of skills that the students are to implement in their computer workshops.

E-mail activities in which students act as editors for each others work are an integral part of the first assignment. In this the students create a document where they reflect on their learning in light of the readings presented to them and their personal computing experiences. Students are also able to access QUT's on-line library catalog, and perform ERIC CD-ROM searches for their main piece of assessment, a literature review.

Whilst studies note that there is little transfer from personal computing skills into classroom use the foundation unit provides skills and understandings for the students to develop a critical attitude towards technology. These activities develop skills necessary for professional practice. Indeed, the skills and understandings lay the foundation for student exploration of the way that software can enhance curriculum delivery.

Applications of Technology for Early Childhood Professionals in the Preservice Program

In the third year of their program the students take a course that is entitled Early Mathematical Processes. The philosophy of the course is grounded in the belief that it is essential for children to be provided with opportunities to develop their abilities and interests by using a variety of learning modes. We attempt to engage our students in learning about the foundational concepts in mathematics and the exploration of ways in which teachers can develop appropriate learning opportunities to encourage and foster their development in young children. One of the major ways that this can occur is via the active exploration and manipulation of concrete materials via play. The role of technology has become increasingly important to the process of learning and understanding, and the creation of learning environments that are based in the new information technologies can facilitate the transition from concrete to abstract thinking in the mathematical domain.

Applications of technology are included at each stage of the teaching/learning process as students discuss the ways in which learning opportunities, based on effective pedagogy, can be developed for young children. For example, to illustrate the ways in which literature can provide a catalyst for the discussion of mathematical content, interactive story books are used as well as traditional texts. The students create and share a curriculum web to illustrate the ways in which the content of a book, such as Just Grandma and Me, can be extended across all areas of the curriculum and then engage in a specific focus on mathematical thinking. Implicit in the book is the idea of spending a day with a close relative of the family on the beach. Children may collect data about the number of members in their family, where their favorite beach is located, how long it takes to get there, the location of train/bus routes. This data may then be represented in various types of ways in a graphical format. In a similar way beach activities may be categorized and "equipment" appropriate for the beach can be used to collect liquids which may be compared or for capacity tasks.

Another basic content area of this unit pertains to the teaching of early number concepts. We have used both Millie's Math House and The Playroom to reinforce number concepts in different ways. In one game of Millie's Math House the child is able to construct a creature with body parts of up to 10 in number. As they arrange their creation, the software is able to tell them how many of each part they are using. In another game, the children have to decorate cookies with a specified number of chocolate chips or can decide how many should go on a cookie of their own creation. The stimulus pictures in The Playroom can provide a good starting point for discussing the number of items that are both located on a page, or created by the child. Such two dimensional manipulation of items provides a useful and complementary activity for the creation of sets with three dimensional materials, and constitutes a valuable transition phase between such activities and more abstract work in traditional paper based mathematical activity.

The elective unit Technology and the Young Child is also based on the belief that young children need to explore in order to make sense of and learn about their world. The experienced early childhood educator organizes learning opportunities to make use of a range of materials and create contexts for learning that support the child's natural curiosity and interests. Within this context applications of technology are becoming increasingly relevant to the education of young children as they afford the opportunity to engage the child in topics and ideas in innovative and challenging directions that were not previously possible. We believe that knowledge about the various applications of technology and their role in the learning process, will enhance the teacher's knowledge base and enable them to develop creative and effective teaching and learning experiences. This course is designed to provide early childhood educators with the opportunity to explore the potential of technology for their programs. They create technologically based projects which are tested by children from a local primary school.

While students enjoy the process of investigating the ways in which commercial software can be used in an educational context, the construction of their own programs seem to promote the greatest understandings of the potential of technology to enhance learning. Last semester, the students were asked to reflect on their experiences. It was evident from these reflections that the process of
constructing an application was a new, and often enlightening, experience. As one student stated:

This assignment was quite a learning experience in that we were working with an alternative medium to the traditional written assignment. It was a fun activity and yet I found I was learning vital concepts, processes and attitudes concerning learning in the early childhood years. This learning was of the deeper level of understanding, not just surface level often encountered in traditional modes of teaching. In the past, incorporating technology into the classroom was not as real to me as it is now due to the closer encounters with technology through Microworlds. (Student reflection, Semester 2, 1996)

Other students reported their first taste of that thrill of achievement those of us who dabble with computer programming know well.

In the beginning I didn’t think I would be able to include a melody (as I am not musically talented) but after I got my dog to run I decided I could achieve anything! (Student reflection, Semester 2, 1996)

Collaboration was also encouraged in a problem-solving environment. Students indicated that the problem-rich (and often frustrating) climate was far less daunting when tackled through team-work. A student wrote:

Help from other students was really important when writing the program as the sharing of problems and solutions was the way most of my learning occurred. Because of this I have now realized how beneficial computers can be for children as a social tool, in promoting interaction with others and to encourage cooperation in problem-solving. (Student reflection, Semester 2, 1996)

Although this system of working together was supported by the lecturer as an authentic problem-solving strategy, it was not formally structured through the formation of pairs or groups. However, the students obviously found it to be beneficial to their learning:

Actually, I thought it was great the way other students helped each other and went out of their way to assist their friends. We worked really well as a team. (Student reflection, Semester 2, 1996)

Finally the experience of having children work with their programs demonstrated to the students that they had produced real teaching tools that would be useful assets to the classroom. This was supported by statements such as:

I was greatly encouraged when I saw the children using my program. It stimulated talk and discussion about the issue of being healthy. The children enjoyed clicking on all the different people and objects to see what they would do. The teacher of the class even specifically sent over two boys because he knew it would be beneficial to them. This excited me as I knew the program I had created was specifically teaching a child in an enjoyable and memorable way. (Student reflection, Semester 2, 1996)

Additional feedback from the students indicated that the unit represented a useful context for learning about technology in early education because it fulfilled the learning objectives that early educators often set for young children. It offered a nurturing, constructivist environment in which tertiary students could explore new concepts and be creative, it catered for individual learners with a wide range of skills and talents and finally it promoted social, collaborative strategies for problem-solving.

Pedagogical and Technological Issues in Using Audiographics Conferencing for Graduate Students

In the graduate program, audiographics conferencing is used to link off campus graduate students with students in classes on campus. The simultaneous linking of computers and teleconferencing has been used to facilitate seminar teaching and dialogic learning for students formerly unable to access study at the masters level. Attempts to provide equity of access were based primarily on the increasing number of women working in early childhood contexts, seeking higher degree study, but precluded because of the distance from metropolitan areas and university campuses (Halliwell, Perry, MacPherson, Grieshaber & Ballantyne, 1994).

Use of conferencing technology has shown it is possible to create conditions where students and lecturers become a ‘class’ with shared agendas, engaging in the critical analysis of existing knowledge and each others’ ideas. Staff felt strongly that students, particularly those who were isolated, should have opportunities to engage in critical debate. The resultant community of learners included urban, rural and geographically isolated students. In the first year of the project, technological issues dominated and staff tended to be in ‘survival’ mode as far as teaching was concerned. During the next year the project moved beyond technological problems and concentrated on the pedagogical climate of the electronic classroom. Most recently we have developed a model for the professional development of university staff interested in using audiographics conferencing for teaching (Halliwell, Grieshaber, MacPherson, Perry & Rossiter, 1996).

