ABSTRACT

The 370 conference papers on information technology and teacher education are presented in two volumes. The 183 papers in the first volume include the following topics: use and evaluation of educational software; preservice and inservice training issues; multimedia portfolios; distance education; diversity and international perspectives; the educational computing course; educational leadership; faculty development; graduate and inservice education; instructional design; instructional innovation; international programs; Mathematics Education; multimedia materials; preservice teacher education; special needs students; Teaching Methods; Telecommunications; Training.

The 187 papers in the second volume address the following topics: preservice teacher education; reading, language arts and literacy; technology applications in research; science; computer simulations; social studies; technology-assisted instruction for special needs students; technology diffusion in elementary, secondary and postsecondary institutions; graduate, preservice, inservice and faculty use of telecommunications; telecommunications systems and services; educational theory; and technology use with young children. The papers are divided into sections according to topic, and an introduction to, and summary of papers is presented at the beginning of each section. An author index is also included in this volume. To Brent Robinson

This Annual is dedicated to the memory of Brent Robinson of Cambridge University, whose enthusiasm and energy went far in making the Technology and Teacher Education Conference, the Annual, and the Journal of Technology and Teacher Education a success. Brent died in September of 1996 and he will be sorely missed. It is difficult to write this dedication to him because he influenced the field in so many ways. He was a scholar who made significant contributions to the literature on technology and teacher education. His papers and his presentations were given careful attention because he had important things to say that went beyond the surface. His "Cambridge model" of technology infusion in teacher education, for example, has been used as a model by programs around the world. Brent was also an outstanding editor and mentor. As the founding editor of the Journal of Information Technology for Teacher Education, he established that journal as a seminal resource and, at the same time, encouraged and mentored many teacher educators who had important things to say but who were still maturing as writers and scholars. His kind and gentle approach encouraged and, at the same time, set goals for important legacy whose personality and style are in great part a reflection of Brent was not, however, always kind and gentle. He believed in and practiced the type of combative intellectual discourse that he saw as one of the critical ingredients of "the Cambridge experience". I spent many hours in hot debate with him, as did quite a few other members of SITE. For example, on a long drive from Houston to Lohn, Texas, we debated the implications of several options for the organizational structure of SITE. When I travel that road now I still associate places with the particular points being made in the discussion. To those who are accustomed to strong debate being a sign of individuals who have closed their minds to alternative positions, Brent was a little hard to understand. That is because he did change his mind when presented with what he considered superior arguments. He, of course, expected you to change as well if serious flaws in your position were revealed. My own debates with Brent, on topics ranging from semiotics to technology integration to religion and politics, had more impact on me than any other experience I have had. And, after Brent's death, several other people made the same comments. His conversations had impact.

Brent was not, however, always kind and gentle. He believed in and practiced the type of combative intellectual discourse that he saw as one of the critical ingredients of "the Cambridge experience". I spent many hours in hot debate with him, as did quite a few other members of SITE. For example, on a long drive from Houston to Lohn, Texas, we debated the implications of several options for the organizational structure of SITE. When I travel that road now I still associate places with the particular points being made in the discussion. To those who are accustomed to strong debate being a sign of individuals who have closed their minds to alternative positions, Brent was a little hard to understand. That is because he did change his mind when presented with what he considered superior arguments. He, of course, expected you to change as well if serious flaws in your position were revealed. My own debates with Brent, on topics ranging from semiotics to technology integration to religion and politics, had more impact on me than any other experience I have had. And, after Brent's death, several other people made the same comments. His conversations had impact.

He influenced both of students and professors. In the summer of 1996, Brent taught a short course at Cambridge for a group of graduate students from the University of Houston. His influence on that group was far more significant than was typical of someone who taught a single course in their program. That was in part because of his style of teaching, which draws students in and makes them a part of the discussion, and in part because he was a broadly trained scholar who both understood and could communicate the interconnections between different special areas of knowledge. It was also because Brent liked people. He enjoyed them and he enjoyed working with others. The Houston students remember particularly Brent taking them on a cruise down the River Ouse. He equipped his boat with sterling provisions, from beer to strawberries, and as they motored from one historic pub to the next, he told stories about the history of the Fens, the area of England he loved.

There were also two other sides to Brent. One was his gregarious, hard drinking, social side. Brent was frequently a center of attention at social events associated with...
conferences. Many people at both SITE and the ITTE (Information Technology for Teacher Education) conference in the UK spent productive and entertaining hours in bars and pubs with Brent, who managed to keep up his part, and more, of stimulating conversations while drinking an amazing amount of liquor. Many of the lasting memories of Brent are from informal contacts. In the months before his death Brent resolved to drink much less, and when he gave the Houston students a fascinating guided tour of Cambridge pubs last summer, he drank non-alcoholic brews.

The last side of Brent I would like to celebrate was his international interests. Brent believed the issue of technology preparation for teachers was a critical one, and he devoted much of his time to encouraging and supporting international work. He made many trips to Russia and other countries; he worked with colleagues all over the world - from Europe to Africa to Asia and Australia. He had both the will and the energy to make a difference. In this area, he was often a diplomat. He respected the culture and traditions of groups he worked with, he learned from them as well as contributed to their development, and he always sought to bring people together to share solutions as well as problems, differences as well as similarities.

Brent Robinson will be sorely missed in this field. Just before he died, Brent was temporarily living in Houston while he taught a course on change and diffusion at the University of Houston. He took two weeks off for his annual sailing vacation in September and flew back to London. The year before, he and his sailing friends had rented a boat and sailed around the Irish coast. The year before it was Scotland. In 1996, it was to be the south of France. Brent died on the ferry from England to France from what may have been a heart attack. Few people in the field of technology and teacher education, if any, did as much in as many areas as he did. We cannot replace him, but perhaps we can continue to make progress in the areas he felt were important.

Jerry Willis
SITE Founder
The papers in this section are organized around four themes: (1) use and evaluation of educational software; (2) preservice and inservice training issues; (3) multimedia portfolios; and (4) technology in the curriculum. In the first selection, Netiva Caftori of Northeastern Illinois University and Marcin Paprzycki of the University of Texas of the Permian Basin note that there is "...insufficient emphasis on the evaluation of the quality of educational software..." They note, for example, that left unsupervised, children may fail to achieve the learning objectives of a simulation by altering the intended objective. They may do so by choosing to get through the simulation in the shortest period of time instead of exercising all of the features of the simulation. The authors proceed to describe social and educational issues which they assert should be factored into software evaluation criteria and to identify changes in curriculum, classroom management, and teacher preparation that come with increased use of software in the K-12 classroom.

In the second paper, Jan Rader of the University of Mississippi describes two strategies for the use of computer-assisted instruction. In the first approach, Teacher-Aligned Lesson Sequence or TALS, teachers customize the CAI software to select the CAI lessons that are most appropriate to their particular instructional objectives. In the second approach, the student is simply presented with CAI material in whatever fashion or sequence the software vendor selected. Using a quasi-experimental design, Rader assigned second, fourth, and sixth grade students to either group. Teachers using the TALS approach were trained in customizing the CAI lessons. Using measures of alignment protocols, Rader concludes that there was significantly greater alignment between CAI and classroom instruction where the TALS approach was used.

In the third selection James Kusch and Alex Pan both at the University of Wisconsin-Whitewater, Gigi Bohm of Union Grove Elementary School and Heide Stein of Cambridge Elementary School used the elementary school students in Stein's and Bohm's classes to evaluate software. The authors describe a four stage evaluation process that they employed.

The second group of presentations cluster deal with issues relating to preservice or inservice teacher training. In the first selection, Thomas Drazdowski from King's College provides a description of the transition of a Methods of Instructional Media course to a Multimedia Design course, pointing out the trials and tribulations faced by students and instructors. In the second selection, Carolyn Thorsen and Robert Barr, both of Boise State University, describe the development of computer competencies to be required in the State of Idaho as they apply to teachers and ultimately to students. They further identify changes that will be required in preservice teacher training and methods of assessment. In the final selection in this group, Michael Szabo from the University of Alberta and Kathy Schwarz from New Brunswick Community College present the results of a survey designed to assess the level of training, infrastructure, and teacher empowerment. Their instrument was sent to a random sample of 1000 teachers within the Province of Alberta.

The third group consists of two presentations on the use of multimedia portfolios. In the first selection Donna Read and Ralph Cafolla from Florida Atlantic University describe a project in which they have their preservice teachers produce HTML-based presentations incorporating audio, video, documents and photographs. They have set up a station that their students employ to convert videotape into compressed video format for computer storage. Sarah Irvine, Judith Barlow, and Elizabeth Nibley, all from American University, together with Sheila Ford from Horace Mann Elementary School describe a project to use digital student portfolios as an instructional, assessment, and evaluation tool. Learning-disabled students worked with teachers and used HyperStudio to produce individual portfolios incorporating electronic stories. The authors report statistically significant improvements computer attitude and aptitude on the part of participating teachers.
and students alike, and similar improvements in standardized test scores for oral and written language and communication assessment for participating students.

The last group of presentations consider other aspects of technology. In the first selection, Sara Pankaskie, Martha Lue, Debby Mitchell, Sheila Smalley and Jennifer Platt, all of the University of Central Florida present descriptions of four technologies in use in their preservice and inservice classes. Included in their description are electronic mail, distance education, the manufacture and use of laser videodiscs, and the use of videotaped presentations to deliver timely information to teachers regarding changes to statewide graduation requirements.

In the second selection, Anna Chan and Beverly Ginsburg, both from the City & Country School in New York City describe the infusion of technology into a progressive school, and in particular reflect upon the changes that it brings to the eighth grade American History curriculum.

In the third selection, Susan Anderson of Texas Christian University describes the use of a computer club that served as a laboratory for experimenting with technologies with children. In addition to the various projects produced by the elementary school children, the club provided the author with a large number of “real life” stories to share with her preservice university students.

In the final selection, Nira Krumholtz from Technion - the Israel Institute of Technology reports on the development of LEGO-Logic, a environment that builds upon the LEGO DACTA Logo product. The LEGO-Logic environment was primarily developed to alleviate the problems that Israeli-students encountered using the earlier product; the command structure was English-based, and English was not the native language for these children.

Ronald Sarner is Distinguished Service Professor of Computer Science and Director of Information Services at the State University of New York Institute of Technology at Utica/Rome. His specialties include policy analysis and methodology, which of late have been directed toward educational technology innovations. His address is SUNY Institute of Technology at Utica/Rome, P.O. Box 3050, Utica, NY 13504-3050. Voice: 315/792-7440, fax: 315/792-7222. E-mail: ron@sunyit.edu.

Rosemary Mullick is Associate Professor of Computer Science at SUNY Institute of Technology at Utica/Rome. Her major areas of interest include the development of social cognition including social perception, research methods, artificial intelligence, and parallels between human cognition and machine “intelligence”. Her address is SUNY Institute of Technology at Utica/Rome, P.O. Box 3050, Utica, NY 13504-3050. Voice: 315/792-7239, fax: 315/792-7222. E-mail: rosemary@sunyit.edu

Deborah Y. Bauder is Director of the Learning Center at the State University of New York Institute of Technology at Utica/Rome. Her research interests include professional development and dissemination of educational technology innovations. Her address is SUNY Institute of Technology at Utica/Rome, P.O. Box 3050, Utica, NY 13504-3050. Voice: 315/792-7310, fax: 315/792-7800. E-mail: debbie@sunyit.edu
In recent years a proliferation of educational software can be observed in all school levels as well as at home and in the workplace. One of the important reasons for this situation seems to be that by interacting with a computer unsupervised learning is possible (more than three students per teacher with no educational guidelines; see Caftori, 1996). At home overburdened parents can leave their children unattended using a program that has a “educational” label and expect that learning may occur while playing. A similar situation may occur in schools, where supplementary learning can be furnished in a computer laboratory. Finally, in the professional arena many firms opt for training through computer based instruction as a cost-cutting measure. It is much cheaper and more flexible to provide employees with training software than to organize a workshop with a paid trainer.

Results of a recent study of educational software use in unsupervised settings were rather disturbing, showing that children did not learn what they were expected (Caftori, 1994a). It was also shown how this learning environment leads to the development of a gender gap (Caftori, 1994a, 1994b). Part of the problem can be traced to the insufficient emphasis on evaluation of the quality of educational software by the educators themselves (Paprzycki & Caftori, 1996). The aims of this paper are to summarize the possible effects of unsupervised usage of the educational software and to suggest a number of changes necessary to avoid future problems. These changes will be related to: a) educational software evaluation, b) technology-based lesson delivery and c) university curricula.

Educational Software

A typical example of software use in educational practice was presented by Caftori (1994a). She describes how, in a Junior High School, a number of computer terminals have been set up so that students can interact with the educational software and learn in an unsupervised mode. It should be stressed that the software installed is clearly designated as educational. It was found that this educational software does not play an educational role in many cases, or at least not the educational role it was intended to play.

An informative example is based on the Oregon Trail game. This game is a history simulation with the educational goal of introducing children to the life of covered-wagon travelers on their way from the Missouri River to Oregon in 1848. In its educational objectives it is suggested that this game induces students to make intelligent decisions based on a limited amount of data and consider alternative solutions when the circumstances suddenly change. It contains a number of problem-solving situations, like river crossing, money and food management and dealing with disease outbreaks. It is also supposed to teach students to arrange the data they have gathered into the “bigger picture” and to establish interrelations between the facts so that they can make appropriate decisions. The overall effect of all the decisions made determines the final outcome of the game. A number of pedagogical problems were observed (for a complete discussion see Caftori 1994a):

- Children concentrate on reaching the end of the trail as fast as possible without regard for their companions or oxen.
- Children take no time to visit the landmarks and learn their history.
- Children shoot animals for the sake of shooting becomes an objective in itself; the type of the terrain and the animals associated with it are not noticed and/or learned by the student.

A number of similar problems were observed when studying how students interacted with other games:

- using trial and error strategies instead of calculations in games like Paper Plane Pilot and Wood Car Rally,
- not playing Where in the World is Carmen San Diego? as the game takes a long time for completion.
playing the game of Odell Lake with the goal of swallowing fish to enjoy the sound effects (instead of learning the predator-prey relationship and the food chain).

In addition to these general problems some interesting observations have been made related to the gender differences in approaching the games (for a detailed discussion see Caftori 1994a and 1994b). Some of these observations match those presented in Christie, (1996), Fryer (1995), Goldstein, Olivares, and Valmont (1996) and Underwood and Underwood (1996), where additional examples can be found.

- Girls were less visible in the computer laboratory and thus participated in the supplementary learning less often.
- Girls in early grades prefer word games (such as Hangman) to construction with geometric figures (such as Mosaic).
- Overall, boys like fast, shooting, fighting, or killing games involving battle or space ships while girls prefer slower games involving writing or school work.
- Even when playing the same game (Oregon Trail) girls have pursued different goals such as reaching the destination (the original goal of the game), or writing epitaphs on tombstones,
- Girls do not like software that does not allow them to quit a section in the middle; boys do not like software that does not provide them with an appropriate feedback.

Summarizing, even though students were interacting with the educational software, they were able to do it in such a way that at least some (if not all) of the specified educational objectives have been missed. Software attributes that were intended to attract children to the game (e.g. competitiveness, animations) actually diverted their attention from the objectives. The observational results confirm also that much software is designed to appeal to boys without consideration of the effect it has on girls (see also Huff & Cooper, 1987).

It is easy to specify what types of changes could have made the Oregon Trail game a more valuable educational tool. For example, when a poor decision is made by the student while traveling on the trail, the software should hint that a more efficient way may exist. When the student strays away from the set goal there should be a reminder provided about the major objective of the game. Similar suggestions can be easily made for the remaining games.

We were more interested in finding out why these deficiencies were not spotted when the games were evaluated, before the label "educational" or "good" was attached to them. We have searched for the criteria that are applied to evaluate educational software. To find the answer we have, initially, studied three issues of the Technology and Teacher Education Annual (Carey, Carey, Willis & Willis, 1993; Willis, Robin & Willis, 1994; Willis, Robin & Willis, 1995) Proceedings of Society for Information Technology and Teacher Education. Our assumption was that since this is one of the biggest conferences addressing the usage of technology in education, our findings will be representative of the state of the art in the area. Later, we have also looked into the most current Proceedings volume (Robin, Price, Willis & Willis, 1996). We were definitely surprised by our findings. First, there is almost no material related to the unsupervised learning. Second, we have located only a total of six papers related somewhat to the issue of educational software classification and evaluation: Byrum (1993), Byrum (1994), Maddux (1993), Paprzycki & Caftori (1996), Persichitte (1995) and Valmont (1994). This is especially astonishing while compared with the number of papers suggesting that teachers should write their own educational software. How are these teachers supposed to do a good job at it if they have no background in evaluating educational software and differentiating between good and bad to start with?

We should point out that in the past there have been numerous papers discussing software evaluation (see for instance Bitter & Wighton, 1987). That was before new powerful hardware and multimedia became widespread leading to the development of new generations of educational software. In Paprzycki & Caftori (1996), we have shown how Oregon Trail can pass the elaborate set of evaluation criteria proposed by Persichitte (1995) and none of the problems reported above can be predicted. However, the topic of evaluation criteria for the educational software does not seem to be very popular at one of the largest forums where such a discussion should take place. This fact, combined with the problems indicated with the educational software, lead us to believe that not only a discussion of these issues should be initiated, but also other areas require additional attention.

Educational Software Evaluation

Since one of the more important problems with the educational software seem to stem from the lack of modern criteria to judge its educational quality we would like to present two groups of issues that need to be taken into account when such a judgment is being passed. This list is very preliminary and should be treated as a starting point for future research.

Social Issues

As discussed above, there exist substantial differences between the ways that boys and girls interact with the educational software and inappropriate usage of such software can further deepen the gender gaps. This seems to suggest that the following issues should be considered:
a) Does the interaction involve hand-eye coordination, problem solving, verbal interaction, or interaction between the students themselves in a cooperative/collaborative mode of learning?
b) Does the software provide a diversity across genders/races among the leading characters?
c) Does the game perpetuate gender/racial stereotypes or prejudices?

d) Does the software discourage trial-and-error type behavior while favoring decisions resulting from thought processes?
e) are the special or interactive effects overwhelming the objectives of the game?
f) Can the educational objectives or a reasonable subset be reached in a limited or prescribed time?

These two groups of criteria should be supplemented by detailed evaluations related to the particular medium and its usage in the classroom or unsupervised setting. For instance, there seems to be a body of experience mounting that may lead to the development of such evaluation criteria for CD-ROM’s used in reading courses (see Goldstein et al. 1996, Land & Taylor 1995, Matthew 1996, Underwood & Underwood 1996 and Valmont 1994).

Changes in the Classroom

The problems described above indicate that even if the quality of the educational software improves the teacher will still be needed in the classroom where computers will be used in a lab or studio environment. At the same time the teacher will have to work as hard, if not harder, to make sure the software employed is appropriate and is used in a manner that enhances the material to be learned. The basic work will be concentrated on developing lesson plans built around the software. Anyone who has observed a lesson delivered in the computer laboratory realizes immediately that such a lesson changes the position of the teacher. As soon as students start working on the computers their attention is diverted from the teacher and it is extremely difficult to get their attention back. As a consequence, the teacher is no longer at the front of the classroom as a center of attention and the class dissolves into units working either individually or in groups. Each such unit pursues knowledge independently and at a different pace. This means that the in-class situation resembles very closely the unsupervised learning. Therefore the lesson plans will have to address this new, different role of the teacher, as guide or helper instead of information provider. An extended discussion of this new role can be found in Caftori (1996).

Curricular Changes

Finally, changes aimed at addressing the problems indicated above should also appear in the university curricula. Our observations of the way that educational software is used singled out at least three areas where serious problems can surface. First, at home, where parents invest in the educational software and hope that this will help their children to succeed. Second, in schools, where undertrained teachers use educational programs in the unsupervised mode to furnish students with supplementary learning. Finally, among educational software developers, who may not be aware of what happens when their software is used in real-life situations by real-life learners. We would like to suggest that this indicates three corresponding areas where the introduction of computers into our everyday lives imposes the need for the curricular update: computer education for the general student population, teacher preparation (pre-service and in-service), and the computer science curriculum itself.

Computer Education for the General Student Body

It may be assumed that most of the students are current or prospective parents and thus they are (will be) the ones who (will) buy the educational software for their children. They should learn that the educational software is not a remedy for the lack of supervised learning and interaction with their children. They should be made aware of what the basic problems related to the unsupervised usage of educational software are. It seems that the most natural course for transferring this knowledge would be the Computer Literacy course. Unfortunately, currently this course is used primarily to teach basic application packages. The situation would change if the idea of “computers across curriculum” suggested in Papszycki, (1996) and used in a few universities, were to be accepted. In this model the Computer Literacy course is being removed from the curriculum. The computer component is introduced to all courses offered in the curriculum. This solution can free a slot to offer a capstone course devoted to the social and ethical issues related to the usage of computers. In this course the considerations related to the usage of educational software could naturally find a home.

Computer Education in Teacher Preparation

Not all Colleges of Education provide the courses necessary for training teachers to integrate computers into
the curriculum (this should be distinguished from the courses devoted to the usage of technology in the classroom settings, which are relatively popular). The need for such an integration and preparation of “informationally literate” teachers has been very well summarized in Niederhauser (1996). Pressure must be exerted to include an Educational Software Methods course into the pre-service teacher preparation core curriculum for all teaching fields. This course should be also introduced and promoted as an important part of in-service teacher training. The content of this course should contain issues related to the in-class usage of educational software as well as unsupervised usage of educational software. A substantial component discussing criteria and methodology of educational software evaluation (including exercises) should also be included. (For a description of a course that could be modified to meet these objectives see Mitchell and Paprzycki, 1993, and the references cited there.)

It should be pointed out, that our proposal goes against suggestions similar to that of Loehr (1996) and Valde et. al. (1996). The first proposal is much too narrow and seems to suggest concentration on the mechanics of technology usage which is a remedial subject that should not be a part of the university curriculum. The second proposal is clearly misguided by suggesting that teachers should have knowledge of computing in a pseudo-programming language. This is not the type of knowledge that will be ever useful to the teachers as they need to know how to utilize the ready-to-use software only and will never be involved in any form of computer programming.

**Computer Science Curriculum.**

First, let us observe that typically most CS students are taught how to write software, how to write it fast, how to write it well (where well means without errors). Almost no attention is given to the content of the created product. In other words, CS students are as efficient in writing software, how to write it fast, how to write it well (where well means without errors). Almost no attention is given to the content of the created product. In other words, CS students are as efficient in writing good software, how to write it fast, how to write it well (where well means without errors). Almost no attention is given to the content of the created product. In other words, CS students are as efficient in writing good software, how to write it fast, how to write it well (where well means without errors). Almost no attention is given to the content of the created product. In other words, CS students are as efficient in writing good software, how to write it fast, how to write it well (where well means without errors). Almost no attention is given to the content of the created product. In other words, CS students are as efficient in writing good software, how to write it fast, how to write it well (where well means without errors). Almost no attention is given to the content of the created product. In other words, CS students are as efficient in writing good software, how to write it fast, how to write it well (where well means without errors). Taking into account the important role computers play in our lives and how they have become an integral part of society, we would like to suggest that such a course should be required of every graduating Computer Science major interested in pursuing software design career. A special track may be offered or even a new minor or major concentration as is suggested by McGuire (1995). He describes how at the American University (Washington, DC) the Art and the Computer Science and Information Systems Departments have combined in a similar effort. It should be pointed out that, in most cases, this will be the role of the School of Education to pressure the Department of Computer Science to develop an appropriate course.

**Conclusion**

In this paper we have tried to suggest to the reader that what is labeled as “educational software” may not be very educational after all. We have also argued that issues related to the educational software evaluation seem not to be very high on the list of researchers in the pedagogical sciences. It is true that evaluating software is part of some existing teacher preparation courses; however, these courses themselves have not been recently evaluated and their outcomes assessed. These considerations led us to propose changes in three related areas: academic curricula, software evaluation and software in-class usage. Whereas our proposals are very preliminary, the point is to generate discussion and stimulate research in these areas.

**Educational Software**

Educational software products mentioned in this text are available from the Minnesota Educational Computing Consortium (MECC), an educational software developer and distributor from Minneapolis, MN.

Vendors Versus Teachers: Who's Best at Aligning Classroom and Computer-Assisted Instruction?

Jan Rader
The University of Mississippi

Experts in the field of educational technology have stressed the importance of integrating classroom instruction and computer-assisted instruction (CAI) (Shore & Johnson, 1993; Blickhan, 1993). However, no research studies examine this process or offer implementation models to assist teachers in aligning classroom instruction and CAI in a computer lab setting using an instructional learning systems (ILS). Many school districts have purchased ILSs as a "turnkey" solution to providing technology for their students, not realizing that the "integration of ILS instruction with classroom curriculum . . . is perhaps the most important element in successful implementation" (Shore & Johnson, 1993, p. 85). "In many labs, the students' regular classroom teacher is often neither present nor directly involved with the integration of instruction received in the lab with what students are learning outside their lab experience" (Komoski, 1990, p. 378).

Due to the complexity of many ILSs, "teachers frequently feel they simply do not have the time or energy to master and integrate an instructional device which is perceived as complex and as only marginally relevant to the existing curriculum" (Shore & Johnson, 1993, p. 88). Consequently, "scheduled computer lab time has been viewed by the classroom teacher as either prep time or free time and rarely as part of regular classroom instruction" (Shore & Johnson, 1993, p. 89).

Purpose

If teachers are not in the computer lab, directing the CAI of their students, who is? The answer is simple—the ILS vendors. According to Komoski (1990, p. 380), "No commercial company should be expected to—or, in fact, allowed to do that job for the schools." Therefore, the purpose of this study was to provide an implementation model for ILSs that would make it easy for teachers to integrate CAI and classroom instruction.

This study introduced the Alignment Implementation Model (AIM) for CAI and assessed the curriculum alignment obtained using AIM in a computer lab setting. AIM was developed by the researcher for use with the Jostens Learning ILS, since nearly five million children in over 12,000 schools across the country use this ILS on a daily basis (Brannick, 1995).

AIM for CAI

AIM was designed as an easy-to-use implementation model, no more difficult to complete than a lesson plan. Using AIM, the teacher:

1. Identifies the classroom instructional objectives;
2. Matches the objectives to CAI objectives;
3. Lists all potentially appropriate CAI lessons with matching instructional objectives;
4. Selects the most appropriate CAI lessons;
5. Designs the most appropriate sequence of CAI lessons;
6. Adds assessment, enrichment, remediation, and reward features as necessary;
7. Describes the teacher-aligned lesson sequence (TALS) and adds other required ILS information as necessary; and
8. Delivers the TALS to the computer-lab system attendant for building into the ILS and assigning to designated students.

Research Study

Research Question

Are teachers able to develop TALS of math CAI more closely aligned with classroom math instruction than vendor-developed lesson sequences (VDLS) of math CAI?

Research Design

A two-group design with repeated measures was used to determine the degree of curriculum alignment between VDLS of math CAI and classroom math instruction, as well as the degree of curriculum alignment between TALS of math CAI and classroom math instruction.

Participants

Three classroom teachers, one computer-lab system attendant, and fifty-one second-, fourth-, and sixth-grade students participated in this twelve-week study in San Marcos, California, in 1994.
Procedures
Student subjects were randomly assigned to one of two groups, E1 or E2. E1 subjects received VDLS of math CAI in the computer lab. (VDLS were developed by curriculum specialists at Jostens Learning.) E2 subjects received TALS of math CAI in the computer lab. (TALS were developed by teachers who participated in the study.)

Participant Training
During weekly 40-minute training sessions, teachers learned how to align classroom math instruction and math CAI using the AIM for CAI. The computer-lab system attendant learned how to build the TALS of math CAI into the ILS and assign them to E2 subjects.

Instrumentation
In order to determine the degree of curriculum alignment between classroom math instruction and math CAI in the computer lab, the Measurement of Alignment (MA) was developed by the researcher. This instrument consisted of several components, including a MA Curriculum Mapping form, a MA Student Subject Score Sheet, and a MA Scoring Protocol.

Data Collection
The teachers completed a MA Curriculum Mapping form daily, recording the instructional objectives taught in math. They attached all relevant instructional materials, including hand-outs, worksheets, homework, quizzes, etc.

The computer-lab attendant and the research assistant generated ILS reports daily. These reports listed the names of the students, the math CAI lessons assigned in the computer lab, and their associated instructional objectives.

Data Analysis and Findings
The math CAI objectives taught to each student were recorded on a MA Student Subject Score Sheet and compared to the math instructional objectives taught in the classroom. Using the MA Scoring Protocol, an alignment score from 0 to 5 was entered for each comparison. For example, an alignment score of 5 indicated that the instructional objective taught in the computer lab was also taught in the classroom on the same school day. Alignment scores were compiled into twelve weekly MA scores for each student subject.

Mean Scores
Mean scores for the MA are shown in Figure 1. Second-grade E1 subjects obtained an overall mean score of 1.34 and E2 subjects obtained an overall mean score of 15.34. Fourth-grade E1 subjects obtained an overall mean score of 0.04 and E2 subjects obtained an overall mean score of 9.13. Sixth-grade E1 subjects obtained an overall mean score of 0.00 and E2 subjects obtained an overall mean score of 12.73.

ANOVA
A two-group ANOVA with repeated measures of the MA (weeks 1 through 12) was performed to compare the mean group scores. For second-grade subjects, the overall results for the MA, \(F(1, 16) = 244.34\) and \(p < .0001\), were significant. For fourth-grade subjects, the overall results for the MA, \(F(1, 14) = 234.19\) and \(p < .0001\), were significant. For sixth-grade subjects, the overall results for the MA, \(F(1, 15) = 332.85\) and \(p < .0001\), were significant. These results are displayed in Table 1.

Discussion
Results indicate that teachers can align classroom instruction and CAI in a computer lab setting significantly better than vendors using AIM. These findings also support Taylor's contention that the "Jostens ILS is a flexible tool which teachers can use as they decide [what is] most appropriate to their particular instructional needs" (1990, p. 4).

The researcher recommends that further studies be conducted using AIM to determine the degree of alignment that can be obtained over longer periods of time, at all instructional levels, and with a wider range of subjects in the both lab and distributed settings. It is further recommended that research be conducted using AIM with other ILSs.

Personal computers have been used in education for nearly two decades. Although there are still many issues concerning computers in the school, such as proper administrative support, sufficient time, computer software and hardware, and access, computers are commonly available in the classroom. Most teachers have adopted the ideas of integrating computers in their curriculum. There are many successful cases of using computers to increase teachers’ work efficiency and teaching effectiveness. For example, teachers use computers to generate newsletters, prepare handouts, organize student databases, create weekly or monthly calendars, and produce report cards. Teachers can also engage students in such dynamic learning activities as reinforcing knowledge and skills via individualized drill and practice and inspiring individual students to think creatively and critically with multimedia authoring systems or simulation applications.

Software companies have been trying to produce educational programs that are motivating for children and are appropriately related to subject matters. Thousands of titles are available today to address instructional needs. However, the value of these programs is unknown to most teachers. Alternately, the educational benefit to some of these programs is hard to detect.

According to Maddux (1993), software can fall into one of the two categories. He states, “Type I software makes it quicker, easier, or otherwise convenient to continue teaching in traditional ways. Type II software makes new and better teaching methods available - methods that would not be possible with the use of computer” (p.212). To gain a better understanding of the value of useful educational programs, the authors set a goal to search for computer software that is educationally appropriate and appeals to children, in other words, motivational software.

What features of software programs enhance instruction and learning? Why should students care about learning with software? Bohm and Stein, two elementary schoolteachers in rural Wisconsin schools, developed a inquiry by which they might assess if software programs enhance the learning of their students and if software programs actually serve their instructional objectives. Bohm is a Title I teacher who teaches thirty-seven second-fourth grade students who have been identified as remedial readers, although among the second graders, six are known to be non-readers. Stein is a fourth grade teacher who teaches nineteen students, four of whom are identified as learning disabled. Bohm and Stein based their study upon an action research model in which they reflected upon the use of software programs (Kusch, 1996), created a plan for action, outlined a way to implement the plan, and evaluated the plan. Their inquiry focused on two related questions: What is motivational software and how do we identify or create software that both enhances and aids instruction and learning?

Purpose

While we as teachers appreciate the potential value of using educational software programs in our classrooms, we are concerned with the quality of software programs. Too often we see educational software that is full of fluff or graphic or audio “junk” (Tufte, 1983). Software junk does not achieve the goals of its creators. We feel that the value of software programs that we and our students use is in the clarity through which they communicate concepts. Sometimes sound, color, and animation enhance what software programs attempt to do but frequently they turn boring or repetitious programs into disasters, and fail to rescue mediocre ideas.

Many times teachers cannot find software that fits or enhances a unit of study; alternatively teachers find that software is fragmented. There may be only a small portion of a particular software program that is geared towards the...
skills that they choose to teach. So, we look for a quality of mobility within software programs where only a portion of the program serves the skill we wish to develop.

Many educational programs are in drill and practice format with a very weak link between real life and program material. Skills presented in a drill and practice format tend not to take our students beyond rote learning activity and fall short of the potential that software programs possess.

We are interested in exploring the educational benefit of any software programs from the viewpoint of both ourselves as teachers and from the viewpoint of our students. We pursue this question with an awareness that the educational benefits of many software programs is hard to detect. Thus, our goal as classroom teachers is to search for computer software that is educationally appropriate and also appealing to our students.

Methodology
The methodology included four stages: 1) reflection, 2) plan, 3) action, and 4) reflection.

Reflection
Children as well as adults, should be motivated to do tasks. The purpose of an activity should be clear and concise. Tasks that are interesting to students tend to keep their attention.

We use the term “motivation” in relation to computer software. Motivation is the common bond that links students and teachers to the same software program. Motivation is an ambiguous term that is often used and is difficult to define. We define software programs that possess at least the following five qualities as motivational—challenging, applicable, appealing, standard, and coherent:

- Challenging software takes students’ understanding to a place where they might gain awareness of things that they already know.
- Applicable software relates explicitly and directly to the day-to-day experience of students both in and out of the classroom;
- Appealing software keeps students’ interest; graphics, sound, and format ties into the concepts and ideas that the software provides;
- Standard software content adheres to skills and standards established by state and school curricular guides;
- Coherent software enhances the curriculum the teacher already is covering, it is not a set of fragmented facts.

Plan
Based on our criteria of what constitutes motivational software, we looked for capabilities between programs through informal interviewing, informal observation, surveys, and lists. To find common features we employed four steps:

- Collect software for teachers and students to evaluate. Make a list of all the software titles in our building. Catalog the software by subject categories.
- Create a survey which students and teachers use to document their interests. Brainstorm with children qualities that they like in computer programs. Formulate a feature matrix in which to compare different software programs from this brainstorming activity.
- Ask children to take a documenting worksheet to mark their subject area interests. Students choose software titles on the worksheet that correspond with their interests in different subjects.
- After children experiment with the programs and after both informal observations and interviews are complete, have students record their opinions of each software program on a pre-established feature matrix.

Action
Five action steps follow:

- Give children the option of working in pairs or by themselves.
- Ask children to pick up their feature matrix. The children are also asked to choose one software program to work with based upon the initial interest survey.
- Children experiment with each software program, rating each noted feature on the matrix for each individual software program. If the children note an unlisted feature of the program that they review they record their observation in the section titled other.
- The process continues by filling out the feature matrix for each software program, until all programs are reviewed.
- After all programs are evaluated and opinions are documented, the children get together with the teacher to draw up and post in the classroom a set of conclusions to the study.

Reflection
After the teacher and her students discuss their findings and the collected data from the feature matrix they complete a software conclusion form. The form consists of ratings for each software program, identification of software programs rated highest on the feature matrix, a listing and narrative description completed by students and teacher of three favorite software program titles with explanations of why the particular programs were favorites, and a brief essay that discussed differences between favorite software programs and those that scored high on the feature matrix.

Findings
Nineteen students from the Stein’s class and thirty-seven students from the Bohm’s class participated in the software evaluation process. We learned that children are
excited about their computer experience and have actually appreciated the value that computers can provide by asking for more time. We also find that most children tend to stay using programs that are challenging, fun, are familiar from past experience.

Stein's class has PC-based computers and Apple II systems while Bohm's class has Macintosh-based computers and Apple II systems. Students in both classes have tried some programs on two platforms. No data is collected to compare the difference between the PCs and Macs. Almost all students do not like to use the Apple II systems.

Computers individualize instruction where students can work on a particular subject based on their personal interests, paces, and learning needs. Such a non-threatening experience can yield higher appreciation and ensure positive attitude in learning with reduced anxiety.

**Teachers' Input**

Findings drawn from teachers' personal insights and classroom observation together with findings drawn from students' evaluation on the feature matrix illustrate how software programs enhance instruction and learning. Additionally, findings suggest ways that collaborative evaluation of software programs informs us of which software programs are motivational from the viewpoints of students and teachers.

There were differences in the ways that Bohm and Stein surveyed students' attitudes and understood how software programs serve to enhance students' learning. The differences are attributed to the way in which the teachers organize instruction with software programs and to the arrangement of students in the two classrooms.

Programs that asked children to operate by using the combination of I, J, K, and M were the most difficult for children in all grades to use since using these keys related to knowledge of left/right and up/down orientation. Bohm found that some of her students had great difficulty working with the I, J, K, and M keys because of their little fingers and their inability to tell left from right.

**Insights-Bohm**

Bohm found that there were differences in the way that students evaluated software programs, since a number of her students were non-readers. Bohm studied the documentation that producers supplied with the software programs. She found that there were differences in the way that software targeted students by their age. For example, software programs for younger students included more animation and sound while programs for older students did not. She stated that software programs that included heavy use of animation and sound attracted users, but offered little useful value for non-readers.

The operational and instructional directions that software programs give influence learning. Bohm found that students generally benefited from directions that stated procedures clearly and with readable language. She cited clarity and readability of language in directions and the number of words with more than two syllables as factors. Bohm stated that her students paid close attention to directions and asked her to clarify them when the directions were vague. She also found that students who were non-readers tended to ignore directions and merely play with keys that made the cursor move.

Bohm found that the ways that students needed to use certain keyboard combinations impeded students use of software. Bohm's students felt that the real life application criteria was most significant.

**Insights-Stein**

Stein made insights based upon whether the software related to content that she covered. She noted that most software programs that she evaluated gave drill and practice for reinforcing computation work that she taught in mathematics. Such software programs added little that was new or different to instruction. Drill and practice programs tended to include a greater number of problem situations repetitively.

She found that there were other software programs which enabled her students to identify new instances of concepts they already learned in studying fractions. Specifically, the program "Speedway Math," depicted toys. It asked students to identify a group of toys of one variety and to name that group as a fraction. Stein found that the Speedway Math use of animation to remove or highlight sets of toys as a fraction enabled students to understand fractions in a different way than the way the textbook described fractions. Another software program "Dinosauring," presented an overview of different geological eras in which dinosaurs lived. Students knew terms such as Jurassic or Cambrian from books they owned or from watching movies. Using the software made it clear to the students that Jurassic or Cambrian referred to distinct periods of time. She observed that her students tended to be drawn toward using software programs which challenged them and diverged from the textbook.

Stein noted that some programs are "user friendly," and so invite students' use. She identified user friendly programs as those which operate without the use of function keys. Unlike Mrs. Bohm's class, Stein found that the quality of visual display in the computer graphics of the programs was motivating. Programs that appeared grainy and slow received low marks. Programs that were crisp and quick received high marks. Stein's students felt the challenge criteria was most important.

**Insights-Students**

The two categories of software as suggested by Maddux (1993) match the software being evaluated. Type I programs support traditional types of instruction and the Type II programs are mostly user-centered and are often more
exciting and challenging. Type I programs are mostly available in the school; there are fewer Type II programs available to our subjects.

Partnerships made using software programs are collaborative. Individuals shared thoughts that influenced the choices that their counterparts made about the software programs. Some students competed with their partner to assign numerical values on the matrix. Other pairs of students were comfortable with hearing different opinions and "bounced" ideas back and forth as to whether the content in the software related to content they had learned in their textbook. In some pairs where there were differences in ability, less able students were less expressive. Students who were non-readers gave high evaluations to programs that contained the most attractive animation and sound. Students who were high achievers sought software programs that challenged them.

Students evaluated software honestly and critically. They participated eagerly and felt that their opinions were recognized and rewarded. Pairs of students from each class cited animation and sound as important and all students listed clear directions as important.

Conclusion

Teachers in this study examined the views of thirty pairs of students who gave a range of opinions about the value of software. Students' evaluations benefited from their collaboration. As students communicated their ideas with one another, they learned to clarify and refine their thinking. Partnership evaluation gives an orderly way to evaluate software since teachers can limit the number of students and type of software programs in the evaluation.

When students reviewed software programs in this study they gained a greater sense of understanding about the software and about content they already learned in their class-work. When partners evaluate software programs they gain a tool to apply in two contexts. They can reuse ideas from the feature matrix since it places participation and thinking at the heart of instruction. The feature matrix helps students relate evaluation to concepts and gives an activity they may use to explain their thinking. Partnerships make both teachers' and students' ideas open to question and comment from others. Partnerships set a standard for evaluation that helps kids explore the relation between things done in school with things done out of school. Thus, kids can see where they need to improve. They can self-assess and work at software programs independently to improve skills.

Implications

Teachers should pair students and encourage cooperation, having students with better skills share experience with one another and encourage less able students to explore new programs. Although computers are an exciting medium for students and teachers, most teachers do not have solid experience in using the software for optimized teaching. Teachers should spend time to learn with students and build a firm relationship when teaching with educational software.

Type I and Type II programs serve different students' needs and can be used for different purposes. In the school, most programs are old and belong to the Type I category. Although most Type II programs seem more challenging and fun, we should not ignore the value of the Type I programs which may serve to support traditional instruction.

Since there are many educational programs on the market today, availability is not an issue, appropriateness is (Willis, Stephens, & Matthew, 1996). In using computer software for instructional purpose, appropriate software must fit in to address the following issues: subject matter, efficiency, ease of use, appeal, adaptability, compatibility.

Several national reports, such as *Teachers and Technology: Making the Connection* (U. S. Congress, 1995) and the recent *What Matters Most: Teaching For America's Future* (National Commission on Teaching & America's Future, 1996), have criticized teacher education programs for not adequately preparing their graduates to use technology effectively in their professional practice. In response to such reports, many teacher education departments are attempting to rewrite their curricula in order to infuse technology use throughout their programs (Kortecamp & Croninger, 1994; Levin & Waugh, 1995; Thompson, Schmidt, & Hadjiyianni, 1995; Valde, Bower, & Thomas, 1996) and are also attempting to design new courses to prepare preservice teachers to use advanced multimedia technologies (Abate & Benghiat, 1993; Abramson, 1995; Beichner, 1993; Hatfield, 1996; Hoskisson, Stammen, & Nelson, 1996; Licht, 1996; Woodrow, 1995). As previously reported (Drazdowski, Holodick, & Scappaticci, 1996), the teacher education department of King's College met in the spring of 1994 to brainstorm and formulate a technology action plan. The result was the creation of a three year technology infusion plan for the department as well as a proposal to restructure the traditional “Methods of Instructional Media” course to become a “Multimedia Design” course. This paper will report on the course restructuring efforts to date.

'Twas the Night before Classes... 

If I had taken a stress test on the night before I was to begin teaching the multimedia course, I'm certain my test results would have been off the chart. This change in course structure was also accompanied by the total relocation of our department to refurbished facilities. As is often the case in such endeavors, the construction timeline did not neatly coincide with the beginning of the spring semester. The night before classes found me in our new computer lab, feverishly trying to load software and shake down machinery, while men on ladders were still cutting ceiling panels and applying touch-up paint. I would not recommend this implementation schedule to anyone because it does not allow enough time to work out potential problems. It does, however, keep a “change facilitator” (Hall, Hord, Huling-Austin, & Rutherford, 1987) from having a boring life. Begin the next day we did, and having our inquisitive students bring life and wonder to the room assured me that together we would work through any opening day bugs, bumps, and crashes.

In keeping with Spradley's (1980) concept of the “grand tour,” I'll briefly describe the context for the multimedia course. The computer lab consists of the following components: 12 PowerMac student workstations each connected to a Pioneer Laser Disc V2600 player with separate Sony color video monitors; 1 Apple LaserWriter Select 360 and 1 Hewlett Packard 560C Inkjet Printer; 1 Apple Color One Flatbed Scanner; 1 Apple QuickTake 150 Digital Camera; 1 Panasonic VHS Reporter Video Camera, VCR, and monitor (to produce QuickTime Movies); a large DA-LITE Screen; and a teacher station with like equipment on a multimedia cart that also includes a Syquest 135 EZ Drive and a Sharp Color LCD panel and 3M overhead projector (this panel was upgraded this fall to a Sharp ceiling-mounted LCD projection system). The main software packages utilized in the course are HyperStudio 3.0 (Roger Wagner Publishing) and PowerPoint 4.0 (Microsoft). The main student text is *HyperStudio 3.0 In One Hour* by Vicki F. Sharp (1995) (see Drazdowski, 1996, for a review of this text). *The Visual Almanac* from Apple Computer is available for the laser disc players. All computers are linked to the college network and Netscape Navigator 2.0 is available for Internet browsing.

The majority of the students in the course tend to be senior education majors, both elementary and secondary, who are in their “Professional Semester” and are about to begin their student teaching experience. Most of the students have completed the course, *Computer Applications for Educators*, which deals primarily with integrating word processing, database, spreadsheet, drawing programs, and the Internet into the instructional process. To maintain the integrity of the previous schedule, the multimedia
course meets every afternoon for two hours during the first three weeks of the semester, with additional lab time for student teams to develop their projects. Students then spend the remainder of the semester student teaching.

Initial Findings

Judging from the early entries of student learning logs, I was not alone in suffering some anxiety about trying something new. Some sample student comments follow:

When I first walked into the new computer lab, I was totally amazed. After the initial excitement wore off, I started to worry. It all looks so complicated. I am what you might call 'electronically challenged.'

Since all I know about Macintosh is how to open them up and use the word processor, I'm in for an interesting ride.

I must admit, walking into the multimedia room, I was a little intimidated.

These computers have so many accessories, how does one know how to begin?

While I was looking at sample stacks I did start to worry. I was concerned because I really do not know if I can make these things on my own and actually have them work.

I feel I am a little behind in this new computer generation and I am nervous in the fact that this class may be over my head.

As I was sitting in class today, I had the same feeling as the first day of Computer Applications class - I was nervous about 'goofing-up' or worse, breaking something!!

Along with these initial fears, there were also signs of excitement and hope:

This lab is truly awesome! Never before have I wished that I was not going to graduate just so I could spend more time learning about all the new technology in this room.

As an older student (many years out of high school) I can see the tremendous benefits that computers have for children today. After our overview of HyperStudio today I know it is something I want (need) to take advantage of during my teaching career.

I'm sure kids would love multimedia. It makes everything come to life and is so much more advanced and interesting than a textbook. This is a giant step in the direction of making learning fun.

I never realized what potential computers had. This class is opening a whole new world of possibilities.

As the students learned the authoring program and became more comfortable with the equipment, they made the transition from nervous novice to power user, with many even beginning to push the limits of the technology and the teacher. By the conclusion of the course students had created many effective multimedia stacks on a plethora of topics, ranging from mitosis and the solar system to beginning Spanish, from eating healthy and dental hygiene to black history, from evolution and English grammar to the battle of Gettysburg, the plays of Shakespeare, and a tour of Paris. Besides giving students the opportunity to utilize advanced technologies and create educational multimedia for classroom use, the course also provides the professor with the opportunity to model constructivist learning theory (Brooks & Brooks, 1993; Collins, 1991; Jonassen, 1996; Vygotsky, 1962, 1978) and cooperative learning concepts (Johnson & Johnson, 1985, 1994; Johnson, Johnson, Holubec, & Roy, 1984; Kagan, 1990; Slavin, 1983). Students were working in collaborative teams, actively constructing knowledge, researching and solving problems, accessing and evaluating information as they worked on authentic, challenging tasks. The classroom environment shifted from teacher-centered to learner-centered, from teacher as fact teller to teacher as guide, coach, and scaffold builder, from teacher always being the expert to teacher very often becoming the learner. The teacher in this situation should be prepared for the kind of movement in their framework of thinking that Kuhn (1962) would refer to as a "paradigm shift," the kind of deep, fundamental shift that will forever alter your perspectives and practices. As Elmore, Peterson, and McCarthy (1996) observe, internal structures of teachers must change if they are to teach better.

Barriers to Change

In his study, Pink (1989) identified twelve barriers to innovation effectiveness, including such things as: too little time for teachers to plan for and learn new skills and practices, lack of sustained administrative support, underfunding or trying to do too much with too little support, and too many competing demands or overload on those attempting change. I have found these same barriers to be present, in varying degrees. Limited funding in the recent budget has not allowed the department to implement its technology plan on its intended schedule. There has been administrative discussion about turning the college into a single-platform campus, a plan, if implemented, that would exclude the computer platform (Macintosh) on which the multimedia course and the department's three year technology plan is based. And as I'm certain any facilitator of change can attest to, finding the extra time
and energy to make meaningful change on the college level with so many competing professional and personal demands is a constant struggle.

The biggest barrier to change I have found to date is the lack of technology-rich environments and technology-using cooperating teachers in our students’ field placement settings. Finding school cultures that promote and encourage innovation can be a difficult task. As the OTA report (U.S. Congress, 1995) on teachers and technology pointed out, “technology does not appear to play a significant role in student teacher assignments” (p.186) and “often, the preservice teachers knew more about technology use than the practicing teachers supervising them” (p.187). I agree with the finding of Hill and Somers (1996), “the extent to which faculty value the benefits of using technology is one of the most significant determinants of its use” (p.310). As a short term solution to the technology access problem, our department has purchased two laptop computers and color LCD panels that can be checked out for field use by our student teachers. Hopefully as more colleges of education and local school districts form partnerships, appropriate training, support, and access to technology for all the stakeholders involved in preparing new teachers will be addressed.

Conclusions

Though generally pleased with our initial efforts and student outcomes in the area of multimedia design, the course restructuring process described in this paper is very much a continuing work in progress. During the next semester I intend to focus more on design theory and the importance of carefully planning multimedia projects, as suggested by McBride and Luntz (1996). It is also critical that I continue personal modeling, for as Jackson (1986) says in his discussion on transformative teaching, “it is essential to success within that tradition that teachers who are trying to bring about transformative changes personify the very qualities they seek to engender in their students” (p.124). I can only hope that as I visit the future classrooms of our graduates, I will find their students actively and collaboratively engaged in their learning, being guided by caring, effective, technology using educators who, in their own ways, have become agents of change.

Thomas A. Drazdowski is an Assistant Professor of Education in the Education Department of King’s College, Wilkes-Barre, PA 18711. Voice: (w) 717 826-5900 Ext. 5921, (h) 717 868-8064. E-mail: tadrazdo@rs01.kings.edu
Computers have become a part of teacher education faster than colleges of education have had time to develop a curriculum for them. Political entities are requesting that teachers be technology literate in exchange for funding; school superintendents want to hire teachers who know how to integrate computers into the teaching/learning process; and finally, many teachers themselves are asking, “What should we know?” The Idaho State Legislature has provided money for both public schools and Teacher Education Programs in the state. Idaho schools receive 10.2 million dollars per year in technology money, and the Boise State University (BSU) Teacher Education Program receives $350,000 per year to re-train 5,000 teachers in its service to use computers and other technology in the teaching/learning process. The legislators demand accountability. They want to know what teachers and students should learn to do and how long it will take. They also want to know how to evaluate teachers’ use of computer technology in the teaching/learning process. Finally, both educators and those who provide funding want to know how student performance will improve because of the influx of machines and training.

The Solution

As a result of requests from legislators, BSU “Technology Outreach Program” (TOP), created a panel of teachers, technology coordinators, and administrators as well as representatives of the local business community. The panel developed a set of computer competencies for K-12 students, a set of 132 competencies for teachers, and a computer-based technology competency test for teachers.

The panel recognizes that “technology” includes other kinds of machines and instructional techniques other than computers. However, it narrowed its focus to computer technology competencies for two reasons. First, most Idaho school districts are using their technology grants for computers and/or networks. Secondly, of the many technologies available, computers are in almost every workplace. They have changed the way the world works and does business. By focusing on computer technology, the panel is providing a decisive definition of computer skills Idaho students will need to be productive citizens in an information-based society.

Assumptions

In order to work from a common baseline, the panel made a number of assumptions regarding hardware and software availability. The panel also used the current level of state funding for technology as a basis for its projections. Given that the current level of funding will remain constant for the next three years, it is reasonable to assume that the resources listed below will exist in most Idaho schools by the year 2000.

Hardware

Because of the growing standardization within the computer industry, the panel felt that platforms (PC or Mac) are becoming less of an issue. Either platform will run all of the software listed below, and in many cases, the software looks the same on both platforms. Consequently, all recommendations in this report apply to either Macs or PCs. In addition, the vintage of the computers is not critical. Ninety percent of competency recommendations can be accomplished on x386 and above PCs or Mac SEs and above. The panel makes the following assumptions regarding hardware and access:

1. A computer (1 hour per day access is possible with ratio of 1 computer to 5 students),
2. A printer (1 per 25 students), and
3. A modem or network connection (1 per 25 students).

Software

Students will have access to the software listed below. If a student is trained to use one specific brand of a software genre and has a reasonable comfort level with computers, then using a different brand of the same genre is a matter of a few hours of self-teaching. For example, all data bases are built around the same model. If students understand the function of a data base, (i.e. to do sorts and queries which result in inferences), it is only a matter of learning to follow a different system of menus to use a different data base.

Specialized skills with software and hardware appropriate to vocational education, such as CAD/CAM, network maintenance and hardware repair, and diagnostic software...
Teacher Skills

The panel has developed a subset of skills for each category listed above. For word processing there are 22 operational (making a piece of software work) skills and 9 instructional skills. Examples of operational skills include cut, copy, paste, and page orientation. Examples of instructional skills include knowing how and when to use a word processor for targeted learning problems like ordering and classification; substitution exercises; grammar; and logical sequencing. Additional instructional skills for word processing include knowing how to use word processors to assist in high level analysis including editing and revision; information analysis including research reports, journal writing, lab reports, and note taking; creating newspapers; group investigations/brainstorming; and composition including creative writing, letters, and writing roulette. Many of these teaching techniques are adaptable across content and grade level.

There are 19 skills in the subset of skills for databases. Those skills include knowing how to do sorts and queries (finds), information formatting (like date, text, and number formats) and the use of conjunctions. Instructional skills include knowing how to set up a lesson in which students use databases to reach a conclusion; analyzing and describing results, and making a prediction.

The panel suggests a subset of 11 skills for spreadsheets including writing formulas and using functions as well as understanding basic spreadsheet terms such as x and y axis. Instructional skills for using spreadsheets include: using spreadsheets to solve story problems; using spreadsheets to do "what if" thinking; using them to teach estimation; and using spreadsheets to show relationships.

For presentation software and graphics and hypermedia software, the panel recommends 19 sub-skills. Examples of some of these skills include understanding of the following: branching, hypertext, foreground, background, and grouping. Instructional skills for presentation/hypermedia software include knowing how to teach students to interpret and present information using this genre of software to enhance speeches and creating non-linear reports.

Recommendations for basic skills in telecommunications include: send and receive e-mail, use the Internet (including uploading and downloading information), and create simple HTML documents. Instructional strategies that teachers should know in conjunction with the Internet include: using telecommunications to talk with an expert, creating simulations, setting up and supervising role playing lessons, and engaging in peer tutoring, data collection and analysis, the electronic debate, and joint document creation.

Additional recommendations for teachers who use instructional/reference software involve learning how to manage the whole classroom for maximum learning assisted by computers. Teachers need to know cooperative learning models like jigsaw as well as how to plan curriculum for use in centers.

Finally, teachers need some basic file management and hardware skills. There are 35 skills associated with hardware and file management. Teachers need to know how to estimate space on diskettes, understand the meaning of different file formats, and how to use operating systems like Windows and the Mac operating systems.

For presentation software and graphics and hypermedia software, the panel recommends 19 sub-skills. Examples of some of these skills include understanding of the following: branching, hypertext, foreground, background, and grouping. Instructional skills for presentation/hypermedia software include knowing how to teach students to interpret and present information using this genre of software to enhance speeches and creating non-linear reports.

Recommendations for basic skills in telecommunications include: send and receive e-mail, use the Internet (including uploading and downloading information), and create simple HTML documents. Instructional strategies that teachers should know in conjunction with the Internet include: using telecommunications to talk with an expert, creating simulations, setting up and supervising role playing lessons, and engaging in peer tutoring, data collection and analysis, the electronic debate, and joint document creation.

Additional recommendations for teachers who use instructional/reference software involve learning how to manage the whole classroom for maximum learning assisted by computers. Teachers need to know cooperative learning models like jigsaw as well as how to plan curriculum for use in centers.

Finally, teachers need some basic file management and hardware skills. There are 35 skills associated with hardware and file management. Teachers need to know how to estimate space on diskettes, understand the meaning of different file formats, and how to use operating systems like Windows and the Mac operating systems.

Student Skills

The panel listed student skills by grade level. Student skills can be classified into two categories: operational and intellectual, much like teachers' skills. Operational skills include the ability to use computers effectively in a workplace environment, and the fundamental experience and knowledge that will allow students to adapt to specialized software and operating systems. Intellectual skills include giving students the ability to use the tools (word processor, database, etc.) to solve problems in the content areas (Language Arts, Social Science, Mathematics, and Science). This two-pronged approach will give students the skills that they need in the work world and should speed and deepen student learning in the academic world.

Skills at each grade level build on skills from the previous grade level ultimately providing a senior high student with a full range of tools and procedures for solving problems. In addition, students should know which tools and processes are most appropriate for a given problem. Kindergartners learn five file management skills, four word processing skills, four different kinds of intellectual skills from instructional software, two graphics skills, and are exposed to presentation software.
Senior high students on the other hand, move beyond learning operational skills and spend the bulk of their time using computers to work faster and smarter. The goal is for the computer to become as transparent to students as pencils and paper.

Vision and Philosophy

Appropriate Use of Computer Technology In Public School Classrooms

The genres of software listed above are the standard tools that business, industry, and science use to record, store, transmit, and manipulate information to get “thinking work” done or to produce a product. They are useful for teachers and students for the same reasons that they are useful in the world of work. Their integration into the public school curriculum represents a “value added” dimension to the use of computers in classrooms. Although these tools are sometimes taught as classes by themselves, it is the unanimous opinion of the panel that their most appropriate use is to speed or deepen student learning in the content areas. There is no value in teaching a student to use a word processor, the Internet etc. unless the student learns to apply the tool to a problem. These problems would most logically be associated the content areas. As students use data bases to study history or spreadsheets to study math they develop many of the same skills that they will be using after graduation in the work world.

Teacher Training

Pre-service Teacher Training

Implementing the student competencies listed below is dependent on how well teachers are trained to integrate computers into the teaching/learning process. Teachers graduating from universities should enter classrooms fully trained in software use and curriculum integration and teaching methodologies appropriate to their grade level. The panel recommends the following:

1. a basic course in appropriate software,
2. an introduction to teaching techniques essential in technology enhanced classrooms,
3. a supervised field experience in which students work with master teachers using technology, and
4. an advanced course in the junior/senior year taught in conjunction with methods courses. This course should focus on integrating technology into instruction along with advanced work with appropriate software.

Inservice Teacher Training

Teachers already in the field should be re-trained. The panel recommends that teachers be trained in the kinds of software listed above in a series of short, single concept classes. In each course, teachers learn a software application and the teaching methodologies necessary to use that software to teach content. They then need time to train children to use the software and to implement technology supported lesson plans. It is a process that unfolds over semesters.

Support

Following training, teachers need continuing support and eventually will need re-training as computer technology and software change. This support should ultimately come from local school district technology coordinators supported by regional centers that are now established at Idaho colleges and universities. Teachers and district technology coordinators need access to technical support (telephone, e-mail, on-site visits by trained BSU staff, and assistance with initial student training).

Products For Assessment and Testing

Because the legislature is interested in results, BSU has developed and piloted several instruments to help technology trainers assess the level of knowledge of teachers before training, test teachers after training, and assess the level of student performance in the classrooms of teachers who have been trained.

Profile

Sometimes BSU trainers are asked to do training in districts where no training other than “word of mouth” training has taken place, or, a patchwork of training has occurred with no coordination or goal. For this reason, BSU turned the competencies into a technology “profile” that can be given to teachers on a bubble sheet. The bubble sheet lists the competencies and teachers respond by saying whether or not they can perform each listed skill. The bubble sheets are then fed into a computer and the results are analyzed. An administrator or a trainer can get a sense of how much and what kind of training is needed in a school or in a district. This, in turn can help administrators project training costs and prioritize topics for in-service days. With equipment, appropriate training topics, and time, teachers master the skills and accumulate the curriculum materials they need to begin using computers as a part of the teaching/learning process. Observations indicate that the time between the appearance of five computers in a classroom and the time when there is measurable change in student behavior and/or performance is three years. Neophyte computer-using teachers progress from using the computer as a reward for good behavior or work and for drill to a sophisticated integration into the teaching/learning process in about three years. At the end of three years they achieve a mastery both they and the students use the machine to gather and manipulate information at speeds yet unequaled in an average classroom.

Competency Test For Teachers

Funding providers are extremely interested measuring teachers’ ability to use computers in their classrooms. For
other topics in educators' preparation, simply passing a class is enough. However, in the case of computers, a complex topic that cannot be measured by a grade in one class, BSU offers but does not require a competency test. Approximately 20 percent of the students who take the class fail the test. Superintendents in the BSU service area have been notified that if BSU graduate looking for jobs in their district say they know technology and have taken the class but do not have the certificate, BSU does not guarantee their technology competency.

The test itself is given on computer and consists of 80 questions drawn randomly from a pool of 200 questions, a practical exercise using a database, and the development of a lesson plan that demonstrates an understanding of classroom management in a five-computer classroom. In this lesson plan, students describe use of one of the tools to teach a topic effectively. They describe curriculum materials, classroom management strategies, and evaluation of student work. The test is constantly under revision. New questions are added as the competencies evolve. Questions are carefully written to require thought and reasoning rather than rote memory. The test is applicable to either the Windows or Mac environment, and students do not know in which environment they will be tested. The objective portion of the test is graded by the computer, and students know instantly whether or not they have passed. The lesson plan is assessed by three graders who have developed a uniform grading scale. If one grader fails a lesson plan and another passes it, it is read by the third grader.

The competency test by itself is not complete. There is a great distance between a teacher who knows how to operate software and one who knows how to create meaningful technology-based lessons that improve students' learning and behavior. For this reason, BSU is also developing an instrument that will measure the quality of student products. In this way administrators or legislators who must evaluate the use of computer technology in classrooms and its influence on students will have a reliable assessment method. The assessment itself will be done by comparing student work to examples of student work that have been sorted by age level, tool, and location on Bloom's taxonomy and have been collected into a portfolio. The portfolio will be a result of a Delphi study in which experts (teachers who have used computer technology successfully in their classrooms) have sorted hundreds of examples of student products along with the accompanying lesson plans and placed them in their proper location in the portfolio. This project should be at a pilot stage by spring of 1997.

**Student Skills Assessment**

A student skills assessment instrument is currently under development and being piloted by BSU personnel. This tool measures student skills against the expectations of the list of K-12 competencies.

---

**Conclusion**

One of the biggest challenges facing teachers and teacher training institutions is to identify what teachers need to know about computer technology and to have a process whereby that knowledge can be tested and verified. Teachers need two areas of expertise with computers. They should have computer skills and working knowledge of computer integration methodologies. If teachers are missing either of these kinds of knowledge, they will be less effective in using expensive resources and in teaching their students. By narrowing and defining the knowledge base, BSU has helped reduce the anxiety teachers feel about the inevitable re-training in which they will participate. By developing an integrated set of testing instruments, BSU is providing administrators and legislators with the information they need allocate precious resources toward making schools more responsive to 21st century needs.

A SURVEY OF TRAINING, INFRASTRUCTURE AND EMPOWERMENT OPPORTUNITIES FOR THE INSTRUCTIONAL USE OF COMPUTERS IN SCHOOLS

Michael Szabo
University of Alberta

Kathy Schwarz
New Brunswick Community College

Instructional technology has great but unrealized potential for reforming educational systems, e.g., increased use of technology in daily classrooms and some fundamental restructuring of the way education is viewed and carried out. Past explorations of why the potential is unrealized have focused upon attempts to get people to change and the complexities of instructional use of computers. Failure of these attempts has led us to turn to the innovative nature of the issues. Our study has led us to conclude that although innovation is widely lauded as a concept, it is rarely carried out to a successful end, either in education or other fields of endeavor. Those rare instances of successful innovation have a common set of characteristics, including the presence of training, a supportive infrastructure, empowerment of those who carry out the work, and a visionary who puts aside common goals to achieve the dream. We call this person or group “the keeper of the dream.”

These elements comprise only a partial list of the environment of successful innovation but they have been described elsewhere (Szabo, 1996). We focused on three areas for the current study: Training, Infrastructure and Empowerment. Training involves the acquisition of competencies necessary to 1) add instructional computing, 2) apply it to issues of curriculum, instruction, and evaluation, and 3) provide leadership to colleagues in teaching and administrative positions. To this list we would add that reform must have a large mass of teachers who are competent in instructional computing. A simple analysis shows there are currently not enough trainers to do the job. We must find alternative ways to prepare educators.

Infrastructure requires hardware, software and telecommunications. Beyond that, however, it demands the strong vision which is held by senior administrators and shared by everyone else in the system. Vision is critical in innovation since very few can predict the ultimate direction innovation will take. Infrastructure also involves a significant commitment of time and other resources. Innovation is inherently risky and a tolerance for making progress through risk-taking characterizes successful innovation. Infrastructure also means immediate access to credible and understandable support for all aspects of the application of instructional computing to teaching.

Empowerment simply means the granting of authority to adapt the vision to local needs while preserving its basic goals. It also means providing temporary teams of people and enabling them to decide how their organizational unit will play out the vision to reality. It rests on the premise that if people share a vision, are given the task to carry out the vision along with the freedom to decide what the vision will look like, they are more likely to become committed to it, to own it, and become keepers of the dream.

Purpose of the Survey

With the framework of training, infrastructure and empowerment conceptualized, the next step was to identify the extent to which these elements are perceived as present or absent by public school teachers. A key assumption of the survey is that ideal learning occurs in a learner-centered environment. In this environment, instructional computing is used as a tool to solve problems and accomplish tasks, and as a tutor to promote effective, efficient and affective or enjoyable learning.

The research sought to answer the question “What is the status of training, infrastructure and empowerment conceptualized, the next step was to identify the extent to which these elements are perceived as present or absent by public school teachers. A key assumption of the survey is that ideal learning occurs in a learner-centered environment. In this environment, instructional computing is used as a tool to solve problems and accomplish tasks, and as a tutor to promote effective, efficient and affective or enjoyable learning.

The research sought to answer the question “What is the status of training, infrastructure and empowerment in support of instructional computing as applied to applications of tool and tutor usage and to promote reform. The status was based on the perceptions of practicing full time public school teachers in the Province of Alberta.

Methodology

A survey technique was used to gather data. Three categories of training, infrastructure and empowerment were created for the survey. Specific items were developed
for the categories of Organizational, Training and Resource Needs. The last two categories were further subdivided into current levels and future needs for promoting the use of instructional computing. A separate research question sought to ascertain differences in these categories among four different divisions of teachers, K-3, 4-6, 7-9 and 10-12.

Eighty eight items were developed for these categories, plus six demographic questions. Respondents were also given the opportunity to add open-ended responses to the questions. To reduce the burden of completing such a large survey, the questions were largely restricted choice and every respondent was given a subsection to complete. The survey was mailed to teachers as part of a regular mailing of the Alberta Teachers Association. Respondents were given stamped and addressed envelopes in which to return the surveys.

**Sample and Data**

The sample consisted of a random sample of 1000 full time teachers from each of the four divisions drawn from 26,500 employees in the Province of Alberta in 1995-1996. The data were summarized as percentages according to the categories and divisions represented.

**Findings**

A sampling of the findings is placed here. Teachers indicated agreement with the following statements from each of the categories:

**Infrastructure**

Teachers suggested that the following are needed:

- access to both newer equipment and computers
- more administrative support,
- easier scheduling of facilities,
- more emphasis on computers,
- network administrators,
- local training, and on call help,
- information about software,
- higher quality, curriculum-specific software,
- tech assistance in each building,
- access to tutorials, projection pads, manuals, periodicals, class sets of software, and
- rapid repairs to equipment.

**Empowerment**

Teachers suggest that the following are required for empowerment to occur:

- subject matter integration,
- access to timely technical on-site help,
- more input into software purchase,
- more input into hardware purchase,
- more student centered instruction,
- teaming with experienced teacher,
- more input on computer usage,
- teachers developed long range plans,
- team approach to computer usage,
- effective classroom methods,
- effective classroom (lab) management,
- incorporation of computers in curriculum,
- evaluation strategies
- strategies to teach computer tool use,
- encouragement for group work,
- strategies to teach specific subjects,
- time to experiment with use, and
- peer support.

**Training**

The following are necessary:

- hands-on training,
- modeling,
- demonstration,
- observation of sound practices,
- continuous training to build confidence,
- team teaching, and
- time to learn. usage

Opinion of the respondents toward selected aspects of instructional computing were also obtained as part of the survey. Six hundred ninety eight completed surveys contained the following information. While most respondents stated that students at all division levels should use computers, the response was stronger as a function of grade level. A considerable number of teachers stated that K-3 students need not use computers.

When asked who should use computers with students, 71% of the sample responded “only those [teachers] interested in doing so.” Ninety nine percent indicated the ideal number of minutes per week of computer use by students should fall between 30 minutes and 8 hours. The ideal ratio of computers to students was considered to be between 1:1 and 1:2 according to 87%.

**A Plan for Action**

Vision for use of instructional computing together with planning for ways in which to achieve the vision are critical. The vision and planning need to begin with Education Departments and continue through the school district, school building and classroom level. The vision and plan cannot be dictated; rather, it must be shared and the plans adapted for local application. At each level, the training, infrastructure and empowerment issues must be addressed simultaneously if instructional computing is to grow and have an impact on the reform of public education.

MULTIMEDIA PORTFOLIOS FOR PRESERVICE TEACHERS: FROM THEORY TO PRACTICE

Donna Read  
Florida Atlantic University  

Ralph Cafolla  
Florida Atlantic University

Over the last five years, educators have discovered the validity of portfolios for evaluating students in elementary and secondary settings. However, using portfolios for preservice teachers at the university level is relatively new (Rogers, 1995; Taylor & Nolan, 1995; Smyser, 1994; McKinney & Ohlhausen, 1995). Another obvious trend in education is the increased use of advanced technology, particularly multimedia technology. This paper will report the results of a project undertaken to allow preservice teachers to combine the validity of authentic assessment using a portfolio with multimedia technology.

The paper is divided into four sections. The first section discusses the theoretical underpinnings of portfolio assessment including a brief overview of Constructivist theory. The next section gives an overview of current research on portfolio assessment in general, with a focus on the use of technology in portfolio development. The third section presents an overview of the hardware and software considerations in the development of this project. This section describes the state-of-the-art multimedia technology used, including scanners, digital still cameras, digital video cameras, and audio input devices to capture work for portfolios. Section four presents a brief explanation of the processes that the preservice teacher would follow to develop a multimedia portfolio. The paper concludes with a discussion of some of the challenges faced in developing the portfolios and gives an update on the projects current status and future directions.

Portfolio Assessment: Theoretical Background

Constructivist Theory

Preservice teacher portfolios are based on the Constructivist Theory of learning, a paradigm which views learners as actively involved in the construction of their own representations of knowledge. According to this view, learning is the process of building knowledge structure by connecting what is known to new information, ideas, and concepts and integrating them to form new understandings. The implications of this theory for teaching are numerous. Table 1 shows some of the differences between this theory and traditional models.

According to Constructivist theory, teachers and students who cooperatively determine performance activities used in the classroom are more likely to engage in real-world experiences, and develop learning skills and concepts in a more meaningful manner. In order to assess the validity and accuracy of learning, the theory maintains that learning is a developmental process; and that the process for completing a piece of work is just as important as the product.

Research on Portfolio Assessment

In recent years, many educators have come to the conclusion that traditional assessments do not provide an adequate means of evaluating preservice student progress. Formal and informal assessment measures such as standardized and criterion-referenced tests fail to reflect the actual learning that takes place during instruction. In response to this disparity, educators at the university level have begun to use portfolios in deciding about goals and standards for excellence in teaching, determining evaluation of these standards, revising curriculum, and planning professional development as they mentor preservice...
A preservice teacher portfolio is a developmental record of a career; it seeks to capture an individual’s capabilities over time. Portfolios reveal growth and performance in areas such as planning, instruction, teaching strategies, classroom management, community service, self-reflection, cross-cultural experiences and professional activities under a variety of conditions. Because they focus on process as well as product, they can be used to diagnose strengths and weaknesses, monitor student progress, and provide feedback on the effectiveness of instruction (Adams, 1995; Barry, 1994; Morin, 1995; O’Malley, 1995).

While there is an enormous amount of literature on portfolios, the research on preservice teacher portfolios is meager. However, a review of the literature suggests three trends that support the use of portfolios for preservice teachers. The first trend is an emerging emphasis on attitudes and self-evaluation of preservice teachers. Second is the increase in the use of alternative assessment and evaluation techniques. Finally is the trend towards implementing portfolios in methods courses and across the curriculum. These trends are discussed below.

Attitudes toward portfolios and self-reflection qualities are emphasized by Barry (1994), Morin (1995) and Matanzo (1996). Barry (1994) points out specific activities that promote reflective teaching including: (a) teaching experiences, (b) journal writing, (c) peer observation, (d) receiving notes/feedback from peer observations, (e) self-assessment, and (f) consultation with the university supervisor. In this study, students seemed to feel that teaching experiences required the most thought and reflection. Morin (1995) recommends that the development of portfolios by preservice teachers encourages self-reflection, since students must demonstrate their teaching effectiveness and growth. Matanzo (1996) used a pre/post test measure to help preservice teachers note perceived growth in a reading/children’s literature class. She notes that a vast majority of her preservice students felt they gained increased self-confidence in their abilities and knowledge to work effectively with elementary students. These articles stress that self-evaluation can be a powerful tool in helping preservice teachers gain insight into their own achievement.

Assessing preservice and beginning teachers by using alternative instruments tends to provide a more accurate picture of the competency of future teachers. Adams (1995) suggests the use of portfolio artifacts in a variety of categories i.e., professionalism or communication, followed by a written rationale for inclusion in portfolios. Reisetter and Fager (1995) explain how a goals based university program which actively involves preservice teachers in a multifaceted approach to assessment is effective. Taylor and Nolan (1995) focus on validity as an important aspect of portfolios. They compared preservice teachers using portfolios with students in more traditional assessment courses. The results of their research support the usefulness of portfolios. Faust and Kieffer (1995) explored the portfolio evaluation process of students by having teachers develop portfolios of their own to evaluate their teaching. This qualitative research project indicated that diverse and sometimes conflicting purposes for evaluation were used by teachers. He discovered that in the process of developing portfolios, both learners and teachers discovered a way to come to a consensus about rubrics used. Standerford (1996) investigated the use of formative and summative evaluation of elementary students by preservice teachers who, in turn, engage in formative evaluation of themselves. Her conclusions point out that interactions with her preservice teachers, and their engagement in formative evaluation with elementary students helped them become reflective practitioners. In summary, these studies point out that alternative assessment and evaluation allows for a multidimensional view of students.

Currently, articles which deal with implementing preservice teacher portfolios in methods courses appear to be the most plentiful. Anderson (1996), Gambro (1995), McKinney & Olhausen (1995), Slater ((1995) and Wickliff (1995) touch on developing portfolios in literacy, children’s literature, educational psychology, physics, music and writing courses. Hoag (1995) describes a project involving preservice teachers in a methods course with training and experiences in authentic performance based assessment with an elementary school. Students learned about rubrics, diagnosis of oral reading, word recognition analysis; and how this performance could be evaluated as part of a student’s portfolio. This cross-educational collaboration model shows how a university and elementary school benefit each other in the development of portfolios for preservice teachers and elementary students. Using portfolios across the curriculum to encourage reflections is explained by McFadden (1994). Portfolios are used in the liberal arts, applied science and teacher education programs at his university. McFadden discusses a variety of models and specific items such as essays, teacher conferences, and reflection as part of a preservice teacher portfolio. All of these authors discuss how they successfully organized and integrated their course objectives using preservice teacher portfolios. Some suggest that students assessed by portfolios feel less anxious about learning course content, contributing to intrinsic motivation for learning. The guidelines provided by these authors suggest that portfolios can be used successfully with preservice teachers and that there are many ways of implementing them. Additionally, pitfalls can be avoided as faculty share their experiences with each other.
Another area of emphasis in the literature is constructing preservice teacher portfolios by incorporating professional teaching standards. Guillaume, Yopp & Hallie (1995), Rogers (1995), and Tracz (1995) all recommend that incorporating national, state, and college goals fosters development and improves the evaluation of portfolios. Pedras (1994) presents the portfolio design used at his university, and suggests that these portfolios include a teaching resume, educational philosophy, lesson plans and many other items. Guillaume, Rogers and Tracz note that careful construction of portfolios by paying attention to quantitative and qualitative data serves to guide future directions of portfolios at their institutions.

**Technology and Portfolio Assessment**

There is very limited research about the use of technology to support alternative assessment, including portfolios. Employing technology, however, offers tremendous possibilities for preservice teacher portfolios. Campbell (1992) describes how laser discs are used in portfolios and notes the importance of parents, staff, and students working together in the development of portfolios. Palmer (1995) suggests the use of integrating disciplines and creating video portfolios of student work. It is clear that there is a definite need to use technology if we are to move ahead in education; developing preservice teacher portfolios is an authentic performance activity for assisting students in achieving a meaningful goal.

**A Multimedia Portfolio**

Rather than taking a traditional linear, book-like approach to portfolio creation, this project opted to use emerging multimedia technology as the media. Every school in Florida has, by law, at least one multimedia computer. Preservice teachers completing this project would have their entire multimedia portfolio on a read/write compact disk, commonly called a CD-ROM. This CD-ROM could be brought to a job interview with a reasonable assurance that the school would have the equipment needed to view the portfolio.

The multimedia portfolios were designed to use various type of media including: computer graphics, photographs, scanned documents, recorded sound, and digital video. The portfolios also integrate the concept of hypermedia, which allows certain text or graphics to act as hot links or buttons. Using the mouse to select highlighted text or an icon links to other parts of the portfolio. This means that the portfolio would not necessarily be presented in the exact same order every time it was used. The interest of the user, in this case a perspective employer, determines the order.

The goal of utilizing multimedia presented several challenges. Each of the types of multimedia described above can be stored on a computer in many different file formats. This makes it difficult to ensure that the multimedia will work on a variety of computer platforms. While each school has a multimedia computer, there is no way of knowing what type of computer it is. Therefore, it became necessary to find a way to create a multimedia, hypertext portfolio that could be read by the largest number of computers.

Fortunately, this problems is quite similar to the one faced by the designers of the World Wide Web. To allow many different types of computers to share multimedia elements, the Web designers developed a language called the HyperText Markup Language (HTML). This allows one to describe the appearance and function of a Web page. Special software called a browser creates, or renders, the page.

Therefore, the developers decided to base the multimedia portfolio on the HTML language. This decision had several implications for the project. First, since it would be created in the language of the Web, it could be placed on the Web without modification. While this institution does not currently have the resources to place the pages on the Web, several students have indicated that they will make provisions with their Internet service providers to take advantage of this feature. It is expected that all of the multimedia portfolios will be placed on the Web in the near future.

The decision to use Web browser software also determined the file format for the multimedia features. The following file types were used:

- **Multimedia Function**
  - Audio: *.wav
  - Video: *.avi
  - Scanned Documents: *.gif
  - Photographs: *.jpg

**Developing the Portfolio**

The process for developing the multimedia portfolio includes student participation in four seminars on campus. The first seminar introduces the preservice teacher to the creation of the multimedia portfolio. Students are instructed in using HTML files, gathering student samples, obtaining graphics (photographs, illustrations, certificates, etc.), locating demonstration teaching videos, and developing sound recordings. At the second seminar students use the multimedia portfolio program and import their text files and artifacts collected onto a Zip Diskette using an Iomega Zip™ Drive. In this way, any new information can be added whenever necessary. Seminars three and four are devoted to importing the video and audio components of the preservice teacher multimedia portfolio, and recording work onto a CD-ROM.

As a future improvement an additional seminar will be added to help students place their multimedia portfolio on the Internet. The preservice multimedia portfolio was originally designed to encourage students to develop a portfolio and they are beginning to move in this direction.
as they use technology to search for employment. To further describe the process of creating the multimedia portfolio, the next section describes the computer hardware and software used in the creation of the portfolios.

The Creation Stations

Two identical workstations, dubbed the Creation Stations, were purchased for use in this project. The first component was a sufficiently powerful multimedia personal computer, Pentium 133 with stereo sound, CD-ROM player, and digital video capture card. The capture card is needed to convert analog video from either a video camera, television, or VCR to compressed video for storage on the computer. A microphone was also purchased to allow the preservice teachers to record their own voices for inclusion in the portfolio. Because of the large size of multimedia computer files, Iomega Zip Drives were purchased. Each participant is expected to purchase their own Zip disk to hold their files. This disk is used as working storage as the project develops and as a final testing and storage area for the final version to be transferred to the CD-ROM. Two read/write CD-ROM players were purchased to create the final product. Other equipment included digital still cameras for photographs, digital video cameras for live video, video cassette recorders to digitize videos taken with regular video cameras, and color scanners for documents.

Software

Much of the software used in this project came with the various media devices purchased. The digital still camera, scanner, and video capture cards came supplied with appropriate software. Generic HTML documents, to be replaced by the preservice teacher as described above, were created with Hot Dog Professional (Sausage Software, 1996) an HTML editor that can be evaluated for free for thirty days.

The student HTML documents were created with Microsoft Word with Internet Assistant (Microsoft, 1996). Internet Assistant is available for free from Microsoft. Participants created their pages in Word and saved them in HTML format. Most modern word processors including WordPerfect and Claris Works allows this.

As the project progressed, it became obvious that software was needed to manipulate the graphic images and convert them to formats recognized by Web software. This was accomplished using LView Pro shareware (MMedia, 1996). This program was used to rotate, size, and convert file formats. Also, since many different preservice teachers would be using the Creation Stations, McAfee Virus Scan (McAfee, 1996) was installed on both computers.

Conclusion

The research on preservice teacher portfolios is growing and appears to be extremely useful in the development of portfolios at the university level. Students engage in self-evaluation and become more responsible for their learning. For the most part, faculty, staff and administrators seem to support this new method of authentic performance, assessment and evaluation. It appears that the greatest problem facing universities is how to manage portfolios college-wide. Developing and implementing multimedia preservice teacher portfolios is an enormous responsibility and task. It requires the cooperation of students, faculty, staff and administrators. Financial support for equipment and technical support to maintain equipment is essential if the project is to succeed. The team in charge of the project must continually revise procedures, be aware of problems, seek solutions to problems, and keep students, staff, and faculty motivated as they move into the future.

Preservice teacher multimedia portfolios represent a breakthrough in education and technology. As we move into the 21st century, we have an obligation as professional educators to help our preservice students learn how to utilize technology by forming accurate, meaningful, holistic, yet creative portraits of themselves.

THE DIGITAL PORTFOLIO AS A LEARNING AND ASSESSMENT TOOL

Sarah E. Irvine
American University

Sheila Ford
Horace Mann Elementary School

Judith Barlow
American University

Elizabeth B. Nibley
American University

This project, designed in conjunction with two K-12 schools in the Washington, DC area (one private school and one public school), examined the use of digital student portfolios as an instructional, assessment, and evaluation tool. This project demonstrates the process through which pre-service and in-service teachers work with students with and without learning disabilities to create digital portfolios using the HyperStudio Authoring Program. These portfolios were then published on CD ROM and on the Internet on the schools’ web pages.

Project Objectives

The major project objectives were:
1. increasing students understanding and use of narrative structure in written and oral storytelling;
2. developing an effective teacher-training tool for the use of technology in education;
3. designing an assessment tool for evaluating students’ technology-mediated projects; and
4. increasing strategies by which students can better learn to use technology as an artistic and performance outlet.

Recommendations to incorporate electronic student portfolios into school-wide curricula were examined, including a focus on teacher training, accountability to district-wide criteria, and maintenance of the program. Following this research-based project, teachers worked with technical advisors to develop a school-wide portfolio system to support performance-based education in a classroom.

Theoretical Framework

The complex task of educating the nation’s youth precludes such simple prescriptions as: “computers improve learning” or “give technology to teachers first”. There is no one right answer, either in terms of specific technologies, uses of technology or how to introduce technology into a school. However, it is clear that technology itself is not the answer to this nation’s educational problems. The power of technology will come from its combination with serious educational reform. Schools must first rethink their missions and structure, starting with the needs of students and instructional principles, before they can understand the way technology will facilitate teaching and learning (Means, 1994). From this point, schools can restructure to meet the demands of preparing students to act as global citizens in the 21st century.

Portfolio assessment and performance-based education are methods by which school can restructure. Portfolios can empower students and teachers to reflect upon the teaching and learning process (Herbert, 1992). Performance-based education is used to give teachers practical information on student learning and to provide opportunities for school communities to engage in a recursive process of self-reflection, self-critique, self-correction, and self-renewal (Darling-Hammond, 1994). The theory of multiple intelligences presented by Gardner (1993) states that children may demonstrate different intelligences (musical, spatial, bodily-kinetic) that may be overlooked by traditional assessment and instructional methods. Using Gardner’s theory as a model, schools and school districts across the nation have begun to use portfolios as an assessment tool. Students and teachers can develop portfolios that present a student’s progress over time, and provide more in-depth information than typical testing and grading procedures used in schools. The next step in portfolio assessment involves bringing current and emerging technology into the model, providing a multi-media presentation of the student’s learning and development.

Standardized tests have been used for some time in schools, and educators are familiar with the different aspects of this type of testing. School systems publish the schools’ standardized scores in local newspapers. The school board then goes into the highest ranking schools to see what programming is being used to achieve the high scores. This allows schools and teachers to reevaluate what they are doing and make the necessary changes. Some middle schools and high schools have developed classes to specifically meet these needs. Teachers in the state of
Maryland have used standardized test results to group students in math and reading, although much of the time, the test and the instructional program do not coincide. Standardized tests are generally used once every three years. They test students' long-term progress; however, the small increments of a student's growth often go unnoticed. Standardized tests examine singular problems that call for particular, circumscribed elements of knowledge and problem-solving skills (Resnick & Resnick, 1992; Means, 1994).

Performance Assessments (sometimes referred to as authentic or alternative assessments) differ from traditional short-answer paper-and-pencil assessments in a number of ways. They use the actual work of the students or teachers as objective assessments (Means, 1994). They measure incremental (or short-term) progress, enabling teachers to look at a student's specific learning problems, strengths, and weaknesses. Performance assessments have indicated that a change in curriculum could be necessary. Instead of facts and figures, teachers are stressing opinions and thought provoking "why" questions. Like tasks or activities that individuals carry out in the real world, the performance tasks to be assessed encompass extended activities that allow for multiple approaches and a range of acceptable products and results. A performance assessment allows students to work as individuals and in groups. It further encourages the motivation and challenges that go along with working in a group. Performance assessment tasks may also require students to write investigative reports and debate conclusions (such as history/social science assessments in the California Learning Assessment). Students may carry out inquiry projects in a chosen subject and create exhibitions that culminate in describing and defending their projects to an audience (Collins, Hawkins, & Frederiksen, 1990; Hawkins, Collins, & Frederiksen, 1990; McDonald, 1993; Means 1994).

The evaluation criteria for performance assessments have to be developed according to expected outcomes. Students must be aware of the objectives for the criteria, and educators must help to foster the learning surrounding objectives. Performance assessments must provide evidence about students' learning and performance in relation to established standards. It is this evaluative perspective on student performance that makes assessments particularly powerful vehicles for learning as well as sources of information for students, teachers, and other audiences (Means, 1994). Many school districts and states are beginning to develop these criteria and have evaluated the criteria with actual work done by students. California is one state that is currently developing standards for its performance-based assessment system. State assessment guidelines for students' mathematical problem solving include: producing clear and coherent diagrams and explanations; communicating effectively; understanding important mathematical ideas and processes; and presenting strong arguments that include effective examples and counter examples (California State Department of Education, 1989; Means, 1994).

The HyperStudio Authoring System (Roger Wagner Publishing Inc., 1996) is a computer program that can be used as an individualized and interactive system for instruction. Instructional units to address content areas or deficiencies can be designed for and by students. The program has potential to be a useful tool for educators who need to customize or create their own applications. By combining the computer technology in the HyperStudio application for data display and retrieval, instructional delivery can be enhanced. Improved focus and attention of students are definite advantages gained when instructors use a hypermedia graphic organizer for the lesson's content. The teacher can also appreciate the subsequent data modification capabilities that HyperStudio affords and the easy storage of charts, maps, or graphs. For example, HyperStudio can enhance a lesson plan on the interpretation of bar graphs by providing examples of such graphs and computer graphics of the sources from which the data are taken. HyperStudio material can be designed specifically for classroom uses. For example, other researchers have used HyperStudio stacks with laser discs and CD-ROM discs to allow students to have access to information on the discs. As teachers designed customized stacks for their own students, the teachers found increased success in their students and felt more comfortable with using computers in the classroom.

**Methods**

In this project, pre-service and in-service teachers worked to facilitate the design and development of the students' digital portfolios. As an instructional technique, the teachers created their own digital portfolios and modeled the use of hardware and software for the students. Teachers investigated portfolios as a tool for assessment and evaluation of learning outcomes, and documented the process of developing the teaching tool. Each in-service and pre-service teacher was expected to contribute his or her own expertise in content areas of the project, as well as in the creation of personal portfolios. Teachers were expected to gain the skills and strategies needed to continue to develop both teaching and technology methods.

Forty students with diagnosed learning disabilities, four in-service teachers, and two pre-service teachers from the teacher-training program at a local university were participants in the project. The focus group of in-service and pre-service teachers was given initial computer aptitude and attitude surveys, and then trained to use the HyperStudio software.

The 40 students in this program had varying types of learning disabilities, including visual discrimination, language/communication, verbal and motor difficulties.
and processing disorders. Other students had no documented learning disabilities. The students were given a standardized test of oral and written language, a computer attitude and aptitude survey, and an oral evaluation of their storytelling/narrative structure skills by one of the in-service teachers.

The program was conducted in a series of phases over six-weeks during the summer of 1996. The program began with oral storytelling activities, with the in-service teachers and pre-service teachers serving as models. Using a Macintosh computer, student were encouraged to develop characters, and tell an oral story about those characters. Students were then trained in using HyperStudio to tell stories that incorporate sound, animation, video and digital images. HyperStudio was also used as a presentation tool for the students to share their work.

All students worked with the teachers to create individual portfolios that included all electronic stories. These portfolios were then pressed to CD ROMs and uploaded to the schools' web sites. Portfolios were evaluated by the in-service and pre-service teachers for development of narrative structure, storytelling strategies, and writing skills such as sentence structure and punctuation. Following the instruction, students were given a post-intervention standardized test, an attitude and aptitude survey, and a follow-up evaluation of oral communication skills. Teachers also completed an attitude and aptitude survey of computer skills at the completion of the program.

Results/Conclusions

As students and teachers became more adept at using both teaching and technology techniques, modules created by the students became more sophisticated, and used more in-depth, advanced features. By carefully monitoring all participant progress (students, teachers, and trainers), it was possible to make accurate statements regarding the effectiveness of the project. This work provided teachers and teacher-educators with a model program in which collaboration, student-centered learning and technology can come together in a meaningful way.

The purpose of this study was training teachers to use available technology to determine the relationship between student developed computer-based instruction and skill mastery. This relation was considered through various perspectives including mastery of objectives, consultant feedback and direction, and portfolio assessment. The students themselves indicated that the instruction in HyperStudio was valuable to them and they felt confident in their ability to create useful and innovative lessons. In addition, students appeared to value the opportunity to develop their computer skills via the HyperStudio system.

Technology has become a large part of students' lives and out of the classroom. New technology in the workplace includes the continuing development of hard- and software for the future. This technology has helped to automate many aspects of students' lives, such as family banking and grocery shopping. Computers and the use of the Internet have become prevalent and widespread. Schools have also begun to incorporate technology, and, based on positive results, will more than likely continue to incorporate it. School media centers are using computers with encyclopedias on CD-ROM as well as the encyclopedias on the shelves. Educators are using computer-assisted instruction (CAI). Based on these facts and ever expanding computer technology, traditional assessment practices, such as the text-based standardized tests discussed above, may not be appropriate. Instead, performance-based assessments, which do not rely solely on writing and text, could be more realistic.

When performance-based assessment is employed, students can use and present the work they have done in a variety of formats, including technological ones. They can use spreadsheets, graphing tools, word processing and sound tools and have access to the world through the World Wide Web and e-mail. Students' horizons and self-esteem can be expanded by giving them the chance to publish their work on the Internet for the world to see.

In addition, as technology becomes more advanced, special educators can provide adaptive and assistive devices beyond what is currently possible. Global technologies offer mobility, multiple modes of communication, translation, and other opportunities to all students, despite the disabling condition. Students can create their own learning environments, thus matching their own learning styles. As research in technology-based education progresses, further uses are certain to be discovered.

The use of technology has become more sophisticated and varied in education. This article presents four distinct uses of technology to enhance preservice and inservice teacher training: e-mail between two universities thousands of miles apart to allow students the opportunity to communicate and problem solve about common problems encountered during student internships; compressed video to provide required courses to students on area campuses; laser videodiscs to deliver instruction in the area of gymnastics; and training on technical information using videotape prepared by an "expert" and delivered with the assistance of a cadre of trained on-site facilitators.

Using Technology in Preservice and Inservice Teacher Education Programs

Technology can be a powerful vehicle for changing teaching and learning in teacher education programs in our colleges and universities (Barnes, 1992). Computer networking and satellite communications technologies facilitate local and long distance collaboration and communication among students in teacher education programs. Compressed, interactive video presentations permit the transmission of college courses through distance education. Multimedia technologies assist preservice and inservice teachers to design professional, motivating products of their own creation. All of these uses of technology can contribute to preservice and inservice teacher education programs that facilitate and encourage our students' engagement, collaboration, creativity, and active learning. This article describes the use of four distinct types of technology in personnel preparation programs developed and/or delivered by faculty at one institution of higher education.

Using E-mail for Problem Solving

"As the world moves into the information age, telecommunications networks have the potential to change the nature of teaching and learning in all aspects of education" (Schrum, 1995, p. 221). The use of educational telecommunications networks can encourage social, collegial, and professional development activities (Schrum, 1995). Preservice and inservice educators who want to increase the use of telecommunications technologies for professional development are developing ways to incorporate technological innovations into their instruction.

One traditional and time-honored method of instruction, the class discussion, has been positively influenced by educational telecommunications networks, including the use of electronic mail (E-mail). E-mail is currently being used in higher education classrooms in journalism, engineering, English, business education, writing, and nursing (Lowry, Koneman, Osman-Jouchoux, & Wilson, 1994). Discussions via electronic mail assist students to reflect upon, share, and express ideas. It also may help them brainstorm and generate solutions to problems and to function as a community of learners.

Project Description

The intent of the project was to create a community of learners who would conduct discussions through the interactive use of electronic mail (E-mail) and brainstorm solutions to real problems. Special Education majors at the University of Central Florida and the University of San Diego used E-mail to communicate scenarios which they developed from problems encountered in their internships. The university students were enrolled in learning disabilities curriculum classes and were also completing a student teaching experience. All participants had received instruction in how to use E-mail. Most students had used E-mail in a previous course to complete an assignment with another student.

Students from each university program were randomly matched to a partner at the other institution. Though they
did not meet in person, students exchanged faxed photos and introduced themselves via E-mail. Each week throughout the fifteen week semester, students were asked to describe a problem they had encountered in their internship and send it to their partner. Partners E-mailed their suggestions for addressing the problem. Students were expected to generate at least ten of their own scenarios and respond to their partner’s ten. All E-mail transmissions were made outside of class time. The expectation was that students would apply the content from their curriculum classes to the scenarios.

Students E-mailed copies of each of their transmissions to the course instructor. This gave the instructors the opportunity to verify that students were communicating, and enabled them to refer to some of the scenario topics during class, thus increasing the relevancy of course content.

Project Outcomes

Several outcomes were realized from this project:

1. Students participated in a “hands on” project which enabled them to use technology as a tool to enhance communication in a non-threatening environment. Students shared information and asked questions of their partners that they might not ordinarily have asked of their instructor or their supervising teacher.
2. Students applied course content to solve real life problems collaboratively with their colleagues.
3. Students were able to share information about diverse groups of children in two extremely different public school settings, and vicariously benefit from an additional field experience or internship.
4. The use of technology resulted in a natural support network for participants by linking together individuals with similar challenges and eliminating the feelings of isolation and helplessness frequently experienced by student teachers.
5. The professional interaction and active involvement provided through the use of technology encouraged further dialogue beyond course topics and stimulated a collegial, working relationship for these developing professionals. Through the use of electronic mail, a community of learners was truly established.

Discussion

This project proved to be successful in addressing the problem of isolation that many Special Education teachers/student teachers face. The use of electronic mail allowed the participants to serve as mentors for each other, and to become empowered with a wider repertoire of teaching strategies through collaborative problem solving. When evaluated by the participants at its conclusion, the project was found to be highly successful with just a few suggestions for improvement. Students occasionally could not access E-mail if the university system was down. Other students had difficulty using passwords. Some students had difficulty scheduling time in the computer lab to use E-mail. Attempts were made throughout the semester to address these problems as they occurred in order to enhance each student’s chances for a successful experience.

Using Distance Education to Reach Students on Area Campuses

The concept of distance education is not a new one. Pennsylvania State University offered its first agricultural courses in the 1890s and added credit correspondence courses for professional engineers in 1918 (Burgess, 1994). The current usage of the term, however, carries a connotation of technology. Distance education now refers to teaching and learning in which electronic devices and print materials are used to deliver instruction to learners who are geographically separated from each other and their teacher (Lane, 1992).

Project Description

The University of Central Florida, located in Orlando, currently has a student enrollment of approximately 28,000. It is comprised of three campuses: the main campus in Orlando and area campuses in Cocoa and Daytona, Florida. One course in the Department of Exceptional and Physical Education, Introduction to Mental Retardation, was targeted for distance education for several reasons. It is a required course for all Exceptional Education majors specializing in the area of Mental Retardation. Due to the limited enrollment, this course is offered only on the main campus. Students on area campuses with an interest in the area of mental retardation have been reluctant to pursue this specialization because of the unavailability of the required courses on their campus and one hour commute to access them on the main campus.

The main site is a carefully constructed, technologically advanced electronic classroom located in the library at the main campus. Monitors were set up on each of the area campuses. Prior to the beginning of class, training in the use of distance learning was given to the instructor for two sessions. (Additional instruction will be provided for future sessions on an as-needed basis.)

Training for the instructor included a thorough explanation of the equipment, dressing and presenting for television, the use of videographics and other media, and a discussion on the use of educational materials.

Project Outcomes

Summative outcomes are unavailable because the course has not been offered in the compressed video format as of this writing. From a formative point of view, however, some things can be said. Historically, the total enrollment in this course has been around 25. With the availability of distance learning on the two area campuses, approximately 40 students have enrolled for the Spring, 1997 semester.
Making and Using Laser Videodiscs for Instruction

Many educators are seeking ways to integrate technology into their curriculum. Physical educators are no exception. There was a need, for example, to find innovative ways to deliver quality, consistent instruction to gymnastics classes in a physical education teacher preparation program. In traditional gymnastics classes, the instructor (or a talented student) had to perform each of the gymnastic skills. This is not only time consuming, but difficult to perform repeatedly with precise movement. The use of a laserdisc allowed the instructor to show slow or freeze frames so students could see consistent and correct skill performances. Also, unlike live performances, movements could be stopped in mid-motion for students to see the body positioning. Reported benefits of using videodiscs in instruction include a reduction in learning time, increased mastery of subject matter, increased retention, more consistency in instruction, faster and easier access to information, and greater motivation and learning enjoyment (Baumbach, Bird, & Brewer, 1993; Hasselbring & Bransford, 1988; Miller, 1990).

Project Description

The first step in developing a laserdisc is to determine what subject matter should be included. In the current case, this was determined by looking at the skills students had to master as a part of the course (e.g., floor, vault, balance beam stunts, etc.). The required skills were performed by a gymnast and videotaped. Following the taping, the instructor assisted with editing and provided a narration. Once the filming and editing had been done and the narration added, the tape was ready for transfer to the preferred medium - laserdisc. The format chosen for this laserdisc was CAV (constant angular velocity). This format was selected because it could be accessed by a laser barcode reader. This provided immediate access to specific frames, a very useful feature for a gymnastics class. In addition, barcodes allowed portions of the laserdisc program to be cut, copied, and pasted in lesson plans.

Project Outcomes

Many different ways to use the laserdisc were discovered during the course of the semester including (a) large group presentations, (b) small group work, and (c) individual viewing.

The most exciting and active use of the gymnastics laserdisc was with cooperative learning groups. Groups rotated through stations at which different skills were viewed, analyzed, and then performed. During station work, small groups would view the skill they were working on as many times as needed. Students welcomed this move to cooperative learning groups and center-focused learning. They began to see each other as resources and the atmosphere was one of excitement as they guided their own learning.

Discussion

Gymnastics requires active learning and hands-on experiences, so a passive use of technology would not be a solution. Production of a laser videodisc with an active application was the answer.

Providing Technical Information to Teachers Through Videotaped Training

Providing training to teachers using video has become fairly common (Lane, 1992). It is an effective way to teach a new approach to a familiar topic (Lambert, Heaton, & Ball, 1994), and an efficient way to deliver training to large numbers of busy teachers in schools scattered over large districts. Special care must be taken, however, when the training content is highly technical and has high-stakes implications for students. A school district in South Florida found the approach described below to be especially useful for “just in time” training on how to implement a new graduation option for students with disabilities.

Project Description

Florida is one of the few states that allows school districts to award differentiated diplomas to students with disabilities. In June 1994, the State Board of Education added another option. This second special diploma option, unlike the earlier one, is not based on course credits and mastery of the state-developed student performance standards. It is based on documented employment and on mastery of a set of exit competencies developed for each individual student.

Requirements for graduation under various diploma options are technical and complex, and implications for young adults with disabilities in their choice of diploma options far reaching. Staff responsible for training teachers were concerned about delivering precise and thorough information about Special Diploma Option 2 in time for implementation within a few months. They felt it would be better to develop a video tape with an “expert” providing the technical information and to train area and district personnel to facilitate teachers while they watched the tape. The original developer of the Special Diploma Option 2 concept was hired to make a videotape and to train special education personnel in how to use it in training middle and high school teachers.

This service delivery format accomplished the following:
1. It assured that identical and accurate information was provided to all the people who were going to implement Special Diploma Option Two.
2. It recognized the time and travel constraints.
3. It gave teachers immediate access to an area level person who had already had training in Special Diploma Option Two, so specific school/area concerns can be addressed immediately.

Process
The two keys to this type of training are to have (1) a video tape with accurate, clearly presented information, and (2) well trained facilitators. Area and district personnel were trained in the use of the video tape. Training tips included general best practices before the training, such as how to schedule training sessions, arrange for the site, invite participants, gather materials and equipment, and prepare the agenda/schedule of training session.

Facilitators were instructed in good practice for training, such as previewing the materials with the participants, facilitating the hands-on activities at various intervals during the tape, leading the problem solving session and accessing resource materials referenced on the tape.

Project Outcomes
Training was delivered to over 400 middle and high school teachers in 40 schools. Participants reported being pleased with the quality of the video presentation and felt the content was covered clearly and comprehensively. They especially enjoyed the still pictures of local students and teachers and the role play depicting a meeting to develop the graduation competencies.

Discussion
In the past, technical information was transmitted to teachers in hard copy, in large group settings, or in smaller groups by people who were not expert in the material. The advent of video technology solves only part of the problem - accurate information from a primary source. A trained person on-site addresses that very human need to interact with a real person who shares goals and concerns.

Summary and Conclusion
Technology and education are natural partners. The four examples of education/technology partnerships described above are just a few of the ways these two fields, one very old and one comparatively new, can work together. It demonstrated technology as an integral part of these teacher training programs not as an afterthought or an add on. Technology did not significantly change the content or purpose of the training. Rather it was used to address student/consumer demand for collaboration across geographic boundaries, convenient service delivery, precision and accuracy in instruction, and shorter turn-around time for training. As with any partnership, it will take time to see how it works. If they grow together, learn from each other, and remain open to change, it will continue to be a productive and exciting partnership.

In order to develop our view of the revolution that technology is creating in education, it is helpful to briefly consider how technology has revolutionized American culture, and how it has left our educators rushing to catch up (Strommen & Lincoln, 1992, p. 1). Technology has revolutionized American culture, and what better way to teach American history then by following the evolution of technology. City & Country School is dedicated to the philosophy of giving children experiences and materials that fit their stage of development. We believe technology is an extension of their learning, another medium in which to creatively engage and organize their experiences. In this paper we present an alternative American history curriculum, one which includes a complete integration of technology, a study of how the advancement of communication affects the social and economic history of America, and the evolution of modern journalism.

City & Country School

From the very beginning of his education, the child should experience the joy of discovery. The discovery which he has to make, is that general ideas give an understanding of that stream of events which pours through his life, which is his life (Whitehead, 1967, p. 2).

City & Country School, founded by Caroline Pratt in 1914, is the oldest continuously operating progressive elementary school in the state of New York, and is recognized throughout the worldwide educational community as a leading model of progressive education. At the heart of this curriculum is "The Jobs Program," which plays a central role in groups VIII's through XIII's (3rd - 8th grades).

City & Country is dedicated to the belief that the desire to learn is one of the strongest of all human drives and that the most important responsibility of educators is to nurture this drive in every constructive way. To fulfill this responsibility, we must remain true to the philosophy of Caroline Pratt — fit the school to the child, not the child to the school. This holds true when using computers as well. We integrate technology into the curriculum to provide a meaningful experience for each individual student. We do not bombard the child with "bells and whistles" software, but instead, introduce the basics of word and database processing, Hypermedia programming, desktop publishing, design and multimedia. Children use the computer as another tool, mastering it through experimentation, research and self-discovery. At City & Country, we value the process of education in our mission to create life-long learners.

The Jobs Program

Childhood's work is learning, and it is in his play — before he ever gets into the hands of teachers in organized education — that the child works at his job. No child ever lavished on a history book the energy he poured into a game of cowboys and Indians. But cowboys and Indians are a part of the history of our country which he must learn. What is wrong with learning history by playing it (Pratt, 1948, p. 8)?

As children grow and the quest for knowledge becomes increasingly based on written text, they are taught the necessary academic skills — reading, writing, and arithmetic. Simultaneously, they begin to investigate the nature of human interaction from a historical point of view. Each group has a specific job related to the school’s functioning as an integrated community. Our students, like inventors throughout the ages, are in the process of figuring out how people communicate. They trace the process of communication and various technological advancements via their school jobs and history curricula — be it the study of native American Indians and Dutch colonies and the need for the post office in the VIII's (3rd grade); westward expansion and the need for the general store in the IX's (4th grade); the study of the Middle Ages, illuminated manuscript writing and sign making in the X's (5th grade); the emergence of paper and the advent of the printing press in Ancient China in the XI's (6th grade); in the XII's (7th grade), the spread of philosophy and ideas in Ancient Greece, book writing and child care with the IVs; and finally, their City & Country careers culminate in the
XIII’s (eighth grade) with the study of newspapers and American history.

The Learner

... there is an intimate and necessary relation between the processes of actual experience and education (Dewey, 1938, p. 20).

Within the City & Country community, teachers strive to create learners who are independent, engaged and who enjoy learning. Education is a continual growth process that never ceases. We believe that the process of acquisition and application of knowledge is more important than a piece of knowledge in and of itself. By way of bringing process or “hands-on” experience to a child, City & Country hopes to arouse a child’s curiosity and strengthen his/her initiative and motivation. On behalf of the learner, we encourage educational freedom, prompting the student to use his/her physical and social environments to build upon their confidence and then to further their understanding and ideas. Simply providing the setting is not enough. These experiences should be ones that lead to personal growth as an individual learner and within a dynamic group. This is where technology can be useful. More than ever, our world is rapidly changing and we need to guide our children so they can adapt to and deal with changes. Computers can be powerful tools and resources for communication, research, organizing information, and artistic expression. Our children can use these skills to help themselves gain the valuable information they need to explore and participate in their world.

Technology at City & Country School

...new tools alone do not create educational change. The power is not in the tool but in the community that can be brought together and the collective vision that they share for redefining classroom learning (Riel, 1990, p. 35).

City & Country and the Institute for Learning Technologies at Columbia University designed and recently installed an “Intranet” or “inner office” computer system for the entire school. All of the Middle and Upper School (3rd - 8th grade) classrooms and administrative offices are wired and connected to a central computer system. Each of the school’s 37 computers acts as a workstation for the students, faculty and staff to access information from any location in our two buildings. Students are able to communicate with each other and staff members by way of student-run electronic message centers, interschool faxing, and in-house electronic bulletin boards. The students also have access to their personal files and the Library’s database system. City & Country is not yet physically hooked up to the Internet, but will be in the coming months. Until then, teachers are downloading web sites locally for student research and curriculum development. These little “bytes” of technology continue Caroline Pratt’s progressive vision to make information available to a child when it is developmentally appropriate without overwhelming them.

When integrating computers into the culture of the City & Country community, careful consideration is given to the following factors: evaluating the developmental appropriateness of computers, in general, and of particular programs or techniques; demystifying the complexity of computers and their accompanying technology; using computers to enhance the children’s learning without becoming “virtual reality”; achieving equity among boys and girls and among those who have or do not have computers at home; and establishing appropriate ethics and responsibilities in the use of computers.

City & Country views computers as another basic or open-ended material, much like blocks, paint, clay, or books, which can nurture a child’s natural desire to learn. Faculty members provide students access to a wide range of experiences and disciplines with computers, tailoring their lessons to encourage problem solving, creativity, and exploration without fear of failure. These lessons include technology when it is necessary, whether it is the telephone, fax machine, computer or Internet. Making sure students have access to computers freely is essential. Empowering students with various forms of technology is the key to a successful curriculum and is at the core of the educational philosophy at City & Country School.

Currently, the students use computers for daily activities to complement and support the their social studies, English and mathematics curricula. They use computers to extend their real-world experiences by keeping electronic journals, schedules and records of their notes, as well as developing multimedia and HyperCard presentations for their research. In addition to writing interactive papers on the computer, they create electronic databases and publish or “post” their work on the School’s Intranet. These programs allow the students to add still images, video and sound clips into their text. In essence, the students and faculty of City & Country are creating a microcosm of the real “Internet” on a level that is meaningful and manageable to everyone.

8th Grade American History Curriculum

When discovery learning strategies are employed ... there is always something to be gained through exploratory and analytical discussion and reflection (Romiszowski, 1992, p. 330).

Prior to the 8th grade, our children study the history of publication from illuminated manuscripts to the spread of the printing press in China, Europe and America. In the 17th and 18th centuries, printers needed woodcuts,
movable type, and leather ink balls to produce enough copies to communicate with the masses. Later on, rotary presses, linotype and keyboards came along and led to the practice of paste up. This is where the students begin when they publish their own penny press newspapers in September. Throughout the year, technology is carefully introduced in stages which corresponds directly with the subject they are studying and researching in class.

In the 1830s, Americans were introduced to the first "modern" newspaper — the penny press. Readers included the literate working class and immigrants; they were hungry for news about neighborhoods and cities, and, most importantly, politics. At City & Country, the students created their own competing penny press papers. This year the "Democratic Demo" and the "Republican Review" took on the characteristics of these 19th century papers and were slanted and biased in their political reporting. In addition, great emphasis was placed on school news. To publish their papers, the students utilized word processing skills from previous years simply to write, format, and print their articles. The children were not allowed to use electronic desktop publishing programs because they were still learning the ins and outs of physically laying out and copying a newspaper.

As our American History study moves into the 20th century, we find that technology affects every aspect of the newspaper industry, from the pressroom to the news stand, from yellow journalism to investigative reporting, from family run newspapers to huge media conglomerates. Over time, newspapers have become more sophisticated in layout, design, and technology. Our students use these models to add new dimensions to their own newspapers. Following their penny press papers, the children use computers to experiment with fonts, color and photographic images. They add Pagemaker, Quark, Photoshop, and Freehand to their software palette. From November to March, they produce their weekly newspapers completely on the computer, paying close attention to all aspects of design. In their final stage of their journalism study, the students abandon their "paper" newspaper and create "electronic" papers. These electronic "zines" and web sites are published on the City & Country Intranet.

In American History, pamphlets and newspapers were essential and powerful vehicles by which to spread ideas and news. As years passed, technological advancements dramatically downplayed the influence and power of the printed word; television and radio became faster vehicles by which Americans got their messages out. To understand this, we examine questions such as, How does a visual image affect the public? Why are certain images of people used and others not? How has television and multimedia changed new print? Other questions arise about how technology influences the "permanence" of information.

How will technology affect their readership? Who are their primary consumers?

Integrated into the newspaper curriculum is the study of the electoral process which begins in the Fall and ends on Election Day in November. At the beginning of the school year, the XIII's were split into Democrats and Republicans and were expected to run a mock presidential campaign in school. They gave speeches, held debates for the students and faculty, distributed their position papers and campaign handouts, and published their penny press newspapers. The students used the computer as their central tool to accomplish all research, writing and publishing. Except for the penny press, they worked completely on the computer, publishing interactive biographical and political information about their political candidates, complete with polling information, photographs, and commercials. They also developed Quicktime movies and electronic sound bites; when you turned on a computer, you automatically received election information and advertising. They began to discover how computers are often more efficient and inexpensive in getting the message out. They followed real world models and found interactive mediums to be more elaborate and potentially more engaging and attractive to their target audience. Experimenting with the technology led them to placing more information in the hands of the reader.

All in all, the XIII's experienced what it was like to run a presidential campaign. They learned how to make story boards, video tape and edit commercials, write speeches, campaign, interview and even deal with political muddling. They did not just read about the election process, but they experienced it.

In the Spring, the children will continue their study of 19th and 20th century mass culture and will again present their research and analyses using multimedia. With each research project, they will develop even more complex and intricate presentations using basic programming in HyperTalk and HTML. By employing Pagemill, Netscape, and BBEdit, the students will create their own personal World Wide Web pages. They will conclude the year with a publication on the Internet, as part of the first City & Country School web site.

**Teacher's & Technology Coordinator's Role in the Classroom**

The key to success lies in finding the appropriate points for integrating technology into a new pedagogical practice, so that it supports the deeper, more reflective self-directed activity children must use if they are to be competent adults in the future (Strommen & Lincoln, 1992, p. 6).

The center of the progressive philosophy embodies, when properly executed, the commitment to student-centered education in which the child's individuality is a key determinant of the way in which the teacher executes...
the curriculum. Like other areas in school, the teacher provides the structure, but the execution comes from the child. In other words, the teacher serves as a moderator and facilitator.

The teacher’s role is to empower children by helping them recognize their abilities in their own creative manner. A teacher guides the class through the content portion of the curriculum, helps them develop the research skills needed to locate information, and shows students how to make connections to understand history better. When it comes to presenting their information though, the children have the autonomy to make their own decisions while meeting the requirements of the assignment. The end result is not the mere regurgitation of facts, but a continuing acquisition of skills.

The role of the technology coordinator or computer teacher is also an important component in the education of the child. As educational institutions introduce computers, a technology coordinator becomes more valuable. She/he is no longer the person who sets up the film projector or makes sure the television is running, but the person who drives communication and information philosophy through the school. In that respect, technology is more than just teaching students the ins and outs of computer software, but it is educating them to obtain the information needed to engage in a multimedia society. A computer need not be a glorified typewriter, but is the vehicle with which the student organizes his/her learning. This requires that a student use the computer for filing information, communicating with others, developing projects, and publishing their work. We instill confidence in students in their ability to comprehend computers, so they can freely decide which technology best suits their needs.

For the students to be successful, the teacher must work closely with the technology coordinator. This is a twofold activity: first, time needs to be allocated for the teacher and coordinator to develop and integrate the technology into the curriculum; and second, the teacher needs to be trained. Scheduling computer time for the students is also essential. This year, the XIII’s (eighth graders) worked in the computer lab daily. The computer became an invisible tool, much like a pencil or piece of paper, in every aspect of their work.

The teacher determines the material that will be covered in a given year, while the technology coordinator has the expertise and knowledge of the computer. Empowering the teacher is always the first step to enabling the students. Training the staff has now become the key role of the technology coordinator. It is imperative that teachers become technically literate and comfortable when using computers. Like teaching students, the technology coordinator needs to be sensitive to the individual. The coordinator needs to teach what is necessary, always making lessons appropriate. City & Country not only embodies progressive education for students but supports a long history of training teachers to become experts in “learning from children.” Together, the teacher and technology coordinator create a program that is developmentally appropriate and academically challenging.

Conclusion

How do we educate the “new child,” raised in a world of instant information, where interactive technologies have led them to believe they can act on the world with the press of a button (Strommen & Lincoln, 1992, p. 2)?

The Middle School and Upper School curricula at City & Country School embody and trace the progression of communication and technology throughout history. We are, in essence, providing experiences for them to understand the process and the impact of these advancements in technology. The discovery of paper had enormous implications on the printing press and literacy, as did the Pony Express when post offices opened up across the country. Now, the proliferation of personal computers, electronic mail and the Internet is making today’s world even more accessible. With the use of technology, we encourage independence and resourcefulness in our students. Nurturing that love of learning and the ability to be autonomous is at the heart of progressive education. It is our responsibility as teachers to provide the experiences that prepare our students for the 21st century.

This is a tale of two schools, two teachers, and two groups of students. The schools are Texas Christian University's School of Education and the Alice Carlson Applied Learning Center, an elementary school in the Fort Worth Independent School District. The two teachers are myself, an Assistant Professor of Educational Technology at the university, and the elementary school's Multimedia Specialist, Charles Williams. The two groups of students are graduate students in my educational computing courses and children attending the elementary school. These entities became connected through a professional development school project and happened to be located on adjacent campuses.

The School

The Alice Carlson Applied Learning Center is a school of choice that is open to all students in the district and operates on year-round calendar. The school's central purpose is to encourage children to learn, both independently and as team members, in a stimulating environment with strong links to the community.

Applied Learning, the approach upon which instructional practices at the school are based, requires that students use what they learn in solving a problem or fulfilling some important need. Finding resources beyond textbooks or encyclopedias is an integral part of this process. Students are required to communicate in different circumstances, using visual, oral, or written means. Educational technology is intended to be a fundamental part of this process.

Children at the school are given the opportunity to join clubs during the regular school session. They may also attend workshops during the fall and spring intersessions. These clubs and workshops allow students to pursue interests in a variety of areas. They provide opportunities to work with local artists, talented parents, university interns, and staff members who sponsor workshops or clubs.

Club Benefits

As a result of the professional development school project, I became involved in co-sponsoring a computer club with the elementary school's Multimedia Specialist. The club serves as a laboratory for introducing and experimenting with new programs while providing a mechanism for professional development for both of us. I use the club to try out software that I'm teaching in my classes. I can then tell my students stories about what happened, show them examples of children's work, and provide them with opportunities to observe children using the software either during club time or at other times during the school day. The school benefits in several ways. The club members benefit by learning more about computers. In addition, the club has become a tool for encouraging the use of new software throughout the elementary school. After it is used in the club setting, the software may then be used in other contexts, either as part of formal lessons or on an ad hoc basis.

Club Operating Procedures

Computer club members are selected through an application process or by teacher nomination. The activities that the club work on are demonstrated and/or described. Interested students are then asked to submit a letter of application, telling why they want to be in the club and stating their qualifications for membership. Some letters are as simple as the one below:

I would like to be in the computer club. I think you should let me in because my teacher thinks I am responsible and computers are something I should have a chance to do. It will also help me write better.

Other letters are a bit more complex:

I think I could be in the computer club because I like computers and I like to learn. I think computers are cool. All I know now is how to play games and use it as a word processor, and I want to learn more about computers. I know that there is a lot more about computers that I would like to learn. We have a Macintosh at home. Through this club, I hope to make better use of the computer at home and school. Thank you for considering me for this club.
The primary qualifying criterion is the child’s motivation to be in the club. Those who are motivated are more likely to be productive and stick with their projects. The club’s size is typically limited to between six and twelve members, with at least two students from each fourth and fifth grade class and an even mix of boys and girls. Girls sometimes need a bit of extra encouragement to participate, as boys tend to apply for the membership more frequently than girls.

Club meetings are usually held in the school’s media center, which is a hub of activity for the school. The lab houses about 20 Macintosh computers, and peripherals such as a scanner, digital camera, laserdisc player, modem, and an LCD panel. When access to the Internet is needed, we have held club meetings in the School of Education’s computer lab, which is within walking distance of the elementary school. This lab also has about 20 Macintosh computers that are connected to the Internet via an Ethernet network.

Each semester at least one program is selected for club members to work on. In the past, the programs have included HyperCard, MicroWorlds Project Builder, HyperStudio, and the Internet. Students are given some general guidelines for the types of projects they can work on, but have a great deal of freedom to choose exactly what they will do. They are provided with demonstrations, instruction, and assistance, as needed.

**Club Projects**

**Hyper-Adventures**

Our exploration of using HyperCard provides a good example of the club’s impact. I had read and heard about children creating hypermedia projects. However, I suspected that there might be logistical difficulties and did not know if elementary school children could handle such projects. I was uncomfortable advocating a hypermedia project to students in my computer courses when I had not tried implementing one myself.

Charles and I decided to try out HyperCard with small group of six fifth graders. Each week a new skill was introduced and students worked in pairs to practice and apply it to the projects they were working on. Once success was achieved with this small group, the size of the club was increased to 12 members. Those in the first group were encouraged to teach the new members how to use the software.

To learn more about HyperCard, Charles attended a summer workshop that I taught and an ongoing course that I teach about hypermedia. These learning opportunities were funded by our professional development school grant.

Our efforts have lead to other uses of HyperCard at Alice Carlson. Charles has taught fourth and fifth grade classes to use HyperCard and has held an intersession workshop on HyperCard for second and third graders. (I was surprised to find out that HyperCard was successful with children that young!) He has also found other opportunities for using the program. For example, he helped two fifth graders do a stack on Texas wildflowers in lieu of a written report.

My students have also seen children working with HyperCard when observing at the school. One student wrote in her journal:

I began to watch two girls work with HyperCard. They were playing a game that they created. It was a game about finding your way out of a forest. I was in awe, literally, because I think this is all so great. This is what I want for my students.

This observation is typical when children are given freedom to choose a project involving HyperCard.

**MicroWorlds**

Club members have also worked with MicroWorlds Project Builder. These projects provided my students with an opportunity to see children using the program. Such observations are particularly important, because the way adults interact with the program can be much different from the way children respond to it. Adults sometimes become frustrated or anxious when attempting to understand and solve problems using MicroWorlds. By watching children work with the program, adults can see the children’s level of engagement and the kinds of thinking that it fosters. One student observed:

I was impressed with how creative the children were in using MicroWorlds. The importance of allowing free exploration, as opposed to the typical “drill and kill” was reflected through this experience. The children learned in an environment rich in mathematical, artistic, and technical operations. Their intense involvement, so much so that they did not seem to want to leave.

Students also have a chance to observe appropriate teaching strategies while children are learning to use the program. One student observed me introduce the program to four boys in the computer club and wrote:

They had obviously learned a little about MicroWorlds already, because when Dr. Anderson asked about certain details of the program, they knew. For example, she asked “Do you remember how to put the pen down?” A boy responded, “Yeah, uh, PD.” Another question asked was, “What would make the turtle turn half the way around?” One boy answered, “Left 160.” Instead of correcting them right away, Dr. Anderson submitted that command so that the kids could see that it wasn’t quite right. After that demonstration, it was easier for the kids to figure out that they needed to turn the turtle just a few more degrees to get it to face the opposite direction.

I have also integrated my class work with the computer club activities by showing the club members some of the projects my students had worked on. The children could get ideas for their own projects by viewing club activities or
they could learn more about the program by modifying or adding their own ideas to the existing projects. At the same time, my students had a chance to field test their projects with children. One student observed three boys working with a microworld about Hawaii and wrote:

The children did a great job in deciding who was going to control the mouse and what they were going to do. If someone did not know how to do something they would help them by telling them how to do it. They were trying to get the turtle to travel to different islands by using the button. They could not seem to get it to get off the first island. I guided them to use the right and left buttons to move the turtle a different angle and then click travel. They seemed to like to try to pronounce the names of the islands. They had the most fun on the next page, [which showed] the earth with a plane that would travel around it, some stars, and other planets. The boys pushed the button and it would play "It's a Small World After All." They would change the plane to into a spaceship then to a space man, then they would blow him up to be really big, then try to find out how small they could make it. One said, "Hey, the smaller it gets the faster it goes! Let's leave it here."

Art and the Internet

Another club project arose out of my curiosity about how teachers could make use of resources available on the Internet. The Dallas Museum of Art had made images from its collection available through a Gopher server. I wondered how this resource could be useful in an educational setting. This project provided me with a source of stories and sample projects to share with my students.

I started by downloading a sampling of images from the museum's Gopher site and bringing them to the school to show the computer club. The club members used image viewing software to look at and manipulate the pictures. They changed the dimensions so that the pictures were tall and skinny or short and fat.

The next week we took the club members on a field trip to the museum. The children were excited to find the items they had viewed the previous week. Some of the students decided to hunt for a gold cup that they had seen on the computer and remembered in great detail. They located a case of gold cups, but did not see the one that was on the computer! This lead them to discover that the museum does not display all the articles in their collection.

Students then selected one of their favorite works of art and incorporated it into a project they created using HyperStudio. Their projects included images from the museum's collection that were either downloaded from the Internet or digitized using a scanner. One of the most elaborate projects was an adventure story in which the user makes choices to find a "sacred blade" that they had seen at the museum.

Surfing the World Wide Web

Later students learned how to search the World Wide Web. The most intriguing aspect was to observe what sites the children were interested in and which held their attention the longest. I started out by providing a web page with links to sites I thought they might like. However, I found I wasn’t a very good judge of that! What ignited the children’s interest was a gaming magazine, brought by one of the students, that contained a web address for a game. Once this site was located, the word spread around the lab. Soon most of the children had learned how to type in an address to go to a specific site. Later they began using various search engines to find things that they were interested in, including, sites about books the liked to read, games they liked to play, movies they had seen, and favorite TV shows.

One of my students, attending a computer club meeting, was able to experience the phenomenon of adults and children learning from each other:

The club had been surfing the net during the school year. They were definitely ahead of me since this was my first real experience on the Internet. I had spent a few minutes with it when it was introduced in class, but I had trouble finding my way around in Netscape Navigator. The students did not seem to have this problem. I was looking over the shoulders of the two boys on either side of me quite often.... There were several times that they asked me questions, as if I should know simply because I am adult. Strangely enough I was able to help them some of the time. But they definitely helped me more.

Later this student, brought her Camp Fire Club to the university computer lab so that they could search for information on the Internet. Several students from my class were also there to observe. One noted the way the children learned from each other:

The boy next to me looked up Disney in order to find something on James and the Giant Peach. The boy who was sitting next to him was still working on information about Bluebirds, but was paying attention to us as well. After about ten minutes of searching, he was able to find James and the Giant Peach. The boy sitting next to him continually voiced ideas on how to find the intended page and what to do once he got there.... Once he had it on his screen, word quickly spread to other students and they quickly tried to find the same page on their own.

The club’s use of the Internet has spawned several other applications at the school. For example, when Charles learned that a first grade class was doing a weather project, he suggested using the Internet as a resource for gathering information on weather patterns. The first graders checked weather in six cities and posted the information on a bulletin board in the hallway. My students have seen this in action when observing at the school.
The little girl wanted to get a weather report off [the Internet] to share with her class. She had been doing this on a regular basis, but had not done so in several weeks. Charles walked her through the steps, allowing her to perform the necessary steps if she remembered them and coaching her through the rest. She began by switching on the modem and going to the weather folder. When she had written down the codes of five cities, she was ready to obtain the weather reports of each. She obtained the weather reports for the individual cities, cutting and pasting each into her document. She then printed the weather reports to share with her class.... It reminded my of the teacher in *We Teach with Technology* (Kearsley, Hunter, & Furlong, 1992) who had his students download information to use in a class project directly from the weather satellite. The little girl's information was only a half an hour old!

Other Internet activities have included reading stories on a web site called "Kidpub" and exchanging e-mail with authors of the stories. One of the poems was published, with the author's permission, in the school's newspaper.

**An On-line Art Gallery**

This year the club is involved in the creation of an on-line art gallery for the school. I anticipate that this will be the most challenging project we have attempted thus far. We identified several tasks required to establish and maintain the art gallery. Students selected a task that they wanted to learn about and be responsible for. Some students worked on a process for soliciting artwork from each classroom, including a letter to teachers and a form to be filled out by the student artist and signed by a parent. Others have learned to use a digital camera or scanner for digitizing artwork. A third group designed and created the web pages that will display the artwork. Breaking the project into parts and allowing different students to gain expertise in just one part will hopefully make this complex task feasible. Later students will be able to teach their skills to others, so that the children will have a chance to learn other skills.

**Summary and Recommendations**

The computer club has provided a mechanism for informing teaching practices at the university and at the elementary school by serving as a laboratory for trying out various technologies with children. It has provided me with a source of "real life" stories to tell students in my classes, a collection of children's projects to show my students, and a setting for my students to observe and interact with children using computers. It also served as a source of professional development for the school's Multimedia Specialist and myself. Besides providing opportunities for a select group of children to learn more about computers, it has helped promote the use of different types of software and hardware throughout the elementary school.

If you would like to start a computer club, Charles and I offer the following suggestions for a successful experience:

1. Select children who are interested. Those who apply for membership in the club are likely to be motivated to participate.
2. Keep the group size small. This makes trying new things manageable and mistakes less disastrous. Once the "kinks" are worked out, the software can be tried with larger groups or whole classes. Students who already know the program can help by teaching their peers how to use it.
3. Encourage collaboration by having students work in pairs or groups. This allows students to learn from each other and to contribute their unique talents to the completion of a project. Children often learn computer skills by watching what their peers are doing and asking them to explain how it is done.
4. Allow students to choose what they will work on, within certain guidelines. For example, specify what program is to be used, but let them choose their own topic or role. Students are more likely to stay engaged in a project for long periods of time if they are working on something they are interested in.
5. Remember that children acquire skills by playing. Allow them to experiment and have fun! While they are doing this, you will learn a lot about what children naturally do with computers.

We hope that you will benefit from and enjoy doing this as much as we have!

**Acknowledgments**

Financial support for the professional development school project was provided by a grant from the Sid Richardson Foundation. The author would like to thank Charles Williams for collaborating on this project and providing information for this paper.

Susan Anderson is an Assistant Professor of Educational Technology at Texas Christian University, TCU Box 297900, Fort Worth, TX 76129. Voice: (817) 921-7943, Fax: (817) 921-7701. E-mail: sander@tenet.edu
LEGO-Logic is a learning environment that integrates creative construction of concrete machines and models with an introduction to computerized process control. LEGO-Logic was developed to facilitate the understanding of both scientific concepts and their technological applications and logical thinking of programming and control. The environment was designed to be suitable, attractive and effective in teaching even young beginners.

Tammy, Natalie and Judy are planning to build a car from LEGO bricks. Tammy and Natalie are building the base of the vehicle and its wheels, whereas Judy is building the vehicle body.

Tammy: I need four motors.
Teacher: What are you planning to build?
Tammy: Very simple, a car.
Teacher: And why do you need four motors?
Tammy: In order to turn the four wheels, of course.
Teacher: Do you know how many motors are in your family car?
Tammy: (hesitates): Maybe just two?

After a few moments of silence, during which Tammy manually moves the LEGO car back and forth:

Tammy (speaking loudly to herself): Actually, two motors will be enough for me. I’ll attach them to the front wheels, and the back wheels will be towed along. (turns to the teacher) Okay, so now I need two motors.
Teacher: But now, I have a slight problem. All the motors are being used by other children, and there is only one left. So your task now is, to turn the two wheels using only one motor.

This conversation between twelve-year old Tammy and me took place at a lesson in the Computer Laboratory of IDEA Center, at the department of Education in Technology and Science at the Technion. The lesson was part of an experiment aimed at examining the possibility of implementing an innovative project called LEGO-Logic. The research was carried out by IDEA Center directed by the author.

The above dialogue can on the one hand, hint at children’s existing knowledge concerning technological concepts and phenomena, and on the other, demonstrate that exposing children to those concepts, in an appropriate learning environment could improve and enhance their knowledge in this domain.

Modern society is characterized by the rapid developments taking place especially in technology. The educational system that aims to prepare the student for life in such a society has to adapt its curriculum to include technology as a vital field of knowledge.

What do We Mean by Technology?

We propose to adopt the term “Technology” as human knowledge that is utilized to answer human needs both material and spiritual needs. This definition reflects the alternative approach to technology which considers technology as one of the components of the social-cultural medium (Hiedegger, 1969; Simon, 1990). Knowledge, skills and resources are combined to help solve various existential and practical problems. Alvin Toffler in his book Future Shock (1970) states that the metaphor that relates technology to machine, has always been unsuitable and even erroneous, since technology was always more than factory and machines. Technology can be seen as human competence and talent to overcome its human biological restrictions by extending its abilities.

The qualification of students to live in a technological world will be evident in their ability to efficiently utilize technology, use existing technology to plan and manufacture new products, and think of directions to develop new technologies. Thus, learning technology has to involve two main activities: using technology and developing new technologies. Understanding the nature of technology and its influence on human life is essential for the development of curriculum for Technology Education.

The Model Used for Curriculum Development

In order to study the interrelations between technology and the human beings and to realize its influence on the
development of society, a theoretical model called “The Spiral Model of Technology Evolution”, was used (Krumholtz, 1996; in press). The Spiral Model describes the interrelations among four factors: human needs, physical phenomena, technological constraints and technological solutions.

Based on the Spiral Model we suggest to distinguish five stages in developing of technological products:
1. Research - to identify human needs or problems that call for technological solutions.
2. Plan and design a solution - chosen out of different solutions that had been suggested.
3. Carry out the Plan - producing the product.
4. Market - the product.
5. Future developments - of improved product or of a new one as a subsequent of usage that triggers new needs.

We suggest an educational approach to teaching technology that allows the learner to experience technological activities and technological processes. A technological process includes the identification and separation of all four factors in the Spiral Model. The learning experience in a technological process starts with identifying a problem - an human need - and ends with raising and choosing a solution - the production of a practical product. Science and technology learning is inherent to the global learning process when the student tries to deal with technological problems and to overcome physical constraints.

The learning environment that allows such activities must fit the learner’s ability level and to relate to individual fields of interest, so that the technology activity will be as real and as significant as possible.

Our Pedagogical Approach to Learning

Our pedagogical approach is based on the constructivism theory of development suggested by Piaget (1954; 1973), that learning is building knowledge structures, and on the educational philosophy developed by Seymour Papert and others - the social constructionism approach (1980; 1991; 1993). The pedagogical approach is built on independent inquiry and self-guided learning and it facilitates the personal construction of knowledge about the external world.

The Learning Environment

In order to give the learner the opportunity to go through a process similar to the process of developing a technological product in real life, we had to choose a simulation system to fit the learner. That is, it has to be easy to use, close to the content of the child’s world of interest and suited to his or her level of development. Moreover, in order to teach scientific and technological concepts and principles in a way that will lead the student from intuitive understanding of the concepts to a more formal, scientific understanding, it is necessary to provide the student with a wide range of concrete experiences using simple models and familiar tools.

We have found that LEGO DACTA computer control systems: LEGO-Logo and the later development ControLab, meets these requirements. They can be used in classes as “Micro-Worlds” that the kids can operate in (Resnick, 1993). We have developed learning activities that allow the learners to experience technological processes. Through the activities students gain practical experience in planning, constructing and operating physical models that are computer controlled. The learners are building models from LEGO bricks, including motors, lights and sensors and using the computer to control the operation of the models. Such models are traffic-lights that simulate real operation, greenhouses that open and close doors according to the temperature, remote controlled wheelchairs, washing machines, conveyor belts that identify boxes with dissimilar size or color, elevators, and racing cars.

Figure 1. A LEGO Dacta computerized model.

The Learning Process

Following the five stages of development of technological products, we suggest that the children experience five stages in the learning process of becoming both users and developers of technology:
1. Learn about human needs - identify one need or demand.
2. Plan and design a solution - suggest a LEGO model that will give an answer to this need.
3. Carry out the plan - build the model from LEGO bricks and program the computer to control the model's operation.
4. Market the product - exhibit the product in the classroom.
5. Suggest future developments - for your LEGO model based on possible new demands it may triggers.

Advantages and Difficulties

Models

Based on our experience with students and with teachers we found that the LEGO DACTA computer controlled models answer our needs to a simulation system that helps deal with the technological world. We realized that the LEGO bricks and the variety of products allow us to choose different models for the different populations. The great variety of LEGO models and building elements made it possible to define an evolving line of models with increasing levels of complexity.

Software

Working with the programming software TC-Logo and later with the ControLab software, we identified some basic difficulties:

1. It takes time to learn a formal computer language properly, in this case the Logo language. This was very crucial considering the time limit of 30 hours we had.
2. For young and novice learners the programming language is too complex, even without considering time limits.
3. The English language is not the mother-tongue of Israeli children, and therefore is especially hard for young learners of grades 3 to 6.

We realized the need to have a programming software that: keeps the powerful ideas of Logo programming like structured programming, simple recursion, closed-loop and open-loop control; is easy-to-use in relation to the level of the user; is user friendly, for example, commands which are represented as icons and not as words; has an on line detailed help screens, to allow inquiry and self learning; and does not require any previous experience in computers.

We defined the concept for a programming software that, in cooperation with a software-house in Israel, was developed under the name of TechnoLogica.

LEGO-Logic - The New Learning Environment

TechnoLogica software, the LEGO models and the learning activities and processes based on our educational approach, composed a new learning environment called "LEGO-Logic". For the teaching of Technology we chose to emphasize the role of the logic of control structures that are defined using TechnoLogica, rather than programming using formal computer language. In that sense, TechnoLogica was developed as an icon based software that allows the user to define various control structures (IF, IF-ELSE, WAITUNTIL, REPEAT) without the need to use any use any formal programming language.

TechnoLogica allows three modes of control:

1. Immediate mode of manual control.
2. Automatic Control: Open-loop control, executing a list of commands.
3. Feedback Control: Closed-loop control, using sensors for feedback.

To let students experience technology evolution, the models are first operated manually. Then, a motor and batteries are added to operate the model by electricity. At these stages the student operates the models in on/off operations, under manual control.

At a more advanced stage of control, the model is connected to a computer and is automatically operated, controlled by TechnoLogica procedures, programmed by the learner. In the final stage, sensors are used to enable feedback in the control loop.
In a final exhibition, part of the marketing phase, each participant raises suggestions for further development of the product that may satisfy new advanced needs triggered by using their model. An example for such a model is an elevator. In the first stage the elevator is operated manually by the user who pulls a string connected to a pulley. In the second stage a motor is connected to the pulley via gears and is operated using batteries to supply electricity. The student decides when to stop the motor when it reaches each floor. The student uses his eyes to identify when the elevator reaches a certain floor.

The more advanced stage is when the motor is connected to an interface box that is connected to the computer. A procedure is programmed to operate the model to run a four times loop of 5 seconds ON and 3 seconds OFF, to allow people to get on and off the elevator. This operation is called an open-loop control or an automatic operation.

In the last stage a light sensor is attached to the elevator and to allow for feedback; when the light sensors “sees” each floor, the computer “tells” the motor to wait for 3 seconds, before going on to the next floor. The future developments for this elevator model suggested by the student are based on a safety need that will arise when the elevator is used. Another light sensor could be used to determine if people are standing in each car and the computer could prevent the movement of the car in each floor.

Research Results

LEGO-Logic was tested with groups of pupils of different ages and with different needs: average students aged 8 to 14 in a special research setting and in normal class settings, gifted kids aged 6-8 and 13-14; and students at the age of 12-14 with learning difficulties.

One of the studies that took place, involved a group of 6th grade students familiar with Logo programming. The experiment made it possible to expose the students prior technological knowledge and to identify their motivation factors.

Another study engage three groups of 7th and 8th grade students who went through the process of developing a technological product according to the learning process that was described above. The research concentrated on identifying the physical concepts and principles and the technology phenomena that could be experienced in the computerized LEGO learning environment. Moreover, the level of understanding of the students on those concepts and phenomena was tested. The analysis shows that
physical concepts such as speed, acceleration, static and dynamic friction, gravity, force and balance were involved and that most students (87%) had reached intuitive understanding of the concepts. Some of the students (24%) expressed more formal scientific understanding of the concepts. The technology phenomena that were identified were mechanical advantage in tradeoff between speed and power in a combination of tooth wheels, the relation between the feedback from the sensors and the control of the machine's operation, and the distinction among manual control, automatic control and feedback control.

The group of students with learning difficulties had reached the intuitive understanding to some extent. What was most significant in their experience, as expressed by them at the end of the learning period, was the chance they had been given to create something of their own—a solution which they invented. Their expressions of creativity ranged from merely giving a name to a given model to suggesting new different operations to its function, and for some of them even building of a model out of their imagination.

**Final Remarks**

The modern age is characterized by the rapid developments taking place, especially in technology. Unfortunately, although major investments have been made in developing high technology, the guiding ideas and concepts are not always clear to the user, who then on a daily basis. In addition, school curriculum touches only a few aspects of these rapid developments, and thus is not properly addressing the need to prepare future citizens to work in today's technology environment. The LEGO-Logic learning environment is one of the answers to this educational situation, an environment that can help deal with the technological world of today. We believe that having gone through such a learning process, students will be more ready to become both users of technology and developers of new ones.

**References**

"The IDEA Center, once called the "Israeli Logo Center", is involved in the past eight years in research, development and implementation within the fields of Technology and Scientific education. The specialty of the center is the development and implementation of innovative learning environments which use computer technology to enhance learning and teaching. Such learning environments that has been developed are for example, Logo and LEGO-Logo. The learning environments developed in the IDEA Center are open environments, which can be implemented in various content areas and be activated with different learning and teaching styles.

**Dr. Nira Krumholtz is the head of the IDEA Center at the Department of Education in Technology & Science, Technion - Israel Institute of Technology, Haifa, Israel 32000. Voice: 972-4-8293112 (W), 972-9-9581724 (H) fax: 972-9-9557665 E-mail: ttrnira@technunix.technion.ac.il http://www.technion.ac.il/idea**
The evolution of distance education in the US has generally paralleled the evolution of technology. In fact, over the past twenty-five years, it has been one of the few areas in education where technology has been central to the teaching task. However, familiar delivery systems such as telephone, radio, and television are rapidly changing with the addition of fiber optics, wide area networks, the World Wide Web, and a variety of other computer technologies. Distance learning students now can receive assignments, take tests, and interact electronically with their instructor and classmates. Distance educators can now deliver instruction through one-way and two-way satellite video conferencing and computer telecommunication tools such as electronic mail, electronic bulletin boards, chats, computer conferences, and mailing lists called Listservs. Courseware can also be delivered all over the world with hyperlinks to documents, graphics files, sound files, and digital movies through the World Wide Web (WWW).

While distance education is not a new form of educational delivery, distance education (as a topic) is a new section in the Technology and Teacher Education Annual. The authors represented in this section provide a wide variety of distance education applications and technologies. The programs and courses described are as varied in their content and sophistication as the technology used to deliver them. Grouping these articles proved to be a challenge. Should they be grouped by technology, or should they be grouped by project or purpose? I decided to take a middle-of-the-road approach. I started with a broad overview and moved to more specific topics and technologies.

The paper by Omoregie opens the section. It provides an overview to the various distance education technology tools. Omoregie points out the importance and need for planning, preparation, and organization of distance education efforts. McManus provides a discussion of distance education at the university level. This paper explores important issues and how universities are redefining themselves in light of advances in telecommunications and changing educational paradigms. Gannon and Blind design a distance education internship for graduate instructional technology students. Such an internship provides students with an overview of all components and activities involved in the distance education division of a major urban university. Hill addresses cost and quality issues of distance education in the college of education at a state university. Specifically, Hill asks: Is distance education as good in terms of quality as traditional learning, and are the benefits of educating teachers through distance learning worth the costs?

Several authors researched and evaluated distance education projects. Daulton, Barlow and Thomerson research student perception of distance learning experiences. McKenzie, Kirby, Davidson, & Clay evaluate the strengths and weaknesses of a state program from both faculty and student points-of-view. Riedling explores the social issues that can restrict or encourage doctoral students in a distance education program.

Using distance education technologies in teacher education programs is a popular and growing movement. Tucker describes an experimental floating lab used to teach hands-on activities to pre-service teachers. Stanbrough & Stinson; Lumpkins, Pippen & Parker; and Barton & Boulware discuss a variety of distance learning activities and technologies they are using in pre-service and in-service teacher education programs. Gere, Miller, Heller, & DeMorner discuss TATE (Teacher Assisted Teacher Education), a two-way video project, designed to provide pre-service teachers the opportunity to observe exemplary teaching practices. Common threads of discussion are: student and instructor needs, strengths and weaknesses of the various technologies, and the use of collaborative instructional strategies.

Parolatnikova uses EdNet to teach beginning Russian to remote sites in Utah. Speziale talks about the Northern Tier Rural Distance Learning Consortium and how it partners with the State Museum, via compressed video, to provide alternative uses of technology. Mims, Newbill, & Schick propose the use of emerging technologies to enhance awareness of cultural diversity.
Several authors describe large projects that combine multiple technologies. Tieke's project describes interactive courses which have WWW access and two-way compressed video in networked classrooms. Nummi, Rönkä, & Sariola's project uses a variety of technologies for linking the students to activities and events outside the classroom. Pohjolainen & Ruokamo-Saari describe the Distance Learning in Multimedia-Networks, a joint national Finnish project designed to develop technically and pedagogically useful methods for distance learning.

New developments in computer technology now make it possible to deliver distance learning completely online via a variety of synchronous and asynchronous communication channels. Allen, Hartman, & Truman, Pitt & Stuckman, and Rose discuss the pros and cons, techniques, and issues involved with this strategy. Gamas uses this approach for collaboration through classroom forums. Mackenzie, Kitto, Griffiths, Bauer, & Pesek describe how they have used online techniques for Problem-Based Learning (PBL) experiences. Leddo's Virtual Schoolhouse is a repository of electronic educational resources and includes a resource room with intelligent agents and intelligent simulations. Stockbrand & Althoff discuss online graduate programs for those unable to take advantage of traditional programs.

Educators and administrators are now beginning to recognize that distance education technologies offer a new way to realize basic missions and goals. What can be accomplished through distance education cannot always be accomplished through conventional classroom instruction. The decision to implement distance education technologies can be a powerful step toward achieving valuable benefits for academic institutions. The innovative capabilities of emerging technologies, combined with the talents and creative energies of faculty and participants, will fundamentally change what, when, where, and how people learn.

Marilyn Heath is a doctoral student in the Department of Curriculum and Instruction, College of Education, University of Houston, 4800 Calhoun, Houston, Texas. Her area of research is distance education with a specialization in computer-mediated communication and on-line learning. E-mail: mjheath@ghgcorp.com
DISTANCE LEARNING: AN EFFECTIVE EDUCATIONAL DELIVERY SYSTEM

Mike Omorogie
Jackson State University

In recent years, researchers have studied the effectiveness of distance learning and its delivery methods. Willis (1994) contended that researchers have attempted to study distance learning effectiveness by exploring variables such as student demographics, motivation, attrition, cognitive style, gender, and achievement. Eiserman and Williams (1987) conducted a study exploring the comparative effectiveness of distance and traditionally delivered instruction which also agreed with Willis’s variables. In the study, they concluded that distance-delivered instruction could be as effective as traditional instruction if the delivery methods were based on the background and experience level of the students. The content examples should be relevant to individual learners’ experiential and cultural background. In a similar study by Omorogie & Jackson (1996), variables such as age, gender, environment, educational level, experience, computer usage, graphic presentations, and video presentations were used to determine the effectiveness of a distance learning course. The study revealed that learner environment and life-time experience have an important role in the planning and organization of an effective distance learning delivery system.

Garrison (1990) examined the impact to the learner in audio teleconferencing and found that dialogue, negotiation, and validation of knowledge must be used in order for this tool to be a successful educational delivery method. Willis (1994) claimed that the success of distance learning relies on the key players — students, faculty, facilitators, support staff, and administration.

Finally, research suggests that the effectiveness of distance learning is based on preparation, educators’ understanding the needs of learners and instructors’ understanding of the target population and their instructional needs rather than excessive attention to innovation and the delivery systems.

The Impact of Planning and Organizing Instructional Materials

The planning and organizing of instructional materials for distance education have increased the effectiveness of the delivery process. Instructors who are involved in distance education spend about a semester before the actual transmission to prepare instructional materials for their courses (Omorogie & Jackson, 1996). When an instructor spends this much time for researching, planning, and organizing, the instructional process becomes strengthened. Some distance learning instructors use graphics, video tapes, and printed materials during their lecture to illustrate content area. Distance learning can also utilize face-to-face instruction with technological tools such as compressed video and computer desktop video conferencing.

While some critics argue that face-to-face instructional process has more credibility than distance education, due to the time students spend with instructors after lecture, traditional classroom instructors sometimes deliver lectures without notes or instructional materials based strictly on the length of time allowed for teaching the course.

Impact of Technological Tools and Software Packages

The rapid growth of computer and fax machine usage in schools has increased long-distance communication between faculty and students (Mackwood, 1994). Students can now communicate with their instructors by the use of electronic mail and fax. New computers are manufactured to include audio/visual communication hardware and software packages. Mackwood also claimed that computers have become the preferred long-distance communication tool in distance education.

Audio/visual equipment and technology tools such as multimedia computer, television, VCR, laser disc player, telephone, digital camera, LCD panel, QuickCam, and PC/MAC TV Converter have changed the instructional process in classrooms across the nation. Instructors and students who use these tools have better chances of teaching and learning.
learning effectively than those with less technology (Morse, 1991).

Companies such as Microsoft, Corel, and Roger Wagner have revolutionized the software market by including incredible presentation packages with a variety of functions for classroom instruction. Packages such as PowerPoint, Harvard Graphics, and Corel applications are used for creating innovative presentations for classroom instruction. HyperCard and HyperStudio software packages allow the instructor to create their own multimedia projects and presentations which have added another dimension to the instructional process. Computer graphics, electronic print, multimedia software applications, presentation software applications, and electronic mail utilized in distance education make communications and learning easier (Verduin & Clark, 1991).

Finally, the declining cost of computing equipment, more available software applications, and telecommunications tools have allowed student access to college and university campuses for interactive conferences with their instructors. Computer networks on university campuses are making it possible for distance traditional students to gain immediate access to the university’s resource centers and the libraries. The overall result from the rapid growth of various modern technological tools is the increased effectiveness of education.

The Impact of Faculty Development

The learner and instructor are the most important factors in distance learning. As the needs of the learner are considered in the planning and organizing stages, faculty needs are also considered. Faculty development remains a critical issue for distance learning to be a successful delivery method. Willis (1994) suggested that for the success of distance education, “Teachers and administrators must work together on identifying and resolving the issues, policies, and biases that inhabit systematic use of distance education meeting academic goals” (p. 288).

Research suggests that distance education preparation should include faculty in-service training, staff support, and administration. Faculty in-service training should include hands-on experience for preparing tests, videos, and graphic instructional materials for the course. In-service training should include the use of technology in the classroom such as telecommunications, and computing equipment. Training should also include techniques for managing distance learning and understanding the unique need of learners. Support staff also plays an important role in the success of distance learning. An office should be created to support the instructor in preparing instructional materials for the learner. Support staff can also play the role of a facilitator or a technical person who makes sure that the equipment is in working order. Finally, the administrator and instructor must actively work to ensure a quality distance learning program. In doing this, they must identify and resolve faculty development issues that might affect the success of the distance learning delivery process.

Conclusion

In conclusion, the study revealed that distance learning can be an effective instructional academic delivery system for adult learners in schools and industries if all the key players are involved in the process. Researchers found improved modern technology tools and software application packages to have also played a significant role in the effectiveness of distance education. Research suggests that there are no significant differences between distance and traditionally delivered instruction. Research also suggests that variables such as student demographics, motivation, attrition, cognitive style, gender, and achievement play a significant role in distance learning. Finally, faculty development has an important role in the effectiveness of distance learning.

REDEFINING THE UNIVERSITY: THE CHANGING ROLE OF DISTANCE EDUCATION

Thomas Fox McManus
The University of Texas at Austin

Traditionally a university has been bound by four walls. Only students who were willing and able to place themselves physically within those walls could pursue a degree. New technologies are pushing at the boundaries of that paradigm. Universities are having to reevaluate their mission and the definition of their constituency in light of advances in telecommunications and distance education. Distance education has the potential to change the basic nature of university education. This paper will explore the issues involved and how universities are redefining themselves in light of this new paradigm.

The Issue
Distance education has a long history worldwide. The British Open University has been granting degrees for nearly twenty-five years (Sopova, 1996). As new technologies have developed, new institutions have grown to take advantage of the desire for students to get away from the traditional higher educational paradigm. In recent years, these opportunities have led to the creation of several commercial educational brokerages (Denning, 1995) and virtual universities (McManus, 1995). In order to compete with these new institutions, traditional universities are considering the possibility of offering degree programs wholly through distance delivery. Advocates of distance-delivered degree programs argue that the changing technology opens needed new avenues for learners to access scarce university stores of knowledge and instruction. The same technology allows universities to leverage existing resources in to new educational markets and programs. But the effective use of distance education requires a shift in paradigms. Universities have to move away from a strict reliance on classroom delivery of instruction. This idea can be problematic (Jackson, 1996) but some argue the change is inevitable and that institutions need to prepare themselves for it (DISC Committee, 1996). The survival of many traditional institutions may depend on how they do so.

The Opposition
There is strong opposition to distance degree programs in some of the more traditional institutions of higher education. Universities who have prospered under the traditional paradigm of classroom instruction and residential degrees are often loath to risk their reputation on new and untried distance education initiatives. The prevailing attitude seems to be that change should be driven by need rather than by opportunity, or just because technology allows them to change does not mean they have to. Their arguments fall into four basic categories: distance degree programs do not offer the same intangible benefits as residential programs, distance degrees are perceived as inferior to traditional degrees and therefore risk the university's reputation, money that is spent on distance degree programs could be better spent on increasing the capacity of the campus, and distance education fosters unnecessary institutional competition.

Distance education undermines one of the foundations of a traditional university education. The argument is that much of what makes undergraduate education at a particular university unique to that institution are the non-academic experiences and the personal interactions which take place in the physical surroundings of the academy (Monti, 1996). These experiences include the intellectual discourse and social networking a student engages in with professors and peers, as well as participation in extracurricular organizations and activities which help promote a sense of institutional identity. According to this view, academic endeavors make up only a fraction of the entire traditional university experience. Some argue (Yudoff, 1996) that distance education cannot offer the students the same sort of interactions and intangible benefits. As David Upton, an associate professor at Harvard said, as a student you should “feel the hot breath of the instructor on your face” (Lublin, 1996).

Another common objection to distance degree programs is that they are of lesser quality than residential programs and therefore will degrade the reputation of the institution which grants them (DISC Committee, 1996). As local
educational monopolies based on geographic access are challenged, students will have a greater choice of where to obtain their collegiate credentials and may opt for convenience over quality. In this way distance education may give rise to more diploma mills and marginal institutions (Stafford, 1996). There is a danger that any university which delves too deeply into the field may come to suffer through guilt by association. Only by maintaining strict quality controls, which are part of the traditional educational process, can such loss of stature be avoided (Monti, 1996).

The initial costs of creating a distance education infrastructure and of developing curriculum for distance delivery are high (Sopova, 1996). Given the tight budgetary confines in which most universities find themselves, this fact alone can keep an institution from trying new ideas. Large state institutions face pressures from their legislatures to serve, first and foremost, the people of their state. Distance education can be seen as spending state money to educate students in other parts of the world. Some argue that the money could be better spent on improving the faculty and facilities at the home institution (May, 1996). Even private universities face budgetary choices which may preclude large investments in distance education.

The last main argument against distance education programs is that they promote unnecessary competition between universities. If, for instance, a flagship state university offers degrees which can be obtained by students living in other cities or states, that university then places itself in direct competition with local branches of the state system, other universities, and community colleges for the students living in that location. This can create friction which may damage the relationships within a state system or between universities (Yudoff, 1996). Geographic separation is the basis for much of the higher education cooperation which goes on today. The removal of this distance could have catastrophic effects on such cooperative efforts.

The Supporters

Distance learning, once considered strictly a rural education strategy, is now recognized as having the potential to provide solutions to some of the problems that states face in delivering quality education to all students (Bell, 1991). Those who support the idea of distance delivered degree programs argue that there several important reasons for a university to make the effort to change. Distance education allows universities to reach a broader audience and provides educational opportunities to those who might otherwise not have them. Utilizing distance technologies enhances an institution's reputation by establishing them as a leader in the new educational frontier. Distance education is the future and those who do not keep up will be left behind. Others say technology-based education prepares students to function in the information age. There are even some who argue that distance education will prove cheaper and more efficient than classroom-based instruction in the long term.

Competition is a strong factor driving the move towards distance education. Distance education requires that universities revise their definition of competitor and of potential student. New technologies allow institutions to compete across the world. A school in Idaho can offer degrees to learners in Texas, New York, and Thailand without requiring the student to leave home. Colleges and universities that overlook the potential of new technology for development of distance-learning programs may find themselves losing students and revenue to other institutions and corporate competitors (Martin & Samels, 1995). Universities have a distinct advantage over commercial educational providers in that they often have a store of unique expertise which they can offer to a prospective student. But if universities don't make that expertise available and convenient to the students, they may choose to turn elsewhere (Stafford, 1996). Competition also drives universities to stay at the forefront of educational practices. Being known as a "technologically advanced school" may give a university the edge it needs to attract the best students and faculty (Lublin, 1996).

Many educational planners now believe that the demographics of the university student population is changing in such a way that traditional classroom-based instruction will no longer be able to serve them (OSSHE, 1996). But technology-based instruction allows for the displacement of instruction in time as well as distance. This allows students who are unable to attend classes when they are normally offered access to instruction at a convenient time. As this need becomes greater so will the need for degree programs that accommodate such students. Institutions which do not take seriously the changing nature of their constituents risk loosing them.

It is not only university demographics which are changing. The world outside the university has entered the Information Age and if universities are to prepare their students to function in this new world they need to adopt new methods and technologies. Policy makers are beginning to recognize that the strength and well-being of both their states and the nation depend heavily on a post-secondary education system that is visibly aligned with the needs of a transforming economy and society. At the same time, the states' capacity to respond to these challenges is severely constrained by limited resources and the inflexibility and high costs of traditional educational practices and by outdated institutional and public policies (Western Governors, 1996). Studies have confirmed that distance education appears to be effective and has been well-received by teachers and students (Bell, 1991). It is even argued that distance education may be less expensive that
traditional instruction (Sopova, 1996). If distance education is cheaper, of equivalent quality, and better prepares students for the future, universities should adopt it and change with the times.

**Personal Perspectives**

I noticed two things in particular about the arguments I read and heard. Many of the arguments were couched in the vocabulary of business rather than academia (Denning, 1995; Twigg, 1995; Lublin, 1996), and there was very little written about people’s fears and doubts about distance education.

I believe that distance education has become the rallying cry for many of the supporters of a business model of higher education. The idea is that universities are providers of a scarce commodity - instruction (Denning, 1995). Students are the consumers. The production and delivery methods may vary but each educational institution is trying to sell its product. Technology simply increases the number of customers you can reach. I think one reason for the link between business and distance education is that information technology is so prevalent in business and when people with a business perspective look at academia they see technology as a way to improve it. There are dangers in this. If higher education is different from business, applying the same philosophies may be inappropriate. On the other hand, technology is not exclusive to the business milieu. Distance education has a growing instructional research base. And it can help universities reach qualified learners who for whatever reason are not able to attend classes on campus. This helps schools fulfill their goal of providing the best education to the all qualified students.

The majority of the literature dealing with the issue of distance education policy in higher education seems to fall on the side of the supporters. Even the opponents have a tendency to urge caution rather than prohibition of distance degree offerings. One reason for this may be that distance education is a popular bandwagon and those with doubt or reservations voice them cautiously lest they be branded reactionary. Despite the fact that it is seldom stated openly, there is resistance. You can see it in the discussions of the University of Texas’ distance education task force (Yudoff, 1996) and in MIT’s Council on Educational Technology (MIT, 1996).

**Conclusions**

Any paradigm shift is accompanied by a period of resistance and instability. I do believe that the propagation of distance education degree programs is inevitable. I think there is a need for them. As the needs of learners change, the methods and policies of the universities have to change as well. But I don’t think we have to change just because we can. I think that universities need to proceed with care and deliberation. The risk of producing bad instruction is high with a new medium. If great effort to ensure quality is not taken then the fears of the opponents may well come true.

DESIGNING AN INTERNSHIP TO GO THE DISTANCE

Ruth Gannon Cook
University of Houston

Mary Ann Blind
University of Houston

What began as an opportunity for a doctoral student in instructional technology to apprentice in the distance education department, turned into a vision of a departmental internship that could be generalized to other university departments. This student went on to develop a clear focus for a model of a distance education internship program. This program can introduce doctoral students to the various components of distance education and give them hands-on experience in the University of Houston’s Division of Distance and Continuing Education. The model evolved to include possibilities that could bridge departmental gaps and involve students seeking exposure to distance education from other academic disciplines.

The decision to approach the distance education director came about because of the need for more understanding of how distance education works. While instruction delivered through distance education is a key component of instructional technology, there is little exposure to it in the instructional technology curriculum. Therefore, it could benefit instructional technology majors to have some familiarity with tele-transmitted and online classes. The director agreed to accept an intern into the department for a semester or two to see if it was mutually beneficial for both the student and the distance education department. If it worked out, the director could consider developing a plan to let more instructional technology majors become interns in the program.

From these informal proceedings, the project began. The project objective was to have the intern observe the program, then turn in a paper describing what distance education was at the University of Houston and what it could be in five years. The understanding was that the intern would observe, assist when possible, and do so without disrupting the employee’s routines and/or deadlines. The intern’s ideal scenario would be to learn about each employee’s duties while working for that employee.

The first several weeks of the internship consisted of creating sign-up sheets for employees to utilize the intern resource, working out schedules for shadowing distance education employees, while accommodating a personal class schedule. As the weeks passed, it became more clear that because of the exigencies of this fast-paced program where each employee rushed to meet unique deadlines, there needed to be some kind of framework for intern activities.

As the first distance education intern, I was discovering that important aspects of the distance education program could easily be overlooked. It was hard to know what I was missing because each employee’s job was so different. So, I decided that conducting a type of “action research” might provide a key to learning more about the big picture of the distance education program (Moore & Kearsley, 1996; Willis, S., 1995; Kinnaman, 1993). Action research is a term for “on-the-spot” observation, usually by teacher/researchers, through disciplined inquiry (Willis, S. 1995). Usually the teacher/researcher is not on the outside, but rather part of the process being observed. In this case, I was not a staff member, but was allowed full run of the division and included in all divisional undertakings. In action research, as the name implies, ultimately some type of action is recommended. It is based on the teacher/researcher’s observations and examinations and may include additional relevant data. Since my action research was informal, it did not include the normal procedural data collection and analysis, instead leaving that portion of the research for future studies. I also realized decided that, due to the small numbers of interns accepted into the internship, it would prove difficult to conduct any formal quantitative-type studies.

This action research might also provide the foundation for the creation of a potential distance education internship program. “Research is the cornerstone of decision-making, but theory is the foundation” (Kinnaman, 1993). I decided the theoretical foundation of this fledgling program should be constructivist, primarily because of the nature of the qualitative research that was giving it shape (Willis, 1995). A constructivist theoretical base for the framework would provide the flexibility to design, observe, and reflect on my findings, then redesign a core program that could develop and evolve as new needs arose (Jonassen, 1994).

My plan was to observe the overall operation of the distance education by attending general departmental meetings, working under as many employees as possible,
and by “hanging out” in the hallways asking questions about distance education. In the course of the remaining weeks in the semester, I was able to work under eight staff members, attended a number of departmental meetings, and managed to stop employees along the way to ask endless questions. I journaled overall observations at the end of each employee assignment and summarized each assignment’s experiences.

However, I felt that I needed to construct a framework of these experiences. Since I am a curriculum and instruction major, I decided to design a boilerplate of what I thought should be covered in an internship. I then shared it with the distance education instructional technologist, my course instructor, and the distance education director to be sure I wasn’t leaving anything out. This boilerplate quickly evolved from a theoretical framework of what might be included in a single semester internship activity to a potential distance education internship program. If the program design were flexible enough, it could provide vital hands-on experience for instructional technology students.

Such an internship program might also provide a solution to another emerging dilemma — how to help students in other academic disciplines acquire distance education experience. Many large universities do not have crossover relationships to permit students to take courses outside their departments. Often the communications, technology, business, and education departments may all have forms of distance education, but those forms may not parallel each other. For example, an online class in a business department may not be the same as a televised class in a communications department. A distance education class in the education department may not utilize some of the components of the Distance Education Division. The internship would give students in other departments the opportunity to literally see what they may be missing. Crossing into other academic disciplines provides an experience that transcends both academic and spatial boundaries.

This internship could be given some structure and serve as a benchmark for other interns, both in instructional technology and other academic disciplines.

**A Distance Education Boilerplate**

A distance education boilerplate could include the following components: a history of distance education, exposure to the various technologies used in distance education, ongoing system designs to accommodate new technological trends, management and administration of the program, and ongoing evaluation of the distance education internship. The distance education instructional technologist concurred with the initial boilerplate, but, after reviewing the boilerplate components, suggested we omit the detailed history of distance education. Instead, a brief explanation and history would suffice since there should already be some awareness of distance education by most instructional technology doctoral students. We would also briefly define distance education at the University of Houston and move on to address the remaining components of the boilerplate, namely the media and technological segments; the ongoing system design; and the evaluative role of distance education internships.

**Distance Education Defined**

The first component of the proposed distance education internship boilerplate is to define distance education at the University of Houston. The definition of distance education according to the Texas Higher Education Coordinating Board, and which has been adopted by the University of Houston, is “the delivery of courses at sites away from the main campus in either face-to-face (f2f) or instructional telecommunication formats” (University of Houston, Division of Distance and Continuing Education, 1996). Distance education at the University of Houston had its beginnings almost twenty years ago and has evolved into a division that offers both credit and non credit classes, undergraduate and graduate courses, and provides an array of delivery vehicles. There are live and taped cable-televised classes, live microwave local classes, and tape-purchase classes. The University of Houston initiated “tape purchase” classes in 1995 to meet the needs of students who could not, for various reasons, access and/or tape their classes. Computer online classes are also now being offered.

**Distance Education Media and Technology**

The second component of the distance education boilerplate would include media and technology. Since this might be the only opportunity for instructional technology students to get hands on experience, each segment of the technology should be noted. It might not be possible to actually go to the remote sites where the classes were transmitted, especially in the case where classes were transmitted via other school system’s cable networks, but it would be possible to see how those classes were conceived, produced, and transmitted. The key types of media and technology are separated from each other because more and more of the classes are going away from televised media and toward online computer classes. But both methods of transmission are vital, and, while it seemed likely that a “marriage” of the two technologies would be inevitable, at least for now, they remained separate.

The first segment of media, consists of televised classes, microwave classes, and tape-purchase classes. In the instance of the televised and microwave classes the classes could be either live or prerecorded. Most credit classes were recorded and periodically recycled several semesters later.

What makes the University of Houston’s distance education program unusual is that it does not purchase prerecorded tapes from outside sources. Rather, it produces
all of its own tapes for various courses. That's what makes it well-suited for internships. Students not only get an idea of how distance education functions, but also can actually participate in the entire process, from the creation of the course to the airing of that course. Under the most optimal of circumstances, instructional technology students might have the opportunity to spend several semesters in the department working on one particular project, like a new course being introduced into the distance education repertoire.

Telecommunications is another technology segment of the internship which includes all aspects of satellite, microwave, and cable transmissions. Learning about these technicalities could be critical for a student who might need to build a start-up program in the future. Without exposure to the various types of telecommunications available, very costly mistakes could be made in the selection of the right program.

Another segment of this component could include some participation by interns in the preparation of online classes, multi-media classes, and emerging technologies. At present, the University of Houston might elect to "farm out" development of online classes to the respective departments delivering those classes. But the collaborative efforts are already underway in several departments, like Engineering and Education.

Administration of Distance Education

The third component of the distance education boilerplate would look at the administrative aspects of distance education. What might surprise most students is the scope of administration required to run this division. The director must not only prepare the courses for transmission and set those courses up in the appropriate telecommunications context, but must also make sure people, somehow, seek out those classes. And that takes marketing. As recently as several years ago, students had little awareness that they could take televised college classes. Now entire degree plans are available to them in certain academic disciplines. The public has to be made aware of these offerings, and in a way, helped to understand what it means to them in their own daily lives. So that means developing brochures, fliers, television promotions, radio promotions, and delivering public relations efforts at junior colleges and trade shows, and even internal efforts to enlist other departments' awareness and participation in distance education. Plus, there are the ongoing accounting and administrative duties and responsibilities and the daily overseeing of operational telecommunications and technological functions. In addition, these duties must always consider the ongoing importance of grant writing to make sure the distance education division has enough money to continue its operations. All the daily administrative requirements seem to never end. The entire web of administration extends through all of these crucial functions and the intern will begin to get the big picture of what keeps a distance education program operational. In fact, even if the intern simply introduces one distance education course into his/her new job, chances are that at least some of the administrative duties outlined above would still apply.

In a large university, like University of Houston, the director's job is Herculean. A skeleton staff works diligently to make sure everything runs smoothly. Funding is an ongoing challenge, so everything, including employees, must stretch to the maximum to get the job done. The hope would be that, while the first few interns might not be fully utilized until the department staff understood what extra pairs of hands means to them, the department would welcome the additional support. Ultimately, there could be interns assigned to each staff member for a period of time. This would give the intern a greater understanding of the staff member's administrative role, and it would provide that staff member with much needed, albeit brief, assistance.

A flexible internship program design would permit the intern to participate in various areas of distance education while performing a practical function for the distance education division. Then each intern could gravitate to the area of most career interest after the basic requirements were met. The success of the first intern could then precipitate a group of "master" interns who could, in turn, mentor and facilitate incoming interns and make sure the interns met certain prescribed performance standards for the distance education division. The interns would have opportunities to view, first hand, decisions made and implemented in the distance education division. This would help interns to integrate their academic theory with practical application. The participate process would bring home to them the relevance of their coursework while preparing them for real world experiences. At the end of their internships they could either move on to their respective fields or remain a little longer as master interns. Either way, they would have garnered a richer experience of distance education than before they entered the internship. They would emerge from the internship knowing that, while their experience may not have been as protracted as those interns in schools with huge media and distance education departments, they have, nonetheless, received a comprehensive experience of distance education.

Evaluation of the Internship

Last, the final component of the distance education boilerplate would include evaluation of the role of distance education internships. While my action research could not tell me the future, it provides me observations of the present. What I discovered in my internship could play an essential role in helping instructional technology and other inter-
ested students to learn more about the functions of distance education. Hopefully, interns would become an ongoing part of the Distance Education Division. The results were still out on how effective the internships would be for both the interns and the division, but feedback from many of the employees in the program rated it favorably. So evaluation will be ongoing. There will be more interns, perhaps just one or two in this initial phase, but, hopefully, there will be more in the future. The idea of the master or senior intern also has merit and should be considered since it would provide the interns with a mentor and the division with someone already familiar with the operations.

The truth of Heisenberg’s Principle of Uncertainty sustains, that what is observed is changed by that observation. It seems appropriate in this case. Internships can be dynamic, and this internship certainly proved to be that, and more. Observation and participation prepared the way for the shift to a new level of student awareness, but also demonstrated a need for more of these types of internships. The “observed” distance education division was not dramatically changed by the internship process, but did remain open to the acceptance of new interns. That’s a start.

Discussion

A hundred years ago a student carrying his books across the frontier and sending his papers back to his teacher would have been called a distance learner. Today a distance learner has a variety of ways to receive and transmit courseware. The bottom line is that distance education is a hot topic, and eventually almost every department in every university will either have, or recognize the need to have, some type of distance education. But five years from now distance education may look very different than it does today. What will remain current will be the need to expose more advanced graduate students to distance education (Loyola, 1994). The need is crucial for instructional technology students, but could also become compelling for administration majors, or majors from a broad spectrum of academic fields. Distance education internships can be a rich resource to both the students and the UH distance education division and can provide knowledgeable graduates that “go the distance” to the academic frontiers of educational technology.

Acknowledgments

Special thanks to Dr. Sandy Frieden, Director of the University of Houston, Division of Distance and Continuing Education, for her willingness to take a chance on accepting interns into the department.

Teacher Education Through Distance Learning: Cost Effectiveness and Quality Analysis

Melanie N. Hill
State University of West Georgia

Distance learning is a technology that has been utilized by the College of Education at The State University of West Georgia for less than two years, yet it has reached more than 500 teachers at remote locations. The university receives inquiries daily from teachers throughout the state who would like for a site near them to receive education courses so that they may achieve certification or a higher degree. In spite of this demonstrated need and apparent success of teacher education through distance learning, concerns continue regarding quality and cost-effectiveness. There are significant costs associated with distance learning and although increased enrollments often offset these costs, the problem becomes one of quality. One common perception is that increased class sizes resulting from distance learning will result in greater benefits through increased revenues. However, quality may be reduced when small group discussion and teacher-student interaction become more difficult to achieve.

The purpose of this research was to analyze the true cost-benefit of distance learning in the College of Education, and to determine how to enable quality in distance learning without financial strain. Specifically, the research addressed the following:

- Is distance learning through GSAMS (Georgia Statewide Academic and Medical System) as good in terms of quality as traditional learning?
- Are the benefits of educating teachers through distance learning worth the costs?

Methodology

This research project was undertaken over a period of six months, beginning in March 1996. Project personnel consisted of the distance learning coordinator and student assistants employed as distance learning classroom facilitators. The student assistants administered surveys to all education faculty who have utilized distance learning and also to all education students enrolled in distance learning classes. The surveys measured attitudes towards distance learning, perceived class quality, student demographic information, and enrollment information. Of 198 possible student respondents, responses were received from 129 (65 percent). Twenty-one surveys were received from faculty (out of a possible 25), representing an 84 percent response rate.

Background

West Georgia's distance learning program is part of the Georgia Statewide Academic and Medical System (GSAMS). This is a two-way "live" video teleconferencing system which allows teachers and students to interact immediately, utilizing audio and video. GSAMS is the largest distance learning and healthcare network in the world. It has more than 370 sites in Georgia, including K-12 schools, colleges, universities, hospitals, prisons, and Zoo Atlanta. GSAMS has been in operation since 1993, and the State University of West Georgia began its involvement in January, 1995.

The primary goal of distance learning at the State University of West Georgia is to provide access to students who cannot take advantage of traditional instruction, and for whom convenience is a critical factor in achieving a degree.

Findings

Quality Issues

Through my research and discussions, it became apparent that a major issue in distance learning is whether or not the quality of a course taught via distance learning is as good as one taught in the traditional manner. Five specific issues regarding quality emerged.

1. Satisfaction: Do students perceive the distance learning experience as positive, and what factors affect distance learning satisfaction? Teachers who take courses via GSAMS from West Georgia's College of Education generally have a positive experience and say they would take another course through distance learning.

- 87 percent reported that their attitude toward distance learning was positive at the end of the term.
89 percent said they would take another course by distance learning.
- 89 percent said they were glad that they took the distance learning course.

The study also measured the correlation between student satisfaction and satisfaction with the instructor, age of the student, distance of the student from the home site, the number of total sites, and the total number of students enrolled in a course.

Satisfaction with distance learning appears to be highly correlated with satisfaction with the instructor. Students who were less satisfied with their instructor also tended to have a less positive attitude towards distance learning.

The farther away the student was from main campus, the more positive his or her attitude was toward distance learning. Using a Likert scale with '1' being the highest, students at the Carrollton site reported the least positive attitude (2.492), while students at locations at least two hours away reported the most positive attitudes (1.523).

Older students were generally more likely to report satisfaction with distance learning courses than were their younger counterparts. 86.6 percent of students over the age of 25 said they were glad they took the distance learning course, compared to 45.7 percent of those under the age of 25. However, older students were generally at sites away from campus. Therefore, the correlation may be due to distance rather than maturity.

Neither the number of sites nor the number of students in a course appeared to have an impact on student satisfaction. Even though it was anticipated that students would be more satisfied with smaller, more intimate classes, some larger classes received higher satisfaction ratings than did some of the smaller courses. (See Table 1)

2. Does student and faculty acceptance of distance learning increase with continued usage and exposure?
Although both faculty and students are often apprehensive about distance learning at the beginning of a term, much of these fears appear to be relieved somewhat once they become in involved in distance learning. Ninety percent of faculty who have taught a distance learning course at The State University of West Georgia say they would use the delivery system again to teach. Among the reasons faculty cite for wanting to use the system again are: the ability to reach students who cannot commute to the main campus, the ability to utilize technologies not available in the traditional classroom, reduction of travel, and the need to keep up with emerging technologies.

Our survey results also show that student satisfaction increases with usage. Eighty-one percent of distance learning students enrolled in the College of Education reported a positive attitude toward distance learning at the beginning of the term, while 87 percent reported a positive attitude at the end of the term. Also, students who had previously taken a distance learning course reported a higher level of satisfaction that did those who were taking their first class via distance learning. (see Table 2)

Correlation between student satisfaction and familiarity with distance learning

| Likert Scale (1 = strongly agree; 2 = agree; 3 = uncertain; 4= disagree; 5= strongly disagree) |
|---------------------------------------------------------------|---------------------------------------------------------------|--------------------------------------------------|
| I am glad that I took this DL course                          | At the end of the term my attitude toward DL was positive     | I would take another course by distance learning  |
| Distance Learning First-Timers                                | 1.951                                                         | 2.224                                            | 1.805                                            |
| Experienced Distance Learners                                 | 1.625                                                         | 1.781                                            | 1.688                                            |
3. Do technological limitations present significant drawbacks to achieving quality in the distance learning classroom? While technological problems (failure to achieve connection, audio problems, video loss, etc.) were frequent (generally occurring in at least one-fourth of the sessions), most problems were solved during test-time and did not actually interrupt class time. Although there are instances of system-wide failures and single site failures causing an entire class period to be canceled, most College of Education faculty had prepared for technological problems by communicating back-up plans to each site on the first day of class.

The greatest technological challenge observed was the actual maximization of the technology. Many students report feeling intimidated by the cameras, the monitors, and having to use a microphone to speak. 35.6 percent reported that they were “more reluctant to ask questions and make comments” in their distance learning class than in a regular class.

4. Do logistical challenges present an undue burden to faculty? In contrast to the convenience afforded to students through distance learning, faculty find themselves burdened with the details of transporting materials between sites, scheduling courses, and helping students register. Formal and informal interviews with faculty suggest that some faculty believe that the quality of their instruction suffers because they must spend such a large amount of time preparing mailings, faxing materials to other sites, e-mailing students at remote sites, and assisting remote students with registration and the procurement of books. Some faculty have responded by adapting their courses in a manner that requires less logistics, such as having fewer written examinations and more class presentations or graded discussions. Others have relied upon the support of secretaries, the distance learning staff, or student assistants to relieve some of the burden. Presently, however, logistics still present a problem as there is no complete solution in place.

5. Do current policies conflict with the goals of distance learning? As the world’s largest distance learning network continues to grow, concerns continue regarding established statewide policies regarding residence requirements, personnel matters, post-secondary options, and cost sharing.

The formal Georgia Board of Regents policy required that all graduate students take one half of their courses on the main campus of the college or university from which they earn a degree. For the majority of teachers who take courses via distance learning, commuting 50-200 miles each way is simply not an option. Although the policy has yet to be formally changed, many Georgia colleges and universities are attempting to address this issue in their own creative ways (such as considering all remote sections and the main campus section to be “one” classroom) until a new state policy is released.

Another problem is that current policies, either state or institution, do not formally address a reward structure for faculty who teach distance learning courses. Because the program depends upon the participation of excellent teachers who will have to work harder to meet the demands of distance learning, the long-range success of the distance learning program is directly related to the ability to find a reward system that pleases faculty without burdening the institution.

Cost Issues
In order to address the question of whether or not the benefits of teacher education through distance learning outweigh the costs, a cost-benefit analysis was performed. The benefit is determined by multiplying the number of students who said they would not have taken the course if they had to commute by the amount of tuition each of these students paid. This is compared to the overhead costs of the distance learning program and additional costs such as mailing, travel, remote site monitor fees, etc. Results for Spring and Summer 1996 showed that the program facilitated the needs of education students at the State University of West Georgia in a cost-efficient manner.

Overhead costs for one year of distance learning are currently $88,507 and include the salary and benefits of the distance learning coordinator, student facilitator wages, telecommunications charges, travel expenses, and supplies. The cost per course is determined by dividing the annual costs by four quarters, and then dividing by the number of courses offered in a quarter. For some classes, additional expenses are also included when fees must be paid to other sites which charge for use of their facilities. During spring quarter 1996, the cost per course was $2766, and during summer 1996, the cost per course was $3166.

Program benefits were calculated by multiplying course tuition by the number of students at remote sites by the percentage who reported they would have commuted to the main campus to take the course. Courses offered by the College of Education generally went to sites at such a far distance that a large percentage (70 - 90 percent) reported that they would not have been able to commute to the main campus. Based upon these calculations, tuition gained for the four College of Education courses offered during spring 1996 ranged from $3234 to $8764. Thus the economic benefits of these courses were greater than the costs.

During summer quarter, fewer classes were offered, each with fewer students enrolled, and the tuition gained per course ranged from $1309 to $2631, representing a financial loss for the quarter. However, fall and winter quarters are projected to reach enrollments similar to those of spring quarter.
It must be noted that the greatest benefits of the distance learning program, its far-reaching effects on teachers receiving higher education, the children they teach and the entire educational system, are simply not measurable. But in order to reach these potentials, the realities of academic budgets and the concerns of university administrators facing financial constraints must be continually addressed. At The State University of West Georgia, this cost-benefit analysis is now performed quarterly and is used in the process of selecting appropriate courses and sites for distance learning. As a result, the distance learning program is better able to meet the needs of its end users without placing a financial burden on the institution.

Melanie N. Hill is the Distance Learning Program Coordinator at the State University of West Georgia, Sanford Hall, Carrollton, Georgia 30118. E-mail: mhill@westga.edu
STUDENT PERCEPTIONS OF LEARNING BY COMPRESSED VIDEO

Marietta Daulton  
Morehead State University

Cathy L. Barlow  
Morehead State University

The rapid increase in the number of college courses delivered by distance learning technologies such as compressed video, has seemingly occurred with little information from the students about their perceptions of the success and acceptance of this mode of instruction. University administrators and faculty seem to have had the most input into the selection and design of courses to be offered. In the early stages of development of distance learning courses, faculty may be concerned with the technological aspects of delivery and less concerned with the impact of delivery on students and students’ expectations from such courses. However, if student needs are to be met and the learning effective, student perceptions of that delivery will be extremely important. Student input will be essential in determining the courses to be delivered, the number of courses to be delivered, and the appropriate style of delivery of such courses.

As distance learning faculty who teach by compressed video, we received training on the use of the equipment and a few tips on how students could work with the technology. However, as the teaching progressed we began to hear comments from our students which indicated they were extremely pleased or very uncomfortable taking a compressed video course. As teacher educators we are also concerned with the effectiveness of the teaching/learning environment, method of learning, and the impact on learners.

A review of the current literature related to distance learning revealed a great number of articles related to distance learning, but few articles related to student perceptions of such learning. The articles related to student perceptions of such learning were more frequently comparisons of distance learner achievement through test scores or grades with students who received instruction in more conventional environments. Hackman and Walker (1995) found no significant differences in the perceptions of students in distance learning classes and those in the traditional face-to-face setting. These findings were similar to the those of earlier studies by Whittington (1987) and McCleary and Eagan (1989) which focused on academic performance of students in distance learning and traditional classrooms. While the academic outcomes warrant the continued use of interactive television as an acceptable mode of instruction, the concept of what students’ perceptions of effective instruction via compressed video are not addressed.

Methods and Procedures

To obtain information regarding student perceptions of distance learning three separate strategies were developed: (1) oral interview, (2) video tape, and (3) questionnaire.

Questions used in both the oral interview and questionnaire encompassed areas of projection and reception, dialogue, clarity, voice, materials, comfort level, and satisfaction.

The questions were developed and field tested. The field testing was conducted with evaluation of the instruments by three graduate students and three professors. Questions were adjusted using the review team input and then resubmitted to the review panel for clarity and exactness. Final adjustments were made and a final product was printed. The questions were asked orally to a random sampling of twenty students from two graduate classes in two different graduate education departments offering distance learning courses. The questionnaire was distributed to two different graduate education classes. It should be noted that the data was collected over a two year period. The oral interviews were conducted with students the first year distance learning was offered. The questionnaire was given to students in the same courses taught by the same professors the second year of the distance education program. Each session was taped to determine interactivity. In addition, some of the interviews were taped to enable a “live capture” of comments during the oral interview. The tapes were reviewed and a narrative included in the result section. The data collection is still in progress, and results will be available in final form spring 1997.

Summary

Initial review of our data revealed that student perceptions of distance learning by compressed video are varied. Students have many reasons for taking courses by compressed video and have different expectations for the content and delivery of the courses. Students who had participated in other media delivery courses, which were not interactive in nature, expressed their surprise and
delight in the interactive levels of compressed video. Most students were positive about the compressed video learning experience and said that they would repeat the experience. However, comments such as “I would not take another compressed video course” and “television is still television” warrant a closer look at the impact of compressed video learning experiences and the expectations of these students. Perhaps there are identifiable expectations that certain students have which could help determine student satisfaction with this mode of instruction. As teachers we need to be more than familiar with interactive video instruction to meet the needs of our students. We need to know more about our students’ expectations and perceptions of learning and how to provide the connections to make this experience positive and effective.

Providing higher education to nontraditional students has become a point of interest for many colleges and universities (McMeen, 1984). In many rural areas, the only way to receive some type of post-secondary education is for learners to enroll in a specialized program or curriculum at an institution a considerable distance from home. Evening and weekend courses are also used, but this is often impractical for many teachers and students due to travel and expense involved (Beare, 1989). Delivery of instruction to learners at distant sites using teleconferencing equipment that permits two-way audio and visual interaction has been used recently to resolve many problems associated with geographic distance and isolation. Distance education can make virtually any subject available to an individual learner in the most solitary of geographic locations; to the elderly, unable to travel, to the house-bound parent of young children, to the poor, unable to relocate, to special needs populations, to the highly mobile service persons and other workers, and to all those who prefer to control the timing, location and pace of their study (Moore, 1989).

Basically, a two-way interactive television system provides an opportunity for an instructor at a “home site” to teach students geographically located at “remote sites.” Students in each remote site can see, hear, and communicate live with the home site and other remote sites. This is accomplished by modifying the classroom to accommodate specially equipped cameras, microphones, and television monitors. The signal between home and remote sites are relayed via microwave, coaxial cable, telephone lines, or fiber optics (Kitchen, 1988).

Effectiveness of Prior Distance Education Efforts

At the post-secondary level, a number of studies have been conducted comparing the educational effectiveness of distance learning technologies (Barker & Platten, 1988; Beare, 1989; Kabat & Friedel, 1990; Ritchie & Newby, 1989). Many of these studies have compared the achievement of remote-site distance learning students with traditional classroom students. Almost without exception these studies have shown that distance learning students achieve as well as students taking courses via traditional methods (Kendall & Oaks, 1992).

Most prior research on distance education has dealt with technologies other than two-way audio and visual interaction. However, study after study has showed that comparable performance can be expected from students regardless of the medium (Ritchie & Newby, 1989). Anderson’s (1978) study indicated that students do learn by televised instruction, that they prefer two-way audio interaction over videotaped instruction, and that students prefer live instruction to either kind of televised instruction.

The Need for Two-Way Interactive Television

Despite present and past research to support the efficacy of earlier modes of distance learning, it is well known that this approach is generally held with low regard (Barker & Platten, 1988). The major problem with earlier methods of distance education was a lack of student/teacher interaction. “Educators have repeatedly stressed the importance of instructional interaction within the learning process” (Ritchie & Newby, 1989, p. 36). The use of two-way interactive television in distance education fosters live, teacher-to-student and student-to-student interactivity and enables distance education to assume its rightful and respected role in the educational process (Barker & Platten, 1988).

Distance Learning at Valdosta State University

In an effort to provide access to educational programs and services that are responsive to personal and community needs, Valdosta State University in Valdosta, Georgia has initiated a new program of offering courses via live two-way interactive television. Previous research regarding this new type of distance learning has shown that no significant differences were found when comparing academic perfor-
of remote- and host-site groups (Kabat & Friedel, 1990). Indeed, this new technology seems to be the next best thing to being there. However, the student is not “there,” and this still creates concerns. Kabat & Friedel (1990) contended that for some students, learning via technology is awkward and is not conducive to their learning style. Not all students feel comfortable learning from a ‘distant’ teacher, and many students feel cheated that they do not get to know classmates at other class sites.

Initial findings based on student evaluations of courses taken in the College of Education at Valdosta State University reveal several advantages and disadvantages of the distance learning system. Remote-site students have commented that distance learning courses saves driving time, makes it easier to take classes, improves the chance of understanding stating that they reduced driving time and gave peace of mind to be closer to home in case of emergencies. However, problems such as the lack of personal contact with professors and other students, the difficulty in getting assignments to campus, a hesitancy to ask questions, equipment problems, and distractions have also been noted.

The Purpose, Methods, and Findings of the Study

The purpose of this study was to compare the perceptions of remote-site distance learning students, host-site distance learning students, and traditional classroom students toward the affective experiences they encounter while taking courses from the College of Education at Valdosta State University. A review of literature revealed that cognitive outcomes are virtually the same between distance education students and traditional classroom students. However, these same studies mentioned that affective aspects such as student/teacher interaction, overall course enjoyment/satisfaction, course structure, and the physical learning environment were often lower for distance education students than traditional classroom students. This study focused on these affective experiences encountered by distance learning students.

The study used a causal-comparative design, and utilized a survey instrument to collect necessary data. The survey instrument contained 21 Likert-scale statements grouped into four clusters (student/teacher interaction, overall course enjoyment/satisfaction, course structure, and the physical learning environment), as well as demographic information and three open-ended questions. The instrument was mailed to an equal allocation sample of 165 remote-site students, 165 host-site students, and 165 traditional classroom students. Data analysis was conducted on a total of 346 returned surveys.

Means and standard deviations were calculated for each cluster area to describe the perceptions of the three groups. An analysis of covariance, using age as the covariate, was conducted to determine if significant differences existed among the three groups. If a significant difference was found for a particular cluster area, pairwise post hoc t-tests were conducted on that cluster to determine which specific groups contained the significant difference.

Results of the study indicated that there were no statistically significant differences between the three groups in regard to student/teacher interaction or course structure. Significant differences were found between the three groups when comparing the physical learning environment. Students in the remote- and host-site distance learning groups responded significantly lower to questions dealing with the physical learning environment than students in the traditional classroom group. Students in the host-site group also responded significantly lower to questions dealing with overall course enjoyment/satisfaction than students in the traditional classroom group.

Discussion

The findings of this study indicate that although the distance education groups had generally positive course experiences, they did encounter problems not found in a traditional classroom course. Equipment downtime was the biggest problem. Students at both the remote- and host-sites reported becoming frustrated due to lost class time spent making adjustments in the equipment to bring all sites online properly. Audio problems and distractions caused by the various distance education equipment were also noted as problems. Host-site students were less understanding of these problems. Many host-site students did not feel they should have to endure these problems seeing no advantages for themselves. Remote-site students were much more understanding stating that they reduced driving time and other advantages more than made up for the few distractions caused by the equipment.

Distance education programs have been shown to be effective in meeting the educational needs of rural and non-traditional students geographically separated from a college or university (Barker & Platten, 1988; Beare, 1989; Kabat & Friedel, 1990; Ritchie & Newby, 1989). However, the majority of past distance education research has based “effectiveness” entirely on cognitive achievement. This study has indicated that the affective experiences encountered by distance learning students often differ from the experiences encountered by traditional classroom students and should be considered when evaluating a distance education program.

By definition, distance learning substitutes communications technologies for personal contact between instructor and students. Problem-based learning (PBL) typically requires intensive instructor contact with students and may be difficult to implement in a distance learning context. However, our course demonstrates that multimedia technologies and extensive use of the World Wide Web can make PBL feasible for both traditional and distance students. We use a combination of videotaped lectures, e-mail, and a comprehensive web site to involve geographically dispersed students in group projects. Since the biotechnology issues we address are often controversial and commonly misunderstood by the American public, our course has a broad potential audience. Consequently, we have developed techniques for providing geographically remote students with on-line PBL experiences which are equivalent to those we provide to on-campus students.

Our interdisciplinary course, Biotechnology: Science and Socio-Economic Issues, has been taught in the College of Agricultural Sciences for eight years. During that time, we have adopted and refined PBL strategies which encourage students to focus on specific topics covered in the course. This unique course brings expert guest lecturers covering topics such as:
- The history of genetic engineering
- Plant and animal tissue culture
- Food biotechnology
- Plant and animal applications of biotechnology
- Consumer acceptance of food products produced through biotechnology
- Biotechnology and the media
- Ethics

This wealth of expertise is not available in any other course in the country. However, students can take the course from virtually anywhere in the world, either through the University of Delaware's FOCUS/distance learning program or via satellite. Several of the lectures were made available for live broadcast throughout the United States by a grant from A*DEC, a consortium of universities that promotes distance education.

Problem-based learning has proven to be a valuable tool for integrating many perspectives on a given topic. Because they don’t live near the university and may work full time, students require more flexibility in their learning experience. As a result, our goal is to provide the same rich learning experience by providing lectures for viewing via videotape or satellite downlink.

Our course demonstrates how network technologies can facilitate PBL in the context of mixed local and distance learning. Local and distance students learn how to collaborate with each other over the Internet. The experience of working in a group is even more valuable when combined with the challenge of working with remote group members. By publishing students’ case studies on a publicly accessible web site, we are developing a public information resource to promote better understanding of some widely misunderstood biotechnology issues. Since we are a Land Grant University, this effort is entirely consistent with the broad public outreach mission of our institution.

Under a grant from the state’s Department of Agriculture (FY 96 Cooperative State Research, Education, and Extension Service Higher Education Program) we are reaching distance students with a series of videotaped lectures. The University Focus/Distance Learning Program offers selected courses each semester. These courses are taught in specially equipped video classrooms to traditional students. Each lecture is videotaped in an unedited fashion. Student-faculty interaction is maintained through special telephone office hours in which faculty advise students and answer students' questions. Students may also schedule appointments to meet with faculty in person or communicate via email. The last unit of the course is a PBL exercise.
in which students in our local classroom are teamed with distance students to analyze and solve a particular problem related to biotechnology in agriculture.

The class web page is divided into public and private areas. The public areas are open to anyone and provide general information on the course and biotechnology as well as links to other biotechnology sites. Private areas are protected by passwords and are accessible only to registered students. The private areas contain class lecture notes and pages for each group's case studies. Within each group's case study page are sections for posting and reading messages.

Each instructor provides their lecture in a Microsoft PowerPoint file. The file has been converted to HTML with Microsoft's conversion utility. The web form of the lecture is identical to the lecture presented in class. On-line class notes are a supplement to both traditional and distance students.

**Case Studies**

Case studies present a biotechnology topic such as: the acceptance of gene-altered plants, animal versus human rights in a famine situation and the use of bovine somatotrophin to enhance milk production in cows. Throughout the case study, questions are presented. Students discuss the case, their opinions and how they would develop a research program to find answers to the questions. Each group has a web page for posting notes and messages. One member of the group takes notes during the discussion. Remote students use the same message page to submit their comments. These are often especially well received by the group because they are fresh ideas not influenced by the group discussion. The messages are not live. That is, the submission of a message is not immediately available to other group members. We hope to include this capability next year.

**Presentations**

After the groups have studied a case, they present their findings to the rest of the class. While distance students cannot currently participate in the actual presentation they can provide materials for the presentation. We hope to allow distance students to participate in presentations next year by asking groups to present their work on a web page. Students will be trained in basic hypertext markup language (HTML). They will then work together to create a public web page.

**Problems**

One of the major obstacles in teaching the course was the classroom itself. The studio is designed for the videotaping of lectures and is not at all suited for PBL group work. For instance, network connections were located at the front of the classroom away from student seating. Students were unable to move their chairs to work together.

One solution would be to hold group work sessions in a different classroom, but we wanted to include the group discussions as well as lectures on videotape. Next year, the class will be taught in a traditional classroom. Special network connections will be added to allow groups to work together on-line.

The technical skills of groups differed. Those groups with a proficient computer user tended to make more information available to their distance group members. This magnified the variation of the experience of e distance students. Distance students required more computer and network expertise as they were required to connect to the web site and use the message center without any direct instruction. Of the four distance students taking the course in the first year, two dropped because they did not have ready access to the Internet. The other two had connections at their work place and, after some initial difficulties, were able to communicate with the other group members.

Passwords, implemented with Basic HTTP authentication, were used to protect class materials. For instance, some materials provided as background for case studies were copied from books or magazines. The material's use in the class is legal under the fair use act. But it is not legal and certainly not appropriate to make this information openly available on the web. Passwords were also used to keep each group's work separate. PBL experiences are created by the exchange of information in the group. Two groups studying the same case will take entirely different paths to their solution. Different passwords were used for each group and each case study. One drawback was that the passwords often proved difficult for students to remember.

**Solutions for the Future**

We found it was necessary to purchase a faster web server. A Sun Sparc Ultra I will replace the currently used Sun Sparc IPX. The new system, scheduled to go on-line Spring 1997, will speed up response time and provide more capacity for web material. Next year we will introduce an automated posting mechanism so messages, once submitted, will be immediately available to the group. We are experiment with Common Gateway Interface (CGI) and Perl scripts as well as Java applications for implementation.

We plan to improve case study presentation by including links to other sources of information. Next year each group project will be presented on the web. Traditional students will work with distance students on an equal basis. Final projects will be accessible on the public pages of the class web site and will provide a forum for public education in biotechnology. As an added bonus, students aware that their work will be available on the web to the public will have more incentive to produce quality presentations.

Other innovations such as live "chat room" session will depend on the capabilities of the distance students. If the distance students are available to participate during class
hours and have access to high speed network connection, we may implement them. Otherwise, the current system should be adequate.

Conclusions
Problem based learning and distance learning can be combined. For the motivated student, the result is a rich and valuable learning experience. I encourage you to visit our web site at http://bluehen.ags.udel.edu/biotech

Often the turn of the century has psychologically sparked change. At the beginning of the twentieth century, Europe and the Americas abruptly shifted to a more mobile, industrial-based society. Americans in the late 20th century are in the midst of a revolution of similar magnitude. Grant (1994) stated that society is being transformed at a rapid rate by new technologies, especially communications technologies, into a culture where one no longer has to be present to be involved. Telecommunications inform, pervade, drive and increasingly shape our behaviors. Americans have come to rely on these technologies to entertain themselves, to communicate with others, and to assist them with a variety of tasks (Coldway, 1988). These changes are taking place rapidly not only in the business world but in the educational setting. According to Blumhart and Cross (1996), in the year 1995, more students enrolled in distance education courses than freshmen enrolling in all the colleges and universities in the United States.

Distance education has captured the attention of campus administrators, faculty unions, statewide coordinating boards and regional accrediting agencies. Schrum (1996) noted that, "Currently, much energy is being expended on distance education in every state and province in the United States and Canada, as well as in many other countries in the world" (p. 30). Yet the impact of distance education in the United States has been negligible when compared to its broader acceptance in other parts of the world. Given the demands for productivity improvements in colleges and universities, technology could remain the most powerful force for change in higher education well into the future.

Purpose of Study

The purpose of this research study was to discover and explore from a student perspective the social issues that restrict or encourage distance education, and to learn from distance education students themselves what coping mechanisms were available or invented in the distance-learning environment. The following questions were developed to address these social issues: (1) Why do students choose the distance education approach to learning? (2) What are the perceived obstacles that distance education students encounter? and (3) What are the perceived coping and adapting processes that distance education students use? This study addressed the observational and empirical gap in the literature by focusing on the social issues of Kentucky doctoral distance students as expressed from their perspectives. In addition, the University of Kentucky (U. of K.) distance doctoral program, the only one of its kind in the United States, provided a special case, worthy of investigation in itself. The data collected during this in-depth exploratory study provided observation and interview-based insights which were contrasted and compared to the speculative literature.

Method

The questions proposed by this study are exploratory in nature because there is essentially no prior research to confirm. Exploratory studies tend not to be guided by hypotheses, because at the outset the researcher does not have sufficient understanding of the phenomena to form conjectures about relationships between constructs.
According to Eckstein (1975) theory-building studies are designed to “find out.” This research was designed to examine the social issues related to doctoral distance education students. It was an observation-based examination of the social issues regarding distance education from the students’ perspective. Focusing on student perceptions, the intention was to recreate for the reader some of the beliefs, practices, and behaviors of distance students.

The Milieu

The Department of Educational Administration began offering courses toward its Ed.D. specialization at U. of K. in the 1980s. In recent years, greater access to the program was desired; as a response, U. of K began using interactive distance education to remove the burden of travel for instructors and students.

Admission procedures for the distance students are the same as those for the on-campus students. Students are admitted on a “rolling admission” basis; new students may start any given semester. The average is four to five new admissions across two distance sites each year. The doctoral majors are required to take a minimum of 43 hours credit. The approximate time for completing the coursework is three years, including summer classes. The distance sites are staffed by a director and a technical coordinator. Support services are also provided such as technology maintenance, student registration, program planning and library support.

The Link

The Kentucky Telelinking Network (KILN) was one of the first major users of the Commonwealth of Kentucky’s Information Highway. The goal of KILN is to design, install, and facilitate a fully integrated digital communications network supporting voice, video and data exchange. The core technology of KILN is highly compressed digital video seen at approximately 30 frames per second.

The Participants

The participants were distance doctoral students studying at U. of K. They were selected because as doctoral students, they were among the most mature, and certainly among the best-educated distance learners in the country. The possible participants in this research consisted of ten students studying in a cohort in Paducah, Kentucky, twelve students studying in a cohort in Owensboro, Kentucky, and thirteen students who had completed their coursework. The participants in this study represented a variety of fields, ranging from nursing and biology to sociology and chiropractic. There were six final participants in this research—five females and one male. Their ages ranged from 31 to 48 years of age. The duration of time spent in this program ranged from four to five years.

Design

The research for this exploratory study was conducted using interviews, participant observations and documents. In order to gain a holistic perspective, interviews were used as the main tool. By interviewing, one is allowed to enter into another person’s perspective (Patton, 1980). Because this was an exploratory study, this research was not driven by a predetermined agenda; patterns of information focused and drove the data collection. The technique of open, unstructured interviews was used; each participant was encouraged to share perspectives on the phenomena.

The study formally began with letters inviting the subjects to participate. Consent forms were mailed to all students in the distance program. The students who chose to participate responded by mail within approximately two weeks. The seventeen participants who decided to take part in the study began by participating in a screening interview. All but one subject was initially interviewed by telephone; the remaining participant was interviewed in person. These screening interviews individually lasted an average of two hours, and in many cases conveyed so much information that the participants felt that they had communicated their messages and did not participate further. All interviews and a group discussion (which provided another level of data gathering and perspective on the research problem) were audio tape-recorded to strengthen the reliability of the data. All of the audio tapes were transcribed and then destroyed. In the second round of interviews, six of the seventeen participants were asked to participate in a subsequent interview, which took approximately two hours each. In round three, three participants were interviewed in order to gain more in-depth, detailed and pertinent information regarding the emerging, unexpected social issues of these doctoral-distance education students. The fourth round consisted of the group interview of six participants which took place at one of the participant’s homes. The fifth and final round was with two participants who agreed to review the final results. These results were mailed to the two participants and they returned the findings with suggestions and comments.

Site visits were then made at two sites, Owensboro and Paducah, Kentucky as well as the “host” site in Lexington, Kentucky. Field notes were taken; neither audio nor video tapes were allowed at the sites. Finally, to complete the triangulation process, documents were gathered. According to Merriam (1990), “One of the greatest advantages in using documentary material is its stability. Documentary data are ‘objective’ sources of data when compared to other forms” (p. 108). The documents for this study included such items as placement procedures, program planning forms, job descriptions, and such.
Data Analysis

Based on the transcripts of the interviews and site visits, the first step of the analysis involved developing a broad, preliminary categorization of data. The second step of the analysis process began the development of subcategories of data within each primary category. Step three involved preliminary understanding of the basic core themes of the experience. These themes were used in step four of the analysis process which included final identification of the themes. Step five completed the analysis—a composite representation of the essences of the experiences of the whole group. The overall objective was to develop an in-depth understanding of the structure of the experience; to condense the data and concentrate on the essence of the experience.

Findings of the Study

The participant interviews produced 61 hours of audio-taped, open-ended questions with expansive answers. When asked to give preliminary interviews, 48.5% of the distant doctoral learner population responded. After their unexpectedly generous and lengthy preliminary interviews, one-third of those who responded were asked to provide additional interviews. These final participants for this study were six students in various stages in the program at U. of K., currently studying or who had studied at two sites, Owensboro and Paducah, Kentucky. In-depth interviews of approximately one to two hours occurred. They were conducted until clear findings emerged concerning his or her experiences and perceptions of social issues surrounding the doctoral distance program. In addition, site visits were made at the two distant sites and the host site. Pertinent documents were gathered to complete the triangulation process.

Profile of Distance Students

All participants had differing personalities, backgrounds, and educational experiences. Yet common characteristics were apparent. These students fit into the non-traditional category. The average age of the students was approximately 35 and most were married and had children. Several of the students had received more than one Master's degree prior to beginning this program. Over 90% of the 35 students were female. These students held “noteworthy” positions in their communities. Few of the students were pursuing this degree for a career advancement or for financial reasons. In general, it was the intrinsic benefits (pride, accomplishment) rather than the extrinsic motivational factors (money, higher status) that prompted them to seek an advanced doctoral degree.

Findings of Question One

Question one addressed the reasons students had chosen the distance approach to learning. The response data revealed three major reasons: availability, convenience, and free tuition for those who were employed at a community college. During the interviews, each participant revealed or her personal situation, discussing how it impacted the choice of the distance education approach to learning. In addition, unexpected issues were voiced which related not only to choice but to group dynamics and individual circumstances as well. For instance, one student was pursuing a doctorate in order to continue in a currently held position. For most respondents, the choosing of a distance program appeared to stem from more than availability and convenience. Social issues also appeared to contribute to the decision once a student realized that further education was feasible. Observations and responses both showed that interaction with other students augmented the initial decision.

Findings of Question Two

As a part of the interviews for this study, each of the six final participants were asked to reflect on the obstacles they had encountered as students in the doctoral distance education program at of K. Approximately thirty obstacles were mentioned. Many of them were similar. Broadly, these obstacles can be divided into seven main categories:

- Problems caused by the lack of personal contact with the distant professors
- Obstacles caused by the slow turn-around time of papers and other materials
- The limited choice of classes provided each semester in the distance program
- Problems caused by having multiple sites
- Obstacles involving quick access to resources, which were needed for papers, presentations, etc.
- Problems concerning the proficiency of the professors at teaching via distance and their attitudes
- Obstacles regarding the distance site support personnel

These obstacles, for the most part, were not seen as critical, and each participant said they had, and appeared to have, individual coping processes which overcame the obstacles. No students remarked that any one of these obstacles or problems would cause them to drop their program of study via the mode of compressed video distance delivery.

Findings of Question Three

The numerous different coping and adapting processes were easily assigned to seven broad categories corresponding to the previously addressed seven obstacles encountered:

- Coping processes due to the lack of personal contact with the distance professors
- Coping strategies caused by slow turn-around time of materials
- Coping processes due to the limited choice of classes in the distance program
Coping used due to multiple sites in distance teaching
Coping processes regarding access to resources and materials (distance library)
Coping with the variety of distance professors
Coping with the differences in distance support personnel.

It was noteworthy that all of the distance doctoral students recognized the obstacles and had devised adequate, and at times creative, coping and adapting processes to overcome these obstacles. Overall, these distance students appeared to display contentedness and pleasure with the overall workings of the program.

Summary
The participants in this research study revealed a wide variety of experiences concerning social issues involved within the doctoral distance education program at the University of Kentucky. The students’ perspectives on choice, obstacles, and coping processes regarding distance education were at times similar, yet may times they differed considerably.

Students chose this mode of educational delivery for the obvious reasons of availability and convenience; however, social, psychological and gender issues were also found to determine choice. It was discovered that no students felt they had made an incorrect choice concerning distance education once they developed an appropriate coping strategy.

Realizing that obstacles and problems existed within this distance program, the students devised creative and appropriate coping processes to address them. These students coped, in general, by using bonding with other students, and by being self-confident, self-motivated, self-disciplined, creative, and assertive. The interviews revealed that none of these distance students would drop the program due to any of these obstacles because they either cope adequately, or the problems were not critical enough to merit dropping the program. Observations showed that the students enjoyed their classmates and worked together to make this experience not only satisfying, but also enjoyable.

There were nonetheless serious issues revealed in this study that resourceful students might not have handled as adeptly. In addition, this research suggested major departures from the current literature.

It appears that the effectiveness of faculty and student contact time, whether in person or via telecommunications will be judged by the level of meaningful interaction. Eventually, “seat time” will become a less important measure of instructional progress, as more emphasis is placed on the possession of knowledge and skills. It is feasible that the proliferation of interactive media tailored to individual needs will help to push higher education toward a new model for instructional delivery. Possibly distance education and, indeed, distance higher education will no longer be a novelty. While it is true that distance education offers potential benefits, it is equally evident that insightful and substantive work in a number of related areas is required. Probably more than anything else, this study revealed that distance education is complex, multifaceted, and has many unknown aspects. There is an urgent need for further research.

In the fall of 1994, the Center for Excellence at Northern Arizona University began an experimental program of offering the complete course work required for elementary teacher certification via Interactive Instructional Television (IITV) on NAUnet. One course, ECI 447: Technology in the Classroom, remained problematic for this initiative because it was a hands-on computer competency course. NAU made an initial investment to create a “floating lab” of 20 laptop computers. Once that effort was accomplished, the ECI 447 was scheduled to be taught via IITV, during the fall semester, 1996. The course objectives were accomplished by using Timbuktu Pro™ 3.0, FlashNotes™, Netscape Chat™ 2.0, and FreePPPTM 2.5v2 software.

The mission of the Center for Excellence in Education (CEE) at Northern Arizona University (NAU) is to prepare education professionals to create the schools of tomorrow. The State of Arizona has given the charge to NAU to address the pre-service teacher preparation needs of the state, especially those areas not serviced by metropolitan areas. To address these issues, NAU and the CEE have implemented a strong distance education program. In the fall of 1994, the CEE began an experimental program of offering the complete course work required for elementary teacher certification via Interactive Instructional Television (IITV) on NAUnet. One course, ECI 447: Technology in the Classroom, remained problematic for this initiative due to its nature. The objectives of ECI 447 are:

- Examination and evaluation of existing software
- Completion of individual and group projects
- Student presentations and demonstrations
- Visitation of the Instructional Human Development Laboratory

The only apparent solution to the offering of ECI 447 was to teach the course using facilities at the state-wide sites, local instructors, and not using the IITV environment. This was problematic due to lack of adequate facilities in some locations and no assurance of quality control. In the spring of 1996, a proposal was submitted for a possible way to teach ECI 447 via IITV. NAU would make an initial investment to create a “floating lab” of 20 laptop computers. This lab would be available on a rotating basis to facilitate the offering of ECI 447 state-wide. The computers would be checked out to each student for the duration of the class. This proposal was approved and the ECI 447 was scheduled to be taught during IITV Fall Semester 1996.

Course Design

To facilitate the instructional process, the IITV studios were networked so that the each student would be able to walk into the studio and plug their laptop into an Ethernet connection that provided access to the NAU intranet. NAU also provided local telephone numbers that allowed the students to connect to the NAU system from home using the 28.8 internal modem of the laptop. Each student had access to their e-mail accounts and access to the Internet using the NAU gateway both during class time and at home. A World Wide Web (WWW) Homepage for ECI 447 was developed to provide additional avenues of access.
To assist the students in accomplishing hands on computer competencies, Timbuktu Pro software was placed on each laptop and on the main computer of the IITV studio. This software allows the instructor to remotely control any student computer. With this captured desktop, the instructor can view any students computer screen no matter where they are located in order to work them through individual problems. If the instructor determines that all students would benefit by observing the process, the IITV studio operator can broadcast the captured desktop through the system and allow all students to observe the process.

Small group activities consist of students from different distant sites developing a class-time presentation on a controversial subject related to technology in the classroom. The students are required to conduct Internet searches and to utilize the products of these searches in their presentation. To facilitate this process, the students use a WWWBoard Version 2.0 ALPHA 1 located on the ECI 447 Homepage. The WWWBoard allows students to develop a dialogue and a set of URL’s on the Homepage that can be accessed and utilized during the classroom presentation. To allow for interaction between students from different sites during class time, Netscape Chat 2.0 software is used. This allows students to be given a problem that allows for spontaneous discussions in a small group setting. Using Claris Homepage students learn to utilize Homepage development software as they create personal pages to be placed on the ECI 447 Homepage.

Preliminary Results

The use of Timbuktu Pro 3.0 was exceptionally successful. Timbuktu Pro for the Macintosh is a powerful remote control software. It provided a solution that allowed the instructor’s Macintosh to connect to and remotely control the student’s Macintoshes during hands-on computer competencies. Timbuktu Pro was also ideal for transferring files. Timbuktu Pro was promoted to provide simple connections whether modem-to-modem over regular phone or ISDN lines, ARA dial-up, over the Internet, LAN, or WAN to give total remote access on demand. Timbuktu Pro takes full advantage of System 7.5. Easy “drag-and-drop” file transfer made it simple for students to turn in large files. The FlashNotes instant messages provided a way to communicate with individual students during class without disturbing the other students.