In extending access to higher degree study to students outside the metropolitan area via this process, a number of technological and pedagogical issues have arisen.
Technological Issues

Initially, a great deal of time was spent ensuring each site was successfully connected with both audio and data links before the sessions commenced. Additional time was necessary for the preparation of graphics which attempted to encapsulate conceptual ideas for critical analysis in each class, and downloading these to the sites throughout the state. Technical faults such as data lines ‘dropping out’ during class time were frustrating, as they interrupted the flow of the session and connections took up to fifteen minutes to be restored. Several ‘drop outs’ in sessions meant severe interruption, although staff and students became adept at continuing to discuss ideas while the data link was restored. Audio links appeared to be a little easier to re-establish than data links. Experience with the technology enabled staff to become more confident with its use and more competent in initiating the required action if a problem occurred.

Over time, staff and students learned the communication protocols associated with teaching and learning in this electronic environment. Students were encouraged to use the on-line facilities to communicate with participants at other sites during sessions to reinforce an idea, or consolidate a point. Initial use of these tools began with students typing and drawing greetings and farewells at the beginning and conclusion of sessions. Techniques for increasing participation in conversations and the lack of non-verbal information from those in isolated locations were other challenges for both staff and students. Timing, pacing and the length of sessions also needed attention in audiographics conferencing, and participants had to become accustomed to the slight time delay characteristic of this type of communications technology. As staff became more confident with the technology, the temptation to fill the gap by speaking gradually waned.

Technical support staff were essential, particularly from the Production Assistant who worked with academic staff in the production and downloading of graphics as well as assisting with the set up of each session and being available to assist when connections were lost.

Pedagogical Issues

Audiographics conferencing technology provided the vehicle for creating the ‘virtual’ classroom. Staff experience and familiarity with the technology influenced the nature and depth of discourse. Those staff using the approach for the first time stated that they felt the “discussion was more superficial than in face to face situations and that students were less inclined to make uninvited comments or to engage in extended dialogue” (Halliwell, Perry, MacPherson, Grieshaber, Lidstone & Rossiter, 1995, p. 1). More experienced staff reported higher levels of discourse and observed that students were making links with associated readings and conceptual frameworks underpinning the ideas discussed.

Student empathy for the lecturer’s position seemingly promoted a sense of group identity and collaborative effort. All teaching staff using audiographics conferencing have made comments about how group dynamics were quite different from prior teaching experiences (Halliwell et al 1995, p. 2). One explanation for this is that often participants interact on two levels. On one level, students participated in the whole group shared discussion. On another level, at times students at a specific site engaged in a local conversation, perhaps exploring an issue in more depth or in a different way from the whole group shared conversation. Use of the ‘mute’ button made this possible without interrupting the whole group discussion and the occurrence can be equated to student conversations which occur “on the side” during a conventional class presentations. Unsolicited sharing of local conversations with the whole group made it possible revealed the depth of such conversations.

For all staff involved in audiographics conferencing, the issue of the relationship between technology and pedagogy has now been resolved. Once staff were comfortable with using the technology, they found it an effective tool for enhancing pedagogy and used it as they would in a traditional teaching context. In addition, staff came to the understanding that audiographics conferencing has particular attributes which can be “exploited pedagogically” (Halliwell, et al 1995, p. 7).

Student Responses

Students’ oral and written responses were obtained for each year the project. Although students reported that they valued the frequency of interactions, some students said that they would have liked the sessions to be more interactive. Most students found the broad range of issues discussed and the opportunity to share and consider ideas at this level very appealing. The students did however, indicate a sense of disappointment about the intrusive nature of problematic technology. Minimization of technical difficulties was considered a priority.

As might have been expected, students in non-metropolitan and isolated areas showed a greater appreciation of the opportunity to study at this level than their counterparts on campus. On campus students felt that they were advantaged because of the presence of the professor, although for much of the time, staff were focusing on interacting with students in isolated areas. All students stated that they appreciated meeting their peers through the technology, and valued the diversity of experiences, situations and perspectives members brought to the sessions. The diversity of teaching approaches and techniques used in the sessions was also appreciated by students.

Open learning creates new challenges for staff and students. Students working in the open learning mode acknowledged the importance of self-motivation and
understood the importance of independent management of their study. Other comments indicated that students felt the role of staff had altered to become one of mentor and guide, one who shared learning rather than provided information (Halliwell, et al 1995, p. 15). Despite conceptualizing audiographics technology as a pedagogical tool for facilitating seminar teaching and dialogic learning, infrastructure changes needed for this approach have created teaching dilemmas that are not easily solved. Technical support for academic staff needs to include a professional development approach whereby staff are provided with opportunities to learn at their own pace in a small group of people who have similar needs (Halliwell et al, 1996). Pedagogically, protocols, formats, strategies and techniques for the desired teaching approach continue to be refined.

Conclusions

Technology permeates many aspects of our lives and provides us with an opportunity to enhance learning for children in our schools. It is evident that we need to prepare early childhood professionals to appropriate technology as a tool for learning as well as to realize its potential for global communication and access to information in remote places. Exposure to technological applications should begin in preservice teacher education programs and permeate core and elective courses so that students are confident and competent to use a variety of technological tools. Applications of technology also need to be utilized in graduate programs so that practicing teachers become used to viewing technology as a valuable part of their lives and learning and may be stimulated into incorporating it into their own teaching programs. This paper has presented some examples of ways that we have attempt to achieve this at QUT.

Following the Vygotskian notion that children learn in their zone of proximal development (ZPD) with the assistance of knowledgeable others, we explore problems teachers confront in choosing and using computers with young children. Teacher’s assistance with the computer is in part related to their perception of what the job of teaching is and how software works to help achieve the teacher’s learning goals. The purpose of this paper is to explore questions concerning the difference between what a software program claims to teach and what is actually learned.

Computers Don’t Teach, Teachers Do

Teacher’s perceptions of the supportive roles of technology for instruction influence the teacher’s use of software. Since the time when technologies such as chalk and chalkboards supplemented the teacher as aides to instruction, every new form of technology has made teaching and learning potentially easier and more effective in schools. Books, films, and television allowed the students access to knowledge that previously had only been available from teacher talk. Because educators’ dominant concepts of schooling focuses on the telling and accrual of knowledge (Cohen, 1988; McDiarmid, Ball, & Anderson, 1989), teachers are seduced into thinking that if the book/television/computer presents the information, their work as teachers is finished. Rarely do teachers focus classrooms on either metacognitive strategies or the application, analysis, evaluation and synthesis of knowledge.

One of the most confusing half-truths about technology, is the belief that computers are necessarily educational. Often children are just entertained with the sensory motor exploration of programs which flash colorful images, respond to their mouse clicking, beep, boom, and talk to them. Children often thrive on the fast-paced action they can get the computer to perform, but little else is learned. In the following vignette we see Josef, a three-year-old, who for three weeks finds Reading Blaster (Davidson, 1992) his favorite program, but learns very little. He seems to roam from one section to another randomly satisfying his need to be entertained but not apparently learning much more than the rudimentary mechanics of how a computer works. A typical session on Reading Blaster is as follows:

Josef launches Reading Blaster, where the evil space witch Illiteri threatens to take all the words in the world. He finds himself looking out of a space ship into space where letters come flying out at him. Using the mouse Josef clicks on the letters, exploding them. On the screen there is a word written with a missing letter which the user is asked to shoot, but Josef is content to just shoot at letters regardless of whether they fit in the designated word or not. A monster attaches itself to the spaceship, sucking out the fuel. Josef clicks on the monster, clicks on some spaceship buttons, but nothing changes.