Another success with the class was the use of the Netscape “chat” software. Discussion groups composed of students from different sites were established. A topic of discussion was given each group and during class time the group was to discuss the issue and then provide an informal presentation to the whole class over the IITV system. For example, when the Instructional Human Development Laboratory made their presentation on using technology for students with special needs the students were divided into discussion groups. Each group was given a part of the computer such as the keyboard or monitor and they were to discuss and then report how these pieces of hardware could present barriers to special needs students. The individuals used the software to discussed both “on task” and “off task” subjects. This technique provided avenues of collegiality and served to breakdown barriers that exist because students are physically separated.

The area of greatest complication and least success was the use of FreePPP 2.5v2 software for at-home access. NAU had established local numbers at the remote sites for modem access. The laptops were programmed to complete the modem dial in using the FreePPP but because of the sensitivity of the system the students had almost no success and became exceptionally discouraged about attempting to use telecommunications at home. Several attempts were made to correct the problems, all with limited success. As a last resort, students were given a step-by-step manual login procedure that reduced the problem for the majority of the students. However, two students were never able to login from home. The failure of successful at home login restricted the success of Internet exploration planned for the class.

Recommendations for Future

The power and versatility of the Timbuktu Pro 3.0 for the Macintosh makes teaching introductory technology based upon hands-on computer competencies a reality. Scheduling for adequate in-class time for hands on problems solving is imperative. An area of future exploration is the use of modem-to-modem connections over regular phone lines that Timbuktu Pro 3.0 provides for helping students outside class time. Careful attention and extra support should be provided to novice users for modem access at home. The manual step-by-step login procedures for the FreePPP should be used from the beginning before anxieties develop to a point that successful login is difficult. The use of the Netscape “chat” software should be expanded so multiple groups can know one another as individuals.

Alternate teaching methods and delivery systems have become a focus of educational programs. Due to the recent development of a distance learning classroom at Emporia State University and the addition of a computer learning center in our division; the Division of Health, Physical Education and Recreation decided to investigate the potential of various educational technologies in order to better serve our mission as a teacher training institution. Our investigation centered on distance learning. What is distance learning? How can it enhance our mission of preparing students for the profession of teaching and providing inservice education for teachers in the field? What technologies would be most effective in accomplishing this mission?

Distance education is a formal, institution-based approach in which teacher and learner are usually separated by location but not by time. Two-way interactive telecommunications systems are used for lecture and visual presentations (Simons, 1995). The Association of Educational Communications and Technology (AECT) cites that many schools in the United States are applying distance learning in innovative and efficient pedagogical ways (Milet, 1996). These technologies provide equity in education (Rutherford & Grana, 1994). They allow opportunities for schools to reach a wider audience, meet the needs of students unable to attend on-campus classes, involve outside speakers, and link students from different socio-economic/experiential backgrounds (Willis, 1992).

Massy & Zemsky (1995) observed two trends emerging with distance learning. The first trend is the new demand for information technology-based teaching and learning, and its substantial growth in the next decade particularly as a economical means of providing more readily accessible post-secondary education and credentialing. The second trend is the profound change in teaching and learning. Institutions can reap the benefits of the great potential that distance learning offers if they transform themselves in fundamental ways.

Whether or not one agrees that today's colleges and universities have a worthwhile core of values that should be protected or that technology should be in part substitute for faculty labor, the potential for increased learning productivity through technology is too great for higher education to ignore. If colleges and universities fail to adapt effectively, other kinds of institutions will take up the challenge. (Massy and Zemsky, p. 11)

We need to not only make teachers aware of the latest technologies, but how we can learn through them and implement them into our classes (Milet, 1996). Viau (1994) stated that minds of tomorrow must be open and able to deal with information that is always changing and increasing. Educators must realize that tomorrow is here today with respect to developing innovative teaching techniques for keeping up with informational changes.

Willis (1990) emphasized that effective distance learning teachers realize preparation is more evident than innovation in the success of this approach. It should be emphasized that a number of strategies that focused on planning instruction, student understanding, and developing new interaction techniques, must be employed for effective teaching.

Course Development

Course Survey
With this information in hand, it was decided to develop a hard copy and online survey to assess the attitudes and opinions of teachers throughout the state of Kansas. In a survey of over 200 responding teachers, a significant number indicated a strong interest in internet courses — with and without limited time on campus. Distance from campus and hectic professional/personal schedules were the main reasons. Courses which helped them to become more knowledgeable and effective teachers were the most requested offerings. In addition, many indicated that their schools' trends were toward more technology-oriented procedures such as student and teacher evaluations plus more curricular emphasis on student proficiencies with computer technology.
**Course Product**

Recently, a new graduate level course, Analysis of Teaching and Coaching, was approved and placed into our curriculum. Since our investigation of distance learning suggested the demand for information technology-based teaching will grow in the next decade and this technology will change teaching and learning profoundly, the course delivery system should utilize a distance learning format. This format would insure that our graduate students would be utilizing the newest technologies available to them professionally. In planning and outlining our course structure, various technologies were implemented. These included interactive television with guest lecturers, internet interaction, electronic mail and bulletin board, video-taped analysis of teaching performances, and the use of various software to analyze teacher performance/student skill progressions.

**Course Delivery**

The Analysis of Teaching and Coaching class was offered for two or three hours credit in order to cater to the needs and preferences of teachers seeking graduate level offerings. The primary distinction between the two and three hour courses was on-campus class sessions. The two hour class had no on-campus class sessions and relied solely on internet and electronic bulletin board delivery. The three hour class was designed for the students to meet on campus the first and last meeting dates of class to ensure more in-depth instruction and personal interaction. A significant portion of the in-depth instruction involved the use of interactive television. An interactive television connection with Illinois State University faculty focused on the current trends in observational recording of physical education teaching behavior. The interactive television experience allowed our students to have personal dialogue with authorities on teacher performance.

**Internet**

Students were required to have access to the following equipment: internet and World Wide Web access, at least a 386 Windows capable PC or Macintosh computer, a video camera, and a VCR and monitor. A class home page was developed containing the course syllabus, assignments and directions for various technological procedures. A hard copy of this information was also produced in a course manual. Links to sources both on and off campus were established including library information that students could access on-line. A class profile was also developed to include pictures and personal information of both instructors and students to insure a more personalized learning environment.

**Bulletin Board**

The bulletin board system, Worldgroup Manager (1995) was the primary vehicle through which course information and class discussion was conveyed.

**Worldgroup Manager** allows students and instructors to exchange messages in E-mail and forums, and participate in live debate in teleconference. Worldgroup Manager allows off-line work such as composing a message, before going on-line to deliver the message. Forums were established for long-term conversations between instructors, students and experts on a variety of pedagogical issues. A discussion question was posted every two weeks for these conversations and was perpetuated through a variety of threads between the instructors and students and also among the students themselves. Another benefit of this system was the privacy allowed for the class as opposed to a universal listserv.

**Video Analysis**

Due to the nature of the course, analyzing teaching and coaching performance to enhance one’s professional skills was to be an obvious outcome. Videotapes were produced of selected master teachers at the elementary, middle and secondary school levels for promoting positive and effective teacher behaviors. Besides observing effective teacher behavior, the videotapes were designed to help the class analyze and evaluate teacher performance. In turn, each student was required to videotape themselves in a teaching situation and critique the situation. Initially, the instructors chose a variety of paper and pencil assessment instruments to use for analyzing and evaluating these master teaching videotapes and the personal videotaped teaching performances of the class. Since it was decided to share with the students a variety of educational technologies, the instructors pondered why not find an available software that facilitates the collection, analysis and reporting of the observable teaching behaviors and could be used with a PC or laptop computer?

**Software**

The advantage of a computer software program that utilizes objective criteria such as time and frequency enables a person with minimal training to conduct an evaluation of someone’s performance. Also, a computerized screen presentation and/or printout with a graphical display of a performance can be an immediate and informative device to make one aware of their teaching behaviors. Simultaneous situations such as time on task, definitive portions of a lesson - introduction, and review, as well as, the duration of those situations can be tracked more easily through this software rather than manually through paper/pencil and stop watch procedures.

After reviewing the current software available for analyzing teaching performance, the decision was made to develop our own software in a Windows environment. The Windows interface would make the computer program more user friendly than current MS-DOS based software available. Our goal was to develop teaching analysis software that would accurately measure and record various
teaching behaviors and communicate useful results quickly to the observed teacher with the goal of improving teacher performance. Our objective was accomplished by developing a PC computer software program, Evaluator (Henry and Hubbard, 1996), that uses a Windows interface programmed in Visual Basic language. It was designed to effectively measure time on task behaviors as well as frequency of teacher related behaviors. The Evaluator allows collection of data for any observable behavior that can be timed, counted or commented on. Specific behaviors to be measured can be determined by the observer prior to actual observation. This software program can be used with a PC or laptop computer input directly in the classroom/gymnasium or in conjunction with paper/pencil recording with later transfer to the software program. The program is designed to print reports, charts and graphs for immediate feedback. Information on the computer software program Evaluator, may be obtained by contacting Guerilla Software, 6826 East Odessa Ct., Wichita, KS 67226.

Future Implications

University teacher education programs must realize that technology-based education is here and is rapidly changing each day. Recent trends in education suggest the demand for information technology-based teaching will grow in the next decade and this technology will change teaching and learning profoundly. It is imperative that our teacher education programs incorporate technological strategies currently being endorsed in public and private schools. Utilizing educational technologies for teacher excellence will improve our teacher education systems so that they are more productive in serving a wider professional audience, and allowing teachers better access to new, innovative, teaching practices.

COLLABORATIVE DISTANCE LEARNING (CDL): AN INSTRUCTIONAL MODEL DESIGNED TO ENRICH TEACHER EDUCATION COURSES

Bob Lumpkins
Henderson State University

Fred Pippen
Pensacola Public Schools

Fred Parker
Henderson State University

The major purpose of the Collaborative Distance Learning (CDL) Model is to provide opportunities for undergraduate and graduate students to interact with teachers, administrators, and students in selected model schools using various telecommunications tools. The specific tools used are electronic mail, listserve, chats via internet using Cu-SeeMe software, video tapes, and telephone conference calls. The model described here is an extension of the Studio Classroom approach described by DeLoughry (1995) and used by Lumpkins (1995) in introductory courses to teach education. DeLoughry quoted Cutler as stating that the Studio Classroom approach is going to transform all of those courses that everybody suffered through in college. The trick, according to Cutler, is to get students involved in their education, and he is convinced that the studio approach works. By bringing students in teacher education classes into direct contact with K-12 schools using video conferencing tools, the study of teaching becomes real and viable. Perhaps the skeptics should consider the observation of Freedman (1995), editor of Inc. Magazine, who stated: “Companies (universities) that find ways to apply technology effectively stand a real chance of achieving a competitive edge. Those that don’t, stand a real chance of being eaten alive” (p. 9).

Participants
Participants in the pilot program included students enrolled in selected undergraduate and graduate courses at Henderson State University during the 1996/1997 school year and selected teachers and administrators from two model public schools. A brief description of the tools and techniques employed in this project are presented in the following paragraphs. Two innovative model school sites in partnership with Henderson State University provided opportunities for participating students and teachers to dialogue about teaching and learning issues and concerns. A major belief guiding this inquiry was that this model would personalize inquiry and enhance student learning.

Distance Learning
Newer technologies are making it possible for universities like Henderson State University to enter into the heretofore restricted distance learning market. At Henderson State, the Studio Approach was used to implement distance learning during the Spring, 1996 semester. A graduate curriculum course used direct classroom instruction combined with electronic mail, use of the internet by the student to glean assignments, and the use of telephone conference calling. Though not true distance learning because most classes were taught within the classroom at the university, this was the first distance learning course offered by the elementary education department and will be expanded during the Spring semester of 1997. Distance learning comes to the student instead of the student coming to the classroom. Distance education is not simply the addition of technology to instruction; instead, it uses technology to make possible new approaches to the teaching-learning process. The distance learning courses may utilize several different formats and distance technologies. For example:

- Station to Station full-motion video
- Internet Relay Chat (IRC)
- Desktop video-conferencing (Quick Cam) The paradigm for desktop video conferencing is that participants sit at their own desks, in their own offices and call up other participants using their person computer in a manner much like a telephone.
- Telephone (computer and Internet lines)
- Video and Audio tapes (Email correspondence)
Cooperative Learning Groups

Cooperative learning groups, consisting of three to seven students from the same geographic area, will be established for carrying out assigned tasks and to provide opportunities for future teachers to observe master teachers and to study the teaching-learning process. Cost and governance problems have caused many teacher education programs to close the laboratory schools doors and seek opportunities for their students to carry out observations and other practice activities in area schools. Considerable savings are being realized by this change, but not without sacrifice. It is very difficult for teacher education professors to secure placements for their students to observe, and even more difficult to have some degree of influence or control over the observations. Other difficulties revolve around time and distance. It is difficult for students and their professors to travel to off-campus sites for class observations and to carry out other assigned tasks such as interviews with teachers and students. The virtual laboratory school where connections with classrooms can be made via live video, taped lessons and conferences using a combination of distance technologies may be the answer to these problems.

The unique partnerships between K-12 schools and universities must be based on the premise that all participants will have something to gain from participating in the partnership. In other words, all are rewarded by one or more services provided by the other partners. The schools provide virtual laboratory school experiences for students in teacher education. University students may serve as mentors or pen pals for K-12 students and the university professors may provide compiled research summaries relevant to questions raised by teachers and also provide certain services within their area/s of expertise.

Experiences with other programs using distance technologies, and generalizations drawn from survey data gathered from both undergraduate and graduate students, and training specific to the technologies to be used in the collaborative distance learning model, must be included in the overall instructional plans. Certain prerequisites such as the student's basic computer literacy and word processing skill level along with availability of internet connectivity must be carefully adhered to if the student is to be successful in courses where information is exchanged using various telecommunication tools. Approximately twelve clock hours of class instruction will be allocated for training in the use of specific telecommunication tools such as video conferencing via internet, developing web pages for posting individual and group research and strategies for locating relevant information on the World Wide Web.

Weekend Seminars

Seminars and conferences are efficient vehicles for exploring issues and debating points-of-view. Each major set of topics studied by undergraduate and graduate students may be launched and/or concluded using these practices. While the students may meet on campus, the speakers may include teachers and administrators who present from their home station via telephone, CU-SeeMe, or video tape. Students enrolled for three semester hours of graduate credit will be required to meet on campus one Saturday each month from 8:30 a.m. to 3:00 p.m. for lectures, seminars and training in the use of selected distance learning tools. A total of five full-day class sessions will be held during the semester, or the equivalent of 30 clock hours of on-campus instruction. The various cohort groups will be required to meet weekly at predetermined sites between the hours of 6:00 p.m. and 9:00 p.m. over a fifteen week period. During cohort meeting the students may work on group assignments and confer with their instructor/s via teleconferencing and electronic mail. In addition to the 75 clock hours each student will accrue by his/her participation in seminars and cohort class sessions, a great deal of time will be required to complete independent assignments. It is expected that the total time commitment of the students enrolled in a three semester hour Weekends@HSU course will equal or exceed the time committed by regular on-campus students enrolled in the same course.

CDL Plan

Laboratory schools, which were once considered to be an indispensable component of teacher education provided opportunities for future teachers to observe master teachers and to study the teaching-learning process. Cost and governance problems have caused many teacher education programs to close the laboratory schools doors and seek opportunities for their students to carry out observations and other practice activities in area schools. Considerable savings are being realized by this change, but not without sacrifice. It is very difficult for teacher education professors to secure placements for their students to observe, and even more difficult to have some degree of influence or control over the observations. Other difficulties revolve around time and distance. It is difficult for students and their professors to travel to off-campus sites for class observations and to carry out other assigned tasks such as interviews with teachers and students. The virtual laboratory school where connections with classrooms can be made via live video, taped lessons and conferences using a combination of distance technologies may be the answer to these problems.

The unique partnerships between K-12 schools and universities must be based on the premise that all participants will have something to gain from participating in the partnership. In other words, all are rewarded by one or more services provided by the other partners. The schools provide virtual laboratory school experiences for students in...
peer support and assistance. Cooperative learning groups and cohort groups are two terms used interchangeably in this particular project. These groups will be expected to meet one evening each week to discuss, to question, and to dialogue with their instructors and other classmates via distance using teleconferencing, electronic mail and net chat.

Collaborative and cooperative learning strategies are strongly supported in the literature as effective tools to use with all age groups. The cooperative inquiry model proposed herein depended heavily on using these learning strategies in a person-to-person format across distance. An example of a typical setting may be where two or more students may meet at a common location and cooperatively work on an assigned activity, conference with the instructor, school personnel at remote sites or other students via telephone, internet (Cu-SeeMe), Email or fax. Information exchanges and data transfers may occur from any combination of students, resource persons and/or the instructors during these sessions.

**Specific Instructional Activities**

Every university student involved in this project will have access to Email and to the internet. This access may be through the university or from other sources such as their place of employment, the regional teacher cooperative, or through a private vendor such as Prodigy or America On Line. Specific projects may be defined by the student while others may be assigned by the instructor. The independently directed activities will require the search retrieval and interpretation of information from a variety of sources and locations. Students may also transfer information to other students and his/her instructor using a variety of telecommunication tools. A great deal of flexibility will be given to the students in how they choose to schedule their time, and a great deal of independence will be given relative to the design of inquiries and reports.

**Cohort Discussion Activity**

One cohort member should assume the responsibility for documenting the discussion by recording a complete set of written notes. The production of a written narrative giving an overview of the discussion will be a general expectation. This written document with a copy of the notes (in electronic format) will be submitted to the instructor no later than on week following the discussion activity. The discussion, if applicable, should be inclusive of both elementary and secondary school perspectives.

**Individual Inquiry Activity**

This type of inquiry is to look into the literature to determine the opinions of experts and to review the research findings relative to a specific topic. Documentation of this research is shown by the production of a short paper (one to three pages with references) which is shared with classmates by posting on the student’s homepage. The inquiry should be approached from either an elementary or secondary perspective.

**Internet Chat**

One chat format will be “asynchronous” where the chat will take place over time with the participant deciding when he/she will login to listen and/or talk. A second chat format to be used will be “synchronous” with participants actively logged in during a set time frame.

**Teleconferencing**

Specific dates and times are established for cohort groups to chat with their instructors via distance using CU-SeeMe tools. Class members will be notified by Electronic Mail at least one day in advance detailing the particular discussion format to be used. One type is “Broadcast” where cohort groups are expected to log onto a specific reflector and join a designated conference during a specific time period.

**Assessment/Evaluation**

Mastery will be determined by written examinations plus the assessment of group and individual assignments and projects. Each student will be expected to develop an electronically filed portfolio of his/her work as the semester progresses which may be viewed by fellow classmates and the instructor. Each student will be expected to develop his/her personal homepage and systematically post the materials and completed projects on the web page.

**Attendance Policy**

Attendance and participation are believed to be key factors directly related to the development of skills and understandings described in the objectives for this course. Because of the uniqueness of the Saturday seminar, it is very difficult to replicate the information given, discussions, specific training in the information given, and specific training in the use of telecommunication tools. Cohort meetings are also unique in the sense that it is impossible to replicate the experience by doing a make-up assignment. Absences, regardless of the reason/s, will be carefully scrutinized and will result in additional assignments. The semester grade may be lowered if the instructor feels that the absences have been excessive and/or if it is not possible to replicate the lessons or experiences missed.

**Conclusion**

We believe the CDL model, along with university and K-12 partnerships using a variety of telecommunication tools, will personalize and enhance student learning. The effectiveness of the Collaborative Distance Learning (CDL) Model will be assessed as each phase of the program is implemented during the 1996-1997 school year. Specifically, data will be collected and analyzed relative to the following questions:
Question #1. Will there be a significant difference in student to student and student to teacher interaction between students participating in this project and students enrolled in traditionally delivered undergraduate/graduate education courses?

Question #2. Will the Collaborative Distance Learning Model significantly affect student motivation and learning?

This paper outlines alternatives for distance learning applications in teacher education programs. Several technologies that focus on audio, video, and computer delivery are examined. In addition, case studies of distance learning programs being implemented at the University of South Florida and the University of North Florida are presented. There are many applications for distance learning in teacher education programs. Distance learning techniques can be used to deliver curriculum in the form of courses, mentoring, or team teaching; they can be used to support the learners via advising, access to resources, or student registration; and they can be used for assessment of students or programs. Delivery systems for distance learning can be roughly divided into audio, video, and computer. Each of these categories include a variety of technologies that can help to enhance instructional interactions between teachers and students who are separated by time or distance.

Audio Technologies
The primary audio technologies for distance learning include audio cassette tapes (one-way audio) and audio-conferencing (two-way audio). Audio cassettes provide an inexpensive way to distribute information. This method has been employed for years for audio books and other information that does not require interactivity. For example, lessons in a foreign language may be recorded and disseminated on audiotapes, allowing students to practice at home, in a car, or whenever and wherever it is convenient for them.

Audio-conferencing involves a real-time exchange of audio information that can take place through telephones or through the Internet. Telephone technologies that can be used to enhance distance learning include speaker-phones, telephone bridges, conference calls, voicemail, and fax machines. These techniques are inexpensive and easily accessible by the vast majority of people.

Audio-conferencing is also possible through the Internet. Recent software programs, such as CoolTalk, allow students with Internet access, an audio card, and a microphone, to talk to others throughout the world. Through Internet telephony, preservice teachers in the United States can communicate with peers or experts for little or no cost.

Video Technologies
Video technologies that can be used for distance learning include linear videotape, broadcast video, and satellite videoconferencing. A common method for distributing video and audio information is through linear videotape. With this approach, a series of tapes can be recorded and sent to students to watch whenever it is convenient. Interactions with the instructor can be conducted through e-mail, telephone, or traditional correspondence methods.

Broadcast video can consist of television broadcasts (usually on public TV), closed circuit TV, or ITFS (microwave) delivery. Broadcast video is generally one-way audio and one-way video. In other words, students may be advised to watch channel 32 at 8 pm for the Business Education course. If the video is broadcast to homes, students can watch it in the privacy of their homes, or they can tape the shows to watch at a later time. If it is sent (via microwave or fiber optic cable) to pre-selected sites, the students must congregate at the sites to receive the broadcast. In some cases, facilitators may be available, and telephone bridges can allow students to ask questions during the lesson.

Although more expensive, videoconferencing can also take place via satellites. With satellites, an uplink is required at the originating site to transmit the video and audio signals to a transponder. The transponder receives the signal and transmits it back to earth where it is received by downlinks and distributed to the classrooms. Satellite delivery is generally one-way audio and video, although two-way audio can be provided with a telephone bridge.

Computer Technologies
The Internet and the World Wide Web offer inexpensive means to conduct two-way interactions between teachers and learners. The possibilities range from a "correspondence-type" course conducted on E-mail to structured courseware delivered through the World Wide Web or CD-ROM. Desktop videoconferencing (with two-way audio and two-way video) is also available through the

Distance Education — 107
computers on the Internet or through high-speed lines, such as ISDN.

A determining factor with distance learning through the Internet is whether the course communications should be synchronous or asynchronous. If two-way interactions are required (either audio or video), then the synchronous options of audioconferencing through a program such as CoolTalk or videoconferencing through CU-SeeMe or PictureTel are possibilities.

If, on the other hand, you want to deliver courseware independent of time, it is possible to develop Internet or Web-based courseware wherein the students can read their assignments whenever it is convenient for them. They can also send e-mail messages to the instructor. Asynchronous courses require more time in the up-front planning, but are less restrictive and less expensive in the delivery.

Case Study: Desktop Videoconferencing Project at UNF

Desktop videoconferencing is the delivery medium for a joint project between the University of North Florida, Lone Star Elementary School, and Sandalwood High School. Business partners, the university, and the public schools are participating in a teleconferencing venture. The university is providing instructional and technical support. A cable television company is giving “in-kind” support to the schools for obtaining the necessary equipment for transmission, and computer and program development companies are providing “in-kind” contributions of hardware, distance learning courseware, and technical support.

Teaching and learning is the focus of this educational partnership between university faculty, preservice teachers in the UNF undergraduate program, and teachers and students at secondary and elementary schools. University personnel will facilitate the instruction for preservice teachers studying science education in the undergraduate teacher education program at UNF and will provide instructional technology support. A biology and a chemistry teacher at the high school and a science educator at the elementary school will assist students in their classes in preparing for and completing the project.

In developing content for the project, a number of sources were consulted: the National Science Standards, the Florida Sunshine State Standards, and the Duval County Public School District program called Academic Excellence and Achievement for All Students (AEAAS). The Florida Curriculum Framework for Science, a guide for teachers to help achieve the Sunshine State Standards, provides the foundation for the work of this project.

By focusing on the following standards, this project will provide participants with an understanding of the importance of science in society, truthful reporting of scientific findings, and the importance of sharing scientific findings with the public.

SC.H.1.4.4 The student knows that scientists in any one research group tend to see things alike and that therefore scientific teams are expected to seek out the possible sources of bias in the design of their investigations and in their data analysis.

SC.H.1.4.5 The student understands that new areas in science are limited by the context in which they are conceived, are often rejected by the scientific establishment, sometimes spring from unexpected findings, and usually grow slowly from many contributors.

SC.H.1.4.7 The student understands the importance of a sense of responsibility, a commitment to peer review, truthful reporting of the methods and outcomes of investigations, and making the public aware of the findings.

SC.H.3 The student understands that science, technology, and society are interwoven and interdependent.

SC.H.3.4.1 The student knows that performance testing is often conducted using small-scale models, computer simulations, or analogous systems to reduce the change of system failure.

Based on these standards, the project uses the “anchored” instruction model with distance learning to address the role of prior knowledge in the development of understanding, analysis of evidence and data, and include public discussions as a form or peer review. Elementary school students, high school students, and university preservice teachers will react to scenes in the hot air ballooning and scuba diving anchor as a preface to studying gases in their chemistry and biology classes. By explaining how these processes are possible students will share prior knowledge by remote links among the three sites. High schools students will collect and qualitatively evaluate data using the CBL-graphing calculator technology. Data will be shared and reviewed among the three sites.

Dissemination of the plans for this project and the findings will be available through postings to the Internet, videotapes of the teaching and learning episodes, and local media. Both university and public school educators and students will share the results of the project through their web pages using data from experiments, graphics, photos, and QuickTime movies.

Another project using teleconferencing technology as a delivery vehicle is part of the Jacksonville Urban Educational Partnership (JUEP). To prepare inservice teachers for using distance learning technologies, inquiry seminars are being developed by 9 inservice teachers and lead faculty from the university of North Florida. This collaborative partnership between the University of North Florida and the Duval County, Florida public schools seeks to better prepare teachers for urban schools and to enhance the achievement of urban students. Through the seminars school-based and classroom-based technology scholars will become “emerging experts” regarding teleconferencing technology.

108 — Technology and Teacher Education Annual — 1997
Inservice and preservice teachers are learning how to use the Florida Information Resource Network (FIRN) as a means of communicating with other teachers and students at both elementary schools in Jacksonville, FL, and with teachers and students participating in the project in Houston. As soon as the infrastructure is completed, participants will use the teleconferencing technology to participate in the Texas STARBASE project. Teleconferencing groupware will be coupled with collaborative learning to assist students in working in small groups, focusing on problem-solving instructional units, and engaging in new ways of thinking.

**Case Study: USF Learn From A Distance Program**

The University of South Florida has offered courses through the Internet for the past four years. In the Spring of 1992, a graduate-level course was offered to a pilot group of four students. Based on the success of this and other courses, the USF Learn From A Distance (LFAD) program has expanded to fifteen courses with approximately 200 students enrolling each semester. The LFAD program offers courses in Instructional Technology, English as a Second Language, Elementary Education, and Psychological Foundations.

Most of the courses offered through distance learning focus on delivery of the course materials through the Internet or videotapes. These courses require two class meetings—an orientation meeting at the beginning of the semester and a final class meeting at the end of the course. These meetings are waived for out-of-state students who meet specific criteria. Between the two meetings, students work through sets of well-designed assignments to meet the course objectives. Most of the course interactions with the instructor and other students take place through e-mail. In addition, several of the courses offer supplemental instruction through Web pages, videotapes, and computer software.

The Special Education program at USF also offers distance learning courses via videoconferencing (through the PictureTel system). There are currently three sites throughout the USF service district that receive courses in this manner. The PictureTel system was selected because of the high-quality video and audio that can be transmitted. Special high-speed telephone lines (ISDN) are required for delivery of the course.

A key component in the success of the distance learning courses at USF has been the establishment of the Learn From A Distance (LFAD) program. Teaching a distance learning course requires additional time and commitment on the part of faculty members. To assist faculty members and ensure a smooth operation of distance learning courses, the LFAD office performs the following service functions:

- Assist faculty with the technology necessary for distant delivery
- Assist in the development of instructional materials
- Duplicate course materials, such as videotapes
- Provide technical support to students enrolled LFAD courses
- Promote distance learning opportunities via mailouts, etc.
- Schedule distance learning classes, including rooms and equipment, if necessary
- Register students for LFAD courses

In the spring of 1997, a new College of Education building will open at USF with fiber optic cables throughout the building and direct links into a satellite uplink. As access to technologies increase, the USF faculty and LFAD office plan to work together to meet the needs of both traditional and non-traditional students.

**Conclusion**

Distance learning technologies are playing a major role in teacher education programs throughout the world. Integrating distance learning technologies into teacher education programs is not an easy task. There are many different technologies to choose from, each with its own advantages and disadvantages. In addition, the development of a distance learning course is extremely time-consuming and demanding for the instructor. Distance learning, however, holds a great deal of promise for meeting the needs of students throughout the world who strive to become teachers, but may not be able to attend traditional classes.

In a recent article, Richardson (1996) succinctly describes the plight of pre-service teacher education. "It is sandwiched," she writes, "between two powerful forces — previous life history, particularly that related to being a student, and classroom experience as a student teacher and teacher" (p.113). While traditional pre-service programs may do a good job fostering knowledge of educational research and theory, and while this knowledge may have some eventual impact on practice, teachers' beliefs and actions tend to be influenced far more strongly by those other classroom experiences. The challenge for teacher education, Richardson suggests, is to find ways to support teachers' praxis, or what might be called their knowledge of practice. That is, what experiences can we provide that will lead pre- and in-service teachers to reflect critically on their long-standing beliefs about education? How might we help them to integrate educational theory and classroom experience? How might we encourage them to become life-long learners, engaged in a continual effort to improve their own teaching? In short, how might teacher education become a more powerful source of professional development, one that does not merely serve as an interlude between other, more formative experiences?

We believe that the emerging communication technologies point in promising directions for improvement. In particular, we are working to design interactive video exchanges between in-service and pre-service teachers. Two-way video-conferencing, linking the classroom of an experienced teacher with students in a university methods class, provides real-time observation of instruction, opportunities for subsequent discussion among participants, sustained involvement with a single classroom, and the ability to record observations for later analysis. What is more important, it provides in-service teachers with a means of continuing professional development and pre-service teachers with a common, and exemplary "text," one that will help to bridge the gap between educational theory and classroom experience.

To foster a knowledge of practice among pre-service teachers, most teacher education programs rely heavily on a period of observation in area schools, and this observation usually fulfills the teacher-certification requirements of the state. In Michigan, for example, pre-service teachers must spend a minimum of sixty hours observing in schools, prior to student-teaching. It is hoped that during this time, teaching candidates will begin to see how various educational theories are being implemented in classrooms. However, research has shown that very few observation sites exemplify the kind of instruction that teacher education programs typically promote. Furthermore, because teaching styles and teacher-student dynamics tend to differ so widely from one classroom to the next, from school to school, and from district to district, professors of teacher education cannot assume that teaching candidates have had comparable experiences in the field, much less assume that they share a common vocabulary for talking about classroom practice. As Carter (1990) explains, this can have a disastrous effect on pre-service learning. Teacher candidates learn best through reflective discussion about classroom practice, but such discussion becomes very difficult in the absence of a shared experience. One solution might be to send candidates to observe all in a single school, or in a single set of classrooms; but this is rarely feasible, given the intrusion and the logistics involved. Another solution, and one that many researchers have begun to explore, involves the use of videotape and hypermedia applications. We believe that these efforts are quite promising. However, they lack the immediacy of response afforded by the "real-time" connection of interactive video. One cannot ask questions of a video-tape, and the explanations offered on hypermedia applications may or may not address the spontaneous questions of individual students. In short, two-way video technology is likely to be the best means, in the long-term, for providing pre-service...
students with a common text for discussion of exemplary teaching practices.

While such exchanges are designed primarily to meet the needs of pre-service teacher education programs, the in-service teacher also stands to benefit. Teachers often lack opportunities for ongoing and serious discussion of practice. The daily pressures of work and the fragmented nature of many professional development efforts afford teachers little time to reflect on what they do in the classroom. Furthermore, as researchers have long observed, teaching is characterized by extreme professional isolation, such that many teachers have no idea what goes on in the classroom next door. However, involvement in a project such as a two-way video link with pre-service teachers can begin to break down that isolation, showing both the pre- and in-service teachers that there is much to be gained from professional exchange. The ensuing questions, discussions, and articulations of pedagogical choice-making, can strengthen an in-service teacher’s knowledge of practice, particularly when that discussion is carried out over the course of an entire semester.

Although the remainder of this paper will focus of the technical aspects of our project it is important to keep in mind that the work did not evolve solely out of the desire to introduce elaborate new technologies into the classroom. Rather, it emerged out of our commitment to employ technology in the creation of a new form of learning community (Lytle & Cochran-Smith, 1993), one that unites pre- and in-service teachers around a common classroom text. All of our efforts at TATE’s technical functioning have been geared towards fulfilling these pedagogical principles.

**Technology Implementation of the TATE Project**

**Set and Setting**

The Technology Assisted Teacher Education program links a university-based English methods class with a middle school language arts class, thereby placing pre-service teachers virtually in the classroom of an exemplary teacher, rather than positioning them as passive observers or recipients of instruction.

In the summer of 1996, Dr. Anne Ruggles Gere, of the University of Michigan School of Education, embarked on a pilot project to develop the use of videoconferencing tools in pre-service teacher education.

The groundwork had already been laid towards the creation of an observable field study. Dr. Gere had, for several years, worked closely with Laura Schiller, a sixth grade teacher at Bimey Middle School in Southfield, Michigan, one of the first teachers certified by the National Board for Professional Teaching Standards, and she had determined that Ms. Schiller’s class would serve well as the focus for the exemplary teaching model. A co-mentoring program was established to provide the undergraduates direct working experience with their sixth grade partners and the sixth graders with personalized instructional feedback. A variety of interactions between undergraduates and their partners were initiated. Dr. Gere’s undergraduate class traveled to Southfield to observe the class first-hand. Phone calls between both groups of students and letter writing were other forms of shared communication. This set the stage for the introduction of the conferencing tools.

Working closely with Dr. Gere, the project team defined the instructional goals and set about the task of initial testing and design. The three primary instructional goals of the project are:

1. Provide pre-service teachers with the opportunity to observe Ms. Schiller’s instruction without unduly impacting the class.
2. Provide pre-service teachers with the opportunity to discuss practice directly with an exemplar teacher.
3. Provide Dr. Gere and her students with a common observational frame of reference upon which to base their discussions of teaching methodologies.

The University of Michigan’s School of Education is fortunate enough to have a state of the art Multimedia Classroom, and we decided that the methods class would be best served by meeting there. This classroom had individual Macintosh workstations equipped with a number of video and audio input devices and the capability to project any station to the large screen.

The Southfield location was, of course, predetermined. We were lucky that Ms. Schiller was extremely adaptable, as standard K-12 classrooms provide some of the worst environments for effective conferencing. We were not without our difficulties, but Ms. Schiller’s willingness to configure the classroom in a way to achieve optimum conferencing immensely aided the project.

**Delivery System**

Initially, the project team looked at low-end IP-based video conferencing applications. Under consideration were Cornell University’s CUSeeMe, White Pine Communication’s Enhanced CUSeeMe, and Apple’s Quicktime Conferencing. All offered a number of pluses and they were relatively inexpensive to implement. However, they were determined to be inadequate to meet the specific demands of the pilot. Color was not of primary concern for our needs, though we quickly realized that students would immediately consider images other than color to be inferior. We needed to have good frame rates and quality video to provide the pre-service teachers with a good observational experience. In many ways the audio quality took on greater importance than the video quality. Packet-switched IP-based video conferencing applications cannot deliver both high quality video at 320 x 240 pixels.

Distance Education — 111
along with telephone-grade audio, at least not at the time we were searching for solutions.

Budget constraints prevented our serious consideration of high-end land delivery systems or satellite links. We had to look at what was a fairly small number of mid-range price options. We determined that point-to-point Integrated Services Digital Network (ISDN) offered us the best option of delivering acceptable levels of video and audio over standard phone lines. After some investigation, the project team chose a product called ERIS, from RSI Systems, Inc. The system met the majority of our criteria, adhering to the current conferencing standards for audio G.711, G.728, and G.722 with full duplex capability and the common videoconferencing carrier standards. Also, ERIS was totally cross-platform compatible and promised future releases of a computer-free option. The ERIS System also allowed for a considerable amount of flexibility, with multiple video and audio inputs and outputs. RSI, Systems, Inc. indicated that the ERIS 1000 offered scalability, allowing the user to dynamically control the bandwidth dedicated to video or audio. A demonstration system was procured from a local reseller, and ISDN lines were installed at the School of Education and at Birney Middle School.

It is at this point that we must stop and reflect on the difficulties we encountered with our ISDN installation. This is not a trivial matter, and would advise anyone entering the ISDN abyss to understand some of the major pitfalls before proceeding with an installation. Though ISDN is not inherently difficult to install, the issues surrounding configuration and peripheral devices make the installation procedure much more complex. On January 23, 1996 AT&T Network Systems, 3Com Corp., Ascend Communications Inc., and U.S. Robotics Inc. announced the formation of an ISDN Forum to promote the use of ISDN. One of the stated goals of the group was to reduce the complexity of an ISDN installation by automating configuration. Currently an end user has to know their switch type and Service Profile Identifier (SPID). The Forum members plan to develop systems that will automate this process, making configuration much more transparent to the user. The problems we encountered were exacerbated by the fact that we were working with two different providers, our Regional Bell Operating Company (RBOC) and the University’s own telecommunication specialists. It necessitated our knowing not only what questions to ask but how to communicate our particular concerns to two different groups. The user must be able to sort through a number of issues. One example would be whether or not a Network Terminator (NTI) is required along with a Terminal Adapter (TA). Basic Rate Interface (BRI) versus Primary Rate Interface (PRI) is another issue that has significant cost and quality implications. Missed communication and the lack of clearly defined responsibilities led to a number of false starts, many wasted hours, and a good deal of anxiety trying to meet deadlines. Our experience has not diminished our faith in ISDN technology, but it has led us to offer up the following bits of advice:

1. Develop a strong relationship with a responsive person at the phone company who will follow through on your order.
2. Be sure you order and receive an NT-1 with power supply (if needed).
3. Be sure all necessary adapters associated with your particular device are purchased.
4. Order the proper line configuration (e.g. 2B+D).
5. Make sure you can be present during the line install and that you see the actual test of your line to confirm operation.
6. Make sure installer does not leave before you receive your SPIDs (phone numbers), dialing prefix (if any), and your switch type (e.g., Northern Telecom, AT&T, etc.).
7. Know where your line enters your room.

Many of these points may seem obvious but should not be dismissed as they can have significant repercussions.

**Room Configuration**

After we determined that our connection was relatively stable, we were able to focus on room set-up, and camera and microphone placement. We used a number of different configurations dependent on the type of interactions we planned. The most common set-up is shown in Figure 1.

At the University of Michigan location we typically had the students sitting around the tables facing the large screen. There were two conference microphones in the ceiling and a headset microphone located at the instructor’s station. All microphones were wired into a microphone mixer for manual level control. We had a camera mounted on a tripod in the front corner of the room that had a wide angle shot of the seminar area. At the instructor’s station there was a Flexcam used for the one-on-one interactions at the workstation. The room has overhead speakers allowing the audio emanating from the Southfield location to be broadcast throughout the room. The overhead microphones allowed the students to converse with their Southfield counterparts.

The Southfield classroom, as I mentioned earlier, posed more problems. One whole side of the room was window, and this, mixed with the overhead fluorescent lighting, posed color temperature problems for the camera. With some use of the existing shades and putting the windows behind the camera placement helped to eliminate some of the registration problems. The remote image was broadcast over an existing TV monitor hung in the front of the class. The private face-to-face conversations took place in the back of the room at the Macintosh computer we provided. Small group observations took place at designated tables and large group interaction usually occurred at the front of the room on the rug.
The pilot consisted of six sessions consisting of ten hours of synchronous conferencing. As indicated, a number of different interactions and observations were attempted. The first two sessions concentrated on face-to-face interaction between the Birney students and their mentors at the university (see Figure 2.). The benefit of this particular type of interaction was that it familiarized the students with the equipment and allowed them the opportunity to become comfortable with its operation.

The small group observation gave the university students the chance to observe the outcomes of particular methods applications such as self-assessment by the Birney 6th grade students. It also allowed for the observation and discussion of peer interactions. Audio and video segments were selected and delivered to Dr. Gere's students and discussed at length.

The large group to large group interaction was fairly dynamic as both groups could see and speak with each other.
other. This was problematic for the Southfield students however, because their monitor was significantly smaller than the large screen projection the University students were receiving and consequently they had a difficult time resolving who the individual speakers were at the University site. One attempt at solving this problem was the placement of a small monitor in the group circle at Birney. The University students were able to get a sense of the classroom dynamics, layout, and management issues but the graininess of the image was a disappointment to some.

Many of the sessions started off with individual to group interaction typified by the university students querying Ms. Schiller on various aspects of practice. We could say that this was our most successful connection as far as the audio and video quality were concerned.

This project is by no means completed, but we have already learned a great deal from it. In addition to what we know about how to work effectively with ISDN, we have also learned the importance of thinking of technology in broader terms rather than simply focusing on the two-way connection. We found, for example, that an occasional conversation via a speaker phone between the university methods class and Ms. Schiller enhanced the video experience. Similarly, video tapes were sometimes useful as the real time connection. After the initial semester of two-way connection, the project team initiated an analysis of the data collected, and that analysis is still in progress. What we can report at this time is that the technology of two-way video has real promise for enhancing the discussions of praxis among pre-service teachers.

Acknowledgments

The members of the TATE project team would like to thank the University of Michigan School of Education in partnership with the Office of Instructional Technology for their financial support of our project.

BEGINNING RUSSIAN COURSE FOR DISTANCE LEARNING IN RURAL AREAS OF UTAH

Alla D. Paroiatnikova
Southern Utah University

This paper deals with the design, development, preparation, and delivery of Beginning Russian, a course taught via EdNet (Educational Network) simultaneously to a class of Southern Utah University students and a concurrent enrollment of high school students at five remote sites of Utah in the fall quarter of 1996. The EdNet and Telelearning Center located on the campus of Southern Utah University in Cedar City, through state appropriations, has been involved in distance education activities for more than 3 years now. It transmits classes to 10 sites in Utah, including both rural high schools and local colleges (Dixie College in St. George). Classes taught on EdNet, so far, include both General Education classes such as Intermediate Algebra, World Geography, and Business core curriculum classes such as Accounting or Marketing. Beginning Russian is the first attempt to teach a foreign language using this new and rapidly developing educational medium.

The reasons for choosing this particular non-traditional foreign language as the first one to experiment with are both objective and subjective. The first reason is that SUU is currently developing a brand new Russian minor program, and the University wanted to make it more visible for prospective students. The second reason is that the instructor of Russian is enthusiastic about new technologies and brave enough and willing to undertake the design and teaching of a telelearning course.

This paper deals with Stage I of the project which consisted of identifying the problems and finding appropriate solutions for effective instruction in the following areas:

- Organization
- Training
- Technology
- Methodology
- Psychology
- Teaching strategies
- Evaluation and assessment

Works by McKenzie and colleagues (McKenzie et al., 1996) and Beers (Beers & Orzech, 1996) provided valuable guidance and insight which helped us to avoid and minimize some pitfalls. However, other “gremlins” became evident even at the preliminary stage. The main reasons for this are as following:

1. This is a “mixed” course. There are on-campus students at SUU and high school students at five remote sites in different parts of Utah. This situation required adaptation of the regular course and integration of new learning designs and media into the course delivery in order to meet the needs of two student groups meeting in different learning environments.
2. Foreign language acquisition implies gaining both knowledge and skills a fact that makes distance learning more challenging than many other academic disciplines.
3. Russian has a different alphabet. This poses extra problems for computer communication, especially for the beginning class, which does not seem viable both logistically and methodologically.
4. This five-credit hour class is taught every day of the week — a situation that has its advantages and disadvantages.

Organization and Training

Southern Utah University is one of eight higher education “hubs” that connects high schools to universities in the state. SUU allows high school students in the rural areas of Utah to enroll in courses that allows them to earn high school and college credits simultaneously.

The organizational strategy developed and implemented by the SUU Telelearning staff included marketing of the class, selection of the most convenient time slot, and organizing training for all the participants. In addition, the staff worked with the university bookstore to provide textbooks, workbooks, tapes, and extended syllabi for the class.

Marketing was conducted in the spring of 1996, along with other telelearning classes. The result was that students
in five rural schools of Utah expressed their intention to participate in the Russian language class with a total of about 25 students planning to enroll. The high number of schools was unexpected since it was not a traditional course taken by high school students. We faced a difficult dilemma, should we limit the class to two distant sites and the on-campus students as was originally planned? Or, should we go ahead and accommodate all the interested students for the sake of promoting the program and try our best to organize a quality instruction comparable to a traditional language class? We decided in favor of the latter alternative, keeping in mind that the class size would decrease during the first two weeks of instruction.

The next step was scheduling. The time slot for the class had to be negotiated so that it would fit into the schedule of the telelearning center, the instructor’s schedule, and the five participating high schools. It seemed like an insurmountable difficulty, but thanks to the excellent working relationships between the Telelearning Center and the principles of the high schools, it was resolved.

During the mandatory training conducted by the Telelearning Center, both the site facilitators and the university distance education instructor received all the necessary information (there is a special package developed for this purpose) and had hands-on experience with the support of the Center’s technical staff. The instructors had a choice of controlling all the technology in the telelearning class themselves or having a technician (usually a part-time student) do it for them. The Russian language instructor, for several reasons, decided to have a technician working for her — this proved to be very wise. She had her hands free to deal with more demanding problems during the class delivery. Out of five sites, just one (at Beaver) did not have a specially appointed facilitator. However, one of the students successfully performed this function.

The University bookstore ordered all the teaching materials for both on-campus students and distant education students and sent them over to the respective sites in time for classes. The bookstore also provided all the enrolled students with the extended syllabus which will be discussed later on.

Technology

The course was delivered on EDNET, a live interactive closed-circuit television system which connects all the public higher education institutions in the state to over 90 sites in Utah. The class was transmitted to all the participating sites from the specially equipped telelearning classes on the SUU campus. For this particular class we had to increase the number of microphones (one for two students) which was required by the specifics of the foreign language instruction. The facilitators at the sites were asked to pay particular attention to the quality of audio equipment and its proper adjustment to the needs of the class. The telelearning classroom is equipped with a computer, VCR, CD-player, cassette player, and ELMO, which certainly enhanced the presentation of material for on-campus students as compared to a regular class in an ordinary university auditorium. The room also had a telephone and a fax machine which facilitated the communication, especially during tests.

Methodology

Methods and techniques to be used in this course were determined by two major factors: goals and objectives, and the specific needs of the student body involved in the knowledge acquisition. Beginning Russian is defined in the extended syllabus as a “communicative introductory Russian language course that emphasizes language proficiency in all four skills of speaking, reading, listening, and writing.” The focus on communication as a goal posed incredible difficulties for the instructor as well as the students at distant sites in view of apparent additional barriers for authentic communication inherent in this mode of instruction. However, the temptation to substitute it with a more easily achievable goal of teaching just reading and translation was rejected as doing a disservice to the students, lowering the plank of instruction, and limiting further progress of students’ foreign language studies, since it is the initial stage of language acquisition that determines to a great extent the student’s attitude towards it.

This goal determined the construction of learning environment as interactive, interpersonal, and communicative-centered. The cognitive, constructivist learning theories of language acquisition, as well as the theory of Stage-by-Stage Development of Mental Actions (Galperin & Talyzin, 1976) proved to be very effective for this technologically enhanced medium of instruction just as they are for a more traditional one. It should be noted that it has been very successfully applied to Computer Based Instruction (CBI) and in mathematics as well (Bouinaev, 1996).

Another goal of Beginning Russian is stated as “Introduction to Russian Life and Culture, from history and traditions to geography, facts, and famous people.” This goal is actually much more easily achieved in the well-equipped telelearning class where we can view videos, listen to the tapes and CD’s, bring pictures from WWW, take a close look at maps and pictures than in a regular university auditorium. In this case, on-campus students can benefit from taking a class in a technologically enhanced learning environment. The goals of the course determined the method and type of instruction as traditional delivery of content with the instructor being not only an information provider but a facilitator of communications and interactions between students both on campus and at distant sites.
The mixed type of student body consisting of both “live” university and high school students, some of whom were more than 200 miles away, required development of methods that would make it into one big learning team where everybody is involved in the ongoing activities. The key methodological elements were teamwork, involvement, cooperation, and interaction in real-time with all students participating as members of one class.

Psychological Aspects

Psychological aspects of this telelearning class were considered of primary importance for its success. It is a highly challenging class for both the instructor and the students considering that communication is the goal of instruction and interaction is the mode of language acquisition. Two major psychological issues had to be addressed in designing and delivering this class: (1) developing camaraderie with and between students and minimizing the feeling of isolation at remote sites and (2) finding effective ways to deal with debilitating levels of anxiety which is particularly difficult to cope with in the situation of increased interpersonal distance and exposure to several different audiences.

The emphasis on cooperative learning and communication focus required that special attention be paid to coping with debilitating anxiety which motivates the learner to flee the new learning task thus stimulating avoidance behavior (Scovel, 1978, p. 139).

Camaraderie is an important factor in learning a foreign language since “familiarity, trust, and comfort with others act to boost students’ certainty that their actions will be well received and their attempts at communication will be welcomed, or at least not ridiculed or scorned” (Pellegrino, 1996, p. 7). Several important elements helped to create this atmosphere of comfort:

- Every student in the class had to choose a Russian name for himself or herself, thus “hiding” their own personalities. This turned the class into a play, a stage, a different reality. It was interesting to observe that after some time the students started calling each other their Russian names even out of class.
- Before the beginning of each class, students from different sites could ask each other questions, find out some personal information such as likes and dislikes, sports, and hobbies, which also helped to create camaraderie.
- At each site students were encouraged to work as a team or in several groups and respond to instructor’s questions together rather than individually. The initial stage helped timid and shy students to become involved in the active process of language acquisition in a “cushioned” environment.

- The class atmosphere was relaxed and humor played an important role in setting the mood of the class in order to establish a more personal relationship with students which made it seem less like “virtual” reality.
- The instructor took trips to visit the three largest groups of students in Escalante, Orderville, and Bicknell. Meeting these students in isolated villages of Utah was one of the most gratifying experiences in the teaching career of the instructor and helped to establish a live bond with the students.

The developed psychological strategies included all the above mentioned elements of creating psychologically comfortable learning environment with the special emphasis on correction techniques. As Pellegrino states: “Aggressive correction, mocking, quick or elevated speech, and condescension are frequently cited examples of others’ behavior that can cause students to feel more certain of negative results” (Pellegrino, 1966, p. 7). The students’ corrections were in the form of either explanation of a particular grammar rule and then all the students were asked to repeat the correct version in chorus or just the latter. Therefore, correction of mistakes was a shared learning process. It was also a cognitive learning process since the student had a very clear idea of what mistakes were made and the correct way to do it.

It should be noted that all students were supposed to participate in this work, not only on-campus students or students at some particular site. Unfortunately, it did not work this way all the time because students got distracted. However, the instructor consistently tried to implement this strategy.

Another important component of the efforts to minimize the anxiety was the testing technique. Since it is the final result or outcome that is important in any foreign language acquisition, intermediate tests (five during the ten-week quarter) were not graded and students did not gain or lose any points for their final grade in these tests. The test was called “control work” which was undertaken to check their language progress and indicate both to them and the instructor what things should be reviewed again (memorized, practiced, etc.). The tests were thoroughly analyzed in class and distance students then mailed them to the instructor for the second review. This effort definitely helped to decrease anxiety and fear of failure, and helped to establish a healthy attitude to tests, correction of mistakes and learning progress in language studies. The students actually knew how they were doing but they did not get discouraged (which is a very common thing in foreign language studies) or felt that they had decreased or even ruined their chance for a good grade at the final exam.

This strategy was especially important for on-site students since they feel much more intimidated by tests than on-campus students due to the physical absence of the...
teacher. They could not ask her any questions without the whole class knowing about it, they could not get an encouraging smile or whisper like “you’re doing great”, etc. which provides psychological support in a stressful test situation.

Another way of dealing with debilitating anxiety, especially at the beginning level of language acquisition, is dispelling students’ misconceptions about the Russian language. Students in the rural part of Utah, like many other Americans, possess a myriad of myths about the difficulty of Russian — especially its non-Latin alphabet, grammar, and vocabulary. One of the first things to do in the beginning Russian class is to dispel these misconceptions so that meaningful learning can begin. During the very first class students found out that they already knew about 120 Russian words -- “international” words like bank, telephone, business, doctor, actress.

In the second class, students learned half of the Russian alphabet (letters that are the same as in the English alphabet). Consequently, they learned the alphabet in less than a week and started to read after the third class. This helped to lower the level of anxiety and to implement a correct understanding instead of misconceptions. Dispelling the socio-linguistic and cultural misconceptions of language learning in the process of class instruction is especially important for distance education students. Very often it is their only accessible source of information. On-campus students can come to the instructor’s office, ask numerous questions and get support, they also can interact (and they do) with Russian exchange students, none of which is available for students in far away rural areas of Utah.

Teaching Strategies

Enhanced multiple teaching strategies were designed from the psychological theories that would facilitate teaching both “live” students at SUU and distant learners. Some of them were already described in methodology and psychology parts of this paper. The basic concept is multifaceted interaction, group work, cooperative learning (different levels of cooperation) and active participation and communication of the whole class (both “live” and distant students). Feedback strategies were particularly important for this mode of instruction and were given special emphasis. These included encouragement, validation, assessment of students results, and active intervention to provide suggestions, comments, and clarifications. Back-up support included video-taped classes, audio tapes, and one hour a day “hotline” (dial up) for students’ questions. Extended curriculum was prepared to serve as a guide for better organized learning. Teaching materials, which included a textbook, a workbook, recorded audio tapes, videotapes, and hand-outs, were carefully selected with the view of their appropriateness for both traditional and distance learners.

After two weeks of instruction it was clear that on-site students needed some extra time to ask their questions and to get some more practice on a one-on-one basis with the teacher. The unusually large size of the class (52 students) made it necessary to have at least one extra tutorial class for distance education students. These students, unlike on-campus students, did not have access to a Russian tutor four times a week and the instructor’s help during office hours. Every Tuesday for the next eight weeks, on-site students could talk to the instructor and get the necessary help. The high school students seemed to enjoy and appreciate this tutorial class that was held just for them.

Assessment and Evaluation

Special questionnaires were developed to assess and evaluate the course. They were distributed among distant learners and on-campus students. Because the class is still in progress at this time, the results of this effort will be known later on in the year.

NEW FOUND RESOURCES IN DISTANCE EDUCATION: MUSEUMS CREATE RICH ENVIRONMENTS

Michael Speziale
College Misericordia

The Pennsylvania State Museum has been conducting educational workshops and seminars for K-12 schools for years. To access these programs however, teachers have had to physically take their classes to the museum in Harrisburg, Pennsylvania. The limitation of distance has significantly decreased the number of schools that have been able to take advantage of the resources available at the State Museum. The Northern Tier Rural Distance Learning Consortium, initially composed of six rural school districts and three colleges from rural northeastern Pennsylvania, is predicated on sharing educational resources over vast distances. The combination of distance education technology and the resources of the State Museum has made the collection at the museum available to a much larger audience. This paper outlines the background of the Northern Tier and the subsequent inclusion of the State Museum as a partner. It also addresses some of the logistical problems faced by museum staff in preparing for presentations.

Background
In 1994 the Northern Tier Rural Distance Learning Consortium began a seamless exchange of resources using video-conferencing (Freeman, 1996). The original consortium was composed of six rural school districts and three colleges located in northeastern Pennsylvania. Lackawanna Junior College, Scranton, PA serviced the consortium as the original two-year higher education institution. College Misericordia, Dallas, PA and Penn State Wilkes-Barre, PA campus were the original four-year higher education partners. Both Misericordia and Penn State have offered undergraduate courses to advanced placement students in participating districts. In addition, the school districts in the consortium have utilized their distance education equipment to share unique and typically underpopulated high school classes such as Japanese and Aviation.

The consortium uses a compressed-video infrastructure to conduct interactive video-conferencing. All participating institutions have installed a Picture*Tel video-conferencing classroom system which is the focal point for transmission and reception of information. A typical system includes several devices for transmitting educational information such as a document camera which can be used to view overheads or three dimensional objects; a computer which can be used to project anything that appears on the computer screen; VCRs for broadcast of videotape; and two cameras which are used for face-to-face contact. These devices have forced distance educators to format their classes for presentation using the technology. Although this may seem to be a barrier, teachers have embraced the opportunity to enliven their presentations utilizing the new technology. The success of the distance education consortium has provided a foundation for additional funding received through a federal challenge grant. As a result, “the consortium will establish links with 60 video-conferencing sites in New Jersey, New York and other parts of Pennsylvania, greatly broadening its potential” (Freeman, 1996, p. 30).

The State Museum as an Outside Resource
Although the primary goal of the consortium is the exchange of classes to strengthen the curriculum, participants have continuously sought alternative uses for the technology. One such alternative has been to access the educational programs provided by the Pennsylvania State Museum. Although the museum’s educational programs have serviced many schools over the years, teachers and students have typically had to rely on field trips to access the programs. Distance education technology has the potential to remove these barriers.

Through funding provided by the Northern Tier and a grant from Bell Atlantic, a system was placed at the State Museum. Grant funding provided initial training for museum staff, follow-up support from College Misericordia personnel, and a salary for an on-site technical support staff person who is responsible for the museum’s Picture*Tel system.

The planning committee for the museum project decided that the first offering by the museum would be a
workshop on archeology. Since the system that is located at the museum is a classroom system which limits its portability, the museum’s staff was faced with the daunting task of converting their teaching materials to a format suitable for transmission via compressed video format.

College Misericordia personnel used a Sony Hi8 camera to record artifacts, dioramas, and displays, that are the focus of the archeology workshop. The college staff then used a Targa 2000 video capture board to digitize the video tape. Frames of the video were exported as graphic files for use in Power Point. In addition to presentation graphics, the museum staff uses hands-on kits containing simulated artifacts which are mailed to the participating classroom prior to the presentation. During the presentation, museum staff use the document camera to show three-dimensional artifacts and computer graphics to show digitized images from the museum’s displays and dioramas. When the presenter makes a reference to a specific artifact, he/she asks the students to refer to their collection of simulated artifacts. This technique offers a hands-on approach even at a distance.

Summary

As a follow-up activity, College Misericordia’s Education Department will be sponsoring a collaborative project in the spring of 1997. Faculty members from the college will work with K-12 teachers and students to build upon the archeology workshops offered by the State Museum. Suggestions such as creating cross level teams who will work at actual archeological dig sites are currently being considered. The follow-up project will help pre-service teachers to identify ways to incorporate outside resources in their classrooms.

Teachers in the distance education consortium are eager to participate, and view the opportunity as a chance to enliven their curricula. The inclusion of outside resources, such as the State Museum’s collection provide ideal opportunities for creativity to soar and for students to experience a fascinating world of applied knowledge.

Michael Speziale
There is a lack of cultural appreciation and knowledge of diversity among faculty, students, community, and the service area of the State University of West Georgia (SUWG). In this immediate geographic area, migration has typically been outward. However, during the next 30 years, immigration from Latin America, Southeast Asia, Eastern Europe, and Africa into Georgia is expected to triple. Studies show that during 1993-1994, 7,520 foreign graduate students studied in Georgia. 1,466 jobs were created as a result of foreign students, and 28,105 language minority children were enrolled in Georgia public schools. Therefore, Georgia’s current and future educators need to have hands-on experience, skills, and tools to promote curriculum and learning environments in which awareness, legitimacy, and significance of diversity within cultures are celebrated. Changes and additions to the teacher preparation program, as well as preparation for successful communication in all areas that deal with human relations, will be a major focus of the future at SUWG.

In order to meet these needs, SUWG, with a service area of 44 counties and a student population of 9,000, has instituted a three-course ESOL (English to Speakers of Other Languages) sequence to assist those teachers directly involved with the education of language-minority children. These classes are transmitted via GSAMS (Georgia Statewide Academic and Medical System) to the various school districts. Teachers who typically do not enroll in the three-course ESOL endorsement sequence, require exposure to and information on the nature of culture/acculturation, language acquisition, and the methods appropriate for use in the classrooms.

Language programs typically impact only students attending school. However, they do not represent the actual number of families living in the area or the gaps in cultural differences felt in many communities — especially those communities where few families have the opportunity to visit other cultures. Although many travel videos and textbooks relate topography and some local traditions, they do not take the place of actual experiences. Furthermore, students and educators visiting foreign countries often have superficial experiences because they stay in hotel and visit sites from a tourist bus with barely enough time to explore the real setting.

**Technology and Teacher Education**

In order to bring about substantive change in communities, curriculum reform must involve changes in the teaching of cultural diversity. The anticipated project will send six university instructors from several departments within the university on a three week cross-cultural experience to towns and cities in Mexico. Mexico was chosen as the first country or residence because 61% of students in the university’s service area are Spanish speaking. The SUWG instructors will immerse themselves in the local culture by living with a Mexican family and becoming participant-observers in school and community activities. Before the field experience begins, a preparatory in-service session will focus on awareness, legitimacy and significance of different ethnic and cultural identities, as well as tools and skills for data collection.

In following years, the project will expand to include undergraduate and graduate students at SUWG who are or will be practicing teachers, counselors, and administrators. In order to give more depth to this project and to provide faculty and students with more knowledge of various cultures, other regions and countries within North America will be included. SUWG ranks 7th in the nation with the number of students completing undergraduate teacher preparation programs and 14th for graduate students. Therefore, this proposed reform has the potential to become far-reaching, and it is possible that other institutions will replicate the program.

This program takes a quantum leap from existing programs and impacts the whole service area of the university. It gives the participants action-oriented hands-on experiences to deal with and understand the diversities within cultures. The learners will share their first-hand experiences through several modes. For example, a professor can be linked with the university closest to their location and can conduct classes using a software program such as CUSeeMe, or satellite transmission, or e-mail. Students and community members can ask questions and discuss concerns, myths, and stereotypes with the professor.
Immediate feedback to such questions could provide a real break from preconceived ideas, and students in teacher preparation programs and graduate programs could gain a more realistic picture of other cultures. School children, relating to their peers and parents what they have learned in school about diversities in cultures, can assist in ending prejudices and/or allow for a better understanding of differences. An enhanced curriculum can provide a means of drawing people together into a more humanistic and caring environment, responsive to the diversity within a community.

Other universities could easily replicate this program. Furthermore, other colleges within a university or departments within a college could also have a stake in the program. The benefits of this program are more far-reaching than just universities, because present educators, future educators, and communities would benefit; affecting, in the long term, thousands of individuals.

**Improvement Through Technology and Travel**

In the past, pre-service and in-service educators have had limited multi-cultural education courses. With an increasing need to infuse multi-culturalism into the curriculum, instructors in all areas of education need knowledge of language and culture to incorporate into content specific courses. The willingness of teachers to change their teaching and to incorporate diversity into their lessons is a stepping stone to success. In the first year of the project, those university instructors who took part in the three-week cross-cultural residency would upon returning, revise existing course curriculum and incorporate this information into their courses. The faculty, would then become a model for curricular change. This first year would produce major reforms in curriculum and pedagogy. In the second year of the program, selected in-service teachers would revise and improve the existing curriculum with their experiences. An introduction to diversity may be more important for those children who live in predominantly mono-cultural settings because these children will be ill-prepared to function in a society that is becoming increasingly culturally diverse.

The SUWG is committed to its revised university mission statement of September, 1996 — “affirmation of the equal dignity of each person by valuing cultural, ethnic, racial, and gender diversity…” and endeavors to “provide significant opportunities for student involvement and field-based experiences.” The primary objective of this project, which is to produce curriculum reform in the area of cultural relevance, reflects the focus and mission of our university. Through the evaluation process below, we will validate the effectiveness of the project.

**Evaluation**

The researchers are examining diversity within cultures and participants response to the diversity. Qualitative techniques are useful for capturing the richness of experience and are highly appropriate to this study, and since experiences will differ from individual to individual, evaluation will require detailed descriptions. Assessment the first year will be a goal-free, process evaluation using qualitative techniques of inquiry (Patton, 1990). Goal-free evaluation allows researchers to gather data on a broad array of actual experiences without narrowing the study to preconceived outcomes. Outcomes will naturally emerge and will eliminate the possibility of missing important unanticipated events. Goal-free evaluation relies heavily on description and direct experience with the program, and most critically, on suspension of judgment about the program. It concentrates on discovering what is actually happening in the field. Process evaluation is dynamic, emergent, and fluid and focuses on experience and feelings of the participants. Such evaluations are useful in programs in which dissemination and replication at other sites are desired. Second and third year evaluations will be formative and summative, respectively. The formative evaluation will focus on program improvement; summative evaluation will focus on program effectiveness.

Data will be collected on participants’ experiences and on their three week residency. Participant data will include (1) Pre/post trip feeling’s about diversity. The Expressive Autobiographic Interview (EAI) technique will be used to gather this data. The EAI technique permits the interview to selectively evoke feelings with a flexible and chronological self-centered framework. (2) A reflexive journal kept by each participant. (3) Observations of participant classrooms to evaluate the impact of cross-cultural experiences. Cultural data will include participant field notes, a video, or videos, of community and school activities recorded by participants, and nominal group session of students at the SUWG who view the films of the field experiences.

DIGITIZED MULTIMEDIA AND DISTANCE LEARNING: DO THEY MIX?

Drew Tiene
Kent State University

As a state university with a mandate to provide opportunities in higher education throughout the northeast corner of Ohio, the Kent State University system includes seven campuses. Some of the six branch campuses are well over an hour's drive from the main campus, and a few are almost two hours away. This part of the country also experiences severe winter weather for several months, making driving conditions rather hazardous at times. Travel between the regional campuses and the main campus, where most of the coursework is offered, can be inconvenient and time-consuming. Providing more coursework at regional campuses via a distance education system makes a great deal of sense.

The "LearnLink" Project

Two years ago, the university established a distance education project to connect all seven of its campuses. After considering the use of full screen two-way television, it was decided instead that the system would be computer-based, with a compressed video component. Partners in this project were IBM and a software company named ILink that had developed computer software for transmitting data across networks. Kent State became a beta test site for this "LearnLink" software, and several courses have been taught at multiple sites using this approach. The term "Distributive Learning" distinguishes this computerized approach from television-based systems which are generally referred to as "Distance Learning."

Each campus will have its own Distributive Learning Classroom. This special classroom is essentially a networked computer laboratory with compressed video capability. Beside each computer is a small color camera with microphone. A part of the computer screen is used for low quality television transmission between participants. The instructor can control who appears onscreen in the video box and what computer screen will appear on all of the students' computers. Students can signal the instructor via the network that they would like "the floor," as it is termed, and they can appear in the video box on everyone's computer. In addition to communicating on Kent's own network, there is access to the World Wide Web through Netscape.

LearnLink supports the Toolbook authoring language, so lessons for this system need to be developed in advance, using Toolbook. The faculty who have offered to teach as part of the pilot phase of the project, including the presenter, have each been assigned a programmer to help them develop lessons. In this way, multimedia lessons have been developed to use for distance education, which include sound, still pictures, and video footage. Kent State's system can provide extremely dynamic forms of lively, interactive instruction that students at remote sites can use, at their own pace, each sitting at their own computer. This "Distributive Learning" system has tremendous instructional potential.

The Potential of "Distributive Learning"

What is the potential of such a system? First of all, the system is computer-based, so it can deliver instruction that takes advantage of the computer's considerable capabilities. One of these advantages is that instruction can be systematically planned in advance and developed carefully, following principles of good instructional design. The lessons, once developed, can be used repeatedly by students in subsequent classes. These lessons can be revised and improved, based upon instructor and student reactions to working with them. They can be made highly interactive. Students can answer questions and receive feedback regarding their responses. The computer can also encourage them, when they are doing well. When they are not, the computer can provide hints and remediation. It can also branch to other parts of the unit, if the material is either too difficult or too easy for the student. Students can move at their own pace through the unit. Instruction can, in this fashion, be highly individualized (Hanniffin & Peck, 1988).

Today's powerful computers have the ability to provide a wide variety of different types of materials. In addition to text, pictures, sounds, and video materials can be incorporated into the lessons. These digitized multimedia materials can enliven a lesson. The visual material can help clarify key points. Audio can also be very helpful, especially for topics like music and language instruction.
In addition to being able to present video segments, the LearnLink system provides a window on the computer screen where a compressed video signal is shown. This signal comes from a small camera, with a microphone, placed next to each computer. This way students can see and hear the instructor, or any student who takes control of the system. This feature allows for face-to-face interaction between participants. Discussions can be held, and participants can get to know one another. It can significantly enhance the social dimension of this type of class and provide a more personalized experience than some other forms of distance learning.

Delivering this instruction via telecommunications lines to students at remote sites has several potential advantages. For the students at remote sites, they need not travel long distances. Because it is more convenient, other students in these locations may decide to enroll. Students who otherwise might not consider pursuing studies at the college level might take advantage of these opportunities (Willis, 1993).

Hopefully, this experience will also benefit the instructor. If the equipment is user-friendly, the teaching experience could be similar to working in a self-contained classroom. Some might find it interesting to teach across multiple sites and meet the challenges associated with this experience.

Overall, the system has obvious potential benefits for students from the regional campus sites. It also may contribute to faculty development. The university itself might benefit considerably. Kent State may be able to augment its offerings at regional campuses and expand enrollment. Higher enrollment would increase income and would also help the institution fulfill its mission to bring higher education to the entire northeastern corner of the state. If LearnLink is ultimately used by other universities, Kent State might be able to market the courses it has developed for use on the system.

The Challenges Faced by "Distributive Learning"

The considerable potential of "Distributive Learning" is matched only by the magnitude of the challenges it faces. The more technically sophisticated a system is, the more prone to glitches it is. Providing computer-based instruction for entire college level courses is an ambitious venture to begin with, even without the additional challenge of trying to send it across telecommunications lines.

To begin with, the project is based upon the assumption that a significant percentage of the average college course should be delivered using computer-based instruction. Most university courses, based upon lecture or discussion, are essentially an exchange of ideas between participants. Whether this exchange can be replaced by computerized activities is debatable. Artificial intelligence is not developed to degree where a computer can effectively replace an instructor as discussion leader. Much of the material described in lectures could be provided as computer text, but reading lecture notes hardly seems like something worth the trouble it takes to create them.

Today's computers are capable of providing more than just text, however. The LearnLink project plans to develop exciting lessons that use the full capabilities of the computer. Instructors are being encouraged to digitize pictures, sounds, and video, as well as text. But multimedia lesson development demands creativity on the part of the instructor. Many college instructors are not used to using non-text materials in their classes and they may be unsure how to effectively do so. Furthermore, very few college instructors will have the computer programming (or "authoring") skills necessary to computerize their class materials. Programmers need to be employed for course development. The process is time-consuming. It can all get quite expensive.

Furthermore, to use commercially available materials, copyright permission must be obtained. This requires further time and effort. At Kent State, librarians are being asked to assist in this process. Publishers can be very concerned about the dissemination of their materials online. Apparently, some have claimed that even printed material in textbooks already purchased by students for the class is subject to copyright clearance.

Multimedia files also require considerable computer memory and processing power. Used to any great extent, they may tax the capabilities of the equipment in the laboratory. In demonstrations of the LearnLink system that have used extremely large video files, there have been problems with machines crashing.

Another problem associated with the amount of processing required by large lesson files is sending them across a network. A considerable degree of bandwidth is necessary. The Kent State system local area network has its limitations, in this regard, as do the T-1 telecommunications lines used to send signals between campuses.

Distance education poses its own set of challenges. Students at remote sites typically find it more difficult to pay attention, ask questions, contribute to discussions, get assistance, and get to know the teacher (Tiene, 1997). Working with students at remote sites is problematic in the Distributive Learning system, for several reasons. In attempting to overcome these disadvantages, a system should provide as realistic a set of signals as possible from the teacher's classroom. However, in the Distributive Learning system, the compressed video signal is jerky and lips do not synchronize with sound when people talk. The audio part of the video signal is also on a delay. Students must wear headsets to hear it clearly. (In the teacher's classroom this becomes somewhat distracting,
since the instructor's voice comes back in the headsets several seconds after the students actually hear it).

There is another problem associated with assisting students at remote sites linked to Kent's Distributed Learning system. The LearnLink software does not yet enable the instructor to see student computer screens, except in “snapshot” still-frame form. This still frame can only be initiated by the student, using a different piece of software expressly for this purpose. In addition, the instructor cannot demonstrate educational software on the system, other than Toolbook files, since it cannot be processed by the LearnLink software that transmits data throughout the system. These capabilities are promised by ILink software developers in the near future. But, for now, these limitations have affected the way in which instruction can be delivered.

It is hoped that many faculty members will enthusiastically participate in the Distributed Learning project at Kent State University. So far, participants in the Pilot Project have been selected from applicants who are given a stipend to cover the extra preparatory time and effort associated with preparing course materials for the system. Whether future faculty will volunteer and whether monetary incentives will be necessary, remains to be seen.

It will be interesting to see if this project allows the university to expand its course offerings and increase enrollment. The cost-effectiveness of the project will depend largely on its doing so. If the LearnLink-based system for Distributed Learning is successful and is adopted by other universities, Kent may eventually be able to sell some of the courseware it has developed, as a pilot test site for the system. Hopefully, the system will live up to its potential and can provide a highly dynamic form of college level instruction across an entire section of the state of Ohio.

The LIVE (Learning In Virtual school Environment project) means research and development of pedagogical models for distance teaching practice in school classrooms. These models help a learner improve information processing and cooperative learning in an open, virtual school-like learning environment. The LIVE project expands a multiple media learning environment and makes it possible for learners to document events and processes outside school. The equipment used enables the flexible, mobile use of audio conferencing, fax, and Internet services. As a result, the distance education network becomes an open virtual-learning environment — independent of time and space.

This article describes a research and development project carried out in a distance education classroom at the Media Education Centre of the Department of Teacher Education, University of Helsinki. The pedagogical decisions are based on the constructivist learning concept in an open and flexible learning environment. Special attention has been paid to the possibilities of using interactive telecommunications in learning situations, especially in videoconferencing. In teacher training, student teachers can include distance teaching practice in their studies which acquaints them with pedagogical decisions regarding distance teaching.

As the result of distance education development at the University of Helsinki, there is an ISDN-based school network consisting of the University, teacher training schools, and small rural schools. The schools in the networks are connected by three ISDN lines which enable the participants to communicate by video conferencing and/or audiographics. Instruction is further supported by telefax and electronic mail.

Theoretical Framework

The theoretical framework of the LIVE project consists of three concepts: (1) virtual school, (2) constructivism, and (3) cooperative learning. A virtual school can be seen as: an information system based on new information and communication technologies, which is able to deal with all the tasks of school without the need for a physical school building. Ordinary physical school and virtual school may also complement each other, i.e. exist in a symbiosis... part of the activities of physical school may be moved to virtual school and carried out there with the aid of information and communication technologies. (Tella, 1995, pp. 14-15)

The concept of virtual school can be linked with the idea of a flexible and open learning environment. Flexibility means independence of time and space, while openness can be seen as the learner's ability to make decisions in a learning situation. A learner can choose the learning materials, the topic, the learning group, or set his/her own learning goals. Such a learner-centered model is based on the constructivist learning concept, which stresses the learner's responsibility and activity in the construction of his/her own knowledge.

Keegan (1996) and Tiffin & Rajasingham (1995) point out that in virtual classrooms, face-to-face interaction at a distance is electronically re-created. Therefore, a learner must reflect on his/her actions with regard to the surrounding electronic reality and especially to the group he/she belongs to. Through reflection which takes place in social interaction, a learner can expand his/her knowledge about the foundations of his/her own actions. In telematic networking this can mean common problem solving in a computer conference or interactive video conferencing between two groups of learners.

While it emphasizes the role of the learner, the constructivist learning concept also changes the pedagogical decisions of the teacher. According to Rauste-von Wright (1995, p. 121) the constructivist learning concept inevitably leads to the emphasis of flexible teaching which pays attention to learners' skills and abilities. From the teacher's point of view, this means a new kind of media planning, where situation-based interaction and flexibility in terms of time and space are central factors in pedagogical decisions. In the LIVE project, the students and the teacher together plan a learning unit, where common and individual learning goals and contents are defined. Special focus is directed toward student interaction and how it can be improved by portable telecommunications.
Modern information and communication technologies (MICT) make it possible to interact in an open and flexible learning network. In turn, this helps students grow into independent learners, because they take responsibility for their own choices and decisions in a cooperative learning environment (Sariola, 1995). Cooperative learning differs from the conventional pedagogical approach which stresses cognitive goals and the role of the teacher and puts a strong emphasis on social aspects and common goals in learning. In cooperative working, interaction takes place mainly between learners and depends on the nature of the task.

Some cooperative learning methods call for more teacher direction than others, but all of them enable students to interact in varying degrees and talk about what they think, know, and feel about what they are learning. In addition, when students study together in small groups, they help each other and, at the same time, develop self-direction and responsibility for their learning. (Sharan & Sharan, 1994, p. 97)

The use of new technologies increases the learner's ability to move about in real life situations without losing the connection to his/her cooperative group. When it comes to the whole school, it would be more meaningful if the working models of teachers and the whole organization were cooperatively-oriented. Such an organization could be called a cooperative school (Johnson & Johnson 1994, pp. 59-62). When this model is combined with MICT, it is possible to talk about a cooperative virtual school.

**What is LIVE?**

LIVE is a three-year action research and development project. The aims of the project are to research and develop: (1) pedagogical networking models in virtual school environment for teacher education and, (2) working methods and practices for cooperative learning in an open learning environment supported by modern information and communication technologies.

Research data will be obtained by participatory and other observation methods, by video recording learning situations, and by analyzing the contents of audio conferences and e-mail communication between learners.

The developmental perspective comes from the fact that the school has been criticized for its slow adjustment to the changing needs of society. On the other hand, Finland has introduced a plan entitled “Education, Training and Research in the Information Society: A National Strategy.” One of the main objectives of the strategy is that “The whole education system will be brought within the reach of information network services, ensuring that educational establishments can use these services. Open and distance learning will be promoted at all levels of education and training” (The Finnish Ministry of Education, 1995). Similar reports have been published in other European countries and in the United States.

The LIVE project expands the MICT-based learning environment and makes it possible for learners to document events and processes outside school with portable communications equipment. This equipment enables the flexible, mobile use of audio conferencing, fax, and Internet services. The use of MICT can support and link several groups of learners together in a synchronous telecommunications network. As a result, the distance education network becomes an open virtual learning environment, independent of time and space.

With the development of MICT, it is possible to create so called LIVE groups. These groups, equipped with integrated mobile communications equipment, can move around in real-world surroundings and transmit real-time two-way messages. A similar idea, studying real-life situations and problems in distance learning, is taken by the Impact North Carolina Project at the Appalachian State University where “Students learn to plan, cooperate, present and deal with real-world processes, and problems that are models of the kind they'll find outside the classroom” (Strom, 1994, p. 13).

This expansion of the virtual learning environment enables fast synchronous interaction between school and surrounding reality. In the development of a virtual school, this means an improvement for the learners. They can follow changing processes in the world on location, transmit information quickly from place to place, process the information in real-time communication, and store the data for later investigation. All of this can lead to better understanding of the course content, which in this case, comes from the world outside school. Through cooperative working, an individual learner can create his/her own learning space for developing his/her information processing skills, problem solving, and understanding. Cooperative virtual school expands classroom-focused videoconference lessons and creates a more flexible learning environment (Husu, 1994; Meisalo, 1996).

**Technological Environment**

The use of the latest telecommunications equipment in the LIVE project means that learners should have the basic skills in MICT. Mastering different levels of usage in computer-mediated communication and telematics management can be described in Figure 1.

In the LIVE project, the technological environment is built on the use of several simultaneous telecommunications systems. The schools in the distance teaching network have been connected to each other by three ISDN lines which enable the participants to communicate by video conferencing or/and audiographics. For sending material, the instruction is supported by telefax and electronic mail. Learners are connected to each other in real-time interaction by mobile phones and lap-top computers or by integrated mobile communicators (Nokia Communicator 9000). Learning resources are supported by WWW tools available in the same virtual network.
The Nokia 9000 Communicator combines digital voice and data services and personal organizer functions into a single, small-sized and unit. In addition to voice calls, the Nokia 9000 Communicator enables users to send and receive faxes, e-mail and short messages as well as access Internet services and corporate and public databases. It also provides users with organizational functions such as an electronic calendar, address book, notepad, and calculator.

All the applications in the Nokia 9000 Communicator - phone, fax, address book, e-mail, Internet - have the same user interface. For example, to send a fax, the user presses the fax application button, writes a note and selects a recipient from the address book. The user can readily confirm a phone call by fax or a follow up a fax by phone call. When the keyboard is closed, the communicator can be used as a GSM phone. When the device is opened for using the keyboard, the speakerphone is activated, allowing the user to view documents from the LCD screen while speaking (Nokia Cullular Data Customer Support).

At the moment, the development of MICT is directed towards advances in mobile communication technologies. In the near future, this development will lead to a situation where communicators can be connected to each other from and to anywhere. Telephone and computer will integrate into one MICT tool. Businesses, homes, and schools can use cordless local area networks called DECT (Digital Enhanced Cordless Telecommunications). The DCS 1800 phone (Digital Cellular System for 1800 MHz), with multiple data transfer capacity (even 100 Kb/s), will be on the market in European cities in 1997. This makes it possible to transfer full-motion video to mobile phones.

As GSM phones have had audibility problems outside cities, satellite GSM phones will be tested in the next few years. The new telecommunications system will use so called dual-mode telephones, which can connect to twisted-pair telephone networks or satellite links (Yrityspuhelin, 1996, pp. 28-30).

Pedagogical Applications of the LIVE Project

The development of pedagogical applications in the LIVE project is part of distance teaching practice at the University of Helsinki. Students in both class teacher and subject teacher education become familiar with pedagogical media planning and cooperative learning methods during the teacher training period. At the beginning of each training period, students are divided into working pairs who then create their own telecommunications networks called teleteams. The members of a teleteam plan a teaching unit and evaluate their own work with help of e-mail and other telecommunications tools and at the end of the course, collect a team portfolio. As a result, teacher training takes place partly in a telecommunications network formed by the students and the teacher trainer.

The working methods and practices during the project are called LIVE working. Working consists of three levels:
**LIVE Level I**

At the beginning of work, learners plan together the contents and goals on the basis of the chosen topic. Next, they form cooperative groups with tasks focused on the same goal. Learners are divided into a local group at school and into a LIVE group. The local group searches for background information from the Internet and other sources while the LIVE group collects real-time information outside school. The first level work can, for example, deal with news. The groups communicate via audioconferencing or e-mail. Finally, the groups evaluate the learning process together. Learning experiences are written down in learner portfolios.

**LIVE Level II**

A distance learning situation is built between two schools and the LIVE groups at LIVE Level II. Work starts with joint planning during a videoconference. The learners in each school are divided into the groups, like Level I, and start to collect and process information.

Both LIVE groups communicate via audioconferencing, collect the information into e-mail messages to all the members of the network, and give audio information to both schools. The role of the LIVE groups is to act as telematic expert groups in their own learner networks. The role of the local groups is to collect further information about the topic from sources at school or from the Internet and ask the LIVE groups for reality-based corrections and explanations about the topic. Level II work could deal with regional geography, for example, and the final product could be a joint report on the topic. Figure 2 shows activities in LIVE Level II.

**LIVE Level III**

At Level III, the nature of telecommunications changes into interactive multimedia. With integrated communications equipment, it is possible to transfer text, pictures, sound and full-motion video effectively. With LIVE working, this means getting real-world situation on video and transmission directly to other learner groups.

A learner can combine audio or video conferencing and audiovisual materials from the information network. The possibility of visualization is a major advantages of videoconferencing. Using a camera, both written and living learning materials as well as techniques in arts and crafts can be transmitted effectively. Compared with audiographics, videoconference gives both the teacher and the learner a better chance to follow events dealing with organizing learning situations. However, with regard to the quality of teaching, the way how the teacher and the learners construct knowledge in the learning situation is even more important (Sariola 1995, p. 12).

**Learning in Virtual School Environment**

As described above, student teachers work in cooperative projects with learners in LIVE projects. LIVE working can change the teacher’s way to work, especially in planning. “In a telematic learning environment the teacher has to consider more carefully than before what kind of communication serves the teaching-learning process best both from his own and the student’s or a student group’s standpoint” (Tella, 1995, pp. 31-32).

In LIVE working, learning goals are based on the learner’s knowledge. The teacher’s role is to show different kinds of models and how goals are set and evaluated. In this situation, the learner’s role is active information searching and responsible working towards his/her own goals and those of the cooperative group.

Since learning in cooperative LIVE working is regarded as a process, the activity during the whole process should be evaluated by both the individual learner (self-evaluation) and the whole group. Through different opinions from the group, a learner can expand his/her own knowledge about learning.

Learning in virtual school environment gives a learner a chance to work on many different levels of telecommunications. The advances of MICT make it possible for school to change into a flexible virtual learning environment and for the learner to build his/her own learning space. Live working expands the activities of learning networks into closer interaction with reality, which leads to a better understanding of the processes of life.

DISTANCE LEARNING IN MULTIMEDIA-NETWORKS: A FINNISH NATIONAL MULTIMEDIA PROJECT

Seppo Pohjolainen
Tampere University of Technology

Heli Ruokamo-Saari
Tampere University of Technology

The Finnish National Multimedia Programme (FNMP) supports the Finnish communication, media and telecommunication industry and improves that field's international competitiveness. The Distance Learning in Multimedia-Networks project is part of the Finnish Multimedia Programme and partners with technical and pedagogical research centres, institutions, and enterprises in a major joint project. The aim of the project is to develop technically and pedagogically useful methods for distance learning through the modern use of telecommunications (hardware) and multimedia (courseware). For example, development of broadband networks (e.g. ATM) makes it possible to carry out real-time and interactive distance learning. Tele-teaching can involve teachers and students using personal computers or workstations to communicate across networks.

Research Partners and their Roles

The Distance Learning in Multimedia-Networks project is formed with both research and enterprise partners. Universities form the project's research units. The Digital Media Institute (DMI) of Tampere University of Technology (TUT) functions as the project's coordinator and other units are its subcontractors. DMI has put much effort to developing broadband ATM-based networks. A media server that is suitable for distance learning will be used to provide video-on-demand-software via the network. A Hypermedia laboratory functioning as a part of the DMI of TUT has produced a hypermedia learning environment for the mathematical sciences (Pohjolainen, Multisilta, & Antchev, 1996). During 1996, TUT and DMI produced WWW courseware for mathematics, telecommunications, and computer science. The participants of these courses are university students of the open university, employees of enterprises, and senior high school students.

The Institute for Extension Studies and the Hypermedia Laboratory of the University of Tampere are two project partners. The Institute for Extension Studies has developed and utilized modern methods of distance learning (TV, radio, audio and video, hypermedia, multimedia) in the fields of adult education, nursery, and municipal studies. The Institute for Extension Studies will produce contents for economics, administration, communication and learning. Participants are mainly adult students from the university, the open university, occupational extension studies and from other cooperation partners.

In the Hypermedia Laboratory of the University of Tampere, necessary tools are being prepared to produce hypermedia and to research modern learning environments. The purpose is to develop hypermedia for distance learning and private study material for professionals who are not educators.

The Information Technology Research Institute of the University of Jyväskylä coordinates the project's research in the city of Jyväskylä. The Department of Data Processing Sciences, University of Jyväskylä, has been directed towards developing interactive distance learning software with special emphasis on properties of group working, interface design and various forms of learning materials. The Department has interests in both producing learning material and developing tools for analyzing distance learning systems.

The University of Helsinki, Lahti Research and Training Centre, has notable experience in arranging distance learning and producing materials. They are testing group learning concepts in distance classes and integration of different media. They also have suitable material for distance learning in the areas of communication, Finnish art history, and environmental protection. The participants of the Research and Education Center of Lahti are adult learners, teachers, enterprise and academic job-seekers.

Enterprise Partners

The enterprise partners of the project are functioning in the fields of telecommunication, media production, hardware design for distance learning purposes, learning...
material publishing and application. The enterprise partners of the project are: Nokia Telecommunications (NTC), Finnet/TPO Ltd., Telecom Finland Ltd., Helsinki Media Company Ltd., Fujitsu ICL Computers Ltd., Yle (Finnish Broadcasting Company), Xenex Ltd., Otava Ltd., KTO (Union of High Folk Schools), KVS-institute, Jarmo Siivari Ltd., JK-O-Action Ltd., Teleste Educational Ltd., STAKES (National Research and Development Centre for Welfare and Health) and the subregion of South-East-Central Finland (the municipalities of Hankasalmi, Toivakka, Joutsa, Leivonmäki and Luhanka).

Project’s Development and Research Work

The Distance Learning in Multimedia-Networks project will research and develop modern learning environments from telecommunications (hardware), hypermedia (courseware) and pedagogical point of view. Distance learning via multimedia-networks will be tested through pilots, and the feedback received from both technical and pedagogical solutions will be used by the research groups to improve the existing solutions.

The functioning of the project is divided into two parts: (1) research work of the joint research teams and (2) research work on the pilots. The three research groups will focus on telecommunications, hypermedia, and methods of distance learning. The aim of the research is to:

- produce information for the project’s functioning
- support pilots
- arrange necessary training
- analyze experiences received from pilots

Telecommunications

When designing a learning environment, different kinds of learning materials, media, and technological solutions must be taken into account. The quality of video and audio and the use of multiple channels are important factors. When using available network connections and real-time video links (Internet, ISDN, Ethernet, ATM), transmission is considered from various spaces, such as teacher’s workstation, traditional seminar rooms, distance learning studios, and other various reception spaces.

The aim of the project’s telecommunication research group is to produce information that is needed in the areas of network, hardware and software, video conferencing and multipoint connections, distance learning equipment, and the increased use of fast networks and video servers. Tentatively they will also assess the possibilities of digital TV/radio, media server, and cable network in distance learning. The research group is also mapping fiber connections, cable connections of homes, and possibly the use of cable modems. Different kinds of accounting arrangements and protection of copyrights in networks must also be considered.

Hypermedia-based Learning Material

Computers can be used in many ways to support learning in multimedia-based learning environments. An interactive environment, which contains the material to be studied and is able to immediately assess the user’s actions and give him/her feedback, can be constructed on a computer.

The project’s hypermedia team supports the pilots by clarifying, testing, and developing tools for producing hypermedia-based learning materials. There are several programs available to convert word processing, mathematical and office software documents to a WWW-format. In the future, conversion programs will integrate tools which can be used produce other learning materials for the network. The team also examines the conversion of sound, picture, video and animation to WWW and accessing learning documents in a technologically easy and pedagogically appropriate way.

Parts of hypertext are created with hypertext links. The amount of links in a normal courseware material can become so large that manual linking is no longer reasonable. A task of the team for hypermedia material is to develop automatic link tools to support the work of learning material producers. A link tool should be able to create so called “context-sensitive” links e.g. analyzing in addition to one word/phrase whole sentences and paragraphs to improve the quality of automatic linking.

The users’ knowledge level should be considered when creating learning environments. Different kinds of navigation should be created for different levels of users. In traditional WWW-environments this is not directly possible. WWW learning environments can be developed by maintaining the knowledge base of a user and on the basis of documents and links generated in real-time. The question of presenting learning material structurally with the aid of SGML-data bases is also connected to this matter.

The technical production of materials does not necessarily produce pedagogically meaningful learning documents. In cooperation with the groupworking and pedagogic groups, this team pays special attention to the definition of the structure of pedagogically appropriate learning documents and experiments within the limits of pilot projects.

The hypermedia material team works in cooperation with the telecommunications group in the using of new technologies like VRML, Java, and JavaScript. Adaptivity of learning environment to available network capacity will be ascertained. The pilots will be supported by offering them technical support and training in producing the courseware materials.

Methods of Distance Learning

A pedagogically meaningful learning environment should include cognitive tools which support, guide and
extend the learning process, and communication tools, which make communication and collaboration between student - teacher and student - student possible. Administrative measures associated with studying (entering for an examination, reading a study guide, studying a course, passing an examination, receiving feedback, criticizing, registration) should also be possible via the network.

The benefits of WWW in education are connected to the interactivity of the material. A good WWW course offers students enough feedback on advancement of learning. Interactivity is supported by direct e-mail connection to the teacher via the WWW-pages and a bulletin board connected to the course for students' discussions.

The activities of the project's methods of distance learning team are divided into the following fields:
1. *Interactivity between learning environment and content.* New and existing learning environments and those quality standards are examined from pedagogical points of view. The team maps appropriate views of learning and learning strategies for network environments. In pilot projects usability of learning material in networks is clarified. Research methods for evaluation of the pilot projects are considered, too.
2. *Tutoring of the students and technical support.* In interface design one should take into account the needs of different kinds of learners. Interfaces for studying languages in adult education and studying information technology at the university level can be very different.
3. *Groupworking techniques in network.* The team considers and develops groupworking in learning via network, groupworking techniques and also software. They cooperate with the network team that clarifies alternative equipment for groupworking technologies.

**Distance Learning Experiments**

The purpose of the distance learning experiments is to test both the technical and pedagogical functionality of the distance learning solutions developed.

The Digital Media Institute at Tampere University of Technology has a broadband network connection (ATM) to Kaukajarvi and to some other schools and to the student dormitory of Student Housing Foundation in Tampere. This environment is used for ATM-based distance learning via multimedia networks. In Kaukajarvi school the first teaching experiments using ATM-connections during spring 1996 have already been made and in this autumn a teaching experiment in Russian language has started. Experimental university level teaching between Tampere University of Technology and University of Jyväskylä using broadband ATM-based network will begin in the spring 1997.

Adult education will be arranged via open universities that already are familiar with it. The contents of adult education are: mathematics, communications, education, languages. Network solutions are based on the Internet, for which student services and counselling that supports interactive private study, is being designed as a part of the project.

Adult education is also arranged as internal education of enterprises. In this project an experiment is carried out with NOKIA/NTC. The purpose is to provide hypermedia-based study material for company's new employees.

The pilots are grouped basically according to contents. In addition, the project includes one technical pilot. The research teams described above support pilots by: producing knowledge, offering technical support, providing necessary training, and participating in pilots' activities in practice.

**Pilots**

Each pilot also has members from interested enterprises and the pilot's subjects. Pilots activities are presented as follows.

**Broadband Networks and Technical Experiments**

This pilot includes the following projects:

"School on the information super highway" (KOUTIVA) project: ATM-based network solution between Kaukajarvi school and the Tampere Teacher Training School, video server and experiments.

Experiments with Project's distance learning equipment in projects for constructing ATM-based network university that have been started by Finnish universities. Student dormitories (ATM/ISDN) are also connected to experiments.

Paying attention to projects using ISDN and modem connections, like "Inforengas" (Network provided by the local telephone company).

Receiving Academic Training Program transmitted from CERN to Finland via ATM connections.

Tests using DMI's media server with digital TV that uses set-top-boxes as soon as the necessary technologies are available.

**Natural Sciences**

The aim of the pilot is to advance natural science teaching in schools beginning with the learning of math. The first experiments using ATM-connections in Kaukajarvi school were realized in Spring, 1996. The pilot cooperates with the Tampere Teacher Training School beginning with university-level distance learning of Matrix Algebra for senior high school students using ATM connections. The pilot extends to The Finnish Ministry of Education’s natural sciences and mathematics development project of comprehensive and secondary level pilot schools. The pilot offers learning material for mathematically gifted students' special education in the Pitkäla High Folk School via the network. The pilot also cooperates with Yläjärvi high school by offering them an Introduction to University
Mathematics course via the network. The pilot is also planning to develop an Extensive Mathematics 1 university-level distance learning course for mathematically gifted college students. The pilot is described as follows:

- **Participants:** are students from comprehensive and secondary level schools
- **Partners:** are Kaukajärvi school, Tampere Teacher Training School, Päivölä High Folk School, and Ylöjärvi high school
- **Subject taught:** Mathematics
- **Technologies used:** ATM/ISDN/Internet
- **Materials:** Solver (Ruokamo-Saari, 1996a; 1996b)
- **Network courses of TUT:** Introduction to University Mathematics, Matrix Algebra, distance learning course of Extensive Mathematics (under development)

**Languages**

The pilot of languages is going to research computer-based language learning and its suitability to support traditional language teaching. In the pilot, language learning techniques are being developed along with learning materials and pedagogical methods appropriate to network environment. Students’ learning strategies and styles are also studied. The subjects of the study are both private study materials and the use of network in the studies. Functioning is divided into observing and technical support. The pilot is described as follows:

- **Participants:** staff of TELE, KVS-Institute and students of high folk schools and residents of central Finland local authority area (KTOL)
- **Partners:** KVS-institute, KTOL, TELE, Teleste and JKO-Action Ltd.
- **Subjects taught:** languages, research of computer-based language learning
- **Materials:** TELE; Teleste, KVS-Institute, KTOL, JKO-Action Oy
- **Technology:** ISDN and modem connections

**Education**

The aim of the cooperation project of the subregion of South-East-Central Finland and the Institute for Extension Studies of the University of Tampere is to develop distance learning and support know-how in sparsely populated regions via education. The Institute for Extension Studies already has a test version of “Network tutor.” The subject is to develop the preparedness of student and tutor. Among the inhabitants of the subregion of South-East-Central Finland, a pilot group will be selected that begins to study the Learning to learn course with the aid of new technology. After the orientation period students and teachers of the area will be motivated to continue studies in educational science and adult education. The pilot is described as follows:

- **Participants:** sparsely populated regions of the subregion of South-East-Central Finland
- **Partners:** South-East-Central Finland Learning Center
- **Subject and materials:** Network tutor, Learning to learn-course from Institute for Extension Studies and after that possibly educational science
- **Technology:** ISDN

**Communication**

The pilot in communication is divided into three items: 1) basics of communication, 2) preparing spoken and written text, 3) technological breakthroughs of audio-visual culture. The basics of the communication include the study section’s Introduction to Communications (5 credits) lectures.

- **Participants:** are students of communication in high folk schools and institutes
- **Partners:** high folk schools and institutes
- **Subject and materials:** Basics of communication by University of Helsinki, A course in audio-visual culture by the Institute for Extension Studies.

**In-house and Customer Education of Enterprises**

NOKIA/NTC continues development of hypermedia-based internal education in cooperation with the Hypermedia Laboratory of the University of Tampere. The aim of the project is to develop hypermedia-based learning environments which Nokia’s own teachers produce. Special attention will be made to pedagogical design and testing of the quality of learning. The pilot is described as follows:

- **Participants:** in-house education of enterprises
- **Partners:** NOKIA/NTC
- **Subject and materials:** educational material of NOKIA
- **Technology:** internal network of the enterprise

Many enterprise participants have been widely interested in different kinds of educational activities that are directed to personnel and customers (network mediated support for products, selling/dispersed education of servicing personnel). More detailed project plans for these will be completed during autumn 1996 and realization of these will begin in spring 1997.

**Notification**

Notification of the project is taken care of via WWW and the project’s homepage, whose address is: http://matwww.ee.tut.fi/kamu/. The homepage is divided into public and non-public parts, the latter is open for all project participants. The public part includes general information and introduction to the project. The non-public part includes:

- Work plans
- Minutes of the management group’s meetings
- Minutes of the supporting group’s meetings
- Reports
• Plans of the working teams
• Information of contact persons in charge.

Each research team and pilot group also update their information on the network during the whole period of the project.

Major Achievements of the Project
In the beginning of the project in autumn, 1996, the following adjustments and mappings have been made:
• Preliminary selections of learning materials and contents have been done and have taken into account the available teaching experiments in the near future.
• The general structure of hypermedia learning materials has been outlined as well as the possible problems in its production. The media and video servers’ potential utilisation has been considered.
• Technical mapping of distance learning has been done.
• Mapping of the interests of the enterprises has been done.
• The essential results during the project’s first nine months have been reached in following areas:
  • Organization is built and personnel elected
  • Working plan has been dealt with
  • Seminars have been arranged
  • Research teams have been formed
  • Pilots have started
  • WWW-pages have been created
  • Educational seminar “Pedagogical methods and technological solutions in distance learning” has been arranged.

Conclusions
The beginning stage of the project Distance Learning in Multimedia-Networks is over and research and development work have started. The aim of this project is to construct real-time operational distance learning systems and to produce hypermedia-based learning environments that are both pedagogically and technologically appropriate. This project collects data and evaluates experiences of pilot projects and develops pedagogical methods and technologies on the basis of these. In the near future the project can be extended within the limits of working plan and budget.

The 20th century has been an era of accelerating change and will undoubtedly continue as the new millennium approaches. The institution of higher education is just one of the many institutions which has been tremendously impacted by change — especially in the field of technology. As a result, we are experiencing the lifting of the bonds of time and space that have been a part of the educational agenda. While there are many forces affecting education, two powerful forces are at work and are demanding that educational institutions make significant changes related to the delivery of instruction. These two forces are (1) the demand for new technology, and (2) the increasing need for significant and continued learning.

The delivery of instruction has been forever altered by new developments in technology. The changes in society have mandated continual learning if we are to function effectively in the future. Although not a new concept, distance education was in the past less flexible and designed to address the needs of remote learners and considered second-rate at best. However, distance education today is emerging as a mainstream delivery system by providing flexibility and responding to a wide variety of learners.

The University of Central Florida's Mission and Distance Education

The University of Central Florida (UCF) is a metropolitan institution in a region experiencing rapid growth and has a student population that is the fastest growing in the nation. Numbering more than 27,500 students, we project a student body of 34,000 by the end of the decade and over 40,000 by the year 2010. The average student age is now approximately 26. Many of these students are adults who may be part-time or are seeking additional education in order to gain or remain employed in central Florida's expanding high-tech work force. Space exists to house only 2,000 students on the UCF campus, resulting in a 90% non-resident student population. For non-resident students, the time and expense of commuting must be added to the effort required to attend classes or to obtain academic support services.

The University of Central Florida has been struggling with many issues related to providing distance education courses and programs. Dynamic growth, changing student demographics, increasing need for lifelong learning, the change in our nation from an industrial base to an information base, and advances in information technology are all forces re-shaping the educational landscape in central Florida. At the same time, the state's public institutions of higher education seek to provide increased access and improved quality and reduced costs, while meeting the educational needs of a growing and increasingly non-traditional student population.

The University of Central Florida has recognized and is responding to these challenges — distance education is just one of the ways. The university has formally recognized that distance education is a strategic method for increasing educational access and opportunities for students within and beyond an eleven county region. We also see that technology can assist in addressing the challenges of a rapidly growing student population and the shortage of classroom space and still maintain the quality with available resources.

Distance Education - Modes of Delivery

Recent developments in information technology make it possible to create a new model of course delivery. This model is called an Asynchronous Learning Network, or ALN. Through an ALN, course material, pointers to information; communication channels such as electronic mail, discussion groups, and channels for live chatting. Interactive quizzes or laboratory simulations are integrated into learning activities. The term “asynchronous” refers to the ability of students to participate at any time and from any place it is possible or convenient to connect into the UCF campus computer network. With asynchronous learning, students become more active and participative than in large lecture classes. Students are responsible for dynamically locating, accessing, and acting upon course-related information. Interactive reviews, quizzes, and exercises can be structured into the asynchronous learning
environment to facilitate self-assessment. Students must be challenged to use their higher cognitive skills to research, problem solve, and inquire about their own answers (Mizell, 1994). Tools such as electronic mail, discussion groups, and computer conferencing facilitate interactivity. Effective course design should make interaction an integral element of the class and also provide for the use of assistants who help the instructor for the duration of the course.

**Faculty and Faculty Support**

There is no substitute for a systematic plan for faculty development and the quality of on-line courses is directly related to the effectiveness of the instructor. Although not a necessity, choosing faculty with certain prerequisite skills creates a better transition for teaching at a distance. More important than technical experience is a faculty member's willingness to learn, try new approaches, and scrutinize their instruction as they adapt to a new instructional format. Faculty must be master teachers and be able to translate their style into an effective distance education format (Barker & Baker, 1995).

Faculty, like students, have varying learning needs. Their teaching styles must be accommodated with either systematic training or one-on-one consultation. Scholar and Anderson (1994) include the following teaching skills that instructors should acquire for distance education teaching:

1. **Understanding the philosophy of distance learning**
2. **Dealing with copyright issues**
3. **Adapting teaching strategies**
4. **Designing interactive courseware**
5. **Identifying learner characteristics**
6. **Organizing instructional resources for independent study**
7. **Using telecommunications systems**
8. **Collaborative planning and decision making**
9. **Evaluating student achievement and perceptions**

**Faculty Support**

System-wide support is critical for effective distance education — from commitment of the individual faculty member to the department (including colleagues and chair) and including the college and the university wide-system. The outcome has to be a team effort. Support from central administration is crucial for the adoption of a systems approach, especially from academic and technological departments. Putting courses on-line is a change process that requires time for campus personnel and departments to accept and adopt. Expecting computer services to respond immediately to distance learning needs, among other campus needs, is unrealistic. Creating on-line courses requires teamwork among subject-matter experts, designers, programmers, graphic artists, and administrators. Furthermore, communication and camaraderie must exist between departments such as instructional resources, computer services and academic affairs and is best established by leadership from top administrators. Without administrative support, development becomes problematic. With administrative support, development can also become problematic when communication breaks down and a "tennis doubles" syndrome occurs. "Tennis doubles" syndrome is when two departments receive a request and each department thinks the other will handle the request (play the ball). But then neither does and the result is a mishandled request and embarrassed team players.

Distance education courses are supported in a number of ways. For example, the UCF has established a formal training program for faculty who will be delivering courses in on-line degree programs. In addition, faculty who are not comfortable with the mechanics of creating web pages can turn to the Faculty Multimedia Center (FMC) in the Office of Instructional Resources. This facility, which is part of UCF’s new media center, exists to provide training and one-on-one support for faculty efforts and includes support for the development of web-based courses and course materials. The FMC also provides graphics, audio, video and multimedia production services for both on- and off-campus instruction. The FMC facility includes both Macintosh and Windows PC workstations with a wide variety of software and a Sun server for the on-line development environment of web-based courses. When course development is completed, the finished files are migrated to the university’s main web server where they become publicly-available.

With the dramatic increase of web site development, the FC needed to develop a less labor-intensive tool for the faculty. Two solutions were found. The first was creation of an automated web page development tool named UCF WebWeaver. This tool provides faculty with a structured environment for the creation of a course web site. The user simply selects the applicable sections and fills in (or copy-paste) various text blocks or graphics. Using UCF WebWeaver, a completed course website can be generated in as little as half an hour. Faculty can use other tools such as Aldus' PageMill or Microsoft's FrontPage in combination with course template files. Both solutions allow the creation of high quality course websites without requiring the faculty to use HTML. Courses requiring more sophisticated resources, such as custom CGI or Java scripts, can be enhanced by skilled programmers once the basic pages are created. Another solution from the professional staff in the Faculty Multimedia Center is the recruiting and training of undergraduate and graduate students to help faculty in website creation and maintenance.

**Designing Quality Courses**

Designing on-line courses requires thorough research. Some critics within the field believe that successful distance education must try to replicate face to face classroom interaction. This is evident in state-wide initiatives to build two-way video and two-way audio networks. To attain the
highest quality teaching and learning at a distance, consideration must be made equally to the theoretical perspectives of learning, subject content, learning context, delivery mode, and learner characteristics.

Distance learning can exaggerate poor instruction. Just as faculty must prepare themselves for a change in roles as distance educators, they must scrutinize their course content with a systematic instructional design process. The Internet combines the advantages of multiple media, is more interactive than videotapes and, unlike CD-ROM delivery, can connect people cheaply from all over the world (McManus, 1995). The use of such varied media requires instructional design.

On-line tools for instruction and the use of e-mail provides opportunities to create learning environments and communities of scholars. However, these tools are not without their drawbacks. E-mail can quickly overload a mailbox and overwhelm the instructor. Furthermore, sufficient server storage space must be planned and provided for. The ability to autosort messages is needed and students need to be instructed on Netiquette. While many students feel that they should get a response within 24 hours, a more realistic time frame is 48 hours. Backing up files and checking for viruses are other activities that must be constantly performed.

There is a delicate push-pull relationship in interactions between faculty - student and student - student. For on-line courses this can be the push of e-mail and the pull of computer conferencing. Unlike the traditional classroom, on-line students are expected to construct their own knowledge, see many perspectives, be more autonomous, be self-motivated and independent, and work collaboratively in groups. Furthermore, students’ access to study resources is greatly enhanced with links to computer resources and other experts (Collins & Berge, 1995; Zack, 1996).

**Student Support Services**

Learner support is an inextricable part of both the on-line course delivery process and overall quality of the program. Well-designed courses will not be well received if the campus appears unresponsive to the needs of distance learners. However, the perception of learner support is sometimes more important than actual need. UCF has only begun to address the need of distant students to access academic support services. To date, distance education students have used services available at one of UCF’s attendance centers. To more fully meet the needs of a distributed student population, a central support center for distance education students is being established within the Division of Enrollment and Academic Services. This office will become a single-point-of-contact facility that will serve the needs of non-resident students. It will provide access to a variety of campus-based support services and distribute required course information and materials. The WWW is also being used as a way to provide student services ranging from course registration and financial aid to library

information. This makes services accessible to distant learners seven days a week, 24 hours a day.

**Strategies for Future Courses**

The problem commonly associated with traditional distance education is the lack of opportunities for collaborative work, debate, dialogue, and conversational learning (Kaye, 1989). E-mail creates some of the push, but yet not enough pull. The limitations of e-mail were clearly shown in a recent web-based course. However, the use of asynchronous computer conferencing through a web browser holds much promise.

Computer conferencing, while still limited, can create learning environments where learners are actively engaged (Collins & Berge, 1995). The technological ability of the software program, combined with the facilitation of the faculty member, allows for the creation of learning environments that foster trust, collaboration, and cooperation (Collins & Berge, 1996). Higher level learning and integration is most effectively achieved through dialogue, which occurs in computer conferencing (Lauzon, 1992). Users liked the fact that anonymity helps facilitate their use of computer conferencing. They felt more empowered, yet daring and confrontational about expressing ideas (Lauzon, 1992). Learners are no longer on the spot and can reflect on the content (McMahan & Dawson, 1995). Guest lecturers may also participate in computer conferencing which allows experts to enrich the learning experience (Collins & Berge, 1996). International borders are diminished within the networked access of the Internet and the WWW.

Some of the drawbacks of computer conferencing for students and teachers are the technical requirements of the software and hardware. Gaining reliable access and overcoming the time-consuming learning curve are obstacles that need to be overcome early on to ensure quality experiences (Collins & Berge, 1996). Lack of visual cues is another limitation to computer conferencing. This includes gestures, body movements, eye contact, and voice inflection. Lack of visual cues may lead to greater misunderstandings and may even escalate into “flame” wars. The anonymity associated with conferencing can possibly create a depersonalized environment leading to abusive behavior (Kahle, 1996).

“Netiquette” training is essential for avoiding unnecessary conflicts. Zack (1995) found that while his business administration students did not want to get into conflicts using e-mail, they enjoyed controversy on the computer conferencing system. Since the actual sequence of talk is rearranged as communication occurs over time, following threads of posted messages can be difficult. This can lead to a disjointed flow of information. Many topics can also be active at the same — a situation that requires time and the ability to sort through various topics (Ocker, Hiltz, Turollf & Fjernestad, 1995). Other difficulties are inability of groups to work easily, difficulty in group decision making
and problem solving, and lack of quality scholarly opinion (McMahen & Dawson, 1995).

In the traditional classroom, the teacher contributes up to 80% of the discussion, but in some studies cited by Jonassen, Davidson, Collins, Campbell, & Haag (1995) teachers contribute only 10-15% of the discussion when using computer conferencing. “The role of the teacher changes in that he or she is no longer the source of curriculum or the expert on a subject matter; therefore, students must engage in inquiry that goes beyond the walls of the classroom” (McMahen & Dawson, 1995).

The most important role of the on-line instructor is to accept responsibility to keep discussion on track and involve learners to act independently, interactively, and interdependently. This accounts for the time spent by teachers up front in designing an on-line course. Collins & Berge (1995) go on to describe the responsibility of the on-line instructor, “Scaffolding for students interaction and meaning-making activities must be provided by the on-line instructor by modeling appropriate interaction and facilitation techniques on screen, and by providing metaphors and analogies to personalize and humanize the transactional space.”

**Future Directions**

Many modern universities still utilize the same resources to deliver academic programs as institutions did a century ago. Classrooms, laboratories, books and faculty scheduled in 15-week terms are still the rule. These technologies can be used in only one place at a time and by a limited number of learners. The mode of delivery is primarily lecture-based, and in most growing state institutions, large lecture sections are common. However, the effectiveness of such courses is limited. The scene in the typical classroom is one of the faculty member actively working and the students passively listening and taking notes.

In the near-term, we see asynchronous learning techniques used for both distant courses and campus-based courses. Perhaps the most significant change will be in the exploration of possibilities for re-structuring the traditional class delivery model by combining live class meetings with Asynchronous Learning Network activity. It is our intent to pursue all available avenues of distance education that adapts well to the lifestyles of today’s metropolitan student. This requires flexibility, adaptability, and openness on the part of all stakeholders involved.

Currently, the push is to integrate computers and the Internet into traditional classroom curriculum. Not only are we bringing the Internet into the classroom, but we are also replacing the traditional classroom with a virtual one. There are many reasons for this push which is not within the scope of this paper. We are more concerned with the issues that accompany this computer and Internet push. The World Wide Web (WWW) contains many opportunities and tools for educational activities. According to Ellsworth (1994), there are an abundance of resources as well as methods for teaching more than just facts. Ellsworth feels the opportunity to contact people from around the globe, can “make any project more dynamic” (p. 5). Another asset is the ability to access the “most current information available” (p. 5). She goes on to say, “it is “fast becoming the largest reservoir of knowledge ever known to this planet” (p. 6). With the growing popularity of the WWW, students no longer need to travel to libraries for information. The information can come to them in their classrooms or at home.

According to Azarmsa (1993), computers can bring the “world into the classroom and make a student’s desk a delta for information flow” (p. 13). Azarmsa goes on to say, Properly structured and facilitated within the existing curriculum, instructional telecommunications can be a powerful tool in the instructional arsenal. It can improve critical thinking skills and help us reevaluate concepts that may ultimately lead to true global education. (p. 13)

The availability of the Internet and easier access to information as well as to educational activities provides educators and learners with new options and choices. Learners attending traditional institutions of education are now provided with new ways of enhancing their education. Global availability to experts in the field and access to the latest research are just two examples of the importance and impact of the Internet.

Technology has exploded into education. As educators we must be prepared to work with these new technological innovations. There are many new educational technologies available on the Internet. With an understanding of technology, educators can integrate it into the traditional classroom and possibly lead to richer learning experiences for learners. Educators need easy access to information which enables them to keep up with the development of new educational technologies as well as understand techniques and methods to best use them.

Computers, The Internet, Support Systems and Our Educational Institutions

Baker and O’Neil feel traditional educational institutes are burdened by “legal constraints, high teacher - student ratios, administrative timidity...and even the physical arrangement of classrooms” (1994, p. 2) which have created “barriers to technology that have yet to be overcome” (p. 2). They go on to say, “technologies have not been embraced and pulled by real needs of the system because institutional focus has been on maintenance of existing goals” (p. 2). In other words “A real market for technology—in the sense of demand for innovative applications by teachers, administrators, and curriculum developers—has not developed” (p. 2). What has happened is technology has been forced to fit into “existing niches, where it cannot seriously threaten existing organizations and staffing structures” (p. 2). Baker and O’Neil state “Technology is acceptable if it does not upset or supplant functions served by people in the system” (p. 2). Therefore, in order to support educators in providing these technological skills to our future workers, the goals of educational institutions need to change.

In order to show just how powerful a tool computers can be, Azarmsa (1993) points to a three month pilot online course offered by The Center for Distance Learning at Empire State College in New York. The course was presented totally online and utilized discussion lists and email. At the end of the study, the work submitted by the
students in the pilot study “was found to be superior, both as to breadth of research and quality of analysis, to work submitted by a previous non-computer class” (p. 138). Azarnsa makes an important point here. Utilizing the Internet and computers can enhance the quality of work submitted by learners. This may be due to the increased access to more resources and information, but this access must be properly structured and facilitated by educators.

Another example of the power of computers in the classroom is provided by Kinner and Coombs (1995) who found that utilizing computers in the classroom setting “can drastically reduce barriers for persons with various physical and learning disabilities, and it can also facilitate interaction among those who are, for whatever reasons, inhibited in face-to-face settings” (p. 53). Professor Norman Coombs from the Rochester Institute of Technology taught an African-American history class that met both in the physical classroom and through a computer conferencing system. Kinner and Coombs feel that utilizing the computer conferencing system reduced such differences as “being hearing impaired, being Black, White, or Green, being shy or not a good speaker” (p. 53). Students who participated in the class were of various ethnic backgrounds and included both hearing and hearing-impaired students.

Students who are hearing-impaired require either that their instructors be proficient in sign language or that an interpreter accompany them to the class (Kinner & Coombs, 1995). When a class discussion is held via computer conferencing, the hearing-impaired student does not require any special assistance “to become part of a mainstream educational setting” (p. 54). One deaf student commented that she really enjoyed taking a class via the computer because it enabled her to “participate in a hearing class” (p. 54). She explained that she was able to get the other student’s views without an interpreter “in the middle of the communication” (p. 54). The student also commented that she felt left out in other more traditional classes.

According to Kinner and Coombs (1995), software and hardware adaptations enable other students with physical disabilities to participate in educational activities via the computer. Kinner and Coombs feel that “Once appropriate access has been provided to the computer, these students function as equals in the computer classroom, and their disability vanishes” (p. 54). They go on to say, rather than the interaction being based on stereotypes such as a person’s appearance, students can interact on the basis of their ideas. Kinner and Coombs also found that students developed a “strong sense of self-discipline” (p. 65) and assumed “more responsibility for their own learning” (p. 65). These are just representative of the many important advantages to utilizing computer technologies in the classroom.

Ellsworth (1994) feels the Internet is becoming “an integral part of life” (p. 5). She goes on to say, “It is used in education, business, and in leisure, and students will need to become familiar with the Internet to become prepared citizens” (p. 5). Educators will bear the brunt of responsibility in providing Internet skills to students and therefore will need programs and resources that will support them in acquiring these skills.

An important support system in our educational institutions consist of the programmers and computer professionals who are there to assist the institution as a whole in its computer related endeavors. These professionals can be an important resource when deciding to utilize computers in the classroom. They can provide seminars to help educators and students learn how to use the technology as well as provide ongoing support throughout the semester.

Professional Development and Computers

It is obvious that educators must first obtain computer skills so that they can in turn provide learners with the skills needed to use computers inside and outside of the classroom. Bork (1993) points out a major problem for providing our students with computer skills.

Almost no teachers currently in the schools have had any acquaintance with computers. Indeed, the teachers now coming out of schools of education have almost zero acquaintance with computers because very few schools of education anywhere in the world are in a position to deal with this question adequately. (p. 77)

Not only are new educators unprepared, support for professional development in many educational institutions is often considered a low priority or nonexistent (Goeghegan, 1994). How can we expect educators to effectively utilize these new learning environments when institutions are not providing for teacher training and faculty development. Bork points out that there is “no coherent use of the computer in education” (1993, p. 77). Therefore, how do we prepare teachers/faculty to use computers effectively within the curriculum? Teachers/faculty can be taught to use the computer, but along with this training, they must also be taught how the computer is integrated within their area of expertise as well as how the computer can be used most effectively in delivery of the course content.

Providing Computer Skills To Learners

Ellsworth (1995) feels computer skills should be introduced at the first week of the course by demonstrating how the computer tools fit into the curriculum and then moving on to actually mastering those skills. Manrique and Gardiner (1995) recommend waiting a few weeks so students can first begin to work with the actual curriculum.
of the course before acquiring the computer skills needed within the course. Although they both differ on implementation, their goals are the same. Both models encourage the students’ understanding of how the tools fit into the curriculum rather than fitting the curriculum to the computer tools.

Manrique and Gardiner (1995) found that many students were “turned off by the mere thought of facing a computer” (p. 126). They felt it would help a great deal if the instructor of the course approached the use of e-mail in a relaxed and confident manner. Manrique and Gardiner state “Thus, the instructor should make an effort to thoroughly learn how to use the e-mail system and not just send the students to the computer center for help when they have problems” (p. 126). Manrique and Gardiner’s point here once again brings up the importance of providing programs and resources for educators to acquire these technological skills.

**Online Resources**

Many resources currently exist on the Internet for educators. One online educational resource is Diversity University (DU) which exists in the Multi-user Object Oriented (MOO) environment on the Internet (Burke, Clapham & Wee, 1994). The DU is a member of Globewide Network Academy (GNA) which is a non-profit virtual organization utilizing the WWW to provide educational resources (Burke et al). Diversity University provides virtual space for educators who wish to use the MOO environment for educational activities. According to Burke et al, examples of these activities have consisted of non-accredited course offerings, global collaborative learning projects, office hours for faculty and teachers, faculty/teacher development seminars, conferences and guest lecturers.

According to Evard (1993) the MOO is software that has been programmed to represent a particular environment. It is a place where people can socialize, participate in educational activities and “meet and collaborate on various projects” (p. 1). Bonefas (1996) describes the MOO as a “virtual ‘space’ where multiple users from anywhere in the world can log on simultaneously and interact” (online, 2nd paragraph). In general, a MOO permits synchronous communication with other users who are connected at the same time. It’s a virtual meeting place where your imagination can create exciting learning environments for students to experience.

**Real Education**

Going a step further, Real Education is a company which has not only developed online classrooms but has created a virtual college campus to house those classrooms as well. Every service that is provided at a traditional campus can also be obtained at the online campus. These online universities contain online catalogues, registration, academic counseling, career counseling, financial aid, bursar services and technical support. The online university structure also provides for an online library, student union, bookstore and of course online classes.

The mission of Real Education is to create and manage online university campuses and continuing education centers for their clients. Their belief is that online students are entitled to have access to the same services as face-to-face students who receive their services from the more traditional campuses.

Search engines have made online educational resources that are located on the World Wide Web easy to find. There are literally thousands of web pages on the Internet which can point the self-directed educator in the right direction. We are certainly not suggesting that these Internet resources replace teacher education programs or faculty development, but they can be excellent sources of information.

**The Learners**

“The central concern of all education is the learner” (Houle, 1974, p.166). Cross states “The emphasis is on learning rather than teaching” (1976, p.52). Manning feels “it is comparatively easy for us to repress or avoid the existence of individual differences whenever it is convenient or economical or comfortable for us to do so” (1976, p. 295). According to Cross (1976), “It takes no special knowledge of research to recognize that we all have characteristic ‘styles’ for collecting and organizing information into useful knowledge” (p. 112). Witkin (1976) states,

> it is easy to see that a teacher’s cognitive style may influence his [sic] way of teaching, that a student’s cognitive style may influence his [sic] way of learning, and that a match or mismatch in cognitive style between teacher and student may determine how well they get along, with important consequences for the learning process. (p. 57)

McKeachie (1991) feels educators need to think about how students learn the material. In McKeachie’s research, he has found that educators really don’t think about the instructional strategies they use. He reports educators tell him “it was just the way it had always been done” (p. 8). It appears that taking into consideration different learning styles is an important step when developing traditional or online course curriculum. When deciding upon one instructional strategy or another to use in an educational activity, these individual differences should be taken into consideration.

According to Kemp, Morrison and Ross (1994), “When an instructor lectures...the assumption is made that all learners are acquiring the same understanding, with the same level of comprehension, at the same time” (p. 139). In this case the learners are forced to learn at a pace which is
set by the instructor and is not "adaptive to individual differences" (p. 139). In other words, utilizing only one instructional strategy will not include other diverse learning styles of many of the students participating in the class.

According to Tyler (1949), "learning takes place through the experiences which the learner has" (p. 63). Two students can be in the same class, but have different learning experiences. Tyler feels this requires the teacher to organize situations that have so many facets that they are likely to evoke the desired experience from all the students or else the teacher will vary the experiences so as to provide some that are likely to be significant to each of the students in the class. (p. 65)

In other words, educators need to include various instructional strategies in their curriculum. Rather than depending on one or two instructional strategies the educator can take into account diverse learning styles as well as create learning experiences that are meaningful to each student in the class. We believe it is the responsibility of an educator when planning and delivering educational activities to utilize the instructional strategies that most effectively produce the interactions and experiences in which learners can learn.

**Instructional Strategies and Online Educational Activities**

Knupfer (1993) feels "Many programs currently used in educational computing do not fully utilize instructional strategies to best facilitate learning" (p. 171). She goes on to say,

If this technology is to be truly beneficial and remain a valuable part of our educational system, we must use what history tells us about good teaching techniques and sound innovative strategies and then apply critical planning and evaluation throughout implementation. (p. 171)

According to Knupfer, we must not let the computers dictate the curriculum. Schools must first formulate their curriculum and then consider how "computers can best serve the instructional objectives and activities of that curriculum" (p. 171). Rather than the "technology driving the curriculum" (p. 171), computers need to be implemented in a meaningful manner.

Effective use of the computer as a resource in education will "necessitate changes in pedagogy" (Knupfer, 1993, p. 171). The teacher once thought of as the source of knowledge, now becomes the "facilitator of information" (p. 173). According to Knupfer, the teacher guides the student toward the solution. In order for teachers/faculty to be successful in facilitating information, they must "be willing to release the control of learning to the students and feel secure in a different role" (p. 173). Within this new role, Knupfer feels the student and teacher learn together.

Knupfer states, "Technology demands that teachers change their pedagogy to accommodate a different delivery system, and a different approach to teaching and learning that utilizes higher cognitive strategies" (p. 175). These new approaches to teaching will not only change the role of the educator, but the role of the learner as well.

According to Berge and Collins (1995), Computer-mediated communication (CMC) provides "electronic mail and real-time chat capabilities, delivers instruction, and facilitates student-to-student and student-to-teacher interactions across a desk or across the world" (p. 2). They feel these uses are enabling and promoting several paradigmatic shifts in teaching and learning, including the shift from instructor-centered distance education to student-centered distance learning and the merging of informal dialogues, invisible colleges, oral presentations, and scholarly publications into a kind of dialogic virtual university. (p. 2)

This reinforces the concept of the learners new role. In a shift from a teacher-centered to learner-centered environment, the change in the role of the educator will necessitate a change in the role of the learner.

There are many benefits to using CMC, but as in any other instructional activity, there are limitations as well. One of the "greatest benefits of CMC is its ability to liberate instruction from the constraints of time and distance" (p. 3). According to Berge and Collins, CMC also promotes self-discipline and requires the student to become a more independent learner by taking responsibility for his/her own learning. A drawback to this is the student who may require more structured learning.

Another advantage to using CMC is the "empowerment of persons with disabilities, physical impairment, disfigurement, or speech impediments, which hinder their equal participation in face-to-face encounters" (Berge & Collins, 1995, p. 4) and "promotes an equalization of users" (p. 4). Although this may be an advantage to some, it is a disadvantage to those that prefer "the social aspects of the classroom and are unsettled by the lack of face-to-face interaction" (pp. 4-5). For those that are hindered by face-to-face learning situations, CMC can be an advantageous environment for learning.

Berge and Collins (1995) list several uses for computer-mediated communication which cover a wide variety of online instructional strategies. They are:

- mentoring, such as advising and guiding students
- project-based instruction, either within the classroom or in projects involving community, national, or international problem solving
guest lecturing, which promotes interaction between students and persons in the larger community
- didactic teaching, that is, supplying course content, posting assignments, or other information germane to course work
- retrieval of information from online information archives
- course management, for example, advising, delivery of course content, evaluation, collecting and returning assignments
- public conferencing, such as discussion lists using mainframe Listserv software
- interactive chat, used to brainstorm with teachers or peers and to maintain social relationships
- personal networking and professional growth and such activities as finding persons with similar interests on scholarly discussion lists
- facilitating collaboration
- individual and group presentations
- peer review of writing, or projects involving peer learning, groups/peer tutorial sessions, and peer counseling
- practice and experience using emerging technologies that may be intrinsically useful in today's society
- computer-based instruction, such as tutorials, simulations, and drills. (p. 3)

There are many instructional strategies available for use in the online environment. These strategies have not been invented for specific online use, but already exist in the traditional classroom. Pitt (1996) found ten basic instructional strategies which can be utilized in the traditional environment as well as the online environment. They are: learning contracts, lecture, discussion, self-directed learning, mentorship, small groups, collaborative learning, group projects, case study and forum. According to Knowles (1991), educators must be able to choose a learning technique that is "most effective for accomplishing a particular educational objective" (p. 3). Instructional strategies are tools that educators have available for use when designing methods to facilitate learning.

Conclusion
In this paper, we have tried to briefly touch on the technology issues facing educators today. There are many issues involving educators, learners and educational institutions which currently exist. We cannot expect educators to be able to meet these challenges alone. Support systems need to be established which can assist educators and their educational institutions in meeting their goals. These support systems consist of education programs which include courses on incorporating technology into the curriculum, high quality professional development opportunities and perhaps even an educational technology course provided for those Ph.D. students who intend on teaching within our university systems.

Technology is exploding into the field of education at an astonishing rate. We cannot stop nor slow this flow of new technologies down, therefore we need to learn to work within it before we are over run by it. Educators need clear and concise documentation that permits them to make informed choices regarding development of on-line educational activities. Educators also need to be provided with education, training and professional development opportunities.

We as educators need to work toward a better understanding of technology and what roles it can effectively play in the field of education. In order for us to be able to do this, we require the support of our institutional administrators as well as the support of the schools responsible for preparing us in the first place.

Electronic collaboration tools are outcomes of the exciting growth of networking and networked technologies that have arisen during the 1990s. Prominent technologies for computer conferencing and collaboration (Bonk, Medury, & Reynolds, 1994) bring students together and enhance the learning environment. Networks, email, bulletin boards, synchronous writing environments, and computer video conferencing are all having an impact. The Internet is also quickly becoming the focus for shared learning environments that transcend geographical and temporal boundaries and alter the limitations of time and place to facilitate the adoption of new learner-centered strategies for instruction.

We begin with an umbrella discussion of learner-centered instructional strategies and focus on our experience with this environment. We will examine the use of electronic collaboration tools that support student interpersonal communication and facilitate learning activities within five university courses: educational technology, freshman English, business telecommunications, social work, and business communication. Instructor-focused instructional strategies and an analysis of student participation within discussion forums will be presented.

Learner-centered instructional strategies are quickly becoming the focus of reform in higher education. According to Barr and Tagg (1995), colleges and universities have historically focused on a paradigm that defined a college or university as an institution that exists to provide instruction. Now, colleges and universities are increasingly becoming institutions that exist to produce learning. Faculty at universities are beginning to recognize that our dominant paradigm mistakes a means for an end. It takes the means or method—called "instruction" or "teaching"—and makes it the college's end or purpose. We now see that our mission is not instruction but rather that of producing learning with every student by whatever means work best. (Barr & Tagg, 1995, p.13)

Physical space and the time-frame for learning opportunities to occur often categorize learning environments (Chizmar & Williams, 1996). Four categories have been identified: same time-same place, same time-different place, different time-same place, different time-different place. The traditional classroom is a classic example of same time-same space mode of learning environment. Within the traditional classroom, most of the organized and monitored learning activities occur within the confines of fifty minute meetings, three times per week, in the same classroom.

Same time-different place modes of learning often focus on distributed classrooms. By electronically linking learners from different geographic regions, opportunities to learn are available to individuals that otherwise would not be economically possible. Audio-conferencing, text-based conferences (online chat groups), and fill-audio and video links are all methods that create same time-different place learning environments. This mode still calls for organized learning activities to occur within the fifty minute classes, three times per week. Its ability to reach learners that are distributed and unable to commute to a single classroom makes it different from the traditional classroom.

Different time-same place modes of learning are created by sharing space but not requiring concurrent attendance. Computer Assisted Instruction (CAI), computer simulations, and reserved-reference materials are used commonly for different time-same place learning environments. CAI and computer simulations often allow students to receive instruction at the student's convenience (different times) but usually require the student to receive the instruction in a computer lab (same place). Reserved-reference materials are often used in libraries to allow students access to limited-supply learning articles.

Finally, different time-different space modes of learning represent true "anywhere-anytime" learning environments. The freedom to participate at different times and different places challenges the instructor to better understand the learning outcomes expected while allowing the students the freedom to plan and control their participation and use of network resources. Electronic resources such as electronic collaboration tools, on-demand audio and video, CAI and simulation software distributed by wide area networks, and the resources of the Internet allow learners control of the time and place when and where learning transpires. Of special interest are the electronic collaboration tools. Discussion forums, synchronous writing tools, email,
listserves, and chat groups create the opportunity to observe evidence of student learning outside the traditional classroom and foster student discourse.

**Instructional Strategy**

The initial setup for a discussion forum needs to be on the server. The process is short, taking perhaps fifteen minutes. Topics within a discussion forum may be posted by the instructor from any computer with Internet access. Students also can post their message responses on any computer with Internet access. This makes maintaining the forum possible from any computer with Internet access. This is the foundation of the same place-different time environment.

![Diagram of Discussion Forum Design](image)

**Figure 1. Discussion Forum Design.**

Prior to setting up the discussion forum on the server, instructors should decide on a name for their class forum. A name descriptive of the course helps the students locate their particular forum. The goal of the first posted message should be to teach the students how to access the forum, how to post to the forum in the correct spot, how to read the thread once the class messages are posted, and how to respond via email to a peer’s posted message.

Creating a simple first message helps students focus on learning the posting process rather than on the content of their message. We have used first messages such as: “Post a message about your experience in using technology in health care” or “Comment on the technology you’ve been introduced to since you enrolled here at MSU. Has your high school training helped you or do you find you are a beginner at this?” Be certain not to ask too many questions since students carry the posted message in their heads once they click to Post Message. One student posting to a first message containing three levels of questions stated, “This is all I can remember of the questions.” We have used a handout on accessing the discussion forum to assist students through their initial posted experiences.

Since accessing the discussion forum is easily learned, the instructor’s second posted message then can be directed more to course content. If the instructor is interested in directing students to a specific web site, typing the Universal Resource Locator (URL) in the instructor’s message will automatically create a link to that site. Students can then just click on the linked URL and go immediately to that site.

Because this is a same place/different time environment, the instructor will not be available to reword or interpret the message for students. The precise wording of the posted message is rather important. Students must understand their task from the instructor’s posted message. When the assignment regarding the posting of a message is given to the students, it is a good idea to brief the students on the message so they can think about their response. This also helps the students understand their mission should the instructor’s posted message seem unclear to some students.

**Sample Student Postings**

We have observed both positive and negative results from our experience with the discussion forums. On the positive side, students are reporting that they find the experience rewarding once they get over some of the technical difficulties. These negative student experiences include the difficulty of using computers for students who have never used the computer. Other difficulties have been due to the server performance and reliability.

Server performance has been poor during the group training sessions we use to introduce whole classes to the discussion forums. The current discussion forum is a Common Gateway Interface (CGI) program that dynamically creates the discussion forum pages that are delivered to the student’s web browser. What this means is that when a discussion forum request is initiated by a web browser, a program is spawned on the server to create the current set of discussion documents. When twenty to twenty-five requests are sent to the server, the program must start over for each of the requests and performance declines. Of course, the discussion forum was not designed to be used primarily as a same time/same place server of discussions. Instead, only a few requests are initiated at the same time for the discussions once the training is completed.

The following messages illustrate some student responses to the use of the discussion forum. Both positive and negative reactions were included.

Other students also saw value with the discussion forums. Their reactions are paraphrased below.

- I think computer technology is something that will be around for the future and as nurses we will be working more and more with computers. I think being able to discuss with other professionals a certain topic is beneficial to patient care and professional growth...
• I think that, minimally, as a prerequisite to beginning the nursing program, an entry level course (BADM 231 - Information Processing) should be had by all nursing students. On-line information can greatly enhance nursing education.

These student messages indicate the students’ involvement in the messages posted by peers, the degree of comfort the students feel with the introduced technology, the student perception of the value of that technology in their lives, the problems experienced within the forum, and their positive reaction to the same place-different time format.

Instructors both posted questions and reacted to student responses. These posts are critical to the success of online discussions.

I feel I am learning a great deal from this class. The most important is that I am getting better at thinking and writing critically. In other classes I am using the techniques to study and to ask questions that are not so clear to me. My writing appears to be getting better also, though I am still uneasy about writing what is in my head. I am not using the computer as a typewriter, I’m using it as a tool. This computer stuff was really exasperating at first, but it is getting much easier. The discussion forums and the e-mail have made it easier for me to use the computer and to get into places of the unknown on the computer system. The more I use the computer the easier it gets. Sometimes it’s hard to access the server itself and that makes my mind a little bit harder to deal with. But, isn’t that what life’s all about, jumping over hurdles, pushing stones out of the way, and learning to deal with things you have no control over. The knowledge that is building up in my brain is phenomenal, and there is still more information coming in daily. WOW.

English 101 has taught me a great deal about writing and how to use assorted sources for my papers. In writing I learned that I have clutter within my papers. I have learned ways to help me pick out what is needed and what can be thrown out. I have, also, learned that revision strategies to pick out this clutter doesn’t develop overnight— it takes time and practice.

Many of the new sources I have found deal with the Internet. One of the biggest sources so far has been from the discussion forums.

The forum has been an important and positive part of the English 101 class. It allows me to express what I have to say on assigned topics—topics which I would usually keep my opinions to myself. I am, also, able to see how other people responded, and receive a greater understanding of the story. There have been many times that I was unsure what a story was about. I went to the forum, read my classmates’ responses, and felt more confident about what I read. Drawbacks are very few dealing with the forum. The problem I see is that the server is sometimes difficult to contact. I could and have sat at a computer for hours at a time trying to get into the forum. Besides this problem, there are scarce other complications. Overall, I give the discussion forums and the English 101 class two thumbs up!

Before I came to college and took English 101, I wasn’t very familiar with e-mail. The Internet was something that computer nerds played with and had no practical use in my life. Well, things changed and what I have now is to e-mail accounts with confidence and I am on the Web nearly every day.

Technology is a large part of people’s lives. I have papers to do which require more than one or two sources. The Internet opens the door to many possibilities. I am thankful that I have teachers that take the time to help us open that door.

Figure 2. Student Reaction.

Instructor’s Posted Message in Nursing

This message was: “Post a clinical question or a helpful tip from your clinical practice. Let us know if you have found a helpful Internet address for clinical information.”

• I found another interesting address that can keep you occupied for hours. http://www-sci.lib.ucir.edu/~martindale/Nursing.html This is the Virtual Nursing Center. Have fun!!

Student Responses in English Grammar

• Syd: I have to agree with you that students do remember the extraordinary teachers. If you have had teachers that struck you by their teaching, then remember what it was you found so appealing and use it in your own classroom. Learning should not always be boring and I know that it is the teachers who really want to make a difference who will.

• I really like your ideas for teaching grammar in context. It makes sense. Teaching grammar out of context does seem sort of useless, it’s like trying to teach the basics of math or science without actually using them. It is almost impossible. I think that reading and writing enhance understanding of grammar. Children and hopefully adults as well learn by looking at the whole picture, not just by examining the parts.

Continuing Education Class for High School Teachers

• We do not have access to the Internet yet, but I can see how it would be very beneficial in the research projects that we do in class.

• Please mail an e-mail address and Netscape program and a new computer to room 5-a, Beach High School. Include a computer-literate slave with the package. Send SOON! Thank you.

Nine weeks ago, I was using a Compaq Presario 7200 with a Pentium Processor. Two weeks ago, my principal gave me a Macintosh II. I have no idea of what programs it has (ClarisWorks, I believe), and it’s not even plugged in— only 2 plug-ins in the room. I am experiencing techno-anemia. This class is helping to boost my immune system (and sanity) until I can get my system up and working.

High School Teacher’s Posted Message

In 1992, the Americas celebrated the 500th anniversary of discovery by the Europeans. Of course, the Native Americans did not consider it a celebration; the decline of the indigenous peoples was rapid and devastating. However, the advent of the Europeans did benefit the growth of the United States. In response to your readings, discuss the advantages as well as the disadvantages of the European occupation of the New World.

High School Student’s Responses

• The Europeans brought a new way of life to a new world. This way of life did not benefit the Native Americans. The Europeans brought disease to the Native Americans, but without the exploration of new places we would not have the technology, religious freedom, etc. that we have today.

• When the Europeans came to the New World, they brought with them centuries of different civilizations. They brought their forms of art, dance, morals, and religion. If this was all they had brought, the world
would be quite a different place from the one we now live in. But this was not the case. They brought with them their superstitions, their forms of war, and new diseases that the natives had had no contact with. This caused unbelievable amounts of damage to the native people. The natives were conquered time and again by the invading Europeans. They were killed by war, their culture suppressed by the invaders' religions and ways of life. But the Europeans did bring some good. They brought advanced medical practices and thoughts of the world beyond the sea. The cultures of the Europeans and the natives mingled and created new, unique societies different from any other on earth.

Both the student's and instructor's postings illustrate student involvement in the messages posted by peers, the degree of comfort the students feel with the introduced technology, the student perception of the value of that technology in their lives, the problems experienced within the forum, and their positive reaction to the same place-different time format. It was also interesting to examine the patterns of postings from a more quantitative perspective.

Patterns of Postings by Time

Discussion forums were used by seven courses: Social Work, two sections of Freshman English, Educational Technology, Nursing Practicum, English Grammar, and a weekend workshop of local school teachers and college professors. Two courses, Management Information Systems and Business Telecommunications, are not included in this analysis due to problems with reporting. Three other courses, Interdisciplinary Issues in Developmental Disabilities, Communication Disorders, and Nursing Theory and Research, had not started their discussion forum activities. Discussion forum activity includes entries made between September 11, 1996, and November 22, 1996.

Instructor Posts

Instructors began the discussion by focusing student discussion on a topic or question. Reflecting the lead time in planning and their familiarity with the discussion forum software, instructors "posted" or made the first entry in each of the discussions an average of one to seven days prior to the first student response as shown in Figure 3.

Student Participation in Forums

Students participated in sixteen discussion questions across seven classes and generated 470 entries into discussion forums. Assignments for the discussion forums varied from class to class with most instructors requiring students to respond to questions within certain time periods. Student responses to discussion forum questions peaked early in the electronic discussions.

Interval Between Posts

Discussion questions were generated by the class instructor and focused the efforts of students around certain class topics. One of the advantages to the this web-based discussion forum was that instructors could post forum questions from the electronic classroom, from their office, and from home. Instructors typically posted topics well before the students were given the discussion assignment. This was reflected by the lead time between the instructor posting the question and student responses. Instructor posting of discussion topics led student replies by an average of just over five days. This indicates that instructor topics typically floated in cyberspace for days prior to the first student response.

A better measure of the starting date for the discussion occurs from the first student entry. The instructor may open a question and not assign it for days. The first entry for students indicates that the students have received the assignment and are responding. Using the first student entry as the starting date for discussions indicates that over half of the student responses occurred within the first two days of a discussion (see Table 1). After five days, over ninety percent of the responses were entered. Nine days after the first student entry over ninety-nine percent of the entries were completed. This indicates that most of the
online discussions peaked early after the assignment and ended after nine days.

Results of this analysis indicate that online discussions have a typical "life" of no more than nine days with a peak participation in the first few days. This is dramatically different than our expectations. One of our beliefs was that online discussions might generate activity throughout the semester and even across semesters linking prior students to current students in a peer focused mentoring environment.

Conclusions

Discussion forums are an important part of the instructional environment at Minot State University. Strengths of the forum include:

1. Topics can be researched and discussed across days and outside of the scheduled class.
2. Students value the online discussion forums for the use of the technology.
3. Students report a greater comfort level with other students after working on online discussion forums.
4. Students and instructors shared more Internet resources and were more likely to examine Internet links from a discussion forum message.
5. Students reported a close link between the use of email and discussion forums and commented on the positive nature of communication that both provided.

Weaknesses of the discussion forum concentrated on technical difficulties with the system we used and included:

1. Slow response times for the server especially during group training sessions.
2. Difficulty knowing where student posts should be placed resulting in some student postings at the topic level rather than within a topic.
3. Too many questions within the instructor's posting resulted in some students either not responding to all parts or having to do multiple replies.
4. The lack of automatic word wrap for messages was difficult for students to adjust to. Students didn't understand where their message had gone.

150 — Technology and Teacher Education Annual — 1997
In March 1996 the Concord Consortium was awarded a grant from the National Science foundation to investigate the use of netcourses as a substitute for on-site teacher professional development courses. The International Netcourse Teacher Enhancement Coalition (INTEC), creates and delivers a graduate-level professional development netcourse targeted at secondary mathematics and science teachers to enhance their use of project-based and inquiry oriented instruction. Eleven school districts and projects (Urban Systemic Initiatives in Columbus, New Orleans, New York, Philadelphia, and Phoenix, a Rural Systemic Initiatives in California, and Denver; school districts in Claremont, California; Hudson, Massachusetts; Scott County, Kentucky; and the Fermi Energy Lab) committed to systemic reform indicated, in the proposal development process, an interest in supporting teacher participation in the project.

An important goal of the project is to test and refine our netcourse model and its supporting technologies. We are experimenting with variations, including changing the size of the leadership team, changing the number of participants in groups, experimenting with the use of face-to-face study groups, as well as experimenting with different means of increasing communications such as digital video, on-line chats, regional meetings, and sessions at professional meetings. We will develop technology to increase the impact of netcourses, decrease their cost, and simplify their administration. The netcourse will be carefully evaluated to determine the costs and effectiveness of our model and its variants.

The final goal of the project is to perpetuate and disseminate the specific netcourse content as well as the general approach. We will continue the netcourses post funding on a self-funded basis, disseminate the support technologies, and help collaborators offer their own netcourses. The success of this project and its self-funded continuation will have major implications on professional development in general, since this model can be broadly adopted. We will contribute to this form of dissemination by making the netcourse model, technology, and evaluations widely available. The Concord Consortium had engaged in substantial research on the state of netcourses in the process of preparing to develop the proposal.

Definition

As we see in the history of any fundamentally new technology, the emerging capacity of information technologies for teaching creates new concepts that need to be defined. The concepts are so new, that there are no agreed-upon terms to refer to instructional activities that rely primarily on faculty-structured learning over digital networks; others have used the term “online education” (Harasim, 1990), the “online classroom” (Berge & Collins, 1995) or “telecourses” (Vogeli, 1995).

Riel and Harasim (1994) provide a good definition of the characteristics of courses using digital networks:

Computer networking for educational purposes represents a new learning paradigm: network learning (Harasim, 1994)...the attributes of anytime, anyplace communication that distinguish network learning make group interaction and collaboration in this medium distinctive. The unique combination of place-independent, asynchrononous interaction among groups of people linked by networks enables new educational approaches and new sets of learning outcomes. (p. 92)

In this model, all course activity occurs on-line, using computer conferencing or bulletin board systems, or, in a few cases, using e-mail interaction. On-line class activity resembles face-to-face classes in many ways: A teacher typically organizes the material, describes the sequence, establishes the pace, and determines the readings and other assignments. However, on-line courses are asynchronous and place-independent; students may live in different cities or even different countries from one another and the instructor. In on-line courses, students read the course materials, then log on to participate in on-line seminars, large and small group discussions, and individual or group projects. Face-to-face meetings do not occur or are optional. (p. 95)
We prefer to use the terms netcourses and netseminars. We distinguish between generic netcourses, which are any courses that rely primarily on networks, and a special subset of netcourses that utilize on-line discussion groups, such as those described by Riel and Harasim, that we have begun calling “netseminars.” It is not necessary that a netcourse utilize seminar-like on-line discussions, but, as we discuss in this paper, our analysis shows that most often this is the strategy of choice for the best instructional use of this medium.

Agreeing on terminology is important because we need to distinguish between kinds of netcourses, ways of using networks for education, and other forms of “distance education.” Of course, netcourses are a form of distance education but the term has become synonymous with either two-way video or live video broadcasts with real-time telephone back to the studio. These high-bandwidth approaches to distance learning are synchronous, relatively expensive, and do not easily support reflective thought and collaboration. Real-time interactions require synchronization that discourages reflection and is very difficult, particularly across time zones. In contrast, netcourses, as we have defined them, do not rely primarily on live video or simultaneous two-way communications.

The project’s instructional approach is net-based, and more accurately described as a netseminar rather than a netcourse. Participants engage in inquiry-based activities, face-to-face meeting with local peers, internet-based discussion, and off-line activities.

Advantages

Netcourses/netseminars have a number of important properties that make them particularly valuable as a mechanism for any kind of learning:

**Any Time**

A participant can use the network at any convenient time: early morning, late night, after work, or on weekends. The episodes can be quick snatches at odd times or long late-night sessions. Emergencies, unscheduled interruptions, or odd vacations, do not interfere. Conversations do not have to be scheduled. Cross-time-zone communication, difficult to arrange in real time, is as easy as talking to someone across town.

**Any Place**

The participants do not have to meet. That means they can be anywhere. Native Americans in Alaska can collaborate with their peers in New York City. International sharing is feasible. Individuals can log on at work, home, the library, or from their hotel when traveling.

**Asynchronous Interaction**

Unlike face-to-face or telephone conversations, electronic mail does not require participants to respond immediately. As a result, interactions seem to be more succinct and to the point, discussion gets off track less often, and people get a chance to craft their responses. This can lead to more thoughtful and creative conversations.

**Group Collaboration**

Electronic messaging creates new opportunities for groups to work together, creating shared electronic conversations that are thoughtful and more permanent than voice conversations. Sometimes aided by on-line “moderators” these “netseminars” can be powerful learning and problem-solving environments that can leave a permanent legacy (Grief & Sarin, 1986; Winograd, 1988; Kraut, et al, 1988).

**New Educational Approaches**

Many new options and learning strategies become economically feasible through netcourses. For instance, the technology makes it feasible to utilize the best faculty in the world and to put together faculty teams that include master teachers, researchers, scientists, and experienced professional developers. Netcourses also can provide unique opportunities for teachers to try and publish innovations in their own work with the immediate support of electronic groups and expert faculty.

**Integration of Computers**

The netcourse learner is guaranteed to have access to a computer, so computer applications can be used that might otherwise be avoided for fear of excluding some participants. This means, for instance, that a mathematical model implemented in a spreadsheet can easily be incorporated into a lesson and downloaded so all participants can run, explore, and refine the model and then publish their findings and improvements.

**Differences**

Asynchronous communications using computers presents a different medium from face-to-face conversation and so has a different set of advantages and disadvantages. For that reason it is inappropriate to simply transfer, to this new medium, the techniques that institutions have developed around traditional lectures, and text-book oriented instruction. There are many people who believe that network-based asynchronous communications will be constraining and awkward. It lacks the non-verbal clues and rapid back-and-forth of verbal conversation between familiar partners. These differences need to be considered in designs that are developed to rely on the strengths and minimize the weaknesses. One of the interesting design problems however it the effects that personal style and preference play in the evaluation of the characteristics of any learning situation. (e.g. For the verbally strong, the rapid back-and-forth may be seen in a more favorable perspective that for the less verbal person.)
There are some who assume that asynchronicity is a temporary limitation that will go away when bandwidth costs drop and we can go back to the familiar synchronous interactions using voice and video. That assumption however is based on maintaining the status quo. How many times have you tried to schedule a meeting or conference call and realized that synchronicity can be extremely difficult to achieve. There are significant advantages to asynchronous learning in terms of thoughtfulness, long-distance collaboration, and quality, that the problems it introduces are outweighed by its advantages. The shortcoming introduced by asynchronicity will become less pronounced as the technology improves, users become more familiar with the concept, more adept in its use, and hybrid approaches are developed that depend on a variety of forms of communication.

**Initial Technologies**

The initial course offering was presented via HTML files served from a Web server, supported by various web-based applications (e.g., HyperNews) received through Netscape 2.0 web client browsers. The instructional model worked for a class of 10 - 15. But there were problems with the technologies involved.

HyperNews, a web-based, threaded discussion area, was a management nightmare. Setting up new discussion areas was a time-consuming process. Submissions made to HyperNews were permanent. It isn't possible to edit a posting, nor could individual postings easily be deleted.

Changes to HTML files was fraught with difficulty. Editing a document, especially one that involved a file name change or location change could break all the associated HTML links resulting in confusion and missing information. Revisions needed to be made in the course schedule as we moved through the pilot phase of the course. Editing the schedule required changing the schedule and insuring all associated references were corrected.

In our instructional model the course content and approach are designed by content experts, then a Moderator, a generalist, works with a cohort of 25 participants to guide them through the course. The design then should allow a scaling up; the second round of the course beginning January 1997, will involve between three and five cohorts of approximately 25 participants each. Ease of replicability and ability to keep cohorts on separate data sets was an obvious concern. The cohorts operate independently, each has its' own moderator. Although the overall schedule is essentially the same for each cohort beginning in the cycle, it is clear that there will need to be schedule variations based on the direction each cohorts' investigations take on.

**LearningSpace**

Concord Consortium had been looking for alternative solutions when we were offered the opportunity to become a beta test site for Lotus Notes LearningSpace. (We were already a member of the Lotus Education Consortium.) At the heart of LearningSpace are five specialized interactive databases that enable users to collaborate in a learning environment. These five databases allow users to engage in problem-solving activities, debates, discussions and exercises that result in the creation of new knowledge; manage and leverage knowledge that is key to an organization's success; access and use stored information; and receive personalized feedback from instructors.

“Networking technologies and the Internet have raised enormously the potential for sophisticated distance learning that is truly distributed,” said Jim Krzywicki, vice president of Lotus Education. “Yet most on-line course offerings are little more than static repositories that bring the learner to the information. LearningSpace, on the other hand, allows the user to interact with that information, with others in the course, and with the instructor, for a truly rich classroom experience. This Notes-based solution literally brings the classroom to the student.”

Lotus Notes, through the Domino Notes Server has speeded the creation of threaded discussion environments significantly. We have created new discussion databases and had them mounted on the server in under five minutes, from creation to making the first web-based entry. Notes has a sophisticated security system which can control individual access down to the page level. Under normal implementation the author of any entry has the ability to edit their entry at any time. A Notes discussion database is also fully accessible to the manager of the database. They can delete the database, change the design, control what others have access to, and can edit any of the data. It is a substantial improvement over HyperNews.

The discussion database is the central building block for LearningSpace’s Classroom database, and a critical component of INTEC’s approach. The Classroom provides the environment where discussion takes place. Participants can create their own discussion threads and determine if they wish the discussion to be public or restricted. The power here lies with the participants. Management and administration time has been significantly reduced over the previous technology.

The Schedule database is the organizing database for LearningSpace. The Schedule is the entry point. Assignments can be sorted by topic, date, or those marked as completed. Discussions, in the Classroom database) are linked to the specific assignments, and stay properly linked, even when the Schedule is changed. Each cohort will access their own copy of INTEC's LearningSpace databases. The moderator will be able to modify the schedule as needed without needing to worry about where other links are or be concerned about breaking links by making a schedule change.
Next Steps

Based on the INTEC experience, LearningSpace will also be used to deliver courses for the Virtual High School (VHS) National Technology Challenge Grant project where Concord Consortium is the major partner. The grant was awarded to the Hudson Massachusetts Public Schools in October 1996. The first student courses will begin in the Fall of 1997. Here the professional development course delivery system, starting in April 1997 progresses from a simple e-mail based discussion, through web-based presentation, to LearningSpace. The VHS courses themselves will be presented in LearningSpace. The teachers will need to become familiar with the LearningSpace environment.

This approach has advantages and disadvantages. It will present a confined development environment. That will initially be helpful but which may later be found to be a restraint. The future will hold the answer to that.

By definition, distance learning substitutes communications technologies for personal contact between instructor and students. Problem-based learning (PBL) typically requires intensive instructor contact with students and may be difficult to implement in a distance learning context. However, our course demonstrates that multimedia technologies and extensive use of the World Wide Web can make PBL feasible for both traditional and distance students. We use a combination of videotaped lectures, e-mail, and a comprehensive web site to involve geographically dispersed students in group projects. Since the biotechnology issues we address are often controversial and commonly misunderstood by the American public, our course has a broad potential audience. Consequently, we have developed techniques for providing geographically remote students with on-line PBL experiences which are equivalent to those we provide to on-campus students.

Our interdisciplinary course, Biotechnology: Science and Socio-Economic Issues, has been taught in the College of Agricultural Sciences for eight years. During that time, we have adopted and refined PBL strategies which encourage students to focus on specific topics covered in the course. This unique course brings expert guest lecturers covering topics such as:

- The history of genetic engineering
- Plant and animal tissue culture
- Food biotechnology
- Plant and animal applications of biotechnology
- Consumer acceptance of food products produced through biotechnology
- Biotechnology and the media
- Ethics

This wealth of expertise is not available in any other course in the country. However, students can take the course from virtually anywhere in the world, either through the University of Delaware’s FOCUS/distance learning program or via satellite. Several of the lectures were made available for live broadcast throughout the United States by a grant from A*DEC, a consortium of universities that promotes distance education.

Problem-based learning has proven to be a valuable tool for integrating many perspectives on a given topic. Because they don’t live near the university and may work full time, students require more flexibility in their learning experience. As a result, our goal is to provide the same rich learning experience by providing lectures for viewing via videotape or satellite downlink.

Our course demonstrates how network technologies can facilitate PBL in the context of mixed local and distance learning. Local and distance students learn how to collaborate with each other over the Internet. The experience of working in a group is even more valuable when combined with the challenge of working with remote group members. By publishing students’ case studies on a publicly accessible web site, we are developing a public information resource to promote better understanding of some widely misunderstood biotechnology issues. Since we are a Land Grant University, this effort is entirely consistent with the broad public outreach mission of our institution.

Under a grant from the state’s Department of Agriculture (FY 96 Cooperative State Research, Education, and Extension Service Higher Education Program) we are reaching distance students with a series of videotaped lectures. The University Focus/Distance Learning Program offers selected courses each semester. These courses are taught in specially equipped video classrooms to traditional students. Each lecture is videotaped in an unedited fashion. Student-faculty interaction is maintained through special telephone office hours in which faculty advise students and answer students’ questions. Students may also schedule appointments to meet with faculty in person or communi-
The last unit of the course is a PBL exercise in which students in our local classroom are teamed with distance students to analyze and solve a particular problem related to biotechnology in agriculture.

The class web page is divided into public and private areas. The public areas are open to anyone and provide general information on the course and biotechnology as well as links to other biotechnology sites. Private areas are protected by passwords and are accessible only to registered students. The private areas contain class lecture notes and pages for each group’s case studies. Within each group’s case study page are sections for posting and reading messages.

Each instructor provides their lecture in a Microsoft PowerPoint file. The file has been converted to HTML with Microsoft’s conversion utility. The web form of the lecture is identical to the lecture presented in class. On-line class notes are a supplement to both traditional and distance students.

Case Studies

Case studies present a biotechnology topic such as: the acceptance of gene-altered plants, animal versus human rights in a famine situation and the use of bovine somatotrophin to enhance milk production in cows. Throughout the case study, questions are presented. Students discuss the case, their opinions and how they would develop a research program to find answers to the questions. Each group has a web page for posting notes and messages. One member of the group takes notes during the discussion. Remote students use the same message page to submit their comments. These are often especially well received by the group because they are fresh ideas not influenced by the group discussion. The messages are not live. That is, the submission of a message is not immediately available to other group members. We hope to include this capability next year.

Presentations

After the groups have studied a case, they present their findings to the rest of the class. While distance students cannot currently participate in the actual presentation they can provide materials for the presentation. We hope to allow distance students to participate in presentations next year by asking groups to present their work on a web page. Students will be trained in basic hypertext markup language (HTML). They will then work together to create a public web page.

Problems

One of the major obstacles in teaching the course was the classroom itself. The studio is designed for the videotaping of lectures and is not at all suited for PBL group work. For instance, network connections were located at the front of the classroom away from student seating.

Students were unable to move their chairs to work together. One solution would be to hold group work sessions in a different classroom, but we wanted to include the group discussions as well as lectures on videotape. Next year, the class will be taught in a traditional classroom. Special network connections will be added to allow groups to work together on-line.

The technical skills of groups differed. Those groups with a proficient computer user tended to make more information available to their distance group members. This magnified the variation of the experience of e distance students. Distance students required more computer and network expertise as they were required to connect to the web site and use the message center without any direct instruction. Of the four distance students taking the course in the first year, two dropped because they did not have ready access to the Internet. The other two had connections at their work place and, after some initial difficulties, were able to communicate with the other group members.

Passwords, implemented with Basic HTTP authentication, were used to protect class materials. For instance, some materials provided as background for case studies were copied from books or magazines. The material’s use in the class is legal under the fair use act. But it is not legal and certainly not appropriate to make this information openly available on the web. Passwords were also used to keep each group’s work separate. PBL experiences are created by the exchange of information in the group. Two groups studying the same case will take entirely different paths to their solution. Different passwords were used for each group and each case study. One drawback was that the passwords often proved difficult for students to remember.

Solutions for the Future

We found it was necessary to purchase a faster web server. A Sun Sparc Ultra I will replace the currently used Sun Sparc IPX. The new system, scheduled to go on-line Spring 1997, will speed up response time and provide more capacity for web material. Next year we will introduce an automated posting mechanism so messages, once submitted, will be immediately available to the group. We are experimenting with Common Gateway Interface (CGI) and Perl scripts as well as Java applications for implementation.

We plan to improve case study presentation by including links to other sources of information. Next year each group project will be presented on the web. Traditional students will work with distance students on an equal basis. Final projects will be accessible on the public pages of the class web site and will provide a forum for public education in biotechnology. As an added bonus, students aware that their work will be available on the web to the public will have more incentive to produce quality presentations.

Other innovations such as live “chat room” session will depend on the capabilities of the distance students. If the
distance students are available to participate during class
hours and have access to high speed network connection,
we may implement them. Otherwise, the current system
should be adequate.

Conclusions

Problem based learning and distance learning can be
combined. For the motivated student, the result is a rich
and valuable learning experience. I encourage you to visit

A VIRTUAL SCHOOLHOUSE

John Leddo
Research Development Corporation

With the federal administration's plan to have all schools connected to the Internet by the year 2000, it is expected that "cyberspace" will play an integral role in classrooms of the future. Initiatives to accomplish this are underway. However, connecting schools to the Internet is only part of the challenge. Another part is to provide teachers and students with resources they can use in the classroom. As the amount of content available over the Internet multiplies, there will be an increasing need for teachers to find places where they can conduct "one stop shopping" to obtain educational materials. We cannot expect teachers to spend the time "surfing" the net and weeding through countless material to find the subset that will be useful to them. The present paper describes a "virtual schoolhouse" which Research Development Corporation (RDC) is developing to serve teachers and students. The virtual schoolhouse is designed to be a repository of resources that would normally be found in a physical schoolhouse, but without the constraint that they be located within the school. The virtual schoolhouse is designed to have, among other things, a virtual library of educational materials, a chat room for teachers to discuss issues in education, a virtual lecture hall where teachers can attend colloquia at a distance, and a resource center where tutoring systems, virtual laboratories, and other teaching aides reside for student use.

It is expected that the Internet will play an important role in the future of education. According to the U.S. Department of Education's National Center for Education Statistics, as of 1995, 50% of U.S. schools had Internet access already. Another 40% were planning to obtain Internet access. New educational content is created and added to the Internet daily.

As this proliferation of Internet resources continues, with anyone being allowed both to create and use content, we must not lose sight of two objectives: (1) there must be organization to the material available, and (2) there must be quality control. One cannot simply send students and teachers into cyberspace and hope that they will find educational material that is both relevant and of high quality. Even the advent of web browsers is insufficient. For example, as an experiment, we entered the topic "high school science" in a popular web search engine. It returned approximately 1,000,000 matches. We then focused the search on "high school physics". A full 400,000 matches were found. The search was focused even more on "Newton's Laws". This produced a match of 10,000 responses.

We argue that such numbers will only increase as more and more people add content to the world wide web. If a topic as specific as Newton's Laws, which is a reasonable topic scope to develop lesson plans around, can produce 10,000 matches, can we really expect teachers to have the time to search through even a fraction of these to sift out the high quality content and examples that may be useful to aid them in class?

We do not believe teachers will spend the time surfing the information superhighway looking for educational content. What is needed are organized resources in cyberspace much the way there are organized resources such as libraries, research centers and schoolhouses in physical space. These organized resources would be places on the Internet where teachers and students could go for "one-stop-shopping" and gain access to materials and activities relevant to their teaching objectives.

A Virtual Schoolhouse

Research Development Corporation is currently developing a virtual schoolhouse. The goal of the virtual schoolhouse is to be a repository of educational resources for students and teachers. These could be in the form of educational research articles, curriculum materials, educational games, simulated laboratories and forums for exchange of ideas. The goal is to provide the same types of resources found in an actual schoolhouse, but without the constraint that educational resources, students, and teachers be collocated at the same place at the same time.

When completed, the virtual schoolhouse will have the following components. First, there will be a virtual library where teachers and students can read educational research findings, commentary and other relevant educational publications. The virtual library will be a place where
teachers can post and download curriculum materials so that these can be shared by all teachers.

Second, there will be a chat room, where teachers can discuss educational issues in real time. The goal of this is to give teachers access to a wider range of professionals than they might find within their own schoolhouse. In our previous research (Leddo, 1995), we found that one of the biggest needs cited by teachers for their own professional development is more interaction with other teachers and related professionals.

Third, there will be a lecture hall where teachers and students can attend, at a distance, professional development lectures. We envision both real time and asynchronous modes of presentations in three forms of presentation: text, audio and video. In cases where presentations are real time, we envision teachers and students having the opportunity for “live” question and answer sessions with the presenter. Where presentations are done asynchronously (i.e., prepared ahead of time and broadcast at specified times), teachers would either have to e-mail their questions in advance or send them after the presentation for subsequent response.

Fourth, there will be a resource room that contains educational technology. These could be in the form of tutorials, simulations, games, automated assessments, etc. Here, students and teachers alike (although the emphasis is on students) can engage in educational activities that provide instruction embedded within them. These technologies have a common theme in that they contain intelligent tutoring system technology (cf. Greer, 1995). An intelligent tutoring system (ITS) is an instructional program that contains a model of what needs to be learned, how to teach it and of the student’s problem solving knowledge. The ITS then tailors instruction to the needs of the individual student.

One of the advantages we hope to realize in the virtual schoolhouse over the way cyberspace currently exists is to embed “intelligence” into the environment. By intelligence, we mean have the schoolhouse appear to have the same “user-friendly” characteristics that a real schoolhouse might have. For example, in a real library, there is a reference librarian who is not only knowledgeable about the resources available in the library but is skilled at eliciting from the patron what his or her needs are so that s/he can be directed to the right resources. As we argued earlier, we do not expect teachers to use cyberspace unless it is easy. Having a virtual reference librarian who can point teachers quickly to the material that is most useful to them is a big step in making a virtual library more valuable.

We now discuss two technologies that we feel will exist to a limited extent in the version that has been developed for Government training.

**Intelligent Agents**

Intelligent agents are software programs that are designed to perform human-like tasks autonomously. For example, one commercially marketed agent observes how a person uses their computer (i.e., what operations s/he normal performs and in what order such as check e-mail, review daily calendar, etc.) and then offers to automate that sequence to save the user time. Another popular use of intelligent agents in cyberspace is to search the Internet for resources that match what a user needs. In our virtual schoolhouse, we see intelligent agents as playing two roles: as an assistant and as a tutor.

Collaborative learning is very popular in education today. The virtual schoolhouse that we are creating is designed to be a distributed environment where students in different locations can communicate in real time and engage in collaborative activities. However, one of the benefits of the virtual schoolhouse is that it is intended to be available at all times. Therefore, there is no guarantee that a student will find a human collaborator to work on a problem with him or her. In such cases, intelligent agents may play a useful role in simulating a human collaborator.

We give two examples of this. We are currently developing an educational game (described in a separate paper, *Internet-based Intelligent Tutoring Games*, in these proceedings) in which a student joins a team of detectives to solve a mystery. Here, the game characters act as co-problem solvers as well as tutors. In this game, the role of the collaborator is largely instructional. The student learns problem solving skills by watching the game characters in action and participating with them. In this capacity, the game characters “assess” the student’s performance by observing behaviors and asking the student questions. Based on this assessment the characters can either proceed with the problem solving activities or pause to give the student remedial instruction.

The second example has been developed for Army leadership training. Here, the agents act as members of the trainee’s team. The trainee is responsible both for directing the team’s problem solving strategy as well as detecting team member mistakes and correcting them. Here, the agents must be programmed to perform a variety of behaviors. First, they must “recognize” the team member commands and be able to carry them out. Second, they must be able to make deliberate errors or adapt their behavior to make teaching points. In the former case, an agent, serving as a team member, might leave another team member unguarded. The team leader must both detect that this has occurred and redirect the agent to avoid the mistake in the future. The agent must be programmed to make this behavioral change. In the latter case, an agent...

are useful to them, but in very “user friendly” ways. We
intelligent agent could be used, for example, in the virtual
learn. If the student needs to know (i.e., has a teaming objective in
versus in text). A good teacher will also vary the way she
approaches and tries to match them to the learning style of
been discussed that can serve as a reference to make new
tries to understand how much the student already knows,
by adjusting the difficulty of the problem or offering a
teaching points.
There is another intriguing application of intelligent
agent technology. Many commercially-available educa-
tional software products emphasize teaching through
presentation of lessons and problem solving. Often people
learn simply by engaging in a dialog with a knowledgeable
source. Here, in the virtual schoolhouse, intelligent agents
can act as virtual teachers to whom students can ask
questions directly. We envision something more advanced
than simply on-line “help.” A good teacher is more than
just simply knowledgeable about her field. A good teacher
tries to understand how much the student already knows,
what level of difficulty they are able to understand material
that can be presented to them, and what topics have already
been discussed that can serve as a reference to make new
points. A good teacher has a variety of pedagogical
approaches and tries to match them to the learning style of
the student (e.g., reasoning by analogy, giving concrete
versus abstract examples, presenting something pictorially
versus in text). A good teacher will also vary the way she
explains something if it appears that the student is not
understanding. Also, a good teacher understands what the
student needs to know (i.e., has a learning objective in
mind) and will often tell the student what s/he needs to
learn even if it is not exactly what they student as asked to
learn.
There is an interesting variant to this. A similar type of
intelligent agent could be used, for example, in the virtual
library to serve as a reference librarian. Such an agent
would serve a similar purpose as a human librarian,
namely, helping students and teachers find resources that
are useful to them, but in very “user friendly” ways. We
envision something far more sophisticated than a search
engine where a person enters a topic and the search engine
looks for matches. As we illustrated in the introduction to
this paper, such search engines may return far too many
matches to be of value to the user. A good reference
librarian spends time to determine the needs of the library
patron. As would be the case with the virtual teacher, this
includes understanding learning objectives (in this case the
patron’s), what the patron already knows, and what level of
material difficulty is appropriate for the patron.
Future work in our virtual schoolhouse will include
these types of intelligent agents. They will be populated in
key areas throughout the schoolhouse. For example, we
envision a general help desk to help new users learn about
the schoolhouse, a virtual librarian to help patrons make
best use of the library resources and virtual laboratory
assistants to help students and teachers use the virtual
simulations as well as gain tutoring in the principles being
taught.

Intelligent Simulations

Another key technology in our virtual schoolhouse is
intelligent simulations. By intelligent simulations, we mean
simulation-based learning environments that not only
model a real or imaginary world (such as a simulated
laboratory or a game), but have teaching mechanisms built
in as an integral part. Both of the environments presented
in the Intelligent Agents section above are examples of
intelligent simulations. The student is allowed to practice
skills in a simulated environment. These environments do
more than simply make the world conform to a set of rules
or principles. Rather, the environments themselves perform
assessments of student learning, have implicit learning
objectives encoded within the activities, and update events
to help insure that the activities and outcomes make
teaching points.

We distinguish a typical simulation from an intelligent
simulation by example. In a typical simulation, a student
may repeat the same mistake over and over and the
simulation will continue running the same way. An
intelligent simulation would respond to the same situation
by adjusting the difficulty of the problem or offering a
tutorial tailored to the student’s needs. A typical simulation
treats every student the same way, i.e., is blind to the
characteristics or needs of the individual student. An
intelligent simulation assesses the needs and learning styles
of each individual student and tailors instructional content
and format accordingly.

There are several types of intelligent simulations that
would be useful to have in the virtual schoolhouse. First, as
we discussed in the previous section, games could serve as
both an opportunity for students to have recreation while
visiting the virtual schoolhouse as well as receive instruc-
tion while playing. In this way, learning becomes a fun
experience.

Second, virtual laboratories can be constructed as a
cost-effective alternative to real ones. By combining
simulated experiments, offering chat and lecture sessions
with real world science and including current research
reports in the virtual library, we can recreate the features of a research center that real world scientists work at. Intelligent simulations would allow students to develop and test hypotheses or models they have regarding domains of science or related fields. For example, in chemistry, the student could "experiment" with creating different chemical compounds and exploring their properties. This would be both cheaper and safer than using a real laboratory. By including an intelligent agent as a virtual scientist, the student would have the benefit of engaging both in exploratory learning and guided learning.

Third, students can use intelligent simulations to pay "virtual visits" to areas of educational interest. These could either be geographical places such as countries or ecosystems they are studying or even different points in time and (outer) space. Such a virtual visit would be much more informative and engaging than reading a textbook description with accompanying pictures as students would be more immersed in a richer environment. Again, intelligent agents could be used either to portray human and non-human characters that are appropriate for that environment or to serve as a virtual tour guide to guide the students through the environment. The virtual tour guide would have similar properties to the virtual librarian in that it would have learning objectives, an awareness of teaching methods, and the ability to assess student learning needs.

We have created our own intelligent simulations through a combination of simulation and intelligent tutoring system technologies. We embed intelligent tutoring system technology into simulations by first constructing an expert model of the subject matter to be taught in the environment. This is indexed by teaching objectives which are then tied to specific simulation scenarios. For example, if the subject matter were Newton's Laws of Physics, then these would be tied to specified virtual experiments that could be run in the virtual laboratory.

We then develop a mechanism for recording student behavior within the simulation. Because students in an exploratory environment can find many acceptable ways to solve a problem, we are not looking for any one particular "right answer." Rather, our expert model looks for what constraints there are on an acceptable solution. For example, in our intelligent tutoring game, students are asked to solve cases using the scientific method. While it is not particularly important in which order they may gather evidence, there are constraints on what evidence is considered sufficient to confirm the hypothesis about who the criminal is and rule out that other suspects may have also committed the crime. Therefore, the intelligent tutoring component looks for whether appropriate evidence has been collected, not the order in which that evidence was collected (there would be too many acceptable permutations of this to enumerate and encode them all). There are some cases where procedures must be carried out in fixed order (e.g., data cannot be analyzed until it has been collected). In those cases, procedural constraints are imposed on the steps that can be taken.

While the student is progressing through the simulation, the intelligent tutoring system is evaluating student actions against its own internal expert model. The expert model is trying to determine the logical outcomes of the student's actions. For example, it may expect that in order for a student to "prove" the guilt of a suspect, s/he must both find incriminating evidence for the suspect and demonstrate that an alternative suspect is innocent. If the student is focusing only on the first suspect and is ignoring the other, then the tutor may realize that the student is violating the learning objective. One possible form of remediation would be to change the culprit in real time and have it turn out that the alternative suspect is really guilty. This could be operationalized by having the tutor plant incriminating evidence (such as the stolen goods) in the alternative suspect's house.

These examples illustrate the power of intelligent simulations to deliver rich learning experiences to students while allowing them to experience widespread access. There is one final opportunity for students to realize within this virtual simulation experience. We are currently developing distributed intelligent simulations that allow multiple students to learn with in real time regardless of their locations. We discussed earlier a simulation for the Army in which a student can practice leadership skills while intelligent agents serve as the collaborators. These agents have a "switch" that allows them to be overridden by a human participant. In other words, one student could be training in the environment. A second student may decide to join the simulation in progress. At this point, the second student assumes the role of one of the agent. The simulation transfers control of that agent from the system to the second student. The student can then direct that agent's behavior, thereby creating a collaborative environment between the two students and the remaining agents. Finally, when one of the students is ready to leave, s/he returns control of the agent to the system.

**Summary**

We see the virtual schoolhouse as a powerful resource for teachers and students. It allows them access to colleagues, mentors, materials and tutorials without the traditional physical limitations which requires that these resources be temporally and spatially collocated with the user. The strength of the virtual schoolhouse is that it represents an integration of technologies, as well as, an integration of resources brought together in one easily accessible location. We hope that paradigms such as our virtual schoolhouse will aid in the transfer of technological
and other societal resources to physical schoolhouses from which they have traditionally been isolated.

At the University of Texas at El Paso (UTEP), the typical university graduate education classroom runs the gamut between two extremes — a lecture presentation by the professor, to a setting where students engage in collaborative learning with the professor. In the lecture class, the professor does nearly all of the work as the students faithfully take notes and asks questions from time to time. In the collaborative context, the professor organizes the syllabus, mentors the students, and helps them maintain focus, but rarely lectures. In both situations, there is often a sprinkling of technology — an overhead projector, a VCR and TV screen, an audiocassette player, a LCD panel tied to a computer, or any combination of the above.

Whether at the extremes or somewhere in between, the campus graduate class is usually professor-motivated and driven and is dependent upon activities that occur in a classroom. The students and professor are committed in time and place. There are scheduled weekly hours and an assigned location for class meetings. While limited absences are allowed, they are strongly discouraged.

The Distance Learning Virtual Classroom

Last year, Walden University began a Master of Science (MS) program in Educational Change and Technology Innovation taught in a distance learning style. Course delivery occurs on the Internet, utilizing America OnLine (AOL) as the service provider. AOL gives Walden access to the Electronic University Network (EUN) and its virtual university settings. Most instruction is handled through a Bulletin Board System (BBS) on which students and teachers exchange postings in a delayed-discussion format. The BBS is partitioned into five areas: 1.) the course description, 2.) the course syllabus, 3.) the lecture and discussion area, 4.) a place for posting and clarifying assignments, and 5.) an area for special projects such as the final course paper. It is in these areas that most of the course activity takes place.

Special communications requiring privacy (such as exams, quizzes, and individual feedback on grades) are handled on AOL e-mail, on the telephone, or by snail-mail. Each professor is expected to call all assigned students prior to the beginning of their course. The purpose of the call is to welcome the student to the course, establish rapport and answer any questions about the syllabus or course material and to exchange other vital information.

The Walden Distance Learning Online Classroom

Student Populations

Walden’s students are drawn from all over the country. In fact, during the first course, one student was working in an American school in Egypt. There is a wide diversity in student age. Many students have delayed taking a master’s degree because of conflict with family, job, travel, and a variety of other needs. There is also great diversity in cultural and socioeconomic background, as well as personal interests, life experiences, technology skills, and educational levels. Some students are taking the program as a second master’s degree because of its strong emphasis on technology and educational change. Others are hoping to improve both their knowledge and their job performance. Still others aspire to find new jobs through the degree. Students find the flexibility of distance learning attractive. It is time-flexible with only a broad tie to specific time commitments, usually on a week-to-week basis. And there is no real commitment to place. Students can participate wherever they can access AOL.

Course Structure and Syllabus

A distance learning course needs to be more highly structured up front than a conventional university course. The syllabus for distance learning must be much more detailed and include weekly discussion topics, activities, and assignments — all clearly spelled out. Assignments are made for each of the twelve weeks which allows students a
full week to respond and to interact with the responses of other students. This one week time-span gives students the opportunity to reflect and encourages thoughtful answers, discussions, and interaction. Students may also engage in a "conversational mode" during which they may interact spontaneously, thus improving the ability to think on their feet. By the end of the course, the students and professor have constructed and shared knowledge.

Expectations for Teachers

Teachers in distance learning classes are expected to be familiar with distance learning methods and delivery systems and to be knowledgeable in technological areas. They are also expected to maintain high levels of interactivity with students using highly developed facilitative, coaching, and mentoring skills. A caring attitude toward students and deep concern for student learning are essential.

Expectations for Students

Students are expected to be comfortable with the technologies used. Admission criteria include testing of communication skills to ascertain that the reading and writing skills of students function at a high level. In addition to self-directed learning skills, students need the ability to interpret and find applications for assigned reading, utilize related research, and critique the work of other students. It also helps if they are able to work both independently and as contributing members of a group.

Time Use and Commitments

Participants in distance learning are generally able to choose their own time commitments within the parameters of the weekly assignments and the constraints of spontaneous group online discussions. There are some students who like to move ahead, posting several weeks at a time. This is particularly helpful if they are contemplating some sort of travel or work assignment which will make it hard for them to hold firmly to the weekly schedule. The challenge, of course, is to keep up rather than let the work pile up. In general, professors who teach both conventional and distance learning courses feel that planning, presentation, mentoring, and general follow-up take more time than that demanded by the conventional classroom.

Relationships

Most of the time, there is only indirect student-to-student and student-to-teacher contact. Working at a distance by computer is impersonal by definition and can be partially personalized only by special effort. There must be constant and caring communication and interaction and strong sensitivity to diverse cultural and thinking patterns. Success is dependent upon the building of knowledge between and among students and teacher.

Testing and Grading

Assessment in online distance learning require different measures of student productivity, especially to assure originality of work. Self-assessment against clearly established standards and expectations is essential. There is a heavy leaning away from true/false and multiple choice models and toward responding through essays. One measure of student progress is to look at how writing, thinking, and debate skills have developed during the quarter. At this time, grading is quite conventional (A-F) with provision for an I (Incomplete) that can be sustained for no longer than one quarter.

Benefits

The most obvious benefits of distance learning are those of taking courses almost anywhere or doing coursework almost anytime it is convenient. Other benefits include an emphasis on the development of reading, writing, thinking, and technology skills. Professors learn from and with the students. There can be many cost-savings, including a major saving for facilities. Travel to learning locations is minimized, as is travel for research, much of which can be done online. Access to other cultures and languages are only two of the myriad possibilities for networking on a much broader scale than in the conventional classroom.

Frustrations

Technology breakdowns and service provider overloads must be the number one frustration of distance learning by computer. Delayed feedback from teacher and students can be another frustration, especially for students who tend to move more quickly than the rest of the class. Some students find frustration in the lack of live, face-to-face and the chance to "emote" with colleagues. For the most part, however, benefits far outweigh frustrations in the distance mode.

Staff Development and International Applications

Staff Development

It takes a team rather than a single professor to facilitate the successful completion of a distance learning course. In addition to the professor, a program director oversees course logistics; in-house technology consultants answer the hard questions about online communication within Walden; student advisors see to the acquisition of materials and timeliness of completing assignments; and EUN technology consultants help with the "big" problems involving the medium. Team members must share a vision of what distance education can do. The staff needs continual training in technology use and satellite-based instruction, constant strengthening of feedback skills and interpersonal communication skills, instructional support for experimentation, and ongoing peer support and inter-change of ideas.
Applications in the International Forum

Distance learning can help students abroad. One of the downside of accepting a teaching job in another part of the world is the difficulty of finding graduate degree programs taught in English, especially if the teacher intends to move from to job every couple of years. Distance education programs can also help the foreign student who wants a graduate degree from an American university, but who cannot leave either country or family.

Summary

The campus-based graduate program at UTEP is designed to serve the needs of a binational population on the Mexican/American border. Yet participation is often restricted by commuting problems and job demands which conflict with campus-based time and place requirement. Online distance education programs could expand graduate degree opportunities for those unable to take advantage of conventional programs.

From telephones, airplanes, and television, to fax machines and telecommunication, technology has virtually eliminated time and distance as barriers to interpersonal communication. Accompanying our global interdependence and interrelationships is the diversification of national populations. In turn, national demographic diversity has led to a growing interest in multicultural education and the education of diverse learners.

It is not unnatural to bring together technology and diversity. Both are compelling and incipient fields for pedagogical investigation, reflection, and application. As educational applications of technology expand, educators ponder how to take advantage of its capabilities to attain multicultural goals. Similarly, as more computers appear in schools, more teachers and students gain access to them. Educators recognize the importance of meeting the needs of learners who differ in experiences, knowledge, values, language, and world view. Thus, we must deliberate on how to equitably and effectively use technology with an increasingly diverse student population.

The papers in this Diversity Section address the integration of technology both in preparing multicultural teachers, as well as in educating culturally diverse student populations. Although each paper makes a unique contribution to the fields of diversity and educational technology, there are several themes that connect some papers.

Barber-Freeman, at Mississippi State, and Ford, Dobyns, and Poe, all at the University of Southwestern Louisiana, focus on applications of technology to content-area instruction of diverse learners. Barber-Freeman addresses the use of cooperative learning and technology in preservice teacher education to enhance the mathematical experiences of African American females. This author also examines cultural differences and learning styles as factors influencing academic performance in traditional classrooms. Ford, Dobyns, and Poe look at the multicultural applications of telecommunications and literature in social studies instruction for the gifted. This paper describes a collaborative project between the university and a middle school enrichment program with a heterogenous student population. Both papers provide valuable background information and report on on-going studies to enrich and strengthen learning experiences.

The next three papers concentrate on distance applications of technology. Dickey and Kolloff share their experiences at Eastern Kentucky University as distance education instructors. They describe the model used for distance learning, the program elements, and ideas for presentation, organization and interaction. These authors provide concrete suggestions based on their personal experiences. The paper by Smith takes a slightly different approach. This author presents a collaborative program at St. Mary's University that brings together preservice teachers with pairs of elementary children in using the World Wide Webb. In this project, college and elementary students worked together to locate information centered around specific social studies thematic units. Both groups of learners benefited from the hands-on experience. Pinneli, at the University of Lecce, highlights the philosophical and pedagogical rationale for using Bulletin Board Systems in preparing multicultural educators at her institution in Italy. This paper offers teacher educators some thought-provoking propositions, as well as personal experiences in the use of telecommunications for teacher preparation. Together, these three papers offer valuable insight into the educational possibilities, potential pitfalls, and distinct advantages of telecommunications.

The last two papers directly address technology integration for multicultural education. In her paper, Allen provides several strategies for integrating technology in a graduate level course on Multicultural Education at the University of Central Florida. These strategies include the use of email, web chat sites, presentation graphics, and internet searches. Each strategy includes hands-on learning, modeling, and guided practice. Chisholm introduces and defines six criteria for the integration of technology in multicultural classrooms. The author provides examples of each criteria gleaned from instructional units created by inservice teachers.

These papers are indicative of the multicultural applications of computers both in teacher education and in the education of our children. As the Disney song reminds us,
“it’s a small world after all” and, as Pinneli suggests, technology has made the global village a virtual reality. The papers in this section represent the effort to connect teachers and their students with world beyond their classroom, as well as to provide all learners with the opportunity to attain academic success through equitable use of technology. Though there remain many unanswered questions and many avenues yet to be explored, the possibilities are exciting and the need for knowledge in these areas is urgent.

Inés Márquez Chisholm is an Assistant Professor of Bilingual and Multicultural Education in the College of Education at Arizona State University West. She is interested in the cultural underpinning of technology applications and in the preparation of culturally and technologically competent teachers.

The mainstream model of education neglects female students because their learning styles do not coincide with individual and competitive learning environments. Mathematics language, its discourse mode, and classroom dynamics are opposite to the way females are taught to interact and communicate (Hanson, 1992). Independence is a quality that society discourages in females but promote in males. Consequently, school girls tend to be more dependent on others instead of being self-reliant (Mann, 1994). Women feel uncomfortable and excluded in a classroom structure that is designed to foster independent, non-collaborative thinking. Females prefer to use a conversational style format in classrooms that foster group consensus and builds ideas on top of each other where the interrelationship of thoughts and actions is paramount (Schwartz, Hanson, 1992). In addition, there is a continuous national concern about the apparent lack of mathematics achievement by females and by the lack of involvement of women in math and science related careers. Specifically, women of color are the most underrepresented group in mathematics and science (Catsambis, 1994).

A crucial step toward correcting the educational inequities is to identify and examine differences publicly and to develop reform agendas that promote educational equity in order to close the ethnic and gender achievement. Martin R. Delaney, the great nineteenth century African American nationalist, identified an important reality when he stated, “To know the conditions of a people, it is only necessary to know the condition of their women.” The study of the conditions of African American females includes knowing and understanding their learning in order to implement instructional strategies that will promote participation of people of color in areas of mathematics, science, and technology.

In 1992, the American Association of University Women (AAUW) published an article How Schools Shortchange Girls. This report highlighted all aspects of education concerning the disparity of educational experiences between males and females. One critical component of this examination focused on classroom interactions - teacher/student and student/student. Through all levels of education, preschool to university, the study found that males demand and receive more attention from teachers than females - particularly true for mathematics and science classes. Consequently, this article prompted considerable attention towards discourse styles in classrooms that overlook females.

America 2000 is a project that places emphasis on national achievement of females in math and science in order to increase the number of women in mathematics and science related careers. Researchers of this project performed an international study using twelfth grade females from fifteen countries. The results indicated that, except in three countries (i.e., Thailand, British-Columbia, and England) mathematical achievement levels were lower for all females’ than for males. The meta-analysis, summary of recent studies of gender differences in quantitative tasks, of Freidman substantiates that it is not the female student, but rather the classroom and social structure that limits females active involvement and achievement in mathematics (Hanson, 1992).

Nationally, there is a poor retention rate of women, especially African American, in mathematics and science. Whitney Ransome, a participant in the National Coalition of Girls’ Schools, believes that poor retention rates for women in math and science are directly related to inhospitable teaching techniques and classroom environment (Mann, 1994). The “a typical classroom” model is individualized and non-collaborative instruction (Hanson, 1992); however, African American females are field-dependent learners (White, 1992). In addition, field-dependency directly relates to cooperative learning (Hanson, 1992; Farivar, 1992).
African Americans Females
Achievement in Mathematics

African-American students need a proactive learning environment to have academic success. A study that used 758 African-American students from Howard University confirmed that a large percentage of African-Americans fell into the extroverted category. Simultaneously, most African-American students are field dependent. According to White (1992), field-dependent learners enjoy working with others to achieve a common goal. However, research shows students who are field-independent, which is not the modality of teachers, receive higher grades (White, 1992).

Research discloses that our educational system is not meeting the needs of various ethnic groups and females. For instance, females and males enter the educational arena roughly equal in measured academic ability. However, twelve years later, females have fallen behind their male counterparts in key areas such as higher-level mathematics and self-esteem in mathematics application (American Association of University Women Report, 1992). Further research shows that the proficiency gap for ethnically diverse groups, specifically African Americans, widens at the upper grade levels (NSF, 1990).

Cooperative Learning and Female Achievement in Mathematics

"Cooperative learning classrooms have been found to be superior to individualistic and competitive classrooms in promoting individual achievement, positive social relationships, and higher self-esteem" (Nidhi, 1991). In a gender-related study involving Lego TC, females' interest and achievement increased when groups were structured to integrate females and males into team projects (Hanson, 1992). Cooperative learning is an instructional methodology in which students work together in small, usually heterogeneous, groups on a single task or towards a single goal which often results with a group reward (Farivar, 1992).

Research shows that the enjoyment of mathematics activities, the level of engagement or time on task increases, and an overall positive affective reaction towards cooperative mathematics activities (Bono 1991). Research shows that females learn better when they work together to solve a problem (Mann, 1994). Gilligan and Belenky stated that females are commonly known to utilize a "connectivist" mode of thinking (Hanson, 1992). A 1977 study researched by McMillan concluded that women in small groups produced more modal productions (Hanson, 1992).

Cooperative learning enhances academic achievement by having students work in teams to clarify concepts and solve problems (Markstein & Posner, 1994). Through numerous studies, it has been determined that females prefer more student centered and cooperative classrooms (Moffat, 1992). A 1977 study researched by McMillian concluded that women in small groups produced more model constructions (Hanson, 1992).

Impact of Technology and Cooperative Learning with Females

To close the gap between males' and females' achievement in mathematics, efforts must be intensified to see that females receive equal, effective education as males (Hanson, 1992). It is imperative that discourse in mathematics classrooms be changed in order for females to have greater achievement in mathematics. If our students are going to be competitive during the upcoming century within a complex society where mathematics, science, and technology play an important role, it will be imperative for them to improve their problem-solving skills and mathematics, science, and technology literacy. Borasi asked the question that will begin the process of solving females underrepresentation and underachievement in mathematics: "How can school mathematics be changed in order to become more appealing to women and better accommodate their thinking and learning style?" (Hanson, 1992). Integrating computer applications provide opportunities to create real-life situations, hands-on opportunities, and provides equitable educational opportunities for the field-dependent learner.

Description of Study

The researcher implemented cooperative learning as an instructional methodology in which preservice students in a methods course worked together in small, usually heterogeneous groups on a single task or towards a single goal in the computer laboratory. There are several types of small group methods. They include: Group Investigation (GI), Co-op Co-op, Finding Out/Descubrimiento, The Structural Approach, Learning Together, Team Assisted Individualization (TAI), Cooperative Integrated Reading and Composition (CIRC), Student Teams—Achievement Division (STAD), Teams-Games-Tournament (TGT), and Jigsaw II. However, for the purpose of this study, it is only necessary to define Learning Together (Johnsons' Method). This strategy emphasizes positive interdependence, direct teaching of interpersonal and group skills, face to face interaction, and individual accountability. All students must perceive in order for a group to be successful - "We sink or swim together" (Johnson & Johnson, 1994; Thousand, Villa, & Nevin, 1994; Slavin, 1986). Students were introduced to the computer using the Learning Together method. They were required to join several lists serves, to interact with the instructor and their peers, explore the web and submit assignments via e-mail.

Data Organization

The number of mathematics education majors at Mississippi State University is small; therefore, the Secondary Mathematics Methods Course is taught during the fall semester only. There were thirteen students enrolled in the methods course during the 1995 fall semester. This was the
first semester that more than one African American female was enrolled in the course. In fact there were four African American females in the class. However, expected number of subjects at the completion of study will be 30-35 students, because the course is currently being offered during the year. Since thirty (30) is the recommended sample size, the extra five subjects are to ensure an adequate sample in case of unforeseen loss of subjects. Each subject was assigned a computer and unlimited use of the computer along with a Mississippi State University (MSU) account.

**Analysis of Data and Results**

The preliminary results of this study showed that African American females interacted more when permitted to assist in the structuring of the lessons; incorporated learning resources (manipulatives and computer) at their respective schools. The study also showed that African American females interacted (e-mail) with the professor more that the other students enrolled in the methods course. Figure 1 illustrates the interaction of mathematics students with the professor via e-mail. Students were required to interact a certain number of times with the professor; however, this illustration shows that forty-three percent of African American females interacted with the professor. Also, thirty-nine percent of European American females exceeded the required amount of internet communication. Whereas, only eighteen percent of European American Males interacted with the instructor.

![Figure 1. Interaction of Math Students with Instructor via E-mail.](image)

**Implications**

Upon reviewing the literature, it was evident that there has not been a single study conducted on African American females achievement of mathematics when instructed through cooperative learning using technology as opposed to being instructed by the traditional method. As a result, the information generated from this study will be a significant addition to the knowledge base of the educational world. Also, results could confirm information from previous studies on the use of cooperative learning using technology.

Despite the fact that issues surrounding the education of females within various ethnic groups in the United States have been highly controversial and emotionally charged for almost twenty years, there still appears to be little consensus among policy-makers and educators about what organizational and educational programs, teaching, and hiring practices are appropriate. Emphasis must be placed on the importance of increasing the number of ethnic groups in mathematics, science, and technological areas that are underrepresented by various ethnic groups, specifically African Americans.

**Applications**

Einstein is noted as saying "...out of fear comes creativity." Many educators are fearful of diversity; yet, other educators have developed programs which were preceded by fear and or diversity (Baruth & Manning, 1992). For instance, when "at-risk" children were identified, the educational system academically developed effective programs which addressed the needs of all students (educated and mis-educated). Respectively, the Civil Rights and women's movements ushered in policies which addressed racial and sexual inequalities and harassment following much public fear and misunderstanding. Therefore, the planning and implementation of programs that promote the acceptance and respect of diversity will continue to be issues facing educators in the twenty-first century.

The results can lead to further studies of African Americans - females and males - in the mathematics, science and technology areas. If the study proves to be successful, educators of study may implement cooperative learning using technology as a major and permanent instruction of mathematics. As time progress, other educators may become interested in using the cooperative learning method. To meet the demand of the educators, the educational institutions would provide the necessary training.

As the nation becomes increasingly aware of the need to enlarge its pool of mathematicians, scientist, and technologists, attention should target African American females. They represent an underdeveloped resource. The most rapidly growing population sector in the United State today is that of the diverse racial and ethnic groups. In order to maintain the nation's human resource needs in all educational areas, it will be imperative to identify and cultivate African Americans and other diverse groups at an earlier age. Research discloses that demographic trends indicate that African Americans represent a younger and faster growing population than do European Americans (Levine, 1989). The increase of diverse ethnic groups will be felt in institutions of higher education. Thus, it is necessary that we begin to examine strategies for increasing the successful achievement of diverse groups within our educational systems.
References

Support for the use of literature in the teaching of social studies is well-documented and long-standing. McGowan, Erickson and Neufeld (1996) note that more than 150 years ago, Johann Friedrich Herbart suggested using literary sources in the study of history as a means of instilling desirable social attitudes in children. They further state that in the past forty years numerous educators have asserted the instructional benefits of literature in teaching social studies (Dahmus, 1956; Dawson, 1965; Norton, 1988). According to Lauritzen and Jaeger (1997), social studies educators suggest that in using historical narratives, students are better able to understand the human condition and specific events if they are “personally linked with the events and characters of the past and present” (p. 39). Advocates of the literature-social studies connection construct a compelling case for this practice by emphasizing instructional benefits in both cognitive and affective domains, as well as highlighting its natural “fit” in the acquisition of knowledge about and understanding of other cultures.

In addressing the cognitive benefits of using literature in the social studies curriculum, and alluding to the power of young adult novels to “encourage student engagement and critical thinking” (p. 227), Bean, Kile, and Readence (1996) report that students read and respond to novels differently than they read and respond to social studies textbooks. Students approach literary accounts “with an open, interpretive stance using their intuition” (p. 227) to figure out that which is implicit in the story. This contrasts sharply to the narrow, focused-on-facts approach students use with social studies texts. In comparing the conceptual understanding of students whose social studies curriculum was textbook-based with students who read selected works of historical fiction rather than the textbooks, Smith (1993) found that students in the literature-based classrooms recalled nearly 60 percent more information than students in the control classroom. Other studies support the claim that students involved in literature-based social studies instruction acquire more concepts and greater conceptual understanding than they do through traditional instruction (Guzzetti, Kowalinski, & McGowan, 1992), and that students in a literature-based social studies classroom become engaged in constructive decision-making about their own learning (Ellis, 1990).

The numerous affective benefits of using literature in the social studies curriculum are immediately apparent to its practitioners, and agreement on this issue is widespread. Among the many aspects of affective growth nurtured through teaching with trade books and recognized by teachers and researchers alike are heightened interest, increased motivation, and deepened understanding (Fassler & Janis, 1985; Michaelis, 1992). Although affective growth is not ordinarily the criterion by which student achievement is measured and reported, feelings of self-competence, constructive attitudes and values, self-motivated learning and self-esteem are closely related to experiences of success (Davis & Rimm, 1994; Silverman, 1993). As a component skill of leadership, Parker (1983) includes interpersonal communication, incorporating self-awareness, concern for others, cooperation, and conflict resolution, all of which are objectives of multicultural education (Michaelis, 1992). Graves states, “Literature is such a humanizing event because so many personal dimensions are present at one time. Children grow to understand the complexities, joys, and wonders of humanity as they act on the world” (1989, p. 779).

The new social studies standards (National Council for the Social Studies, 1994) support a curriculum that fosters multiple perspectives. One method of providing students with broader and deeper exposure to the diversity of human experience is to involve them in exploration of other cultures through literature. Through culturally diverse literary materials, students “examine ideas, issues, personalities, and groups from multiple perspectives” (Kim & Garcia, 1996, p. 208).

Too frequently the only images brought to mind in connection with specific cultures are negative stereotypes. Gay (1994) states that “descriptions and role functions of
Native Americans are translated into negative stereotypic images and used as mascots for... athletic teams" (p. 51). Hernandez (1989) adds that this same kind of stereotyping affects how an individual feels about their own group, culture (p. 26). Gay (1994) quotes Kimball as saying that cultural perspectives and experiences act as “screens through which human potential is filtered, interpreted, and made meaningful” (p. 49). If so, understanding another culture may help to understand one’s own culture.

**Technology and Content Area Instruction**

Technology has allowed the classroom access beyond the traditional textbook. In no subject has this access provided greater potential than social studies. In addition to the vast amount of readily accessible information available through software (i.e., CD-ROM encyclopedias), technology has provided access to computer-mediated communication (Jonassen, 1996). Not only can students access vast amounts of information through Internet resources, but students can utilize networking to work with other students.

Riel (1996) views the Internet as “a place where people can go to meet others with similar interests, build new settlements, share knowledge through teaching and learning, and form communities around common practices” (p. 10). She points out that the classroom in today’s society is constraining in that it “isolates both students and teachers from the experiences that will help them understand the past, develop skills for building a future, and prepare for their role as citizens” (p. 14) but the “best way to reform schools is to lessen the gap between what is learned in school and what is needed in society” (p. 14). Telecommunications is a way to effectively lessen this gap since learning activities become more reality-based (Kearsley, 1993). Computer-mediated communication enhances socialization (Margolies, 1991) as it extends communication beyond face-to-face situations to interaction at national and international levels. Collaborative learning is enhanced (Berge & Collins, 1993) as time constraints are lessened due to the flexibility of access through email.

The use of technology in instruction is supported by the constructivist view of learning. Constructivism maintains that the learners construct their own personal knowledge rather than serve as receptors of knowledge. The construction of their own knowledge makes the knowledge more meaningful. White (1996) addresses three essential components necessary in a constructivist social studies methods class: (a) reflection, (b) active student involvement, and (c) development of a community of learners. Although White addresses these as essential components for pre-service teachers learning how to teach social studies, they are also essential for students who are learning social studies. All three components can be addressed through the use of computer-mediated communications.

Trentin’s (1996) term “telematics” includes computer-mediated communications. He defines the Internet as “a powerful resource for accessing distributed information and interpersonal communication” (p. 98) and indicates that an added value inherent in telematics includes using student’s writing as motivation for communicating their ideas and experiences. Students may propose an idea, support their position, argue their beliefs with a minimum of conflict and often with a degree of anonymity that allows a freer expression of their opinions. Also computer-mediated communications through email and the Internet is a great equalizer (Forcier, 1996) since students can communicate with anyone who has access no matter the racial, the socioeconomic, the political, or the geographical situations. This makes computer-mediated communication “a flexible and productive tool for the classroom teachers” and “provides an inexpensive and immediate means of obtaining and communicating information” (Ryder & Hughes, 1997, p. 53).

**Social Studies Instruction for Gifted Students**

Few would argue that students differ in areas of interest, motivation, and intellectual potential. It is also indisputable that all students, including highly able students, should be provided with educational experiences commensurate with their abilities (Renzulli & Reis, 1985). Definitions of giftedness vary among states and districts, yet educators concur on the types of educational experiences that should be provided to enable these students to work at the level of their highest potential. These include concept learning rather than skill learning, interdisciplinary curriculum, independent learning, the use of higher levels of thinking and experiences that are paced according to the needs of individuals, rather than to a prescribed grade-level sequence (Clark, 1992; Delisle, 1991; Gallagher, 1985). Renzulli (1994) synthesizes these practices as he recommends: “perhaps most important, opportunities for students to exchange traditional roles as lesson-learners and doers-of-exercises for more challenging and demanding roles that require hands-on learning, first-hand investigation, and the application of knowledge and thinking skills to complex problems” (pp. 15-16).

Social studies is considered an appropriate content focus for gifted students because of the common goals that link the fields of social studies education and gifted education, such as encouraging inquiry, critical and creative thinking skills, decision-making skills, investigation of real-problems, and leadership skills (Breitner, 1987; Stewart, 1985).

**Purpose and Procedures**

The project participants will include fifty students in grades 6-8, three teachers and three university faculty...
members. All student participants have been identified as gifted and are enrolled in a middle school enrichment program. The ethnic composition of the student participants is as follows: thirty-seven Caucasian, eleven African-American, one Asian-American, and one Hispanic-American. The students represent all socioeconomic levels.

The purpose of this project is to develop social studies concepts and skills using selected literature and telecommunications. The National Council for Social Studies provides the following definition: “Social studies is the integrated study of the social sciences and humanities to promote civic competence (NCSS, 1994). The project described in this report has been designed in accordance with (a) the thematic strands that are the basis of the new social studies standards and (b) the essential elements for civic competence (NCSS, 1994). Participants will be engaged in concept and skill development from the following thematic strands: (I) Culture; (II) People, Places, and Environments; (III) Individual Development and Identity; and (IV) Global Connections. The objectives of the project include (a) providing opportunities for interaction among students of various cultures through technology; (b) assisting students in learning about populations in other regions of the United States; (c) encouraging interest in the history, geography, politics, and traditions of the cultures studied; and (d) developing research skills using trade books and Internet resources.

A bibliography of selections providing both fiction and nonfiction accounts of Hispanic and Native American cultures in the southwestern United States was developed by university education faculty members. The bibliography, appropriate for high ability middle school students, will be provided to gifted students in the 6th, 7th and 8th grades at a middle school in southwestern Louisiana.

The students will choose their own reading materials from this list. The students will work in cooperative groups, and group composition will be based on interest in reading the same book or author and exploring the same culture. Individual students will keep response journals and annotations of books will be generated by groups and published via an Internet home page. As students read selected books, they will develop questions based on the information gathered during their reading and research into the culture. Each student or group of students, via Internet, will then conduct an interview with a middle school student in the western United States who represents the culture depicted in the selected trade book. The purpose of the online interview is to allow each participating student to learn more about other cultures through interchange of information with an age peer who serves as a primary source.

Results

At the time of this writing the project is in its beginning stages; therefore discussion of results is in terms of a variety of expected student products. As part of the reading of trade books each student will keep a response journal including points of interest to the student along with the student’s corresponding reflections; issues about which the student wishes to know more and potential interview questions. Student-generated annotations of the trade books will be published via an Internet home page, and these annotations will become part of the cultural bibliography provided to students next year as this project is continued. A content analysis of the response journals will be conducted. When students have entered the Internet/interview phase of the project, each will keep a log of time online, and total time online will be examined by student group, by title and author, and by student gender. Students will compare the literary cultural accounts with the cultural perceptions of the interviewed student. Teachers and university faculty will record their observations of behavioral indicators of student interest in the literature and the culture and purposeful engagement with the Internet. As a final assessment of the project all participants will engage in an evaluation session during which students, teachers and university faculty will reflect on the experiential approach to cultural understanding compared to the textbook/didactic approach to learning about other cultures. These results will establish the feasibility of extending the project into the next academic year and expanding it to include other student populations and additional cultures to be investigated.

ENHANCING MULTICULTURAL EDUCATION WITH TECHNOLOGY

Kay W. Allen  
University of Central Florida

The changing demographics of the school population have been a topic of concern among educators at all levels. Professional organizations, reform reports, and accrediting agencies have all called for curriculum change that is inclusive of the cultures that are represented in schools in the United States. There have always been students in our classrooms which we did not see or hear. However, this invisibility is being challenged. “Old silences have been shattered; long repressed voices are making themselves heard” (Greene, 1993, p. 185).

In exploring factors that affect understanding and appreciation of diversity, Ladson-Billings (1991) analyzed the extent of preservice teachers’ knowledge about diversity in the United States. Her findings revealed students lacked basic facts concerning diversity. She concluded that prospective teachers needed to learn not only the basic facts, but needed to engage in substantial exploration of societal inequities. Similarly, King (1991) proposed that teacher education must incorporate multicultural experiences that encourage students to closely examine their attitudes and beliefs about issues related to diversity. The response to this task at institutions of higher education has been to attempt to provide curriculum that better prepares the teachers of tomorrow for the realities of the classroom. The challenge is to provide meaningful change that facilitates students looking honestly at their values and developing the strength to publicly affirm these values. The concept of diversity must become personally relevant and be viewed as essential to effective teaching (Allen, 1995).

Computers are already in the homes of about one third of the American population and in middle class neighborhoods, up to 75% of families own computers. The prediction is that 80% of all families will have home computers by the year 2000 (Debehah & Smith, 1994; Friedman, 1994). Therefore, it is essential that educators be at the forefront of those in our society who have access to, and proficiency with technology.

As technology achieves the status of allowing the transcendency of time and space, the traditional textbook or professional journals in hard copy are no longer the mediums of choice for sharing information related to multicultural education. The traditional printed materials can no longer keep abreast of the rapidly changing world conditions and the knowledge explosion that is a part of our daily experiences. Additionally, the traditional approach to instruction is no longer an effective delivery system to prepare students for dealing with the complex demographics of the schools. Today, instead of reading about a situation in another country, individual can go “on-line” to speak directly with people who are more closely involved in the incident. Today, we can get information and a perspective from people who were previously denied a voice.

Given these circumstances, it is necessary to employ the technological advances to give students in a multicultural education learning environment the opportunities associated with this kind of learning. Appropriately utilizing technological enhancements also provides an environment that is more inclusive of a variety of learning styles.

In this paper, I will share a variety of strategies that are employed in a graduate level course on Multicultural Education. The strategies include using e-mail and web chat sites to engage in direct communication. Students are required to develop group projects and they correspond with each other and with people of other cultures via e-mail. Another strategy is to use appropriate presentation graphics programs in the presentation of their investigative findings related to a cultural investigation/immersion project. Finally, students engage in research based issues dialogue utilizing material gathered from the internet and professional journals. Each of these strategies involves modeling, hands-on training, and guided practice to facilitate the students becoming proficient in the needed skills.

Technology and Communication

There is no doubt that technology has changed and enhanced the ability to communicate with others. One important aspect of this change has been the removal of barriers previously associated with communication. For example, it is now possible to send “letters” that are received instantly. One strategy employed in my multicultural education class is the use of e-mail to communicate among the students and from teacher to student and vice versa. This is particularly beneficial as students work together on group projects. Time and distance barriers are no longer a problem. They can work from their home sites and still work...
together as a group. Another aspect of the communication process is that the students are able to speak directly with people about whom they would have previously only read. This greatly enriches their understanding and appreciation of cultures outside their personal experience. This is accomplished by accessing chat sites. As the students explore the internet and find addresses which provide appropriate opportunities to talk with people in other countries and/or cultures, they share these sites with their classmates.

**Technology and Instruction**

The second strategy that will be discussed is the use of presentation graphics to enhance their cultural presentations. Students are exposed to the use of technology as demonstrated by the teacher. Units of instruction in this class include the use of PowerPoint and HyperStudio. After students have seen the integration of presentation graphics into instruction, they become participants in a workshop designed to teach the use of PowerPoint and other multimedia tools.

**The Steps in this Multiphase Model are:**

1. Observation of the use of presentation graphics and multimedia technology as components of instruction.
2. **Formation of Teams**
   - Each team identifies a culture about which they wish to learn. Teams begin investigation to gain awareness and understanding of the culture for the purpose of being better prepared to teach students of that culture.
   - Students attend a workshop in which they learn how to use presentation graphics and multimedia technology as components of an instructional strategy. Specifically, they learn to make instructional material using PowerPoint or HyperStudio, and how to integrate material from CD ROMs, laser discs, and the internet.
   - Students work in teams to develop an instructional unit of their chosen culture. Into the instructional unit, they integrate the use of presentation graphics and multimedia technology.
   - Each team “teaches” their unit. As the other students participate, they again see the use of presentation graphics and multimedia technology as they gain understanding of another culture.

**Technology and Issues Dialogue**

Multicultural education is a complex and complicated field of study. Banks (1993) developed a model of five dimensions which include: content integration, knowledge construction, prejudice reduction, equity pedagogy, and the empowerment of the school culture and social structure. Expecting educators to successfully implement some of these dimensions requires them to function at complex cognitive levels. Therefore, it is important that they develop these skills as a part of their training.

The issues dialogue is a series of discussions on topics related to diversity in society and specifically in educational settings. The goals of this project are (a) to challenge students to analyze typical habits of mind that many teachers bring to their work, (b) to explore ways in which these attitudes have contributed to the oppression of groups of people and the effects of this oppression, (c) to encourage students to find research that supports and/or refutes the belief systems, and (d) to engage in critical thinking in comparing material from the internet to traditional refereed professional journals.

Through a series of discussions related to assigned readings, the class identifies controversial issues related to diversity in society and schools. This list is narrowed to a manageable number of items. Pairs of students then make a choice of the issue they wish to research. One member takes the “anti” position and the other the “pro” position.

Students are introduced to on-line work and provided with the vocabulary that will facilitate their searching. This is accomplished through modeling and hands-on practice.

Over a two week period, students research their topic both on the internet and in professional journals. They are required to gather, analyze, and categorize their findings. The process of critical thinking is key at this point. They compare the quality of the internet and the professional journal findings. They are asked to consider such things as the source of the material, the research base of the position, the purpose of the writings, etc. For example, an article that has no citations, but which is strictly opinion, would not compare as favorably with an article that gives sound citations to justify various statements.

After this critical process, the students are required to come to class prepared to present their views and provide justification for their positions. While keeping in mind one of our class guidelines that “We will be hard on ideas, but gentle with people,”, we engage in a point/counterpoint type interaction.

Because many students exhibit discomfort with exploring issues such as racial privileging, oppression, and cultural devaluation in schools, this project serves as a way to remove the more personal involvement. Because they are essentially role-playing the positions they take, they are more free to examine attitudes, beliefs, teaching practices, and institutional policies that negatively effect cultural groups in society and schools. As Springhall & Thies-Springhall (1981) noted, placing students in slightly more complex roles with an activity base shifts the learning process form a passive mode to that of an active analyst.

Since the students in the multicultural education class are, for the most part, either practicing or preservice teachers or administrators, they will directly influence a multitude of lives. Much of the future of our society depends on the values and beliefs that they take into their schools. It is
important to remember that education at its best is a process of exploration, of discovery, and ultimately of self-transformation. School is a national institution that more than any other influences the lives of all children. "...school affects how students understand and pursue their life chances" (Grant & Sleeter, 1988, p. 19).