The spaceship runs out of fuel and the program returns to a main menu. Josef finds his way into a multilevel maze where he is supposed to read clues and move characters, allowing him to win. He spends five minutes clicking on various pictures and characters which beep and move. Finally, he finds himself in a different maze where he moves and characters chase him. Though the program is designed to test his ability to put words in alphabetical order, he simply moves the character until time runs out and the program moves him to a different section.

Sequences like the one above occur over and over. Josef continues to choose the program, although he has many others to choose from. What seems significant is the apparent willingness of Josef to stay in the program sensing the entertaining noises, movement, and mouse interaction as he clicks constantly. After a period of time in a section of the program, time for that section runs out and he is moved to another section. At one point, he clicks on the monster which attaches itself to the screen, but neither that action nor his clicking on the spaceship control buttons seems to result in any purposeful consequence. He doesn’t know the rules or code (reading), but is nevertheless entertained. To contrast to edutainment where a child’s main goal is to have fun and learn in the process,
this is empty entertainment. Since this program is not in Josef's ZPD and his hand-eye coordination is already good, he learns nothing.

Although this example is extreme, the child's engaged interaction with the program that purports to be educational often satisfies educators who are hoping that prolonged engagement with educational material will result in learning. This 'logic of confidence' in the educability of technology is of course a long-standing one in American education (Cuban, 1986). Teachers have confidence that students doing workbook pages are learning and that simply watching informational videos is educational.

While it is true that people can learn from computers if they already know how to manage and organize information, it is the learner who must use the computer strategically during the process of learning (Reilly, 1992). Computers can present information and even suggest ways of using or organizing information, but it is the learner who must engage the strategies for the learning to have long-lasting effects. In contrast to mature learners, young children employ inefficient learning strategies (Steiert, 1993), and therefore often benefit from the assistance of knowledgeable others to develop strategies for using software as a learning tool (Mehan, 1985).

Past literature in teacher education and technology emphasizes the importance teacher guidance for student success using computers (Brennan, 1991; Charney, Reder & Kusbit, 1990). Teachers can provide a context conducive to using and learning from the computer (Michaels, 1990), strategic models (DeVoogd, 1995), and general metacognitive guidance (Salomon, Globerson, & Guterman, 1989). How technology is used, the functions it serves, and the extent to which it advances educational practice is critical to improving learning (Kulik & Kulik, 1989).

There is a need to be more specific in the teacher education literature concerning the software, contexts, roles, routines, and procedures that help teachers provide a context where students learn strategically. Teacher assistance that is directed toward the child's zone of proximal development is a promising place to begin.

**Teacher's Assistance in the Zone of Proximal Development**

All good educators know that children cannot learn something that is far beyond their ability to comprehend. This insight has even become sloganized as "developmentally appropriate practice." But what a child can do with assistance is not beyond him. According to Vygotsky (1978), the ZPD, or the distance between the child's current functioning and the child's potential functioning, that is, what the child can do with assistance, is the area in which development occurs.

The ZPD has profound implications for education. Currently accepted good practice dictates that teachers match the material they are trying to teach to the child's mental level. But the Vygotskian perspective would argue that this is not the best educational practice. Vygotsky argued that, “This procedure oriented learning toward yesterday’s development” (1978, p. 89). Vygotsky was not alone in his awareness of this problem. For example, a Piagetian perspective would suggest posing problems that are just beyond what the child can do, so the child has to construct a new solution. But Vygotsky is more specific in his prescription of how teachers should proceed; specifically, teachers should determine what a child does on his/her own, and the limits of what the child can do with adult assistance, and then concentrate on what lies in between. By concluding that the child has the potential for those abilities, even if they need help now, it provides a powerful way of working toward a child's potential.

Toward these ends, Vygotsky suggests several types of assistance adults may offer children, in addition to simple teacher demonstration. For example, the teacher might initiate a solution which the child must complete, provide cues, or ask questions that focus the child on a particular path to solution. These are tutorial functions that can also be assumed by a computer program (and which are much superior to the drill and practice frequently offered as tutorial assistance).

Alternately, children may work together to solve a problem (Damon, 1984; Slavin, 1987). This might be thought of in terms of the ZPD, or it might be thought of in terms of the cognitive benefits of reconciling competing perspectives or attempts at problem solution (Mugny & Doise, 1978, Tudge & Rogoff, 1989). Collaborative work on computers is, of course, an especially rich educational context (Newman, Griffin, & Cole, 1989).

**Opportunities and Limitations of Software**

Like any curricular media (books, paper, manipulatives) each piece of software has its particular limitations and opportunities for instruction. Even though one can teach science from a book, it is generally recognized that books limit the possible conceptual growth of children compared to actually doing experiments with science materials. And yet few have examined the limitations of software and the teacher's contribution to children's learning during computer instruction (Samaras, 1996). Different software provides varying opportunities and limitations for strategic learning.

**Interaction of material and user.** Though a minimal requirement for software is that materials be developmentally appropriate for the child, this criteria is at best a limited prescription and useful primarily only to begin to cue the teacher to what materials the student might be able to understand and work with. Regardless of how teachers
or software manufacturers assess the appropriateness of the software, that assessment can only be an approximation unless the evaluator can observe the interaction between the child and the software.

The fact that material is at an appropriate difficulty level for a child of a particular developmental level begs the question of what a child’s possible interest and possible engagement with the software might be. Actually, thinking of the material as a separate entity is somewhat misleading. Although we can analyze the design features of a program, it is more important to examine the interaction between the individual and the program. So, the focus becomes not the features of the program juxtaposed to the features of the learner’s mind, but rather, the interaction between the two. In other words, what does the student make of the material, how is it used and how is it interpreted, and, conversely, how does the material constrain or enable particular thought and action? These are not features of either the material or the individual in isolation, but emerges in the interaction between them.

**Josef Plays with Pooh.** To briefly illustrate the interaction of child and software, we return to Josef, the three year old, using the animated storybook, Winnie the Pooh (Disney Interactive, 1996). During Josef’s interaction with the software, notice both the potential for learning for and possible misconceptions about educational benefits. In the next paragraph, although the text in the storybook is read to Josef, he does not respond to the text, but instead responds to pictures of things.

Josef initially clicked to an illustrated page of text with Pooh, Christopher, and Eeyore. Words in the text were highlighted as they were being read by an off-screen narrator. Though Josef clicked around while the text was being read, the program did not allow any of the other features of the page to work until the text was recited and Christopher’s extra-textual comment was expressed. Finally, when Josef clicked on the door in the tree, Piglet popped out of the door and said, “If you want to play a game with me click on the toys (in the corner of the screen).”

Instead, he clicked on the door again and Tigger popped out, jumping up and down like a pogo stick. He says, “Look, Jack in the box. Jack in the box.” Next, Josef clicked on the balloon, which changed into the shape of Pooh. He smiled, then clicked on the balloon several more times as the balloon changed into the shapes of various characters in the story, smiling all the while.

Note that Josef does not appear interested in the text on the page although it is read and words are highlighted as they are spoken. If the teacher used this program for Josef reasoning that he would learn about the flow of text and the association of written text to spoken text, the teacher might be disappointed. Josef’s action does not imply any such interest or ability. In fact one might conclude that his clicking while the text was being read was an indication of disinterest and lack of engagement in the text.