The World Gets Smaller When Our World Gets Bigger

Dorothy R. Smith
St. Mary’s University

The Education Department of Saint Mary’s University, a small liberal arts college in San Antonio, Texas, implements projects that make teacher education a practical program for the development of teachers as life-long learners in a culturally diverse, technologically enriched educational environment. As a member of the Center for Educational Development and Excellence (CEDE), founded in 1992 and funded for three years by the Texas Education Agency, Saint Mary’s focuses on educating professionals skilled in teaching students from a multicultural background, many of whom are considered “at risk” of failure in the elementary and secondary schools in San Antonio. The faculty of Saint Mary’s bring extensive experience to this task, based upon their work with a 10% minority enrollment, many of whom are the first generation to achieve higher education in their families.

The Texas Education Agency’s Long Range Plan for Public Education, 1996-2000, proclaims that all Texas children must have access to a quality education that will enable them to achieve their potential and fully participate, now and in the future, in the social, economic, and educational opportunities of our state and nation. This proclamation presents a challenge to be met by education faculty and all persons involved in the Texas educational process.

The Texas State Board of Education’s plan (1995) estimates that by the turn of the century the number of persons in the state’s labor force will increase by 128% for Hispanics and 35% for African-Americans compared to 6% for whites. The jobs to be filled by these new workers will be knowledge-based, requiring technical skills and a solid foundation of theoretical and applied knowledge.

Students enrolled in Texas schools today will be expected to fill these positions. However, 1994-1995 state test data indicate that only 50 to 60% of the students at any grade level pass all of the tests they take. Economically disadvantaged students in grades 3-8 and 10 achieve 27 percentage points below students who are not at this economic level. Similar disparities are evident when comparing students from various ethnic and racial groups. In an attempt to provide students the opportunity to acquire confidence and skills that will enable them to develop an awareness of the global environment, St. Mary’s developed the following collaborative program.

To meet the goals of increasing students’ confidence and skills, a partnership united forty third grade students from a low performing, inner city school that is in the San Antonio area noted for gang activity; two third grade teachers, an instructional specialist, a principal, twenty-one teacher education students, and the St. Mary’s supervising professor. The college students were enrolled in SS3300 - Essential Elements of the Social Sciences that requires ten hours of a practical teaching experience. The objective of this partnership was to develop problem-solving thematic units incorporating technology. Exploration of the globe via the tele-computing activity structure would provide all students, college and elementary, opportunities to answer theme-related questions that were to be solved using electronic connections. A world-wide tracking map demonstrating communication with other people and places was placed in the school corridor to expand the experiences of students who have had extremely limited global contacts.

We predicted that, through aroused curiosity, student observers currently not involved in the program would become actively involved as they become motivated to expand their awareness of a culturally diverse world.

Social studies was chosen for this project since it is most often neglected by teachers as they focus on “the basic, the important areas, the skills”. Learning magazine (1995) reported that students do not choose social studies as a favorite subject. Editors cited research that suggests it is the way we teach, not what we teach, that sparks interest in a subject.

After our initial project plans received approval, the instructional specialist was surprised to discover that the dedicated phone lines were in place. However, the available Macintosh LC was not adequate and the modem was not functioning. This should not have been unexpected. Handbock (1995) reported that the 1993 census data stated that fifty-two percent of the computers in schools were obsolete. Since no funds were available to rectify the
problem, the specialist submitted a grant proposal to the Texas Education Agency to cover: (a) a TENET account, (b) a computer with adequate capacity for Internet use, (c) a modem, and (d) coverage of phone line costs. This proposal was approved during summer, 1996.

When school began, materials were not in place. Weeks passed with everyone becoming anxious to get started. To accelerate plans, the school children visited the Saint Mary’s Computer Lab. Twenty-one computers were reserved for two hours on the designated day. College students paired with two elementary students and selected a station. The mentor students had previously updated or learned needed skills so they would be able to instruct their young partners. The entire group used WWW to seek information on medieval times. Excitement was evident in every area of the lab as the young visitors found pertinent information and waited patiently for each “precious” bit of knowledge to be printed, even when it took extra time due to the overload on the campus telecommunications operations.

One Pre-service Student Wrote in her Critique of this Experience:

Students also had the opportunity to visit the St. Mary’s campus. During their visit our Social Studies class guided the students through the Internet in the computer lab. The college students guided the students in finding information on castles and medieval subjects. The kids loved it! They were so amazed at all the information that could be accessed at the touch of a finger. They were so excited to see how fast the information printed.

Following this visit, each college student worked ten hours helping the classroom teachers implement the program. Plans had called for six thematic units to be studied throughout the school year. Topics for development were chosen not only to meet state and district grade objectives but followed guidelines identified by Bluemenfeld, Krojeck, Marx, and Soloway (1994). Topics must be feasible, worthwhile, contextualized, and meaningful. These were: (a) investigation of money, (b) medieval times, (c) landmarks, (e) space travel, and (f) motion. The college students had the opportunity to be involved in only two of these, medieval times and landmarks.

These students were fortunate to be able to view realistic application of cooperative groups working to incorporate cross-curriculum problem solving projects into thematic units. This learning style had been chosen since most Hispanic students were thought to prefer environments that are student-centered, include small group and hands-on activities, and provide opportunities to exchange information with peers. (Poiriot & Canales, 1993). Moreover, direct involvement permitted the pre-service students to become aware that the real world differs from that of the text. Developing an integrated curriculum takes much time, effort, and a strong structure with defined parameters. Students become aware of the interrelations of all information. As Eisner (1991) stated, the very term “social studies” suggests an integrated approach.

Using brainstorming techniques, the pre-service students were required to develop graphic organizers illustrating the connections among subjects and based upon relevant and appropriate experiences. These were shared with classmates and retained for sharing with future on-line peers.

Student-generated strategies were:

A. Art:
1. Study types of medieval artwork and artists. Draw a medieval type portrait or picture using medieval style.
2. Create a family shield.
3. Draw and construct a castle.
4. Draw a sketch of medieval homelife.
5. Make costumes of the dress of friars, serfs, etc.
6. Design a stained glass window.
7. Make and decorate ancient paper using glue and brown paper.
8. Construct models of the types of shelter used by people of this period.

B. Language Arts
1. Write a creative story with yourself as a medieval character: knight, squire, peasant, serf, etc. Use new vocabulary appropriate to medieval period.
2. Create a story about a visit to a castle.
3. Write letters to the king and queen.
4. Write a skit using medieval character.
5. Write a paragraph of the steps a man followed to prove his worthiness to become a knight.
6. Write a story describing the difficulties experienced while building a castle.
7. Write an announcement using medieval language or hieroglyphics.
8. Write a letter asking to be rescued from a castle. The letter should be authentic in appearance.
9. Pretend you are living in the medieval period and are writing in your diary.
10. Write a skit about a confrontation between two knights.
11. Write a story about the life of a young girl or boy of the period.
12. Develop a time-line following experiences during one day in the life of a knight.

C. Mathematics
1. Study types of currency. Compare food costs of the medieval era and today.
2. Study measurement through the use of maps and scales.
3. Study taxes in medieval times. Make comparison graphs.
4. Create a kingdom.
5. Make graphs illustrating the time spent hunting, eating, working, etc.
6. Investigate, discuss, and develop problems based on the construction of a castle.
7. Reconstruct the medieval economic system and have students purchase items using this system.
8. Turn word problems into situations utilizing medieval themes.
9. Investigate the quantity and kinds of food needed to feed all the people in the castle.
10. Use a map scale to determine distance from towns to rivers and other villages.

D. Music:
1. Listen to types of medieval music and look at instruments. Make a medieval musical instrument.
2. Create a mandolin and play along with medieval music.
3. Listen to medieval music. Identify instruments.
4. Dress appropriately and dance to medieval music.

E. Reading:
1. Have students research information that connects medieval music and art.
2. Read “Sword in the Stone”. Respond in journal as to how they would remove the sword.
3. Develop a play with kings and castles. Read a book about the medieval period.
4. Analyze role of characters to gain knowledge as to life during the period.
5. Read about Knights of the Round Table, dragons, castles, and King Arthur.
6. Develop a choral reading activity around a specific theme: knights, castles, dragons, etc.
7. Have students read a story of medieval times and recreate the story dramatically.
8. Read medieval stories and have students write different conclusions.
9. Read fiction and non-fiction, analyze characters and plot lines.

F. Science-Technology:
1. Study and illustrate simple machines used in medieval times. Make a simple machine.
2. Investigate how drawbridges operate. (levers and pulleys)
3. Use the computer to locate information about medieval castles, clothing, music, etc.
4. Investigate what resources were available during the medieval period.
5. Investigate inventions of this period.
6. Research catapults, machinery, and weapons used in medieval times.
7. Develop timelines of the impact of the medieval period on history.
8. Investigate the types of plants that were used for food and the irrigation methods used at that time.

Students identified the following programs to be included within their units to enrich planned activities:
1. Surfing the Web
2. Kid Pix - Spinmaker Educational
3. Kidwriter, Kidwriter Gold - Spinmaker Educational
4. Once Upon A Time Vol. II - Compu-Teach
5. Classroom Newspaper Maker - Tom Snyder Productions
6. Kid Works 2 - Davidson
7. The Graph Club with Fizz and Martina - Tom Snyder Productions
8. Time Liner - Tom Snyder Productions
10. National Gallery of Art - Voyager - Laserdisc

After the brainstorming sessions students selected specific objectives to be addressed in their unit plan. Lesson plans included specific content appropriate to the objectives. Following Walmsley’s (1996) suggestions, all plans centered on student- and teacher-generated interests. The instructor scrutinized all activities to assure appropriate depth of knowledge, rather than superficial time-wasters. The instructor regulated the length of the units; however, the education students also self-monitored and adjusted their units. All mentor teachers were encouraged to expand their own knowledge through surfing the Web, CD-ROM, and library usage. Final plans included focus activities, strategies to enrich instruction, independent review materials, and many innovative methods of assessing learning.

At the conclusion of the first unit most pre-service teachers responded positively to the project. For example, one preservice teacher indicated:

We studied castles and helped the students by giving them some ideas on different kinds of castles. The students displayed their finished products in the hallways of the school so that other students could view them. This gave the students a great sense of accomplishment. This was definitely a positive learning experience for them. Overall, any field experience was a positive experience. I learned a lot from the students as well. ___________ is a great school. It is a school I would actually consider teaching at in the future.

A debriefing with the educational specialist produced the following information:
1. E-mail contacts have been initiated with teachers in Australia, Hawaii, and areas in the United States.
2. Service teachers “loved it” because the students were so excited and they learned without feeling pressured.
3. The teachers learned to work as facilitators within a flexible schedule.
4. The teachers plan to continue developing the units. Some have began using their home computers for the first time.
5. Students worked at higher levels than previously observed.
6. Lack of enough time in a day was cited as a negative.
7. All involved in program are eager to share their experiences with others.

The college supervisor noted that pre-service teachers discovered that some experienced teachers were threatened by the use of technology. They find their role is changing from lecturer to facilitators and mediators. They are becoming aware of their need for computer skills as well as an ardent desire to integrate technology into the curriculum if they are to be ready for the 21st century student. Some are finding stumbling blocks in order to prevent implementation. Even the greatest of these, the lack of available time, can be overcome when teachers recognize the extremely positive end-results as desirable.

Each collaborative effort between the teacher education program and elementary students is a new experience. Both groups are learning together and the benefits are tremendous. The experienced teachers learn and review skills and pre-service teachers acquire skills and experiences that will prepare them for their future careers. These people are all truly becoming members of the global society as they share on-line communications with “real people” in near and distant places.

182 — Technology and Teacher Education Annual — 1997
The increasing importance of distance learning in higher education has led many colleges and universities to incorporate distance courses into their education curricula. Distance education refers to teaching and learning situations in which the instructor and the learners are geographically separated and use electronic delivery systems. The role of the student in this process may be referred to as distance learning and the instructor's role may be referred to as distance teaching (Lane, 1992). The use of new delivery systems are changing the roles and behaviors of both instructor and learner. Each must adjust to the model that they choose.

There are many different distance education models. Some models can be described as follows:

**Model A:** Interactive telecommunication technologies are used to extend a classroom-based course to one or more different locations. Students and faculty are required to be in a particular place at a particular time. Class sessions involve synchronous communication.

**Model B:** Students are provided a variety of materials and access to a faculty member who provides guidance. Contact between the student and instructor is achieved by a combination of technologies. Presentation of course content is through print, computer, videotapes or their combination. The students can view course materials at a place and time of their own choosing.

**Model C:** This model is similar to Model B but may be presented to groups of students. These groups of students can come together periodically in a specified location for instructor led class sessions (The Institute for Distance Education, 1996).

Because there are many different applications, purposes and technologies, educators are challenged to carefully plan models of distance education that meet the needs of the student yet still provide a quality academic program. This challenge makes it necessary for instructors and students to become aware of the principles of effective distance learning strategies. Therefore, a description of the experiences from educators and students in the process of distance education could provide valuable information in planning effective distance education programs.

The purpose of this paper is to provide a description of two educators' experiences as distance education instructors. Information will be presented in three parts. First, a description of the distance learning model which was used to deliver two different graduate courses will be presented. The description will include a listing of program elements such as: scheduling, site locations, class size, technical support, staff support, library services and material distribution/delivery. Second, some experiences that the instructors and students had in changing presentation and learning pedagogy will be presented. And, third, experience based application ideas in the areas of presentation, organization and interaction will be listed.

Changes in Presentation and Learning Pedagogy
After interviewing a small group of adult learners,
researchers Sebastion, Egan, Welch & Page (1996) con-
cluded that, "Distance learners value instructors who are
well prepared and organized" (p. 158). They also con-
ducted that distance learners like instructors who displayed such
behaviors as relating to them by looking through the camera
lens, pacing activities well, using humor, and appears to be
comfortable. In order to accomplish many of the valued
characteristics listed above, the instructor and the student
should receive some assistance in the use of equipment and
technologies. Instructors should receive presentation and
material development training. It is also suggested that
students be introduced to equipment and interaction
procedures. After training and introductions to the use of
equipment are completed, instructors and students need to
make changes in their teaching and learning pedagogy so
that each adjusts to the two-way video learning environ-
ment. Examples and descriptions of some areas of change in
pedagogy for distance instructors and learners are provided
below.

Great care must be given to plan for and develop an
interactive environment that is comfortable for the distance
learner. To do this, the instructor and site facilitators must
present an orchestrated effort to use effective classroom
management strategies such as confirming attendance,
distribution of materials, and creating seating arrangements
for small cooperative groups and the viewing of presented
materials.

When planning materials and activities, the instructor
should remember to incorporate all three domains of
learning: cognitive, affective, and psychomotor (Verduin
and Clark, 1991). Content presentation, assignments, and
questioning techniques should incorporate all levels of
cognition. These levels of cognition should range from
knowledge, to comprehension, to synthesis and evaluation.

Viewing the students and/or instructor is often limited
by the television camera operator. Therefore, the instructor
and students need to adjust to interacting with the
individual(s) seen on a monitor. Also, since there is often a
delay in audio delivery, the instructor and the students find
it essential to modify speaking behaviors in a manner that
accommodate this delay.

The instructor and students should prepare and deliver
materials well in advance of a course meeting. These
materials should be well organized, correctly sequenced and
easy to distribute. Color-coding, decorating, stapling
materials often assists students in locating the necessary materials in an efficient manner. Site facilitators should help distribute materials as the instructor concentrates on material presentation. Great care should be taken to focus material development on the main concepts of the course content. In this case the expression “less is more” may be a good idea.

Printed materials that are presented through the document camera should be developed that are bold in font size (36 point font) and color. Document cameras require print materials that are printed in “landscape” to match the format of the television screen. Distance learners appreciate some variation in presentation strategies such as the use of videos, demonstrations, peer commentaries, guest speakers, and the viewing of realia. Materials that are attached to the walls or presented on chalk or white boards are often difficult to see at distant sites.

Distinct verbal or visual cues should be established to begin and end the time of instruction or small group activity. A routine procedure to begin and end class helps the distance learner to recognize important transitions. A visual sign that announces the title of the course, group time, breaks, and/or the end of the class can be broadcast to the site monitors.

Two-way video provides a high-level of interactivity among participants. Questioning may occur between the instructor and learners, or between learners with other learners. Five or six questions may be presented on an overhead slide. Learners may select one to five responses. The instructor may then facilitate the interaction among the learners at the various sites.

Grouping of learners for interaction and/or presentations may involve forming cooperative groups among learners at various sites. On the other hand, grouping may also occur among learners across centers as they choose various topics for presentations. Thus, the learners can be grouped according to topic or issue rather than location. Computer technology such as e-mail or class listservs may facilitate discussion among group members.

Because there are many more elements involved in the learning process during a distance learning experience, the instructor and institution should plan for assessment in more than course instructional design, learning achievement, and instructor effectiveness. The instructor and students should be given the opportunity to provide information about the effectiveness of the technological systems and concerns about management or administration. It is also important to receive feedback about implementation elements such as: video and audio quality, interaction between students and the instructor during class sessions, delivery of materials, availability of other resources, etc. (Rezabek, Cochenour, Bruce, & Shade, 1995).

Experience Based Application Ideas

As both instructors and learners participate in distance learning experiences, adjustments are made to meet the demands of the delivery system and specific class needs. The student and teacher find that there is a constant demand for behavior and learning style change. Therefore, some helpful hints from persons who experienced distance learning events could motivate, assist, and reassure future participants. Some of these experienced-based application ideas are listed below in the areas of presentation, organization, and interaction.

Presentation over the two-way video system requires more than an instructor delivering a dull lecture. Learners live in a media world and their attention drifts if not stimulated. Therefore, it is essential that instructors relax and become themselves. Planning for interactivity at least every ten minutes alerts the learners and focuses their attention. Humor also tends to decrease any tension that may develop from having to be “on camera”.

Organization of the content should be well defined as discussed in the section on planning. On the other hand, instructors should also allow for the “teachable moment” and spontaneity. The best learning may come from this type of interaction.

Interaction among the instructor and learners, learners and learners is essential. But, allowing for local conversations about the content is just as important for learners to negotiate meaning of content or develop questions for interaction.

Summary

Participating as a learner or instructor in a distance education experience can be a rewarding one. Students may appreciate the location of the sites and the use of emerging technologies. The instructor may appreciate the opportunity to present information through a new medium or be able to contact distant learners for interaction and information exchange.

Education communities are embracing the concept of distance learning. Many universities and colleges are offering more academic and professional development programs every day. Interest is increasing and the use of distance education is rapidly growing. Therefore, educators and students must prepare for changes in instruction and learning.

As educators prepare for distance education instruction, they realize that they should make more adjustments than just printing their materials in landscape instead of portrait format. And, there is more to consider than just looking into a camera and saying hello to everyone at the distant sites (like entertainers did on children’s television shows such as Romper Room). It is essential that they adjust their presentation, interaction, and organization techniques. Such elements as technology, content, student needs, facilities,
Distant learners also have to make adjustments. They need to change and adapt many learning habits concerning acquiring information, performing in class, exchanging materials, and completing course assignments. All participants in the education community should carefully weigh the advantages and limitations of distance education. A careful study of how distance learning events can effect short and long term outcomes is advised.

SIX CRITERIA FOR TECHNOLOGY INTEGRATION IN MULTICULTURAL CLASSROOMS

Ines Márquez Chisholm
Arizona State University West

As the ratio of students to computers continues to decline (Hayes, 1992), computers have become a ubiquitous presence in American schools. In 1992, there were approximately 400,000 computers in our schools, about one computer for every 13 students (Anderson, Beebe, Lundmark, Magnan, & Palmer, 1994). Giving additional momentum to this trend is President Clinton's "Technology Literacy Challenge" and his goal of making all teachers comfortable with computers (NCATE, 1996). Clearly, "the tools of teaching and learning are rapidly moving from the traditional chalk and blackboard to computer terminals" (Reid-Wallace, 1996, p. 7).

At the same time, the United States is experiencing a rapid cultural diversification which reverberates in American schools. Between 1980 and 1990 the total foreign born population grew by 40% (Waggoner, 1993). Moreover, the majority of recent immigrants come from non-European, non-English-speaking countries (Croninger, 1991). In 1990, of the forty-five million school-age children in the nation's public schools, some 9.9 million lived in households where a language other than English is spoken (Menchaca, 1996). If current trends persist, by 2050 the total number of Native Americans, Asian Americans, African Americans, and Hispanics in our country will surpass the number of White Anglo Americans (Lee, 1995, Wise & Gollnick, 1996). Indeed, in 1990, minorities already constituted between 24% and 96% of the total school enrollment in eighteen states and the District of Columbia (OERI, 1992). These children bring with them learning styles, beliefs, interpersonal styles, and expectations that "create a different context for learning and teaching" (Pond, 1996). Thus, the classroom teacher is thrust into a cultural milieu that brings together the learner's culture, the teacher's own cultural background, and the computer culture. (Chisholm, 1995-96).

If schools are to prepare children for the challenges of the next century, teachers and administrators will need to implement educational strategies that help develop technological and interpersonal skills (D'Andrea, 1995). To educate a population that differs widely in income, ethnicity, language, and culture, schools must implement strategies and programs that are flexible, supportive, and equitable. Unfortunately, although there is much information on computer hardware and software, textbooks "say a great deal less about how to teach effectively with computers" (Ryba & Anderson, 1993, p. 11). The issues facing educators as they integrate computers into teaching, therefore, are pedagogical as well as technological. Of these two, the pedagogical issues have received the least attention.

Accompanying this dearth of information on teaching with computers is the lack among many teachers of the necessary knowledge and skills for working with minority students. Teachers and students generally live in geographically and existentially different worlds (Gay 1993). While almost a third of all elementary and secondary students are minority (Gay 1993), ninety-two percent of new teachers are white ("By the numbers," 1994). Similarly, though a growing number of students live below the poverty level ("America's changing students," 1996), most teachers are middle class and reside in small or mid-size suburban communities (Gay, 1993). Consequently, their experiences, expectations, and reality are different from those of their students. Since only 13% of employed teachers are minorities, most students never have a minority teacher (Wise & Gollnick, 1996). Teachers, therefore, need to develop both cultural competence, that is, "the ability to function comfortably in cross-cultural settings" (Chisholm, 1994, p. 47) and cultural literacy, a knowledge and respect "of the history, traditions, and values of persons from diverse backgrounds" (D’Andrea, 1995, p. 46). This cultural competency and literacy must then carry into the educational use of computers.

Adding to the complexity of teaching in a multicultural classroom environment are the cultural properties inherent to computers. Computers, as cultural artifacts, connote the values, preferences, and cognitive schema of their creators (Chisholm, 1995-96). Hence, they are not culturally neutral, but, rather, culturally bound. Thus, if schools are to provide a high quality education for all children, teachers must apply equitable and culturally responsive strategies to the use of computers in culturally diverse classrooms. These strategies...
will benefit all students by meeting a variety of needs and differences.

**Equitable and Culturally Appropriate Strategies**

What, then, constitutes equitable and culturally appropriate strategies for educational computer use? There are a multiplicity of factors associated with culturally responsive teaching. Some aspects of culturally appropriate teaching are overt, such as using software with graphics that portray a variety of racial and ethnic people; some are covert, such as valuing interdependence and collaboration during computer activities. Equitable and culturally appropriate strategies do not require the impossible task of incorporating every aspect of cultural differences. Nor do they imply that educational goals and expectations in culturally diverse classrooms should be inferior or more limited than in traditional classrooms. Rather, culturally responsive teaching calls for the incorporation of some features of the child’s own culture (Au & Kawakami, 1991).

Furthermore, equitable and culturally appropriate strategies in educational computing must be broad enough to be inclusive of diverse learners, yet specific enough to be valuable as a guide to multicultural teaching. Such strategies should not be so prescriptive as to squelch individual creativity or personal differences in teaching and learning. In addition, such teaching strategies must be grounded in sound pedagogical practices. Among the factors identified by experts in the field as important to effective teaching of diverse students are the selection of appropriate content and classroom materials, the choice of culturally responsive instructional approaches and methodologies, and the structuring of a supportive educational setting (Banks, 1993; Ladson-Billings, 1994; Reyes-Blanes & Daunic, 1996). In short, equitable and culturally appropriate use of technology must be good teaching for all students.

**Multicultural Elements in Technology**

I propose six elements for integrating technology in culturally diverse classrooms: cultural awareness, instructional relevance, classroom environment, equitable access, instructional flexibility, and technology integration. These elements, based on the research on effective teaching of diverse students, meet the above criteria. These elements are not exhaustive of good practices for technology use with diverse learners, but, instead, focus on key multicultural aspects. Recently, the author applied these six elements in the evaluation of thirty-two teacher-generated instructional units that integrated technology. These application of these elements proved both informative and effective in identifying how teachers integrated computers for diverse learners. Extensive thematic units illustrating some of these elements are available at the Creighton Elementary School District Website www.ariz.com/lomalinda.

The first element, cultural awareness, refers to instruction and learning activities that demonstrate support for differences in learning preferences and language. Although there is much variability between individuals within a cultural group, research suggests that across cultural groups there are different preferred ways of learning (Griggs & Dunn, 1989; Jacobs, 1990; Rhodes, 1990). Awareness of cultural and individual learning preferences and behaviors is essential for culturally responsive technology use. This awareness grows out of a knowledge of multiple intelligences and learning styles, as well as from knowing one’s students through careful observation, conversations with parents, and direct communication with students.

An example of the application of cultural awareness to educational technology comes from one of the teacher-created units. Ms. J found that many of her children acquiring English as a second language benefited from kinesthetic activities. Consequently, she designed hands-on learning activities, such as tallying the number and types of transportation that passed in front of the school during a thirty-minute period. She then had students transfer their observations to the computer as charts, graphs, and, eventually a slide show. Thus, the teacher provided her students with learning opportunities that took advantage of their strengths and then linked these activities to computer applications.

The second element, instructional relevance, exists where educational technology, topics, activities, programs, and resources relate to the children’s background, prior experiences, current knowledge, and personal interests. Instructional relevance induces students to become actively engaged in their own learning. When learning makes sense and is important to children, intrinsic motivation emerges (Wlodkowski & Ginsberg, 1995).

There are three types of relevance: personal experiences, prior learning, and immediate relevance. Explicit reference to previous learning to previous learning helps the student organize new learning within the framework of existing knowledge. Thus new concepts gain relevance through their association with prior knowledge. Associating new learning with personal experiences links learning to personal events, knowledge, understanding, perceptions, emotions. Thus new knowledge becomes relevant as it acquires personal significance. A learning activity has immediate relevance when the student finds the activity purposeful, pertinent, challenging, and product-oriented. In short, immediate relevance emerges from interesting and engaging activities.

An example of relevance through prior knowledge comes from a unit on oceanography in which the teacher asked her students to recall things that are necessary for survival. They then word processed their lists. Next, students used their personal experiences to talk about the beach. Finally, the teacher created immediate relevance by sharing objects she had found on a west coast beach. Students then
compared these objects with objects found at an east coast beach. They drew conclusions about the differences in the objects found on the two beaches and used a CD ROM encyclopedia to find additional information.

The third element refers to the classroom environment in which the computer is used. The culturally responsive environment is inclusive and demanding. There is an expectation for higher level thinking and academic success from all students. Activities provide for differences in learning preferences and afford opportunities for both individual and collaborative work. It is a safe, accepting environment in which individuals genuinely respect all forms of diversity. Therefore, the student's family and culture are part of the learning experiences.

An example of a culturally responsive classroom environment is that of Mr. R. Using an interactive simulation program, students worked in small groups to resolve the social problems presented by the program. They learned to give each other feedback, monitor their responses to disagreements, and negotiate solutions to problems. This activity required higher level thinking, collaboration, and interpersonal skills. A second example is that of Mrs. S who had students compare and contrast their own culture with that of the native American cultures they were studying. Students then created Venn diagrams on the computer showing the similarities and differences. In this lesson, the students used higher level thinking and developed a deeper understanding of native American cultures by associating it with their own experiences.

The fourth element, equitable access to technology, refers not only to the students' access to the hardware, but also to varied software. Teachers determine access to computers by deciding who uses the computer, with whom, for how long, and for what purpose. Equitable access means that children can use the programs that best meet their own needs. Consequently children may not all use the same programs or in the same ways. However, equitable access does not mean that less knowledgeable students or those with learning needs should be relegated exclusively to drill and practice programs. Though they may use and benefit from such programs, equitable access means that they also use other more challenging and interesting programs. Moreover, equitable access provides for language differences. Though provision for a child's dominant language may be taken from the form of dual language or native language software, there are other types of language support. These alternative forms of support include peer facilitation and adaptive instructional strategies.

One teacher who provided instructional adaptation to increase student access to computers created a flow chart in Spanish so that her monolingual Spanish speakers could work independently in creating HyperCard stacks. Another teacher provided peer support by pairing native English speakers and non-native English speakers at the computer. The proficient English speaker could read the menus and help the English learner to navigate the software. A third teacher allowed students to prepare their computer-generated reports in their native language; bilingual students translated the reports for the class.

The fifth element, instructional flexibility, supports differences through varied modes of instructional delivery and evaluation. There is instructional flexibility when teachers present instruction and assess learning in ways that support multiple intelligences, varied learning preferences, and differences in linguistic ability. Culturally supportive classrooms give student choices in content, learning modes, and assessment methods (Wlodkowski & Ginsberg, 1995). In using technology, students select programs and media, choose topics, and pick the partners with whom they work.

A fifth grade teacher demonstrated high instructional flexibility by encouraging students to choose partners for their projects, allowing them to select an aspect of the class topic for a focus, and having them decide their responsibility for their share of the work. Although all students used HyperStudio to design their presentation, students progressed at different rates through the various stages of their projects. Another teacher provided alternative ways of demonstrating learning. His students could choose to create a slide show presentation, create a graphic demonstration, or create a three-dimensional model.

The sixth element, technology integration, refers to the degree to which technology becomes an integral part of student productivity and information gathering for all learners across a variety of academic disciplines. Tutorials and drill-and-practice applications are not generally productivity-focused programs. Their purpose is to provide practice on specific content or skills. Although they can be useful for their specific purpose, they limit creativity, problem-solving, and thinking. Technology integration goes beyond such program uses to the application of computers for purposeful, productive, and challenging educational endeavors. Technology becomes an essential part of the curriculum and learning activities. Therefore, learning with computers becomes meaningful and practical.

Technology integration is evident in a geography unit in which students used a map software program to locate U.S. cities and gather information on those specific cities. Students then used a spreadsheet to compare the population of the cities and graph the results. They also created a treasure map on the computer and wrote directions for other groups to follow. As this example illustrates, the unit integrated social studies, language arts, mathematics, and several computer applications. In addition, the students attained several final products, rather than engaging in rote skill practice. Moreover, the activities called for higher order thinking, creativity, and interpersonal communication.
Discussion

The six multicultural elements for educational computer use presented here incorporate many of the practices identified in the multicultural literature as effective in teaching linguistically and culturally diverse students. The multicultural elements include such effective practices as the incorporation of student language and culture, use of students' prior knowledge and experiences, support for a variety of learning styles, active student participation and interaction, implementation of cooperative learning, and respect for diversity of opinion. Thus, sound pedagogical practices underlie the six elements presented here.

Although the author successfully applied these six elements to the evaluation of computer-integrated instructional units for multicultural classrooms, the multicultural elements still need validation through additional research and application to a variety of classrooms. Once validated, they will have direct application in the professional preparation and development of teachers. Teachers can learn to self-assess the cultural congruency of their computer use by utilizing the six elements as a checklist. Education faculty and student teacher supervisors might also use the six elements in observing student teachers use computers with a diversity of learners. Finally, in-service training on computers could incorporate the six multicultural elements so that teachers become culturally and technologically competent.

Further research on effective teacher use of technology in multicultural settings is needed. Researchers have investigated teachers' computer training, perceptions and attitudes toward computers, and educational applications of technology. Nonetheless, there is an urgent need for further exploration of teachers' multicultural understandings and their application of instructionally compatibility strategies in working with diverse learners. As the nation moves towards increased educational use of computers, the absence of culturally compatible strategies will only widen the academic and socioeconomic gap between those who have computers at home and those who, at best, experience them only at school.

This paper discusses bulletin board systems (BBS) as one very useful tool for supporting intercultural education courses. The theoretical basis for the proposal is the idea of interculturalism as an educational response to the interest aroused by actual interaction with multiethnic and multicultural societies. This paper describes a basic system that, from our point of view and presents a pedagogical plan and, then, discusses a special educational plan.

Education today is set within the historical and cultural context of a society that is increasingly complex, continuously-changing, becoming more international, and moving towards a crisis model of dealing with rigid structures and traditional values. In such a context, the problem of communication becomes very important; the problem is how to establish relationships both at a personal level and between groups, people and nations, without competitive comparisons or disparagement.

Many individuals, and groups, in society today feel considerable discomfort in a wide range of interpersonal relationships that require communication and interaction. That, together with intercultural incompetency when approaching and meeting the “other” (Paparella, 1996), are a sign of the need for an education that drives and orients us towards an ethics of comprehensive cooperation, in fact, toward an intercultural ethics.

So, I agree with Rossi who remarks that “communication today has a lot of strong contradictions that characterize our society and culture” (Rossi, 1992, p. 98). In fact, it is easy to verify that when a person’s self-identity derives from the affirmation and recognition received from others; that person’s free and autonomous development is often denied. So, while the dignity and the value of each person is recognized, at the same time, there is often a “phenomenon of the hierarchicalization of the cultures” which classifies and ranks members of cultural groups (Fitzinger, 1992, p. 71).

Today’s focus on the problem of communication across different cultures has not caught up with the explosion of cross-cultural communication opportunities made possible by a new communicative practice: telecommunications. The new technologies for distance communication have achieved, by now, a capillary diffusion. The characteristics of the technologies available have rendered even the most sophisticated informational applications easy to use. The informational network, Internet, connects every corner of the globe, forming a community of electronic exchange that has indeed resulted in the foreseen global village.

The Role of the University

The university is where new forms of intervention should be promoted and tried; it is the environment from which new proposals, new values, and ideas should emerge. In short, the university is the natural cradle and catalyst for innovation and change.

Among the activities carried out for many years now by the Department of Pedagogical, Psychological, and Didactic Sciences at the University of Lecce in Italy is the study and research of intercultural education. Work in this area at the university has become an important influence on a post graduate course for teachers, Intercultural Education and European Dimension of Teaching, which Professor Angela Perucca directs. The program structure we describe here is an appropriate response to the new formative demands that come from our schools and which will benefit not only teachers, but also their students.

Distance Learning and Intercultural Communication

Telecommunications, seen as access to information nodes and to remote resources, was at first an experience reserved for the few. Now it has become a very cheap resource available to all. In just a few years, it has led to the development of a planetary web, a distance communication highway connected by the famous Internet, “the net of the nets.”

At the University of Lecce, we prefer to use bulletin board systems as a specific tool of communication among individuals and groups of individuals. Thus, we plan to develop collaborative and training activities in the field of intercultural education that incorporate electronic bulletin boards. The fundamental purpose of our plan is the design of a theoretic framework to develop intercultural education.
Telecommunications as a Useful Strategy

Distance learning, open learning, and collaborative learning certainly were born in a pre-telecommunications era. They, nevertheless, can find in telecommunications a source for enrichment, development and substantial modifications. Telecommunications brings informative and remote resources, as well as permits equal participation and interaction among individuals of different cultures, sex, age, and religion.

"Despite the growth of technological possibilities, there exists a certain scarcity of conceptual models relative to the employment of telecommunications in the learning processes" (Olimpo, 1992, p. 7). There is, first of all, a discrepancy between the actual rhythm of technological innovations, which are necessary for mastery and integration of technologies into every day activities, and the internal slowness of the cultural transformation. Second, we find an innate resistance in the academic world to understanding and using new tools, methods, and resources. Finally, we find a certain incapability in the technological world to present practical applications for the new tools that it makes available.

These difficulties have often contributed to wide conceptual and operational discrepancies between technology and education. These discrepancies have sometimes caused a myopic vision of the positive impact that telecommunication experiences can have on the formative development of teachers. This impact, from our point of view, can be expressed in terms of three dimensions: horizontal, vertical, and diagonal.

On the horizontal axis are the technical formalities that telecommunications imposes. These technical formalities affect the cognitive effectiveness of the media (Briano, Midoro, Trentin, 1995-96). On the vertical axis are the cognitive-heuristic dimensions that are linked to the use of distance-training systems, as demonstrated in the literature on this topic. The third dimension, the diagonal, evidences the participation of users in a wide, atypical community. Such participation stimulates teachers and students to a broader involvement in the study, awareness, and exploration of new cultures. As preceding experiences in this area confirm, communication and learning via a network develops in students and teachers "a sense of community to which they very strongly belong" (Aa.Vv, 1995-96). This community goes beyond the social circle in which they are physically situated to the telecommunications virtual community in which they participate. These experiences produce a sense of responsibility in sharing language and ideas. They drive users "to a collective-building process of knowledges" (Aa.Vv, 1995-96, p. 85).

Learning as a social experience becomes truly possible through telecommunication. It is, necessarily, the key-idea that will drive the development of systems for distance education. On-line education implies an interaction of the user in a real and personal exchange of learning that overcomes individual isolation and encourages the exploitation of a relationship with the group and the sharing of meanings (Briano, Midoro, & Trentin, 1995-96, p. 62). There are some methodological and formative reasons that strongly support the pedagogical value of using the new technologies for distance communication as an intercultural key.

Reasons for Using BBS

Many reasons have led us at the University of Lecce to prefer BBS over other distance communication tools. First of all, the use of this electronic mail system could be an effective strategy to protect users against the disorientation that they would inevitably experience upon first
entering the Internet. This disorientation is certainly detrimental to learning. Although a first-time visitor to the Internet can immediately have an idea about the numerous possibilities offered by the net, such as discussion groups, news groups, and social networks, it is likewise easy to realize that most of our students are absolutely lacking in methodology and reference points which may guide their electronic interactions toward a purposeful goal. Electronic communication can be created for and by a random group of users who establish the rules and the objectives of their on-line interactions. However, things are very different when using the internet for didactic or educational purposes.

BBS are one of the most popular lanes on the great super highway of information that is the Internet. Using the already existing telecommunications network, BBS offer a preferred means for exchanging messages among a closed, or at least definable, number of users. Secondly, there is a personal dimension implicit within electronic communication. Any one who subscribes to a BBS becomes part of a public group of people. He or she participates in a public list of names of people who share certain rights and duties. In fact, subscription to a BBS implies acceptance, more or less formal, of some communicative conventions and of the rules for interaction among users. Each one is subject to periodic controls from the administrator of the system. The expansion of the group to affiliate groups can be decided according to the purpose of the group. Potentially, each BBS could have an endless number of users, but the system can be set up in a specific way. The users determine the types of user "privileges", the kind of participation, i.e. active exchange of messages or only "reading," the nature of discussions, and the type of messages.

The opportunity, on the one hand, to have a basic software tool that selects, organizes and leads the user to the discovery of information, and, on the other hand, the possibility of forming groups of people that responsibly decide to comply with the system, are strong reasons to legitimately prefer this tool. Another important factor influencing our preference of BBS as a useful tool for educationally structured exchanges, is the interface interaction. Those who keep abreast of the application of these new technologies to learning know well the importance of human-computer interactions and, in particular, the design of the interface (Anceschi, 1992) The user interface is a membrane comes between the individual and the computer. This membrane becomes thinner and more transparent the more it meets the cognitive, ergonomic, and communicative needs of the human mind. An answer to such demands is offered by the FirstClass software platform. This software has the advantage of facilitating the interaction of the user with the system through an extremely intuitive and simple graphic interface which only requires the use of the mouse and the management of icons.

Additionally, all FirstClass BBS are part of one or more One Net network and offer the capability of diffusion and of access through a single site. They provide access to discussions of public interest and of public utility promoted by different BBS. Thus, they allow users interaction on a more extensive circuit than a single BBS provides. Each FirstClass BBS accessed through this broad network is organized into a system of gateways that allows all registered users of specific BBS to participate in an international circuit. With this system, each BBS user could decide to communicate with an extensive circuit of consumers interested in a specific topic.

New Possibilities

We move, then, to the third question: What new possibilities does this electronic tool offer the field of education? One of the particular characteristics of the BBS is the possibility of organizing virtual meetings and collaborative groups for the purpose not only of distance interaction, but also for the achievement of a specific educational goal. Building a social space within the global village allows one to approach distance communication in a clearer and friendlier way. The matter is not only to add a human dimension to cyberspace, nor merely to provide appropriate activities with specific educational objects that follow sound methodology and promote the interaction. Instead, it is also a matter of taking advantage of the principal benefit of telecommunications, that is, its ability to "widens the frontiers of the classroom by developing a net attitude" (Olimpo, 1992, p. 11) and adapting this frontier to an educational and learning plan.

These kinds of experiences can truly encourage interpersonal dynamics, individual growth, and group development. Such exchanges facilitate sharing problems and solutions to situations that have originated under conditions of isolated thought and organization. Some experiences in this area (Olimpo, 1992, p. 11-12) support the position that, in using telecommunications as a learning tool, the creation of work groups involves several steps:

- Formation of a circle in which the members of a group are known.
- Choice and planning of a learning objective.
- Collaboration among the members relative to the objective.
- Creation and sharing of the final relationship.

This structure highlights how, in a broad interactional system, the success of, or at least the capability of conducting effective educational exchanges, is linked to the preliminary formation of closed groups of users, i.e., of virtual classes. Also, from a functional point of view, a finite structure optimizes the exchange of documents, simplifies the verification of exchanges, and increases the capability for rigorous evaluations.

Training on the use of a BBS for distance communication can occur in different work spaces so as to require communicative exchanges, transfer of documents and informative materials, and research and production of elaborate shared
projects. Among the structured activities that the instructor can use are:

1. The creation of lecture spaces, that is, thematic areas for public debate moderated by an “expert” who manages the technical aspects of the electronic forum and assures the quality of the content;

2. The formation of closed groups, virtual classrooms of students who participate in an educational course of learnings transmitted through the teachers remote station. These participants will contribute to the development of the formative course in varying ways, according to their own experiences and culture. They are linked to the same predetermined educational plan, which assures the authenticity of their intercultural experiences.

3. The on line participation among two or more users of the same BBS in real-time direct debates and question-and-answer exchanges that allow them to know each other.

In addition to these three specific experiences, there is another aspect that should not to be undervalued. This additional element is the possible use of BBS as a personal mailbox which lets people stay in touch, one on one, or one to many, with other users and across great distances. The ability to exchange, within the space of a day, personal messages and documents with BBS subscribers from the other side of the globe constitutes an incentive to develop foreign language proficiency. In addition, the use of a common tool for the mediation of ideas and exchange documents also provides an incentive to become open to the “other”, that is, to broad cultural and individual differences.

In synthesis, this media has a double value. It offers the capability to stay in touch with a different social and cultural reality from one’s own, thereby establishing affective relationships around the world. It also makes possible the formation of geographically distributed groups that are of a limited and manageable size, thus optimizing the completion of functional assignments.

Conclusions

According to Secco, “interculturality is not a new discipline which has to be inserted among the others; rather, it is a diagonal dimension, “that crosses all teachings and implies engaging in the revision of teaching methodologies and of educational plans” (Secco, 1992, p. 55). The goal is to avoid all forms of monoculturalism; the plan implemented at University of Lecce answers this demand. As often happens when someone wants to establish a good collaboration between those who are knowledgeable about the new technologies and those who engage in the formative development of teachers, operationalizing such a proposal requires very careful planning and consideration of the different professional competencies each participant brings. This cooperation involves the development of a technical plan and the design of a functional network capable of supporting an ever-growing circle of users. Similarly, it demands the formation of a pedagogical design that gives meaning to the initiative and, above all, that moves the collaborative work toward the attainment of educational objectives.

The Department of Pedagogical, Psychological and Didactic Sciences at the University of Lecce affords students an innovative, educational experience in its teacher preparation course, Intercultural Education and European Dimension of Teaching. The content and organization of this course creates an environment suitable for initiating students into telecommunications and for establishing a net of students and teachers for the purpose of applying integrative and intercultural educational practices.

It is possible through initiatives of this kind, across different cultures and nations and in a unified way, to establish a macro-circle that is united by a similar purpose and by the same pedagogical goals. Thus, the telecommunications “cable”, could become the correct metaphor for this global electronic linkage.

In the preface to the book, *Integrating Educational Technology into Teaching*, Roblyer, Edwards, and Havriluk (1997) assert, "Everything has changed so quickly, in fact, in education and in society at large, that it is often difficult to determine just what is happening and what response is required of us. We teachers stand before technology as we would a mirror. What we see is determined largely by what we are and what we consider important. We may see technology as a creature of speed, precision, and efficiency, able each day to squeeze more tasks into an hour of time than we could the day before. We may explore and discover, able to lead others to see the images we see, to pursue the new worlds we envision. We may see something else, something novel and original, capable of making possible the unimagined and undreamt-of—an agent of reform, change, and progress" (p. v).

The educational computing course is growing and evolving as it tries to keep pace with learning theory, teaching practice, learner needs, and curriculum integration. Questions such as, "What should be taught?", "How should it be taught?", and "How should the learner be evaluated?" are all valid and relevant to the evolution. The papers in this section address many of these questions.

The first issue to be addressed is idealism vs. realism. With all the objectives that need to be accomplished in a three-hour course, how can these objectives be realistically met? Aschermann's paper discusses the new NCATE standards for technology and the OTA report, then asks the question, "How does a teacher education program begin to deal with the standards of NCATE and the conclusions of the Office of Technology Assessment?" He concludes that "a proper balance must be found between idealism and what is actually taught." Even after this actual teaching, when the preservice or inservice teacher is ready to apply the new knowledge in the classroom, planning for technology use must occur and re-occur. The next paper by Galloway and Blohm discusses the importance of planning for technology with the process of integration being guided by technology-using educators.

The next four papers deal with the restructuring of the educational computing course and the technology component of the teacher preparation program. Sindt, Summerville, and Persichette discuss the changes made to the educational computing course so it more closely relates to teacher preparation courses. The revisions and results are discussed, and although it was concluded that much effort was required for the changes, the achieved results were worth the effort. The next paper highlights the issues considered for the redesign of the technology component by the teacher preparation faculty and the educational technology faculty. The author feels new courses which feature "an integrated, project-based format" lay a strong foundation for the preparation of future teachers. The paper by Keizer and Wright emphasizes a constructivist approach to the computer course that results in self-discovery and adaptation by the learner, but more importantly, this approach leads to exploration that never ends. The paper by Farragher, Francis-Pelton, and Riecken presents a model for teaching content-area subjects with technology.

Other papers in this section deal with the evaluation of students, particularly with the use of portfolios. Russell and Butcher describe the evolution of student evaluations and the applications of portfolios. Carlson addresses portfolio assessment and its application in two case studies assessing learning of instructional technology.

With the restructuring of the teaching of the educational computing course and the revamping of evaluation procedures, the course content has also been revised. Two of the papers in this section deal with the use of the World Wide Web. Hattler presents the Web as one important vehicle for integrating technology and provides "driver education" for navigating the information superhighway. Woodcock provides evidence for using the Web as an interactive and affordable teaching tool.

This section concludes with a paper by Finch presenting the issues of whether or not the educational computing course should be included in the university's list of required courses. Both sides of the issue are presented equally with the readers drawing their own conclusions.

Wren M. Bump is a visiting professor at Texas Southern University in the Curriculum and Instruction Department. She is also the instructional technologist for the College of Education at Texas Southern University where she leads and supports a faculty technology group as they develop computerized courseware. Wren also teaches courses in the instructional technology program at the University of Houston. Her main interest is teacher training and preparation.
Today it is assumed that all graduating teacher education students will be familiar with and will be able to use the instructional technology that is available to schools. Beginning October 1, 1995, teacher education programs seeking National Council for the Accreditation of Teacher Education (NCATE) approval must meet the following NCATE standards for technology:

- **Standard 1.C.1 Content Studies for Initial Teacher Preparation** expects that candidates complete a sequence of courses and/or experiences to develop an understanding of the structure, skills, core concepts, ideas, values, facts, methods of inquiry, and uses of technology for the subjects they plan to teach.

- **Standard 1.D.2, Professional and Pedagogical Studies** expects that professional studies for all teacher candidates include knowledge and experiences with the impact of technological and societal changes on schools and with educational technology, including the use of computer and related technologies in instruction, assessment, and professional productivity. (Wise, 1995, p.1-2)

A 1995 report from the US Office of Technology Assessment, Teachers and Technology: Making the Connection, expressed a major concern: “Despite over a decade of investment in educational hardware and software, relatively few of the nation’s 2.8 million teachers use technology in their teaching.” It was concluded that the returns on the huge capital investment were negligible because

- teachers did not have adequate training to prepare them to use technology effectively in teaching,
- teachers reported feeling inadequately trained to use technology resources, and
- technology is not central to teacher preparation (Office of Technology Assessment, 1995, OTA).

How does a teacher education program begin to deal with the standards of NCATE and the conclusions of the Office of Technology Assessment? Four alternatives can be considered:

- ignore the NCATE and state standards required in technology,
- integrate the learning about and the use of technology into the entire teacher education program,
- require an instructional technology course of all students, and
- create a combination of the integration and requirement alternatives.

Trade-offs evolve from the selection of any of the above. The teacher education program at Missouri Western has accepted the fourth alternative. The rest of this paper discusses the required course for all elementary education majors and how the class changed from a 1970s audiovisual class to a instructional technology class for the late 1990s.

Requiring an instructional technology course or modifying an existing course creates a problem for the person who is assigned to teach that class. How can the traditional “audiovisual course” move to an appropriate instructional technology course for the 90’s? What is appropriate for the teacher of 1996 who will also be teaching in the 21st century? How can the preservice course develop the technology proficiencies with the latest educational technology but at the same time prepare the new teacher for the realities that will be faced in many of the public schools? Which operating system do students use while in the class? How does the class move students from simply knowing how to use technology to a complete integration of technology within the teaching day? How does the instructor cope with the idealism of what the course should contain to what is realistic in terms of what is actually possible in a two credit hour class? How far can computer novices be taken in a short semester course? How should the course be structured so that the confidence level and attitudes of students about technology become greater?

Missouri Western State College (MWSC) has required an audiovisual class for all elementary majors since the
late 1970's. In 1992 the course made a radical change from "audiovisual" to "instructional technology."

The old "audiovisual" course consisted of learning how to operate "sophisticated" equipment like the 16mm projector, how to make color-lift overhead projection transparencies, how to preserve instructional materials with the dry mount press, and a study of the appropriate procedures for the evaluation, selection and utilization of instructional materials. The 1980s course was expanded to encourage preservice teachers to experiment with video production and utilization.

By 1992 it was again time for a major change in the class. All students at MWSC have personal electronic mail accounts, but few knew how to log-in for the first time. Some students were familiar with the computers of the time but would only use the computer for remediation of multiplication tables or word processing.

If a radical change in the class were to come about, decisions had to be made very early. Is the new class going to be a theoretical textbook oriented class or a hands-on class with practical application projects? What should have the higher priority: learning of content or the practical application of fewer ideas? Should students study and investigate topics such as distance education, telecommunications, LOGO, Hypercard, ASCII, baud rate, spreadsheets, computer gradebooks, data management, desktop publishing, networking, bytes, bits, Internet, computer operating systems, theories of learning related to technology use, graphic design, instructional development, technology related to subject matter disciplines, and others.

Constantly a conflict developed between idealism and realism — what it would be nice to do and what is practical to do because of the entry level of students and the time available. Initially idealism prevailed. All of the above listed topics were studied plus students were required to demonstrate the skills of using several computer programs.

Changes were made in the two credit hour class, but the changes were not made without frustrations and pain. Students are resistant to change. From peers, they had heard about what they would study and do in the former "audiovisual course." The new course required a new conceptualization of instructional media. Many MWSC students are re-entry students or older females who have never touched a computer. The use of an institution computer lab was beset with problems. Students would learn one method of doing something. Overnight the lab technicians would reconfigure the computers so that to a novice there was no connection between the process used one day and the process that had to be used the next day. Something as simple as finding Word 6.0 on the harddrive became a daily challenge. Students had an extremely difficult time realizing that the new class would require computer lab time. They understand that time must be spent in a biology lab doing biology assignments because of the specialized equipment associated with biology. They could not understand, however, that a computer application course would require the use of computers at times other than the regularly scheduled class time.

The new course developed credibility problems. Students would talk to teachers in the area who would profess disbelief about the new MWSC class. "Technology" to many of these teachers meant the occasional use of the overhead projector or videotape. Again the question: should teachers be prepared to move with ease into the existing world of education, or should preservice teachers be trained to become leaders in schools that house older and more traditional teaching styles? Preservice teachers could not see any value in learning something that could not be applied the next day in an elementary classroom. Why learn to use Internet when this is not available in rural northwest Missouri schools? Why learn to use Macintosh application programs when the area classrooms either do not have a computer, or the only computer available is an Apple II-e?

Instructional and lab times became a disaster. Trying to demonstrate and explain the process to use a computer program to twenty-five novices is almost impossible. Invariably one person (or twenty people) will get lost on step three. One false step on a computer can take a person on a completely different path. Which of the twenty people with hands in the air does the instructor help and at the same time be able to finish the explanation or demonstration within a sixty minute class period?

Students became very frustrated trying to use the Internet. If a person used explicit directions from the instructor to reach a particular web site and were then were denied entry into that site (peak time usage), it became the fault of the instructor. Within one semester, a class that had for twenty years been very favorably evaluated by students became the least popular class within the Department of Education.

Three years later a middle ground between idealism of what should be to the realism of what actually is possible for a preservice instructional technology course has been found. Many of the earlier problems have been minimized. Students now know what to expect from the class. Rather than making color lift transparencies and using a dry mount press, they will be doing computer application assignments. Area schools are quickly updating the use of technology. The dissonance between a campus class and the realities found in the schools is becoming minimized. School administrator comments are now beginning to filter back to MWSC. Missouri Western students have technology skills that are much more developed than those of students from other area colleges. Thus, a reason to employ a MWSC graduate. First year MWSC graduates
are already assuming leadership roles in area schools. A lab assistant has been employed to help with the twenty hands in the air. (The computer lab assistant is a grandmother who previously took the class. She is able to solve procedural problems with application programs.) Computer labs are open for more free use hours. During the past three years additional faculty within the Department of Education have integrated the use of technology into other classes. The burden of teaching “everything” a preservice teacher needs to know about technology is being shared by most of the staff members. Attitudes of students are beginning to shift. They know and realize that they will be using different forms of technology in the classes offered by the Department of Education. Additionally, they know that many of the things being done in the campus class can be immediately applied during a clinical experience.

An additional shift in attitude was made by the instructor of the instructional technology course. Rather than to try to teach “it all” within a two credit hour preservice class, it was decided that the purpose of the class was to teach basic computer usage skills and to develop a positive attitude about the use of technology. Earlier, students acquired good information and did in-depth projects. In doing this, however, student attitudes became very negative to the point that many stated that they would never use a computer again. Computer anxiety was increased and confidence level was decreased. The idealistic course produced the opposite combination of desired preservice attitudes.

Today, a more non-directive and non-threatening approach is taken in the class. The overall goals of the class are to develop a favorable attitude about technology and to teach foundation skills that can be expanded at a later date. If beginning teachers are going to use technology, computer anxiety needs to be reduced while competency in skills and confidence must be increased.

Pelton and Pelton (1996) studied the correlation between teacher attitude and the acceptance of technology. Their research led them to conclude “Although many teachers believe computers are an important component of a student’s education, their lack of knowledge and experience lead to a lack of confidence to attempt to introduce them into their instruction. This lack of confidence then leads to anxiety and reluctance to use technology” (p. 167).

The research shows that personal confidence building should be an essential part of a technology course. Knowledge about computers and technology do not guarantee that a teacher will integrate technology into a course of study. A key component is attitude and a course that is realistic.

Today, what is realistic in terms of content and student performance? Final student grades for the MWSC technology class are in large part determined by the depth that each student selects, e.g. contract grading. A student who contracts for an “A” will complete the following projects:

- Basic Word Processing,
- Advanced E-Mail (set up, save files, create signature file, subscribe to and participate in professional education discussion groups, compose and send mail),
- Advanced Internet/web search (use of search engines to learn how to navigate on the Internet),
- Advanced PowerPoint presentation program using a concept from the state mandated list of concepts (application of instructional development process, demonstration of PowerPoint processes as build, transition, insert picture, insert clip art, multiple colors, etc. and an instructional plan for the use of the program),
- Advanced development of a personal web page (application of html tags and the selection of a state mandated concept for which web sites have been found and an instructional plan developed), and
- Overhead transparency production (three processes using technology).

The above projects keep the student busy for almost an entire semester. Those who enter the course without the knowledge of where to turn the machine on are able to proudly show what has been accomplished: use of electronic mail, PowerPoint instructional program, and a personal homepage. Tangible products show the non-computer person that it is possible to learn how to use a computer. Confidence and skills encourage the learner to continue learning about technology and the integration of technology into lesson plans.

Should the course be more intense in terms of content? Does the course really prepare the beginning teacher for the first seven years of employment? The purpose of today’s course is different from that of the early 1990’s. Today the major goals are increasing the confidence level and basic skills to use technology. Every instructor would like to have the assigned credit increased for a class that is being taught. Should all MWSC students be required to take two three-credit hour instructional technology classes? Definitely the answer is “yes.” Realistic? “No.”

Are the above course goals being met? The summer class of 1996 was restructured. Student course evaluations reverted to the high levels of the mid-1980’s. Observation of students engaged in pre-student teaching and student teaching assignments shows they are using and integrating technology into their teaching. Evidence indicates that students are not forgetting about the course after they receive the final grade. Instructor intuition says that the course goals are being met.

Additional empirical evidence, however, is needed. Students in the fall 1996 sections of the class were asked to...
complete a questionnaire that assessed attitudes about
technology and the use of technology for teaching. In mid-
December students will complete the same questionnaire.
Data from August and December will be analyzed to
determine if experience in an instructional technology
class creates a more favorable attitude and greater confi-
dence about technology. (The questionnaire is a modified
form of an instrument developed by Pelton and Pelton
1996.) Additional observations will be made to determine
if students do use more technology in the MWSC clinical
experiences.

Completion of the course projects and the course in
general meets NCATE accreditation standards and
expectations for knowledge and use of technology. The
course also begins to deal with the concerns listed in
Teachers and Technology: Making the Connection. (OTA,
1995) Students at MWSC are learning how to teach with
technology rather than simply learning about technology.
The required technology course goes beyond the current
requirements for teacher certification in the State of
Missouri. Data collected in the fall of 1996 will determine
if the course is increasing the confidence level of
preservice teachers to use technology in their teaching.

In four years the required MWSC course has evolved
from an innovative course for the 1970's to an innovative
course in the 1990's. Change creates frustrations in both
students and instructors. A proper balance must be found
between idealism and what is actually possible.

As virtually every school district in the country is now on some path toward computer integration, administrators and teachers everywhere are aware that computers and instructional technology are becoming a fundamental part of education. While many have been the pioneers of educational computing development and thus have clearer notions and directions, it is necessary for all educators to establish a foundation in supported technology for survival in the 21st century (Mageau & Chion-Kenney, 1994).

Many are addressing this by procuring grants, allocating funds and other resources to establish or enhance their technology program for the future. The key to that future is planning. It has been said that, “The plan is nothing; planning is everything” (Eisenhower). However, the nature of the planning process and the philosophy or perspective and expectations about the role of technology in education can drive the planning process toward a fruitful bounty for all or, unfortunately, toward a failed crop of dinosaur hardware, frustrated educators and students unprepared for a technological future. In other words, in spite of “rapid advances in multimedia technology….many teachers continue to emphasize the same instructional strategy (lecture) and technique (chalkboard) as educators did of the 1920’s.” (Barron & Orwig, 1995, p. 3).

The role of technology is vital in teacher education and is essential in a constructivist model of teaching (Brooks & Brooks, 1993). Certainly, computer technology has become a fundamental part of education across the curriculum and will likely be more so in the future. Instead of simply being a source of information, computers are becoming multimedia workstations for students. Innovative use of technology combines telecommunications (email, video-conferencing, online resources, Internet navigators), multimedia authoring (home page editors), user-friendly, convenient applications software and turns students into producers as well as consumers of content (Avots, 1994). The role of the classroom teacher is evolving from that of a giver of information to that of a facilitator of student learning. New technologies already exist to help teachers complete that evolution (Downs, Clark & Bennett, 1995).

The process of planning for technology integration should consider teacher beliefs and teachers' knowledge about technology which affect the decisions they make about strategies, procedures and materials for instruction (Hutchinson & Kung, 1995). The use of technology must directly relate to the context of teaching specific course subject matter (e.g., searching online databases via the Internet about volcanoes as part of a geography unit). Teachers need to see that technologies are selected and included according to sound instructional planning and not merely haphazardly placed within a lesson or instructional sequence (Wong & Smith, 1995).

Although than 90 percent of teacher training institutions require prospective teachers to take a course in technology for teaching and 85 percent or more require or recommend that the course be taken in the 3rd or 4th year of the program (Vagle, 1994), there is still a lack of demonstrated inclusion of technology in teaching methods courses. Citing a lack of assistance, time for development and unavailability of technologies, few methods professors use current computer hardware or software as an integral part of their presentation of teaching methods (Vagle, 1995).

A key concern is how much prospective teachers are aware of the technological revolution in accessing and communicating information and whether they are using technological resources to participate in the interflow of information within and outside classroom instruction (Slaughter & Knupp, 1995).

This paper examines the role of technology in learning and the implications for planning processes. New data are presented which reveal the perspective and awareness levels of preservice teachers about specific technologies, the role of technology in education, and how they will prepare for integrating technology into their professional lives.
Methodology

A survey was administered to 20 preservice teachers to determine their level of knowledge and understanding of computer technology and their perspective on how computer technology will affect their future as teachers. Subjects were first and second year education students at a midwestern university enrolled in a beginning educational computing course. The survey was administered at the completion of a one-semester beginning-level computing course for preservice teachers. Virtually everyone was inexperienced with computers before the taking the course.

The course involved projects with standard applications software (word processing, database, spreadsheet, graphics). Students also studied the usual computer history, terminology, and equipment. However, after only one such course, students would still be considered beginners and relatively inexperienced.

The survey was administered in two parts. The first specifically focused on what subjects deemed essential for classroom teaching in the 21st century. Subjects were asked what types of computer input/output innovations they knew about and to describe each for teachers and students of the 21st century. The survey solicited their responses to the following areas:

1. What hardware innovations in computer technology (e.g., input/output devices) would be considered essential for teaching and learning in the 21st century?
2. Describe the value or role of each device for teachers and students in a 21st century classroom?
3. Describe your primary method or resource for learning to master the technology tools and applications of the 21st century classroom?
4. What person, persons, or institution has the primary responsibility for educators reaching this mastery?

In the second part of the survey, subjects were asked to categorize specific technologies as hardware, software, communications, peripheral or multimedia. Multiple selections were allowed. That is, an item could be classified as both hardware and communications. Subjects were also asked to rate each innovation device as essential, useful, or useless. Subjects could also mark that an item was unfamiliar to them and was therefore not classified.

Items presented were:
- Video E-Mail
- Computer-TV-Internet Integration
- Digital Computer Cameras (Still & Video)
- Poster-Size Color Printers
- Professional-Level Video Editing
- Video Desktop Computer Conferencing
- CD Rewritable Disks
- Desktop Web Publishing
- Digital Personal Message Pads
- Desktop LCD Projectors
- Plain-Talk Text-to-Speech Capability
- Home Page Editors
- Multi-platform Servers
- Mobile Computing Assistants (e.g., Newton)

Responses were tabulated and compared, and a descriptive analysis was generated to detail the nature of knowledge levels and perspectives of the immediate future of instructional technology. The survey also collected data on respondents' gender, age, computer experience, and career directions.

Results

Respondents were almost 80 percent female, and 60 percent of respondents were elementary education majors. 75 percent were between the ages of 18 and 22 with 25 percent older. About 75 percent had taken some sort of previous course in computing in college, high school, or elsewhere. About half claimed to use a computer at home regularly for their needs as students. While about half occasionally visit computer stores, most seldom or never use the Internet, attend seminars or other events, nor read computing magazines. Subjects were asked whether technology will be an integral and fundamental component for studying and learning and for teachers in terms of professional service, basic teaching skills and classroom instruction. All respondents believed that technology was very important (50 percent extremely so) for education in the 21st century.

Part One

In part one of the survey, respondents named a large variety of things which they considered essential for teaching and learning in the 21st century. Items included miscellaneous hardware from keyboards to fax-modems and voice synthesizers and software from word processing and hypermedia to e-mail and Internet access. The largest number of responses named printer options, computer voice control, touch screens, and CD-ROM. 20 percent of respondents had no ideas and described nothing. The remaining 80 percent described their choices for the three most important technology items. A summary of those items and descriptions follows:

- Fast computers were described by respondents as interesting and efficient. Speed is important.
- CD-ROM technology was described by respondents as providing easy, unrestricted access to lots of information, were durable and versatile. Unfortunately, one can't change CD information. For teachers, CD's hold interesting information (e.g., encyclopedia), and students can use CD's for homework. Possibly due to subjects' misconceptions, CD-ROM technology was also described as serving as a visual aid and to be used for storage. Subjects thought that CD's can make subjects easier to teach (as compared to merely being a tool which must be properly fit into instructional planning).
Touchscreen technology was included by a large number of respondents in spite of being relatively older technology. Descriptions accounted for touchscreens being useful for the disabled and for making computers easier and important for children. Students may find such technology less intimidating, more fun, and useful as a learning tool. It was suggested that a touchscreen might be useful in graphics or drawing tasks and that students may find it less intimidating, more fun and useful as a learning tool. Respondents thought that touchscreens could encourage the use of visual aids.

Spreadsheets and databases were included and considered useful for teachers and students alike. Respondents basically described their own experiences from the course they were completing (spreadsheets as gradebooks, databases for helping students complete assignments). They oddly described a database as better for records than for manual files presumably meaning that computerized storage was better than using paper file folders.

Modern technology was described by respondents as important for connecting to other machines and provides limitless access to information including exchanging faxes. Respondents thought that they can be expensive and problematic in that people don't know how to use them. Teachers can download professional services and students can access information for reports, contact other students and conduct research. Apparently unknown to respondents, modems are cheaper than ever before and still one of the most inexpensive components in a computer system.

Respondents also described other items such as hard drives, monitors, mouse, graphics, hypermedia, and software in general, specialized or enhanced printers, networking and direct voice control. Interestingly, respondents even included the importance of calculators and Braille keyboards and the possibility of a whole-class input device for group responses. They were also aware that the Internet or web can provide important access to information, people and ideas; and that teachers can distribute assignments to students through the Web.

While respondents described a scanner as an important input device, expensive and difficult to learn, they mistakenly thought that teachers could scan a gradebook worksheet they forgot to save. Of course, without OCR (optical character recognition) software, scanned text cannot be converted from a mere image into text which can be directly edited.

In summary, very few responses in part one indicated knowledge of newer or emerging technologies (Internet use: 15%, Hypermedia: 5%, Voice activation: 20%, Enhanced or braille keyboards: 20%).

Regarding the resources for learning about such technologies and acquiring the skills needed to use them in teaching, respondents primarily selected college classes (44%) and self-study (35%). However, respondents offered a rather disturbing response to the question about who has the primary responsibility for teachers' reaching that mastery. Subjects were split evenly between public school/college versus teachers themselves as having the primary responsibility. The concern is that individuals may expect to passively await the delivery of knowledge and skills from their instructors rather than taking the initiative to learn on their own. Also, this is contrary to data which accounts for over 83% of computer-using teachers learning to use computers and software on their own (Galloway, 1997).

Part Two

In the second part of the survey respondents classified technology innovations (left blank if unknown) by type and usefulness. Items were primarily labeled as communications and described least as peripherals. Items were described more as software than hardware even though most involved both.

The ratio of known and classified items to unfamiliar and blank items for the overall group was 50/50. The items with which most respondents were familiar included video e-mail (72.2% of respondents), computer/TV/Internet integration (68.4%), digital cameras (61.1%), and poster-size printers (61.1%). The items with which respondents were least familiar included home-page editors (36.8%), multi-platform servers (26.3%), and mobile computing-assistants (26.3%).

Generally, items were considered more useful than useless at the rate of 13 to 1. Less so, items were considered essential only 1/3 as often as merely useful. Those items most considered essential were video e-mail and video-desktop conferencing. Those items most considered useful were video e-mail, poster-size printing, computer/TV/Internet integration, and digital cameras. Only 4 items were labeled by any respondents as useless: computer/TV/Internet integration, digital cameras, mobile computing-assistants, and digital personal message pads. Respondents identified most of the listed hardware products as software rather than hardware, which might be a more applicable descriptor. Respondents seemed to value video-based technology over print output or data input devices. On the contrary, however, they do not seem to value digital computer cameras which might be used for capturing their own video images and real-time footage for presentation or product development.

Subjects generally demonstrated little knowledge of the technologies. Only two respondents (10%) read computer magazines and publications as a source of information while only one (5%) visits computer retail stores regularly.
Discussion

This set of subjects (students across two classes) is obviously small and thus limits the scope of these findings. Nevertheless, these subjects did seem quite typical of preservice teachers as beginner users of technology and as students at the early stages of a teacher training program.

While the group as a whole seemed generally familiar with technology for beginners, individually they were more limited. Although there was an occasional insightful notion, there was also a number of limited or confused and misunderstood ideas. Educators' fundamental misconceptions of computing can encumber the integration process and slow or limit progress. The support of teachers in learning to use technology must be a significant and fundamental part of any integration or adoption plan.

Data suggest that preservice teachers need to be increasingly encouraged to explore the progress of emerging technologies for teaching through professional publications, teleconferences, and Internet sources. Such technologies should be demonstrated and included in required class research and class presentations. Teacher preparation institutions must do more to stay current with new technology purchases and to integrate their use into the instruction and student activities throughout the teacher education program. Instructors of teacher education courses traditionally not involving technology should begin to adopt and model the use of various technologies for teachers to better understand their application.

Although teacher-educators and institutions should do more, the teachers themselves must recognize a greater degree of responsibility for their own mastery. It is the individual’s marketability, usefulness, and effectiveness which is at stake, and the individual must take action. Most users over the past twenty years have taught themselves, and while as a society we must improve the quality of services our institutions provide, it is ultimately up to the individual to seek out the resources and put in the time and energy to gain the knowledge and expertise of new technology.

Planning for integration and computer development typically targets the expenditure of funds and acquisition of exciting technology. Occasionally, planning addresses pedagogy and the nature of learning as it will be with technology in place. Unfortunately, such planning models typically do little to address the nature of the misconceptions, confusions, and limited learning and experience of the educators who must implement the changes. Technology cannot be adopted or successfully integrated into teaching without competent, trained, technology-using educators guiding the process.

The purpose of this paper will be to discuss the changes to the undergraduate educational technology classes at the University of Northern Colorado. To meet the needs of the restructured teacher preparation curriculum, it was determined that the required educational technology component also needed to be revised. As part of the restructuring, the original course was split into two separate courses, one which students take early in their college career and the other to be taken later in the their teacher preparation program. Both courses were designed to be more closely related to the students' teacher preparation courses. The educational technology component of the preservice teacher preparation program is taught almost entirely by doctoral students in Educational Technology with supervision by a graduate faculty member. This paper will discuss how those changes were accomplished.

Original Structure of Educational Technology Course

The original Educational Technology course was delivered in a loosely structured fashion. There was no official syllabus, and every instructor taught some basic computer applications (e.g., word processing, Hypercard, Pagemaker), but other content decisions were left to each instructor. The course was taught to upperclassmen, usually the last semester before student teaching. Students were not able to apply these skills to their professional preparation because the experience was so late in their coursework. There was, virtually, complete emphasis on the “tools” and little or no relationship to the use of the tools in the classroom. Also, since this course was a known part of the teacher education program, the faculty in other departments expected students to have certain skills, which might or might not have been included, depending on the instructor. This course was taught three times a week in 50-minute segments.

As part of the teacher education program revision process, the educational technology faculty worked with the teacher education faculty to design the educational technology component for the teacher education program. The original course was split into two courses, with the first emphasizing basic computer skills and various software packages, and the second concentrating on more advanced computer applications and the integration of various educational technologies within the classroom setting.

Pilot Implementation

During the spring of 1996, the first revised educational technology courses were piloted. These classes were taught once a week for 50 minutes, a significant decrease in the amount of time spent in class. Essentially, this course consisted of the “tools” portion of the original course and used the same packet of supplemental instructional materials. The only “tool” not included in the pilot course was Hypercard. At the end of the pilot, the course was informally evaluated by discussions with the instructors of the pilot classes. The formative evaluation concluded that the syllabus attempted to cover too much content. In addition, the pilot syllabus for the new course was not detailed enough to outline specifically what was to be taught. The evaluations of the course and the instructors were positive, overall. However, student comments indicated that their preference was for instructors to spend more time on the subject material. Based on the results of the pilot, the instructors and the coordinating professor used the summer to revise the instructional materials, the syllabus, and the required projects before full implementation of the new teacher preparation curriculum in the fall of 1996.

Final Revisions

Syllabi for the two courses were completed first. The syllabi were developed by the coordinating professor and approved at the college level. They were reviewed carefully for their contribution to the teacher education program. The new syllabi were designed to provide students with a broader understanding of educational technology; even though each course has a different focus.
The first course (ET201) is the "tools" class, while the second course (ET301) deals with issues of integration, how to use various technologies in the classroom, and some advanced skill development. The syllabi include specific course outcomes and correlate all of the course outcomes to current NCATE standards. Some examples of course outcomes for ET201 are to design and demonstrate a brief lesson using presentation software, and to design and produce simple video programs for instructional purposes; outcome examples for ET301 are to design a proposal requesting classroom equipment for specific instructional purposes and work cooperatively with a practicing school library media specialist to identify roles and expectations for collaboration within the school setting.

After the syllabi were completed, the professor and instructors worked together to develop projects directly related to the outcomes specified in the syllabi. Each project had specific requirements that must be fulfilled, and the course outcomes were clearly identified for each project. Along with the projects, evaluation rubrics published to allow the students to understand fully what was expected of them for each assignment. In addition, a textbook was selected to provide supplemental information for the students (Merrill, Hammons, Vincent, Reynolds, Christensen, & Tolman, 1996). Additional readings were assigned from Instructional Media and Technologies for Learning (Heinich, Molenda, Russell, & Smaldino, 1996).

Once the projects and syllabi were designed, major revisions were completed on the instructional packet so that it paralleled the syllabi. The original ET401 packet was expanded/revised into two parts: one for ET201 and one for ET301. The ET201 packet had the following sections revised and/or added:

- Macintosh and Computing basics (revised)
- Microsoft Word 6.0 (revised)
- Microsoft Excel 5.0 (added)
- Aldus Persuasion 3.0 (revised)
- Microsoft PowerPoint 4.0 (added)
- Software Selection (added)

The ET 301 packet had the following sections revised and/or added:

- Aldus Pagemaker 5.0 (revised)
- Hypercard 2.2 (revised)
- Software Selection/Evaluation (added)

The revisions and additions were designed to make the supplemental packet more user-friendly and to enable the students to be more independent as they work on the projects. The packets include individual tables of contents for each software application; expanded, step-by-step instructions for each project; and additional suggestions for extensions for those students who wish to do more than the assignments required.

Final Results

All sections are currently taught with every instructor using the standardized syllabi and projects described above. This should ensure that every student who passes the class has the same basic knowledge and skill set. This approach should also eliminate the possibility that a student might complete the class without the knowledge/skill level expected by faculty in other departments.

To continue the formative evaluation, the coordinating professor and instructors met at midterm to discuss implementation concerns. At this time, changes were made to the rubrics and to projects which were judged too ambitious to be accomplished in the time allotted.

Another problem addressed related to the availability of resources for the students. Too few computers in the existing lab will be alleviated with the addition of a new computer lab for the spring of 1997. The lack of VHS video cameras for student use continues to be an issue with only three cameras for 330 students.

Other ideas for revision include moving the copyright and distance education components from ET201 to ET301 and adding web page design to the ET301 course. Class size and teaching load for these courses are also a continuing concern. In conclusion, the course revisions have required much effort by many people, but we feel the results have been worth the effort.

206 — Technology and Teacher Education Annual — 1997
Today we are faced with a challenge. The needs of the rapidly changing instructional environment for K-12 education are placing new demands on the preparation of our future teachers. In an attempt to meet these new demands, many teacher preparation institutions are focusing efforts on restructuring their entire undergraduate program for teacher preparation. The University of Northern Colorado, whose primary mission is the professional preparation of educators for Colorado, began their redesign effort in 1994. The result is a fundamentally different model for undergraduate teacher preparation which emphasizes integrated, field-based experiences at every stage. This new model was implemented in the fall of 1996.

This paper discusses the most important considerations for the redesign of the technology component of the new teacher preparation program. The educational technology component has historically been a single, service course offered by the graduate program in educational technology. Although there was little attempt to integrate, or parallel, the content of the educational technology course with any other portion of the teacher preparation program, this course was the recipient of the STATE Award for Best Information Technology Course in 1994. Since that time, statewide K-12 student standards of performance have been instituted, professional teacher licensure has been mandated, licensure for practicing educators has been refocused on a performance-based portfolio system, state teacher preparation standards have been instituted (which include technology use and integration standards), and there is progress being made toward the completion of evaluation criteria for the higher education institutions and faculty associated with teacher preparation. It was under these parameters that the educational technology component for teacher preparation entered the redesign tumult.

The Issues

The primary issue which drove the redesign of the technology component was a strong desire on the part of the educational technology faculty and the teacher preparation faculty to integrate both technology proficiency development and pedagogical development across all stages of undergraduate teacher preparation. Clearly, public schools today place an increased emphasis on teachers' abilities to appropriately use multiple technologies and media in their preparation for and delivery and evaluation of structured curricula. Technology use is no longer viewed as just an extension activity or a tool for the classroom management of the 'active' learner. To address this issue, the current technology courses require students to complete structured projects which have been designed to meet multiple standards/criteria and which can easily be accomplished within the curriculum of their other teacher preparation coursework. For instance, in the early technology course, students must use electronic presentation software to create a short, instructional presentation relevant to their content or grade level. While enrolled for the technology course, students are also enrolled in an introductory seminar that includes a field experience component. Many students completed this technology requirement by creating the presentation for their seminar cohort or as a brief practice teaching experience for the classroom which they observed.

Recent advances in hardware and software are a concern when designing these technology components. While students may have access to relatively high-end equipment and updated applications in the university setting, the reality of technology access for many public schools is still far from the university standard. It is difficult to create experiences for these preservice teachers which 'whet their appetite' for the potential of technology to aid effective instruction without frustrating their attitude about professional growth when they see limited access to the tools they are trained in within the school setting. Ignoring the disparity, however, does nothing to prepare our future teachers either professionally or culturally.

Another issue for consideration is the increase in the number and types of technologies appropriate for educational settings beyond the computer. These two technology courses include content, at the beginner level, in distance education applications, video production, information literacy, copyright, trends in educational technology, changing roles of public school professionals, media selection and instructional design. Each of these topics serves to extend the students’ knowledge base and increase...
their understanding of the breadth of the educational technology field.

Finally, the technology component redesign was heavily influenced by the state mandated professional standards for teachers which relate to technology use and the use of portfolios as the evaluative tool of choice for inservice teachers. The preservice teacher preparation program now utilizes portfolio-based evaluation criteria which supplement traditional coursework evaluation to judge students’ readiness for the next stage of the program and to demonstrate professional growth as the student enters the career market. The new technology courses allow students to meet multiple objectives with the integrated, project-based format. With each project, students have the opportunity to:

1. meet required technology course objective(s),
2. use the technological skill to complete requirements in another teacher preparation course,
3. extend their personal uses of multiple technologies,
4. add to their personal portfolio documenting professional growth, and
5. engage in the same types of professional practices which must be self-disciplined as an inservice teacher.

The Future

The preparation of future teachers is a tremendous responsibility during these times of dramatic change and increasing expectations. The potential contribution of educational technology is dramatic if our preservice teachers know how to use the various technologies and when, where, why, and with whom the technologies are most efficiently and effectively utilized. The technology courses designed as required service components to the University of Northern Colorado undergraduate teacher preparation program will, hopefully, move our future teachers closer to reaching their personal and professional potential. Continued formative evaluation of these technology courses and attention to the mutating instructional environments within our K-12 schools are the tasks which now confront the educational technology faculty. There is much work ahead, but a strong foundation has been laid for preparing our future educators.

Many educators and policymakers think of subject matter and pedagogy as separate entities. "The apparent assumption of such policies is that pedagogy and subject matter are not only separate, but that they are fixed in a zero-sum relationship, such that increases in one area necessarily result in decreases in the other" (Kennedy, 1990, p.13). But some teachers who are thoroughly competent in content are incapable of effective teaching (Ball, 1990). There is emerging evidence that the teacher's knowledge of content is not as important as the knowledge developed by the learner.

The typical curriculum at the K-12 and college levels is based on a structure where important knowledge is identified for students to acquire, usually stated as behavioral objectives or outcomes. The teacher and the curriculum disassemble knowledge, breaking it into small segments that are considered easier for the students to learn. In some classrooms, task analyses are so complete that each step of the learning sequence is identified. The teacher's role in the classroom is to transmit knowledge to students, a process that has defined steps and procedures separate from the subject matter content (Rosenshine & Stevens, 1986). The student's role is passive, to listen, sometimes take notes, and answer questions (Ausubel, 1963, 1968). In this model the teacher's performance is based on "effective" eye contact, different kinds of questions, appropriate pauses to allow pupil reflection, introduction of concepts, redirection of student questions, and so forth. This instructivist process disassembles knowledge into small bits for students to comprehend. The constructivist model, on the other hand, assumes that prior knowledge affects the process; therefore, current knowledge is constantly constructed and individualized (UMPERG, 1996).

At the University of Alabama, the instructional technology faculty of the College of Education was faced with staff reductions and limited equipment for basic computer skills' instruction. To maintain a quality product with limited resources, the faculty developed an asynchronous model of instruction based on constructivist principles. Using methods familiar in distance education, a course was specifically designed that essentially tripled the enrollment without increasing staff or the number of computers available. In this paper, we discuss the constructivist model and how it is applied in the course outlines, explain how technology can be a capital-intensive strategy, and describe some of the experiences of using constructivism where students, instead of the teacher, organize information, explore the learning environment, conduct learning activities, and monitor their learning.

**Constructivism**

Conventional instruction has grown out of a positivist tradition, a belief system that embraces and endorses scientific methods that enable scientific inquiry to lead to understandings of problems and their remedies. Much educational research has been undertaken to find "what works" in natural classrooms so these techniques can be understood as a process-product model to be transmitted to new teachers (Rosenshine & Stevens, 1986). Constructivism has emerged in opposition to conventional teaching, from the perspective of research and as well as from other education aspects. The contrasts are evident throughout education: constructivism versus instructivism, quantitative versus qualitative, standardized testing versus performance assessment, whole language versus basal reading, and fundamental epistemological conceptions. Rather than emphasizing content and presentation, the constructivist is interested more in creating authentic learning tasks, engaging the learner in realistic, thematic learning activities, and attempting to interpret the needs of learners as they become evident. These reflective teaching practices avoid interpretations of reality but direct energy into the development of individual students to accept responsibility for learning.

In keeping with the theory, constructivist principles for teaching seem far less clear, relying on the clinical skills of teachers and reflection. Brooks (1990) contrasts traditional teaching with constructivist instruction: "The traditional way of structuring lessons is concept introduction, practice, application, and further exploration, if time allows" (p.
69). But models of learning based on constructivist principles must adhere to a sequence in which exploration comes first, for this is how it occurs in a natural context for all organisms (Brooks & Brooks, 1993). Much of the incentive for constructivism is in response to the practices of memorization (Lipman, 1991) and “deconstruction” of content by the teacher. Rather than lecture and specific step-by-step presentation, curricula have been based on projects, authentic tasks, real-world contexts (e.g., Anderson & Roth, 1989; Roth, 1989). Constructivism asserts that learners create meaning and are not passive recipients of information. There is substantial evidence to show that students do not learn effectively by passive reception of information or by memorization.

Constructivist theory is based on the observation that learners construct mental models of physical phenomena. The teacher’s knowledge of content, while important, is insufficient, alone, because “knowing” content does not mean that one can also teach it. Teachers must be able to make subject matter understandable to students, which requires more than a knowledge of subject matter. For knowledge to be more than information, and for students to become constructive, the curriculum must avoid piece-meal, decontextualized, teacher-transmitted learning.

The conceptual framework for all programs in teacher education at the University of Alabama, is organized around the theme that educators are reflective decision makers who facilitate student learning (Conceptual Framework, 1995). This conceptual framework has existed formally for several years and is periodically revised. In principle, according to the conceptual framework, reflective teaching is the analog of constructivism. While some faculty object to the emphasis on reflection and construction to the apparent exclusion of behavioral principles, constructivist views clearly dominate. The faculty is guided by a belief that educators are facilitators of student learning, a more comprehensive view than conceptions of the educator as a manager, a technician, an academician, or a therapist. This concept brings into focus the important role of learners as active participants in the teaching-learning process.

**Basic Computer Course**

The basic computer course requires students demonstrate skills in word processing, database and spreadsheet use, presentation graphics, electronic mail, and Internet searches. Students who can demonstrate competency in these skills can “test out” of individual course sections or the entire course. While the course has changed frequently because of improvements in hardware and software applications, in the past, it was presented in a conventional manner. Students were provided with daily lectures and whole-class instruction. With cutbacks in staff, the faculty decided to implement a new model based on constructivist principles for philosophical and experimental reasons, and to meet a practical need.

The course was radically redesigned with a shift from whole-class to small-group instruction, from individual to tutorial instruction, from lecture to coaching, from summative tests to performance assessment, and from isolation to cooperative learning (Wiggins, 1993). At the outset, the intention was to have student outcomes identical to traditional courses, except that a greater number of students would be enrolled. The basic framework for the course was changed from large group lecture and individual practice to teaching practice based on coherent themes, reflection, and relevant contextual experiences. The curriculum is based on major concepts rather than a long list of objectives; it is focused on competencies rather than meeting externally imposed criteria. The intent has been for students to learn content and skills within an authentic context of carefully selected authentic problems (Carter, Cushing, Sabers, Stein, & Berliner, 1988) and to practice skills over a long period of time. The classrooms are less teacher-centered and more student-centered. The students know the requirements and the assignments, but receive individualized, group, and project-based instruction. Students are expected to assume responsibility for their own learning with respect to the time they spend studying and working in the computer labs. Faculty, graduate assistants, and peer coaches (students who have had these classes and are hired by the technical support group) give students guidance but not step-by-step instructions. Therefore, these “teachers” become “facilitators” and “coaches.” The students explore software programs through tutorials at individualized speeds and engage in authentic, real-world projects.

**Classroom Examples**

Two teachers in parallel classrooms assign the same word processor problem. While the teacher in the first classroom writes all the instructions, step-by-step on the board, the other classroom teacher allows the students time to learn the commands independently. The students from both classes finish with no problems. Later, when faced with a similar assignment, the students from the first classroom cannot complete the assignment without the step-by-step instructions, while the students from the second classroom remember where to find the commands that aid them in assignment completion.

At the University of Alabama, the instructional technology faculty take the second classroom approach. After a brief explanation, an assignment is given. The students follow tutorials and graduate teaching assistants and peer coaches are available to assist each learner on a problem-solving basis. The students ask themselves what, when, where, and how questions related to the assignment. What do I need to know to solve this problem? Where do I find the needed commands? When will I obtain the needed
results? How will I work on this problem? The students search pre-existing knowledge to find answers, thereby incorporating new knowledge along the way. By doing this, the students have an active participation in the shaping and augmenting of their learning.

At the introductory level course, students are assigned specific skills to master regarding word processing, database, spreadsheet, and presentation delivery. Each section begins with a simple exercise, followed by a second implementing additional skills, and then a third exercise as a self-discovery. For example, the students' third word processing assignment is to construct a personal resume. The third spreadsheet assignment organizes a home grocery budget. The instructors do not give a "laundry" list to follow, but instead, allow each student to explore the various programs. Independent thinking is encouraged, thereby creating individualized computer-related realities for lifelong applications.

This philosophy is carried through the upper level computer application courses. At the 300 level, students implement prior skills learned while completing various Internet applications. At the beginning of the semester, students enjoy a "scavenger hunt." The students begin their "hunts" on one common home page and from there link to various sites based upon each student's interests. By the hunt's end, students have developed and exhibited skills such as downloading information and saving graphics to diskette, have developed a database of favorite musical groups, and have "booked" airline and hotel reservations. Independent thinking is encouraged, thereby creating individualized computer-related realities for lifelong applications.

Within each course, the instructional technology instructors’ goal is to individualize learning so that each student creates his or her own meaning, therefore creating a sense of ownership in the end-products and skills achieved. It is the faculty’s general belief that this is important in order for the students to embrace the technology for lifelong learning and use.

Course Analysis

In the fall of 1996, one year after this model’s implementation, the department authorized a survey to assess attitudes of those students enrolled in the undergraduate computer application courses. A group of graduate students in a survey research course administered the survey and analyzed the data. The results shared in this paper summarize the survey analyses (Hardin, Keizer, Saphore, Tinley, Wright 1996).

The instructional technology faculty had specific questions it wanted addressed in this survey. They were:

1. Are the courses perceived by students as different from other courses?
2. Does the coursework increase students' confidence in computer usage?
3. Demographically, are there any major differences in attitudes toward computer use?

Survey Instrument

The instrument consisted of two parts: Likert items, and demographic information. The Likert items were based on a five point scale from low (1-Strongly Disagree) to high (5-Strongly Agree), with 3 as undecided. The Likert scale items were developed to aid researchers in measuring attitudes toward computers, computer technology, and the undergraduate computer application classes at the University of Alabama. Demographic information in the categories of sex, grade point average range, classification, and course enrollment was added for future correlation to determine differences among respondents. Within the operationalization process, specific statements were written to aid in measurement of the independent variables.

Analysis

Numerical values ranging from one to five (1-5) were assigned to the scaled responses for scoring. A score of 5 is high and a score of 1 is low. Any score of 3.5 or above was considered to be in agreement with the statement, and scores of 4.5 or above were considered high agreement. Conversely, scores below 2.5 showed disagreement and scores of 1.5 or below showed high disagreement.

The students enrolled in the undergraduate computer application classes at the University of Alabama, during Fall, 1996, seemed to perceive these courses as being different from other courses at the university. For the research question, "Are the courses perceived by students as different from other courses?" the mean score for total population was 4.22, with 88% either agreeing or strongly agreeing (Graph 1). In general, agreement with this statement also increased with Grade Point Average (GPA). Furthermore, agreement increased with the class levels. For example, those students enrolled in 400 were more likely to agree than those students enrolled in 100.

Graph 1. Are the courses perceived by students as different from other courses?
With the second research question, "Does the coursework increase students' confidence in computer usage?" the researchers used several items in the final analysis. These items assessed confidence in using the computer independently, intimidation toward computers prior to taking the class, and perceived self-confidence increases. The responses were reported across the items for the total population and for various subgroups. The respondents agreed (3.6) that the coursework increases their confidence in computer usage. All GPA groups and each class level (100, 300, and 400 groups) were in agreement. Of the total population, 63% either agreed or strongly agreed that the coursework increases their computer usage confidence (See Graph 2).

The third research question was, "Demographically, are there any major differences in attitudes toward the importance of computer technology?" Again, several items were used to answer this question, including assessing computer ownership, importance of computer skills in today's job market and in school performance, and self-directed computer knowledge growth. The data across the items were compared with gender, GPA, and class level subgroups. The data suggested that gender and class levels do not have an effect on attitudes toward the importance of computer technology while GPA does have an effect. The group with the highest GPAs showed a 15% increase in agreement over respondents in the average GPA group (See Graphs 3, 4).

In conclusion, the researchers’ data seemed to indicate that while the respondents do perceive the courses as different, most agreed that the courses increased their confidence in computer usage. Further study using a stratified sample from specific demographic groups could reveal additional information to aid the instructional technology department.

**Graph 2.** Does the coursework increase students' confidence in computer usage?

**Graph 3.** Taking GPAs in consideration, are there any major differences in attitudes toward the importance of computer technology?

**Graph 4.** Taking GPAs in consideration, are there any major differences in attitudes toward the importance of computer technology?

**Conclusion**

This survey authorized by the instructional technology department somewhat validated its constructivist approach in the College of Education's computer application courses at the University of Alabama. While the learning sequence must begin with exploration, the teacher, as facilitator of learning, also must encourage that such exploration never end. Through real-life experiences, the major concepts should become individualized. Through such contexts, as technology changes, the student can adapt because the preparation for adaptation came through self-discovery. As Nicholas Negroponte states in his book, *Being Digital*, "True personalization is now upon us" (p. 164).

Many universities now require students to complete a course on using computer technology as part of their teacher education programs. These programs are often designed to familiarize students with existing technology, tools, and software. Unfortunately, most undergraduate programs do not provide enough time to cover the scope of technology use in the classroom (Bruder, 1989). Recent studies indicate that less than one-third of students leaving teacher education programs felt that they were prepared to teach using technology (Handler, 1993; Scrogan, 1992; Fulton, 1989). Powell and Reiff (1993) found that most students agree that computers should play an important role in the schools, yet indicate a lack of confidence and are insecure using computers to teach others. Barker (1994) noted that teachers show great enthusiasm for using computers, but find it difficult to integrate technology into the curriculum.

Those that use computers use them primarily for enrichment and/or remediation (Becker, 1991.) A 1995 study by Huinker, Fuller and Ellwood found that computers were rarely used in any math and science classes. Most preservice teachers have had only limited exposure to computer technology during their public schooling. This trend continues at the university level where 44% of faculty either disagreed or strongly disagreed with the notion that computers could be beneficial to the teaching process (Misfeldt & Stahl, 1991). Darby (1992) states that there is an unwillingness on the part of universities to recognize and reward effort put into improving teaching, including both the use and development of computer-based materials. The resulting curricular lag in universities causes even recent graduates of professional programs to lack adequate understanding and skills in the use of technologies that they will be expected to use in their careers (Hurd, 1988). Thus, we believe one reason for this disparity between the intentions of the teacher education programs and the reality in the schools is that new teachers have had very limited exposure to appropriate models of how the computer can be used in a classroom setting.

This paper describes a preservice technology course taught at the University of Victoria using the elementary science, math, and social studies curriculum as the focal point. The main goal of the course is to provide students with a model of how to teach these subjects with technology rather than just how to use technology. The content of the course includes the use of computers for discovery learning, experimentation, simulation and modeling, forming and testing conjectures, problem solving, decision making, computation and data processing as well as communication, information retrieval, and course management.

Technology tools used to facilitate these activities include spreadsheets, database, Hypercard/Hyperstudio, Internet applications (including html and web page construction), computer concept maps, graphics packages, computer-based lab equipment and software, CD ROM/laser disks and other multimedia, as well as some subject specific packages. Students learn these tools by participating in sample activities in class in one or more of the three subject areas.

The course is team-taught by three curriculum and instruction specialists in the areas of science, math, and social studies. It begins with a segment including a general introduction to computers in education, ethical issues surrounding computer use, and introduction to the Internet, searching strategies, and html. Students begin constructing their own web page as an ongoing assignment. Following this introductory component of the course, the three instructors each teach a separate segment of the course, focusing on tools which have application in their particular subject area.

Computer Applications in Science

No one doubts the major impact the computer has made in society in recent years, and the impact has been strong in science education. Its power revolves around its versatility as both a production tool and a presentation tool (Newby, Stepich, Lehna, & Russell, 1996). Because of its impact and potential, it is essential that elementary science teachers recognize its power and how it can be used for learning.

Many colleges and universities that train science teachers do not require a separate course in computer applications such as this course (Ed-E 438A) offered at the University of Victoria. Preservice science teachers may
take a computer literacy course as an elective or may get brief exposure to microcomputers in various methods courses (Woerner, Rivers, & Vockell, 1991). Since a microcomputer is only one of many instructional tools that preservice teachers must study, little time is spent examining and implementing various science software programs. Hence preservice teachers may lack the expertise needed to make good use of the new technologies available to them.

According to Maddux, Johnson, and Willis (1997) the Office of Technology Assessment (OTA) has announced preliminary findings for a new study, and their findings underscore the need for excellent faculty preservice and inservice at all levels. The National Educational Advisory Board (1993, p.1) has summarized these findings and identified the following problems:

1. Practicing teachers do not have the expertise to use educational technology wisely.
2. School districts are not increasing spending for inservice training to keep up with spending for new hardware and software.
3. Teachers in training see very little technology used in their education courses or in their student-teaching placements.
4. College faculty members do not have the expertise needed to integrate technology into the teacher education courses they teach.
5. There are serious computer hardware and software shortages in colleges of education.
6. There is not enough good technology inservice education offered to college of education faculty members. (1993, p.1)

These findings underscore the importance of competent instruction in the use of technology for teachers at all levels. This course attempts to eliminate some of the problems mentioned above through the activities listed below.

Introduction to Using Microcomputers in Science Teaching

Students are introduced to computer applications in the science area by first developing an awareness of the major types of applications in science teaching. These include:

A. Providing Instruction
- tutorials
- simulations
- instructional games
- drill and practice
- data analysis
- word processing
- microcomputer based labs
- equipment management
- record keeping

B. Managing Instruction
- word processing
- information retrieval
- database creation and use, test generation and administration

C. Integrating Microcomputers into Science Teaching
- scheduling and using microcomputers for instruction
- demonstration
- station activities
- multiple microcomputers
- designing a lesson
- instructional strategies and microcomputers

Instruction then moves to ways to use the computer as a tool in science teaching and how to implement these tools in instruction. Topics discussed include:

Information Acquisition
- telecommunications
- optical disks
- microcomputer based labs (MBLs)

Analytical Tools
- databases
- spreadsheets

Graphing/Statistical/Transformation Tools

Creativity Tools

Communication Tools
- setting goals
- planning for implementation
- locating courseware
- sources of information

The science component of the course finishes with a section on how to integrate such new technologies as interactive video, Internet, and CD-ROM into the science class. Science assignments for the course include the following:

1. a) Develop a science database (any science area) that will:
   i. require up to three search criteria
   ii. include low level and higher level questions that can be answered by searching or sorting the database
   iii. generate and test hypotheses
b) Describe how you would use this database in a classroom (select the grade) situation.

2. Develop one detailed lesson plan in science to demonstrate how a microcomputer or microcomputers can be incorporated effectively into the lesson. The software packages demonstrated in the lab or software package of your choice may be used.

3. a) Locate the top 10 Internet sites that you believe would be most useful to elementary science teachers.
b) What is the value of the Internet to:
The Task:

Develop one question to be assigned to students in this course. It should be phrased in such a way to require consideration of the information contained and available through the CD-ROM version of the World Book Encyclopedia. The assignment must take advantage of this incredible database and search engine, rather than merely duplicating what could easily be found using the print version. The objectives of the assignment should include evidence of familiarity with the disc and its structure. These are sample questions:

- Is "regeneration" limited to plants?
- What does gravity have to do with black holes and ocean tides?
- Why does safety have so much to do with science?
- Have nuclear accidents occurred frequently?

Please provide your question together with the answer supported by printed references from the CD-ROM.

Mathematics Component of the Course

Tool packages investigated in the mathematics portion of the course include both generic packages such as Clarisworks and subject-specific packages such as Geometer’s Sketchpad and Tesselmania. Students begin by learning the general features of the package and then participate in problem-solving activities using the software.

Clarisworks is introduced first as it is a popular software package often used in schools. The spreadsheet is a good tool for mathematics as it is readily adaptable for problems that are iterative, recursive, or tabular in conceptual format and enables teacher and students to tinker with values of variables, constants, and step size as well as to explore the tempting “what if?” type of questions in the problem-solving process.

Spreadheets can enhance the user’s insight into the development and use of algorithms and modeling for the solution of mathematical problems. They free students from being hampered by laborious manipulation of numbers and allow them to concentrate on the mathematical problem itself. This permits the in-depth exploration of meaningful mathematical application without concern for the possible complex calculations needed.

Sample problem-solving activities in which the students engage using spreadsheets include:

- Estimations - then make actual calculations and/or graph;
- Make predictions based on initial data gathered;
- Statistical surveys and analysis of the data using both formulas and charts;
- Metric (or English) measurements of the body, objects of various sizes, perimeters, areas;
- Equations, functions, relations;
- Time needed to accomplish various tasks;
- Mathematical Patterns - spreadsheets are ideal to use as an exploration tool to investigate various patterns because of their ability to do quick calculations and to copy formulas to new locations using relative addresses rather than absolute addresses;
- Discovering Properties.

The students are next introduced to a variety of draw and paint programs including Clarisworks, Superpaint, Kid Pix, and Tesselmania. Students learn to use these packages both for managing instruction (e.g. preparing handouts with geometric figures on them) and as tools for students to use. Sample activities students complete in this section include creating figures with various types of symmetries and transformations, and making tessellations using both generic paint programs and Tesselmania, a dedicated tessellations package.

Geometer’s Sketchpad is a graphics package which allows exploration of geometric concepts by constructing figures using traditional Euclidean means and then dragging on points or lines to modify the figures. Students participate in investigations to learn how to use the package and also to discover some geometry relationships they may not have previously known. Sample investigations include:

1. Midpoints of parallel chords: Trace the midpoints of a chord as you drag a line in a parallel manner. Then use the information about this locus of midpoints to shed light on tangents parallel to a line.

   Construct circle AB and line CD. Construct E & F, intersection points of the line and circle. Construct segment EF and midpoint G. Add segments AE and AF. (See Figure 1). Trace point G. Drag CD in a parallel manner. Make a hypothesis about the geometric object traced by point G. Test your guesses.

   ![Figure 1. Diagram for investigating midpoints of chords.](image)
2. Midpoints of chords dragged with a fixed point: Trace point G as you drag point D (line CD will be fixed at point C). Make a hypothesis about the object traced by the midpoint. Since location of C may affect the trace of G, make an animation button. Select D and the circumference of the circle. Choose Action Button in the Edit menu and Animation from the popup menu. Double click the button to activate it. You can use the animation button to experiment with the trace of point G for different locations of point C.

The math component of the course finishes with a section on various mathematics software packages for the elementary student. Students engage in model activities for a variety of packages, such as Millie’s Math House, How the West was One + Three x Four, The Factory, Puzzle Tanks, Maps and Navigation, Safari Search, and Blockers and Finders. Following this, students discuss the strengths and weaknesses of each package and share other ideas for incorporating their use in a mathematics class.

Assignments consist of planning classroom activities using the tools of this section of the course. Students must design math activities which use spreadsheets, a graphics package of some type, and any other package of their choice. Criteria for marking assignments consists in equal parts of demonstrated mastery of the technology and appropriateness and quality of the planned classroom activity.

Social Studies Component of the Course

The third segment of the course begins with an overview of computer technologies in social studies. Students participate in a computer-based simulation using computers and laser discs linked interactively. They also discuss the use of CD-ROM technologies in the social studies field. Several sample CD-ROMs are presented, and students choose one to review in depth. Reviews must include a discussion of how the CD-ROM would be used with students, the age and grade level for which the CD-ROM is most appropriate, and the advantages and disadvantages of this media compared to other forms of representing the same content.

Electronic mail as a tool for knowledge building and sharing is discussed, and successful model projects are highlighted. Students also investigate other ways in which the computer can be used as a tool for representing knowledge, using concept mapping tool packages, and presentation software.

Hypercard, the original multimedia tool, is introduced, followed by alternatives such as HyperStudio, a more user-friendly package for the elementary classroom. Students learn the elements of hypermedia design and then use these principles to build a stack that utilizes material from a laser disk. The stack must be designed to be interactive and require the learner to do something with the video and text rather than simply read or watch what is presented on the video.

Summary

The format of the course has been very successful. Students have the benefit of instructors with expertise in a subject area who can use technology in their subject. Participation in model activities allows students to become learners in the subject area while learning to use a variety of computer tools. Students completing evaluations consistently rate this course as one of the most useful in their preservice teacher education program.

In many schools, students are being evaluated on the basis of portfolios that document what they can do in language arts, science, social studies, and other skill areas. Portfolios often include such items as student-produced books, videos, and audiovisual presentations. (Heinich, Molenda, Russell, & Smaldino, 1996, p. 64) This article describes the evolution of student evaluations. Traditionally a major, if not the sole, method of student evaluation was paper-and-pencil tests. In the past, some instructors assigned a number of small-scale, disconnected practice exercises. Later they offered a menu of projects of a larger scale. Today the trend is to encourage students to compile portfolios of professional quality work, organized around major themes. The nature of portfolios and their advantages and limitations will be explored. The use of portfolios in two different educational technology courses will be described.

Evolution of Projects

Educators frustrated with standardized testing and conventional paper-and-pencil assignments are having students demonstrate their achievements by compiling portfolios of their work. Many educators feel that preparation of portfolios gives a truer, more rounded view of an individual’s strengths and weaknesses. Further, portfolio assessment is consistent with the constructivist philosophy, which emphasizes that what is important is the knowledge that students themselves construct (Heinich et al., 1996, p. 96).

With increased attention on multidisciplinary inquiry, open-ended explorations, and more complex learning tasks, the focus of evaluation has shifted from traditional student achievement measures (e.g., paper-and-pencil tests) to case studies of student work (e.g., portfolio outcomes) (Seely, 1994).

One example of this shift is the evolution of projects in media utilization courses. Twenty-five years ago many instructors required every student to do the same small-scale projects — a bulletin board, an audio tape, one dry mount, one permanent rubber cement mount, one temporary rubber cement mount, etc. Later instructors provided a list of projects from which students could choose. In fact, at their suggestion, our Instructional Media textbook (Heinich et al., 1996, p. 96) included “Possible Projects” in its first four editions. Now many instructors are using portfolios — a collection of projects often related to a single topic and a single audience and that usually include student comments and reflections about their projects.

What is a Portfolio?

Paulson, Paulson, and Meyer (1991) describe a portfolio as “A purposeful, integrated collection of student work showing student effort, progress, or achievement in one or more areas. The collection is guided by performance standards and includes evidence of students’ self-reflection and participation in setting the focus, selecting contents, and judging merit” (p. 295).

Components of a Portfolio

The idea of portfolio assessment, then, is to measure students’ achievements by their ability to create tangible products exemplifying their talents. Portfolios may contain the following components:

- Written documents such as poems, stories, lesson plans, or research papers,
- Media presentations, such as slide sets or photo essays,
- Audio recordings of debates, panel discussions, or oral presentations,
- Video recordings of the student’s athletic, musical, or dancing skills,
- Computer spreadsheets of student data, and
- Computer multimedia projects incorporating print, data, graphics, and moving images (Heinich et al., 1996, p. 96).

Advantages and Limitations of Portfolios

On the following page Table 1 lists several of the advantages to using portfolios. And even though there are many advantages of using portfolios, they also have limitations. Table 2 lists a number of the limitations of portfolios identified by the authors and confirmed by their experiences.

Applications

Portfolios have been used for peer review, to show progress and experiences, to demonstrate abilities and experiences, and during employment interviews. Other uses include showing competencies, focusing on learning, reflecting on experiences, and assessing accomplishments.
I have used portfolios in an instructional media course for preservice and inservice teachers and in a technology for teachers course. Fortunately the classes have enrolled fewer than 30 students and the staff has included two instructors (a professor and a graduate student) which facilitates grading of portfolios. For large-enrollment courses it may be necessary to cut back on the magnitude of the portfolios or to increase the number of evaluators.

**Media Utilization Course**

Several years ago I began using a portfolio approach to evaluation rather than written quizzes and a final exam in my media utilization course at Purdue University. My co-instructor suggested the idea and proved you can "teach an old dog new tricks!" After trying portfolios for one semester, I was willing to give up paper-and-pencil quizzes and unrelated projects for portfolios.

How a portfolio approach to evaluation is being used rather than written quizzes and a final exam in a media utilization course will be described. Student select, modify, design, and produce a collection of media and methods to teach a topic of their choice to an audience of their choice. At the end of the course, the complete portfolio is also evaluated in terms of how well the portfolio "hangs together" as an integrated product.

Students select, modify, design, and produce a collection of media and methods to teach a topic of their choice to an audience of their choice. The topics tend to be broad ones like aviation, biology, calculus, dinosaurs, engineering, forestry, home economics, and industrial technology. The audiences may be specified by grade level (fifth graders, middle school students), employment levels (assembly line workers, upper level managers) or age level (senior citizens, preschool children) with whom the students are familiar. Students meet individually with the instructor(s) to discuss their topic and audience as well as their course goals.

Select. Using the Appraisal Checklists in either paper or electronic form included in *Instructional media and technologies for learning* (5th ed.), students preview different media/materials for possible inclusion in their portfolios. Each preview is accompanied by a brief explanation (one or two paragraphs) as to why the media would or would not be effective in teaching the portfolio topic. If the material was judged appropriate to be included, the student specifies how it would be used.

Modify. Students also modify existing media/materials. These materials are selected based upon congruence with the portfolio topic and audience. For example, a student could add slides of a local environment to a commercial slide set or use an existing set of visuals but change or omit some of the labels or captions. Students are cautioned to be sure their handling and use of materials does not violate copyright laws and restrictions that are described in the textbook.

Produce. As another part of the course portfolio, each student produces different pieces of media for the chosen topic and audience. They are required to incorporate different types of media which encourages them to expand on their current media production skills. For example, they can not produce two audiotapes, but they could produce an audiotape, a bulletin board, a set of overhead transparencies, and a videotape. The choice of media formats is up to each student, but they must be varied. Where appropriate, the projects are evaluated using the corresponding Appraisal Checklist from the textbook.

Design. Each student designs a lesson using the ASSURE Model described in the textbook. The student again chooses the topic and audience. The recommended length of the lesson is from 30 minutes to one hour. The student can use the printed template in the textbook or the computer template in "The Classroom Link" as a guide.

The design must include:

- **Analyze Learners** including the general characteristics, entry competencies, and learning styles of the students/trainees.

- **State Objectives** describe the learning outcomes and are written in the Audience, Behavior, Conditions, and Degree (ABCD) format.

- **Select Methods, Media, and Materials** provides a rationale as to why the methods, media, and materials have been selected, modified, or produced.

- **Utilize Materials** describes how the materials and media will be used. The students describe how they will preview the materials, prepare the materials, prepare the environment, prepare the learners, and provide the learning experience. (The 5 Ps of utilization)

- **Require Learner Participation** describes the activities which will get the learners involved, particularly through practice with feedback.

- **Evaluate and Revise** indicates how the objectives will be measured and includes evaluation of learner achievement, media, methods, the instructor’s role, and the overall process. To ASSURE quality instruction, it is important to evaluate and revise the experience, if necessary, before future use.

Evaluation of Student Portfolios

The individual components (select, modify, produce, and design, ) are evaluated as they are completed. Students are encouraged to make weekly progress and not to put everything off to the end of the course.

At the end of the course, the complete portfolio is evaluated in terms of how well the portfolio "hangs together" as an integrated product. How well do the pieces fit together to support a user’s understanding of the selected topic? Is the portfolio well organized, making it easy to locate specific items? Is the work neatly arranged and attractively presented?

Technology Course

In an instructional technology course that integrates computers, media, and instructional design at Florida State University, I used portfolios as the major part of the course evaluation. This course typically enrolls 30 students. The portfolio format was based upon the work of my co-instructor Terri Buckner. The textbook for the course is *Instructional Technology for Teaching and Learning* (Newby, Stepich, Lehman, & Russell, 1996).

**Goals.** Student state their goals for the course. The course enrollment ranges from undergraduate education majors to graduate students who were employees of the Florida Department of Education. Each student meets with an instructor to discuss and review goals. The goals can be modified and adjusted during the course.

**Artifacts.** Materials (lesson plans, work samples, materials developed, evaluations, position papers) are used to illustrate progress toward the stated goals. The nature of the goals determines how the artifacts are organized in the portfolio. Each section includes an index listing the artifacts in that section.

**Caption.** A short written description is included with each artifact stating what the artifact represents in the portfolio. The purpose of each artifact is to convince a reader (and the instructors) that learning has occurred. Each caption/description is a part of that argument. It is recommended that descriptive captions be between 50 and 250 words.

**Rubrics.** Students develop the rubrics (explanation of evaluation criteria) for assessing their own portfolio. Each section of the portfolio includes a scoring rubric used to “quantify” the student’s learning. For example, a student
might want to assess each section on a five-point scale. Each scale point has a description of what would constitute a rating at that level. The student provides a description of each scale point.

**Self Evaluation.** Students complete a self reflection comparing their results with their intentions. Students evaluate their own portfolios twice during the course. Each evaluation includes the strengths and weaknesses of the goal statements, the artifacts included, and a self-reflection on how they are progressing in learning about technology, teaching, and learning. During the course this reflects what was learned to date and what still needs to be explored. The end-of-course evaluation addresses how the student plans to proceed after the course.

**Peer Review.** Twice during the course two classmates review each portfolio using the rubrics developed by the student who produced the portfolio. The purpose of peer reviews is to help students look at their own learning from a different perspective. The reviewers are given the goal statement, the artifacts, the captions, and scoring rubrics. This not a grading session, but an opportunity for students to share what each has done and to receive feedback from peers for the purpose of improving the learning experience. Copies of the written review are given to the students who did the portfolio, are placed in the portfolio of the reviewer, and are given to the instructors. Reviewers look for a match among the goal statements, the artifacts, and captions produced. If the scoring rubrics are not understandable, the student is given an opportunity to revise them before the end of the course. Both the portfolio developer and the reviewer learn from the experience. Peer feedback includes an oral report (debriefing) between the two students followed up by a written report that becomes part of each student's portfolio.

**Instructor Review.** The instructor review procedure is identical to peer review except it is graded. The instructor evaluations occur midway through the course and at the end of the course.

**Summary**

Portfolios have been used for peer review, to show progress and experiences, and during employment interviews. Other uses include showing competencies, focusing on learning, reflecting on experiences, and assessing accomplishments. It was pointed out that some colleges and universities use portfolios as a graduation requirement.

Portfolios can make learning more interesting. They tend to be individualistic and can allow students to determine what they want to learn during a course. As a perspective over time during a course or curriculum, portfolios pull together a lot of information and artifacts. These materials lend themselves to formative evaluation and revision. Portfolios have the added advantages of allowing students to organize their knowledge, skills, and materials, to develop an in-depth understanding of the content, and to show peers and professionals what they have learned and can do.

Instructors who have used portfolios point out that they may require more time from the student and the instructor. Another concern was lack of precision in evaluating portfolios. Since portfolios are individualized, not all students may learn the skills taught in a course. The relative emphasis on process versus content was mentioned. An over-emphasis on the electronic aspects of portfolios was seen as a potential limitation. A final drawback was the quantity of materials in a portfolio and how to display and store these materials.

ASSESSING PERFORMANCE IN INSTRUCTIONAL TECHNOLOGY: USING THE PORTFOLIO

Randal D. Carlson
Georgia Southern University

Few educational reform movements have received the approval and attention of such a wide range of educators as the current trend toward direct assessment of student performance. This attention was foreshadowed by Messick (1994) and reinforced by many of the prominent current theorists and practitioners (for example, see Educational Leadership, April 1989, May 1992; Phi Delta Kappan May 1989, May 1991). Many groups who are interested in content-specific areas are calling for increased emphasis on assessment of authentic tasks (National Council of Teachers of Mathematics, 1993; Hansen, 1991). The underlying assumption for all groups is that students are better assessed in the context of accomplishing relevant, meaningful tasks rather than decontextualized, artificial exercises. These alternatives to standardized testing have taken on several monikers - the most common of which include:

- **Performance assessment** - a term associated with the nature of the product or performance that is assessed. The performance or product produced must be a valid example of the skill to be assessed. Note that the skill does not have to be accomplished in a real-life context (Meyer, 1992).

- **Authentic assessment** - a term associated with assessments that are situated in the appropriate performance context. These assessments may include performances, observations, exhibitions, and interviews. The key characteristic of this type is the performance context as opposed to the nature of the product (Wiggins, 1993), and the more inclusive term.

- **Alternative assessment** - a term used to indicate the new collection of procedures and techniques that require the student to construct responses to questions as opposed to traditional testing which requires students to select a response to items constructed by the item writer (Ryan & Miyaska, 1996).

This paper addresses one specific method of authentic assessment, portfolio assessment, and its application in two case studies assessing learning of instructional technology. Suggestions for practitioners who wish to use this method are provided at the conclusion of the paper.

**Portfolio Assessment**

**The Portfolio**

A portfolio is a "a systematic and organized collection of evidence used by the teacher and student to monitor growth of the student's knowledge, skills, and attitudes" (Vavrus, 1990, p. 48). Flexibility and student ownership are essential elements in portfolio assessment. This does not mean, however, that there is no structure to it. On the contrary, the portfolio must be highly structured for two reasons: The portfolio must provide an intersection of objectives (skill required), instruction (skill learned), and assessment (skill evaluated). Unstructured or ill-formed assessment instruments tend not to reflect the task to be learned, thus failing to provide necessary congruency among the learning elements. All parties interested in the assessment must understand the purpose and components of the portfolio. It is also essential to help students establish a sense of ownership. This can be established by negotiating the portfolio's makeup and determining how scoring of the assessment instrument will be accomplished (Lescher, 1995).

**Types of Portfolios**

There are two types of portfolios: process portfolios and product portfolios. They differ from one another in the makeup of the body of evidence and the purpose of the assessment instrument. Contrasting the two, one may think of the process portfolio as a record of accomplishment throughout the term (daily homework) while the product portfolio is the final exam (a one time record).

Process portfolios show a student's work along a temporal path with samples taken throughout the period. They provide a rich and dynamic record of the student's changing, growing capabilities and attitudes. This record helps to show the route that the student followed to reach his/her current ability level (Lescher, 1995).

On the other hand, product portfolios attempt to document the very best work produced by the student (Cole, Ryan, & Kick, 1995). The student will not include...
all their work in this portfolio, but will select only examples of excellence. The student usually will select these examples.

**Content of Portfolios**

The artifacts that comprise the portfolio assembled by the student must be negotiated between the student and teacher. Possible components include:

- Traditional tests (which may be corrected by the student)
- Samples of in- and out-of-class work assignments
- Reports of experiments
- Laboratory notes
- Teacher observation of in-class performance
- Student logs or journals of in-class learning activities and accomplishment
- Student reflections concerning their feelings about learning activities
- Essays and writing samples
- Video and audio samples of performances

**Scoring Rubrics**

A rubric, a set of criteria against which the student’s work will be judged, is necessary to make a collection of materials and an assessment. According to Ryan & Miyasaka (1996), there are four basic types of scoring rubrics:

1. **Holistic**, which specifies no criteria, but instead uses overall judgment in arriving at the score,
2. **Modified or focused holistic**, which uses holistic scoring but with embedded criteria so that students and instructors can concentrate on critical performance areas,
3. **Analytic**, which involves making judgments of specific, but individual dimensions or characteristics, similar to judging subsections, and
4. **Modified analytic**, which includes analytic scoring with a total score so that an overall grade may be tallied.

**Discussion of the Cases**

This paper discusses the application of portfolio assessment to two instructional technology courses. These courses address the use of technology in educational settings, both for personal productivity and for instructional use, using the portfolio assessment method of compiling multiple samples of a student’s work that are produced at various times throughout the assessment period. Each portfolio is similar in the general products that must be exhibited, but different in the specific content and nature of that product. There are two general cases discussed. Case 1 is very highly structured and leaves the student little choice as to what to include in the portfolio.

Case 2 provides the student a broad latitude in assembling the makeup of the portfolio.

**Case 1**

**Instructions to the Student.** This course requires the production of specimens of various activities that will be addressed during the quarter. You will be responsible for completing all activities, however, you will be asked to choose, in consultation with the instructor, which activities will be submitted at the conclusion of the course and the weight each graded activity will carry. Table 1 is a list of activities that are grouped into similar enterprises.

<tr>
<td>In small groups, produce a short HyperStudio stack that includes a color image that has been scanned from a document, a digital photo, and a short segment of digitized audio and video. You must also hand-in the document that was scanned, and the separate files that were used to construct the stack.</td>
</tr>
<tr>
<td><strong>Group 6 - Progress</strong></td>
</tr>
<tr>
<td>Students will be able to show how they have improved their skills over the period of the course. Included in that activity will be the diversity of projects that were presented for evaluation.</td>
</tr>
</tbody>
</table>

**Portfolio contents.** The makeup and grading of the portfolio were negotiated, but boundaries were set so that
students were required to produce a sample of several types of technologies. The following table illustrates the variety of student portfolio makeup that was allowable. The column Minimum % indicates the required percentage for the whole group. A sample of appropriate weights for the activities for two different students is included in the last two columns. Note that the total of the group minimum equals 90%. Even if an activity were weighted 0%, it was still required to be accomplished.

Rubric. While Table 2 defined the makeup of the portfolio, and gave guidelines for the weighting of each activity, each activity also was graded, so a scoring rubric had to be established to grade each activity.

One that typically was used for production of the materials in Table 2, Groups 1 thru 5 was:

- Errorless - Full Credit
- Few errors - 85% Credit
- Many Errors - 70% Credit
- Not accomplished - 0% Credit

One that was used for the scoring of progress in Table 2, Group 6 was:

- Major - 100% Credit
- Substantial - 85% Credit
- Limited - 70% Credit
- None - 0% Credit

Observations. Case 1 was highly structured. The instructor provided the framework used by students to assemble their portfolio. It was a product portfolio (Table 2, Groups 1 - 5), although there was a small element of progress included (Table 2, Group 6). Modified analytic scoring was used. By design, students were allowed to decide which elements would be most important in each category.

In practice, many students used the default weights (represented by Student 1 in Table 2). Some students chose to weight only one product per category heavily and limited the weight assigned to the rest of the products in that category. These students tended to be the ones who had little prior knowledge. They appeared to adopt a strategy of minimizing their exposure, while students with a more complete background displayed an “I can do that” attitude.

Students also appeared hesitant to enter into any negotiation with the instructor. This class was a class of adult learners (mostly teachers) who typically have accepted a traditional view of the assessment process, and therefore may have been hesitant to suggest a formula that differed from the instructor’s stated default.

The material turned in varied in quality and quantity. Because the students had the option of turning in an “electronic portfolio,” they found it easier to dump all their work onto disks and submit it as part of their portfolio. Only two students (out of 18) provided an index of products or rationale for their selection. Because of this, the “portfolio” for the majority of the students became much more a collection of performances rather than a systematic, ordered display of accomplishment and progress.

Scoring of the portfolio and the portfolio elements was problematic because the rubric used was not well defined. Both the students and the instructor had difficulty judging what student produced material met the stated criteria. This resulted in lower reliability for the score than would be desirable.

Case 2

Instructions to the Student. Compile a portfolio of your work throughout the quarter. It must include your lab journal. This journal represents your lab notes on how to apply media to teaching. This journal may be derived from your readings, class lecture, or class lab time. The portfolio is intended to document your course learning activities, concentrating on progress made throughout the term. It may include any graded or ungraded exercises that you want to show me and any graded work that was less than perfect that you have corrected.
The activities in Table 3 were graded throughout the course of the term. In practice, this grading method differed little from traditional assignments accomplished and graded throughout the term. Abbreviated requirements for each graded activity are listed in Table 3. Supplemental checklists were distributed during the term in advance of each graded activity so that students would know the specific requirements and scoring of each graded activity.

Table 3.
Course Requirements, Case 2

<td>50%</td>
<td>Progress over time</td>
</tr>
</tbody>
</table>

Observations. Case 2 was unstructured. Students had wide latitude over what to include in their portfolios. The only required element was the lab journal. This was intended to be a progress type portfolio, although it also included elements of the product portfolio as well. The rubric used best exemplifies the modified holistic scoring technique. Each student had already been graded on a number of performances (products) throughout the quarter. They had this opportunity to correct their mistakes, show the progress that they had made, and highlight any special features of their experience.

In practice, students were very anxious about the form of the portfolio. These traditional undergraduates (preservice teachers) have become accustomed to assessments where the teacher asks the question and they respond with an answer. They very much wanted a "model" portfolio they could use as an example. Given the instructor's reluctance to specify the contents of the portfolio, the students tried to cover all the bases with a strategy of handing in everything they could find.

Scoring the portfolio was again problematic because the rubric used was not well-defined. This rubric required the instructor to judge on a continuum the proper accomplishment of the described criteria. This resulted in lower reliability for the score than would be desirable.

Recommendations for Practitioners

Based on the observations found in these cases, the following guidelines are suggested for those who are interested in implementing portfolio assessment strategies. One must remember that each portfolio is different. As such, guides that will help direct portfolio assessment activities may be useful, but strict rules may not be possible. Unless your students are thoroughly familiar with
this type assessment method, plan to teach them what a portfolio is and, specifically, what your assessment objectives are. A little time up front will produce marvelous results later on. Plan your assessment as carefully as you plan the rest of your course. Systematically look at your learners and your objectives. This will help you to choose the most appropriate portfolio type and rubric.

The more concrete the rubric anchor behaviors are, the easier the portfolio will be to grade and the fairer the assessment will be. Be sure that the instructions and expectations for the portfolio are clear to the student. These concepts are new to most students, so your intent may not be as intuitive to them as it is in traditional assessments. Help the students to question and think about the assessment by giving some intermediate range goal. It seems that unless forced, many will put off thinking about the portfolio until it is due. Don’t make the choices too hard. Especially if this is the first time that students have been involved in using an instrument like this, providing some structure is helpful to the student and results in a better assessment of the student’s progress and accomplishments. Require students to provide a rationale for the inclusion of portfolio components. Ask students to write reflections about how they have grown by talking about the various artifacts in their portfolio. This may help students accomplish summarization of the material and skills.

Technology for Preservice Teachers: “Driver Education” for the Information Superhighway

Jean Anne Hattler
Chatham College

In this paper, a professor of education discusses the challenges rapid advances in technology have presented to collegiate departments of education in their preservice-teacher coursework and to classrooms in general. Specifically, use of the Internet's World Wide Web (WWW), the information superhighway, will be presented as one important way to integrate technology and the vast amount of information it makes available. The discussion includes a look at how several segments of the nation view the current and future implementations of technology in American education. Following will be a brief review of the commitment of a small liberal arts college to technology and the corresponding revision in preservice-teacher coursework in its education department. This will include Internet websites which offer innovative and practical possibilities for teaching and learning. In summary, this paper offers “driver education” for traveling the information superhighway to preservice teachers.

Connections: The Internet and the Classroom

In the presidential debate of October 6, 1996, President Clinton stated, “Every classroom in America should be hooked up to the Internet by 2000 (Clinton, October 6, 1996).” Clinton was reiterating his commitment to The President’s Educational Technology Initiative, described in his State of the Union Address where he said that our schools ...must be connected to the information superhighway, with computers and good software, and well-trained teachers. (Clinton, 1996).” We are working with the telecommunications industry, educators, and parents to connect every classroom and every library in the entire United States by the year 2000.” Indeed, to get closer to this goal, President Clinton has proposed an additional $2 billion in federal money be spent this year on instructional technology for elementary, middle, and high schools so that every 12 year old can log on to the Internet (Wagner, 1996). How can the president’s goal of making teachers as comfortable with computers as they are with chalkboards (Pearson, 1995) be attained?

Today, reform in education mandates improved teacher training. It is appropriate, then, that President Clinton mentioned well-trained teachers in his technology initiative. How can preservice teachers best be trained technologically? This paper addresses that challenge by looking at one college and its “driver education” for traveling the information superhighway for preservice teachers. It discusses the commitment the college has to graduating technologically literate students and the ways in which the Internet is infused into teacher preparation courses.

Chatham College is a small liberal arts college located in Pittsburgh, Pennsylvania. In a small college, access to information is vital to keep students current with developments in all academic disciplines, and it is imperative that students have equal access to resources and research. The college has recently invested in developing a strong campus network by using fiber optics, Microsoft NT, and a Rolm telephone system, and by placing high-end multimedia in faculty offices and student computer labs. Electronic mail and campus-wide access to the Internet are now available to the entire college community.

For the past twelve years, there has been a college-wide commitment to graduate technologically literate students who must demonstrate proficiency in word processing, spreadsheet, database, and bibliographic searching before completion of the teacher’s certification program. Now, the challenge is to take computer proficiency to a higher standard. What is the most effective way to infuse technology into coursework in the teacher education program and to ensure that our preservice teachers will be well trained in technology? What is the best “driver education” for preparing preservice teachers to implement today’s technology in their classrooms of tomorrow? How do we empower teachers with the ability to make the best use of technology? If computers are an important innovation that can revolutionize the teaching-learning process, do the teacher certification courses reflect this? Further, are there changes in course assignments,
syllabi uses, and content that support this approach? Finally, how are professors of education using technology in their own teaching and research?

**Need for Technology Instruction in Preservice Education**

According to a 1995 article based on a comprehensive study from the Office of Technology Assessment (OTA), *Teachers and technology: Making the connection*, schools' access to various technologies is rising steadily. The OTA estimated that there are about 5.8 million computers in the classrooms of American schools—about one for every nine students (O’Neil, 1995). The report cited classrooms where teachers were taking advantage of new technologies resulting in innovative, engaging, and varied learning opportunities for students. International research projects, communications with scientists via e-mail, and multimedia research papers were all given as examples.

However, the report pointed out that most teachers are not adequately trained to use various technologies in their classrooms and the picture in preservice programs is not much brighter (O’Neil, 1995, p.11). OTA found that “overall, teacher education programs in the United States do not prepare graduates to use technology as a teaching tool (O’Neil, 1995, p. 11).” The biggest barrier to technology use is time—for training, for trying out technologies, and for exploring uses of technology and discussing the role technology can play in teaching instruction.

In a study conducted by Carnegie Mellon University in conjunction with the Pittsburgh public schools, interviews were conducted, and teachers were surveyed about their use and experiences on the Internet. The educators were positive about the benefits of Internet in the classroom, commenting that it makes students aware that they are a part of a global community and gives them a wide variety of resources to stimulate their thinking. “It does more than boost enthusiasm or expand sources; it fundamentally alters the roles of teachers and students” (Peha, 1995, p. 20). The teacher becomes more of a facilitator, helping students to find and use information. However, two-thirds of the teachers who responded to the questionnaire said that they “survived... [the Internet] without any formal training, relying instead on printed literature and experimentation” (Peha, 1995, p.22). The suggestions offered for overcoming difficulties related to introduction of the Internet into the curriculum included more time for exploration on the Internet, more online support, more step-by-step instruction time, and more collaboration and commitment with other parties involved in Internet activities.

A recent article in *US News and World Report* described six classrooms around the United States that promote learning through technology. The educators in these schools reiterated the need for good teacher training in technology, saying that “training is the most crucial ingredient of an effective computer program and the one that is underfunded the most often” (Wagner, 1996, p. 92).

Adding to the challenge for untrained or undertrained teachers is the incredible speed of the technological advances. Consider what has occurred in less than three decades. In 1969 when the Pentagon tried an experimental system of linking destinations together over an electronic network, Arpanet. By the mid-80s it had grown into a broad network, called the Internet, for educators, researchers and government (Mills, 1996). In 1977, Microsoft was a start-up company (Polsson, 1996); in 1981, the IBM PC, the microcomputer that “legitimized the industry for the rest of the world” was introduced (Polsson, 1996). Then, in 1991, The World Wide Web (WWW) was activated on the Internet (Zakon, 1996).

Very recent technological advances have certainly created a gap between the rapidly changing technology and the increasing need for information technology in teacher training. How do we get onto the information superhighway and know what to do with the information available? How can educators integrate technology so that computer-literate students are skillful, reflective, mindful users of information or as Hyerle (1996) describes them, “infotectives” (p. 16).

This author believes it is incumbent upon professors in teacher training programs to integrate information technology in the coursework for teacher certification. By adding technological assignments via the Internet to our teacher certification courses, preservice teachers can be better prepared to meet the technological challenges present in the classrooms of tomorrow.

The following provides description of courses available at Chatham College (Chatham College Catalogue, 1996-97) that are relevant to a technology-infused curriculum for teacher preparation. The author shares assignments for these courses that integrate information technology via the Internet. This constitutes Driver Education for traveling the information superhighway.

**Integration of the Internet into Teacher Preparation Courses**

*ED 301: Perspectives on Education* is a broad-based course which introduces prospective teachers to the profession of teaching and explores social bases of education. Students examine the roles of the teacher and the school both in the past and in contemporary society. An assignment which is particularly applicable for the Internet asks students to evaluate educational reform initiatives. Several websites are helpful:

http://www.ed.gov/pubs/Reform/index.html, where students can access findings from a national study on school-based reform; and http://kt12.cndir.org:90/resourcecntnts.html, a site that explores technology and...
school reform. By accessing the Pennsylvania Department of Education's web site at http://www.cas.psu.edu/pde.html, students can find information on many alternatives to traditional education, including home schooling, school choice, school vouchers, charter schools and magnet schools. Students are further able to learn about the position of the Pennsylvania legislature on each of these topics. To track reform initiatives on a national level, students can access information from the US Department of Education by locating the site at http://www.ed.gov/.

**Ed 303: The Multimedia Classroom** blends state-of-the-art theory and practice and involves students in a shared learning environment integrating technology and the arts. A specific assignment for this course requires students to demonstrate ability to use the computer for research into children's literature, particularly to locate web sites containing information on authors' backgrounds, literary analyses, and the use of children's literature in the elementary classroom. An excellent web site for these purposes is Kay Vandergrift's Reading in Children's Literature, http://www.scils.rutgers.edu/special/kay/childlit.html, where lists of children's literature, including publication information, are offered. Other sites that students found helpful are: The On-line Books Page at http://www.cs.cmu.edu/Web/books.html and The Children's Literature Web Guide at http://www.ucalgary.ca/~ca?=dkbrown/index.html.

**ED 308: Communication Skills in Education** is a course that guides students as they investigate the interrelationships between listening, speaking, writing, and reading. Students must write a literacy unit. Useful websites for finding age-appropriate children's books include http://www.ucalgary.ca/~dkbrown/index.html, where students can find children's literature and information about the authors and http://www.cs.cmu.edu/Web/books.html, for books online. Another helpful address for finding educational software is http://www.edutainment.com.au. This allows students to consider software they might like to purchase for use in their future classrooms.

**ED 312: Elementary School Curriculum** explores teaching in specific content areas, including mathematics, science, music, art, social studies, health, and physical education. A major assignment for students in this course is to design a curriculum unit on a topic of their choice. Because students can choose from a wide variety of topics, many students find websites from "the educator's ultimate World Wide Web hotlist" (Dyrli, 1996) especially relevant. Some sites for locating general curricula are Ed Web at http://edweb.cnidr.org; World Education Exchange http://www.hamline.edu/~kjmaier; and The Schoolhouse at http://www.awrel.org/school_house. Websites that students found helpful for curriculum units in the social studies include Environmental Systems Research Institute at http://www.esri.com and Science and the Environment at http://www.voyagepub.com/publish, an award-winning magazine that takes its readers globe-trotting to discover the state of the environment around the world. Two excellent websites for social studies include the Library of Congress Web at http://www.loc.gov and http://www.census.gov, which gives students information about any city in the United States, answering questions about the ethnicity, age, and number of the people who live there. Another web site applicable to many topics in social studies is Welcome to the White House at http://www.whitehouse.gov/WH/Welcome-plain.html.

**ED 320: Principles of Secondary Education** focuses on the characteristics of the secondary school student and the structure and climate of the high school. The Internet is an excellent resource for many of the students as they complete their research assignments on topics specific to adolescent development or schooling. Websites that students find helpful include http://education.educ.indiana.edu/cas/ado1/risk.html which covers many topics on issues relating to adolescent development, including health issues (sexuality, alcohol, drugs), developmental issues (ADD and eating disorders), and mental health issues; http://www.healthwire.com/women/grgirl.htm which includes issues girls face while growing up, such as low self-esteem, depression, anxiety, etc.; and http://www.priory.com/journals/adsui2htm contains a helpful article on suicidal behavior among adolescents. Another web site that students find interesting is http://educ.indiana.edu/cas/tfforum/tfforum.html, a site maintained by the Center for Adolescent Studies at Indiana University. This site contains excellent learning resources for secondary students, parents, and educators such as Teacher Talk, a newsletter for secondary and preservice teachers.

**ED 321: Teaching Methods for Secondary and Adult Level** offers students a range of teaching strategies and classroom management techniques in the context of their major fields of specialization. For this course, students are assigned the task of finding lesson plans on the Internet which they adapt for their classrooms. Some sites with particularly strong lesson plans include the AskERIC Virtual Library at http://ericir.syr.edu and Columbia Education Center's Mini Lessons at http://youth.net/cec/cec.html. A site for environmental science lessons which students find helpful is EE-Link, Environmental Education on the Internet http://nceet.snre.umich.edu. Students also enjoy visiting http://educ.indiana.edu/cas/tfforum/tfforum.html, a site maintained by the Center for Adolescent Studies at Indiana University. Another web site which preservice teachers find helpful for their own professional development is the 21st Century Teachers Website at http://www.21ct.org, a site where information about the technological skills that will be needed by teachers in the
next century is disseminated by several key educational associations including the NEA, AFT, and the National PTA.

ED 322: Teaching in a Multicultural Society is designed to help future teachers understand the complexities of teaching in a culturally diverse classroom. Instruction provides preservice teachers with the knowledge, insight, and understanding to work effectively with students from various social classes, religious, ethnic and cultural groups. Individual differences that affect teaching and learning are emphasized; instructional concepts and strategies for multicultural classrooms are offered. In this course students are required to research a particular cultural group and find at least one foreign web site. Students also were able to locate excellent multicultural books for use in classrooms. Helpful sites include the Multicultural Book Review at [http://www.isomedia.com/homes/jmele/homepage.html](http://www.isomedia.com/homes/jmele/homepage.html) which reviews various children's book. A web site that allows classrooms to find partners with shared interests in other parts of the world is the Intercultural E-mail Classroom Connections at [http://www.stolaf.edu/network/icee/icee-form.html](http://www.stolaf.edu/network/icee/icee-form.html). Students have located the web site of the Japanese National Tourist Organization at [http://www.nttpjapan/TCJ/TC.html](http://www.nttpjapan/TCJ/TC.html) to learn about Japanese culture. Students have also accessed Origami at [http://www.cs.ubc.ca/spider/jwu/origami.html](http://www.cs.ubc.ca/spider/jwu/origami.html). For examples of how to fold paper into origami. Other homepages students visit for intercultural research include China Home Page at [http://www.ihep.ac.cn/china.html](http://www.ihep.ac.cn/china.html) and Global Show and Tell at [http://emma.manymedia.com:80/show-n-tell/](http://emma.manymedia.com:80/show-n-tell/). Projects and accomplishments of children around the world are shown via the Internet. Students researching the Native American cultural group found [http://indy4.fdll.ccmn.us/~isk/](http://indy4.fdll.ccmn.us/~isk/) an excellent homepage containing information about culture, art, education, science, history and Native American sources. At this site was information about how students could meet Native American students on the Internet. The site at [http://www.pitt.edu/~mitten/ailabib.htm](http://www.pitt.edu/~mitten/ailabib.htm) offers excellent activities which can be used in the classroom as well as a bibliography and guide for choosing Native American literature.

**Conclusion**

This paper demonstrates that the Internet is a teaching resource that merits inclusion into teacher preparation courses. If preservice teachers are to become technologically literate and bring technology into their classrooms effectively, it is imperative that preservice teacher education include both depth and breadth of technological access. Specifically, use of the Internet in the preservice-teacher classroom exposes these future teachers to online learning. Websites and examples of Internet-related assignments integrated into specific courses at Chatham College are offered as road maps, or "driver education," for preservice teachers to travel the information superhighway. Connecting classrooms to the Internet is an exciting, innovative method to help our students become active network citizens in a global community by training them to access and explore the World Wide Web and its myriad of resources on the Internet.

The author appreciates dialogue with members of the Chatham College education faculty and preservice teachers related to the integration of technology into their courses.

PROPOSED SHORT COURSE ON THE DEVELOPMENT OF WEB BASED TRAINING

Mark E Woodcock
National Cryptologic School

The National Cryptologic School (NCS) is the training department of the National Security Agency (NSA). It is responsible for the education and training of NSA’s large, geographically diverse, and often highly technical workforce. Its mission includes both highly tailored courses in state of the art technology and all-hands awareness training; as well as the education of its own training staff. Because of the variety in students and material, a wide assortment of delivery techniques are employed. One type of mechanism which has received increasing attention is Computer Based Training (CBT).

Some Advantages

CBT is a particularly interesting technique for NSA because its workforce is predominately computer-literate and has direct access to a centrally-networked computer (i.e. it’s on their desk). CBT offers training which is available to the user without dislocation, is in a familiar environment, and is delivered via an existing infrastructure (the network). This infrastructure, with a few additions, can easily be used to aid in the administration of the courses (Arthington, 1996). Currently at NSA, the CBT is primarily commercial off-the-shelf (COTS) leased/purchased courseware, which runs on DOS platforms (or by use of a DOS simulator) and is delivered by use of the Web (actually ftp, but there is a nice Web interface).

Further Advantages of the Web

The possibility exists, however, to make direct use of the Web as the presentation (as well as delivery) mechanism. Courseware in this model would have a number of advantages over ordinary CBT:
1) because there are Web browsers for each of the major computer platforms (e.g. Unix, DOS, Mac) (Barek, 1996), simulators would not be needed to make courseware compatible,
2) courseware could be run in parallel with the application being trained, and
3) courseware could be delivered in page-sized chunks, neither clogging the network, nor overburdening end-user machines.

Yet, all of the benefits of ordinary CBT would still apply.

The Curriculum

The foundation of the education and training curriculum at the NCS is the Instructional System Design (ISD) process. This model has five major phases. Four of the phases follow in a mainly linear order—analysis, design, development, and implementation; they are performed in parallel with the evaluation phase. Consequently, the heart of the curriculum is a sequence of courses directly addressing these phases: Training Needs Assessment (ED-190 or ED-195), Developing Objectives and Tests (ED-170), Instructional Program Development (ED-181 and ED-182) and Training Methods for Instructors (ED-101).

Students may add to this base by selecting specialized electives which address assistive technologies which may be employed (ED-205), the material being taught (e.g. ED-031, ED-103), particular platform techniques (e.g. ED-121, ED-222, ED-218), and the varying types of training (e.g. ED-125, ED-E11). Currently, the only course focused on CBT techniques is the last one listed (ED-E11, Introduction to CBT).

The intention is to extend the curriculum to offer training on a variety of CBT development techniques. The genesis of this proposal was a request of the author to encode his efforts to develop techniques for Web-based development (along with actually developing training in this manner) into a course in this curriculum.

The Web

The Web is actually the hypertext transfer protocol (HTTP), a client-server protocol running on top of the Department of Defense (DoD) protocol suite. The servers are processes running on server machines, which have access to a multiply-linked collection of information pages (the Web metaphor follows from thinking of the links as
strands of thread, and the pages as knots); the clients are
browsers, which request the information from the servers
and present the data and graphics (or sound, movies, etc.)
to the user. The protocol is distributed and stateless, which
has several interesting consequences for training developed
with the technique presented in the proposed course.

Since the protocol is stateless, it doesn’t know what
page was accessed last (or, in fact, if any page has been
accessed). With a great deal of programming expertise, it
is possible to create an environment where the user is
restricted to the designer’s choice of the next page in the
training, but this (the construction of such an environment)
is not practical to teach, and a tool for providing such an
environment is not being developed. This means that
the user can move forward and backward with ease, and skip
randomly through the material with little experience.
Lesson flow models, the ordering of the pages intended by
the designer, (Barker, 1996; Dee-Lucas, 1996) will have to
be compelling, since the technology will not enforce them.

On the other hand, since the Web provides multiply-
linked pages, a wide variety of lesson flows can be
implemented. The course will offer tools which facilitate
some of the most common techniques for organizing the
presentation, but once the student acquires some skill in
manipulating HTML (HyperText Markup Language is
used to describe the contents of the information pages)
many more could be implemented.

Second, because the protocol is distributed, users are
not obliged to limit themselves to the server containing the
courseware. While this can be seen as a negative (the
audience might wander off and never return), it should be
viewed as a way of tapping into additional training
resources. Students can be directed to other information
sources (so the developer does not constantly need to
reinvent the wheel), or they can——on their own——search for
additional information on a particular topic.

The Course

The course design is intended to be consistent with the
various factors identified above. Different learner-style
models (Barker, 1996; Dee-Lucas, 1996) will be surveyed
and techniques for addressing the major styles will be
presented.

Course Description
Title: HTTP/HTTP CBT Authoring
Weeks: 1  Days/Week: 3  Hours/Day: 8
Total hours: 24  Class size: 20
Objective: The student will be able to organize and present
topics (in which they have expertise) as CBT in the
form of intranet Web pages (using HTML). The
materials produced will be useful as both training
materials and desk references.
Evaluation: Graded, Project

Description: This course will have two major parts: using
HTML to build course modules and training pages, and
creating quizzes using quiz generation tools (Wood-
cock, 1996).

Student qualifications:
1) ED-E11 (Introduction to CBT)
2) Basic Web Authoring Skills
3) A topic which could be the basis for a CBT

Method of instruction: Platform instruction. This course
will involve a significant amount of in-class work on
the computer, developing a CBT module.

Course Outline
Day I
0800-0900  Course Introduction
0900-1000  Web Theory, HTML Refresher
1000-1130  Lab 1: Sample Web Class, Page
Creation
1130-1230  Lunch
1230-1330  Module Preparation: Objectives, Evalua-
tions (Power, 1996)
1330-1430  Lab 2 (non-computer): Module Struc-
ture,
Objectives
1430-1600  Lab 3: Develop Module Skeleton

Day II
0800-0930  Lesson Flows, Storyboards
0930-1030  Lab 4 (non-computer): Storyboard
Course Module
1030-1130  Page Building Tools
1130-1230  Lunch
1230-1600  Lab 5: Build the Module

Day III
0800-0900  Quiz Builder Concepts: HTML Gate-
ways, Forms
0900-1000  Original Quiz Generator: Use, Building
&Maintenance
1000-1130  Lab 6: Create a Quiz
1130-1230  Lunch
1230-1330  Multiple-Choice Quiz Generator & the
Database Checker
1330-1530  Lab 7: Create Multiple-Choice Quiz
1530-1600  Course Evaluation and Tearful
Goodbyes

Commentary
The proposed course is designed to be the practical
application of the skill acquired in the Introduction to CBT
course. The students will be encouraged to use this time to
implement a course in their area of expertise, using the
same network as they have on their desks. The connection

The Educational Computing Course — 233
between the task and training environment should be very large.

This paper presents thought-provoking issues of whether or not an introductory Computer and Information Science course should be included in a college or university's general educational requirements. Both sides of the issue are presented in an unbiased fashion. This paper draws no conclusion to the issue, but rather encourages the reader to think about the issue and to apply their thinking to their institution's general education policies and goals.

The faculty and administration at William Woods University have been struggling with this question for the past five years. While most faculty and administration members agree that a computer literacy course is beneficial to students, there is no consensus that such a course should be used to satisfy education requirements. A brief perspective of the course and general education requirements at William Woods University will help in this discussion. CIS 100 - Introduction to Computer and Information Science is an introductory-level computer literacy course. It meets for a full semester and is worth three credit hours. The course description describes the course as: "An introductory course providing comprehensive coverage of a broad range of preliminary computer and information processing concepts, application, issues, concerns and trends" (William Woods University Catalog 1996-1997, page 97).

The method of instruction is primarily lecture-based with computer lab support. This means that the student will, on average, be working on a computer in class once every two weeks. CIS 100 is open to freshman through seniors and has no prerequisite. Traditionally, two sections of twenty-five students have been offered in both the fall and spring semesters. The class enrollment is always full, with additional sections being offered upon occasion at night and during the summer sessions.

General education requirements at William Woods University consist of thirty-two credit hours. These hours are broken down in the following manner:

- English Composition 6 hours
- Oral Communications 3 hours
- Mathematics 3 hours
- Fine or Performing Arts 3 hours
- Humanities 6 hours
- Natural Sciences 7 hours
- Behavioral & Social Sciences 3 hours
- Freshman Seminar 1 hour

This course work encompasses seven instructional objectives for general education at William Woods University:
1. Written and Oral Communications: The ability to communicate effectively
2. Numeracy: The ability to analyze, interpret and manipulate numbers
3. Critical Thinking: The ability to examine problems logically, to assume and independent perspective, and to conceive pragmatic solutions.
4. Humanities: Knowledge that enables one to comprehend the traditions and values of one’s culture and those of others.
5. Aesthetics: Knowledge that enables one to appreciate beauty and refine one’s artistic taste.
6. Natural Sciences: Knowledge that enables one to comprehend the physical world as revealed through scientific investigators.
7. Social Sciences: Knowledge that enables one to better understand the behaviors of self and others and the role of the social environment.

The question has been raised by the faculty at William Woods University of “Why should CIS 100 be allowed to satisfy requirements in general education?” Proponents of allowing the course to count as general education often cite the following “facts:”

1. Computer skills are now mandatory in today’s workplace. One would be hard pressed to name a profession in which computer skills would not affect the efficiency or outcome of the work being performed. It is stated in the university’s mission statement that William Woods is a “profession-orientated university” (William Woods University Catalog 1996-1997, page 5.) This is often interpreted to mean that one of the university’s objectives is to prepare students for the work force.
“professions-orientated university” should take steps to ensure that its graduates are computer literate and ready to continue utilizing computers in their chosen careers. Many feel that requiring CIS 100 - Introduction to Computer Science is a step to fulfilling this objective of delivering skilled graduates to the world of work.

2. The course can be efficiently delivered. With a student population of approximately 600 full-time students, one or two sections of CIS 100 per semester should meet the needs of the students over their tenure at WWU. A lecture-based class can be delivered in an auditorium setting, increasing the number of students served while decreasing the number of sections offered. This suggestion is a cost-cutter over the current way the course is taught.

3. The General Education guidelines can be revised. The CIS 100 course appears to fit with the mission statement and not the seven general education objectives. It would then appear that there is a discrepancy between the seven general education objectives and the university’s mission statement. William Woods utilizes a standing Curriculum Committee, whose membership is made up of representatives from the seven academic departments and the academic dean. It is entirely within the jurisdiction of the Curriculum Committee to revise the general education policy at William Woods to reflect changes in the university’s mission or academic objectives.

While many faculty feel that including CIS 100 in general education is a good idea, there seem to be just as many who don’t. They cite the following to support their view of the issue:

1. CIS 100 does not “fit” into any existing General Education categories. All general education courses “fit” into one of the aforementioned categories of study. While an argument could be made that CIS 100 fits in the Mathematics category, it would certainly be a stretch in logic since the course is literacy, not numeracy based. The same faculty argued that the seven general education objectives should not be amended to pander to any department’s desire to have their course(s) included in general education.

2. If the course is beneficial, the students will take it anyway. This is already being borne out by looking at the full enrollments of the course. CIS 100 is already a required course in seven different majors at William Woods University, and subsequently is already required of a large portion of the student population. Opponents of this statement point out that between the 32 hours of general education and a major course of study up to 72 hours, there is precious little room left for students to be taking purely elective courses, and may not have the choice to take the course unless it was required.

3. Students already have computer learned skills in high school. While many students do have a certain exposure to computers in high school, it would be difficult to assume that all students are computer literate upon graduation of high school. Faculty can argue that college-bound students are probably smart enough to gain exposure to computers for their own benefit. Requiring a computer literacy course would be redundant for most of these students with computer exposure and constructing a competency test would be too time-consuming to be worth doing. Therefore, don’t require computer literacy course for all students but make it an available option for elective credit.

4. CIS 100 is already required for seven majors on campus. Why should it also count towards general education? If seven of the most popular majors are including CIS 100 in their requirements, does this mean that most students are taking the course anyway? Putting CIS 100 into general education would be a useless gesture and a waste of time.

While this is an issue that will not likely be solved any time soon, it does get faculty thinking about the whole concept of general education - from how it aligns with the university’s mission to how to proceed with revising the general education objectives. This feat, in itself, is a worthwhile outcome of debating the merits of having CIS 100 - Introduction to Computer & Information Science included in general education.

E-mail: tfinch@iris.wmwoods.edu
This is the first year that the SITE Annual has included a section on Educational Leadership. A talented instructional leader is a key ingredient in creating the climate conducive to efforts that attempt to bring about change in classrooms, school districts and university settings. The critical importance of leadership in accomplishing change was described by Prasch (1991) in a presentation concerning changing the preparation of educational administrators. He spoke then of the need for leaders to include the use of emerging technologies in operating new programs. A 1995 National Information Infrastructure (NII) report highlighted some of the leadership challenges that occur when technology is used in schools. They concluded that it will take sustained commitment of leadership at school, district, and other levels of leadership that touch educational settings. The issues raised by Prasch and the NII are mirrored elsewhere in the literature and make a strong case for this new section.

Over the years we have had many sessions at the conference and papers in the Annual that have examined leadership issues in many forms. These have included the impact of the teacher/leader as a change agent, the importance of the principal as instructional leader, and the leadership required to revise and re-vision teacher education programs to better prepare preservice teachers to use technology.

In this section you will see that the authors have approached the concept of leadership thought a variety of lenses. These lenses include looking at Educational Leadership in terms of the prospective administrator, the roles of practitioners in the field, school change and organizational issues, and issues in higher education.

**Prospective Leaders**

In order to prepare principals to take an leadership role in integrating instructional technology into the curriculum, Roden offers us an outline of an ambitious preservice program. This program concentrates on analytic skills and hands-on practice with computer-based decision making tools. It focuses on both large scale capital and funding concerns, and classroom curricular issues. The rationale is based on a set of core skills that new principals must have when they assume their leadership roles. The course of study includes using technology to incorporate and understand statistical information, understand networks for distributed data and resource access, and incorporate software for curricular improvement.

Kaufman believes that although educational institutions reflect an organization design for learning, they themselves do not reflect the systems-based approach that in an integral part of organizational learning. Her paper describes a Performance-Based Principal's Program that is intended to enable future principals to foster a systems approach. Of additional interest to the reader is the realization that the basis of the work is a carefully crafted technological interface that has been placed over an existing quality curriculum. The design was guided by theories about the learning process and adult development.

Administrators in our K-12 schools frequently complete their educational experiences with little or no preparation in using technology to accomplish their professional activities. In his description of an experimental course, Yan provides a look at one course that was designed to meet their specific needs in this area. Administrators were provided skills and practice in authentic activities, kept journals to document their learning and reflections, and worked together to accomplish tasks. Overall, the course was deemed a success, and may serve as a model for other educational programs.

MacNeil describes the use of an Electronic Meeting System (EMS) for synchronous group problem solving and decision making for prospective administrators. Case studies provide opportunities to identify problems and propose solutions. In this project, one group used the EMS to analyze a complex case, while others were given the same case but directed to use the more traditional model of
analysis. Results suggest that more creative solutions were
generated, and that more egalitarian models were used. The
use of EMS was proposed as a way to allow for more
brainstorming, to create a record of the dialogue and
postings, and to move beyond simplistic solutions. Some
cautions were also given regarding extended time to reach
consensus, tendency to digress from goals, loss of account-
ability, and possible lack of clear direction in using the
EMS. Further research using EMS in this area and with
this population is suggested.

Practitioner Leaders
Murphy and Gunter begin by acknowledging the
importance of the role of the administrator in the use of
computers in schools. In addition they provide information
on specific guidelines for instructional leaders implement-
ing computer integration. When all of this is said and done
the question remains whether or not the teachers them-
selves feel supported by their administrator. The purpose of
this study was to measure and report the amount of
perceived administrative support teachers received and
what factors impacted their perceptions.

North's paper describes a professional development
project for secondary principals and senior teachers in
Northern Ireland. Using qualitative methods, North
provides insight into a new staff development model of
teaching this system with a multimedia CD-ROM, as
opposed to the traditional paper based training model. The
training project is based on three levels of training, "Show
Me", "Let Me Try", and "Tell it to me Again." Video
conferencing was used to allow education managers to
interact with tutors for a variety of support and testing
activities. Results reported include information about the
effectiveness, efficiency, and cost effectiveness of using this
new program.

Driskell and Cobin describe how principal leadership
initiated ongoing support for teachers learning to integrate
technology into the curriculum. The designation of a
Technology Facilitator helped teachers create lesson plans
that included technology experiences and exploration of a
variety of useful software. The paper focuses on ideas for
others who might want to implement a similar position in
their own setting. The collegial collaboration provided in
ones own setting is a powerful motivator for teachers to
attempt new instructional strategies.

In their paper DiBlasi, Steinle and Hall describe the
efforts of the Durango School District to carefully plan for
their technology implementation. At first efforts were
expended to get the hardware into the schools, but ulti-
mately the need to focus on staff development became
clear. The district hired a Technology Coordinator, created
a Department of Educational Technology, and began a
systematic approach to involve all educators. Using a "train
the trainers" model, one educator in each school took
responsibility for organizing, training, and supporting
others at that school.

Lare describes several instances where teachers were
provided unusual access to computers to encourage their
involvement in the use of technology in the classroom. The
key to the program is making the technology available to
the teachers in their own time frame. They were then able
to explore, take risks, and see applications for these tools in
their own instructional life.

School Change And Organization Issues
It is very easy to assume that technology provides an
indisputable and universal benefit. We are reminded of the
importance of continuing to examine and question in the
paper by Nicholson in this section. She reminds us of the
economics surrounding technology and how it can create
pockets of inequity throughout the educational system.
What is our responsibility, if we believe the first statement
of the paragraph, to secure convenient, affordable access for
students?

School districts are required to make projections in
order to solve complex problems, and now the potential
exists for computer systems to assist administrators in this
task. In his paper Taylor provides authentic examples of
specific activities that intellectual agents (programs that
search for information and organize it) might perform to
assist internal decision making and problem solving
systems for educational administrators. One primary
advantage is that intellectual agents will anticipate the
questions and issues before humans, and their projections
will assist in making thoughtful decisions in areas such as
distribution of funds, teacher shortages, and transportation
patterns. This paper provides a look into the future of these
tools, and creates a framework in which to consider the
possibilities that are on the near horizon.

Gunter and Gunter identify significant problems
associated with rural economic and educational develop-
ment. The loss of population and weak tax base make it
less likely that students and institutions can join the
information age and provide access to global resources. The
authors describe one attempt to change this pattern by
joining educational and economic interests in rural
southeastern Alabama. This project, The Southeast
Alabama Network, was designed to bring full access to all
schools, health care providers, businesses, and citizens
throughout seven rural counties. Significant effort will be
spent on training and support organization to encourage
thoughtful implementation of this new access.

How can Information Technology provide assistance to
educational leaders? Facemeyer examines the three types of
leaders described by Senge. He provides a series of pre-
mises about IT in aiding leaders and their work. IT, in
various formats, can be systematically applied to provide
each type of leaders with help for the management issues they face.

"What is it that leaders do and how do they do it?" is a frequently asked question. Swartz provides one person's perspective on the answer to that question. He also tells us about some of the misconceptions that abound and ends by reminding us the importance of all stakeholders being involved if change is going to take place.

Dubenezic provides resources to support those in schools who are leading the way to help teachers integrate the WWW into the curriculum. He includes materials that specifically address content area materials but there is also a focus on professional development among the sites provided. Dubenezic also provides a URL for a site he has developed so that you can access all of the sites described.

**Issues In Higher Education**

It was difficult to decide where to place this next paper. It most certainly deals with school change and organization issues but does so while examining how higher education plays a role in preparing leaders to participate in this change process. Saito reviews the recent technological development and its influence of education planning. He seeks to illustrate the notion of information literacy and its importance to educational planners. He provides specific ideas on how information literacy can be accomplished.

Davis and her colleagues are examining an important issue in the use of Information Technology. They recognize that IT affects most sectors of our society but ask if we really know what its role is in teaching and learning in higher education. They found little documentation of the few examples of ways in which IT can assist teaching and learning. The research study is still in progress but Davis shares the evidence they have found to date.

Howard and his co-authors have produced an Information Systems course that takes advantage of multimedia and hypermedia. Although the course has been successful in the eyes of the authors and their students many faculty are hesitant to join in and use these tools in their own teaching. This paper describes the process on assessment and discusses the key question of making technology mandatory or optional for teaching and learning.

Kveton and Vesla describes efforts of the Czech Technical University (CTU) to meet the needs of students and educators with respect to Information and Communication Technologies (ICT) as suggested by the European Union. They describe trends in Europe, the current campus wide information system at CTU, and perspectives of the management information system. Efforts also include policies to implement ICT into education, research, and management.

In the American public schools, we have traditionally looked to the principal as the curricular leader. A good principal can lead by example, can motivate teachers and students, and has a clear understanding of the relationship between people, curriculum and the physical spaces of a school. We assume that an effective school leader could walk into most any classroom and muddle through any lesson, performing at least a serviceable job. The major exception to this assumption is educational technology. No principal would ever declare “I don’t know much about math” or “I was never much for reading”, yet many commonly make this declaration about computers and the role of technology in the classroom. As a result, technology tends to exist in schools outside of the core curriculum, used as an end in itself, rather than a means to support the central teaching mission of the school. Despite spending considerable amounts of money for hardware, networking connections and software, technology in schools tends to be what happens in the computer lab, or a disjointed, haphazard portion of classroom life, seldom connected to or supporting instructional objectives in a meaningful way. Many teachers want to use this technology in a more effective way, but need help and direction in the relationship between technology and the core curriculum.

To address this need, the following program outline was developed. The goal of this program is to train preservice administrators in the skills needed to be highly effective technology leaders in schools. Principals will be able to manage technology both as a large scale capital project and at the classroom level. In addition, principals will be given coursework in analytic skills and hands-on practice with computer-based decision making tools. This paper is an outline for how such a program would be structured. It appears that there is a clear and urgent need for leadership in the technology area, and a program which targeted preservice school administrators would be a positive first step.

Rationale
There is a need for a new breed of school leaders is required who have the skills to:

- Use technology and analytic tools to make policy decisions based on internal and external data.
- Effect site-based management by developing data systems to track, manage and analyze fiscal, academic and demographic data.
- Provide leadership for school-wide implementation of instructional technology, as both a long term capital project and a classroom level teaching system.
- Use large external databases to develop more effective measures of relative school performance.
- Provide quantitative and qualitative data for district and state level constituents.
- Use the proper statistical tools to understand and express student performance data, while appreciating the limitations of quantitative measures of human learning.

Proposed Course of Study
There is a need for school leaders who are able to manage technology and data as a part of their administrative life. At best, many administrators take a few computer courses aimed at enhancing generic skills with software. A program which is tailored to develop a small cadre of administrators who have strong analytic and technical skills would be unique in this area and perhaps in most areas. From where I sit, my bet is that most higher education institutions are not nimble enough to offer a dynamic program which will constantly evolve to provide current material. To this end, the following is a core series of courses, to be taken as a cohort and in order.

1) Applied Statistics for School Leadership
This course would include an overview of the content taught in most Masters level research courses, but with an emphasis on the following:
Hands-on use of computer software to teach relevant decision making skills using realistic school-based data sets.

Emphasis on the skills needed to reduce complex data and present the findings effectively to varied constituents.

Emphasis on interpreting student performance data and communicating results in a balanced and sensible manner.

Emphasis on working with live fiscal data to make decisions based on various financial assumptions.

2) Distributed Data Systems in School Settings
This course will focus on the planning and implementation of a building or district level technology plan. Topics will include:
- Network typologies and standards.
- Budgeting and capital planning for technology projects.
- Relational database systems for administrative and classroom functions.
- Connectivity to World Wide Web (WWW) and Internet resources.
- Computer security and ethics.
- Staff development and training issues.
- Distance learning technologies.

3) Technology in the Classroom
This course will concentrate on the use of technology at the individual student level and its role in the learning process. The goal of this course will be to prepare administrators to be instructional leaders in this area. Topics include:
- An overview of educational software and multimedia titles.
- An understanding of the relationship between lesson objectives and different types of software.
- Using technology for better assessment.
- Using WWW resources across the curriculum.
- Integrating live data into the inquiry process.
- Technology and the writing process.
- Using technology to simplify classroom grading and administration.
- Developing one’s own software with authoring tools and visual programming languages.

4) Planning and Dissemination Project
This will be the final phase of the program. Students will work independently under faculty council to develop and disseminate a project for professional growth. Some possibilities include:
- Analysis of state or federal education statistics to provide policy data for other school practitioners.
- Development of a technology plan in conjunction with an area school district.
- Development of a cohesive series of classroom software programs which support a portion of the New York State curriculum.
- Development of a database system for comprehensive school management and reporting in conjunction with a local school.
- Development of a “Lead Teacher of Technology” training program with a local school district.

This program would fill a need, would generate interest sufficient to allow for competitive admission and would lead to a very robust placement rate. More than that, this type of program would support the use of technology as an integrated part of the core activities of a school, rather than an ancillary activity by involving the key leaders within the school.

Schools, like many organizations, are in the midst of unprecedented transitions. Educators at all levels find themselves adapting to a playing field on which the components of their own training may no longer be aligned with current realities. A technological restructuring of the workplace is one such reality. The innovation shared in this paper links technology with beliefs about organizational learning in order to better prepare candidates in a school principal’s program to address the needs of adult learners on their teaching staffs.

Guiding Beliefs and Theoretical Foundations

In recent years, Peter Senge’s (1990) ideas about learning organizations have successfully aided various institutions in the throes of realignments and transitions. Claiming that the collective disciplines of personal mastery, mental models, team learning, and shared visions contribute to both individual and organizational betterment, Senge points to a systems approach as the distinguishing factor in successful transition efforts.

I contend that although educational institutions reflect an organizational design for learning, schools themselves do not reflect the systems based thinking that is central to organizational learning. The work described here is intended to enable future school principals to foster a systems approach. It reflects my view of administrators as both leaders and learners, and as vital parts of a larger system of parents concerned for the future of their children, of business communities concerned about the competency of future employees, and of politicians concerned about public spending. The broad-based conceptualization of school leadership that frames this work:

1. acknowledges teachers as instructional leaders who will, and indeed who must, play new roles in research, evaluation, and decision-making within today’s schools,
2. believes school principals must address the learning needs of their adult staff with the same level of commitment with which they approach improved learning for children and youth, and
3. depends on the craft knowledge of veteran educators aspiring to become school principals for establishing sound interfaces between curricular and pedagogical needs and technological platforms as they share their growing administrative competencies within six core areas of a Performance-Based Principal’s Program. These major areas are: curriculum management, instructional supervision, evaluation and research, educational innovation, organizational management, and human relations.

Placing a technological interface over an existing quality curriculum in school administration was shaped not only by my interest in Senge’s work, but also by three other guiding theories about the learning process and adult development. One is Zuboff’s (1988) distinction between using technology to automate or to informate. Automating technologies make existing work more efficient. Informating efforts involve stretching people to think differently about the work they do and applying technology to redesign that work. The informating potential of the Internet is reconfiguring our traditional portfolio documentation of administrative competencies while simultaneously enabling the entire cohort group of twenty principal’s candidates to expand their knowledge base for guiding more informed decision making.

Traditional theories of learning emphasized programmatic content. A second influence on this work are recent findings in cognitive science (see Perkins and Salomon, 1989) which point out that the experiences encountered in new learning are as influential as the content that is learned. This supports Buchminster Fuller’s (in Senge, 1994) argument that if you want to teach people a new way of thinking, you should not waste valuable time trying to teach them at all, but instead provide a means through which new approaches can be utilized. The websites described in the presentation of this paper illustrate how this third assumption, in particular, helped reshape one program in educational leadership.
Preparing for the Changing Nature of Leadership

Lou Gerstner, (1994) CEO of IBM, claims that nothing matters more to America's schools than finding competent principals to lead them. Although the role of the school principal is frequently cited as the key element in school reform, it is not the solitary role of times past. It is a role that demands skills in team building, shared decisions making, and increased technological competency.

The Performance-Based Principal's Program at Indiana University of Pennsylvania (IUP) is nationally recognized by the Association for Supervision and Curriculum Development and the National Association of Secondary School Principals for its design in preparing school principals. Following a five-week summer seminar in School Administration, candidates translate the six core competencies of the curriculum into an context specific Action Plan that details how specific requirements in each category (for example, inclusive practices in Management of Curriculum) will be addressed through their work in the urban and rural settings in which their supervised internships take place.

A student in the seminar in school administration first introduced the possibility of a technological approach to sharing growing competencies and challenges into the IUP Principal's Program. Mr. Alan Johnson created an online electronic page detailing his work in the program's major competency areas. His initial efforts motivated redesigning the program in order to model the informing potential of technology. Use of the Internet thus demonstrated technology as a useful tool in sharing individual accomplishments and problems with fellow students and supervising faculty members during the candidate's supervised internship. This replaced technology being one separate component in the core area of educational innovation. Mr. Johnson's webpage can be accessed at http://ramsesjr.jtwn.k12.pa.us/~anj/iup.html.

Technology, Policy, Power, and Practice

The most recent National Educational Summit pointed to technology as a major element of school reform. But policies emerging from this vision offer little promise for school betterment if computers are used primarily as automating rather than informing instruments. Policy is at best an enabling device (McLaughlin, 1987). Real change is a people dependent process.

As educational leaders endeavor to develop rather than to dictate a readiness for change in school cultures, two messages from contemporary leadership literature seem particularly relevant. These are: 1) an inquiry orientation that moves teaching and administrative roles closer together, and 2) increased attention to the interactive nature of leadership and followership that includes rather than excludes such elements as conflict, confusion, and complexity.

A technological orientation to inquiry expands the role of teachers to program designer and planner and distances instructional tasks from the prepackaged curriculum materials of past decades that were critiqued for their de-skilling impact on educators as effective change agents. An inquiry orientation is apparent, for example in principal’s candidates' websites that details useful strategies for authentic assessment and inclusion of special needs students in the core area of curricular management. An emphasis on both improved student achievement and teacher empowerment is evident too in student home pages that address improved supervision methods.

An outstanding example of attention to conflict, confusion, and complexity regarding technological decisions is apparent in Al Johnson’s website that allows administrators to seek out answers to questions about technology and school finance, questions that may be embarrassing to ask publicly because administrators with high levels of instructional wisdom often have low levels of technological expertise correlating with their age more than other factors. Answers resulting from shared experience to such questions can result in considerable savings for school districts if administrators are committed to asking and to answering questions that matter.

Cuban (1992) warns that inquiry which screens out rather than includes elements of uncertainty results in asking only those questions for which we already know how to find the answers and not the questions that matter most in improving our schools.

Sense making rather than generalization is an expected outcome of contemporary information gathering. As leadership roles become reconceptualized beyond one who dictates courses of action based on recent trends to one who gathers and uses the best information possible, it is essential that leadership programs in higher education provide clients with technological access to quality information in addition to traditional text and journal resources. In a commitment to this strategy, IUP’s Principal’s Program now offers to its principal’s candidates an administrative website that fosters quick and useful links through which core competencies can be strengthened. This site can be accessed through IUP’s home page at http://www.iup.edu (developed and maintained by Tom Jones, graduate assistant and technical coordinator for the Principal’s Program). Mr. Jones can be reached at cymru@twd.net.

Conclusions and Problems

Theories that anchor organizational learning define individuals, their problems, and their achievements as part of a single system. This project resulted from combining this principle with the informing potential of the Internet
in preparing leaders for tomorrow’s schools. Integrating the technological platform of websites on the Internet permitted the expert knowledge of separate individuals to contribute to the collective wisdom of the entire group. In the process, the involved adults all expanded existing technological competencies in ways that enabled them to model an integration of technology and organizational learning for their future staffs. This process of personal growth and shared knowledge fosters the connections between autonomy and accountability that educators desire and the public demands. It inspires actions that are motivated by aspiration rather than desperation. And it encourages teachers to structure their own professional growth.

A large portion of student time, it must be noted, is consumed by the investment in learning how to develop competency-based portfolios as websites. A large portion of student funds can also be consumed if the candidate invests in the necessary hardware and software to utilize the benefits of this shared technology from home rather than traveling to a university or community location with access to the Internet. We hope that future grant funding will enable our program to supply each candidate with a laptop and online Internet subscription service for the duration of the 12-18 month Principal’s Program. Through these continued efforts, we intend to transform one higher education program into a national example of organizational learning.

Many graduate programs in educational leadership require students to take courses in leadership and management, but few of them require students to be technologically competent. Preparation of technology leadership is an important theme in educational leadership programs (Means, 1994; Kearsley, 1990; Picciano, 1994). To meet the increasing needs of developing computer competence for future school leaders, a graduate course in educational technology was offered in the department of school administration and supervision at the University of Texas-Pan American. This paper reports the implementation of the course.

Course Objectives and Contents

The objectives of the course are to help future school leaders become competent in integrating educational technology:

- understanding the nature of educational technology and the various data processing methods used by educational administrators;
- becoming an intelligent consumer of educational technology;
- developing the skills used in the planning for and administering computer technology in schools;
- increasing the likelihood of the future use of educational technology to guide professional practice.

The course covers the following four categories of administrative uses of technology: word-processing, communications, data analysis, and data management. The students also explored Mac School (Bickford, 1993) — a student information system, including (a) finding information, (b) tracking and reporting attendance, (c) generating report cards and transcripts, and (e) creating scheduling system.

Strategies for Learning Activities

On the basis of principles derived from the current research on teaching and learning technology, the following strategies were used as guidelines for classroom learning activities:

- Structure the lessons with adequate introduction and guided practice.
- Lecture as little as possible.
- Introduce interactive computer activities as quickly as possible.
- Provide large blocks of time for extensive hands-on experience.
- Encourage peer interaction and continuous sharing of information.

Course Emphases

Emphasizing Current Issues in Educational Leadership and Technology

This course provided graduate students in educational leadership program an in-depth look at the use of existing technologies in educational administration. Class participants were required to review literature that examined the use of computers and related technologies in the area of educational leadership. Students were required to interview school teachers and administrators on their beliefs and practices in educational technology. Based on their own experiences and interview data, the following issues were discussed in the class:

- Educational technology and site-based management.
- Educational technology and educational reform.
- Educational technology and effectiveness of educational leadership.

Emphasizing Step-by-Step Hands-on Exercises

Basic Computer Competency Worksheets were provided to students. Through step-by-step, hands-on exercises, students were able to build competencies in educational technology. They were able to use technologies to perform administrative tasks on day-to-day basis.

Emphasizing Self-reflection

Students were required to keep learning journals. The following questions were used to enhance their reflective thinking:

- What happened this week that worked well? Why?
• What happened this week that did not work as I expected? Why?
• What are some questions I would like to ask my classmates and professor?
• List one specific area that needs work. What can I do to improve in this area?

Students' reflections on these questions were focused on the following categories:
• Reflection on classroom instruction and discussion;
• Reflection on the knowledge and skills learned in class;
• Reflection on strategies of learning educational technology;
• Reflection on anxiety and stress in learning educational technology.

Emphasizing Portfolio Assessment
The course is based primarily on a criterion-referenced portfolio assessment. Portfolios contain collections of students' work over time. The students included their reflection journey, projects, term paper, presentation notes, and anything contained evidence that they have engaged in self-reflection. During the course of developing the portfolio, students might include all work in the portfolio for purposes of reflection, self-evaluation, and revision. However, at the end of the semester, they selected the pieces that best demonstrate their growth and achievement.

Learning Accomplished by the End of the Course

Word Processing
The class participants were able to use word processing programs to compose, revise, correct, combine, rearrange, and to print it in a wide variety of formats. For example, they were able to use a mail merge to write a letter to students' parents.

Communication
The class participants were able to use enormous and growing resources for educational administrators with a mainframe computer—including such applications as electronic mail, Internet, listservs (electronically facilitated discussion forums), Gopher, World Wide Web (WWW) and the Texas Education Network (TENET).

Data Analysis
The class participants used computers to perform data analysis. For example, they used the electronic spreadsheet to analyze a school budget or other quantifiable data, such as enrollment projections, time schedules, or test averages, as well as to translate raw data into bar graphs, pie-graphs, and tables.

Data Management
Class participants were able to build a database to store a brief sample of the school records such as student records, personnel records, inventories of school equipment, financial records, and special management records. For example, they were able to build a database for a school that including student name, age, birthdate, parent’s name, address, phone, emergency contact, and doctor’s name.

Summary
Overall, students reported that the technology learned in this course has benefits in a variety of areas. Many students have integrated educational technology into their daily administration tasks. Providing the technology is, however, only the first step in moving towards effective educational leadership. Further supports are needed to help our future education leaders to integrate the technology into their educational reform activities.

Both the legal and the business schools have a long and extensive tradition of using cases to prepare future members of their professions. The use of case studies to prepare principals has not nearly so long a tradition (Merseth, 1991). Efforts to improve the preparation of prospective school administrators often include the use of case studies as an instructional strategy. The case study method provides actual situations in which participants can refine problem solving skills. The school reform movement or, as Fullan (1996) terms it, school reculturing, requires that administrators develop skills that can assist them and their staffs in implementing changes that benefit students. A closer alignment between theory and practice in the developmental programs for school administrators has many advocates. Culbertson (1964) pointed out the discontinuity between the study of administration and practice. The results of a 1984-85 national survey of the status of school administration preparation advocates a closer alignment of theory to practice; since then most university programs have changed emphasis. That national survey found that most preparation programs concentrated on procedural issues rather than on ethics and leadership issues. The survey also reported that a shift in priorities was underway and predicted that future preparation programs would focus on improved instruction, field experiences, evaluation procedures, and interagency coordination (Gousha, 1988).

The 1987 report of the National Commission on Educational Administration recommended that preparation programs for school administrators should be more like those in professional schools that emphasize theoretical and clinical knowledge, applied research, and supervised practice. Relevance in professional preparation programs is not unique to the study of educational administration. Schoen (1987) described the rigor of relevance in all professional schools. Criticism of professional training programs has often focused on the remoteness of the academic programs from the problems in the field. The passive nature of most instruction and the failure to present theoretical constructs in ways that are meaningful to students and practitioners continues to be a problem in preparation programs. The use of case studies as an instructional method is directed to solving the problem of teaching theoretical constructs in ways that are meaningful so that future school leaders will be good decision-makers.

Case Studies and Leadership Preparation

Professors who use the case study method to prepare school administrators believe that the use of case studies assist in the development of skills essential for good school leadership. Generally it is thought that through the use of case studies participants acquire analytical skills and the ability to think clearly in ambiguous situations. Synthesizing information and conceptual development are other dimensions of the case study method. Development of mature judgment is also nurtured through the process, as it requires the examination of one's value system and testing that system against the law and others' expectations. Finally, development of communication skills related to listening to others, seeing divergent points of view, speaking and writing clearly, understanding one's self, and the use of imagination and intuition are all considered important aspects in the development of school leaders.
The case study method requires that participants be reflective at each step in the process. Thus, the procedure is not linear but rather dynamic and open to the restatement of the initial problem if necessary. This is essential in that limiting problem solving by following rigid, static steps may result in identifying the wrong problem or supporting problem. Finally, since the method is dynamic, it requires time to use effectively.

Given the previous rationale it would appear that the case study approach to preparing school leaders is a wise one. The ambiguity of the school environment requires that principals have leadership skills that focus on the purpose of school and use flexible approaches to achieve the purpose. But does the case study method meet the needs in preparing candidates for the role of principal?

The answer to those of us who work in preparing future school administrators lies in the observations of the students. More often than not the identification of the problem and the solutions using the traditional case study method have superficial results. Using the case study method means accepting that there are no right solutions, however; some solutions are better than others. Many of the reasons for the inadequate response from using the case study method can be found in the theories of groupthink and escalating commitment (Hellreigel, Slocum, & Woodman, 1992; Janis, 1982). Group dynamics tends to guide the quality of the identification of the problem and the subsequent solutions. There are also disadvantages if there is pressure within the group to conform or if there is a forceful member or dominate clique that ramrod decisions. Strong, vocal, and occasionally, the least knowledgeable people can become the most persuasive in the process.

Once a direction has been taken, as inappropriate as it may be, more and more resources, including valuable time, are directed toward the inappropriate result.

An alternative form of meeting environment known as Electronic Meeting Environment (EME) is now possible through the application of information technology that attempts to make meetings more productive. Through the use of this technology future administrators are given the opportunity and the support for issue identification and prioritization procedures, which facilitates achievement of group consensus. Computer-based technologies provide effective tools to drive more productive meetings. These hardware/software combinations, commonly known as electronic meeting systems (EMS) have begun to find their way into a variety of educational environments (Aiken & Riggs, 1993).

**Electronic Meeting System (EMS)**

EMS endeavors to make meetings avoid groupthink and escalating commitment and also become more productive. EMS technology is designed to improve the productivity of many collaborative planning and decision making processes (RICIS, 1994). Through the use of this technology, group involvement in decision making can be accelerated. The use of EMS for the preparation of school leaders also has several other benefits. The public school principal of today needs to develop skills in group decision-making. Group involvement is a necessary condition for site-based and total quality management. Best and prevailing practice increasingly involves collaborative methods and group consensus building and or including involvement of various interest groups, or representatives, of groups, in educational decision making. Nunamaker, Dennis, Valacich, Vogel, and George (1991) have presented a strategy for understanding EMS processes, focusing on the characteristics of the group to be involved in the process, the tasks to be completed, the context of the organization and culture, and the outcome to be achieved. These items provide a framework for evaluating and understanding this and other examples of EMS and also establish an organization for a research agenda on system use (Spuck, Prater & Palumbo, 1995).

**The Process**

This study involved students in graduate classes in educational leadership studying the role of the principal. The study used a case as the bases for creating a decision-making situation. The case was about a principal who had recently been assigned to a dysfunctional high school with a mandate to establish a functional and improved school. The principal was an experienced administrator and was able to create a very much improved school environment, however, the principal had continuous difficulty regarding the relationship and the performance of a recalcitrant secretary. The case presented many positive and negative situations and involved many participants. Clearly the case was not unlike situations and dilemmas that educators work with on a daily basis.

The students were familiar with the use of cases and used the following procedure as a guide. Students, in groups of five or six, were encouraged to take a position after reading the case carefully and outlining the key points. Then they were expected to frame the central problem in a sentence or two. Next they identified secondary problems and indicated how these related to the central problem. After identifying supporting problems they found supporting information, looking for internal consistency and being careful about assumptions. The next task was to develop alternative solutions within the context of forces that enable or restrain them, or those that maintain the status quo. Students were then required to evaluate their alternative solutions, subject them to scrutiny, and use a T-account to list advantages and disadvantages. A T-account is a simple chart in the form of a T that allows you to list the advantages and disadvantages in a parallel structure for visual clarity and impact. The process also required that a
list of activities, identification of responsible parties, presentation of a time line, and statement of measures of intended outcomes be included. They then select the alternative most likely to solve the problem or bring about the desired change, or suggest a better option. Finally, they were expected to create a plan for implementation, including a method for adjusting.

This case was used in a traditional manner as described above during four different semesters, with groups of five or six students for a total of 24 experiences. On all of these traditional occasions the student groups identified the secretary as the problem for the case. The groups identified some punitive measure from reprimand to firing the secretary as a solution. The class that used the EMS had 39 students. For our purposes, 13 students used the EMS and the other 26 students stayed in the typical configuration. These five groups used the same case and were to follow the guide as stated earlier. The groups were to be used to compare if the resulting identification of the problem would be similar.

For the purposes of this study the EMS used an approach based on the Nominal Group Technique. This approach is a refinement of brainstorming that focuses on generating alternatives and choosing one. This approach is recommended where group members fear criticism. The following steps were used: members silently list their ideas, all ideas are listed on chart with discussion allowed for clarification but no criticism, finally a written vote is taken (Van deVan & Delbecq, 1974). This process encourages members to pool their judgments in order to solve the problem and then determine a satisfactory course of action.

Results

The group of thirteen graduate students identified 61 possibilities as possible problems. The students were asked to vote to narrow the selection down to the top fifteen. The sixty-one possible problems had many similarities, however, an attempt to group them together was not successful. The group was then asked to prioritize the fourteen selections. The sum of the rank ordering and the mean were calculated and the standard deviation from the mean was also provided. The ballot showed that most of the students identified the main problem as the lack of support from the Superintendent but the result was not significant. The significance level is found by the program calculating the consensus threshold using Ventana’s coefficient of consensus (VCC). The value of 1.00 represents complete consensus and the value of 0.00 represents no consensus. The VCC = 1.00-((STD / (high Limit - low limit )) * 2). The significance 0.18 showed very little consensus as a result of 0.65 would be considered significant. The lab assistant then narrowed the choices to five and the students voted. This time the VCC was calculated at 0.26 which again showed little significant agreement among the decision makers.

The next step in the process was to generate solutions. Each of the five identified problems were examined for solutions. Problem one created 45 solutions. Problem two-15, problem three-11, problem four-11, problem five-9. After identifying solutions for the problems they were asked to vote again on the critical problem. The students were then directed to predict by brainstorming the advantages and disadvantages of the solutions for the problems. The generated lists of advantages and disadvantages created a great deal of data that needed to be sorted.

The identification of the problem with the EMS system although not significant, focused on the Superintendent and his/her lack of support for the principal in handling the difficulty with the secretary. The other five groups of five or six students identified the problem as being a difficult secretary and the need for the principal to proceed with progressive discipline. The EMS students focused more on the problem of lack of leadership in the organization and the relationship between the principal and the superintendent. It should be noted that although, there is no one correct answer when using the case study approach, because a case reports the author’s bias, all details cannot be given and the assumptions that the students make in determining the analysis cannot be controlled. It is worth noting that a different outcome resulted from using the traditional case study method and using EMS, which suggests that there are better analyses and perhaps better solutions than others. It is also worth noting that because the EMS students identified a different problem, the solutions they provided were also very different. The main point is that if they don’t have the right problem identified, they are not going to provide useful solutions. Competency as a school administrator requires the ability to think critically and identify the problems that need solutions. The core of school leadership is the ability to make good decisions.

As a follow up, six experienced and successful school administrators were asked to read the case and react by identifying the problem and the solution. The result using EMS more closely followed the analysis of experienced school administrators. The results indicated the need for more study and analysis on the reasons for the different outcomes, and more study as to why the process of using the traditional case study method produced more superficial results, at least in this situation. There are also several advantages to using the EMS over the traditional case study method that make the system a very useful teaching approach when developing decision making skills.

The Advantages of Using EMS

There is an staggering amount of data that is produced and easily sorted using the EMS system. The variety of
Ideas make the group's work more focused on solving the problem rather than defending a solution. Olaniran (1994) made the observation that using electronic brainstorming produces significantly more fresh ideas. The use of EMS allows the calculation of the data to be produced by the system and the results are available throughout the meeting as well as in summary at the end of the session. A complete record of the meeting is available for analysis at the end of the meeting. All participants can input their ideas simultaneously. Opportunity for equal participation of all group members is provided. Large groups can work together to effectively provide more information, knowledge, and skills to work on the task.

Using the EMS removes a major barrier of members seeing and hearing which ideas are whose. It encourages members of the decision making team to think and create solutions rather than playing the politics of supporting an ally or friend. Nelson & Quick (1994) report that the Boeing Company study of its meetings found that 20 percent of the team members did 80 percent of the talking. Using EMS frees members' participation, and relationships become less important as the focus is on determining a best result. Although time can be considered a liability it can also become an asset using the EMS.

**Some Problems Using EMS**

Using the EMS can be more time consuming than using the traditional method of working in a group on a case study. The groups not using the EMS were finished with their deliberations much earlier than the EMS student group. The anonymous nature of the meeting can also encourage frivolity and distract others from the task, although some humor does add to the meeting. Another problem with anonymity is that it encourages irresponsibility and the accountability for ones actions can be lost which creates ethical implications. Educational settings, which often require public accountability, cannot be anonymous. Using EMS is and can be fun; hence, there is a need to be careful of the Halo Effect.

**Discussion**

Issues and problems occurring within the schools are becoming increasingly complex requiring more innovative solutions to problems. Yet the preparation of administrators focuses on developing systematic decision-making skills. These strategies come from the business model. While school leaders engage in some activities that are similar to those found in business, the more critical areas that administrators are required to address deal with individuals, both staff and students. The factors that need to be considered in school decision-making are more complex. Case study methods adopted from law and business schools need to be re-examined as a method of instruction for use in the preparation of school leaders.

As was observed, the case study method is often used in a superficial manner and resulted in identification of problems and solutions that are inappropriate for a school environment. Students tended to look for a right answer and thus were likely to focus on surface problems rather than underlying problems. Thus, the solutions would ultimately not solve the root of the problem and were unsatisfactory for the school setting. Using the case study approach it is necessary to be aware of these limitations.

This EMS approach used with a case study suggested a higher level of decision-making than the traditional case study method. Through the use of this technology future administrators were given the opportunity and the support for issue identification and prioritization procedures, which facilitates achievement of group consensus. Immediate feedback and real-time results meant no waiting. The importance of having a complete record of the meeting was a distinct advantage of the EMS. Individual entries, as well as the entire process, were recorded and analyzed. Decisions that require planning and problem solving or reculturing with task assignments can benefit from the EMS.

Just as some decisions are best made by individuals and some by teams or groups, some decisions are better suited to the use of the EMS. Decisions that would tend to be very emotional or those that require expedient action would best be served by the EMS. Decisions that will result in hurt feelings and poor relationships that can cause an organization to become dysfunctional could be best served by the EMS. Decisions that need to be made avoiding the groupthink phenomena can be well served by EMS. Meetings that require new or better solutions that can be best achieved using brainstorming have the advantage of simultaneous input using EMS. The importance of rapid polling on decisions is important for decision making that requires immediate feedback. Future administrators may benefit from experience in this form of decision making and problem solving.

In their review of the research base of elementary computer instruction, Benjamin, Bryant, and Mack (1990) noted the importance of the role of the administration as one of the important dimensions of the use of computers in school. The authors recommended guiding principles for administrative involvement in and support of computer instructional use which included administrators: 1) serving as role models for technology use, 2) updating their own skills, 3) visibly supporting staff members in the use of technology, 4) setting high expectations for technology use, and 5) promoting purchases and effective use. Administrators should serve as role models, start small, and encourage teachers to have computers at home (Weal, 1992). Barker (1990) noted that until the faculty and staff members see that their chief administrator feels comfortable talking about and working with the new technologies, it is highly unlikely that they will feel any sense of urgency to learn new skills themselves (p.37). Principals play a critical role in either minimizing or maximizing the acceptance of technology by the teachers (Fisher, Dwyer, & Yocam, 1996). These authors noted that principals must make a commitment to support schoolwide instructional change and the integration of technology by supporting teachers and providing them access to the technology.

Ornstein (1992) presented 16 guidelines for instructional leaders to implement in support of computer integration. Included in these guidelines was the need for school principals to know how to work with computer systems, become involved in instructional decisions surrounding computer use, and encourage teachers to integrate computer instruction in the curriculum (Ornstein, 1992). Waetjen and Bellisimo (1992) encouraged administrators to cooperate with teachers and others to research and observe the impact of computer applications in the schools. Nuccio (1990) noted that the principal's role in the successful integration of computers in the instructional process is just as vital as the principal's role was found to be in the effective teaching research of the 1980's. Zappone (1991) concurred with the emphasis placed on effective leadership in the successful integration of computers by including leadership as one of the key components of computer integration. In spite of the importance of leadership, inadequate support of teachers in the use of computers was listed as one of the prime factors interfering with the effective use of this technology in the schools (Branscum, 1992). In a study of computer instructional use, Murphy (1993) found that administrative support for the use of technology significantly contributed to the amount of use of the computer for instructional purposes by teachers. Strong, positive administrative leadership also was noted as a key variable for the planning and effective use of technology (Roblyer, Edwards, & Harviluk, 1997) with some authors calling for a redefinition of the meaning of educational leadership and the role of the school principal within a technological paradigm (Bennett, 1996, p. 57). Bennett (1996) noted that if principals are to be successful in a technological context, they must use develop six broad categories of tasks: defining/communicating mission, supporting/supervising teachers, promoting a climate encouraging computer use, managing technology, monitoring student progress, and managing curriculum/instruction. Sergiovanni's (1996) nine responsibilities of leadership (purposing, maintaining harmony with consensus, institutionalizing values, motivating, managing, explaining, enabling, modeling, and supervising) accentuate these essential characteristics of school leaders who support effective integration of technology.

The purpose of this study was to measure and report the amount of perceived administrative support received by teachers for the use of computers and related technology in instruction. Teacher attitudes, accessibility to computers, and training were considered in the interpretation of data regarding administrative support.

Procedure
The subjects of the study were 76 teachers of kindergarten through 12th grade, 44 of whom were also graduate
students enrolled in a survey of educational technology course. The group included 13 male teachers. The experience of the teachers ranged from one year to 26 years (25 respondents had 1 to 5 years of experience, 17 respondents had 6 to 10 years of experience, 13 respondents had 11 to 15 years of experience, 11 respondents had 16 to 20 years of experience, and 9 respondents had 20 or more years of experience).

The survey included five sections: General Information, Training, Access and Use, Administrative Support, and Opinions and Beliefs. The General Information section asked for demographic data (position, grade level teaching, gender, years experience), and whether the teachers had a computer at home. The training section queried the teachers about the amount and kind of technology training they had received. The Access and Use section asked the teachers about the availability of/accessibility to computers in the school for instructional purposes. In addition, the teachers were asked to give an average amount of time of usage of the computer by students and the types of instructional usage employed. The Administrative Support section asked the teachers to indicate how supportive they perceived their administration to be about their use of computers and related technology. The last section, Opinions and Beliefs, asked the teachers to respond to 12 general statements about the use of computers in the classroom.

Although the focus of this paper is on the role of the administrator the other sections of the survey will be briefly addressed.

Access to Computers and Related Technology at Home and School

Home Access

Of the respondents, 66 had a computer at home (25 of the teachers not enrolled in the technology course had home computers; 41 of the teachers enrolled in the technology course had home computers). The types of these home computers ranged from older model Apple IIs and IBM 286 systems to Macintosh multimedia systems and pentium based models. Of the teachers surveyed 57 reported owning IBM compatible machines and only 15 owned systems with multimedia capability.

School Access

Access to the computer at school for instructional purposes was reported by 74 of the 78 respondents, however, the kind of access was limited. Availability of older machines including Tandy and Apple II models was reported by 21 respondents. The use of newer models was reported by 40 teachers and 32 of these teachers utilized the multimedia capabilities of these computers for instruction. Only six of the teachers not enrolled in the technology course had a computer(s) in the classroom. The other 26 of these teachers taught in schools with labs, however one teacher added a specific note that while the school had a lab, her students were not provided access to it. Of the 44 teachers enrolled in the technology course, 18 had only one computer in the classroom, 24 had more than one computer (two to seven computers) available in the classroom, and 13 taught in schools with labs. In some cases teachers reported both lab access and classroom computer availability.

Instructional Use of Computers and Related Technology

When queried about the usage of the available computers, 46 of the teachers reported either drill and practice or rote use. Three of these respondents used the computer for drill only. Thirty-seven used the computer for tutorial or concept development purposes, 36 used the computer for instructional word processing, data base work, spreadsheet work, or graphics, and only 32 teachers mentioned the use of multimedia. Sixty-six percent of the teachers used the computer for drill/practice/rote purposes, 47 percent for tutorial/concept development, 46 percent for word processing/data base/spreadsheet use, and 41 percent for multimedia applications. Some teachers reported more than one type of use.

Reported amounts of technology use ranged from zero to two hours per student per week. Only eight teachers did not indicate use the available computers and 61 of the teachers reported only one-half hour or less of use per student per week.

Technology Training

The reported technology training of the teachers included self-teaching, coursework, and workshops. Twelve of the teachers had no training and most of the respondents enrolled in the technology course (26 of the 44 teachers) had no training prior to the current coursework in which they were enrolled. Forty-two of the teachers reported that they were self-taught, and 48 had attended workshops. Some teachers reported experiencing more than one kind of training.

Attitude of the Teachers

The overall attitude of the respondents was scored as high. Twenty-four of the teachers attitudes fell in the average range and none of the scores fell in the low range for either the group enrolled in the technology course or the group not enrolled in the technology course.

Perceived Administrative Support

Teachers were asked to rate the level of administrative support they believed they were given in terms of computer usage for instructional purposes. Of the 32 teachers not enrolled in the technology course, only four teachers indicated high levels of administrative support, 11 indicated average support, and the majority of the respondents indicated low levels of support. However, of the teachers enrolled in the technology course, only five teachers indicated lower levels of support, 14 indicated average
support, and 25 of the respondents indicated high levels of support.

As a group, the surveyed teachers who reported the highest levels of administrative support also reported more and varied use of the technology for instructional purposes, especially for multimedia use and application software (word processing, data bases, spreadsheets). This finding was noted in the analysis of all of the teachers, but was especially evident among the teachers not enrolled in the technology course.

Conclusion

The role of principals and other administrators is critical to the successful implementation of instructional technology planning and use. The leadership role is crucial to the acceptance and adoption of educational technology by teachers (Bowden, 1994). Van Dusen and Worthen (1992) revealed strong leadership as one of the factors that facilitated the implementation of integrated learning systems while an absence of dynamic leadership risked ineffective use. The widespread rush to integrate technology in schools has required school administrators attitudes and actions [to] become more important than ever to the future of education (Bennett, 1996, p.57). In spite of this reliance on the administrative role to encourage improved technology use, many teachers report a lack of support for the integration of the technology in classroom instruction. Instead teachers report minimal levels of support, lack of encouragement, and an absence of advocacy for the use of instructional technology.

References

This paper offers a review of a pilot project in the application of multimedia and communication technology to promote professional development of Northern Ireland secondary school principals and senior teachers in their practice of education management. The development of effective and efficient methods of professional training through the application of the new technologies is widely seen as an achievable goal. The project described below represents the early development of one group’s efforts in this domain.

**Pilot Project Description**

The pilot project is owned and developed by the CLASS (Computerised Local Administration Systems for Schools) organisation and is both strategic and operational in its focus of intended interventions. At the strategic level, it represents a collaborative exercise in utilising an existing professional development infrastructure, including both government agencies and commercial enterprises, to deliver inservice training to four secondary schools using multimedia CD-ROM and supported by tutors using intermediate band communication. At the operational level, four ‘technology-ready’ secondary schools, who were selected because of their good track records in the use of information technology, agreed to participate in the professional development exercise.

Three of the four schools decided to engage their senior management teams in the training programme, consisting of principal, vice-principals and senior teachers. The other school decided to use the training opportunity to develop their pastoral care team which consisted of two vice-principals, three heads of school and seven heads of year. In total, twenty-eight teachers engaged in the project. Their levels in IT literacy varied from high users to zero users. Approximately 35% of the teachers considered themselves to be nonusers of IT.

The CLASS project’s partnership model is reflected in its components, each of which were contributed free of financial charges by the respective public or commercial organisation. SIMS Ltd. provided the knowledge engineering component of a traditional classroom-based training package on Management Information Data Access Systems (MIDAS). This was converted into a beta-release version of an interactive multimedia CD-ROM training module by the Northern Ireland Centre for Learning Resources (NICLR). The multimedia learning system was supported by a CLASS training centre-based human tutor and linked to the pilot schools through an ISDN2 video conferencing facility using Vision Technology VC 8000 system and TeamVISION communication software provided by (BT) British Telecommunication plc., which also provided the ISDN installation and line costs. The hardware was supplied by Fujitsu ICL in the form of five Ergo-Pro X40/133-16-850 Mb computer systems. Coopers and Lybrand gave advice on project management and the Northern Ireland Regional Training Unit (RTU) offered advice on school management issues and evaluation methods. This complex but effective partnership model was managed through a Liaison Group which met under the chairmanship of the Director of CLASS. The CLASS project itself was managed by a senior CLASS officer supported by an assistant and a technical officer.

The pilot project represents a possible early stage in the Department of Education for Northern Ireland’s (DENI) current overall strategy of examining ways in which computer-based management information can lead to improvements in the quality of school-based decision-making. The professional development of teachers through effective inservice training is seen as a key activity of this strategy. However, it is increasingly difficult for schools to offer sufficient inservice training to meet these professional development needs. Factors such as high cost of substitute teachers, loss of key staff, distance to training centres and finding suitable training times for economical size groups mitigate against the provision of traditional classroom-based professional development programmes. The CLASS pilot project represents an initiative that could provide a potential platform for flexible inservice provision, empowering schools to manage their own professional development needs at a time and to a level that meets local requirements and with minimum disruption to pupil learning.
Methodology and Research Focus

This study is located within the qualitative tradition and utilises data obtained through unstructured and semi-structured interviews of key participants, observation of learning situations and planning and development meetings. Data was also collected through self-reporting of teachers who completed a personal training log in which they recorded time spent on each unit, problems encountered and reflections on their experience. The project has been in operation for one year and has included course design, multimedia material production, technical development and initial technical training of the participating teachers. The professional development programme itself was undertaken by the teachers over a thirty day period, although the principals and project managers of the four schools were engaged in training and development programmes with the CLASS team for six months.

Teaching and Learning Models and Strategies

The teaching and learning strategies employed by the CLASS project utilised the technologies of multimedia CD-ROM and video conferencing. In broad terms, the CD-ROM provided a fundamental skills-based training programme in the use of MIDAS, with the teleconferencing technology providing a student progress monitoring facility through a skills test exercise and teacher development through online tutor support.

To place the training programme in context it is necessary to point out that CLASS is a powerful, fully integrated management information system installed in all Northern Ireland schools. The MIDAS component looks across the system’s database and modules, providing details on staff and students as well as summary financial information. In each of the project schools MIDAS is hardly used. Indeed, most of the project school staff were unaware of its existence, although CLASS is used extensively by teachers with particular specialist interests such as curriculum planning, examination entries and financial planning. In part, the reasons for this non-use are due to the slowness of response to a query and unfriendliness of the system’s MS DOS interface. For example, the average time from logging into the system and extracting say a students’ list in MS DOS MIDAS is approximately six minutes. However, CLASS are currently upgrading Northern Ireland’s schools with the faster computers and a Windows 95 interface which will address these problems. The staff development training package has been timed to coincide with this upgrade programme.

The MIDAS multimedia CD-ROM was designed to reflect the structure of a learning objectives driven, paper-based classroom training model and organised into five units covering the required skills for data access. From the trainee’s perspective, the CD-ROM provides a direct visual representation of MIDAS software. After logging in, they are offered five training units set in a Windows interface.

The learning strategy employed is structured around the three logically developed, integrated approaches of ‘Show Me’, ‘Let Me Try’ and ‘Tell it to me Again’. Following Units 1 and 2, which demonstrate the structure of MIDAS, describe icons and features of the Windows interface, trainees are ‘taught’ the functions of MIDAS through a series of simulated school information gathering activities based on simulated practical, school-focused problems.

The ‘Show Me’ aspect of the learning package offers the user an automatic demonstration of an aspect of MIDAS. In this function, an audio explanation accompanies a moving pointer tracing the pathway required to obtain task related information. The tempo of the pointer is automatically varied according to new-knowledge requirements. The pace of instruction has been designed to ensure that competent trainees do not become bored and each ‘Show me’ activity is short enough to give ‘the unsure’ the incentive to try the routine again.

The ‘Let Me Try’ allows users to perform the task for themselves. However, because the simulated MIDAS is not totally responsive, students cannot fully interact with the data. If a student moves down an incorrect pathway, the software offers an error message requesting an alternative route to try.

The ‘Tell it to me Again’ function provides the solutions that should have been obtained by the trainee during the learning process, offering reinforcement feedback. At times during the process, students may access the task question, which is frequently lengthy and detailed in their information gathering requirements, through operating a ‘pull down’ window. Interestingly, only approximately half of the trainees discovered this function, emphasising the invisibility of hidden menus.

In pedagogical terms, the first aspect supports the development of knowledge, the second the acquisition of skills and the third reinforcement feedback or suggested route for further study. The aspiration of the CD-ROM designers to produce a ‘low text’- ‘high human interaction’ visual learning environment has been largely met.

Video conferencing technology was used (a) to provide tutor support for teachers who may encounter difficulties in using the CD-ROM training package; (b) to provide a communication link between trainees and the CLASS project manager; (c) to allow testing of teachers to take place on completion of study programme; (d) to support the CLASS project team in carrying out formative evaluation; (e) to facilitate communication between CLASS support managers of the four schools with a view towards examining school specific practical applications of MIDAS and assisting with development issues once schools started to use the real data of their school; (f) to allow project schools to develop professional networks; (g) to raise project
schools’ awareness of the potential of intermediate band communication systems and develop necessary skills for their use.

From a trainer’s perspective the constructed learning environment, emerging from the coupled video conference tutor support system and the CD-ROM, offers a three element overall pedagogical structure:

(a) Knowledge acquisition is offered through low interactive, high visual, automatic multimedia display of relevant aspects of MIDAS. Here learners move through the MIDAS package at their own pace, repeating or reviewing the essential procedures and gaining knowledge of the structure of MIDAS.

(b) Skills acquisition is achieved by allowing the learners to utilise the acquired knowledge in preset simulated problem solving activities.

(c) Understanding of the system and its value in improving school-based decision-making will be developed through the tutor support programme facilitated through video conferencing.

**Some Research Outcomes**

The CLASS project is ongoing. The observations which follow are based upon the fulfilment of phase II of the project - the completion of training. The next and, arguably, most important phase will explore how senior and middle education managers have integrated the new knowledge, skills and understanding into their professional processes in their schools. Within these boundaries it is possible to offer some observations on efficiency and effectiveness issues about education management professional development facilitated by the educational technology outlined above.

**Effectiveness**

How one should measure the effectiveness of a professional development project will always be an open question. At this stage in the project it is only possible to assess the achievement of short-term goals which were, broadly, the acquisition of those skills that would allow senior and middle managers to use MIDAS. However, in addition to learnings which occurred as result of the formal curriculum, there were other kinds of learnings taking place that more easily fit the concept of the informal, or hidden, curriculum. Each of these kinds of learnings having an impact on the professional development of education managers and, in turn, on the development of the school organisation.

**Formal Learnings**

Two major indicators used to assess a project aim of ‘helping staff acquire new and relevant skills’ were a self-reporting monitoring log and an externally administered, through a video-conference link, competence test of four, unseen, school-focused practical problems. From the data received through the personal logs, which were supported by personal interviews, each person fully completed the multimedia training programme, successfully operated the video conferencing system and successfully completed their competency test questions, although the speed and efficiency of achievement of their answers to test questions varied significantly. The mean time to complete test was 262 minutes with a standard deviation of 86 minutes. The mean number of errors made was 2.07 with a standard deviation of 1.54. The ease with which each participant completed the training programmed and time they spent in training, see below, also varied.

**Informal Learnings**

There were two main kinds of learnings from the hidden curriculum. Firstly, the experiences of the project impacted positively on the participants’ attitudes towards information technology. For the previously nonusers and low-users of IT, the project enabled managers to ‘overcome hesitancy’; ‘see computers as less threatening’; ‘become more confident in using a PC’; ‘be familiarized with operating procedures’; ‘increase their (professional) status with colleagues’. Secondly, the common experience of engaging in the project further contributed to a sense of corporate identity of the four management groups through, in part, having acquired the same information management skills, ‘we now have a more even platform of knowledge’. In part, too, the reflective processes that were an integral part of the project, created opportunities for each team member to contribute to and learn about each others area of school management concerns. There was also evidence that the shared common experience of feeling vulnerable and sharing of solutions to problems encountered, mainly of a technical nature, contributed to the development of interpersonal relationships useful for team-building.

**Efficiency**

One of the major incentives for the development of independent learning systems is the potential efficiency gains they offer over traditional training patterns. From the schools’ and teachers’ perspectives there was the major efficiency gain of reduced financial cost of training. Because teachers carried out the training during school time or at home on personal computers, there was no need to attend a training centre and employ substitute staff to cover absented classes at about £100 per day per teacher. However, the average time spent by teachers engaged in the training programme was greater than that anticipated in the traditional training model. The designed time of imparting the skills for MIDAS in a traditional setting is 180 minutes. However, the mean time spent by teachers undertaking the independent learning model was 206 minutes with a large standard deviation of 116 minutes. Although teachers on average spent longer on the training exercises when using the multimedia package, it should not be said that it was a more inefficient mode of delivery.
Rather, we believe, that it reflected the valued nature of individualise learning in that it supported a wide range of learner needs, allowing the 40% of the teachers who required more time to be accommodated whilst allowing the other 44% to complete the training in less than the projected training time. (12% completed in about 180 minutes.) Also, and importantly, there have been no empirical studies undertaken to test teacher skills proficiency using the traditional training model. Nevertheless, this efficiency aspect will be the focus of further study.

Cost-Effectiveness

Measures of cost-effectiveness need to take account of all qualitative outcomes balanced against financial and other costs, and are frequently comparative in nature. With respect to the CLASS project, a full cost-benefit analysis would need to extend beyond the project boundaries for a full appreciation of the involved factors and would be expected to take account of a range of savings that would accrue from large scale strategic developments. There are, however, some clear financial costs and benefits. For example, although capital outlay is high, with multimedia CD-ROM commercial production cost about £40,000, hardware costs (multimedia computers and intermediate band teleconferencing equipment) about £5000 per school site, the training support staff costs are only about 30 minutes per trainee. There are financial savings for the school of about £100 per teacher, although there will be opportunity costs to the school due to teachers engaging in the training programme during school day and utilising a teacher as the school programme manager. Once the investment in capital outlay has been discounted through economies of scale and opportunity costs of teachers engaging in the programme minimized through the careful planning of inservice training by the school so that it occurs at times when teachers have sufficient free space, then there are clear financial benefits to schools and the education system they serve.

Conclusion

There is understandable interest in the economic dimension of professional development programmes. Nevertheless, it is the perceived quality gains that are also of interest. Although this study was not designed directly to compare an independent learning model with traditional training methods, it was of interest to note that each teacher stated that they qualitatively preferred the school-based, independent learning model. There were a number of significant reasons given to substantiate this preference which appeared to fit within the two categories of 'personal' and 'organisational':

Personal

(a) The opportunity to determine one's own time and space for training. This is supported by the wide variation in the times during which the multimedia package was used— from 8.00 am to 10.00 p.m.— and length of time spent using the system— from a total of 85 minutes to 560 minutes. (b) The opportunity to make mistakes in private, thereby reducing personal embarrassment. (c) Easy access to the CD-ROM to support revision when the teacher moved at a later point to using real data. (d) There was a belief that the training increased the professional status of the teacher in the eyes of colleagues. This belief was particularly strong in the cases of previously nonusers of IT.

Organisational

(a) A key benefit of this training model was that it allowed each member of a specific management team to train simultaneously, thereby supporting school-based strategic development: an option not possible in the traditional model. (b) There was an equal distribution of corporate skills, providing a common platform for organisational development. (c) The training activity positively contributed to team-building, particularly in the development of interpersonal relationships. (d) The training model also was perceived as promoting the path of participatory style of management through opening up hitherto specialist areas and promoting discussion of problematical organisational concerns.

Despite the overall enthusiastic teacher support for the CLASS project's use of an independent training model, there were a number of lessons about the design and delivery of this model on a wider basis. Firstly, a technical support system within each school needs to be available. In about 25% of the individual sessions teachers encountered some form of technical difficulty and required support. In 5% of these sessions, where support was not available, the teacher quit, expressing strong feelings of frustration at the loss of time. Secondly, low motivation was experienced in teachers during those periods when the multimedia sessions were low on interactivity and high on information output. High motivation occurred during periods of high interactivity, helpful progress feedback, a sense of discovery and exploring content that had strong practical relevance. Thirdly, the training model needs to be carefully managed at school level with attention paid to auditing of individual progress and ensuring individuals are not experiencing unmanageable conflicts of priorities on their time. For successful school-based development, timing of the introduction of the training programme is crucial.

Phase III of the CLASS project is currently being undertaken by the four schools. The crucial question which now needs to be answered is: "Will the newly acquired individual skills be incorporated and further develop the quality of the school's educational processes?"

258 — Technology and Teacher Education Annual — 1997
One of the many important responsibilities of a campus administrator is the development and articulation of a shared vision for technology integration on a school campus. With the constant thrust for schools to do everything possible to encourage technology infusion, the campus administrator must make decisions based on the needs of teachers and staff on that campus to make technology reasonably accessible and applicable. Providing a campus facilitator to orchestrate the use of technology on the campus is one essential way to effect technology access and application among the entire staff.

Training teachers to use and apply technology is an ongoing process for each campus in the nation. School districts create many different scenarios for technology training which include inservice days during the school year, staff development during the summer, release days while teacher's classrooms are covered by substitute teachers during the school year and offering after school training sessions. Some districts employ a director of technology to oversee the technology plan for the entire district, the big picture. Many school districts have technology trainers who help train teachers to use specific software for the classrooms or for general computer literacy. The district technology trainers generally respond to K-12 teachers, librarians, administrators and support staff. Linda Roberts, project director of the Office of Technology Assessment (OTA) commented in a landmark study called Power On!, “that despite good intentions, the best information, and the hopes of planners, schools have at most established demonstration centers for what might be. The school districts have demonstrations of what is possible, but if you go into a typical school, you will see that teachers in the classrooms are hardly using computers at all. School districts are good at innovation, but fall down in implementation” (OTA, 1988). OTA’s 1995 study, Teachers and Technology, found the barriers to teachers actually integrating technology into the curriculum had not come down. According to that study a majority of teachers reported feeling inadequately trained to use technology resources, particularly computer-based technologies. Also, although some schools have made progress in helping teachers to use basic technological tools they still struggle with curriculum integration, which is central if technology is to become a truly effective educational resource (OTA, 1995). Other research points out that new teachers are not ready to use technology in the classroom and must be trained along with the veteran teachers on campuses. Collis (1994) concluded that the majority of teacher education makes little or no reference to computer related technology, and much computer related teacher education is stimulated and delivered by persons without an academic background in teacher education.

After all the training workshops and inservice opportunities offered by a school district, the teachers are faced in the trenches with trying to use technology on their specific campus with the curriculum that is to be taught. Now THAT is what the whole integration process of technology is about. The variables are many: grade, subject, computer platform, software, accessibility and more. If technology is to be integrated in to the classroom, teachers need constant support.

The creation of the Site Specific Technology Facilitator role or the Local School Technology Coordinator role is one answer to the problems that face a campus administrator when encouraging technology integration on his/her campus. Job descriptions for the "facilitator" will vary depending on the campus or school district but generally the idea is to encourage the use of technology in the classrooms and to do lots of hand holding while the teachers try to implement each specific detail for using computers for instruction, research or project-based applications. The facilitator’s main job is to lure teachers into technology integrated lessons. Explaining lesson plans for teachers and creating ways in which technology can be integrated into the lesson for that subject (many times changing the classroom environment from the traditional one to a more project-based collaborative
learning situation), gathering the software and hardware available for use by the teacher and helping her/him understand the roles that technology can play in extending the lesson is all part of the hand-holding. There is something to be said about taking the teachable moment and going with it, especially with reluctant users. A teacher should understand that being an expert in the use of technology is not required. Students in the classrooms of the near 21st century are ready and anxious to use technology. Once teachers see how alive the classroom becomes during the technology integrated lessons they rarely go back to the non-technology traditional classroom.

Suggestions for the Campus Facilitator

After several years of experience we (a building principal and facilitator) would like to offer some suggestions about facilitation.

1. Focus first on the teachers who are easiest to encourage. Ask them to allow you to look over their lesson plans and make suggestions where the available campus technology can be used. In many instances scanners, digital cameras, modems or other computer hardware can be brought into the classroom for the lesson. Knowing the possibilities will allow the non-technology using teacher creative about how to use technology to extend the lessons.