Instead, Josef appeared to prefer more animated and less abstract symbols by clicking on the balloon and the door in the tree. He is interested and able to understand pictorial representations but not textual ones. He responded to the character coming out of the door by clicking on it again and then saying, “Look, Jack in the box. Jack in the box.” When Josef clicks on the balloon, he responds to the text by smiling and clicking on the balloon repeatedly.

Part of the intended lesson was surely to help the child recognize the relation between written and spoken language. Presumably the software is instructive in this way for some children. But Josef did not spontaneously use the software in a way that would promote this recognition. Perhaps it was simply beyond him, but we do not know this. A responsive teacher could have intervened, using the software with Josef, focusing him on educationally relevant aspects of the software by means of comments and pointing.

Further observation of Josef’s interaction with the software provides additional insights:

Josef clicked on the pile of toys in the lower left corner, which launched the computer into a section where Piglet asks the child to help him find toys he thinks Christopher might like to play with (Figure 1).

**Figure 1.** Piglet tries to find some good toys to bring to Christopher.

Then he gives the viewer clues about what he is looking for. “I’m looking for something that has wheels that is yellow.” Josef clicks on the blocks. Piglet responds with very pleasant intonation, “I’m afraid that’s not it, but keep trying.”

Josef looks at his father and in the same pleasant voice says, “Dad, you say but keep trying, Joe. Dad, you say, but keep trying Joe.” Josef then clicks on the skate.
Finally, Josef clicks on the correct answer (the yellow children are learning, and not simply trust promises on the clear is that teachers have an important role to play, did find unanticipated opportunities for exploration and learner exploration. Cognition and Instruction, 7, 323-342. Cohen, D. (1988). Plus ca change... (paper #182). East Lansing: Michigan State University, National Center for Research on Teacher Education.

Teaching philosophy, computer programs, and collaborative learning are interwoven in scaffolding the development of creativity in young children. Adding technology into the learning environment requires a re-examination of philosophical foundations and restructuring of interactions which are supportive of the desired learning. Early childhood educators generally hold constructivist views and support methodology that facilitates the young learner's creation of meaning. The type of software and hardware available in the eighties led many early childhood educators to avoid significant use of the technology with young children. The nineties provide an expansion of the pool of open-ended software designed to be controlled by the child. This improved technology provides the opportunity for constructivist teachers to utilize computers in ways which are congruent with their own philosophy and to open windows for young children to become involved in the process of creating meaning through this technology.

Creative thinking is critical to higher level thinking and problem solving (Gardner, 1993; Guilford, 1956; MacKinnon, 1964; Torrance, 1962). These skills are demanded for the next century by the SCANS Report (USDL, 1992), are specified in the national goals (Committee on Education and Labor, 1994), and are emphasized in the mandated curriculum in most states. The rapid expansion of open-ended software supporting higher level thinking and problem solving is occurring concurrently with the increased emphasis on these cognitive skills. Studies of cognitive development suggest positive effects of developmentally appropriate computer experiences including increase in: problem solving skills, higher order thinking skills, mathematical reasoning, scientific concept formation, and language development.

In contrast, the computer software most frequently used with young children in school settings is structured in format. Research suggests that structured drill-and-practice software programs do not advance skill and are associated with significant losses of creativity (Char, 1990; Clements, 1991; Clements, Nastasi, & Swaminathan, 1993). Additionally the use of computers with children identified as at-risk for school failure shows promise for intervention. Yet, many schools continue to purchase expensive computer laboratory software and utilize the precious 30 to 45 minutes per week per child in a drill-and-practice modality valuing product as opposed to process. These research insights and field observations led to this current research addressing development of higher level thinking skills of kindergarten boys and girls through utilization of a cooperative learning computer experience utilizing either open-ended or structured software.

**Historical Foundations**

Early in this century the developing computer was seen as a producer of information and persons concerned with computers were ultimately concerned with the products produced. As the technological revolution unfolded, and with spiraling advancements of development and use of this equipment, the computer began the transition between product and process. The growing shift between a behaviorist, product driven orientation to a constructivist philosophy focusing on the process of human interaction exemplifies the product-process paradigm within the technological realm (Clements, Nastasi, & Swaminathan, 1993; Papert, 1992).

In perhaps no other field is the difficulty of this product-process shift as evident as in the field of education. While educational programs are typically designed to provide instructional methods and to assess student ability to assimilate and evaluate information as well as to communicate their knowledge, these programs seldom utilize the information technologies in the same manner as other professions. Technology is now at the center of most business operations, research endeavors, and the arts. Until educators begin to construct programs and curriculum which provide for the use of technology as the basic building block for student-centered construction of knowledge, the use of technology as a product rather than a process will dominate educational practices and philosophy.
In contrast to other professions, education continues to focus on the computer as a support for product-oriented education rather than as a tool to explore the process of higher level thinking (Mehlinger, 1996). The evolution of this process orientation requires not only the appropriate equipment and software but also the preparation of those who structure the computer experience and integrate these tools into the established curriculum (Withrow, 1990).

**Early Childhood Perspectives**

Early childhood researchers of the 1980s (Brady & Hill, 1984) argued against use of computers with young children citing the danger of the abstract nature of the computer environment being used by children who had not yet reached concrete operations. More recent research suggests that young children can benefit from developmentally appropriate use of computers within a meaningful context (Char, 1990; Clements & Nastasi, 1992; Clements, Nastasi, & Swaminathan, 1993) prior to concrete operations. Open-ended, unstructured software supportive of higher level thinking provides technical tools to support this philosophy and gives birth to a technology creativity triad in which teachers, technology, and collaborative learning are work together to provide the best possible computer learning environment for young learners.

**Teacher Roles.** Teachers must be prepared to select software that: matches the developmental age of the child; offers child control and choice; and provides the opportunity for use of higher level thinking skills, reflective thought processing, and the development of creativity. Various studies contribute to identifying the criteria from which to define developmentally appropriate software, establish methods for selection, and design the computer experience. Since children generally respond positively to use of the computer, it is vital that the teacher provide the discrimination in selecting the most appropriate software.

Concurrently, research has examined the roles of cooperative learning activities and of mediated instruction in enhancing higher order thinking and problem solving. Use of mediated instruction during the cooperative, open-ended computer experiences has been supported by Pogrow (1990). Since computers offer visual, tactile, and listening modalities, students can learn through whichever modality they prefer. They can test their own ideas privately and at their own speed. They receive immediate feedback and teachers can engage them in thinking about whether the results were their expectation or not. Socratic questioning techniques during a cooperative learning experience offers a firm foundation for structuring technology use with young children.

**Technology Choices.** Identification and selection of appropriate software is a critical issue to be addressed in teacher education. According to Haughland and Shade (1990), the type of software chosen by adults for the children to use is the key to developmentally appropriate experiences. It is important to keep the question in perspective since only twenty percent of all software available for young children provides this type of learning environment. On the other hand, the software used most frequently in school settings is structured despite research evidence that this type of software does not advance higher level thinking skills and is not supportive of early childhood philosophy (Char, 1990; Clements & Nastasi, 1992; Clements, Nastasi, & Swaminathan, 1993).

The choices made by teachers must be congruent with their philosophies and support the complexities of cognitive development of young children. The design of computer environments, must be governed by structuring technological experiences for young children which allow them to use their own questions to guide their building of knowledge through the transformation capability of the computer (Scardamalia & Bereiter, 1991). Studies suggest that it is this capability of technology that aids learners to elaborate their mental models and correct previous misconceptions. “Computers also have the capability of creating dynamic, symbolic representations of nonconcrete, formal constructs that are frequently missing in the mental models for novices” (Kozma, 1991, p. 197).

**Cooperative Learning.** Extensive research has linked higher-order thinking behaviors to interactions with appropriate computer programs as well as to use of cooperative learning principles and adult scaffolding of technology experiences. This link between higher-order thinking and use of computers provides a significant intervention for at-risk children and offers support of individual learning differences. Providing for individual differences through cooperative learning and the development of creativity involves the structuring of the computer learning environment design so that students work together toward a common goal (Nastasi & Clements, 1991). Students should be provided with the opportunity to experiences another individual’s perspective which in turn may scaffold their experience so that they might reach a new level of development (Bowman, 1990). Teachers need to play with their own ideas regarding the use of computers to promote deep, meaningful, cooperative, and creative learning (Clements, 1995a).
control group. Additionally, this experimental study explored the possible differences in performance between students designated at-risk by the school district and classmates not so designated.

Procedures

The four dimensions of the Torrance Test of Creative Thinking (TTCT), fluency, flexibility, originality, and elaboration, plus the criteria of abstractedness and thirteen criterion-referenced indicators were the dependent variables upon which the effects of different types of computer experience were measured. The sample was pretested and posttested for this 15-week study utilizing the verbal and figural tests of this creativity measure in Form A and in Form B. A two-way analysis of co-variance (ANCOVA) was used to compare the adjusted posttest mean scores between the groups and to examine the at-risk variable. Three hypotheses relating to figural creativity measures and three hypotheses pertaining to verbal creativity measures examined the gains by groups, the differences between at-risk students and those not at-risk, and the interaction between the groups by risk status.

Findings

Group I utilizing open-ended software made significant gains in both verbal and figural creativity (fluency, flexibility, and originality) over Group II utilizing the structured software and Group III, the control group. There were no significant differences in the adjusted posttest mean scores of figurative creativity, and no significant interactions among the groups by risk status.

Group II evidenced statistically significant gains in both verbal and figural creativity (fluency, flexibility, and originality) compared to Group III, the control group. No significant differences were identified between at-risk and not-at-risk groups, and no significant interactions were identified among the groups and risk status.

Conclusions

Conclusions drawn from this study provide insight concerning factors significantly influencing the education of young children through the use of technology. The technology explosion offers new approaches and support for teaching higher level thinking and provides a scaffold for the development of creativity. Additionally, the impact of open-ended software on creativity provides an important question for continued research exploration. These implications coupled with the advantages of using a variety of software within a cooperative education learning structure for young learners during a computer experience cannot be overlooked. Designing a technology program based on the theoretical tenets and philosophies of developmentally appropriate practice, cooperative learning, and the higher level thinking skills used in creative endeavors has been proven to be an important factor in early childhood education (Clements, 1986, 1987a, 1991).

In spite of the supporting research, many educators have been hesitant in implementing such a program in the area of technology. While many school districts pay credence to developing creativity through developmentally appropriate programs, few districts are actually implementing a technology program which is truly integrated and attempts to educate the "whole child."

This lack of implementation is not linked to lack of concern for the young child, but relates directly to the societal and political pressure felt in many of today's classrooms. This type of pressure still dictates the manner of educational assessment, a standardized test. Teachers of young children are, in many cases, held accountable for the scores produced on these types of tests. Unfortunately, many teachers are afraid to switch from computer programs and methods of using technology designed to facilitate the test, to a more developmental approach using computer programs that do not provide daily practice on similar test items. The use of technology within the school setting falls prey to the fear of utilizing this expensive equipment in a manner which may not provide instant proof that mastery of specific skills has taken place.

However, switching from a traditional use of technology to a model which reflects the tenets of developmentally appropriate practice, cooperative education and development of creativity should not cause teachers to fear the impact on standardized testing. The critical findings in this study clearly indicate that students participating in a "newer model" of technology use which provides a foundation from developmentally appropriate practices and cooperative education make strong gains in development of creativity which impacts higher level thinking skills. The development of higher level thinking skills in turn has a direct impact on performance on standardized tests. The practice of implementing technology use with young children in a highly structured and controlled manner in order to build the foundation for increased test scores should be eliminated. While the standardized test may still exist as a reality for many teachers, this does not need to be the impetus for the manner in which time at the computer is structured for young children.

The "old model" of technology where one child works in isolation on highly controlled computer programs gives little opportunity for problem solving situations to arise or to be created by children working together within a computer environment. As this research suggests, a variety of software, both structured and open-ended, can influence development of creativity as long as students are allowed to engage in computer experiences which are reflective and supportive of problem-solving situations. As shown in the test results of verbal creativity, Group I, which engaged in open-ended software, was found to make statistically significant gains in all three verbal creativity measures.
when compared to either structured software Group II or the control Group III.

More surprisingly, is the result that the structured software Group II was found to make statistically significant gains in all three verbal creativity measures when compared to Control Group III. This finding attests to the power of the structure in which children work together at the computer. No longer is it relevant to think that each child needs their own computer. Rather, it is in the group discussion of various ways in which to manipulate the structured software in order to allow more user choice which can increase development of verbal creativity. While most students appeared to be more motivated and engaged for longer periods of time on the open-ended software, the structured software offered motivation to students to practice basic skill development in a group setting.

With continuing emphasis on developmentally appropriate practice from early childhood professional organizations and the emergence of technology as an acceptable medium for young children’s explorations, more teachers are beginning to implement the “new model” of technology described in this study. Many teachers are beginning to refine their computer skills and knowledge of appropriate software for young children, incorporating additional factors such as cooperative education, and integrated curriculum within the manner in which computers are utilized in their classrooms. Hopefully, through the actions of professional early childhood teachers and organizations, many districts will begin to see the inappropriateness of utilizing technology as a tutor for standardized testing. Until then, early childhood educators can begin and continue to implement “new models” of technology that are appropriate for young children, and feel secure that allowing children to explore these intriguing environments will increase higher level thinking skills.

**Recommendations**

The results of this study provides several recommendations for educators in the field of early childhood education. Given the current research in the area of using technology with young children, it is clear that a recommendation be made to educators to begin implementing a “new model” of technology use such as the one described in this study. With contemporary society involved in a continually shifting paradigm, it becomes necessary for education to supply a working environment in which children become immersed as they seek to solve problems. Technology programs designed to help children build higher level thinking skills should be based on the current research and the philosophical tenets of developmentally appropriate practice which support the growth of the “whole” child, not merely constructed to increase achievement on standardized testing.

The classroom should reflect the changing world at large in which children come to learn how to become part of the larger society in a positive manner. Through involvement with all tools, including technological environments, children engage in learning and experience growth in the psychological, socioemotional, cultural, and scholastic components of their development. When the additional factor of recognizing and providing for cooperative experiences within the motivating realm of a computer experience, students begin to understand their own strengths and preferences and recognize the similar and differing strengths and preferences of others. Thus, through these provisions, teachers have begun to facilitate an empowerment process internal to the individual student who can then become responsible for their own learning. Such intrinsic motivation for a student to develop their optimal growth does not come from extrinsic motivation as exists in the “teach the skills, drill the skills, and test the skills theory.” Educators are encouraged to look at the type of technology programs supplied in early childhood classrooms, and judge their effectiveness based on the knowledge gained through research of technology use and young children and the philosophy of developmentally appropriate practice.