2. Be available for teachers so that the lesson/lessons will be successful. A computer supported lesson may have some problems, but the campus facilitator can troubleshoot on the spot and make adjustments to help teachers avoid problems in the future.

3. Some traditional lessons may need to be revised to better utilize technology. Helping the teacher revise the lesson by brainstorming how to set the challenge for the lesson, deciding the goals and objectives of the lesson, identifying the learning strategies to be used, deciding how students will construct their knowledge (what resources are available), what will be the performance criteria, who will access the work and how, and how will students communicate their results are all important steps in revising a lesson plan. Encouraging the teacher to give constant feedback is very important for all student involved.

4. Teachers who have used technology in their classrooms will be advocates for those who are not yet even considering the concept. It's contagious.

5. Campus facilitators should encourage teachers who have used technology successfully in their curriculum to present their successful technology-based subject-specific lessons to other teachers and to become mentors for these teachers.

6. Campus facilitators can provide listings of campus hardware and software, peripherals that can be used on the campus such as laser disc players, digital cameras, video cameras, VCRs, video digitizers, and so on.

7. Time is generally a problem and timing will always be an issue. Planning the lessons takes time. All the hours that are not instructional hours on the campus are used. Before school, lunch, conference periods, planning periods or after school times are all used to by facilitators to help and encourage teachers to use the technology on the campus.

8. Posting technology conference dates and workshop dates is helpful.

9. Writing a few paragraphs about teachers who are using technology on the campus in the principal’s weekly campus bulletin gives a positive spin on technology integration. A campus technology newsletter would help and encourage teachers to use technology.

10. Some schools do not have open labs or available computers for each student. The campus facilitator should be able to help the teachers in a one computer classroom develop workable concepts for instruction, and help others learn how to use a handful of computers in a collaborative learning situation.

11. Connecting the teachers on the campus with teachers on other campuses in the school district or other school districts who are using technology is exciting and should be encouraged. This can be via telecommunications or meetings teachers must already attend.

12. A mobile technology station can be set up for the campus. This station could consist of a large computer, laser disk, VCR, LCD panel, overhead projector or any combination of equipment. This station can be used by the students and teachers in many ways.

13. Faculty meetings is a time to make quick announcements about new technology or up coming technology training.

14. Helping the teachers understand the power of telecommunications and how to access available modems on the campus to use e-mail or the Internet is a vital part of technology training. Use of the World Wide Web is one the most misunderstood resources and one that can be used in so many creative ways.

15. Encouraging teachers to use technology to support instruction, assessment, curriculum development, communication, collaboration, research, text and multimedia production, resource access and classroom management is the overall thrust of the campus facilitator.

The role of a computer facilitator is best performed by a person with a love for technology and a keen interest in integrating it into the curriculum. Teachers have a huge amount of work to do each day: planning, increased paperwork, dealing with students with special needs and meeting curriculum requirements just to mention a few. Even the most dedicated teachers find it hard to find the time to plan lessons using technology. A campus facilitator
who is given the time by the principal to help teachers use available technology on their campus provides a jump start for the teachers.

E-mail: jcobbin@tenet.edu
No, we didn’t pass the four million dollar technology bond issue, but we had a district technology plan. Now what? Durango School District is located in rural southwestern Colorado with a population of 12,000 in the city and 30,000 in LaPlata County. There are 4,500 students in 1 high school, 2 middle schools, and 7 elementary schools. In 1991 our new Superintendent was concerned that there was no comprehensive plan for technology in the school district. Requests coming from the schools were as varied as the educational philosophies of each school. Later that year he accepted an invitation from IBM Corporation to conduct a study of Durango’s technology needs and facilitate the development of a district technology plan. A technology study team composed of administrators and teachers was formed. Input was gathered from teachers, support staff, administrators, students, parents, and community members. A five year technology implementation plan was developed and presented to the Superintendent and Board of Education for approval in April, 1992.

When we developed our technology plan we established guidelines to produce the completed plan. The guidelines have been revised over the past three years but the basic concepts are still in place. The major areas included in the plan are: the technology team, assessment, visions, what is available, funding, acquisition, staff development, implementation and evaluation. The complete outline is included in the appendix.

New Position- New Directions

The new position of District Technology Director was filled with a teacher on special assignment in the Fall, 1992. Also during the Fall the district held a bond election to finance a new elementary school, middle school, and to implement technology. The building bonds passed, but the technology portion failed. Although the technology bond failed, the Board of Education and Superintendent remained committed to placing technology into the hands of our students, but at a much slower rate. The Board reprioritized the capital reserve funds and allocated $500,000 to begin implementation of the plan. The district technology committee submitted recommendations to the Superintendent on how to begin putting computers into the schools. They were approved and the computers were ordered.

Technology and Software

Since 1992 we have received over $2.5 million and installed local area Novel networks into 7 elementary schools, two middle schools and one high school. There are five computers in every fourth and fifth grade classroom with a mini-lab of 15 computers in the media centers. There is a variety of instructional software available to students including IBM courseware, Jostens’s Learning Corporation, Edunetic’s, and other third party programs. At the middle schools there are two large computer labs with 25 computers in each and a variety of configurations for 50 other workstations with Computer Curriculum Corporation and IBM courseware. Each middle school has a technology lab with 15 modules. At the high school there are four computer labs with 25 computers each for word processing, curriculum courseware, business, multimedia and science technology. There is also a technology lab. All libraries in the district are automated using McGraw Hill’s Columbia software. The district office was networked in Fall, 1996. We are in the process of putting Internet networks into the middle schools and high school, upgrading existing workstations, and putting a plan together for a science impact energy grant that we received for the elementary schools.

Now We Have It, How Do We Use It?

From 1992-1995 the District Technology Director was the only person in the educational technology department. Duties included selecting, purchasing and assisting in set up of the networks, maintenance, public relations and staff development. The first year the fifth grade teachers had computers placed in their classrooms. Teachers received training from the coordinator and some vendors. The next year technology was placed in the sixth grades and those teachers were trained. After that technology purchases escalated dramatically. The high school received very little in the way of staff development. Follow-up training was haphazard.

In 1995 the District Technology Director believed that the time had come for the Board of Education and Superintendent to increase the staff of the technology department. The number
of computers had grown, maintenance was overwhelming and staff development was not happening. Support was beginning to wane.

That fall one halftime district trainer was approved by the Board of Education. This person was responsible for training the elementary and middle school teachers on the networked courseware. New users received one day of release time for training and after school inservices were offered. The District Technology Coordinator was responsible for training high school and middle school teachers on the newest networks. Interest and skill levels began improving. As training increased, the demand for even more grew dramatically. Graduate technology classes were offered through a state college and a new plan for training was developed.

**Technology Staff Development**

Staff development must be well-organized and ongoing, and it must address a full range of needs. It must be an integral part of your plan and your budget. While the focus of this section will be primarily on the teaching staff, system-wide implementation of technology requires the effective training of other employees as well. Administrators will need to know the pros and cons of various technologies, how to determine whether desired learning outcomes have been reached, and how to use technology to run their buildings. Office support staff must learn how technology can help with their day-to-day tasks of running the school. Library personnel must learn not only how technology can assist in their work, but also how to help students and teachers tap into the larger bank of resources that will be available to them.

Over the past year we have discovered that staff development implies more than training — it also refers to professional growth. Teachers must not only know how to use various technologies, but also must clearly understand how technology changes the learning process. Staff development must not only teach specific skills but also develop teaching strategies and explore the impact that technology will have on teaching methods.

Experience has shown that many factors make planning and carrying out staff development programs difficult, including shortages of time, money, motivation, and capacity to provide for ongoing technical assistance within the schools. These issues must be recognized and addressed as part of your Technology Plan.

Vicki E. Hancock, Assistant Director of the Education and Technology Resources Center at the Association for Supervision and Curriculum Development (ASCD), suggests that any staff development consider including the following:

1. Teachers should have plenty of opportunity to reflect — to read, think, and talk — about the benefits and limitations of technology.

2. For lasting impact, staff development should be ongoing and systematic, not simply a series of one-shots.

3. Large workshops should be supplemented by peer coaching and modeling, so that teachers can benefit from each other’s expertise.

4. Staff technology training should be based on the actual curriculum for which teachers are responsible.

5. Staff development sessions must provide hands-on, exploratory experiences with technology — not abstract theory, but actual ‘messing around’ with machines. (Hancock, 1993, p. 7)

Schedule specific times for teacher technology training in the school calendar throughout each year. Earmark some of these times for training in specific skills that will be needed to progress along the implementation timeline. But leave some of the training dates open to allow for training in areas that develop as the program progresses. Designate some of the sessions for system-wide training and some for individual classroom applications. Remember that training must be ongoing throughout the year, so be generous in your time allotments.

It is essential that there is an ongoing commitment to staff development. Businesses match every hardware or software dollar invested in technology with a matching dollar for training, while educators spend five percent of their technology budgets on training. For our 1996-97 budget the Durango School District has allocated 14% of its technology budget for Technology Staff Development. We feel that for every $1 spent on hardware, schools should budget $ .25 for staff development.

Whatever level of investment you choose, the effectiveness of your technology implementation will be in direct proportion to the effectiveness and thoroughness of the training you provide. Access to technology is not enough — we must learn how to use it and incorporate it effectively.

**Areas of Training and Staff Development**

All training must include hands-on computer time, both during and after the workshops, to allow trainees to become familiar with the actual applications. Make sure that training is also followed with staff exploration and planning time for the integration of this new material into the classroom.

Remember to include professional and clerical personnel from your school system. Invite some of your stakeholders to participate as well. The training can be broken down into 10 categories.

1. Introductory training — a basic course to familiarize both teachers and administrators with the general capabilities of technology; an important initial offering

2. Computer ethics instruction — all technology users must be made aware of the do’s and don’ts of accessing and copying software programs and files
3. Technology-specific training — system-wide coursework in the use of CD-ROM, computer graphics, networking, e-mail, databases, multimedia, etc.

4. Subject/grade level training — workshops to explore applications (software programs, online communications, CD-ROMs, etc.) that are available for specific subject areas or grade levels

5. Software courses — to expand the use of technology through exploration of HyperStudio, PageMaker, Windows, and other products.

6. Curriculum writing courses — to provide opportunity for teachers to come together and develop curriculum materials that integrate technology into their classrooms

7. Classroom management strategies — to learn use of the computer in record-keeping, document production, etc.

8. Technology as an assessment tool — to explore the use of technology in authentic and portfolio assessment.

9. Internet — introductory use of the computer to get staff their drivers license to get started on the information highway.

10. Process training — seminars and discussion groups focusing on the ways in which technology is changing the educational environment, the role of the teacher, how teachers modify classroom techniques, and the ramifications of this.

As you identify the components of your staff training program, you may want to consider recommending that your school system include a required level of technical competence as a condition of employment for future staff hiring. This will allow you to maintain a common level of knowledge and ability on which to base staff training. We are in the process of developing this segment of our Technology Staff Development to make teachers more accountable.

Provide for Ongoing Support and Feedback

While formal staff training is an absolute necessity, an additional component is also necessary if teachers are to become comfortable with technology — they must have access to "someone down the hall" for answers when things go wrong or for new ideas when they are ready for them. This is where our T3 program enters the picture. This will be addressed by one of our T3 individuals later.

The best way to provide this support is for your system to hire a minimum of one person as a Technology Specialist, or Technology Director. It will be this person’s responsibility to troubleshoot problems, provide information, and act as a catalyst for further implementations. The Technology Specialist can also coordinate maintenance, upgrade software, and manage the network.

In addition, each building should have a person (teacher or administrator) to serve as a resource to help staff with basic questions when the Technology Specialist is in another building. Make sure that the staff knows this person’s identity and the extent of the support that he/she can provide. These individuals take on an even more important role if your system does not have a Technology Specialist.

A third way to provide ongoing staff support is through developing a resource bank of people at local universities or businesses who would be willing to give some time to your school system to assist with staff development issues. Try to arrange for a volunteer to be in your building on a regularly scheduled basis. If this is not possible, make specific arrangements with them ahead of time, so that you can let them know when needs arise. These types of ongoing support are vital. They provide the hand-holding, person-to-person process that will help teachers to be successful with technology.

As you begin implementing technology, you will want to establish a vehicle for monitoring the effectiveness of the training and support in each building. A system-wide team of teachers with representatives from each building can be helpful in this process. These teachers can also help to identify training needs as they arise in individual buildings. As Hancock said, "Initially, teachers are inclined to use the computer to reinforce things they’re already doing. Later on, they begin to adapt their instruction to the computer. Finally, they begin to explore the capacities of the new machine" (1993, p. 13).

In our Durango School District a half time staff training position was created in 1995. Our desire was to develop a training program based on the staff’s needs. Each school district staff member completed a skills needs assessment to determine which classes should be offered. Upon completion of the surveys classes were developed. The goal was to provide technology staff training in the areas of the following:

- Basic Computers and Windows Operation
- Word Processing- Microsoft Works and Microsoft Word
- Spreadsheets
- Library Automation
- Basics of Network Operation, IBM ICLAS, Schoolview, Internet, Multimedia
- Hyperstudio
- PowerPoint
- Integrating Technology into the Classroom

The school district contracted with Adams State College to provide graduate credit for all of the classes offered. Attendee’s can receive graduate credit for a minimum charge of $35.00 per credit hour. Our desire was to provide sophisticated training to the staff so that they understand what technology can do and understand its potential. All courses emphasize hands-on experience and
demonstrate the “WHY” of technology in the classroom. When we develop a class we always ask:

• Where are you going?
• How are you going to get there?
• How will you know when you arrive?

Our staff development program was developed with the idea of the teacher must change into a facilitator. Our philosophy adopted the approach of moving from the old “Sage on the Stage” to the newer “Guide On The Side.” We try to also remember the “Goof on the Roof.”

In March of 1996, the Director of Technology and staff trainer developed a new program for the district called T3 (Train-The-Trainer). Durango’s T3 program was developed using the basic structure of Train-The-Trainer that has been written about in numerous educational publications by Joyce and Showers. The concept was to have a trainer at each elementary school, two trainers at each middle school and 6 trainers at the high school. The program was presented to the school board and explained that in lieu of being paid for the time each trainer would be provided a IBM Thinkpad with CD-ROM, sound card, modem, network card and an Internet account. The trainers attend the classes offered by the district Staff Development Trainer and the Director of Technology. The T3 individuals in turn train the teachers at each individual school. This puts a Technology Specialists in each school.

We are currently working on a variety of projects to encourage teachers to become involved in using technology. This includes creating “plain English” instruction manuals, developing a staff computer purchase program in which the teachers and the district each pay half, and a program in which a teacher can earn a computer by completing a prescribed instruction and training program. We are also designing Computer Cruises and Computer Train Tours for staff training and encouraging the development of a business partnership with businesses in Durango.

Obsolescence Plan

The Technology Plan for the district was adopted and implemented in 1992. At the time of adoption who would have thought that equipment would be obsolete in such a short time span. Technology changes so rapidly each week it is very difficult to keep up.

In 1995 the Director of Technology developed an Obsolescence Plan. The plan was unique in that it did not state a time frame to replace equipment. It was based on software needs and curriculum implementation needs. There is a part of the plan that does phase out old equipment after five years. But the unique part of the plan is that as software needs change, more memory or larger hard disks are needed, money is in the budget to do it.

From the Trainer’s Perspective

Technology has arrived at the Durango school district. Buildings have been networked. Labs are stocked with multimedia machines, scanners, and the latest in scientific probeware. The labs at the middle schools and high school have been made ready for the Internet. Small cells of energized teachers have begun work on attacking the enormous learning curve that accompanies technology, yet more still needs to be done.

The Train the Trainer (T3) program was instituted to help teachers throughout the district to overcome the inertia and trepidation that can impede learning how to use and integrate these powerful tools. It is no longer acceptable for just the building techies to implement computers into their teaching. More teachers need to enter into the world of computers and begin adapting them into their practice.

The program was set up to get at least one technology trainer in each of the ten schools in the district. This person is responsible for training teachers and support staff in the use of software and hardware in the building. Trainers conduct inservice programs and then provide follow-up help. They also help put out minor technical fires to take some of the burden off the district technology trouble-shooter.

As a group, the trainers are a very diverse lot. Few of them would be classified as the building computer nerds. They came into the program with a wide range of expertise, but share a strong desire to build upon their existing knowledge and learn new technologies. They have agreed to share their expertise with colleagues and students as they take on new learning. Trainers are also dedicated to make the existing building technology available to all students, teachers, and support staff.

Initially, a survey was conducted at each building to find out the needs of the staff. The results indicated that staff wanted to learn more about management tools such as data bases, spreadsheets and electronic gradebooks. They were also eager to explore multimedia CD-ROM’s and authoring tools like Hyperstudio. The most emphatic response however, centered around learning how to use the Internet in the classroom.

A training schedule was set up for the year, and one hour training sessions were scheduled once or twice a month after school. This approach has worked well at some schools, but other strategies have been tried as well. Some trainers have found it more effective to work with small groups or one-on-one. They have ferreted out snatches of time at breaks, during planning times, or before or after school. This individualized sort of training has been very effective because it usually focuses on a specific technology issue that the teacher has brought to the trainer. As the teacher moves forward with their use of the new technology, the building trainer is available to provide support and serve as a sounding board for the technology related details. One-on-one training was most effective during my computer infancy while struggling with word processing and gradebook software.
It is important to develop information literate students that are able to access and utilize all the tools at their disposal. Students are certainly not afraid to use whatever we provide them in the way of computer equipment. Before we prepare students for the 21st century, we must prepare teachers to facilitate their learning. It is clear that staff development is directly tied to student effectiveness in using technology. Our training program is developing teacher proficiency in two ways. First, it helps teachers better manage students by making them more proficient at using word processors, data bases and gradebook programs. Additionally, teachers are going beyond using the computer for simple drill and practice. Now they are adapting and inventing new uses for technology in their curriculum. The computer is a major factor in building a student's knowledge of the world of the world around them. Our task is to make teachers aware of these tools and their potential usefulness to themselves and their students.

Our final comment is a statement found on the Internet. We could not locate the author but we feel that it really gets to the heart of the staff development issue. “Technology minus training equals junk.”

Appendix
Technology Plan Guidelines
A. The Technology Team
1. Identify your stakeholders
2. Choose your Technology Team
3. Provide a base of knowledge for all team members
4. Define your task
5. Resources for getting started

B. Assessing Where You Are
1. Where are you technologically?
2. Where are you educationally?
3. What does the State mandate in the field of technology?

C. Formulating a Vision
1. Develop a vision statement
2. Communicate your vision statement to your community

D. Exploring the Available Technology
1. Multimedia technology
2. Connecting computers in networks
3. Online communications
4. Telecommunications

E. Exploring the Possibilities of Technology
1. Technology and the curriculum
2. Art
3. English/Language Arts
4. English as a Second Language (ESL)
5. Foreign Languages
6. Goal and Skill Objectives for Computer Skills (also called Scope and Sequence)
7. Mathematics
8. Music
9. Science
10. Social Studies
11. Special Education
12. Student Performance Assessment
13. Vocational Education
14. Technology and resource management (libraries/media centers)
15. Technology and school administration
16. Facility design and system configuration

F. Developing a Technology Plan
1. Set specific goals and objectives
2. Identify your equipment needs
3. Develop a timeline
4. Develop a budget
5. Identify internal and external influences on your plan
6. Gain approval of your plan
7. Consider equity issues
8. Involve your community in the plan
9. A Checklist for your plan

G. Funding and Acquisition
1. Raise funds through grant proposals
2. Corporate donations of equipment and services
3. Local fundraising efforts
4. Off-price purchasing
5. Partnerships with outside organizations
6. Things to watch for

H. Staff Development
1. General areas of training and staff development
2. Determine your areas of need
3. Select appropriate training models
4. Provide for ongoing support and feedback
5. Support staff home use of technology

I. The Implementation Process
1. Begin the implementation with a pilot program
2. Build on your successes
3. Arrange for ongoing support for staff and teachers
4. Bolster your accomplishments with a public relations program

J. Evaluation and Continuation
1. Find out how you are doing
2. Keep things current
3. Keep the momentum going

K. Emerging Technologies and Issues
1. Keep your eye on new areas of technology
2. Track the progress of important Initiatives

L. Extending the Use of Technology Beyond School Walls
1. Choose compatible home hardware and software
2. Make the home-school connection
3. After-school programs
4. Adult programs
5. Special programs

THE KEY TO TECHNOLOGICAL INNOVATION:
THE TEACHER

Douglas Lare
Marywood College

In the innovative examples cited in this paper, efforts at technological innovation centered on the teacher. School officials devised ways in which teachers could personally use innovative technologies at home. Situations were created whereby teachers were not only instructed how to use the computers and other innovative technologies, they were also provided with the means to experiment and explore at their leisure. In these programs, as teachers became comfortable with the machines, and experienced first hand the practical applications, the use of the innovative technology as an instructional tool almost became inevitable. As evidenced by these examples, the key to technological innovation in the schools may be the teacher.

The Development of Instructional Technology

Computers and related technology have been in schools for close to twenty-five years. Each year, the administrative applications of the computer are becoming routine in school life. Student records are kept on computers, and business offices would be lost without them. As in the business world, there is a strong suspicion that computers and related technologies have made the school’s central office more cost effective and efficient.

The use of computer related technology in the classroom has been far less extensive than in the central office. There are exceptions, and the literature abounds with isolated cases where innovative administrators, teachers and students are effectively using technology to enhance learning (Wagner, 1996). Yet despite the impressive proliferation of computer software for instruction in K-12 schools, there has been a relatively small volume of significant data showing the overall advantages of this type of instruction (Adams, 1989). Some studies do, in fact, uncover advantages (Bracey, 1988). Others are less conclusive. Ognibene (1989) suggest that this current plateau might be due to a number of factors including the inherent conservatism of schools and teachers, the difficulty of integrating technology in the classroom, and the resistance of teachers to practices that present a perceived threat to good interpersonal relationships with students.

So, as an instructional tool, computer related technologies have received mixed reviews in the research literature. The enticing instructional potential of the computer has yet to be realized in most schools.

Technology and Teacher Training

Although computers are not quite ready to be thrown in the educational technology scrap heap, there is perhaps a danger that unless a new direction is found, the use of computer related technologies as effective instructional devices will continue to bypass many schools. Teachers, since they are the primary instructors in schools, have always been the key to educational innovation. It would make sense, therefore, that teachers would also be the key to technological innovation. It would follow that if teachers actively use computer related technologies, then there is a strong chance that the use of computers would become a more integral part of instruction. This almost common sense notion has led to countless numbers of inservice programs which attempt to tackle the issue of teacher training and support with respect to the use of computers (Barker, 1994). Just about every teacher in the United States has attended a computer workshop or at least felt that this is something s/he should do someday. Usually these programs, lasting a few days, familiarize the teachers with computers and available software (Brennan, 1991; Outen, 1994; Zeitz, 1995).

Despite all these good intentions, and despite the impressive short term gains as reported in the literature, few studies can be cited which point to effective training techniques which impact a teacher’s use of the computer on a more long term basis (Ingram, 1992). Teachers return to the routine of school life and rarely have the time to practice what was taught. Often, computer related technologies might not be available just when a teacher is free. Most school schedules are not set up to be conducive to teachers
extending instructional skills. Therefore, the one or two
days a year when teachers are asked to broaden their
horizons rarely pays off with a significant chance in how
teachers use technology.

As might be expected, it is difficult to promote the use
of the computer in the classroom when teachers themselves
do not understand how to use the technology, or have the
time to learn on their own. Therefore, since most teachers
do not teach computer classes or have access to equipment,
the advantages of the technology which are so apparent to
more frequent users in those isolated cases is not made
available to many of the students. In short, despite all the
hardware and all the efforts at training, there is still
something missing which has inhibited efforts to effectively
use the computer as an instructional tool.

Unique Programs in Teacher Training

Yet there are situations which have taken a different
approach to teacher training. Not surprisingly, they are off
the “plateau” and are exploring areas of computer use
which very few schools consider. Although the details of
these novel programs vary, they generally attempt to get
computers and similar technologies into the homes of the
teachers on a permanent basis.

The Lake Washington School District in Kirkland,
Washington, had land for sale in 1987. Some of the money
generated from the sale was used to offer a unique com-
puter program to teachers over the summer. For two weeks,
teachers would learn about computers and how they can be
used as tools in the classroom and at home. At the end of
the course, instead of being paid in cash, teachers took the
computers home and used them as they saw fit. The result
of this offer was that 98% of the faculty participated in the
program (983 teachers) at a cost of 1.6 million dollars. The
following year, computer use in the classroom increased
dramatically, as might be expected, and teachers were
anxious to receive additional training and equipment.

In the Catasauqua School District, Catasauqua,
Pennsylvania, a similar program was instituted although
the goals were far more modest. Beginning in 1989, the
program included extensive training on the computer. At
the conclusion of the course, teachers took the computer
home in lieu of pay. To date, over 30% (35) of the faculty
have participated in the program. The total cost has been
$25,000. Again, as might be expected, it is the faculty who
have participated in this program which have most often
requested software, have reserved computer labs, and have
conducted inservices in neighboring districts on technology
uses. Not all the teachers participating in this program
were oriented towards using technology in the classroom.
Many were anxious and worried. However, those inflicted
with technology anxiety have made significant strides since
they have assumed ownership of their own machines.

Strategies for Implementing Programs

As cited in these two examples, a program such as this
can be inclusive or piecemeal, depending on the district’s
financial and political situation. There are several guide-
lines that are helpful as educators ponder the possibilities of
unique technology training programs.

Work with the Board

In both cases cited, the school board was very support-
ive, initially. As financial burdens stretched the resources
of one of the districts, the board reluctantly decided that
this type of program was a luxury which would be misinter-
preted by the public. Unfortunately, this mind set may be
typical in many districts since the board could have
difficulty seeing the connection between permanent and
effective technological innovation and having computers
purchased for teachers to use in their home. At least a year
should be spent preparing the school board for this
program. It is also a wise idea to fully explain the program
to the business office and school solicitor. Inevitably, you
will need their support when working to convince the
board, and they will help you answer the important
questions concerning whether the technology received
should be counted as taxable income.

Inform the Public and Other Constituencies

This type of program is not something to hide from the
public. The more it is advertised and promoted in a positive
way, the more likely the board will support the program in
the future. And it is best not to look at a program of this
kind as a one shot summer inservice. Plans should be
established to make this an option for ongoing teacher
training into the future. In addition, if all teachers cannot
be accommodated the first year, it is wise to establish a
procedure whereby all feel that a fair selection system has
been used. A committee composed of teachers that would
be responsible for selecting applicants, might work best.

Build in Accountability

One district “lent” the computers to teachers who would
return them upon retirement. In this plan it is important to
make sure there are the necessary legal forms which
guarantee the return of all equipment. Require frequent
reports the first year, documenting how the computers are
being used at home. Invite several teachers to attend board
meetings and report on changes in their instructional
strategies.

Consider Options for Funding

One district simply gave the computers to teachers
instead of payment for extra summer work. Another district
“lent” the computer to the teacher for as long as the teacher
worked in the district. Many districts are now offering
interest free loans whereby teachers can borrow money for
the express purpose of purchasing computer related
technology.
Build in a Training Component

This is a critical phase in the development of this program because it not only provides the foundation for future use of the technology, it also puts the teachers in touch with other teachers in the district or building who will be experiencing similar anxieties during and after the training period. Organizing the training with district or building people is also a good idea, since this also targets and individual within the organization who can answer the many questions which will arise from all participants in the future.

Be Accommodating

It would be best to have one type of machine available for all participants. Yet many teachers might apply for this program who already have technology at home and are looking for enhancements. They should not be denied this opportunity simply because they have already taken the incentive to explore innovative technology at home. In addition, most districts have a great variety of educational technology available throughout the organization. It is best to work with each participant, prior to the training, in order to determine what best suits that individual teacher’s needs.

Spread the Word to Other Districts

After the first year, teachers should be encouraged to spread the word both within their training class, through organized meetings, or in other districts at inservice workshops. Teachers talking to teachers about innovative use of instructional technologies is perhaps the most powerful, and effective, message available.

How the Program can Influence Instruction in the Classroom

Technological innovation, as evidenced by the significant isolated cases we often hear about in popular literature, is often spearheaded by innovative teachers and administrators (Wagner, 1996). These individuals frequently have access to computer related technologies at home, and have no doubt experimented with their instructional ideas on their own time.

Yet if we are to expand these cases of technological innovation outside of the isolated cases, we must establish a process whereby all teachers in a building or district have the option of learning about technology on their own time. All the inservice and training will inevitably fail unless teachers have the chance to practice, on a daily basis, what they learn.

The key to the unique programs cited above is that teachers can use the computer whenever they wish. The training is important. But the critical component is the fact that teachers have access to the machine on their own time. They are then able to explore, take risks, and see applications which would elude them during the day. As might be expected, in districts taking this approach, the use of effective, innovative technology has dramatically increased.

Computers are used in music and English classes. Teachers are more willing to experiment with math problem solving software. The Internet is becoming a routine research option. Science teachers regularly use interface devices. School newspapers are published on computers. In short, the intuitive advantages of innovative technologies in all its forms is taking hold in these districts. And teachers are leading the way.

270 — Technology and Teacher Education Annual — 1997
INCONSPICUOUS INEQUITIES: THE MYTH OF UNIVERSAL ACCESS

Bobbi Nicholson
West Virginia Graduate College

The technophiles are hopelessly naive (or self-deceiving) in their understanding of social problems. They are unaware of (or choose to ignore) the fact that when large changes, even seemingly beneficial ones, are introduced into a society, they lead to a long sequence of other changes, most of which are difficult to predict.... In fact, ever since the industrial revolution technology has been creating new problems for society far more rapidly than it has been solving old ones (in Sale, 1995, p. 308). The author of those words has given America much to ponder over the past few years, although unfortunately it wasn’t his prose but his performance that captured our attention. The sixteen bombings executed by Theodore Kaczynski, accused of being the Unabomber, clearly mark him as the most deranged among the neo-Luddites.

Kirkpatrick Sale argues, however, that contrary to dismissing his idea that the industrial system in which we live is “a social, psychological and environmental disaster for the human race,” we should put it at the forefront of the American political agenda (p. 305). Sale goes on to say that Kaczynski’s treatise is not irrational, nor is there anything “wild-eyed or rabble-rousing” about it. While we may find the method by which he aired his grievance objectionable, the grievance itself sounds familiar.

Industrial Society and Its Future

Kaczynski’s creed is consistent with a growing body of work in the Luddistic tradition that questions the widely held belief that technology constitutes an indisputable and universal benefit. While some of that work admittedly lapses into diatribe, most raises legitimate questions for we who consider ourselves technology advocates; questions which, as their authors point out, have been ignored in the stampede to integrate technology into virtually every nook and cranny of American society. Some of these concerns are social, some academic, some economic or political, and others combinations of these. One of the more troubling is the widespread perception that electronic technologies have the capacity to radically democratize public education by increasing access, an argument which requires some examination.

There are some preliminary questions to consider, the answers to which will provide the basis for confronting the issue of universal access. Specifically, those questions concern what our expectations are for the technology and whether, at least at this point, those expectations are realistic.

HyperExpectations

Donella Meadows, an adjunct professor of environmental studies at Dartmouth, in a recent commentary offered a means of distinguishing between the sane and the insane. In a discussion of the futility of focusing on the disposal of toxic waste as opposed to reducing its production, she drew the analogy of a leaky faucet. The insane, she said, go immediately for the mops and buckets. The sane, however, turn off the faucets first. While she offered the analogy in the context of environmental concerns, the same may be said for any context wherein we fail to consider the source(s) of our anxieties or problems.

Like Meadows’ insane, we’ve been frantically mopping, trying to stem the tide of user-friendly software, CD-ROMs, high-speed modems, a veritable deluge of unrecognizable acronyms, search mechanisms cleverly disguised as comic book characters, navigational tools that mimic rodents or worms, and enough World Wide Web locations to ensure information overload for even the most casual user. Buckets in hand we continue to bail, too busy begging the question to wonder if anyone’s turned off the faucets long enough for us to assess what’s happening. The context of mental competence may be extreme, but the question remains: What do we plan to do with the flow of information? In the rush to determine how to integrate the latest technology into America’s schools, we’ve had little time to consider what, in the broad sense, we want it to do.

What’s the answer? To put it in its most reductionist terms, we expect technology to halt our purported economic decline by rescuing an education system perceived to be on the skids. We expect it to restore our economic hegemony and stem the now-infamous tide of mediocrity believed to be engulfing our public schools. Democrats and Republicans, politicians and business leaders alike accept this
solution as an article of faith. In this theology, our digital deliverance is at hand:

Those who preach the faith include educators who believe computers will enable us to teach and learn more effectively; researchers in artificial intelligence who talk excitedly about machines that ‘think’; politicians who herald the arrival of the high-tech industry as economic and political salvation; and, of course, computer companies that promote a glowing image of a smoothly functioning universe. The media have seized that image with gusto, generating books, articles, and stories about the miraculous and utopian nature of this brand-new cultural superstar (Brod, 1984, p. 3).

Public figures like Senator Bob Kerrey of Nebraska and filmmaker George Lucas argue that “access to information will be the currency of power and knowledge” in the Information Age, and that failure to provide universal access to the Internet will render America’s students unable to compete or even function efficiently in the global marketplace (“Access,” 1995). Amita Goyal of Virginia Commonwealth University and Alka Harriger of Purdue University agree that in order to produce employees suitable for today’s workforce, institutions of higher learning bear the responsibility to “prepare students to master the skills to be able to compete for the best jobs in the competitive information technology field” (1995, p. 63).

Much of the anxiety over students’ performance and preparation is thus inextricably linked to their ability to function in a highly competitive, technology-intensive economic environment, a proposition that many find arguable. That America’s students are consistently outperformed by their foreign counterparts, for example, is a favorite theme of IBM CEO Louis Gerstner who alludes to national outrage over our students’ finishing “at or near the bottom” on international tests of math and science. His remedy is predictable: “We need to recognize that our public schools are low-tech institutions in a high-tech society. The same [technological] forces that have brought cataclysmic change to every facet of business can improve the way we teach students and teachers” (1995, p. 4).

Since the rationale for equipping the nation’s classrooms with computers relies on the characterization of public schools as inferior, Gerstner and others who share his view (Finn, 1993; Innerst, 1995; Ravitch, 1995) find it necessary to ignore reports to the contrary. And while an increasing number of scholars have emerged to defend public education (Berliner & Biddle, 1996; Bracey, 1995; Rose, 1996), the perception of incompetence persists, as does the conviction that employment in a nontechnical field is a thing of the past. The October 11, 1996 edition of USA Today featured a letter from President Clinton and Vice President Gore saying that by 2000, “60 percent of all jobs will require advanced technological skills” (in Bracey, 1996, p. 136). There is no subsequent description, however, of what precisely those advanced jobs and skills are, and attempts by researcher and author Gerald Bracey to solicit either a definition or a citation for the figures were unsuccessful. Both, however, are contradicted by the US Department of Labor’s Employment Outlook 1994-2005 (1995), which predicts that the majority of jobs requiring a college education will not be high-tech jobs, and that the occupations that will account for the largest numbers of jobs will be low-skilled. The Outlook further reports that among the skilled jobs available, most will feature a degree of specificity that will require extensive on-the-job training regardless of the employee’s education credentials (1995).

What accounts for our tenacious faith in the power of technology to transform, even in the absence of a demonstrated need for transformation? Perhaps one of the problems with encouraging a more cautious view of the promise of emerging technologies is the historic equation of technology with progress. In this familiar scenario, technology propels economic growth and a corresponding improvement in the human condition, thus explaining its description as “the handmaiden of democracy” (in Gillespie and Roberts, 1989, p. 7). When we express anxiety about that vision, wondering whether it’s more problematic than it seems, we are assured by those in the vanguard that there’s no reason for concern. Microsoft’s Bill Gates, for instance, is confident that “although ‘dislocations’ will occur (meaning: you’re fired), the net result of these disruptions will be a more empowered, better educated, wealthier populace” (Levy, 1995a, p. 56). What’s missing in that formula, however, is an understanding of technology’s inevitable locus in contemporary social, economic and political contexts.

CyberRealities
Technology has, as Andrew Gillespie and Kevin Roberts recognize, “an inherent ‘bias’ ... it can never be neutral or independent of society’s broader social and political biases” (1989, p. 9). Myron Tuman agrees, suggesting that technology in and of itself cannot make ours a healthier society absent its embodiment in institutions of social reform. What happens again and again, he says, is this: “[I]n the absence of such institutions, just the opposite happens ... those in the best positions to use the technology do so for their own narrow interests while society as a whole suffers” (1992, p. 133). To the list of technology’s potential outcomes then, we may add its capacity to reinforce the status quo by further stratifying a society already clearly divided between the haves and the have-nots. Tuman refers to the latter as members of a new global underclass, arguing that the same patterns of inequality associated with print literacy persist (p. 4). Suneel Ratan observes that if there were any doubt that the computer has become firmly entrenched as a member of
the American family, it has been dispelled: "For the first
time ever, consumers in 1994 bought $8 billion worth of
PCs — just a smidgen away from the $8.3 billion they
spent on TVs (1995, p. 17). In America's poorer areas,
however, families sharing a home with a computer are
fewer and farther between. Computer Intelligence InfoCorp
reports a distressing but predictable disparity between PC
equipped households and their less digitally blessed
neighbors, pointing out that 70 percent of households
without personal computers have annual incomes of less
than $40,000, while 63 percent of the PC-equipped homes
have incomes above that figure (Ruby, 1996).

Stephen Levy, writing in Newsweek's final 1995 issue,
cites Vanderbilt University business professor Donna
Hoffman's description of the predominantly upper class
clientele of the Internet: "[T]here's no controversy about
what online users look like .... They're demographically
attractive — upscale, overeducated people" (1995b, p. 27).
While it is no surprise that the higher the income level of
the family, the more likely they are to have access to the
latest in virtually everything, the disparity is more apparent
with computers than just about any other item. What are
the cost estimates? Bill Gates suggests that, depending on
architecture and equipment, the cost to connect one
information appliance (e.g., a television or personal
computer) to the "information highway" is approximately
$1,200 (1995, p. 61). Andrew Kohut of the Times Mirror
Center for the People and the Press points out the differ-
ence is even more pronounced when the education level of
the respondents is factored in. Among college graduates
with children, 49 percent of the households surveyed had a
PC, compared with only 17 percent of the homes in which
the parents had only a high school diploma (in Furger,
1995). At the individual user level, 65 percent of those
online have college degrees, while only 20 percent of the
general population does; and an astonishing 93 percent
report some college attendance (Ruby, 1996).

These social circumstances are, of course, reflected in
the education arena. Trends identified in the eighties
(Becker, 1986; Becker & Sterling, 1987) that confirmed
that wealthier school districts tend to have equipment and
access unavailable to poorer ones continue in the mid-
nineties, with schools in the suburbs having twice as many
computers per student than their urban counterparts (Ratan,
p. 17). A two-year study by Janet Ward Schofield of the
University of Pittsburgh (1995) reveals further cause for
concern. As gifted students have special educational
opportunities designed only for them (e.g., field trips, guest
lecturers, etc.), these academically advanced students also
have more access to computers than do their peers, a
situation Schofield says "is likely to widen the already
marked gap in achievement between students from more
and less affluent backgrounds" (p. 216). At the school
under study, college-bound students, regardless of the track
they're in, have the option of enrolling in a computer
science course. Schofield notes that this opportunity is only
theoretically open to non-college-bound students, most of
whom take general math courses, since Algebra I is an
"informal screen" through which students who wish to
enroll must pass (p. 215).

Kohut, pointing out the obvious, says, "If the road to
equality is access to information technology, then there are
some real roadblocks in place" (in Furger, 1995). Among
the roadblocks is the finding of a survey conducted by the
American Association of State Colleges and Universities
that reports that more than two-thirds of 250 participating
institutions either have or are considering a computer-
competence requirement for students ("Colleges Target," 1995, p. 6). While the survey isn't clear on whether the
competence is to be an entrance or exit requirement,
obstacles remain for those students who haven't had the
technological advantages of their wealthier counterparts.

While the computer-on-every-desk vision is perhaps
impractical, there are some creative solutions that can at
least help mitigate the technology gap. Ratan reports, for
easy, that the information technology industry clings to
its faith in market forces, arguing that competition will
drive prices down making equipment, software and access
more affordable (1995, p. 17). Although interpreted by
industry-watchers as a stalling tactic to avoid government
regulation, many agree the scenario is plausible. Those
constantly on the prowl for the latest gadgets or upgrades
could create a vigorous secondhand market wherein
discarded equipment or programs/software can be made
available to the less advantaged. Ratan sees it as a sort of
used-car market for high tech, although eventual obsoles-
cence is a matter for some concern (1995, p. 18).

Additionally, a number of advocates for wider access
are focusing on efforts to place equipment and access to
networks and online services in public locations, such as
libraries or community centers. They're also pursuing
attempts to find ways to make presently-equipped facilities
open to the public at convenient hours. A number of public
schools, for instance, might be willing to keep their doors
open in the evenings and on weekends if they could afford
to pay staff and utility costs. All of these efforts are
commendable, feasible and deserve our support.

What is not helpful are initiatives in several states,
mine among them, which have a striking Wildean technol-
ogy-for-technology's-sake character. During the 1995
regular session, for example, the West Virginia Legislature
passed Senate Bill 547 which has among its goals a
provision that computer usage will be integrated "into all
[higher education] coursework," and that all full-time
college or university freshmen "will own or lease a
computer" (pp. 78-79). Faculty's academic freedom
considerations aside, requiring students to own or lease a
computer creates more problems than it solves. The speed
at which technological advances occur will render the machine obsolete by the time the student graduates, and lease-to-own schemes are notoriously expensive. Combine only those two problems and the result is a student who not only pays more for a computer than it’s worth, but who upon graduation finds her purchase is only marginally useful at best. Families who can afford the latest technology will continue to buy it, much as they continue to buy other kinds of goods and services. Attempting to mitigate the economic disparity between these and their less comfortable neighbors by ensnaring the latter in dubious lease/purchase schemes, however, is misguided. It is precisely this kind of techno-infatuation that Cuban (1986) advised against, recalling that at one time people held absurdly exaggerated expectations for classroom use of film strips, overhead projectors and television. In terms of both cost and efficiency, it makes more sense to concentrate our efforts to assist the technologically disadvantaged on public access than on private ownership.

There’s no universal panacea for closing the information gap, but we should neither be deceived by the inconspicuousness of the have-nots nor misled by the persistent utopianism of billionaire technophiles who are clearly out of touch with reality. Gates’ pronouncement that computing is now “astonishingly inexpensive” is not only naive but irresponsible (in Levy, 1995a, p. 60). If we intend to use advanced technology in a constructive fashion, if its implementation in our classrooms reflects a commitment to unleashing its considerable potential, then we owe it to our students to do everything we can to secure convenient, affordable access for them.

Former Silicon Valley workers Lenny Siegel and John Markoff, in The High Cost of High Tech, explain the motive of the technology industry’s interest in computerized classrooms: “To most manufacturers, the schools are primarily a vehicle for building a consumer market for personal computers. Though school sales are significant ... the home market is five times as large and it is much more profitable” (1985, p. 80).
INTERNAL VS. EXTERNAL INTELLECTUAL AGENTS
IN THE MANAGEMENT INFORMATION SYSTEM OF SCHOOLS

Raymond G. Taylor
North Carolina State University

In the past year a great deal has been written about the future of personal and corporate intellectual agents. Depending upon the degree of speculation involved, these agents live in the information world of the Internet and represent the interests of their owners and creators. In their simplest form, they search for information and for connections among information that are known to be of interest to the person or organization they represent. They then serve the distillation of their work to their masters upon demand. What was purely speculative a year ago is in practice today. New companies such as AutoNomy in Cambridge, MA., are in the forefront of offering authoring programs that can generate such intellectual agents. But the speculation stays ahead of the practice. Other theorists and futurists assign far more intelligence to the intellectual agent of the near future than searching, filtering, and sorting, and claim that it is within reason to suppose that such agents could soon embrace a heuristic that allowed them to be self-adjusting, capable of self-improvement, and facile at organizing other agents. Thus, the agents could be self-structured in an ad hoc hierarchy to accomplish more sophisticated goals and complete more complex tasks, enlisting and dismissing subordinate agents as quickly as is required to fulfill the demands of the superior agents.

Given the current state of artificial intelligence and the enormous economic base behind the Internet, what appears to be a mere fantasy today is likely to metamorphose into an improved and implemented version tomorrow. With apparent intelligence and access to unfathomable interconnectivity, the intellectual agents of tomorrow, and the real and virtual organizations that employ them, will be as dominant in the information space as computers are in today's physical office.

**Internal Connectivity as a Prerequisite**

For schools and school administrators one of the primary limitations to the entire notion of external intellectual agents working within the Internet, is that there are no existing links between such possibilities and the internal activities of the school. The databases of schools tend to be disconnected or nonexistent. Thus, without any intraconnectivity the best an external agent can do is deliver information to a human agent at the boundary of the school. (Boundary is used within this paper in the systems analysis sense: the interface between the school and the external world, that is, between whatever is defined as school and what is not school.) The mechanism for the use of intellectual agents when there is no intraconnectivity would probably be in the form of one or more school employees enlisting intellectual agents for their own interests or amusement. The intellectual agents would not be able to inform school practice except through the intermediation of the interested human agent.

Worse still, without any intraconnectivity there can be no automatic seeking of information that might be useful to the internal decision-making processes of the school. Every need within the school would first have to be appreciated by a human agent. That agent would then have to have the ability, interest, time and persistence to take the need to the boundary of the school and translate the need to the intellectual agent. If the present low ratio of technological utilization to technological availability within schools is any indication, the intellectual agent would rarely be employed.

A solid management information system (MIS) always exploits the relevant internal information sources, processes that information through the lens of appropriate models, formulates the rudiments of decision support, and then informs that support with external information if it is needed. Thus, intraconnectivity is a prerequisite to the systematic and intelligent use of external agents.

This same MIS process is witnessed in industrial organizations with expert decision support systems, and thus they are well-positioned to exploit the benefits of sophisticated external intellectual agents. By contrast, schools and most local governmental agencies are not
similarly prepared internally and yet they are often determined to purchase equipment and participate in the outward-looking part of the electronic information revolution. The problem is as old as the fields of systems analysis, database design, and intraorganizational cooperation and sharing. Schools present a clear case where the new technology depends upon the successful implementation of the old — where the organization must be functionally sophisticated before it can responsibly exploit new opportunities.

Intraconnectivity and the Internal Agent

There are rarely any models within the school management information system to support decision making, such as Markov models for personnel policy evaluation, binary programming models for redistricting, cohort survival models for enrollment forecasting, and queuing models for the management of CAI and its resources. Instead, human models for enrollment forecasting, and queuing models for programming models for redistricting, cohort survival and sharing. Schools present a clear case where the educational manager needs but may not have the prerequisite skills or awareness to ask for.

Notwithstanding these historic constraints to the advancement of computer assisted decision making, decision science and its underlying computer hardware technology are on the edge of a breakthrough that could substantially improve the rate of adoption and the utility of the tools for educational administrators. More specifically, the capacity of microcomputers to solve full-sized realistic management problems is now available and inexpensive, as are robust computer programs designed to handle such problems without fully involving their users in the underlying technical complications. Once intraconnectivity is appreciated and implemented, decision support models can “live within the bowels” of the information system, constantly updating themselves and yielding information that the educational manager needs but may not have the prerequisite skills or awareness to ask for.

Consider an example recently studied by a doctoral student at North Carolina State University. (Winters, Taylor & Williams, 1996). Working within an industrial education environment, she built a Markov model based on how trainees moved through the skill levels of a certain Computer Assisted Instruction (CAI) module. There were perhaps eight skill levels, seven of which were needed for certification. Every so many minutes, a snapshot was taken within the CAI system. The snapshot updated the Markov matrix (probability of moving from any one skill level to any other). After enough persons had been through the CAI module, several analytical possibilities emerged. The instructor could make optimal interventions, because he would know who was functioning at or below any given percentile in terms of past (normative) performance. He could also tell, based on the first passage time analysis within the model, how long it would be before some given percentage of the total group would reach mastery. Or, put differently, he could tell how much longer the present group would have to work before 80% of his machines would be available to a new group.

So far, the above illustration relies heavily on the human agent, but let us suppose that the instructor or CAI systems manager were not required to make any of the inquiries suggested above. Instead, a Markov system was automatically created and updated for every CAI module as it was installed. Further, an electronic alarm would tell the instructor (on the instructor’s screen) that the person at machine 14 was well outside the band of normative performance and needed help. And, let us suppose that every half-hour a forecast for the group and a forecast for the future availability of the resource (the computer room, in this case) was made and a suggested schedule for the next group was produced. These auto-reporting mechanisms could occur without the CAI manager knowing any of the underlying technology or without him even knowing that he should seek such information.

Given sufficient intraconnectivity, the information generated by the Markov model would flow to all other decisions that might be affected by its activities — the records of the students involved, the teacher who was next in line for using the facility, the manager who purchases equipment (based, in part, on the backlog of demands on existing equipment), the curriculum department which prepares or purchases the CAI modules, and so on. All of these possibilities depend upon intraconnectivity among databases within the school — a technical problem that was long ago resolved through various forms of open database connectivity, enterprise computing, and local area networking. And, these possibilities likewise depend upon inexpensive and reliable software for the decision support models — again, a requirement that was long ago resolved by STORM (Emmons, Flowers, Chandrashekhar, & Mathur, 1992), LINDO, (Schrage, 1991), various spreadsheet add-ins, and numerous other popular solvers.

Consider one more illustration based on an entirely different management problem. In many cities in the United States, there is, either voluntarily or as a result of court intervention, an effort to racially balance the enrollments within public schools. This is done by creating attendance boundaries that capture, for each school, a certain proportion of children from each pertinent race. The goal is to have the balance within each school similar to the balance within the overall system. Some students and their parents resist such assignments by changing their place of residence. Thus, flight and other demographic phenomena require that attendance lines be periodically changed. The danger is that one or more schools will get
out of balance before administrators are aware of what is happening. If the system is under a court degree, such imbalance can cause considerable economic and political problems, as well as a sudden disruption in the educational program of children who must change schools with little notice.

Now, let us suppose that the transportation information system is GIS-based and thus can convert addresses to X-Y coordinates as well as performing many routing and scheduling functions, and let us suppose that the student information system (which includes race and address) were sufficiently linked to each other and to a forecasting model. The model could then make forecasts based on small areas within the system’s perimeter, monitoring and projecting numbers of students and their racial composition. As those small areas change demographically, a forecast for the schools to which those areas are currently assigned could likewise be forecast and could yield warnings that certain schools would, within one year, be outside a preset tolerable balance. A binary linear program could then annually find the optimal assignment of areas to schools, balancing race and minimizing distance. In April or May of each year, the system would automatically report recommended changes in boundaries for the coming fall. If the changes were approved, the system would notify parents and cause a recomputation of bus routes and schedules. The underlying technology would not need to be understood by the user, nor would the user have to ask all the right questions in order to receive the recommendation.

Other Examples

There are countless examples of how intraconnectivity could support internal decision-making systems and can be of great value to school administrators. As these examples are offered, they will sound more like methods than agents. We will return to this distinction later, but for the time being, keep in mind that an agent is often no more than an automated method. A very brief description of several possibilities follows:

Merit pay systems could employ linear programming to make an optimal distribution of funds. In such a system, the objective would be to maximize the amount of salary money awarded to each teacher for performance on each merit compensation variable, subject to all the constraints of the employing institution and the agreement between the employer and employees. Such variables might include teaching performance, professional development activities, school citizenship, extra duties. The constraints would include merit money available, and limits on the amount of merit pay that can be obtained by any one teacher. Records of the teacher’s performance and participation factors would be stored annually in the employees’ personnel file, and would be accessed by the merit pay system. Likewise, the policies of the school board affecting the budget and other constraints would be filed in the policy parameters database and could be accessed by the merit pay system. Little or no administrative intervention would be required to generate merit pay amounts, post them to the payroll department, and print notices to individual faculty regarding their merit pay for the upcoming year.

Systems for the analysis of impending teacher shortages could use Markov analysis, a tool that is ideally designed to help analysts understand the current and predicted behavior of systems that change over time. In terms of the teacher shortage problem, those states might include: a) being enrolled in a teacher training program in a particular field, b) being a first year teacher in that field, c) continuing beyond the first year, d) taking an unpaid leave from teaching, and so on. By tracking the movement of individuals once every year with respect to these states, an overall understanding of the way teachers move through career paths can be determined. This determination yields answers to many policy questions (such as whether certain incentives actually pay off in terms of teacher longevity) and, as a corollary, allow the school manager to gauge impending shortages. (See, for example, Taylor, 1990)

Again, with sufficient interconnectivity, the information needed for such a model can be captured from standard personnel records.

General scheduling problems (rooms, teachers, courses, times of day) can, if the scale is small enough, use binary programming, or for large scale scheduling problems, some sort of matrix/conflict system. In any case, much of the work commonly associated with the use of these methods could be automated within the MIS so that annual or semianual schedule-building would not be daunting.

The use of nonlinear programming for finding the optimal locations for new schools in growing school systems was impractical until recently. Now, however, the presence of powerful nonlinear solvers for PCs has made the use of this tool very cost efficient (See, for example, Brooke, Kendrick & Meerhaus, 1991). By drawing on information that is already available in the transportation and student management information systems, new facilities can be properly sized and located, substantially reducing long-term transportation costs. This is especially true when such problems are constrained by racial or other social balance requirements as in the United States. The data for such solutions already exists in school systems that have a GIS-based transportation management system and a student information management system.

There are many policy analysis issues that can best be studied by integrating available information, rather than by experimentation or trial and error. For example, it is impractical to determine the outcome of certain facility or transportation policies by experimentation — no school system can build multiple structures or set up multiple transportation networks just to see which works best.
Likewise, it may be immoral to study other policies by experimentation. Can a system in good conscience try several different personnel management policies (such as retirement rules) just to see which works best? By simulating the physical or social environment on the computer, many such policies can be tested, or their outcome predicted, without dire consequence. In other cases, instead of simulations (which may be too exacting for the soft issues involved) the systematic recording of the consequences of prior policies, especially in the areas of curriculum and student management, may prevent making the same mistakes in cycles just a little longer than the length of the institution’s memory. Whether by simulation or archiving, the use of the computer and its potential for saving, sharing, and assembling information can reduce the risks of policy formulation.

All of these cases illustrate the work of internal intellectual agents — small programs or procedures that live within the MIS and invoke certain automated procedures in a richly interconnected, internal information space. The methods become agents by way of gaining independence, or rather, by way of not depending upon human agents for each inauguration or for connections with input information and output activities. In the examples above, the linear programming method became the basis for an intellectual agent that took care of the annual merit pay calculation and implementation. Likewise, the Markov method became an intellectual agent that routinely evaluated the possibility of personnel shortages, and so on.

The External Agent

Virtual organizations are very different than the traditional organizations we know so well. The structures of virtual organizations are more fluid and their existence, in many cases, are short-lived and time-bound. Their sizes will expand and contract rapidly according to the complexity of their goals and the ease with which they acquire and process the contents of the information space.

Traditional organizations tend to have narrowband links to the information space and currently favor using such links to reach through the information space to other traditional organizations or persons (e.g., e-mail, ftp, search and download). Thus, in present practice, the information space is used by traditional organizations more for its communications capability than for its capacity to embrace abstract information. By contrast, the virtual organization is native to the information space and is served by equally abstract intellectual agents. These agents can search, filter, and sort information, and can be scripted to achieve goals by adaptively assuming roles and taking actions including the enlistment and dismissal of other agents.

In human terms, the practical success of the virtual organization depends in large part on its relevance to the physical world, which, in turn, depends on the intellectual agent and its ability to use the translation protocols that move raw data and processed information across the barrier between the physical space of traditional organizations and the information space of virtual organizations.

The intellectual agent will gradually take on the persona of its creator as it works and relates to other agents within the information space. However, the degree to which the agent is successful at representing its creator will change as the technology improves and as the interconnectedness of the information space deepens. A few years ago, the agent was limited to clever answering machines and paging, today to home pages and search engines, tomorrow to personalized logic driven filters and sorters, and, soon enough, to capabilities that are sufficiently heuristic and self-organizing to defy reverse engineering. When that time comes, our agents will have a kind of intelligence that is superior to ours with respect to the information space, much like computers today have certain processing capabilities that cannot be rivaled by any human being. Persons and traditional organizations will, nevertheless, have their own specialized intelligences and intuitions that are well-adapted to surviving in the physical world.

Some intellectual agents will call on and direct the activity of others (much like a subroutine is called in a computer program). The experience of these agents (that is, a log of their success in achieving their goals and a mapping of those evaluations onto the strategies attempted) will be used to improve their capabilities. Because this is largely a data management problem, the agents should quickly become facile at independent self-improvement. Due to the heuristic, self-learning, adaptive nature of these agents, it is possible that some will take on a "personality" of their own, and behave in ways that are not consonant with the goals of their creator. Computer viruses, for example, can start as harmless pranks but end up being extremely proficient and destructive intellectual agents.

The External Agent and the MIS of Schools

The relevance of the fully-developed intellectual agent serving schools is still rather obscure due to the undeveloped nature of the education information infrastructure as explained early in this paper. However, there are three observations that can be made with confidence.

The first is that individual teachers and administrators who are network-savvy can already enjoy the benefits of available primitive agents. Particular topics for academic research, administrative problem-solving, or policy development can be given to intellectual agents with the demand that the net be periodically searched for new items.
and placed in the human agent's mailbox. Although this does not reach to the high level of informing the MIS of schools, it does start to build an internal appreciation for the coming benefits of intellectual agents.

The second observation is that intellectual agents can be set to the task of monitoring and saving information about the emergence of agent-generating programs, so that as the capabilities of intellectual agents expand, school MIS managers will be aware of the possibilities and will start to tie their vision of the future to the emerging technology.

The third observation is that one of the most important products of education is information and information-processing — and this is true at the learning-teaching level, the teaching-supervision level, the supervision-administrative level, and the administrative-governance level. The more an institution is tied to the processing of information — as opposed, for example, to manufacturing a physical product — the more easily it can model itself within the information space as a virtual organization. It is within the parallel virtual organization that the intellectual agents work (setting merit pay, forecasting, scheduling, allocating resources, and so on) and it is at the boundary between the virtual and traditional organization that this work is exposed. The transformation of this abstraction into management decisions and physical actions may remain in the domain of the traditional organization and its human agents unless such decisions and actions are delegated to the virtual organization and accommodated by the boundary translation protocol. In any case, schools are ideal candidates for a high level of cooperation between traditional and virtual realities due to the paramount role of information within schools.

First things first. As interesting as all these new developments may be, the first group of tasks for schools is to get the information they already have organized and interconnected, making use of the best principles of MIS. The second group of tasks is to develop strong internal intellectual agents within the MIS to inform the management and teaching functions of schools, making use of the best methods for decision support. Then, the final group of tasks is to make full use of the external abstract world of information by building a virtual model of the school within that world; a model which mimics the traditional organization and shows it the most goal-directed practices.

Educational Leadership — 279
As communities enter the 21st century, the continued prosperity of their citizens will depend upon economic stability and growth. Economic stability and growth will be defined by the ability of a region's education system to graduate students with the required basic and technical skills needed for employment and life long learning. In 1991, President Bush set the stage for his America Goals 2000 strategy by stating that, "Building a world-class work force must be a national priority. Improving America's capacity to educate and train workers is critical to the future of this county." President Bush also stated, "Think about every problem, every challenge we face. The solution to each starts with education" (Blount & Kearn, 1991, p. 1). In testimony before the Senate Committee on Commerce, Science, and Transportation, on May 25, 1994, the United States Secretary of Education stressed that how the United States implements technology into educational reform will define the success or failure of the United States (Riley, 1994).

Background

Many areas in the United States are experiencing a critical shortage of skilled workers. Due to the lack of skilled workers, development of workplace skills and related training is currently a major preoccupation of businesses and industries (Wagner & Venezky, 1995). This critical shortage of skilled workers throughout the United States has become so serious that many rural American communities and some entire rural regions are seriously at risk of becoming ghost towns of the 21st century. Without an educational system providing skilled workers for a region's businesses and industries, the entire infrastructure of a region begins to break down.

Global communications is quickly transforming American society in dramatic ways. Since the advent of the railroads during the 19th century, no single technological revolution has had such a profound change on the everyday aspects of American society. Unfortunately, this latest technological revolution caused by global communications is not equally impacting urban and rural regions.

Many rural areas are suffering a double threat to economic stability and a basic quality of life. First, educational institutions are not graduating students with the required basic and technology skills to fill the desperately needed entry-level positions in businesses and industries. Second, skilled workers in many rural areas, especially in financially plagued states, are out-migrating by the thousands for higher paying jobs in other states and metropolitan areas. This out-migration causes an erosion of a region's tax base and correspondingly limits the amount of funds a region can budget for education. Rural areas are finding it more and more difficult to provide funding for educational resources that are found in many urban areas. Unfortunately, many rural school districts must rely on local taxes to fund technological and other educational improvements (DeYoung & Lawrence, 1995). The decreased tax base caused by out-migration provides less funding for educational improvements that could produce skilled workers so desperately needed by local businesses.

Historically, educators and economic developers have not collaborated their efforts to jointly solve regional educational problems. In many communities, especially rural areas, few mechanisms exists for economic developers and K-12 educators to share ideas and cooperatively solve educational problems that dramatically impact business and industry. In addition, educational institutions, both K-12 and post-secondary, often do not have direct personal knowledge of the needs of local businesses and industries. At the same time, many business leaders lack an understanding of financial and other problems associated with education. In some regions, educators and business leaders do not actively communicate with each other. Business leaders rarely visit school classrooms or meet regularly with educational leaders to gain first hand knowledge of the multitude of problems facing educators. In addition, very few school administrators, teachers, and university professors regularly visit regional businesses to gain an understanding of the problems businesses are experiencing when hiring their graduating students.
Due to many reasons, including under-funding, public scrutiny, and the increasing threat of lawsuits, educating K-12 students has become a very complex social issue. Administrators of K-12 school districts are finding it more and more difficult to graduate students who possess the required basic skills and technology competency necessary to enter the workforce or to be able to succeed at institutions of higher education. At the same time, economic development professionals in many communities are continuing to use the same economic growth efforts and techniques that they have always used. Unfortunately, without sufficient skilled workers to fill the employment needs of their communities, economic development efforts are no longer reaping any short term or long term benefits.

In the words of President Bush, “Think about every problem, every challenge we face. The solution to each starts with education” (Blount & Keam, 1991, p. 1). Economic developers and business leaders in economically depressed regions need to redirect their economic growth efforts in a new direction to be successful.

To assist K-12 education, economic developers and educators must work together to provide leadership in the acquisition of technology and the integration of technology in the classroom. Integration of technology into K-12 education requires an extensive commitment of funding, human resources, and technical expertise. Due to these significant impact factors, many school districts, especially under funded rural school districts, simply cannot integrate technology alone.

Computing and telecommunication improvements are occurring at an incredible pace. The dramatic technological advancements that have occurred since Toffler described the Information Age in his 1980 book, *The Third Wave*, have been dramatic. When the microprocessor was invented in 1969, it could process approximately 60,000 instructions per second (Shelly, Cashman, Waggoner, & Waggoner, 1995). Today’s Pentium Pro microprocessors can process up to 300 million instructions per second. By the turn of the century, Intel has predicted their microprocessor will process two billion instructions per second. Intel projects that by 2010, Intel microprocessors will be capable of processing one trillion instructions per second. As technology has progressed, there is no doubt that K-12 school administrators are not only overwhelmed by technology advancements, but also how to fund and integrate current and emerging technologies into individual classroom curriculums.

Today initiatives that combine educational and economic development resources are needed to improve the quality of graduating students. Many of the serious problems facing education could be solved by combining the independent efforts of educators and economic developers. Most, if not all, communities in America have numerous economic planning and development agencies with talented professionals dedicated to community planning, assisting existing businesses and industries, and attracting new business and industries. Most communities receive economic planning and development assistance from various federal, state, and local sources. In Alabama for example, in addition to numerous federal and local agencies, Alabama’s counties are served by 12 nonprofit state mandated regional planning commissions. These 12 planning commissions assist their communities and citizens with economic planning, technical assistance, program resource development, and services that will improve the overall economic stability and growth.

**Economic Problems Impacting Rural Alabama**

At the 1995 Annual Meeting of the Southern Growth Policies Board, Southern governors and industry leaders expressed concerns that, “... without substantial improvement, the South’s public schools may prove to be the region’s Achilles heel” (Southern Growth Update, 1995, p. 2). Economic growth in rural Alabama is becoming virtually nonexistent, and economic stability is challenged by a significant lack of skilled workers. Economic stability and growth in many rural areas of Alabama are dramatically impacted by decades of under-funding of public education. Neal Travis, President of Bell-South in Alabama recently stated, “Only one of about 10 job applicants screened is found to be qualified for entry level employment.” Bobby Dees, Director of Adult Education in Alabama, recently stated, “…over 450,000 Alabamians are functionally illiterate and thirty percent of Alabamians annually lose their jobs because they are deficient academically and cannot be trained” (Smith, 1995, p. 1).

Global communications is transforming American society in dramatic ways. Unfortunately, the lack of global communications in rural areas like Southeast Alabama is particularly profound. Students must have access to the Global Information Highway and basic technology skills to be employable in the future. Over the past few years many states have educational technology in K-12 education. Alabama began funding $75 per teacher for all educational technology for the 1995/1996 school year. However, most rural schools in Alabama average 15-25 teachers which results in each school receiving between $1,125 and $1,875 for educational technology for the entire school year. It is not surprising that a number of rural high schools in Alabama are still teaching typing on typewriters instead of using computers.

Unfortunately, because of an increasing lack of technology, the education gap between many regions in Alabama and the rest of the nation is increasing at an alarming rate. Many young people graduating from rural high schools in Alabama are doomed to join the “lost generation” of American youth who simple do not posses the required
basic and technology skills necessary to become productive employees or succeed in higher education.

The Solution: The Southeast Alabama Network Project

In an effort to prevent many of Alabama's communities from becoming economic ghost towns of the 21st Century, economic developers in Southeast Alabama believed what was needed was a new and joint approach to help solve several of the region's education problems. The Southeast Alabama Regional Planning and Development Commission, in conjunction with regional educators, set out to establish a leadership bridge between education and business.

A grass roots partnership was formed between the Southeast Alabama Regional Planning and Development Commission, K-12 education, post-secondary education, county commissions, local Chambers of Commerce, other economic development agencies, business leaders, and concerned citizens from seven counties in Southeast Alabama. Hundreds of professionals combined their efforts to first identify the primary education problem in Southeast Alabama and then design a plan, complete with funding sources, to aggressively attack the problem. Identification of the primary educational problem in Southeast Alabama was easy, high school graduates were not graduating with the necessary basic and technological skills to be employable in today's technology based job market or succeed in higher education.

The partnership's solution to the identified education problem is a project called the Southeast Alabama Network. The Southeast Alabama Network is a cost-effective, nonprotein network project that will provide local Internet connectivity to all K-12 schools, institutions of higher education, health care providers, businesses, and citizens in seven Southeast Alabama counties. The network will provide free connectivity for all K-12 schools, libraries, and underprivileged citizens in Southeast Alabama, the population of which was estimated in 1995 to be 281,141 with 50,627 students enrolled in 109 K-12 public schools.

The infrastructure of the Southeast Alabama Network is designed to provide all students, teachers, and citizens with a computer/modem access to the network by dialing a local number. Alabama students and citizens who do not own a computer will be provided free access at many locations throughout the local communities, including K-12 public schools, institutions of higher education, libraries, housing areas, and other locations. The project will be managed by an Advisory Board of Directors made up of economic developers, educators, and business professionals from all seven counties and will be operated under the nonprotein status of the Southeast Alabama Regional Planning and Development Commission.

The most important service the Southeast Alabama Network will provide is user defined global information access. Hundreds of icons and home pages, and thousands of hyperlinks will be defined by regional users. Numerous User Working Groups will be organized to define regional needs in specific areas; such as, education, medical, agriculture, and many others. The Internet is a heavily traveled global highway, unfortunately it also has many off ramps to sites that contain adult information that should not be available in K-12 schools; parents and teachers must take control and monitor the sites that students have access to (Black, 1996). The K-12 Education User's Group will help assure that administrators, teachers, and parents maintain an active role in what students view on the Internet.

An extensive training plan has been designed to train educators and citizens. Regional post secondary institutions will play a key role in the network project by providing training for the region's current and future workforce. Throughout the United States, many failures to integrate and use technology have been reported. The variable most indicated as leading to failure has been a lack of training. The Southeast Alabama Network's training plan will ensure success of the project by providing training throughout the life of the project.

The Southeast Alabama Network project is designed as a model project that could easily be adopted by other regions. The Southeast Alabama Network project is the result of a joint effort of educators and economic developers to work together to solve regional problems. Economic developers, business and civic leaders, and concerned citizens must progress past the era of complaining about public education and get involved in educational improvement initiatives. The Southeast Alabama Network project is an example of how economic developers and educators got together to improve a region's workforce. Many joint initiatives between economic developers and educators could be organized in other communities for the purpose of graduating students who possess the skills necessary for employment and life long learning. By combining talents, funding, and other resources of economic development agencies and education, many initiatives could be designed to begin solving many of the problems facing K-12 and post-secondary education.

Administering Formal Structures Supporting Senge's Three Levels of Leadership

Kevin C. Facemyer
Director of Virtual Washington State University

This paper addresses the systematic application of Information Technologies (IT) to the management of the three types of educational leadership described in Senge's chapter: Leading learning organizations: The bold, the powerful and the invisible in Leader of the Future (Hesselbein, Goldsmite, & Beckhard, 1996). In that chapter, Senge describes three types of leader: the executive leader, working above the workers (Deans, Provosts, and Superintendents); the line leader, working with the workers (Chairs, and Principals); and the leader, (untitled worker/peers who demonstrate leadership from within organizations) working among and between everyone in an organization. The application of IT to these different leaders can benefit these leaders and organizations. This paper combines the theoretical elements of leadership and technology with empirical evidence derived from management of a Virtual University initiative conducted at a large land-grant university in the Pacific Northwest.

This paper will articulate the premises of IT and its ability to aid educational leaders, describe three types of IT enhanced leadership and the technological support best suited to each, and then forward a hypothesis, called Virtual Leadership which outlines the use of IT in leadership.

The Premises

In promoting or offering a hypothesis about IT and leadership it is necessary to provide the premises describing the utility, or the set of assumptions about the utility, of IT in aiding leaders and their work. This is an important step in light of recent evidence that, just because the work situation is technologically enhanced, it may not be better, or more efficient. It is important to understand that this is not a blanket endorsement of IT and its ability to help workers. It is a specific claim surrounding the application of IT toward specific ends and in specific situations to assist leaders and leadership activity.

Premise One: Information Technology (IT) can positively change the mechanisms of leadership in educational systems.

We should first begin with a description of what IT means. In this context IT most often refers to three main features of the technological environment: (1) Computers and their networks as telecomputing communication systems, (2) computers as groupware and groupwork aids, lastly and least (3) computers as personal productivity aids. The extent to which each of these roles is used by different levels of leaders is variable. There are some patterns of use but no firm trends or rule bound uses to which each type of leader uses these technologies.

In the first context, the role of telecomputing is obvious within any framework of leadership. Whether it is using the Internet or an Intranet as in Gardner's storytelling (Gardner, 1995) or Burns' transformational leadership (Burns, 1978), IT and its use as a communication system clearly has great positive potential. Through an Intranet, or the Internet, the power of reaching millions of people quickly and sharing data or software is clear. In one day Microsoft provided a million copies of its browser over the World Wide Web (WWW). This is clear evidence of the power of a coordinated set of messages combined with a leadership strategy designed to move huge amounts of information (in this case software) quickly and efficiently. Compare this to the communication opportunity posed by a popular sports event such as the Superbowl, with an estimated 20-30 million viewers, who are assumed to see 30% of the commercials, and of whom about 20% remember them. In that scenario, less than 2 million viewers get the message, and fewer yet take actions based on the information presented in this medium. This set of diminishing returns of broadcasting and consumerism compared with the focused application of narrowcasting (Lick, 1965), to distribute products and services highlights an efficiency of message and delivery. In the Microsoft example, few extraneous messages are received, little extraneous effort is applied to consumers, and there is still great potential for mass distribution, provided of course the deliverable needed is online. A more recent example occurred during the
presidential campaign where Web sites were a strategic element of each campaign. This is a clear illustration of the potential of a leader’s use of IT for telecommunications.

In the second context, the use of IT a coordinator of groupwork is evidenced by several researchers as we begin to see the formation of world wide virtual teams (Geber, 1995). As leaders begin to use IT for coordinating groupwork it becomes clear that a vast potential for distributed teamwork exists. As Premise One is formulated we need to see only evidence for the positive possibilities. It may be here that IT excels at assisting leaders at all ranks.

The third context, placed last, is personal productivity. The capacity of IT to assist leaders in this area exists but is limited in its impact on followers. It cannot be omitted however, because of the obvious impact on followers if all types if IT are not part of a leader’s perceived repertoire of techniques. As a role model, the leader’s stance on the use of IT in personal productivity modes should be made clear.

In summary, Premise One states that Information Technology may advantageously change the patterns, modes, or arrangements of a leader’s work (Sproull & Kiesler, 1991). At a fundamental level, the mechanisms of leaders’ work may changed by It’s presence on the educational canvas.

Premise Two: Different uses of IT are appropriate for different types of leaders.

The correct placement of leaders and the IT applications they deploy are critical to the messages they promote as leaders and the work they do in relation to the organization. The day to day maintenance of a listserv serving the organizations operational needs might not be a suitable use of an executive leader’s time. While an executive leader could easily and reasonably facilitate a listserv of peer executive leaders he would, in this context, be working as a network leader. The creation and management of a generative problem solving/strategy generation Web site might not be an appropriate network leader function; this work might be seen as disruptive rather than constructive.

These exemplify the negative possibilities. Several positive examples exist and will be described in the Development and Description section. There, IT uses of different types of leaders will be described and contrasted.

Premise Three: While the conscious use of specific IT strategies benefits different types of leader in different ways, the patterns of use can be defined, described and facilitated.

The systematic application of IT to leadership strategies in these three different arenas constitutes a new hypothesis that is to be developed into a theory of leadership.

A brief overview of the hypothesis that will be developed in the third section, IT Leadership Hypothesis (a theory of IT facilitated leadership) is provided here in the form of a model building on Senge’s three types of leadership.

Development and Description of IT Use

Executive Leaders

Technological management of different workers, let alone different types of leaders, is a challenge. Some simple technological solutions exist for managing the complex communication strategies of executive leaders: e-mailing lists, anonymous suggestion e-mailboxes, technological eDelphi™ techniques as well as typical listservs. I will explore these and their use in relation to the executive leader, focusing on creating structures (data gathering and decision making systems, strategic planning procedures and local area broadcast techniques) aimed at aiding communication and discussion making.

If we agree that key executive leaders’ (such as Deans, Provosts, and Superintendents) roles include data collection, group problem solving, vision setting (strategic planning), intra-agency vision dissemination, and inter-agency communication; then it is clear that IT can provide several specific types of assistance for a leader engaged in these activities. Several examples of this assistance are provided here.

<table>
<thead>
<tr>
<th>IT Use</th>
<th>Typical Needs</th>
<th>Typical IT Used</th>
</tr>
</thead>
<tbody>
<tr>
<td>Executive</td>
<td>Data collection, problem solving, creative vision setting (strategic planning) and intra-agency vision dissemination, &amp; inter-agency communication</td>
<td>Data collection systems (eDelphi™, and online surveys), Groupware (Lotus Notes, Sequel shared document environments), &amp;Internet based communications.</td>
</tr>
<tr>
<td>Line</td>
<td>Interactive consensus-building, group coordination, &amp; traditional intra-agency communication</td>
<td>Program and exec vision description through WWW &quot;broadcast&quot;, shared documents, and group calendaring as well as review online worker products.</td>
</tr>
<tr>
<td>Network</td>
<td>Local, supportive diverse goal activities &amp; grass-roots idea generation</td>
<td>Project based WWW page coordination, informal communications, team coordination through &quot;Project home pages&quot; and revisable drafts and reports.</td>
</tr>
</tbody>
</table>
Data Collection. Data collection for executive leaders can be problematic. Opinions summoned from followers are subject to yesism (workers agreeing too soon with perceived management positions), groupthink (opinions reflecting group norms rather than personal stances or data derived positions) and simple recalcitrance. Extracting useful opinions about the work followers do or opinions they have can be facilitated successfully by several types of IT. Internet based automated survey techniques are useful when inventorying skills, or equipment. Internet deployed eDelphi™ techniques can be important agenda setting tools. Focus groups convened on listservs or as threaded discussions can provide insights to the prevailing attitudes of a faculty as well as garner useful input about recasting executive agendas.

Group problem solving. Shared document environments can provide useful settings for the generation and refinement of organizational stances. Often the meeting time used to collect ideas and develop strategies is inadequate, and often viable strategies such as shared document creation or cycled editing are useful alternatives to real-time meetings. There are several commercial programs that are designed to collect ideas and coordinate projects. Generative approaches to the use of computer models and simulations can provide valuable stimulus to groups examining problems. In situations where groups and committees are created to solve problems, specific software programs, Internet pages and groupware can help in a leader’s attempt to facilitate and guide a team working on a specific problem solving task.

Vision setting (Strategic planning). IT’s use in strategic planning could incorporate several of the techniques described above. IT aided focus groups, Internet deployed surveys, and carefully targeted e-mailings could create the foundation of data collection for any strategic planning project. The creation of organizational mailing lists and the project or issue specific listservs could become critical features of any strategic initiative.

Intra-agency vision dissemination. After strategic planning or in relation to ongoing changing organizational position or stances, intra organizational communications through WWW page postings, or targeted e-mailings should form the basis of ongoing use of IT for critical communications. Without direct paper-less initiatives, IT can become an accountable and reliable form of communication. In times when faculty snail-mail boxes are cluttered with junk mail and are often unvisited or at least unpurged, e-mail has vastly higher reliability in many settings. As receipt capabilities are incorporated into e-mail systems, it becomes harder and harder for faculty and students to claim they didn’t receive a memo. This e-mail use, coupled with an appropriate Web presence, can form a stable and reliable form of communications infrastructure.

Interagency communication. An executive leaders work is more often interagency than intra-agency. Often in order to coordinate interagency cooperation the Internet or the WWW is a simple way to begin shared document interaction across agencies and platforms. Partnerships are easier to start and maintain as documents are served at common sites. Progress and announcements are easily shared when the interagency group share an Internet “home”.

These solutions are brief glimpses into the opportunities available through Information Technology and its application to aiding executive leaders’ goals. In no case are these untried ideas or principles. Rather they are viable applications. The extent to which these techniques work depends often of organizational expectations and leader’s consistency of application and vision. In settings where e-mail and Internet are not directly assumed parts of the organizational expectations, these IT based solutions may not be profitable. But even in the less than successful IT applications, there are often hints that behavior and organizational expectations are shifting to incorporate and expect participants to engage in these IT uses as followers. As that happens the executive leaders will see that their use of IT can be easier and more profitable.

Line Leaders

For managing the tasks of line leaders a more generative set of technological solutions exists. Group-shared collaborative document generation systems, Web based form-processed Webpage generation and locally hosted Web Centers form the foundation of systems that enhance the line leader’s effectiveness and productivity. While line leaders tasks serve a set of clients they in turn inform the practices, management and decision making of their executives. In this way, with the correct systems, they lead the organization into new techniques and strategies. The systemic administration of technologies that aid this type of leader are critical to educational organizations’ successes.

If we agree that key line leaders’ (such as chairs, and principals) roles include interactive consensus-building, group coordination, and traditional intra-agency communication, then it is clear that IT can provide several specific types of aid for a leader engaged in these activities. The following are some examples of successful applications of IT toward these issues.

Interactive consensus-building. The development and maintenance of WWW Homepages depicting the mission of organizational subunits has been an impressive tool in several consensus building processes. Without the use of specialized software, simply the online presence of documents representing the unit’s work and mission as well as documents describing specific initiatives seems to galvanize groups into a discussion of their shared circumstance. Beyond the general aid that online documents can provide...
toward consensus building, there are several commercially available IT techniques that can foster interactive consensus building throughout the development of shared documents through Lotus Notes, or across a Sequel server.

**Group coordination.** The simple coordination of shared documents through regular postings on the Internet makes these updates available to all involved workers, any time and from anywhere. Group calendaring through WebEvent shareware or MeetingMaker™ are also important techniques for managing committees or teams.

**Traditional intra-agency communication.** The traditional intra-agency communication of yearly reports, or committee updates or budget reviews can be posted on the Internet (limited addressing on the server limits the document distribution to local participants if necessary) for ease and speed. Often in meetings (convened in rooms with browsers) brief updates can be accomplished by a brief visit to an up-to-date online document. The rapid inspection of figures, graphs of readings of short narratives can provide critical and timely updates in cross organizational communications.

**Network Leaders**

The technological and social systems used to enhance the leadership capacity of network leaders is complex. The systems supporting the effectiveness of network leaders is typically personal and/or social but there are trends toward shifting to technologically enhanced social structures for network leaders. Managing these technological structures to aid network leaders is the most challenging of the proposed formal structures, because by their very nature they defy formalizing. Despite that caveat, there are tips and approaches that work well to enhance the effectiveness of this type of leader.

If we agree that key network leaders' (such as untitled worker or peers who demonstrate leadership from within organizations) roles include local, supportive diverse goal activities, maintenance of informal communications systems, and grass-roots idea generation, then it is clear that IT can provide several specific types of aid for a leader engaged in these activities.

Again, the use of e-mail, Internet pages and listservs can provide support for various initiatives (specific goal activity, informal communication and grassroots idea generation) of a network leader. The formal use of e-mail lists by a network leader can often produce large swings in opinion and knowledge. Often the informal relationships that emerge to identify or facilitate an internal network leader are IT related. Often we are faced with an executive decision which requires us to turn to and rely on a network leader for implementation. Often there is embedded in our organizations an expert who is often more directly reachable by IT methods than by traditional face to face methods. Conversely, the network leader often prefers, through tradition or experience, to address individuals or groups via IT.

This is in no way an exhaustive list or a detailed description of the specifics of the formal structures that support the three types of leaders. These glimpses provide an overview and brief descriptions of the types of formal structures that have been found to work well in some specific settings.

**IT Leadership Hypothesis (A Theory of IT Facilitated Leadership)**

This attempt at a brief formal description of the features of an IT enhanced theory of leadership. It builds on the construction of three types of described by Senge (1996), incorporates the five features of Gardner's (1995) descriptions of leaders and is combined with the spectrum of IT use described by Brown (1996). It is also influenced by my interpretation of IT's impact on characteristics of leaders.

Gardner's six features of leadership are Story, Audience, Organization, Embodiment, Indirect versus Direct modes, and Expertise. Story & Audience and are features of a leader's sphere of influence. Story generally only applies to executive leaders in this construction. Story has very little application to line or network leaders. Organization, Embodiment, Direct and Indirect modes, and Expertise are features common to all types of leader. Embodiment is the degree to which the leaders are consistent and is identified with the messages they portray. Direct and indirect modes of leadership describe the extent to which a leaders influence is within his or her area of expertise. For example, Dr. Martin Luther King’s influence was through his civic activism. His original area of leadership was church related, yet his major influence on America was not through his original organizational constituency, therefore his leadership path was indirect. Einstein and Feynman are examples of leaders whose influence was also indirect. Statesmen and politicians are typically viewed as direct leaders in that their chosen path is associated with their influences. Jimmy Carter holds a Ph.D. in atomic physics and did not gain influence indirectly through his expertise in physics, thus his was direct leadership, while Ronald Regan might be described as having come indirectly to power through proficiency in acting thus his leadership might have been described as indirect. Due to this distinction I equate the elements of Expertise with Indirect leaders while I equate the element of Organization with Direct leaders. I recognize that this distinction is an oversimplification.

Originally proposed as a description of instructional uses of Information Technology, the PIG mode described by Brown (1996) outlines escalating uses of multimedia as three points of use along a continuum: Presentation, Interaction, and Generation—or PIG. The first is demonstrated through Presentational use of IT on the World Wide
Web as a broad or narrowcast medium. Presentation uses include direct e-mail and top-down shared document environments. Interactive use of IT includes prepared WWW interactive forms, shared document environments as well as conventional e-mail use. Interactive forms if IT use are more than simple data collection or forms submission. Interactive IT uses include creation and production of working documents, mission statements and project outcomes or solutions. Closely related to Interaction, IT use that generates ideas, products or solutions is Generative. Generative use if IT includes collaborative shared document systems applied toward problem solving, or interactive decision making systems.

The following matrix outlines the relationships between different types of leaders, their use of or attention to, Gardner's six features of leadership (in italics), and the correlating levels or relative importance of the different types of IT use (P, I, or G).

This model is offered in the same spirit as Gardner did in his work Leading Minds (1995, p 297). He says, "I fully expect that studies of other leaders - direct or indirect, or a Monnet-like amalgam of these two species - will undermine certain generalizations and give rise to many others. Thus scholarship advances. Rather than fearing such refutations or modifications, I welcome them."

I offer my outline of the interaction between types of leaders, IT uses and six features of leadership as a theoretical framework for exploring the complex interaction of IT and leadership. This work is presented, not as an answer, but as a framework for asking a question, a question about leadership in a time when the symbiosis between man and IT is becoming more and more evident.

Acknowledgment

I would like to thank Asymetrix, Boeing and Microsoft and acknowledge their gifts of software and funding, which in part supports the efforts of Virtual Washington State University. With generous corporate partners such these, recognizing their stake in higher education, the future of public higher education institutions seems to be on firmer ground.

Technology and Teacher Education Annual — 1997
How Administrator James Wears Technological Hats to the Giant Peach Schoolhouse

John A. Swartz
Sam Houston State University

Ask any child, “Who is responsible for those Chrysler ads, “Either Lead, Follow or get out of the Way,” and he might answer “James from the Giant Peach story.” Ask any adult and he will probably answer, “Lee Iococca.”

Iococca is one of a growing number of charismatic, messianic CEO’s who, some claim, are motivated by a desire to create a fame or glory niche through a revolution they cause in their respective industries. Such charismatic leaders, others claim, are born with the skills to lead. They maintain that such skills are neither taught in the schools, nor caught on the job. In a true sense, James came to the Giant Peach with all the skills necessary to lead the menagerie of animals within this “time-bomb” peach to safety.

Many maintain however that leadership can be taught, that there are certain steps or elements or stages which, if put into practice, will insure that a business or school will be successful. The very successful Harvard Business school has a tight curriculum based on case study which it believes prepares leaders of tomorrow. If they thought that the scenario of James delivering the Giant Peach to safe port was replicable in business, they might use his as a case for discussion. However if teaching leadership is necessary to it would be difficult to explain how James used the many skills of the menagerie, and in the end was honored with the large monument in Manhattan.

Many maintain that leadership is caught on the job; that great Presidents would have been mediocre if the situation or crisis had not confronted them in office. The potential leader can walk a journey between hands on control or shared control; between taking credit and giving credit for success; between blaming others for failure, or assuming responsibility for failure himself.

Whether leadership is innate, taught or caught, Suters (1992) maintains it is critical to know what leadership is, and it is just as critical to know when you are leading and when you are not. When you are leading you are not producing results, but supporting others who are.

What Leaders Do, and How They Do It

In his book, the Unnatural Act of Management, Suters (1992) claims there are two main functions of leadership, planning objectives, and their execution, and planning strategies, the organization of resources, staffing, communicating, monitoring and enveloping associates. Suters then describes how the leader in business accomplish their work by quoting a plaque which illustrates the vision of Lao-Tzu:

As for the best leaders, the people do not notice their existence. The next best, the people honor and praise. The next, the people fear, and the next, the people hate... When the leader’s work is done, the people say, ‘We did it ourselves.’ (p. 59)

Assessing Leadership

There are many sources for leadership, motivations for a leader, many functions of leadership, and many ways of assessing success. The old school claims you can assess the effectiveness of a leader by how well his followers enthusiastically pursue a goal to success, while believing that they did it themselves.

The Gameplayers’ Needs

When the Harvard Business school investigated major quality manufacturers in the auto industry in the United States they found four elements which were benchmarks. And all of these elements focused on the workers:

Many experts believe that it is rooted in their sensitive organizational behavior management policies. Nissan and Honda workers are made to feel that they are important, that they have a say in how things are done, that their skill and attention to product quality is the key to their company’s success, and that if the company prospers, everyone will share the profits. (Kelly & Kelly, 1986, p. 52)

Harvard discovered that leaders of quality industry are concerned about their product, but also pay attention to the needs of a major game player in their industry, the worker. If the needs of the workers in the schools, the faculty and staff are to be realized Glasser (1992) suggests lead management rather than boss management:
The crucial difference between boss managers and lead managers is mainly in how they understand motivation. Bosses refuse to accept that they cannot "motivate" the workers with what they believe will cause the workers pain or give them pleasure, especially when they also believe that what they are asking is good for the workers. Following this belief, bosses constantly look for new sanctions or rewards to “make” the workers work. Leaders, on the other hand, know that they cannot make the workers work hard if the work is seen as unsatisfying or they are seen as unconcerned about the workers needs. (Glasser, 1992, p. 43)

But what about the workers in the schools? In so much of the reform in today’s schools, the teacher is the focus of the problem. In many areas of the country, teachers were tested at great expense. The assumption was that if we remove our problem teachers, the schools will become great. These gameplayers were considered the culprits.

Since that initial testing a computer revolution has occurred. Society has seen the need for providing technology to the schools, a need for tying all schools to the “Information Superhighway.” Savvy administrators who are not sure what the equipment should do, have furnished schools with a great deal of equipment and provided little training, and more often than not blame the teacher for failing to use the equipment effectively.

Douglas McGregor (1960) in The Human Side of Enterprise explained one myth behind this attack on teachers. What McGregor concluded from a study of management programs was Theory X “the average human being has an inherent dislike of work and will avoid it if he can.” His Theory Y maintains that the average worker finds work “as natural as play or rest.” McGregor maintains that General Mills success was based on the second vision of workers. When applied to schools, Theory X develops programs to weed out those average “lazy” teachers. Theory Y finds ways to support and enhance the work of all teachers who find their work as play. The focus in the above approaches is on one gameplayer, the worker.

Applying the Harvard benchmarks to teachers can we say that they are made to feel important, have a say in how things are done, see their skill and attention to quality as a key to school success, and feel that if the school succeeds they will share the rewards?

In the above approaches schools are fragmented. Focusing on one gameplayer has been the problem of the schools in the past. Odiome (1990) speaks of the trustee theory of management which involves concern for all the gameplayers in industry, workers, stockholders, consumers, suppliers and managers.

In the schools the local community has come to expect a quality product in intellectual growth of children. And this intellectual growth is measured in only one area, ability to score well on standardized tests. But who are the game players in the schools? As in industry gameplayers are the workers, teachers and staff; stockholders and consumers are the local community, suppliers are the community and the parents or guardians in particular. The product is growth in children and not just the intellectual growth measurable on a standardized test; the product is growth in children but also in all of the gameplayers. And the managers are those leaders in the schools who are expected to serve as trustees of it all. In the end applying the Harvard benchmarks to all the gameplayers we can say that all the gameplayers are made to feel important, have a say in how things are done, see their skill and attention to
quality as a key to school success, and feel that if the school succeeds they will share the rewards?

The Our Team Good Guys Bad Guys Myth

In a recent work on leadership, *Leading with Soul: an Uncommon Journey of Spirit* (1995), the authors list a group of misconceptions of leadership. The major common denominator in all of these is an adversarial relationship, or a dichotomy between opposites. The authors criticize those who claim leadership is waging war, championing a cause, changing history, or following recipes. They criticize the expanded dichotomies of male-female, work-play, career-family, thinking-feeling. The authors add that we make too much of heroes, and that rather we should begin with ourselves (soul) but not by ourselves (spirit).

Few will deny that many schools stand in an adversarial relationship with parents, students and teachers. The task of the school leader is to turn this relationship around. The wise principal will think of the many opportunities to bring parents, students, teachers, staff, parents, the school board and the community, all of which are good guys, together. The implementation of technology can be the vehicle for bringing all the gameplayers together through communal planning. When all the gameplayers see their own needs addressed through a collaborative vision with shared ownership for its realization.

The Our Team Winning or Our Team Losing Myth

The Good-Guys Bad Guys myth is destructive in planning and implementing vision. In addition the Our Team-Their Team myth can also be a major obstacle to success. The school reform lobbies, and newspaper journalists have set school against school, and district against district in comparing ability to do well on tests. A magnificent plan and collaborative strategies can be undermined by a need to do well on state tests, a very limited measurement of success, indeed. The great leader, like James in the Giant Peach, knows the importance of his local community and all its gameplayers. Unconcerned about who gets the credit for the success he will do what he can to fulfill the needs of the teachers, students, parents and communities. A great leader knows that his online people, the teachers are closest to the needs of students. Teachers, the on-line workers, intuitively know what works, what is needed to fulfill the needs of their students, parents and communities.

If we set dreams and visions and goals together, and see that we all win by doing our best, we needn’t ask about winning and losing. If we could see that the only losing is when we fail to realize the greatness in all of the gameplayers, we would be better motivated. Norman Lear (1984), the successful director of leading network shows has this to say about how we teach our children:

We have been raising generations of children to think that there is nothing between winning and losing. The notion that life has everything to do with succeeding at the level of doing one’s best is lost to these kids. If we really believe that we are on the planet for the long term, we will encourage our youth to understand that not everyone catches the brass ring on the carousel of life. The rest of us better enjoy the ride for its own sake, or life has no meaning at all. (p. E 23)

The Goal Line Myth

So often in planning we limit our dreams, and visions and goals to short term objectives. We are too often satisfied with minimal results. The secret is to involve all the gameplayers in owning a wide vision, developed by themselves, and the realization of that vision through strategies developed by themselves.

The vision must be wide. The wise leader will provide opportunities for all the gameplayers to share in a wide vision, a vision wider than some technologies and wider than some needs of some constituents. Some, in dealing with technologies, would limit the vision to their favorite technologies and to some gameplayers. Others would limit the vision to the five computer competencies; from word processing, to desk top publishing, to presentation software, to multimedia, to network surfing, and would limit the needs to those of students. I suggest including all Media possibilities from the early technologies such as overheads, slide projectors and filmstrip projectors, and from the five computer technologies to the range of distance learning possibilities. I suggest addressing the needs of the students, teachers, staff, parents, and all the gameplayers in the community. Each of the gameplayers can choose the technology they wish to use and identify the need it will address. A community with minimal resources as well as a community with great resources can plan the same dreams. And to the extent all the gameplayers are involved in the decisions, to that extent they will do what it takes to realize them.

Many of the gameplayers in the community have felt isolated from and unrecognized by the community. In *The Cry for Myth*, Rollo May (1991) describes the contemporary American as one who like the salesman, Willy, in *Death of a Salesman*, does not know who he is. He is caught up with the business of being a number one salesman and forgets who he is as a person:

> The endeavor to find the myth of our identity is shown in the way we, like Willy, sell ourselves- our work, our ideas, our efforts, even as it involves, as with Willy, a shine on our shoes and a smile on our face. And we may find one way or another when our myths let us down, that 'we never knew who we were.' (p. 44)
We may see that the only goal in life is to sell ourselves. This involvement by the community can enable all of us gameplayers to find our very selves through working with others in the community. We may be limited to a goal which takes us nowhere. Or we may allow our dreams to take us everywhere. In his chapter, "Dreams are Goals with Wings," Kriegel and Patler (1991) sees goal planning and achieving as important but limiting:

The key to sustained performance is finding something larger than a goal, something bigger to shoot for. Something that moves you. A dream you can chase. A vision that inspires... when we have a dream and pursue it, nothing is impossible. We tap into power, personal resources, and creativity that we never thought we had. We can accomplish what had previously considered impossible. In the process we discover that the biggest limit is our mind telling us what our limits are. (p. 35,7)

All the Way Home

Doesn’t “This little piggy went to market” end with “This little piggy had roast beef and cried wee, wee, wee all the way home”? Both the planning of vision and the implementation of the strategies will enable us as a team to transform a school and a community. The presence in the community of all the gameplayers will insure that some ‘mythtalces’ are seen for what they are: limited vision.

Mythtalces:
Administrators alone should get the credit or the blame for success or failure.
The vision and curriculum of the school are the responsibility of administrators alone.
The business of the schools is limited to the teaching of children.
The curriculum should focus on intellectual growth alone.
The old ways of teaching worked in the past, why not now?
The classrooms environment has little to do with learning.
The only valid technology for use in schools is computer technology.
The job of the schools is not to entertain children.
Staff training is unimportant; parent education is unimportant.
Available money determines the vision of the schools.
Teaching moves from education to entertainment as the video screen moves beyond 25”.

Teachers and children need competencies in technology; parents do not.

A Mission for Tomorrow

General George Marshall, whom President Truman called America’s greatest general, once said that there is so much we can accomplish if we are unconcerned about who gets the credit. He added that when constituents devote all their efforts to accomplishing one goal “all will go well with America, but just as soon as ulterior purpose or motive creeps in, then the trouble starts and will gather momentum like a snowball.” (Bland, 1986, p. 616)

If we are to make the schools exciting environments for learning for the whole community we must plan together with objectives, goals and dreams; we must involve all the gameplayers. James provided reactive crisis leadership by involving different insects and animals in salvaging the large peach. However, today’s administrator needs to act proactively, engaging the whole community if the Giant Peach School House is to celebrate powerful learning opportunities!

AN ANALYTICAL REVIEW OF WEB SITES RELATED TO THE PLANNING, ADMINISTRATION AND MANAGEMENT OF TECHNOLOGICAL INNOVATIONS IN EDUCATION

Charles Dubenezic
James Madison University

This paper will identify and examine specific Internet sites that allow school technology leaders and other educators to quickly and easily locate the information they need related to the effective implementation of technology in schools. The sites have been placed into categories for ease of use. These categories include Lists of Web Resources Created for Technology Coordinators and School Library/Media Specialists, Internet Directories and Indexes on Technology and Schools, Specific Sites Related to Technology and School Restructuring/Reform, Specific Sites Related to Telecommunications and the Integration of Technology into the School Curriculum and Other Interesting Web Sites Related to Educational Technology. The first two categories include what can be considered gateway sites, that is web pages that identify or lead to other web sites. The remaining sections tend to link to sites containing more specific information.

The web pages described here can be accessed by connecting to this paper online at the following URL, which will be regularly updated: http://www.eml.jmu.edu/TEIR/SITE97.html. A related paper by the writer, Finding the Best Web Sites for Educators, can be accessed using the URL: http://www.jmu.edu/TEIR/Web96.html. URLs for all reviewed sites will be found at the end of this paper.

Lists of Web Resources Created for Technology Coordinators and School Library/Media Specialists

The following resources provide an efficient way of identifying a variety of web sites related to the effective and ongoing implementation of technology in schools.

The Resource Page for Technology Coordinators is an excellent site and is indispensable for school technology personnel. Because it is easy to use, contains links to all types of information, and is frequently updated, the Resource Page for Technology Coordinators is one of the best for every day use. It allows users to sign a register which enables other technology coordinators to contact them through e-mail.

When an in-depth exploration of a topic or issue is required, The Technology Coordinators Home Page provides an extensive bibliography of both print and online resources related to the job and responsibilities of the School Technology Coordinator. This site is well organized, comprehensive and one of the most descriptive educational technology. This is evident in the section on Educational Management Resources and Issues, an area of interest to school administrators. Overall, The site complements the above web page as it includes references to many print documents and links to additional web sites.

Librarians Information Online Network (LION) is invaluable as an informative and comprehensive resource. Among the many sections related to educational technology, those on Automation for School Libraries, Internet Mailing Lists and Newsgroups for School Librarians, and Publishers and Library-Related Vendors are especially useful. The School Librarian Web Pages by Peter Milbury, and School Library Hotspots are two other helpful lists that complement the LION site.

General Internet Directories and Indexes

Several Internet directories and indexes provide listings of both general and specific categories on various areas of educational technology. They provide the searcher with a gateway for identifying useful information and can be especially helpful for persons unfamiliar with the field. Most of these directories and indexes are updated on a continuing or frequent basis and thus will be very current.

The Yahoo Directory, one of the first to be developed, still remains an excellent and comprehensive of available directories. The Education directory contains two categories of special interest to school technology personnel; Distance Learning, and Instructional Technology. The
Computers and Internet Directory includes catalogs on the Internet, Multimedia, and Personal Computers.

While not as inclusive as the Yahoo Directory, several sub-directories of the Magellan Directory contain useful information on educational technology, including Computing, Education, and the Internet. For interesting web sites in the latter section examine the categories of Cyberspace Issues and Fun and Funky. What makes this directory so helpful and unique are the reviews and ratings. The reviews can be accessed by clicking on the word, ‘review’. The ratings are explained at the top of the directory by going to ‘About Magellan’.

The A2Z Directory includes the 10% most popular sites on different subjects maintained by Lycos. It’s subcategories are easy to use and provide many relevant documents arranged alphabetically. The ‘Find Related Sites’ option is especially helpful. Subject areas of interest to educational technology users include Computers, Education, and the Internet.

The Argus Directory on Education contains over 90 up-to-date hypertext directories on specific aspects of education that are maintained by individual librarians and educators. It has a worldwide emphasis and many directories are rated according to how helpful and comprehensive their listings are. One area that relates to educational technology is a comprehensive section on Distance Education. Under the Distance Learning heading are links to information on Project Based Education, Tele-collaboration, and Telecommunication. Within the Education section links to information on Teleconferencing, Research, Grants, Funding, Educational Resources, Educational Technology as well as Electronic Classrooms, Multimedia, Distance Education can be found.

The U.S. Department of Education web page provides extensive information not found elsewhere on the Internet. Sections that contain a lot of documents and sites related to educational technology include The Secretary’s Initiatives, Publications and Products, and Other Sites. The latter includes a subsection on Federal Government Educational and Library Resources that links to such sites as the Regional Technology in Education Consortia. The South Central Consortium contains several interesting programs, including TrackStar, which allows the user to use and create interactive Internet-based learning materials in all subject areas.

The WWW Virtual Library on Education, the WWW Virtual Library on Educational Technology, and the Education World Index are selective collections of web sites on various aspects of education and technology. They are useful to the searcher who seeks general ideas of what is available on this topic. The category on Education and the Internet includes useful sites related to teaching with the Internet.

From the Search the Internet with the Internet Sleuth selecting Computers links the user to magazine and software databases that are not as easily found in other directories. In addition to the general Computers link there are links specifically for information on graphics, Mac, PC, and Unix among others. The site is also interesting for the controls that are used in the various search capabilities.

The Technology Resources section of the Education Place Directory, sponsored by the Houghton Mifflin Company, contains a very detailed listing of sites and provides an excellent introduction to and overview of many specific issues and concerns of interest to school technology leaders. These include Funding and Grant Information, Acceptable Use Policies, and Technology Plans (including assessment and staff development). There are also sections on Educational Technology-related Conferences (limited), Commercial resources, Online Journals and Magazines related to educational technology, Using the Internet, and a Glossary of Internet Terms.

Specific Sites Related to Technology and School Restructuring / Reform

EdWeb is a hypertext book that provides an interesting and flexible way to examine the many issues related to educational reform and information technology. It contains links to other resources and is a work-in-progress. A good place to begin.

Computers as Tutors: Solving the Crisis in Education is a more traditional book on this subject. It explores what we need to do to make computers the effective learning tools that they can be when used effectively by educators.

This list from the Armadillo WWW server has links to major documents from the past decade and current web sites that relate to technology and school reform.

Technology and Education Reform is a research project sponsored by the US Department of Education that examines nine school sites where school staff are active participants in using technology to promote educational reforms.

Constructivist issues are addressed well at two particular sites. The Institute for Learning Technologies (ILT) sponsors an interesting variety of large scale projects related to using technology and constructivist learning theories to achieve effective educational reforms. The Instructional Technology Connections page from the University of Colorado at Denver provides an extensive review of teaching, learning and the use of technology from a constructivist perspective. Links are offered to many interesting articles and curriculum resources.
Specific Sites Related to Telecommunications and the Integration of Technology into the School Curriculum

Classroom Connect and the Global Schoolhouse provide extensive resources to help educators locate and share experiences, curriculum ideas, and teaching materials related to using the Internet with students. Both are must-see sites. While you are at the Global Schoolhouse, examine the set of excellent articles on telecommunications in the classroom.

For specific ideas and activities on how students and teachers can use telecommunications see Jill’s Page for Educators! created by Jill Tucker. The section on Lesson Plans and Student Work are valuable. They contain many exciting and practical uses of the Internet. The Student Work area includes examples of curriculum-based, student created html documents.

The Web66 site also provides much needed information for educators to use the Internet for classroom activities and to link to other schools. Many ideas and resources are provided. A highly rated site.

The Institute for the Transfer of Technology to Education is a program of the National School Boards Association to promote the effective use of technology in public schools.

ICONnect, is sponsored by the American Association of School Librarians and provides several resources to help schools get connected and to effectively use the Internet for learning.

The National School Network Is a partnership of schools, museums small businesses, network service providers and others who are assisting schools in creating state-of-the-art applications for networking in education.

The Center for Children and Technology investigates the important roles that technology has in supporting and sustaining qualitative change in the nation’s schools. It is a primary source for obtaining current research reports on educational technology in K-12 schools.

Teaching with Electronic Technology contains many links to higher education sites that provide information about conferences, publications, and general discussions of teaching with electronic technology.

Telecom Information Resources is a great site to visit with its over 2,000 links to information sources on the technical, economic, public policy and social aspects of telecommunications.

Other Interesting Web Sites Related to Educational Technology

Alliance for Technology Access provides information on Assistive Technologies.

Legal Copyright Issues Related to Web Site Management - contains many helpful and current articles on all aspects of copyright use and the Internet

My Keepers Page - Great quotes about education and technology

Your Own Web Guide by Electronic Learning Corp. is an interactive hypertext tutorial all about the different aspects of the World Wide Web. A great resource to use with persons new to the WWW.

Technology Planning Tools (from SCR-TEC) contains a variety of useful online tools and resources to help with integrating technology into schools - including decision aids, cost-modeling tools and computer lab layouts.

Valuable professional reading is provided on several sites. From Now On - The Educational Technology Journal contains lots of topics of interest to school technology leaders. You can subscribe for free.

Librarians On the Leading Edge - Librarians as Pilots, Information Mediators, Infotects and Curators is a challenging article that examines the emerging roles of the school media specialist in the age of technology and the Internet.

Opening Minds With a New Set of Keys is a thoughtful article that presents a brief, interesting, and easy to understand rationale for effectively using technology in schools

Charles Dubenezic is a faculty member in the School of Education at James Madison University.
UNESCO (1976) defines "literacy" as the ability "to read with understanding and to write simple messages related to his (or her) everyday life, and sometimes to do simple calculations" (p.62). While a debates continues as to the criteria for "understanding" and "simple", the term is often borrowed in other concepts such as "computer literacy" and "information literacy". Various international communities have attempted to identify essential competencies that constitute these concepts as they play increasingly an important role for the human development. This paper reviews the recent technological development and its influence on educational planning, and seeks to illustrate the notion of information literacy that is particularly of importance to the educational planners.

Evolution of "Single-Computing" in Education

The history of computer-based networking goes back to the 1950s when the first submarine cable was installed in the USA for the purpose of exchanging information. Since then, communication satellites have been put into orbit (1960s), and electronic mail, computer conferencing, and bulletin board systems have become available (1970s). These computer-based information exchange services have improved and expanded dramatically throughout the 1980s until it is now said that the online population of computer network users is exceeding 40 million people.