An examination of the use of technology within its societal context should be addressed. The argument that children should be exposed to computers now in order to prepare them for their future is no longer adequate. The computers of the future will have little in common with the computers of today. Artificial intelligence and sophisticated computer interfaces will make keyboarding skills and “computer literacy” courses obsolete. Appropriate programs which provide for young children to become engaged with technology should be designed to empower students to develop the type of higher level thinking and problem solving skills which will be necessary to understand and work with the computer systems of tomorrow. When such programs are put into place, children are provided with the capabilities and motivation to successfully work with and invent the technological advances in the 21st century.

Many young children have problems employing cognitive strategies correctly in math. Lindquist (1987) points out how discouraging it is to watch second graders struggle with elementary problems such as, Mary has 6 apples. Burt has 3 apples. How many more apples does Mary have than Burt? A second common problem occurs when nine-year-olds reverse in subtraction, for example 450 - 168 = 318. The children’s strategy is to subtract the smaller number from the larger. Often children don’t realize that 450 and 168 are only two numbers of three digits each one. In addition to poor cognitive strategy employment, young children experience problems learning basic math skills (e.g., counting, numbering, sorting, grouping). Although is common for those in education to attribute these problems to learning disability, we argue that most of these problems could be explained by a lack of appropriate math problem-solving models.

Children usually learn to count or to add by watching how the teacher solves a problem on the blackboard and then solving some exercises themselves in workbooks. Teachers explain the process of solution of any math task using words, symbols and gestures. Probably, they are the best facilitators of solving models but they can only offer them for a short period of time because, usually, there are too many children in the classroom and all of them ask for the teacher’s attention.

The workbook, in contrast is more accessible for all children in the classroom. Children look at the numbers, symbols, graphics and signs to learn to solve, for example, an addition problem, but all these things are displayed on a static media: the pages of the book. Workbooks cannot include sound or animation. They can’t reinforce the performance of the student to maintain his/her attention and they do not inform children on how well they are doing the exercises. Mainly and most importantly they do not model the procedure of solving math problems.

**VISPRO.Cálcul**

All these limitations can be overcome with the computers and multimedia technology. Computers can offer dynamic models of math problem resolution and can so repeatedly. They have the capability of politely and explicitly describing problem-solving strategies using sound, images which explicitly teaches problem-solving strategies more effectively than instruction that relies only on memorization of isolated facts (Steinberg, 1985; Thornton, Jones and Toohey, 1983).

We have developed an interactive multimedia software with SuperCard® to teach basic math skills. This software shares a philosophical background with the VISPRO.Grafies (Bornas, Servera, & Llabrés, 1996a; 1996b). With our program, dynamic models are displayed on the screen and children learn how to solve math problems by visualizing the processes involved in the calculating operations. VISPRO.Cálcul is easy to use, flexible and open. Every teacher may adapt the program to his/her classroom. The program itself allows changing the displayed pictures, the displaying speed, the number of example-cards, and the complexity of the exercises.

The application includes six modules with a similar structure. First, some models are displayed showing a basic calculating process. The importance of imitation as a learning procedure has been long recognized since Albert Bandura (1977; 1986) developed a technology of imitation. For example, the computer could show the process of adding in this way: first, two apples are selected with a circle and moved into a basket; then three other apples are taken and moved into the basket. Finally the apples are counted and a number appears near each one: 1, 2, 3, 4 and 5, so five apples are into the basket.

Secondly, children practice with some exercises related with the examples. Each card-exercise has a help button...
that shows the dynamic model again if necessary. These modules are sorted by their complexity. They are:

a. series,
b. counting,
c. adding I,
d. tens,
e. adding II (including tens), and
f. subtracting.

The first module focuses on the concept of series. The computer will show how to make up a sequence of shapes (e.g. yellow rectangle, green triangle, blue circle) or figures (e.g. cat, dog, fish). When the child clicks on one of such sequences or series the program begins to construct it by placing the first figure at the top left corner of the screen, the second one beside, and the third one on the right side of it. The program draws a line under the three figures so that children realize that this sequence has the same figures as the model sequence and that the figures follow the same order (e.g. cat - dog - fish). After a few moments another cat-dog-fish sequence is coming up on the computer’s screen, and the program repeats the process until the page is full. Some cards of this module allow children to choose which figures will appear in the sequence before it is constructed. The Series module helps children to learn concepts like before and after or on the left and on the right side of something.

The second module is about another essential skill, counting. In spite of its simplicity, to count things requires a process and this module shows this process to the young children who are learning this skill. The program show, for example, five turtles on the left side of the computer’s screen and the numbers one to nine on the right side. The first thing the program will do is to group the five turtles by drawing a circle around them so that all of them are into the circle. Then the program assigns a number to each turtle which appears next to the figure: 1, 2, 3, 4, and 5. Finally the program draws a line from the circle to the number five on the right side of the screen and highlights it. In addition to the modelling cards where children can see these processes, the counting module includes counting exercises. In these cards the child has to click the button that holds the correct number of figures shown on the computer’s screen (there are always nine buttons with numbers one to nine).

The Adding-1 module is the third section of the VISPRO.Calcul program. This module shows the process of adding up to ten things. There are exercises and modeling cards. When doing exercises children have to click the number that represents the correct result of the adding. If the answer is correct, the program displays a new exercise card. If not, the program gives appropriate feedback and prompts the child to try again. There is a help button in all of the exercises cards. When the child clicks this button, the program takes the child to the modeling card where the adding process is shown slowly. The card shows some figures (e.g. three flowers), the plus sign (+), some more flowers, and the equals sign (=). The process is as follows: the program counts how many flowers are in the first group and writes the numbers one, two and three beside each flower. Then the three flowers are moved to the right side of the equal sign and the number three appears into a field below the figures. The program repeats this process with the second group of flowers, it places the plus sign and the new number after the same field. When all the flowers are in the right side of the equal sign the program counts the flowers (writing the numbers beside the flowers) and then puts the equal sign and the total number after the field.

The next module refers to the concept often showing that numbers from 11 to 19 can be divided into a group of ten and numbers one to nine such as 15 = 10 + 5. This program shows how to add, for example, 12 and 5 birds making one group of ten birds and adding to this group the remaining 7 birds: 12 + 5 = 10 + 7 = 17 birds. While in the Adding-1 module the additions where displayed horizontally, in this module numbers are displayed vertically.

Adding-2 is the fifth module of the program and it shows the type of adding exercises that children will find very often in their school workbooks. This module does not present moving figures. It emphasizes the adding strategy and it focuses the child’s attention to the most important issues of this strategy:

1. Start with the right column;
2. Do not forget adding; and,
3. In the next column if the first result is greater than ten, write the numbers in the correct place (aligned with the corresponding column).

The last module, Subtracting, has a structure very similar to that of the Adding-1 module. The modeling cards display the process of subtracting as follows:

1. The program counts how many objects are in a group;
2. Then it puts a mark beside the objects to subtract and counts the numbers;
3. The marked objects are eliminated and the others are counted; and,
4. At the exercise cards children have to eliminate objects, count the remaining ones, and write the result of the subtracting calculation.

As in other modules, if the answer is correct, the program displays a new exercise card. If not, the program gives appropriate feedback and prompts the child to try again.

In our opinion, teachers might use this interactive program as a resource to facilitate the acquisition of basic math skills, as well as a means of preventing or correcting the problems they normally find in this area. Impulsive
children, who usually do not pay attention to the teacher’s explanations to the whole class, would benefit from this software because they just need to pay attention for a short period of time to the computer’s screen. We know, however, that this empirical question requires experimental research to test the efficacy of the software. Presently, we are carrying out some studies with it and the preliminary results are very interesting which we hope to present at SITE ‘97.

1368 — Technology and Teacher Education Annual — 1997

1371
The reconceptualization of the teaching of mathematics in the past decade has focused on mathematics as “the science of patterns” (Schoenfeld, 1992). If mathematics is indeed the science of patterns, then teaching young children to identify and construct patterns may be the first goal of early childhood mathematics education. To achieve this goal, teachers need to have effective and inexpensive tools to help students seek and construct patterns and order out of chaos. Though software programs could be effective in achieving that goal, quality software is difficult to find (Shank & Edelson, 1989/90) and prohibitively expensive. Some teachers have started to construct their own software out of a desire to use the computer effectively. The purpose of this study was to assess the efficacy of teacher-made software designed to teach first grade students to recognize and construct patterns.

Since Piaget’s (1954) seminal work, researchers have recognized that mathematical thinking in young children starts with concrete physical manipulatives. As children mature into adolescence, they may abandon the concrete objects and think mathematically in a purely abstract way. Using computers, one may move beyond the level of physical manipulatives without moving directly into the abstract realm. A computer can allow children to make symbolic visual representation (cybernetic manipulatives) of concrete objects and manipulate those objects as an intermediary step toward abstraction. In fact, for some children below the age of abstract thought, cybernetic manipulatives may supplant the need for concrete manipulatives entirely. Thompson and Thompson (1990) found that average and above-average performing fourth graders using cybernetic manipulatives developed a deeper understanding of the number system and its algorithms than did peers who employed concrete manipulatives; among the weakest students, the groups did not differ.

One advantage to employing cybernetic manipulatives is the computer’s ability to capture and store learning actions. For young children, the ability to capture and store a learning action on disk and also on paper allows affords the opportunity to engage in mathematical discourse with the teacher at a later time. Teacher-student discourse is essential to learning mathematics and at the heart of learning heuristics and metacognition (Mead, 1943; Resnick, 1988; Rogoff & Lave, 1984; Schoenfeld, 1992; Vygotsky, 1978).

The potential for cybernetic manipulatives to assist young children in their thinking about patterns combined with the need for inexpensive software led us to ask our first research question: Will engaging in teacher-made cybernetic manipulative activities increase first-graders’ ability to construct and recognize patterns? We hypothesized that it would. Our second question was whether the intervention would affect higher and lower scoring students to the same degree. We had no reason to suggest that our findings would differ from those of Thompson and Thompson (1990).

Method

Design

The design of our study was a two-group post-test only design.

Participants

Participants in the study were 29 first grade students in a new lab school associated with a mid-sized university in North Texas. The students were randomly assigned to two first grade classes. The control class consisted of 5 boys and 10 girls; the experimental class consisted of 8 boys and 6 girls. Although the school was located in a new subdivision, a number of students in each class were bussed in from a low-income area.

The teachers of the two classes were both veterans who had applied to teach at the new school and been accepted over many other applicants. Those selected to teach at the new school made a commitment to the use of cutting edge technology in their classrooms. The study took place during September and October of the first year of the school’s existence. Each classroom had three computers available to children in addition to the teacher’s computer.
In addition, the first grade and kindergarten classrooms were built around a pod which held four additional computers which were available to the children.

**Treatment**

The treatment was developed by the second investigator who was the teacher of the experimental group. The treatment consisted of having students manipulate teacher-made and student-made cybernetic manipulatives. The cybernetic manipulatives were constructed on a draw document; the medium was inert, and the computer imposed neither constraint nor support structures on the participant. (For a discussion of interactive as opposed to inert media and constraint and support structures, see Kaput, 1992.)

On some activities, the draw document had a pattern started on the bottom half. On the top half of the document was a pool of cybernetic manipulatives which could be used to complete the pattern on the bottom half. On these activities, participants were directed to recognize and complete the pattern by clicking on the desired manipulatives in the pool and dragging them to their appropriate places in the pattern.

On other activities, the pool of manipulatives was at the top of the document, but there was no pattern started on the bottom of the document. Participants were directed to click and drag the manipulatives to construct a pattern of their choice. In still other activities, participants were directed to construct their own cybernetic manipulatives with which to create their own patterns.

The first activity in the treatment consisted of having the children use five red circles and five blue circles as cybernetic manipulatives with which to make a design. In the next activity, red and blue rectangles were added to the circles. In activity three, triangles were added. The activities became increasingly complex and ended with circles. In activity three, triangles were added. The computer imposed neither constraint nor support structures on the participant. (For a discussion of interactive as opposed to inert media and constraint and support structures, see Kaput, 1992.)

On some activities, the draw document had a pattern started on the bottom half. On the top half of the document was a pool of cybernetic manipulatives which could be used to complete the pattern on the bottom half. On these activities, participants were directed to recognize and complete the pattern by clicking on the desired manipulatives in the pool and dragging them to their appropriate places in the pattern.

On other activities, the pool of manipulatives was at the top of the document, but there was no pattern started on the bottom of the document. Participants were directed to click and drag the manipulatives to construct a pattern of their choice. In still other activities, participants were directed to construct their own cybernetic manipulatives with which to create their own patterns.

The first activity in the treatment consisted of having the children use five red circles and five blue circles as cybernetic manipulatives with which to make a design. In the next activity, red and blue rectangles were added to the circles. In activity three, triangles were added. The activities became increasingly complex and ended with patterns of numbers and number families, e.g. 4 + 2, 2+ 4. The last activity consisted of number patterns: 3—4, 4—5, 5—6. Both the experimental and control groups studied pattern recognition and construction in traditional ways.

**Instrument**

Our instrument was a worksheet consisting of numerals in patterns which the students were to continue. The patterns were ones to which the children had not been exposed previously.

We gave full credit of 5 points for each missing numeral that a participant supplied that indicated that the participant recognized a pattern within the provided information and continued that pattern. However, we discovered that some students simply started the pattern over rather than continuing it. That suggested to us that children did not recognize the pattern within the provided information, but knew that repeating the information given would constitute a pattern. Therefore, we gave credit of 1 point for each numeral supplied in such a manner. Incorrect responses were scored 0. A total score of 45 was possible.

**Procedures**

The assessment was conducted by the senior researcher. Before the instrument was distributed, participants placed a cardboard shield around their desk in order to ensure that each child's answers were her own. Participants were then given a copy of the instrument and directed to complete the worksheet doing their best. Students who raised their hands to ask for assistance were told that they could not receive any help and to try their best.

During each class's assessment, the participants' teacher was in the room. The senior investigator was known to the children because she is field coordinator and scholar-in-residence at the school. In that capacity, she had visited the classrooms of the participating children.

**Results**

First, we subjected the groups' scores to a 1-tailed t-test of independent samples. The groups differed at p=.06. The mean of the experimental group was 17.5 (SD=12.6; SEM=3.4); the mean of the control group was 11.4 (SD=11.4; SEM=1.9).

In order to determine whether the difference between the groups in the number of boys and girls biased the outcome, we then subjected gender to a 2-tailed t-test of independent samples. The groups did not differ (p=.85). Males had a mean score of 14.8 (SD=11.5; SEM=3.2) and females had a mean score of 14 (SD=10.1; SEM=2.5).

Next, in order to determine whether there were an interaction between treatment and gender, we subjected the scores to a 2-factor analysis of variance (ANOVA). There was no difference across the groups (p=.64).

Next, we subjected the 7 lowest scores in each group to a 2-tailed t-test for independent samples. The groups did not differ (p=.54). The experimental group had a mean score of 7.3 (SD=5.8; SEM=2.2) and the control group had a mean score of 5.7 (SD=3.5; SEM=1.3).

We then subjected the 7 highest scores in the experimental group and the 8 highest scores in the control group to a 1-tailed t-test for independent samples. The groups differed at a statistically significant level (p=.005). The experimental group had a mean score of 27.7 (SD=8.3; SEM=8.3) and the control group had a mean score of 16.4 (SD=6.2; SEM=2.3).

**Discussion**

Our results suggest that inert cybernetic manipulative activities which are constraint and support-free can increase young children's ability to recognize and construct patterns. Furthermore, the activities appear to be a powerful tool when employed with students who score on the assessment place them in the top half of the class.
However, students whose scores place them in the bottom half of the class do not appear to benefit from the intervention.

Although participants’ scoring in the top half of the class on the assessment does not assure they are among the top half of the class in intelligence, it may be that the higher-scoring students tend to be the more intelligent children. Such an argument has a great deal of intuitive appeal. If indeed that is the case, then it may be that because cybernetic manipulatives represent an intermediary step between the use of concrete manipulatives and pure mental representation, one must function well within the concrete operational stage in order to benefit from them. Children who are six years of age but who are developmentally in the bottom half of their class may still be in the preoperational rather than the concrete operational stage and therefore developmentally unequipped to benefit from manipulating cybernetic representations of concrete objects. It may be that they are even developmentally unequipped to recognize and create patterns by manipulating concrete objects. If that is the case, then perhaps when the children in the bottom half of the class reach the developmental stage of concrete operational thought, they will then show gains when exposed to cybernetic manipulatives. Future research in this area may provide useful information.

Our study has a number of problems. First, although the students were assigned to the classes at random, it may be that the groups were not equivalent in their thinking about patterns before the treatment was implemented. Because we did not conduct a pretest, the issue remains unclear; we did not conduct a pretest because the treatment did not start out as a research project. The second investigator developed and implemented the treatment as a normal part of her classroom teaching. When the senior investigator observed in her class, the second investigator shared that she had invented the treatment and that she was delighted with the results that she was observing. The senior investigator suggested that they collaborate to assess the treatment, and the formal investigation began. In the coming academic year, we plan to replicate the study using a two-group pretest-post test design.

The second problem involves time spent on the study of patterns. Although the teachers have identical schedules, it may be that they differed on the number of times during the day that they talked about patterns in classes other than mathematics. For example, during language arts, science, or social studies, the teachers may have differed in the frequency with which they had the children note patterns embedded in their activities. In order to address this problem in future research, teachers would need to document the frequency with which they engaged in helping children recognize patterns in classes other than mathematics.

A third problem also concerns time. Because the cybernetic manipulatives were available to the children in the experimental group during free periods, it may be that the added amount of time in which they were engaged in thinking about patterns, rather than the cybernetic manipulatives themselves, caused the improvement in scores. It also may be that only the children in the top half of the class in the experimental group elected to use the cybernetic manipulatives during free time; children in the lower half of the class may have preferred other types of free-time activities. Therefore the length and frequency of exposure to the treatment may differ drastically between the high and low scoring students in the experimental group. Controlling access to the treatment for a limited time may yield useful information in future investigations.

Acknowledgments

The authors wish to thank the Gordon T. and Ellen West Foundation for their generous ongoing support of this and other research at the Gordon T. and Ellen West Division of Education at Midwestern State University, and of all research at West Foundation Elementary School.

1374 — Technology and Teacher Education Annual — 1997

ERIC
Journal of Technology and Teacher Education

EDITORS
JERRY WILLIS (University of Houston) and DEE ANNA WILLIS (University of Houston)

ASSOCIATE EDITORS
HOWARD BUDIN (Columbia University, USA), DORIS M. CAREY (University of Colorado-Colorado Springs, USA), NIKKI DAVIS, (Exeter University, UK), HELEN HARRINGTON (University of Michigan, USA), D. LAMONT JOHNSON, (University of Nevada-Reno, USA), CLEBORNE D. MADDUX (University of Nevada-Reno, USA), BRENT ROBINSON, (Cambridge University, UK), ALEXEI SEMENOV, (Institute for Advanced Technologies, Russia), and ANDRIA P. TROUTMAN (University of South Florida, USA)

JOURNAL OF TEACHER AND TEACHER EDUCATION (JTATE) is an international quarterly that serves as a forum for the exchange of knowledge about the use of information technology in teacher education. Information technology is defined broadly and includes the theories, concepts and strategies involved in professional education as well as relevant hardware and software. The content of this peer-reviewed journal covers preservice teacher education, inservice teacher education, graduate programs, and staff development in areas such as curriculum and instruction, educational administration, instructional technology, and educational computing for all disciplines. JTATE is the official journal of the Society for Technology and Teacher Education.

Article Topics
Topics, as they pertain to information technology and teacher education, include but are not limited to:
* Inservice and Graduate Programs
* Integration into Methods Courses
* Issues and Theory
* Instructional Design and Authoring
* Research
* Multimedia/Hypermedia
* Management and Projects
* Preservice Teacher Education
* Telecommunications

Contributions
Please send four copies of your manuscript in APA format to the AACE office (see address below). Journal contributions may take the form of:
* Research papers
* Case studies
* Experimental studies
* Tutorials
* Review papers
* Courseware experiences
* Qualitative studies
* Viewpoints

Society for Information Technology and Teacher Education (SITE)
The primary purpose of SITE, a society of the Association for the Advancement of Computing in Education (AACE), is to foster the exchange of knowledge about the use of information technology in teacher education. This includes theoretical research and professional practice knowledge. SITE deals with technology as a topic in teacher education as well as technology as a vehicle for teaching other topics. Subscribers of JTATE automatically become members of SITE. Through AACE, the Society also sponsors an annual conference and publishes the Technology and Teacher Education Annual.

Annual subscription & membership: $65 (non-U.S. add $10 postage; U.S. funds/bank)

For further information on the Society or other AACE divisions and publications, contact:
AACE, P.O. Box 2966, Charlottesville, VA 22902 USA
804-973-3987; Fax: 804-978-7449; E-mail: AACE@virginia.edu; http://aace.virginia.edu/aace
NOTICE

REPRODUCTION BASIS

This document is covered by a signed “Reproduction Release (Blanket)” form (on file within the ERIC system), encompassing all or classes of documents from its source organization and, therefore, does not require a “Specific Document” Release form.

This document is Federally-funded, or carries its own permission to reproduce, or is otherwise in the public domain and, therefore, may be reproduced by ERIC without a signed Reproduction Release form (either “Specific Document” or “Blanket”).