While all of these communication systems have taken full advantage of the latest information technologies, the field of education has, sadly, been adopting them very slowly. In broad terms, we may discern three main phases in which computer-based information technology has reached into the world of education in the following manner.

1. The 1970s were characterized by the computer as subject matter (that is, computer studies were concerned with teaching about computers as used by computer scientists);
2. The 1980s were characterized by the computer as an instructor of a specific subject (that is, computers were used as non-interactive drill and task masters for Computer-Assisted Instruction); and
3. The 1990s were characterized by the computer as an interactive all-purpose problem-solving tool (that is, among other things, the computer moved into interactive areas such as simulation, projection, and many forms of complex analysis).

The above evolution focused on users operating their computers in a "stand-alone" or individual learning environment.

The Emergence of "Networked-User Computing" in Education

The networking capability of the computer has been recognized recently as an effective strategy for establishing collaborative learning environments for mass education (see Figure 1). This movement from single-user skills (developed mostly through courses in "computer literacy") to networked-user skills (requiring knowledge and techniques beyond basic computer literacy, which may be described in broad terms as "information literacy") can clearly affect not only students and teachers, but also the world of educational planning. These trends have major implications for training programmes in any institutions in developing and industrialized countries specializing in educational planning and inevitably call for a general rethinking of not only their working style but also their curriculum content.

Many planning institutions in the world have successfully moved from computer literacy to information literacy by adopting the mixed use of interactive delivery systems. For example, network communication is used for the delivery of instruction, provision of support, exchanging views, etc. These institutions have identified some important networking tools in order to access information, share and disseminate knowledge, and learn collaboratively. These tools include: 1) sending and receiving e-mail messages with instructors, other trainees, and outside experts; 2) joining and using the news groups (or a bulletin board system) to share messages asynchronously at a public place; 3) participating in computer conferencing to
communicate synchronously (real-time) in a virtual classroom or seminar; 4) navigating in the World-Wide Web environment to browse and access to inter-linked network of information; and 5) searching for and retrieving information on databases using research tools (Price, 1996).

Figure 1. From computer literacy to information literacy.

Trends in Educational Planning

In the world of educational planning, an obvious major contribution of this trend of improved availability of relatively low-cost interactive technology has been the possibility to address one of the high-priority planning issues in many countries regarding the management of information systems. The rise of management of information systems is based on several trends on educational systems seen in the international community, especially in developing countries (Chapman, 1990):

1. Educational systems have been expanding rapidly in size and coverage;
2. Educational programmes have become more complex with manifold goals/objectives;
3. Pressure for more efficient use of resources has increased due to constrained financial support; and
4. Accountability requirement for the donor community has been increased.

Therefore, in many countries, having more and better information has been considered indispensable for sound decision-making in educational policies and practices.

New Role of Educational Planners

The UNESCO-IIEP Workshop on “Issues and Practices in Planning the Quality of Education”, took place in Paris in November 1989. One of the most important ideas to emerge from that workshop was that all educational planners at different levels are required to manage different kinds of information in order to support sound decision-making in educational policies and practices (Ross & Mählick, 1990). This notion encourages the rethinking of the new role of educational planners as a “link agent” dealing with information between policymakers and the researchers. That is, the educational planners are now expected to: 1) be sensitive to the general concerns of policy makers; 2) operationalize these concerns into researchable questions; 3) build and manage information systems; 4) analyze and interpret educational information; and 5) provide policy options to address the policy concerns and to support the informed decision-making.

With this new role of educational planners, it is becoming increasingly important that planning institutes ensure that essential information literacy skills required for policy dialogue are taught in their educational planning curriculum. These important tasks might be considered to make up the concept of Educational Management of Information Systems (EMIS).

Framework for Educational Management of Information Systems

Figure 2 shows a conceptual framework for educational management of information systems. The system as a whole can be understood as a process of assuring informed decision-making on educational policy. At each stage, educational planners have an important role (Saito & DiasDaGraça, 1996).

Stage 1: Educational Management of Information Systems (EMIS) Context

At the first stage, educational planners can try to be sensitive toward general policy concerns that are considered high priority issues. Then they can transform these general concerns into either specific research questions or concrete daily planning inquiries.

Stage 2: Operationalization

Educational planners will break down the research questions into separate components to prepare “operationalized questions”, and will identify necessary indicators in order to respond to the policy concerns.

Stage 3: Data Format and Source(s)

Planners will identify the level of aggregation for data and the format of data that are required in order to address the policy concerns. Some data may be available in paper format, other in electronic format. They will also decide whether data should be collected using a sample survey or population census.

Stage 4: Data Collection

If no data are available, data collection instruments are designed, and subsequently field data collection exercise will be conducted. If data are available on electronic form already, the data collection exercise will be done through “data retrieval” from diskettes, CD-ROMs, or online.

Stage 5: Database Building

If the field data collection is undertook, or if data are found on paper format, this is the stage to put them in the format that can be “read” by the computer. Planners can define the structure of the file with necessary variables, and enter/clean data.

Module 7: Data Processing

a. Conduct a descriptive analysis based on a set of education data regarding inputs to school, pupils achievement, etc., in order to examine the level, observe changes, compare against criteria, or analyze the disparity and equity. ✓ ✓ ✓
b. Improve the technical quality of examinations by analyzing test items, reviewing and rewriting test items, and analyzing curriculum. ✓
c. Conduct a correlational analysis between two variables based on a set of educational data. ✓
d. Conduct a regression analysis to identify the impact of a set of selected independent variables on the dependent variable based on a set of educational data. ✓
e. Conduct a path analysis in order to study the relationship among a number of factors and their individual and overall impact on the dependent variable based on a set of educational data. ✓
f. Estimate school age population by single year by using the Sprague multipliers method. ✓
g. Calculate indicators of access and participation, internal efficiency, resource utilization, and measures of disparities, based on given data, in order to diagnose the educational situation. ✓ ✓ ✓
h. Project population based on simple mathematical formulae or complex demographic theories. ✓
i. Project enrolment by calculating the trend of enrolment on a few years in the past and to estimate it for the next year enrolment in order to identify the resource needs. ✓ ✓
j. Use a simulation model to test several hypotheses or scenarios to project school enrolment, financial aspect, and manpower requirement. ✓ ✓
k. Prepare a prospective map which proposes new schools and/or classrooms based on the analysis of zonal disparities combining several indicators. ✓

Module 8: Reporting

a. Produce a document of moderate length that is in a style appropriate for policy or research reports. ✓
b. Produce a document or computerized visual presentation that include graphs that summarize data in a manner that ensures better communication of the meaning of the data. ✓ ✓ ✓
c. Produce a document with policy interpretation in order to formulate policy suggestions. ✓ ✓

Module 9: Policy Input

a. Make data accessible in the electronic format. ✓
b. Share reports with the decision makers through Policy forum. ✓ ✓

Note: 1 = A five-day module 2 = A two-week workshop 3 = A semester-long course

Stage 6: Database Management

Using the database created or retrieved electronically, planners will manipulate files (sort, filter, aggregate, merge, etc.), and manipulate data (re-coding, creating variables, etc.). This is also the moment to “archive” the data for the future use.

Stage 7: Data Processing

Several process can take place at this stage. One example is the use of data (mostly aggregated data) for projection and simulation. Another example is to conduct statistical analysis using dis-aggregated data to examine the level, compare the mean, analyze the relationship between two variables, identifying the cause/effect, etc.

Stage 8: Reporting

Based on the data processing, educational planners will summarize the results by using tabulation or graphs/charts in order to prepare a report which better communicates the results. The report could be prepared as a research report, an indicators report, or a policy document.

Stage 9: Policy Input

As a feedback loop, educational planners will share reports with the decision makers through policy forum. The report should provide some policy options that can be chosen for better informed decision-making.

Scenarios for Potential Curriculum

This suggested framework provides a skeleton for a modularized curriculum for Educational Management of Information Systems. That is, the system as a whole can constitute a comprehensive curriculum for EMIS, and at the same time, each stage of a system is a building block and can form a “module”. These various modules can then be identified and assembled to make a course. Within the suggested framework of EMIS, generally three different scenarios can be considered depending on the context: 1) a five-day module 2) a two-week workshop; or 3) a semester-long course (see Table 1).
Curriculum for a Five-Day Module

A five-day module could be a part of a continuous annual training course designed for practicing educational planners. Different “modules” are presented at different times of the year; this module can be offered within the first quarter. The trainees must have used computers to perform basic operations. They must have basic understanding of educational planning terms/jargon, and concept of “first-level” indicators on access, efficiency, and resource management. The suggested contact time for this module is 20 hours. A special emphasis is placed on the important role that educational planners can play at the front end in the identification of policy concerns and transformation of the policy into specific indicators. Regarding the technical aspect, more stress is placed on building and manipulating the database system rather than complex statistical analysis.

Curriculum for a Two-Week Workshop

This workshop can be presented as a stand-alone intensive course independent from a regular training programme. The contact time would be approximately 30 hours. Greater heterogeneity can be expected in terms of the participants’ computer competencies. Therefore, more time should be allocated to the introductory part than the five-day course as part of the annual training programme. In the two-week intensive workshop, while the identification of information needs and the policy input are portrayed as one of the most important planner’s role, increased stress is placed on the important distinction between aggregated data and dis-aggregated data and their consequence in the type of data processing possibilities.

Curriculum for a Semester-Long Course

This type of course is normally seen at any tertiary institutions. Contact time increases to 40 to 50 hours spread throughout the semester. This type of course is ideal when presented as a streamed “information literacy” course which is parallel with other courses. That is, the course on Educational Management of Information Systems can be considered as extra insertion points with appropriate timing to enhance various types of educational planning tasks presented in other courses.

Conclusion

The convergence of technology has influenced not only the media and communication, but also the world of education, more specifically educational planning. This development has an implication on how and what educational planning institutions can teach in terms of both the content and the method for training programmes in the area of educational planning.

The curriculum should address the important aspect of “information literacy”, that is, information literacy required for policy dialogue. All training in this area must focus on the knowledge and skills that educational planners require in order to adopt the role of a “link agent” — operating between educational policy makers and educational researchers. Trainers and curriculum designers at educational planning institutions should be able to choose the knowledge and skills to be included in the curriculum according to the budget/time to be spent on the course and the complexity that need to be covered in the course.

There is no question that Information Technology is affecting most sectors of our society, but what is its role in teaching and learning in higher education? Some suggest that IT could bridge the gap in helping countries such as the United Kingdom (UK) to afford the high participation rates that we need to turn our information society into a learning society. Others suggest that the costs outweigh the benefits. The Higher Education Funding Council for England commissioned a six month research study into IT assisted teaching and learning in HE (ITATL) in order to inform the Council. While the original specification was rather ambitious, timely results were essential. This is due to the current review of Higher Education in the UK led by Sir Ron Dearing, which is due to report in July 1997. Therefore, the research study's final consolidated report will be validated against an invited seminar of policy makers in January 1997 before its wider publication.

Background of the Study
The research study is directed by Professor Niki Davis in the University of Exeter School of Education Consortium for Educational Telematics (COTE). The Exeter consortium has a long history of research and development in this area. For example, they were a key institution in the national project to improve IT in UK initial teacher education (INTENT) and have undertaken projects within the UK Teaching and Learning with Technology Programme (TLTP), the Joint Information Systems Committee’s New Technologies Initiative and for the Department for Education and Employment. They also work closely with several major companies including British Telecom PLC and ICL. The economics team have been involved in the TLTP programme and commercial organisations.

The research team is multi-disciplinary, multi-site and multinational. The principal researchers roughly split into educational and economic researchers. Both have collaborated on all aspects of the project, which provides an almost three-dimensional view for the study. Colleagues in the USA, the European continent and Australasia have helped set the study within an international context too. The principal researchers and their institutions include: Niki Davis, Penni Tearle and team: Consortium of Telematics for Education (COTE) University of Exeter, UK; Patrick Dillon: University of Reading, UK; and Steve Ehrmann: Annenburg CPB Project, Washington, DC, USA.

Literature Review, Including International Comparison
The literature review has been led by Dr. Patrick Dillon. Many publications were used in detail, including Diana Laurillard’s seminal book “Rethinking university teaching.” and a book edited by the first author with Bridget Somekh on the effective use of IT in teacher education (Somekh & Davis, 1977). The team has also used the grey literature which is not freely accessible, even over the Internet. By grey literature we mean papers that have been written for local consumption within universities and other organisations. These have included course evaluations or reviews, where IT is discussed. Policy documents which underpin the delivery of IT or teaching and learning within a department or institution. We have also collected views on the most important parts of this field from other parts of the world. Analysis of the recent articles influencing practitioners’ thinking showed no generalisable characteristics, but it was noteworthy for range and diversity.

The journal Educational Technology Abstracts was analyzed to determine the main themes reported in the literature over the last five years for a relative index of ‘scholarly effort’ (2143 abstracts). The major primary focus...
found was instructional media. There was significantly less effort on learning, assessment and relatively little effort on instructional resources. The secondary focus was more on tools, applications, and teaching. There were considerably more papers on research and development than on superficial examination. CD ROM and multimedia together represented the largest grouping of instructional media covered, although there was a relatively large amount of research and development in audiovisual and broadcast. Internet and communications were still emergent. There was a dominance of computer-based over telecommunications-based and the items on instructional design were numerous.

There was a wide range of research and development in teaching and learning, especially evaluation. The relationship between instructional design and topic, such as teaching, was significant. Analysis of subject applications showed a predominance of subjects where routine or mechanical skills play an important part; or the knowledge component can be precisely specified or there is a well defined professional base. There was poor representation of creative and performing arts and subjects where skills/knowledge is less easily defined and/or specified.

Case Studies of IT Use Within Programmes of Study in HE

The literature review provides an overview of the field as reported by others. We have also captured and documented a small sample of case studies to provide a set of rich descriptions of the ways in which IT can be used in a range of disciplines and institutions. Given the time constraints it has not been possible to take strictly comparable cases, but the important theme is to bring alive the issues which arise when IT is used to assist teaching and/or learning, and the associated costs and benefits.

A range of themes from literature can be seen in our six case studies:

- Merging market sectors where higher education links to leisure, commerce or other phases of education.
- There is a trend towards increased networking between several organisations, not just universities.
- Educational contexts change when IT is employed.
- Higher order cognitive processes can be significantly enhanced.
- Authenticity and transferable skills can also be significantly enhanced.

Issues also arise:

- Management of innovation and information is required, but is often absent.
- ITATL is in response to pressure, but the cause of the pressure varies.

- Overarching models of teaching, learning and management are not tested.

This paper will only briefly describe two case studies where IT was used to assist teaching and learning in a course. Readers should refer to the final report which is available from COTE in the University of Exeter (Davis et al., in preparation).

A Course in Orthodontics in the University of Bristol Dental School

Multimedia CAL with high quality images (of people with open mouths showing their teeth), simulations of a variety of processes and dental procedures and self test assessment was created to replace seminars in an existing course in orthodontics. The quality is high and it is linked to the student's text book, which is the standard in the field, at least in Europe. The leader of this development and the person who specified the style and content is Professor Chris Stephens. Significantly, he is also one of the editors of the text book and he has over ten years' experience in developing IT in teaching and learning, having been involved with the development of an expert system earlier. The creation of the CAL materials have been funded by several sources, including funds from the publisher of the text book which have been used to pay the writer of the CAL software. Central assistance was available to digitize the medical images. Students use the material in an open access lab near the library and the software is on the LAN. The learning is structured on the cases that the students encounter in their laboratory work. Assistance to develop expert orthodontics knowledge and skills are provided during these practicals. The pressure driving this development, according to Professor Stephens, arose from the lack of expertise in the UK in this subject and the need to create a new masters course to address the shortfall. The loss of seminar courses, during which specialist staff demonstrated techniques, has permitted the delivery of an additional masters programme for about ten students who use the same CAL materials at their level. Professor Stephens feels that it may also be possible for practising dentists to use a version of materials in their dental surgeries to learn 'on the job' in the future.

The UK Open University Postgraduate Certificate of Education

This is a part time course over eighteen months which students study at home and in two local schools. IT assistance to teaching and learning is provided in several ways, including the loan of a personal computer with modem, printer and computer conferencing software and an integrated package including a word processor and database called ClarisWorks (Selinger, 1997). Our study reviewed the case for electronic communications (First
Class), which included personal e-mail. The 1,000 student teachers in 1995 were surveyed at the end of their course. They had found the computer conferencing valuable in helping them, as remote students, feel part of a university community. The computer conferencing had been perceived as most useful for information. Reflection on their practice as teachers was about half way down the list and valued by approximately 30% of the sample. It was not a compulsory element of the course because the Open University's policy is to provide information in a variety of forms and to permit the student to choose the one most suited to their needs.

It should be noted that this course was new and did not have to fit in with existing structures. In addition, it was given special dispensation by the government bodies, who valued it particularly for its ability to train teachers to work in more remote locations where there were shortages of teachers. Networking of organisations was evident in two ways: staff from other institutions and schools act as local tutors and collaborating school staff attend mentor training provided by other universities. It was notable that the course was created by a multi-disciplinary team which included an educational technologist.

Economic Assessment

The review of the literature showed that costs were almost always unclear and that benefits were even less clear. Opportunity appeared to be important. Although many papers suggested that economies of scale would occur tomorrow, the IT rarely persisted for a long time. Either the IT platforms or the subject matter was subject to change in a few years, or even annually. Estimating value for costs and benefits is at an early stage. The multilayered approach required can be considered to be in concentric circles moving from the centre outwards in this order: learner, teacher, department, organisation, the social system (including regional and national government). Costs can be either private or public and be assigned to one or more of the many of the actors in these layers. This is explained in more detail in our final report. Early evidence from case studies suggests a three way model:

1. No economic benefits, or
2. Benefits less than costs, where there are no REAL economic benefits (often due to a measurement error) or
3. Real economic benefits because benefits are greater than costs.

The economics research can be summarized as follows:

- Evaluation of ITATL needs careful use of measurement to assess both costs and benefits. However, costs are almost always obscured and it is even harder to provide a measure of each benefit. Clarification is easier where objectives are identified at an early stage for the way in which IT is expected to assist teaching and learning.

Finally, time does not seem to be a critical factor, despite our early expectations, although it is a significant cost.

Policy and Implementation: Community Views

The research project also involved higher education community participation through seminars and forms on the World Wide Web. Participants included a high proportion of agents of change, including those who develop applications or are involved in institutional and staff development. They also included users (teachers), service providers of IT and library services, and those who manage them, including Vice Chancellors and principals of institutions. Some of these experts provided a section of the final report on a theme. In many cases the points raised echo those of findings in other phases of education. We now use these to provide an indication of issues relating to policy and implementation.

Steve Ehrmann, from the USA, noted that there was little choice for UK higher education: "Damned if you do: damned if you don’t." IT will cost, often more than it can be shown to produce in identifiable benefits, but institutions that do not use IT will get left behind and their courses will not be perceived to be up to date. Participants from companies such as British Telecom noted that the same had applied to their business in the previous decade. Firms also noted the need to use IT to support social interaction, but that the interaction would be costly in terms of time, both that of teacher and student. Bridget Somekh, with her background in educational research, noted that higher education was applying what was known about innovation and change, so strategic support and awareness raising of this was necessary. Educational Technologists were clearly important to the quality of these innovations and Eileen Scanlon for UK Open University noted that their course teams always incorporated this as a service course creation and evaluation. This change in working styles for staff and students was drawn out further by Greville Rumble, who is predicting that, in future, teaching staff may work for many organisations at one time and students may follow the teacher, rather than have a course designed and delivered by one university. The flexibility that IT can provide was noted as of particular importance for access to the curriculum for those with special educational needs, and this attention to individual needs was also good for all learners.

Summary of Points from Our Research

ITATL was seen to succeed on occasions where: teaching was of skills and routine tasks or the topic amenable to specification and did not change too quickly. Often the link to a professional context or teaching based on relevant cases significantly enhanced the quality and
student autonomy. As yet few examples of the way in which IT can be used to assist teaching and learning in higher education have been well documented when taking place in disciplines related to creative arts or in a commercial or industrial location (on the job). Where ITATL does occur, it appears to be in response to one or more of the following three pressures: to increase numbers taught, or to improve access for students or access to experts, or where staff personally want to improve teaching and learning.

At the time of writing the research study is incomplete. However, early evidence suggests one general finding in relation to this new field: the benefits of economics and education appear to go together. We also have some tentative suggestions towards national planning. Support should be provided to those planning for innovation using ITATL. Staff, including managers in HE and companies, need awareness about what can be done, especially good practice. At the same time they need information on the management of innovation and change. Those implementing ITATL should plan to implement formative evaluation and to disseminate their work within higher education and beyond it to others who might find the content valuable in other forms. Indeed new models are required for teaching and learning, which recognize that the educational system is complex with many layers and actors. Appropriate models for costing and change may be similar to those for a weather system with an element of chaos within the complexity. These models should be evaluated against the evidence. Although we have started to generate a model (using the Stella software), it is far too early to suggest that we have already captured all the factors or been able to set a reasonable range of values for each parameter we have identified. We may be at the start of a new field in educational research.

We know that IT can be seen as the answer to the problems of increasing numbers in higher education within a falling resource, but we think that IT is unlikely to prove to be such a global savior. However, ITATL is likely to be good for aspects of Higher Education. We have been attempting to evaluate what it is good for and how it can be delivered effectively for the teacher and for the learner, as well as for the UK. Our research will continue, so we will be pleased to receive further information. Send your items to: ITATL, COTE, School of Education, University of Exeter, Exeter EX1 2LU. Email: COTE@exeter.ac.uk

IN SEARCH OF A DEPARTMENT-WIDE TEACHING PHILOSOPHY THAT INCORPORATES MODERN TECHNOLOGY

Richard A. Howard
United States Military Academy

Joe Adams
United States Military Academy

William Lane
United States Military Academy

Curt Carver
United States Military Academy

Over the past three years, our department has produced an Information Systems course that takes full advantage of multimedia and hypermedia (MMHM). Based upon Bloom’s Taxonomy, learning style theory and cooperative learning, the course material is available 24 hours a day via the World Wide Web (WWW) for students as they prepare for class. The course director also utilizes elements of the material during the scheduled lecture period. This course has been highly successful in terms of student achievement and source material for academic research. Students walk away from the course with a deep understanding of the stated course objectives (Biehler & Carver, 1996), (Carver & Biehler, 1994), (Carver & Howard, 1995), (Carver, Howard & Lane, 1996a), (Carver, Howard & Lane, 1996b). The chief developer, Carver, has published over 20 papers around the world documenting all aspects of the project. Regardless of the course success though, many faculty members question the overall effectiveness. Their attitude is best stated by “Prove It!”

The department leadership is struggling with the concept too. How much technology do we make mandatory? How much is optional? The corporate world is moving towards MMHM in a big way (Adams, Carswell, Ellis, Hall, Kumar, & Motil, 1996). Shouldn’t we be going there too?

In short, we are looking for a department wide philosophy in regard to teaching and technology. This paper will discuss these issues in detail. We will start with the practical benefits of using the World Wide Web. We will then examine the proven affects on learning through MMHM courseware. In contrast, we will then discuss what we do not know about the effectiveness of MMHM courseware. We will look at why we believe the WWW should be considered an effective teaching tool by looking at the underlying learning theory. Finally, we will complete the discussion with several recommendations and conclusions.

Practical Benefits of The WWW

Before we adopt a new technology, it is important to validate how the technology will benefit us. In some cases, the benefit is obvious. We can accomplish some tasks more quickly or with less resources then we were able to without the technology. In other cases, it is not so obvious. Some aspects of using MMHM courseware via the WWW are practical, some have already proven to be effective and some have not been proven at all. The following is a list describing some of the practical benefits to using the World Wide Web for instruction:

Students can view media elements many times. In the traditional classroom setting, a student may only see the information presented by the instructor once or twice. The student is expected to take good notes during the lecture period and study from those when appropriate. With the WWW, a student may “replay” some media element prepared by the instructor over and over again. The student can study what the instructor thinks is important on many occasions. Taken to the extreme, the student can almost replay the key points of an instructor’s lecture whenever he or she decides to study.

The same material can be presented in many different forms: movies, sound, text, and/or pictures. In the traditional classroom setting, a student may only see the information presented by the instructor once or twice. The student is expected to take good notes during the lecture period and study from those when appropriate. With the WWW, a student may “replay” some media element prepared by the instructor over and over again. The student can study what the instructor thinks is important on many occasions. Taken to the extreme, the student can almost replay the key points of an instructor’s lecture whenever he or she decides to study.

The same material can be presented in many different forms: movies, sound, text, and/or pictures. In the traditional classroom, the teacher is limited to some form of lecture. In the interest of time, an instructor can present one or two viewpoints at the most. If a student is not clear on a concept, the teacher usually handles that on a one-to-one basis by presenting the material a little differently. On the WWW, a teacher can present the material in many different ways and make all presentations available to the entire class.

Likewise, the teacher may utilize other educators’ work on the web. If a student is having trouble with a particular concept, the teacher can point that student to other web
Electronic search engines incorporated into the MMHM courseware allow both the student and teacher instantaneous access to related information. In a traditional classroom, a key course concept may be distributed across a course lecture, a reading assignment, a laboratory exercise and a research project. It is generally up to the student to connect the dots so to speak with some gentle urging from the instructor. If a course incorporates a search engine, it becomes very easy to find all the references to a course concept throughout the course material.

Handouts are always available. Large printing requirements become a thing of the past. Many items that educators handout are looked at once by the students and then thrown away: course administration, syllabus, and other documents. With the WWW, students can access the pertinent documents, glean the required information and pursue their course of study. No paper is produced or wasted. On occasion, the educator may still wish to produce a hard copy document. That is OK. Putting a backup copy on the WWW will ensure that everyone will always have access to it. Some students may want to print the document as well.

Course changes are instantly available to all students. If the syllabus changes, all students have access to the change as soon as the instructor makes it. There is no longer any need to publish addendum or additional pages.

Some of the same practical benefits associated with the WWW are also available if the course utilizes a file server. The same movies, sound files and text files are as easily stored and made available on a file server as they are on WWW server. The advantage of the WWW over the standard file server is that with the WWW, the author of the home page can easily explain what each file is and what the student should use it for. With a file server, those accessing the file have only the file name to guide them.

What Do We Know about Multimedia and Hypermedia Courseware

Empirical evidence suggests that some students learn the course material faster in a MMHM environment rather than a traditional classroom/textbook environment (Najjar, 1996) (Tjaden, 1996). The implication of this observation is not clear. Perhaps a teacher could schedule more time for a practical application of the course material: a course project if you will. Perhaps a teacher could include more material in a course. More study is required in this area; but, presumably, a teacher could take advantage of this situation.

Preliminary evidence suggests that some students retain course information longer if they participate in a cooperative learning environment that takes advantage of a student’s individual learning style (Howard & Carver, 1997). As discussed below, the WWW makes it easy to address a student’s individual learning style. Again, more work is required in this area; but, if the preliminary evidence holds, students could end up with a deeper understanding of course material.

Developing full blown MMHM courseware is work intensive. It took Carver two years of development before his course was fully functional (Carver & Biehler, 1994) (Carver et al, 1996b). He did not do it all at once. Instead, he started small and built upon it. Still, moving a course from the traditional lecture style/textbook class to a WWW courseware class requires a substantial commitment from the teacher.

MMHM development tools are generally not designed for the average teacher. Many are very complicated. The tools of the trade include high-end workstations and a collection of expensive software that will handle the video, graphics and sound manipulation. Start up costs are high and there is a large learning curve attached to all of the software. Developing rich MMHM documents on the web is difficult at best.

Adding MMHM documents to course web pages is relatively simple. Once the media has been developed, placing the items on a web page takes little or no effort. Basic Hyper Text Markup Language (HTML) is not very difficult to learn. Placing documents, like word processing and slide show files, on a web page is no more difficult then using old word processors like Wordstar or using Latex to publish documents. The idea of embedding commands at each end of a body of text is the same. For example, if a teacher would like to bold face the following text “Four score and seven years ago” the teacher would simply place the bold tag at each end: \textbf{Four score and seven years ago}. When viewed in a web browser, the text would appear in bold face.

What We Do Not Know about Multimedia and Hypermedia Courseware

Empirical evidence does not suggest that students using a MMHM course are better prepared then students participating in a traditional course. In many experiments, the student grades from both groups (traditional VS MMHM) were not significantly different (Rice, 1996) (Shih, 1996). One interesting note is that Carver determined that his best students, his A and B students coming into the class, performed better than expected at the end of the course. His average and poor students, his C and D students coming into the class, still did average and poor work at the end of the course. Carver’s conclusion suggests that even if a teacher develops the best courseware in the world, it will not help the student who does not study (Carver et al, SIGCSE 1996) (Tjaden, 1996).
Practical benefits notwithstanding, is the effort worth the time investment? This is not clear. More study and experimentation is required in this area to make a definitive decision. Using Carver’s work as a benchmark, two years is a lot of time for any teacher to invest especially if the average course grades do not improve. Still, if the preliminary experiments hold true, having students retain the course information longer and learn it faster may be worth the time investment.

**Underlying Learning Theory**

If so many issues regarding MMHM are unresolved, then why have so many people and organizations embraced the technology? One thought is that this is just the latest fad. The WWW is new and exciting and people are just now attempting to justifying it.

Another, more scientific approach, is that the WWW makes it so easy to subscribe to and teach with a particular learning theory. Many learning theories have been proposed over the years (Adams et al, 1996). Although they differ in the details, they have a common feature. From Gagne’s Conditions of Learning to Gardener’s Multiple Intelligences to Felder’s Scale, students have a particular way in which they like to receive information. If a teacher focuses the lecture toward each student’s learning style, then more students receive the information in a manner in which they are comfortable. Presumably, this will enhance their learning and performance in the class.

To use the Felder model as an example, one student may be a visual learner. This student may have trouble learning anything unless the teacher uses some sort of picture or diagram to describe a concept. In contrast, another student might be a verbal learner. This student can completely assimilate a topic simply by reading about it or listening to a straight lecture from the teacher. This visual/verbal dimension is one aspect to how students may prefer to receive information. The average student will fall somewhere on the line between these two extremes. In the Felder Learning Style Theory, five different learning dimensions exist (Howard, Carver, & Lane, 1996b).

Organizations may be adopting the MMHM paradigm because it feels like it should work. Using learning theory to explain this feeling, the WWW makes it very easy to incorporate all the different learning styles into the presentation. Movies, sound, pictures and text can easily be organized to support every existing learning style on each topic in a course regardless of the learning model to which you subscribe. Intellectually, this approach should be hugely successful. The fact that grades have not improved in the preliminary studies is perplexing.

Some scholars have suggested that using grades to evaluate a teaching methodology is too blunt. (Howard et al, SIGCSE 1996) (Najjar, 1996). Other measures are required. This is why proponents of MMHM courseware are encouraged by the preliminary studies on student learning time and knowledge retention.

**Recommendations**

Adopting a department wide teaching methodology is a difficult task. At the United States Military Academy, it may be easier then at other institutions because of the military organization, but the task is still daunting. It seems logical that a department would subscribe to one teaching methodology; but, in truth, the way a teacher teaches is a highly personal thing. To suggest to a group of teachers that they change their method is tantamount to telling them that they were teaching incorrectly in the past. This, coupled with the failure of researchers over the years to substantiate any major benefits to learning theory, makes it difficult to convince faculty members to apply the theory to their courses. Thus, one cannot decree that the faculty will change their style. Instead, the faculty must be convinced and encouraged.

After looking over what we know and what we do not know about using the WWW to teach, the practical benefits mentioned above at least merit further experimentation. The long term benefits to teaching and learning may or may not materialize. At the very least, then, using the WWW to teach is simply another tool in the teacher’s utility belt. The problem then is motivating faculty to at least give it a try.

The first thing that is required is a department wide seminar that teaches the basics of HTML. Hopefully this will be a hands on seminar that will last no more than an hour. In this hour, each faculty member will gain an understanding of how easy it is to create Web pages and will introduce a basic structure to a course home page. The department can schedule advanced sections at a later date; but, the main goal of the initial training is to demonstrate ease of use. The tools of the trade at this point are a web browser and a text editor.

Although the department should not mandate a teaching philosophy, it should impose some minimum web structure. For example, we suggest the following structure:

- Course Title
- Course Syllabus
- Course Description
- Picture of the various instructors associated with the course.
- E-mail address of the various instructors associated with the course.

At this point, some faculty will see for themselves the practical benefits and begin to incorporate some WWW elements into their course. Others will not. This is to be expected. We are not looking for the entire faculty to convert their courses to the Web overnight. We are
attempts to introduce a new teaching tool and to encourage its use.

Finally, department leadership must encourage an open dialogue regarding issues that the faculty discover as they experiment with this new tool. The only way to do this effectively is to have the leadership embrace the technology too. The leadership should encourage informal discussions regarding the advantages and disadvantages of the web and should provide some sort of feedback on a recurring basis to the entire department. Perhaps after a year, the leadership may decide that using the WWW and MMHM courseware is a waste of time or that it is the only way to go. The only way to decide this is for everyone to get their hands a little dirty.

Conclusions

As stated in the introduction, we are looking for a department wide philosophy in regards to teaching and technology. The question concerning how much technology we make mandatory is a crucial one and a delicate one. Mandating a change in teaching style without articulating the benefits to learning or to practicality seems to be a waste of effort. Change for its own sake is not a good idea.

In this paper we have listed the many practical benefits of using the World Wide Web. We described how researchers think that using MMHM and learning style theory together enables students to learn the subject matter faster and to retain it longer; however, using MMHM and learning style theory together does not seem to improve the overall grades of any particular section of students.

We learned why MMHM and learning style theory are a natural match with the World Wide Web. We showed how the very essence of the WWW makes it easy to subscribe to and utilize any of the many popular learning style theories. Still, without a proved improvement in grades, mandating a change to this style of teaching is probably not wise.

We are then reduced to recommending the WWW as just another tool in the teacher’s utility belt. Future research may or may not prove that using the WWW in conjunction with some learning style theory is beneficial to the average student. Until that time, the WWW is one more technique at the teacher’s disposal to enhance the student’s learning experience. What is left then, is to show the faculty how to incorporate the Web into their classes.

Finally, we must keep an open dialogue. Encourage the faculty to try the web in their courses. Discuss the good things and the bad. Some will find it extremely useful. Others will not. But we must encourage them to try. To quote Howard D. Mehlinger, “Today there are no learned people, only the learning and the slipping-out-of-date.” (Kirkley, 1996).

310 — Technology and Teacher Education Annual — 1997
We are agreed that a modern university will be more and more unthinkable without computers and networks. Everybody seems to be talking about the future Information Society, about e-mail, the Internet and the World Wide Web. Some universities already have excellent campus networks, others are only now beginning to establish an appropriate infrastructure.

However, all universities are faced with these or similar questions:
1. How to find funding for Information and Communication Technologies (ICT)?
2. How to obtain adequate software and courseware appropriate to the university curriculum?
3. How to give teachers new tutorial skills for such ICT, software and courseware?
4. How to make the best use of ICT in teaching, learning, research and administration?
5. How to deal with mediocre teachers and university managers, who will lose power, status and money in future competition with outstanding teachers and university managers?

It is generally known that the information society is a global society, so ICT will influence the whole society, not on a national but on an international level. It is therefore necessary within CTU to pursue all the trends that the information society as a whole follows, and to join in international cooperation. Because the Czech Republic is one of the candidates for European Union (EU) membership, CTU mainly follows the trends arising in EU countries and universities. Before describing the CTU projects in education, research and management, we will first mention some important EU documents. We believe that these documents will be of interest to any university.

Next we will describe ICT implementation at CTU. Brief information will be provided about the CTU Manager System and Campus Wide Information System. The projects aim to formulate CTU policy for introducing ICT into the educational processes, research activities and university administration. Our activities are planned to fit in our broad cooperation with international organisations and universities in the Czech Republic and abroad. The RUFIS'97 international conference is one such important means of cooperation. The conference is prepared for September 24-26, 1997, in Prague. More detailed information about the conference is given at http://www.cvut.cz/cp1250/cc/icsc/NIU/index.html.

Education in the Information Society: Visions, Projects, Tasks and Perspectives

Bangemann's Report and other EU Documents

An important report has been Bangemann's Report "Recommendations to the European Council: Europe and the global information society" which is available at http://www.ispo.cec.be/infosoc/backg/bangeman.html, 1994. Generally speaking, this report outlines the EU vision of the information society and the benefits it will deliver to our citizens and to economic operators.

Comprehensive resources dealing with the Information Society (IS), including EU Projects in the area of Higher Education, can be found at the well-known EU Information Society Project Office Webserver, available at http://www.ispo.cec.be/. On the URL http://www.ispo.cec.be/infosoc/educ.html interested readers can find the EU's basic plans in the area of Education in the Information Society.

Similar projects have been proposed for cooperation between EU and Central and Eastern Europe Countries (CEEC). For information about this, see Second Forum of the EU and CEEC in Prague, http://www.ispo.cec.be/peco/forum.html and also 30 themes for European initiatives and actions, http://www.ispo.cec.be/peco/peco002.html.

Perspectives of ICT at the CTU Prague

Managerial Information System (MIS)

One of the most obvious domains in which ICT may impact the University's daily life is in management. The existence of CTU INTRANET (mostly fibre glass lines) and a relatively good awareness of modern management methods provide a good environment for the introduction of a sophisticated software system which will serve as a tool on all levels of University management. It is impos-
sible to present the structure of MIS in full detail here. Let us just outline its main features.

MIS will consist of the following main components:
1. Study
2. Research
3. Public relations and marketing
4. Financial management
5. Personnel and wages
6. Library
7. Information center.

These components will share information contained in communal databases so that all new information and every change will need to be entered only once. Some components are at the pilot project stage, while others are under development. One of the most important features of MIS is limited authorization of access for individual users. This is a very sensitive topic, given that some extremely smart and enterprising students have access to the University LAN.

**Campus Wide Information System (CWIS)**

The basic principles of organization, management and control of the CTU Campus Wide Information System were agreed by the CTU rector’s advising council on 10.6.1996 - see http://www.cvut.cz/cp1250/INFO/vis.html.

In contrast to MIS, the CWIS should be accessible to as many users as possible. It is therefore based on the WWW and Gopher platforms, see http://www.cvut.cz. The usual problem of keeping the displayed data up-to-date and avoiding unnecessary entry of new items is solved by direct interconnection between MIS and CWIS via SQL. This means that a subset of MIS information will be permanently selected for display and automatically transferred into CWIS whenever a change occurs, performing all the necessary format and type conversions.

CWIS, of course, presents much more information, for example, important CTU publications (CTU Bulletin, Acta Polytechnica scientific journal), personal pages of CTU faculty members, and pages of projects and institutions closely cooperating with CTU.

Wherever possible, the information will be transferred into CWIS automatically, without manual interference. This concept is backed by a hierarchy of information managers (department, faculty and University level), who coordinate all important changes and improvements in the system. However, it must be admitted that changes in ICT tools are easier to make than changes in human minds.

**Project: “Policy for implementation of ICT into education, research and management at CTU”**

Although there are many local and international initiatives in the area of “Implementation of ICT in higher education and research”, most are directed towards creating an infrastructure. The information society is not only an infrastructure, such as the Internet, but also a society of people who are able to cope with fast changing ICT and are skilled at using it effectively to achieve their goals. See http://www.csc.fi/forum/JH/iteurope.html, Implementation of new information technologies in European higher education and research, Confederation of European Union Rectors’ Conferences Recommendation. Following this recommendation, the CTU management should discuss the following items:

1. To create principles of policy for implementation of ICT into education, research and management, including a definition of objectives, strategies, budgeting and timing;
2. To establish a training and integration plan for staff, aiming at achieving efficiency in the implementation of new learning models based on ICT;
3. To implement resource centres in support of production, diffusion and research on new methodologies and new technology-based learning material;
4. To stimulate the participation of non-technological departments in new ICT-based learning processes;
5. To provide incentives for the implementation of Internet based courses, either autonomously or as a part of degree courses;
6. To provide incentives for electronic publication via the Internet of lecture notes, problems, laboratory manuals and other documents related to each subject;
7. To provide all students full individual access to e-mail;
8. To stimulate the electronic publication of student papers and projects via the Internet.

**Project: “Integration of ICT into the CTU Educational Process”**

ICT must be put into the classrooms of a wide variety of subjects. Information technology is an essential prerequisite, but infrastructure alone does not constitute an information society.

The project aims:

**To Support the Creation of a Common Information Space and Supporting Services**

Once teachers have acquired basic skills for using the WWW, this skill must be put into practice. The project will moderate special interest groups and provide a structure for a common information space and services.

**To Transfer Skills to Teachers and Students**

Teachers and students must learn to go beyond the simple use of e-mail and browsers and actually contribute materials to the Web, e.g. by designing their schools’ home pages, designing educational materials and learning to work in groups to exploit the WWW for these purposes.
To Make Results Widely Available

The above activities will result in material, such as a school starters kit, training and educational material, which will be made available through publishers and the WWW.

An example of teaching material being prepared for publication on WWW is computer-aided learning materials for Physics. There is long experience of creating and using computer-aided learning materials at the Department of Physics, Faculty of Mechanical Engineering, CTU. Computer Aided Seminars accompany lectures in Physics I and Physics II (a two semester course). We have prepared about 30 computer models for each semester, including aspects of modern physics.

Our main goal was to approach physics through some real-world examples, where it is not necessary to eliminate certain influences because the problem does not have an analytical solution. This is followed by a different formulation of the task and different approaches in applications. With this approach, we can define problems which extend beyond the scope of present-day studies and teaching at technical universities.

While preparing CA Seminars in the Physics course, we had to cope with the following tasks:

choice of appropriate software - a user-friendly environment enabling easy display of graphs, tables, animation, etc.

choice of appropriate problems - which formed the main part of our work. Not only was it necessary to coordinate seminars with the lectures, but we also needed to find some problems that are interesting for students and which cannot easily be solved without computers.

intrinsic structure of problems - problems which cannot be solved using analytical mathematical methods; problems which can demonstrate some important physical law where the numerical values of the variables are extremely important, interesting, worthwhile and applicable to further technical courses and in working life; computer-assisted instruction in classical problems (similar to textbook examples).

Technology continues to develop at an accelerated rate, bringing new opportunities for teacher educators to share with students what could hardly be imagined even a few years ago. As an example, the ability to tap into the tremendous research resources of the World Wide Web is evolving into an essential skill for students and faculty alike. Nonetheless, technology is still not central to the teacher preparation experience in most colleges of education today. Watkins (1993) suggests that the application and use of educational technology is at best a piecemeal and uncoordinated effort. However, like other educational reforms, practicing teachers and university faculty are expected to function within an environment generated by this Information Age with little or no assistance or training. In order to deal with these issues, teacher education programs are attempting to both model and infuse technology use into their teacher education curriculum and to assist faculty in this endeavor. This section documents a wide variety of issues and initiatives involving the integration of technology in teacher education programs.

To document an individual faculty member’s approach, Wilkinson describes his personal journey in conquering his fear of technology. His desire to conduct research and communicate through e-mail inspired him to continue reading and learning until he mastered the technology maze. This article is complimented by O’Bannon’s general discussion of integrating technology into a comprehensive faculty development program. She suggests that change in this area is a pyramidal structure leading to new ways of thinking and acceptance, but such change is not without a myriad of barriers placed by the fears of the very people change was meant to assist. She further suggests that professional development on the part of teacher education faculty must be continual with one-on-one training and mentoring as the best foundation for basic preparation.

The next three articles discuss methods of faculty mentoring using technology. In the first two cases, students are assigned to a faculty member to work one-on-one to help the faculty member integrate technology into his/her teaching. Beisser, Kurth, and Reinhart discuss an effective mentoring program with an undergraduate student and a college instructor that provided a successful partnership. This collaboration resulted in increased technological competencies and application for both the mentor and mentee, and suggests potential for future implications at the college level. At New Mexico State, Gonzales, Hill, Leon, Orrantia, Saxton, and Sujo de Montes have found a similar mentoring program, using doctoral students, to be effective. Their pilot program presents a viable solution to increase the faculty member’s knowledge of technology in concert with their needs and/or interests while the doctoral student, gains from the close interaction with various faculty members.

Finally, Hubschman discusses an exploratory study of what might happen with a mentoring program and e-mail. Her findings imply that e-mail may be a more positive methods for faculty to communicate with graduate students, in that the mentored group communicated more often than the neutral group on matters of class activities and personal situations.

As seen in recent years, the faculty in higher education faces imminent challenges through declining budgets and expanding enrollment. Therefore, faculty and administration alike must demonstrate methods of adding value to information in ways that are appropriate to meet the need of the student population. The next group of papers focus on assisting faculty in expanding technology skill in many such areas. Madden and Madden propose methods of using the computer that faculty find on their desk to create “professional calling cards” through the use of desktop publishing templates. Truman and Sorg suggest instructional design courses using the World Wide Web to allow faculty to deliver online, interactive courses employing distance learning strategies. Designing online, Web-based
The centralized approach discussed in this article supplies Design and Delivery at the University of North Dakota. delivery systems through the Center for Instructional distributed learning environments, and distance education strategies in innovative ways in traditional classroom settings, provides educational opportunities to investigate technolo-

gies. The project was the key to this successful project. Using collaborative models to diffuse technology into their faculty development efforts, Hoadley and Pike review provides educational opportunities to investigate technologies in innovative ways in traditional classroom settings, distributed learning environments, and distance education delivery systems through the Center for Instructional Design and Delivery at the University of North Dakota. The centralized approach discussed in this article supplies methods for providing assistance to faculty, students, and administrators to meet the technological needs that can be duplicated on any college campus. A similar initiative is discussed by Ritchie and Hoffman where tools, techniques, and training are being developed to initiate leadership for online course publication throughout the California State University system.

In this collection of articles, the locus of faculty and administration collaboration is the key to the models that have been initiated. Abbey focuses on inclusion of appropriate technologies using a diffusion model to reflect the best practices in education to incorporate technology for both integration and personal productivity. Formal and informal assessment is an on-going component of this model. Skeele and Daly discuss the Curriculum Development Initiative grant program at Seton Hall University that encourages faculty to redesign programs incorporating technology into teacher education. This program assists and financially supports faculty in developing expertise in the use of newly acquired technological resources and in modeling the creation of lessons by infusing technology into their university classes. Falk, Lochhead, Jacobs and Mooney investigate a technology-based faculty development community funded by the National Science Foundation for increased collaboration among leaders in teacher development. Their analysis of this community concentrating on teacher development has proven to date that this field is still emerging, but this research is developing a core of expertise beneficial to all.

The remaining papers focus on the critical components of the faculty development process in K-12 environment by improving teaching and learning in the uses of technolo-
gy. Hampton and Allen explore how West Virginia teachers learn about the Internet and its educational potential using the RuralNet project run cooperatively through the state's two universities. Training in this project consisted of a five day workshop and an online course developing teacher awareness of integrating technology into their everyday teaching by using the Internet to create a water quality unit. Norton and Wagner discuss a university/school district collaborative that facilitates intranet and internet connectivity in each classroom including digital, audio, and video connections. The infrastructure developed supports and enhances existing learning opportunities and pushes learning vistas in new and creative directions. At Laval University, Quebec City, Canada, teacher educators are developing a tele-learning research network to enable future teachers. Laferriere relates how the Professional Development School model has inspired this network of associated schools to create a community of tele-linked project-based learners. A collaborative training effort at Washburn University and a local elementary school trains the K-6 faculty and preservice educators using a facilitator model. In this article, the educational technology faculty from Washburn teach lessons in the elementary classroom with the teachers acting as another participant in the learning experience. Preservice educators assist in the lab to observe the lesson and the methods used in technology integration. This project exhibits the many benefits of site-based collaboration.

This section proposes many ideas as to how university faculty and teachers, with a understanding of technology, can redefine teaching by providing hands-on access and training on new technologies, bring faculty together across disciplines, provide mentoring, include team approaches to teaching and research, change the focus from content to the learner, examine learners in terms of their styles and strategies, and generally improve faculty involvement in the use of technology.

Lamar Wilkinson was fifty before he learned how to open an electronic window. This simple task to my children was a mystery to me, even though they kept telling me there was nothing to the computer; stop being afraid. Enter the twenty-first century. They laughed with loving kindness and a lack of understanding towards my fears. These fears, as I reflect upon them, reminded me of the year I gave my mother a Jacuzzi foot massager for a Christmas gift. Later that year, I found the massager hidden and asked her about the gift. She said, “Oh, well, yes. I meant to use the foot massager, but you know how tired I get after working hard all day. I guess I forgot, but don’t worry; I’ll use your gift.” A year later, the massager was still hidden. I laughed at my mother’s fears and antiquated ways of thinking. Now I was experiencing some similar concerns and fears because I didn’t understand computers. Computers were like monsters or aliens, something that was beyond my understanding. In reality, the only monster or alien was my own deep fear of learning something unfamiliar.

Many years ago I purchased a Tandy 2000 computer system that sat on my computer table. My children used this monster with elegance. I was afraid to touch it, even though I knew that I needed to master this machine. Then, I purchased a an Intel 386 personal computer with four megabytes of random access memory (RAM). A friend gave me a copy of Gookin’s (1991) book entitled, DOS For Dummies, to help me understand my computer. I used this particular equipment a little more frequently, but not beyond typing and printing some correspondence. I purchased Thomas’s (1993) book, DOS 6: Instant References, to increase my limited knowledge of MS-DOS. The book was an excellent resource, but my fears seemed to increase.

This fear of computers, coupled with my own personal fear of writing, prevented me from publishing articles about my counseling and psychology work. I kept stating that I did not like to complete paperwork. If I needed to revise my resume, I would type the entire document. Any revisions or new addition involved retyping everything again. Doing any paperwork was a tedious, laborious, and boring process. This aversive and negative process reinforced my limited interest in writing and publishing.

The psychology department where I work recently employed a new psychology department head. This individual is very fluent, well qualified, and knowledgeable in the use of computers and well published in the field of psychology. His expectations of the faculty to publish, which requires computer literacy, increased my personal resolve to learn about computers.

The event that exemplifies my accepting this computer challenge occurred one day while driving from Ruston to Shreveport, Louisiana. Because of my personal desire to send e-mail to my daughter Andrea, in Washington, D. C. I made a commitment that I would learn about computers. From that moment, my computer journey into the twenty-first century began.

Even with this firm commitment to learn about computers, the project was not a simple process. I had a great deal of trouble operating any computer either at the university or at home. Each day I realized more and more the need to learn about computers, personally and professionally, but when I would ask for assistance or discuss my computer problems with others. I found it was difficult following their explanations and directions. Later several colleagues shared, laughingly and kindly, that when discussing computers with me they observed that my face would go blank as I became overwhelmed during the discussion. The fact was that I felt inadequate, intellectually inferior, and confused even trying to understand the simplest information about technology.

Still, as much as I wanted to learn, I realized I simply could not understand what computer literate colleagues were saying. I imagined that everyone in the world was computer literate, and I alone lacked knowledge in this area. When I needed help editing material, they would say “just center the paragraph,” or “use justification to put the material into proper form.” They spoke in a computer language I didn’t understand; until I mastered this, I was not going to be able to learn about computers. I began reading many different computer books: Rathbone’s...
crashing my computer. Many times I felt discouraged and didn’t, saving material to the wrong drive, and finally knew how function keys did particular task when I really ences involved misnaming or misplacing files, thinking I work caused the loss of this paper. Other learning experi-
ings involved going to computer stores asking questions which were helpful for this next stage. This phase in my develop-
ment involved going to computer stores asking questions like: “How many megahertz?”; “What’s the RAM?; and “What’s the print speed per page?” In addition, it was also helpful to collect the detailed descriptions on different computers, printers, scanners, and monitors. I found that studying these leaflets at home at my leisure was more beneficial because I became overwhelmed with the sales pitches about computers. Finally, I very carefully drafted my ideal computer from all my research and investigation. The configuration consisted of a 200 MHz Intel Pentium microprocessor, 32 megabytes of EDO RAM, a 3.1 gigabyte hard drive, an 8x CD-ROM drive, 28,800 baud fax/modem, a 17” non-interlaced color monitor (with 0.28 mm dot pitch), Hewlett-Packard Deskjet color printer (600x 600 dpi), and a flat bed scanner (with OCR capabili-
ties). Maran’s (1995) Windows 95: Visual Pocket Guide, Harvey’s (1992) WordPerfect for Windows Quickstart, and Kelly’s (1988) Mastering WordPerfect 5 were extremely helpful to collect the detailed descriptions on different computers, printers, scanners, and monitors. I found that studying these leaflets at home at my leisure was more beneficial because I became overwhelmed with the sales pitches about computers. Finally, I very carefully drafted my ideal computer from all my research and investigation. The configuration consisted of a 200 MHz Intel Pentium microprocessor, 32 megabytes of EDO RAM, a 3.1 gigabyte hard drive, an 8x CD-ROM drive, 28,800 baud fax/modem, a 17” non-interlaced color monitor (with 0.28 mm dot pitch), Hewlett-Packard Deskjet color printer (600x 600 dpi), and a flat bed scanner (with OCR capabili-
ties). Maran’s (1995) Windows 95: Visual Pocket Guide, Harvey’s (1992) WordPerfect for Windows Quickstart, and Kelly’s (1988) Mastering WordPerfect 5 were extremely helpful to collect the detailed descriptions on different computers, printers, scanners, and monitors. I found that studying these leaflets at home at my leisure was more beneficial because I became overwhelmed with the sales pitches about computers. Finally, I very carefully drafted my ideal computer from all my research and investigation. The configuration consisted of a 200 MHz Intel Pentium microprocessor, 32 megabytes of EDO RAM, a 3.1 gigabyte hard drive, an 8x CD-ROM drive, 28,800 baud fax/modem, a 17” non-interlaced color monitor (with 0.28 mm dot pitch), Hewlett-Packard Deskjet color printer (600x 600 dpi), and a flat bed scanner (with OCR capabili-
ties). Maran’s (1995) Windows 95: Visual Pocket Guide, Harvey’s (1992) WordPerfect for Windows Quickstart, and Kelly’s (1988) Mastering WordPerfect 5 were extremely helpful to collect the detailed descriptions on different computers, printers, scanners, and monitors. I found that studying these leaflets at home at my leisure was more beneficial because I became overwhelmed with the sales pitches about computers. Finally, I very carefully drafted my ideal computer from all my research and investigation. The configuration consisted of a 200 MHz Intel Pentium microprocessor, 32 megabytes of EDO RAM, a 3.1 gigabyte hard drive, an 8x CD-ROM drive, 28,800 baud fax/modem, a 17” non-interlaced color monitor (with 0.28 mm dot pitch), Hewlett-Packard Deskjet color printer (600x 600 dpi), and a flat bed scanner (with OCR capabili-
helpful in giving me additional knowledge about my software requirements.

With my new hardware and software, the mechanics of developing an article for publication became much easier than the old fashioned way of typing and editing. This new ability to cut, paste, and copy saved time. Being able to block and delete any sentence or paragraph, move the material to any other part of my paper, underline or italicize words or phrases was invaluable. The ability to use spell check, thesaurus, paragraph indentation, alignment, and justification reduced my fear of writing. Learning about and using technology has simplified writing and made it a wonderful experience.

Since I started my journey to learn to use technology, I have found many other colleagues in other disciplines as well as my own, who also have a limited understanding of computers. I felt by writing this paper and presenting it at a technology and education conference that I could share with other professionals my experiences and struggles and that through these encounters others would benefit.

Preparing pre-service teachers to meet the needs of students in the Information Age requires adequate training in the use of technology and its integration into the curriculum. Colleges of education have been and are still being blamed for being negligent in adequate technology training for preservice teachers. A survey of graduates in teacher education conducted nationally indicated that only 29% felt competent to use computers in teaching and learning (US Congress, 1988). Even more dramatic are the findings of a later national survey by Fratianni, Decker, and Korver-Baum (1990) which revealed that a mere 19% of student teachers ranked technology training in teacher preparation as adequate. More recently, the Office of Technology Assessment reports, in Teachers and Technology: Making the Connection, that technology is not a primary emphasis to the teacher preparation experience in most colleges of education in the U.S. and most new teachers graduate with limited knowledge of the ways technology can be used in their professional practice. (US Congress, 1995).

Many universities have relied on a single technology class to carry the burden of informing preservice teachers not only how to use the equipment and software but also how to integrate the technology into curriculum. Such is an impossible feat. It is mandatory that preservice teachers have educational experiences, throughout their preparation programs, that show how computers and related technologies can be used for instruction and as learning tools if they are to be competent using technology in the classroom (Byrum & Cashman, 1993). The need for training in teacher preparation has existed since computers initially appeared in K-12 schools. Shao (1989) reports, "Only a third of all public school teachers have even ten hours of computer training—and the time is mostly spent learning to use the machine, rather than how to teach with...But in general, little is being done to remedy the training gap—by the education colleges, school systems, or the companies that sell into this market" (p.110).

Guidelines

Assisting the infusion of technology in college of education training programs are two national organizations, NCATE and ISTE. The National Council for Accreditation of Teacher Education (NCATE) is the official council for accrediting teacher preparation programs and the International Society for Technology in Education (ISTE) is the professional education organization that is responsible for recommending accreditation guidelines to NCATE. Current guidelines were adopted by NCATE in May 1994 and presently govern the accreditation of colleges of education. Included in these guidelines are standards for teacher educators which state, "higher education faculty are knowledgeable about current practice related to the use of computers and technology and integrate them in their teaching and scholarship" (ISTE, National Standards for Technology in Teaching and Learning, p.2). In lieu of research findings and in order to meet NCATE standards, it is apparent that colleges of education must make faculty development a priority.

Technology Integration Requires Change

Change is not an event, it is a process. And as with all processes, it does not happen with a single event or even a series of isolated events. It is a gradual building of activities in a pyramidal structure leading to integration of the change as a new way of thinking and acceptance as the norm. There is resistance with any change. However, Roberts and Ferris (1994) suggest that reasons for resistance to technology integration in colleges of education are complex. There is no single culprit, but rather a myriad of barriers. Three of the most serious barriers are lack of adequate hardware and software, lack of active support from administration, and faculty who are unwilling to take the risk and make the commitment.

Initially, considerations must address the hardware/software holdings in the college. Equipment has a very short "shelf life"; state of the art equipment today becomes...
meaningful, significant changes takes considerable time. Holodick and Scappaticci (1996) suggest that making struggle with resistance will defeat the effort. Drazdowski, technology integration as a priority issue for change, the meeting the resistance. If top leadership do not place changing advancement of technology.

Funds must be allocated for the upkeep and upgrade of equipment and software to keep up with the rapidly changing advancement of technology. The active support of the administration is key to meeting the resistance. If top leadership do not place technology integration as a priority issue for change, the struggle with resistance will defeat the effort. Drazdowski, Holodick and Scappaticci (1996) suggest that making meaningful, significant changes takes considerable time and hard work by all involved stakeholders. Further, based on findings in their quest for change, they explain that "desired change occurred more effectively when department members did not feel neglected and believed that they were an important part of the decision making process, and department chairpersons were not threatened, but inspired by the special talents of their faculty." (p. 492).

Often resistance of faculty lies in their comfort with existing methods. In order for change to occur, faculties must be willing and ready to accept the importance of this change and see the personal benefit. Becoming competent and at ease, when using or modeling the use of computers, requires more than a casual brush with this technology. Roberts and Ferris (1994) report that it takes approximately 1000 hours of training for a faculty member to feel comfortable enough with technology to think about integration issues. And even after this amount of training, it is essential for faculty to commit to keeping up with the ever-changing market. This commitment of time and effort may be frustrating for faculty at any level, especially those higher ranking members that are trying to slow down during the waning years of long careers.

Rutherford and Grana (1995), suggest that the resistance to change is caused by an array of faculty fears. Included in these are "fear of change, fear of time commitment, fear of appearing incompetent, fear of techno lingo, fear of techno failure, fear of not knowing where to start, fear of being married to bad choices, fear of having to move backward to go forward, fear of rejection or reprisals" (p. 512). Roberts and Ferris (1994), after interviews with faculty members, reveal that barriers for lack of integration include: technology is not seen as important to their specialization, lack of knowledge of available hardware and software, time commitment, lack of support personnel, rapid technology changes create inability to stay current, using technology is risky and faculty find it hard to take risks, and using technology is frustrating. Other research, (Hirumi & Harmon, 1994, Galliher, 1995) support these findings.

What's Being Done and What Works?

Teacher education faculty must not only develop expertise in using the array of technology that exists but also feel competent to model its use and integrate the tools into the curriculum. Providing faculty the opportunities to learn these skills has been problematic in many teacher education institutions. (Thompson, Hansen, and Reinhart, 1996).

Research (Berliner, 1988) maintains that professional development must be continual in order for any degree of proficiency to be attained. There are various models being developed and/or practiced in colleges of education for the infusion of technology. The models that report the most success with Berliner. These models have other similarities. The similarities that report the most success include needs assessments, workshops, one-on-one training/mentoring and follow-up. Workshops and seminars provide opportunities for faculty to be introduced to various aspects of technology however the integration of these technologies into the curriculum requires more intensive training. "One shot" training sessions do not significantly effect behavior however, continued training with follow up can be effective. (Strudler, 1991; Kortecamp & Croninger, 1994; Thompson, et al, 1996). Strudler (1991) suggests that working with faculty one-on-one is the most effective method to facilitate the integration of technology into teaching and learning. Success has been reported when using this method of training for faculty using graduate technology students or faculty members as faculty mentors. Using state-of-the-art technology classrooms in professional development schools to serve the multipurpose of training preservice teachers, university faculty, and teachers and students at the Professional Development Site is also being practiced with much success.

Summary

Most teacher preparation programs are not preparing preservice teachers for instruction in the 21st century. In an information-rich society, some faculty continue to use traditional methods of instruction. In order for new teachers to be comfortable with technology, university faculty must model technology in the classroom and integrate these tools throughout the preservice preparation period. In order for this to happen, many faculty members must change. This change will be long and slow; however, with adequate equipment and software, a supportive administration, a willing faculty and a plan, the challenge of meeting the needs of students in the 21st century can be met.

Blanche O'Bannon is an Assistant Professor of Curriculum, Instruction and Leadership, College of Education, Louisiana Tech University, Ruston, Louisiana 71272. (318) 27-2766. E-mail: obannon@vm.cc.latech.edu.
We are at a point in the history of education when radical change is possible, and the possibility of that change is directly tied to the impact of the computer (Papert, 1980). Nearly two decades ago, Papert prepared us for the Information Age at the time when excitement for the potential of technology to enhance learning abounded. What he did not state is that “radical changes” are slow to occur in teacher education programs at the university level. Use of computers is pervasive in the personal lives of most college students, yet their professional preparation implementing technology in education reflects only rudimentary levels of sophistication in most teacher training institutions.

While many colleges of education require an initial technology course on basic computer literacy, too few teacher education programs have faculty who are modeling instructional methods that integrate computer technology (Handler & Marshall, 1992; Office of Technology Assessment, 1995). Teacher training programs must recognize the need for training in technology, taught either in a specific class or across the curriculum. While scholars have advocated integrating technology in both methods and foundation courses (Berger & Carlson, 1988; Billings & Moursund, 1988; Bitter & Yohe, 1989), coursework needs to be redesigned to integrate technology in courses so that computers are used in relevant contexts. Computer technology should facilitate content learning from carefully designed course goals and objectives which, then, can be developed using appropriate technology-based activities and practices (Todd, 1993).

Preservice teachers learn to teach the curriculum using the technology they have learned or seen being modeled in their college classrooms. Without role models to observe in methods courses, preservice teachers are deprived of opportunities to witness models for teaching with computers (Bruder, 1989; Fulton, 1989). According to Wetzel (1993), most college professors simply do not use it, in spite of adopted competencies that education majors should learn how to use computer productivity tools for effective instruction, and how to demonstrate that ability.

The International Society for Technology in Education (ISTE) and the National Council for Accreditation for Teachers (NCATE) have established Foundation Standards that suggest such competencies as the use and evaluation of computers and related technologies; to operate software, multimedia and hypermedia, and telecommunications to support instruction; to demonstrate skills in productivity tools for personal and professional use, to understand equity, ethical, legal, and human issues related to technology; and to stay current in educational applications of computers and related technologies. In spite of the National Standards first initiated in 1991, many universities have not adhered to these guidelines nor have they taken leadership role in this movement (Wilson, 1995).

However, this poor response to technology may be due to the fact that many college of education faculty lack the requisite skills to model teaching techniques using computers much less to infuse ISTE Foundation Standards. Therefore, it is necessary for them to receive assistance in learning how to use computers, as well as implementation of computer technology in their respective courses. Using graduate students to mentor college of education faculty has shown to be an effective technique for integrating technology into the coursework of preservice teachers (Brewer, 1995; DeWert & Cory, 1996; Thompson, Hanson, & Reinhart, 1996; Thompson & Schmidt, 1994; Zachariades, Jensen, & Thompson, 1995; Zachariades & Roberts, 1995). However, not all colleges and universities have graduate programs in technology and, therefore, do not have available graduate students to serve faculty needs.

Consequently, the use of undergraduate students as technology mentors is a viable option for addressing technological needs of college faculty members. Such a mentoring program could facilitate the development of basic technological competencies, implementation of technology in college course goals and objectives, and reflection of the mentoring process. However, the success
of any mentoring relationship is dependent upon several key factors:
1. Developmental, multidimensional relationship (Clemson, 1987)
2. “Spontaneity and personal fit” of the mentoring relationship (Clemson, 1987, p. 86). So that participants in a mentoring program have the freedom to choose one another.
3. Both the mentor and protégé should benefit from the relationship (Clemson, 1985).
4. Mutual respect and trust (MacArthur, et. al, 1995; Clemson, 1987)
6. Open dialogue between mentor and protégé allowing each participant to express their feelings, talents, knowledge and expectations (Gehrke, 1988)

The more success factors present in a mentoring relationship, the more beneficial the relationship will be to the participants.

The Study
The purpose of this study was to investigate the approach of mentoring a college of education faculty member by an undergraduate education student. Sally, a social studies methods instructor, and Jason, an elementary education major and vice president of The Educational Computing Club, were brought together because of their desire for more technology experience. Their mentoring experience took place during the Spring 1996 semester at Iowa State University. The participants were asked to try to meet at least once a week for an hour throughout the semester. Participants were interviewed, observed, and asked to keep a journal of their mentoring experiences, as well as, provide a copy of any e-mail correspondence between each other during the mentoring process. Sally was able to establish her own goals for the mentoring experience thus, providing her with an individualized learning plan. The following perspectives from the participants reveal many of the keys to successful mentoring relationships as previously mentioned.

College Instructor Mentee's Perspective
Given that one of my philosophical tenets as an educator is that the “teacher is a learner,” I was eager to interact with one of my social studies methods students who had demonstrated tremendous technological sophistication during the previous semester methods course. In fact, his class project, an interactive internet e-pal program using HyperStudio resulted in an additional two-credit independent study. I felt increasingly challenged by the need to develop my social studies methods course using technological competencies which I, admittedly, lacked.

Having had absolutely no formal coursework, in the use of technology, I was initially satisfied to use my university office computer for word-processing, e-mail messaging, and intra-university communication. My limited infusion of technology was not related to “technophobia,” but rather, to lack of understanding of what the computer can do and how technology could transform my college-level course.

Aware that I am a role model for my elementary education students and realizing preservice teachers benefit from integrated technology in their teacher training courses, I was anxious to begin to learn from my student, Jason. We established weekly meeting times and shared goals and objectives for our collaborative sessions held in my office. My introductory objectives included learning how to prepare mailing labels, access the internet, and use Word 6.0 while my end-of-the semester competencies included use of PowerPoint, HyperStudio, how to prepare a data base using FileMaker Pro, and assemble an address book in my e-mail. Notably, there were functions of the computer I did not know that I should know!

Admittedly, I had information “gaps” in my acquisition of technological knowledge. Importantly, our one-to-one mentorship provided a risk-free atmosphere to ask rudimentary questions about files, folders, menu bars, tools bars, and how an application works. Guided by my initial objectives to learn basic word processing and communication skills, Jason Kurth first provided assistance in response to my inquiries. Eventually, he introduced more complex productivity tools to present and organize information, in particular, those which would relate to my social studies methods course he’d taken the previous semester.

Once I realized that fundamental comprehension of one computer program helped me understand another and knowing that I could use an application without knowing every single feature of that program, I felt free to investigate various software applications and to progress to networked services!

Weekly journaling kept me aware of my three goals established prior to the mentorship:
1. To increase my own technological proficiencies personally and professionally,
2. To impact student learning by modeling technology integration in my class, and
3. To expect students to incorporate technology in their lessons and activities.

Throughout the semester, as I learned new skills, I was courageous enough to implement them in my social studies methods course or at professional meetings and conferences through:
• Organizing e-mail address books and groups,
• Using electronic communication with my students as well as university colleagues,
• Preparing databases of names and addresses for professional and personal use,
Undergraduate Student Mentor's Perspective

When I was presented with the opportunity to participate in this mentoring project, I was excited and accepted immediately. Opportunities such as this are rare for undergraduate students. Having taken a number of educational technology classes in my coursework and having worked in our Technology Support Office, I was ready to apply all that I had learned. At this point in my academic career, I felt challenged to “produce” or “provide” something above and beyond the usual undergraduate curriculum. Needless to say, I was eager to work with Sally, my Social Studies Methods instructor the previous semester, to help her learn to integrate technology into her personal and professional life.

During our initial meeting, Sally Beisser and I set up weekly meeting times and shared our goals and objectives for the mentorship. Sally had brought a printed list of fourteen goals she wanted to accomplish throughout the semester. I had also printed a list of my goals for the semester which were actually quite different from hers. I was participating in this mentorship with the expectations of playing a role in helping Sally become the leading example of a computer using educator for other faculty to follow. The specific goals that I printed out for our first meeting were lofty, specific, and teacher oriented. My goals addressed what I wanted out of the mentorship and not what Sally wanted. After the meeting, I realized that Sally had taken ownership of her goals, and I felt it was important to work towards meeting those specific goals rather than my own. However, I realized that my goals would still play a role in the progression of the mentorship and that they could not be totally ignored.

Initially, Sally Beisser focused her attention to learning several applications and learning a lot of the functions and features of the programs. I tried to emphasize the relationship between the applications — how various programs have similar features and functions. Towards the end of the semester, Sally began to transfer that knowledge and began to recognize the relationships between applications, and as a result, began to focus less attention on the details, thus, shifted more focus to the big picture.

A number of factors played an important role in the success of this mentorship: positive reinforcement, attention to individual goals, one-on-one working relationship, and communication. The relationship between Sally and myself was extremely positive. I would give her positive reinforcement, not only during our sessions, but also in my e-mail correspondence with Sally between sessions. And Sally was such a great role model by the way that she was always giving me, the teacher, positive reinforcement.

Sally came into this mentoring relationship motivated by the desire to attain technology goals relevant to her personal and professional lives. Thus, my decision to focus our attention on Sally’s goals and objectives made each session personal and relevant to her. If I had only focused on my own specific goals, the entire mentorship would have lacked relevance, and Sally’s interest would have diminished quickly.

There is little doubt that our one-on-one working relationship was a key factor in our success. Working in this situation, we were able to form a positive relationship,
not only a professional but a personal friendship, too. Developing such a positive relationship helped make this a truly enjoyable experience for both of us. Because we worked one-on-one, both of our needs and concerns were addressed immediately, as opposed to a workshop setting, where it is typical of participants to become frustrated when help is not immediately available. Another benefit to working one-on-one is that our total attention was on the task at hand, thus allowing us to make significant progress in a short amount of time.

Communication was also a major factor in the success of our mentoring relationship. We were in constant communication with each other, either by seeing each other in the halls or via e-mail. Oftentimes, I would send Sally a brief synopsis of what we had done and what we/she accomplished during a session. I would occasionally provide a quick review, sometimes outlining the basic steps involved in completing a particular task, and at other times even send her homework! Though not very many undergraduates have the opportunity to send their professors homework, I felt it was important Sally spend time working with technology during times other than our sessions. While one factor may have weighed more heavily in our success, it was the combination of factors that accounted for our overall success.

**Future Implications**

The reality is that many teacher preparation programs do not have graduate students to mentor faculty on the use of technology as seen in a number of studies mentioned above. Encouraging teacher education faculty and new teachers to use technology in teaching and learning is possible using effective mentoring with undergraduate students to increase technological competencies and applications in teacher preparation courses. One-to-one mentorships can provide cost-effective, personally-rewarding experiences for both students and faculty with motivation and freedom for faculty to learn at their own pace. The mentorship team can explore and investigate responses to individual technological needs, address challenges of complex and open-ended problems, rely on inquiry and invention rather memorization of procedures in instruction manuals. As Harrington (1991) suggests, there is a difference between preparing teachers to use technology and using technology to prepare teachers. If we only prepare teachers to use technology we limit the conception of the role of technology in education. Empowering undergraduate students as facilitators of technological learning experiences for university faculty enables both to take more responsibility for acquiring technological competencies. It's a win-win solution. Papert would be proud.

326 — Technology and Teacher Education Annual — 1997
As we get closer to the 21st century we see an emphasis placed on technology in education. Recent trends show "a new insistence that teachers must become technologically literate" (Ely, Blair, Lichvar, Tyksinski, & Martinez, 1996, p. 33). Unfortunately, colleges of education are not adequately preparing teachers to use technology in the classroom. This situation is due, in part, to the fact that faculty are often not able to model its use (Wetzel, 1993; Staman, 1990). New Mexico State University has implemented a pilot program using masters and doctoral students in the “Learning Technologies Program” to mentor faculty one-on-one to integrate technology into their courses.

Preparing preservice and inservice teachers for an Information Society where technology plays a prominent role requires that education faculty be knowledgeable about technology resources and model their uses. Yet, research indicates (Colon, Willis, Willis, & Austin, 1995; Office of Technology Assessment [OTA], 1995) that teachers do not feel adequately prepared to integrate technology into their teaching. According to the OTA study, technology is not a central part of the teacher preparation experience in most colleges of education, despite its importance to teacher education. Most new teachers graduate with limited knowledge of how to integrate technology into their teaching.

In recent studies, faculty identified lack of knowledge about software, time constraints, and limited recognition of technology’s potential as obstacles to effectively integrating it into their curricula (Wetzel, 1993; Staman, 1990). For many college of education faculty, technology experiences have been bad at best. These faculty often receive outdated hardware and non-supported software. In other words, castoffs from other departments where technology use among faculty is considered mandatory. To further complicate matters, on some campuses computer science departments supply the only training available. Unfortunately, these trainers may carry preconceived ideas about college of education faculty and their ability to acquire the necessary skills to integrate technology.

Willis (1993) argued that questions about hardware, software, and teacher training are no longer the most important topics in educational technology. Today the major issues are related to instructional strategies, instructionally appropriate software, training and support as a process, and facilitating organizations. A study by Oke (1992) found that teacher training in the application of technology in education, not familiarity with technology, must be emphasized in preservice teacher education.

The literature on the use of technology by college of education faculty comes to the same conclusions as the literature regarding technology and the K-12 faculty. If technology is to become the tool of choice for learning and information sourcing its use must be modeled by faculty and administration members alike. In order for this to occur, an environment of support and commitment needs to exist at the university and within the department for faculty to be exposed to, acquire and implement technology into their course work. Other institutions have found mentoring to be an effective way to encourage their faculty to begin integrating technology into their courses (Thompson, Schmidt, & Hadjiyianni, 1995). At New Mexico State University (NMSU), we have implemented a pilot program using masters and doctoral students (who are experienced teachers and users of technology) in the “Learning Technologies Program” to mentor faculty one-on-one.

Pilot Faculty Mentoring Program

We began our pilot program in the fall of 1996 with five faculty members and five graduate students matched up by area of interest and expertise. The participating faculty, all volunteers from Curriculum and Instruction Department, include a literacy educator, a bilingual educator, a multicultural educator, an ESL educator and the department chair. Each faculty member and each
graduate student has written up a set of goals to be accomplished during the semester. They meet each week face-to-face for approximately two hours to work towards these goals. The goal of the program is that when the semester is complete, the faculty members will feel comfortable integrating technology effectively into their courses. In the spring of 1997, we will interview the faculty members and visit their classes to see how they are progressing with their technology use. Below we will review tendencies in technology use in multicultural and literacy instruction and relate them to the mentoring relationships.

Multicultural Education

Multicultural Education and Technology. The curriculum of the twenty-first century will be driven by: (a) the shift from an industrialized, print-driven age to an information, computer-based age, and (b) the increasing diversification of the United States (D’Andrea, 1995). The need for a new technology oriented multicultural curriculum calls for preservice teachers to both master technology skills and understand the concepts of culture and cultural diversity.

The central role of schools of fostering academic success for all students and multicultural education represents a promising means to achieve this goal. Being multiculturally literate requires being respectful of the history, traditions, and values of people of diverse backgrounds. Teachers and teacher educators in today’s schools, with their diverse cultural and linguistic populations, have the challenge of developing curricula for their students that is meaningful, interesting, and engaging. Technology offers opportunities for success in this endeavor for students and teachers alike (Gonzales, 1992).

Garcia (1993) argues that the use of technology in multicultural education is the return to the earliest form of information delivery: one-on-one communication. When interactive systems (interactive video, hypermedia, and hypertext) are used in the classroom, both teacher and students are continually adapting the learning process to reflect individual needs, interests, and past experiences. Technology also allows educators to alter content for level of difficulty, or mode and speed of presentation. No two students need be treated alike, and individualization can become the norm.

The Multicultural Graduate Mentor’s Experience. One of the major goals of the mentoring experience with the multicultural educator was to learn some management techniques to aid in becoming more comfortable with technology. At the beginning of the semester, the biggest problem reported by this faculty member was her student’s resistance to using technology. She also felt somewhat uncomfortable using the computer in a professional or classroom setting.

After the initial meeting, it was found that the professor used the computer to explore the Internet and to use her email account. Students in her classes were required to keep electronic journals. As a multicultural educator, she is concerned with the depersonalization of education, and one of her fears was that the technology of electronic journals may feel more impersonal. Her fears were allayed by the recognition that the journals were more contemporary, more current and alive.

During the semester, the faculty member and the doctoral student explored various pieces of software and found HyperStudio to be the most advantageous for her work. Prior to this mentoring experience the professor was using the lecture method as a means of instruction. Although she did not feel comfortable just lecturing, she did not know another effective way to introduce the course material. With the use of technology, she now has a more interactive method of instruction available to her and her students.

Another important aspect of the relationship between this faculty member and the doctoral student was the open dialog characteristic of every meeting. Dialog centered not only around technology, but around multicultural education and how it affects every aspect of life in society. The doctoral student gained multicultural insights from this mutually beneficial experience.

Near the end of the semester, the professor was asked what she planned to do with technology in the future. Her plans included finishing her HyperStudio project, asking students to evaluate software using multicultural standards, and keeping the electronic journals. Above all, she realized that professors are the students’ role models when integrating technology into the curriculum. Now that she has had this mentoring experience she feels more comfortable modeling its use.

Literacy Education

Literacy and Computer Technology. To understand the relationship of computer technology in reading and language arts today, there needs to be a review of some of the problems of the past and a preview of future potential alliances. In the late 1960s, the 1970s, and the early 1980s, educators frequently viewed reading and reading comprehension as a set of discrete skills. Reading instruction often focused on the teaching and practicing of individual skills (Cooper, 1997). The efficacy of this kind of approach to reading instruction was seriously questioned (Goodman, 1965; Rosenshine, 1980; Smith, 1971), which led to a strong movement during the late 1980s and the early 1990s to view reading and writing from a more holistic perspective. From this vantage point, authentic experiences, referring to reading with real texts with real, student-centered purposes, was of paramount importance.

Reading and computer technology trends were not moving in synchrony. When many reading and writing
programs had been skills oriented, there was little or no computer access in classrooms. When hardware and software access became more commonplace, the computer programs supported more traditional teaching and skill development (Neill & Neill, 1990) which was not adopted in the classrooms by holistic, literature-based trends in reading. Maddux (1993) stated clearly that the field of educational computing had been plagued by an abundance of poor quality software.

New software trends and hardware capacity of the 1990s often: (a) provide for student-centered, open-ended features, (b) encourage interactive responses and active intellectual involvement, (c) incorporate full length reading text, (d) support the writing process, (e) require problem solving, and (d) include interactive multimedia (Thompson & Montgomery, 1994).

Reading and language arts educators are currently more likely to embrace what technology has to offer. Galloway (1994) determined that students were motivated and interested by the inclusion of multimedia video prompts in the writing process. Others (Boone & Higgins, 1992; Davis & Shade, 1994) suggest applications for integrating hypermedia with content area reading and writing; and Reilly (1994) confirms positive effects of students composing and producing their own multimedia video images. Electronic books also may provide distinct advantages to readers by extending opportunities for interaction between the students and the story (Sharp, 1996; Harrington-Lueker, 1996). Sharp reports that electronic versions of well-authored text can expand and support print by both capturing the children's interest as well as fostering skills.

The Internet increases ways teachers can transform classroom projects, such as with research support services like ERIC and WWW search tools (Black, Klingenstein, & Songer, 1995). Another form of Internet use is expanded through electronic journaling. For example, a study of a reading education class reports positive uses of electronic mail which increased reflection and visions of email as a pedagogical tool (Anderson & Lee, 1995).

The recent trend in reading education appears to be towards a balance of the skills tradition and holistic methodology, and an expanding concept of literacy that includes technology in preparing students for the “real world” (Cooper, 1997). Technology is now more in synchrony with the search for authenticity in the reading and language arts arena, and there are multiple ways in which reading and technology can interface (Willis, Stephens, & Matthew, 1996).

The Literacy Graduate Mentor’s Experience. The literacy professor and her mentor have established a working relationship integrating technology into the reading courses. Initially using the mentor to model the integration of technology into language arts classes as a “guest speaker,” the professor has progressed to using the mentor as a consultant. Multiple uses of technology have been presented and utilized by preservice teachers in many ways such as newsletters (Bilingual Writing Center, 1992), multiple charts and posters Print Shop Deluxe (1992), laserdisc technology in combination with Hyperstudio (1995) and Desert Classroom (1994) programs, story writing with My Own Stories (1993) and Storybook Weaver (1993), email journaling, and Internet searches.

The mentor facilitated this kind of integration by previewing materials, modeling, and problem-solving in private two hour sessions each week. The department of Curriculum and Instruction was supportive by providing a multimedia teaching classroom and near-by labs with both Macintosh and IBM formats. The mentor supplied the technical basics for using this classroom. With this kind of support, the professor was able to redesign teacher preparation curriculum in reading and writing instruction to incorporate computer technology. Having success with the preservice teachers, the professor has achieved a confidence level to continue this kind of integration in future classes. Specifically, she desires increasing the use of the Internet and multimedia possibilities.

Conclusion

If faculty members are comfortable with technology, they are more likely to integrate technology into their curriculum. The one-on-one interaction between doctoral students and faculty members may present a viable solution to increase faculty technology knowledge concordant with their needs and/or interests. From this relationship, doctoral students also gain from the close interaction with different faculty members who share their expertise and model behaviors for the future professors.

330 — Technology and Teacher Education Annual — 1997
The purpose of this study was to see if using electronic mail (e-mail) would open another channel of communication to graduate students. Interrelationships between faculty and students contribute to the success of the graduate student (Galbraith & Zelenak, 1989). Mentoring is a one-to-one relationship between mentor and mentee which can help mentees develop their personal, educational, or career potentials. Since electronic mail is one way people can relate on a one-to-one basis, it was hypothesized that a mentoring relationship through electronic mail could lower the alienation felt by many graduate students in a commuter university, and lead to higher achievement and attitudes toward academic classes.

Model: Force Field Analysis of Mentoring

Lewin’s theory of force field analysis was applied to the concept of mentoring graduate students. Lewin (1935, 1948) developed the model of various forces (negative and positive) acting upon an individual. The same forces may vary in direction (whether negatively or positively affecting the individual’s attainment of the goal) and in intensity (strength of force or drive in steering individual toward the goal). Figure 1 shows a typical graduate student with some negative force fields such as finding time to schedule class time along with work time, the stress of finding time to study, the financial costs of college, and the loss of family and personal time. Positive forces would be external motivations (such as better jobs, increases in salary, and increased opportunities for job promotions) and internal motivations (such as self-esteem, confidence, career satisfaction, and the overall quality of life). This example shows forces of differing lengths. By increasing the strength of positive forces, and/or reducing the strength of negative forces, the student can attain the goal of graduation.

Statement of The Hypothesis

This study emphasized the positive forces of a good mentoring relationship as contributing toward a student reaching the immediate goal of completing the class successfully. This study proposed to see if this mentoring can be accomplished through e-mail, and if mentoring by e-mail can be an effective way of increasing student achievement and student attitude toward the course and educational research in general. Therefore, it was hypothesized that (1) students receiving mentoring e-mail messages would score significantly higher on an instrument measuring attitudes toward educational research than those not receiving mentoring e-mail messages, and (2) students receiving mentoring e-mail messages would score significantly higher on objective exams covering the research material than students not receiving mentoring e-mail messages.

Method

Subjects

Sixteen males and 83 females from four graduate level educational research classes at a state university were randomly assigned to one of two e-mail treatment groups (Hubschman, 1996). One group received mentoring messages through e-mail, and one group received neutral messages through e-mail. Mentoring e-mail, which was defined as e-mail that includes one or more of the qualities of establishing trust, offering individualized advice, introducing alternatives, challenging the mentee, motiva-
The Hardy Educational Learning Profile (HELP) was a self-administered and self-scored cognitive learning style instrument designed especially for adult populations. The purpose of the profile was to determine one's preferred style of learning (Hardy, 1995). The first page consisted of instructions and demographic information. The second page was a worksheet displaying word pairs according to the three cognitive dimensions of interaction, gathering information, and processing information. The third page was the self-scoring design. The last page was a summary of cognitive learning styles according to one's self-scoring. The scale for introversion/extroversion was scored on a range of 10-60 with scores toward the higher end indicating someone who was outgoing and verbal, eager to discuss and debate, and learning through action and doing. Scores toward the lower end would indicate a reserved and nonverbal person, and one who likes to reflect and listen.

E-mail and Course Evaluation Survey. An e-mail and Course Evaluation Survey (Hubschman, 1996) was administered at the end of the treatment. This qualitative dimension asked for students' attitude toward e-mail, attitude toward the course, and any general comments they had about the course or treatment groups. Student anonymity was protected.

Procedure

Two sections of the introductory graduate research class were taught by the researcher, and the other two sections were taught by different colleagues. The same textbooks were used, and the same objective midterm and final were given to all four evening classes. The researcher obtained mainframe computer VAX accounts (VAX) so that the students in all four classes were able to send and receive e-mail the first night they went to the computer lab. A Congratulatory Letter from the researcher was individually sent to each member in the randomly assigned control group. E-mail and Course Evaluation Survey. An e-mail was individually sent to each member in the randomly assigned control group. Neutral e-mail, which was defined as messages that relay general information in an impersonal, generalized way, was individually sent to each member in the randomly assigned control group.

Data Collection Instruments

Attitudes Toward Educational Research Scale. The Attitudes Toward Educational Research Scale (ATERS) was developed by Isakson and Ellsworth (1979) in order to develop a measurement instrument that would assess the attitudes toward educational research of teachers who are enrolled in an educational research class. Fifty questions were arranged in a Likert-type scale (5 points, from strongly agree to strongly disagree) to measure teachers' attitudes toward educational research.

Hardy Educational Learning Profile. The Hardy Educational Learning Profile (HELP) was a self-administered and self-scored cognitive learning style instrument designed especially for adult populations. The purpose of the profile was to determine one's preferred style of learning (Hardy, 1995). The first page consisted of instructions and demographic information. The second page was a worksheet displaying word pairs according to the three cognitive dimensions of interaction, gathering information, and processing information. The third page was the self-scoring design. The last page was a summary of cognitive learning styles according to one's self-scoring. The scale for introversion/extroversion was scored on a range of 10-60 with scores toward the higher end indicating someone who was outgoing and verbal, eager to discuss and debate, and learning through action and doing. Scores toward the lower end would indicate a reserved and nonverbal person, and one who likes to reflect and listen.

E-mail and Course Evaluation Survey. An e-mail and Course Evaluation Survey (Hubschman, 1996) was administered at the end of the treatment. This qualitative dimension asked for students' attitude toward e-mail, attitude toward the course, and any general comments they had about the course or treatment groups. Student anonymity was protected.

Procedure

Two sections of the introductory graduate research class were taught by the researcher, and the other two sections were taught by different colleagues. The same textbooks were used, and the same objective midterm and final were given to all four evening classes. The researcher obtained mainframe computer VAX accounts (VAX) so that the students in all four classes were able to send and receive e-mail the first night they went to the computer lab. A Congratulatory Letter from the researcher was waiting when they first accessed their VAX account. The researcher started the mentoring relationship by taking the initiative in establishing a relationship that is conducive to open communication. Questions were asked about the advisee's interests, goals, and reasons for pursuing graduate study, and when the student preferred to be contacted. It was expected that those in the mentoring e-mail groups would reply to, and compose, more e-mail than those in the neutral e-mail groups. It was also expected that introverts would reply to, and compose, more e-mail than extroverts.

Results and Conclusions

Hypothesis One. Hypothesis One stated that there would be a significant main effect of method of e-mail communications treatment on the students' attitude, as measured by the ATERS. Table 1 shows the factorial analysis of method of treatment and level of introversion/extroversion as independent variables, and score on the ATERS posttest as the dependent variable. Neither main effect (group or level of introversion/extroversion) nor interaction of group and level of introversion/extroversion was significant at the .05 level of significance.

Table 2 shows the means on the ATERS posttest of the introverts in the mentoring group, introverts in the neutral group, extroverts in the mentoring group, and extroverts in the neutral group. Extroverts in both treatment groups scored higher on the attitudes posttest than introverts in both groups. Extroverts in the mentored group scored approximately 1 point higher on the ATERS posttest than extroverts in the neutral group. Introverts in the mentored group scored almost 9 points higher on the posttest than those introverts in the neutral group.

Our conclusions relative to Hypothesis One are as follows: Although there was not a significant difference in the main or interaction groups of method of e-mail communication on attitude toward educational research, introverts in the mentored group had higher attitudes toward research (by almost 9 points) than introverts in the neutral group. Extroverts scored higher than introverts in both groups.

Hypothesis Two. Hypothesis Two stated that there would be a significant main effect of method of e-mail communications treatment on the students’ achievement, as measured by multiple choice final exam grades.

Table 3 shows the means for final exam scores, broken down into treatment groups and interaction between treatment and level of introversion/extroversion. Extroverts achieved higher final exam scores than introverts in both treatment groups (51.57 for mentored, 52.02 for neutral). Introverts scored almost two points lower in both treatment groups (49.01 for mentored, 47.75 for neutral). Introverts in the mentored group had higher scores than those in the neutral group, though not to a significant degree.

</table>

Our conclusions regarding Hypothesis Two are as follows: Although no significant difference was found in main or interaction groups of method of e-mail communication on achievement as measured by the objective final exam (by using a factorial analysis), introverts in both groups scored higher than introverts. Mentored introverts had higher scores on the final exam than introverts in the neutral group.

Responses to E-mail by Treatment Group. The factorial analysis of variance (ANOVA) shown in Table 4 shows that the mean responses of the mentored group was 6.89, while the mean responses of the neutral group was 3.09. Introverts responded more often to e-mail messages, whether they were in the mentoring or neutral treatment group.

Discussion of the E-mail and Course Evaluation Survey

The five-question e-mail and course evaluation survey was administered to all four classes at the end of the term. Since the surveys were completed anonymously, breakdown of replies by treatment groups was not possible.

Positive and Negative Aspects of E-mail. Replies to the positive and negative aspects of e-mail were combined in the first two questions. Responses varied from lack of time to lack of interest. Students mentioning lack of time referred to the fact that no extra credit was given for using e-mail, and that not enough time was given in teaching the fundamentals of e-mail. Some students felt that more of the course should have been interrelated to e-mail by posting assignments and articles on e-mail. Other students mentioned that they didn't have computers or couldn't find computers in the lab, or that their computers at home or work didn’t have modems. Other students mentioned they were computer-phobic, and couldn’t relate to the new technology.

These negative impressions of e-mail correspond to the research which mentions problems of integrating e-mail into the curriculum (Meacham, 1994; Yao, 1993). It is anticipated that as more computers are sold with modems to connect to the Internet, and that as more students are
required in classes and the workplace to use e-mail, that this problem will be resolved.

Positive responses to the use of e-mail included the opportunities to get quick responses to drafts of papers and questions, the convenience of communicating without having to meet in a certain place at a certain time, the uniqueness of learning something technology-related, and the rapport developed between teacher and student. This corresponds to literature on e-mail (Berge & Collins, 1995; Velayo, 1994) which mentions that some students might find e-mail a more comfortable outlet for expressing their feelings.

E-mail's Effect on Attitudes Toward the Class. The third question asked if the e-mail affected attitudes toward the educational research class. A relationship between e-mail usage and educational research was mentioned by 29 students; no relationship was said to exist by 35 other students. Students expressing a positive relationship mentioned the connectedness to the course, the teacher, and the college. Being able to get research information to and from other students, and finding it easier to ask questions and get advice through e-mail rather than in class were also mentioned. The majority of the responses mentioned no relationship between e-mail correspondence and attitude toward educational research. They ranged from "No, e-mail is fun, while educational research isn't," to "No, I enjoy educational research with or without e-mail."

Since the answers to this question were not grouped by treatment group, it is hard to say if the mentoring e-mail group would have answered in a more positive way than the neutral e-mail group. The premise of this study was that mentoring through e-mail would also develop this positive attitude. It appears that at this time teachers who wish to incorporate e-mail in their course should add it to their syllabus. Self-directed students will seize the opportunity to learn; those who do not feel that it applies to the particular class will avoid the situation. By planning time for computer instruction and finding a location where computers are available, teachers can assure that all students are comfortable with e-mail communication. Articles and general information can be sent to the class. Questions can be sent to students, and they can send the answers back by e-mail.

Discussion of the Qualitative Analysis of Mentoring and Neutral E-mail Responses

Students in both the mentored and neutral groups used e-mail to ask questions related to e-mail, exams, to get feedback on research paper tasks, and to thank me for sending them information. Both groups used the one-to-one correspondence to confide personal information, and both groups sent me information they thought would be useful to me. Research supports the use of e-mail as another outlet for communication (Berge & Collins, 1995), and the positive effect of mentoring for both the mentor and the mentee (Confessore & Confessore, 1992; Daloz, 1986). The teacher had more individualized time with students, and could provide more advice and alternatives tailored to the individual student, and, in some cases, challenge and motivate individuals to grow mentally and/or professionally (Cohen, 1995).

For the duration of this study, this researcher logged onto the mainframe computer and read and responded to e-mail messages three times a day on weekdays, and at least once daily on Saturdays and Sundays. It was hoped that prompt responses to e-mail would be positive reinforcements to continued e-mail. More messages from the mentoring e-mail group dealt with personal feelings and comments, while more responses from the neutral group wanted specific information on using the computer or my feedback on their research paper.

Summary

Even though this study dealt with the effect of mentoring e-mail on students, it can be seen that those in the neutral e-mail group also benefitted from the one-to-one correspondence. The opportunity to communicate at a time and place convenient to the student, and the knowledge that affirmation of that message would be sent within 24 hours was used by students, whether they were in the mentored or neutral groups, and whether they had been classified as introverts or extroverts. It is suggested that e-mail communication be considered in other situations. E-mail can be of benefit to the student at various levels. The lower levels of relaying general information about the class and the university can be used. Higher levels of communication would include one-to-one communication and discussions among research groups. At the highest level of communication would be the mentoring opportunities, and the chance to guide and challenge the student to envision and achieve higher goals.

Implications

The implications of these findings are that mentoring might be a positive way for teachers to communicate with graduate students, for it was found that those in the mentored group communicated more often than those in the neutral group on matters concerning class activities and personal situations. In addition, introverts in both the mentored and neutral groups responded more often than extraverts to e-mail messages from the researcher. Qualitative analyses of anonymous comments by students and e-mail messages from both the mentored and neutral groups revealed the benefits of e-mail to those who used it. Finally, it was noted that more than 50% of the students in the study did not respond to any e-mail messages from the researcher.
Recommendations

The conclusions and implications drawn from this study serve as a basis for several recommendations. These fall into two categories: recommendations for educational practice and recommendations for future research.

Recommendations for Educational Practice
1. Students should be given adequate hands-on time during class to learn the basics of e-mail before being asked to use e-mail for communicating.
2. Students should have more access to computers. Over time it is expected that more students will own computers capable of connecting by modem to the university mainframe. Until that time, more computer labs should be available to students.
3. Teachers should require e-mail usage in their classes, to insure greater participation. General information can be distributed to a class via e-mail.
4. Teachers should send mentoring e-mail messages to their students in order to increase the positive one-to-one relationships needed by adult learners.

Recommendations for Future Research and Theory
1. Research should be conducted in a classroom situation where e-mail is an integral part of the course, so that student access to computers is not an intervening variable.
2. Research should be conducted with a greater sample size, so that gender can be included as an independent variable.
3. Future research should explore the lower scores in achievement and attitudes toward educational research of introverts, as compared to extraverts.
4. Future research should explore the variables responsible for student nonresponse to e-mail, such as computer anxiety and learning styles, so that educators can find ways to reach these students.
5. Follow-up studies should be done to see if the mentoring relationship established for this research through e-mail continues.

Declining budgets in post-secondary settings have led to a corresponding reduction in secretarial assistance to instructional staff. Faculty members are suddenly finding themselves with a computer and are expected to produce documents that have a professional appearance. In response, they are throwing their hands up in frustration, as their lack of knowledge and experience in page layout places them at a significant disadvantage. For individuals accustomed to being in control, this situation may also contribute to the reluctance of many to utilize the available technology. Some faculty have openly stated that if they simply refuse to do it, the university will have no option but to return secretarial support to the levels to which they had come to expect.

Too often, professionals have taken for granted the skill that has resided in their secretarial pool when it comes to producing a polished looking document, even something as simple as a letter. Now, suddenly placed in the role of having to duplicate these same results through their own efforts, it has become obvious that office professionals were doing more than “just typing.” An attractively designed letter, syllabus, or paper is a professional’s calling card, their representative to another individual when personal contact is not always possible. A good impression is important.

The Challenge

Within every institution or setting, there tends to be a spectrum of personal skill when it comes to technology. When focusing on those who display reluctance to involve themselves with computer technology, one of the most frequent comments is that it wouldn’t make sense for them to spend time using the computer because they are unable to type. Naturally, the urge is to suggest a popular, computer-based typing program which would assist them in acquiring the skills. There is no doubt that the individual who can touch type has an advantage when it comes to producing a document. Exploring further, though, is important. Given that they would have low to moderate keyboarding skills, the next question arises, what are they going to do with them?

Knowing how to operate a kitchen machine doesn’t make one a chef. In the same vein, knowing how to type doesn’t necessarily guarantee an attractive final product. Yet, it is often presumed that before someone can produce a piece of which they will be proud, they are first going to have to master keyboarding. Perhaps the reverse is really the way around this. Show a professional how to produce an attractive document their first time out, and just maybe that will serve as the incentive to become more skilled at both keyboarding and computer technology.

Let the final product be the incentive rather than the diligence to master keyboarding eventually leading to a reward. Your aim is to motivate and as Boylan (1996) states, motivation creates momentum. Motivating someone creates “an energized attitude” which in turn leads to motivation. “What’s motivation? Getting people excited so that they act in a focused direction” (Boylan, 1996, p. 157). Institutions need to find an array of possibilities that might serve to motivate and engage the individual at the person level. Change may be mandated from top-down but lasting change only occurs from the inside-out. The individual is the lowest common denominator in the change process, and the most powerful.

Implications

A private conversation with a dean at a large university recently revealed that this issue is having larger ramifications for post-secondary institutions. His own college had faced secretarial cut-backs a couple of years before, and faculty were now producing their own documents without guidance. It wasn’t until he encountered samples of these documents out in the community, that he realized that faculty knowledge of page layout was impacting on the impressions people were forming of the university. He saw this as a more serious issue when it came to competing with surrounding institutions for students, especially when it came to contract classes, which are situations where businesses or school districts have a population of students drawn from their work place settings and universities are contracted to provide the instruction for those individuals. His concern was that outside agencies would interpret a poorly designed document as reflecting the skill level of the faculty at the institution.
Williams (1994) produced an excellent resource that addresses the needs of novices, *The Non-Designer's Design Book: Design and Typographic Principles for the Visual Novice*. In the opening statement the author, speaking from the perspective of a professional designer, says the book was produced for students who understand that a better-looking paper often means a better grade, the professionals who realize that an attractive presentation garners greater respect, the teachers who have learned that students respond more positively to information that is well laid out, the statisticians who are seeing that numbers and statistics can be arranged in a way that invites reading rather than sleeping, and on and on (Williams, 1994).

The point is that the design of a document is an important issue, that it does have an effect on the way information is received, and, at the heart of that, it may combine with personal reluctance to form another barrier to impede effective utilization of technology among post-secondary instructors with limited skills.

**Is There Another Way Of Looking At This?**

Rather than view this refusal to adopt technology as a sign of lack of cooperation, it is more important to see it as an ego-protection device. Highly educated individuals, unaccustomed to feeling inept, are suddenly placed in situations where they have limited, if any, support and little experience. Culbert (1996) argues that the key to motivating individuals to change is understanding the psychological perspective of that person. How do they see what's happening? "Self-interests and personal, work-related effectiveness agendas significantly impact - even wholly determine - how people see events at work, and ultimately how they think to operate given those perceptions" (Culbert, 1996, p. 30). He points out that all people wish to be seen as competent and effective in both their work place and personal settings.

While every institution needs to communicate a vision of where they want their people to be, and the goal they are striving to fulfill, Culbert (1996) reinforces the importance of the individual in this process. Instead of pointing to a mark on the wall and telling someone that's what they're going to have to aim for, he suggests administrators need to look at where the person really is. His advice is to "engage them where they actually are" (Culbert, 1996, p. 33) and facilitate ways of having them incorporate the larger vision into their personal agenda. So, when it comes to getting faculty to use computer technology for everyday tasks, what is the pay-off for them?

The budget cuts that have reduced secretarial support are not likely to be reversed any time soon, so that faculty have no choice but to take personal ownership for much of their work. At the same time, these individuals also want their work to be seen in a positive light, an important aspect of which is a professional look. Practicality suggests that running all faculty through a design course is not feasible. Apart from heavy workloads limiting available time to fit in another workshop or meeting, design is not only a skill, it is a talent. Recognizing that mastery of page layout will be uneven among faculty, how then can institutions facilitate people producing documents that reflect well on the individual and the institution? How can administrators give faculty, especially the reluctant user, the confidence and ability to produce an attractive, credible document their first time?

The answer to the question is far simpler than it appears. Surprisingly, a tremendous number of people using common word processors are not aware of the page layout features built into the software. Even reluctant beginners can produce a newsletter or brochure that compliments their professional selves. People have tended to use the word processor as a typewriter without a carriage return resulting in underutilization of the many features that can make the job easier and the results quite professional-looking.

Recently, a faculty person with very limited computer skills, saw a newsletter this author had produced. Complimenting the final product, the faculty person commented that they would never be able to produce anything like that. Knowing the computer system that had recently come to reside on the individual's desk, the author pointed out that if the faculty person wanted, she, too, could produce a document that was a mirror image of the one she was presently admiring without having to know much more than how to type in the content. The secret is templates.

**A Look At The Possibilities Of Templates**

All of the major word processing packages residing on faculty desks including Microsoft Word, Corel WordPerfect and Lotus Ami Pro, have built-in templates. These templates are professionally designed documents covering a variety of tasks, including business letters, brochures, newsletters, signs, and a number of other categories. Most of the latest versions also include the ability to convert certain features to HTML. In addition to those already in the software packages resident in the building, commercial design packages are also available for purchase, and many cover a vast array of possible projects.

The only effort required on the part of the end-user is the content. A faculty person can call up the newsletter template (usually there are three or four designs to choose from), follow the on-screen instructions, enter their information, and a while later, they have a beautifully designed document. A complete novice to word processing will need some assistance to get up and going to use templates, just as they would regular word processing.
facing a blank screen but the end result is what is different in the two scenarios.

The valuable feature about templates is that they can also be generated locally. Faculty are required to fill-in countless forms every year. Electronic templates of these forms can be easily produced and distributed to faculty, decreasing effort. Another point to consider is that faculty supervising students have a variety of communication tasks, many of which are common to all colleges. Producing a document template for each situation assures administrators that students are all receiving the same core information, while at the same time, allowing faculty opportunities to personalize the letters, yet cutting down the time required to produce them. At the most rudimentary level, templates incorporating the institution’s letterhead can be stored in electronic format so there’s never the need to hunt for the right stationery again.

Most high-end word processing packages also allow for the incorporation of “macros” into documents. This would allow templates to be produced which would prompt the user for information. Think of it as word-processing with a guide.

Finally, use of templates also serves as a teaching function. Using professionally designed templates exposes faculty to models of how documents should look. They learn that a Times Roman font is more appealing than a Courier font. They see how professionals would design a page. Inevitably, they will begin to utilize some of those same features when they produce their own original work.

Templates are nothing amazing. In fact, they’re very ordinary. But most faculty are unaware that they have such powerful and flexible assistance only a couple of mouse clicks away. As technology, regardless of its sophistication or complexity, is fundamentally a tool, the critical question for most in higher education is whether a given tool can improve the caliber of their work. As templates address issues of format and layout, instructors can be freed to focus on the clarity of a document’s content. If an attractive product that clearly communicates has been produced by leveraging their existing skills rather than demanding that they acquire new ones, faculty may regard the technology as an empowering tool rather than an impending threat. Thus, readily available templates can be valuable tools in reaching faculty who need to master technology skills and don’t know where to begin.

Established in 1963, the University of Central Florida (then called Florida Technological University) began classes in October 1968 with an enrollment of less than 2,000 students. Today UCF is a metropolitan university that has five colleges, two branch campuses and a downtown center that serves over 28,000 students. The institution has had a history of ad hoc distance learning activity to serve specific populations over the years. In the summer of 1996, an initiative was made by Academic Affairs in the Provost’s office to begin a systematic process of faculty development for the creation of on-line courses within certain academic programs. The success of this faculty training has lead to rapid institutionalization of distance learning with an emphasis on faculty development.

Demographics in Florida

Enrollment projections in the State of Florida indicate that an increase of 35% is anticipated between the years 1990-2001 for graduating high school seniors (State University System Addendum to the Master Plan 1993-94 to 1997-98). These figures do not take into consideration the numbers of adult students returning to school. The need for alternative delivery systems is evident. The state task force on distance learning defines distance learning as:

Planned learning that normally occurs in a different place from teaching; as a result of the separation of learning and teaching, special techniques of course design are required, as well as special instructional techniques and special methods of communication by electronic and other media (State University System Addendum to the Master Plan 1993-94 to 1997-98, p. 2).

Factors Leading to Delivering On-line, Interactive Courses

The University of Central Florida has six feeder community colleges in its service area. These schools and UCF serve 11 counties within the Central Florida region. A consortium among UCF and these six community colleges was established in the late 1980s, called the Central Florida Consortium of Higher Education (CFCHE). The Consortium applied for and received one of five distance learning demonstration projects awarded by the State University System in 1995.

The Consortium’s Distance Learning Demonstration Project had three areas of interest: faculty development, learner support and a survey course. Advisory committees were created with participants from every member school. The authors were also involved with the Distance Learning Demonstration Project. Steve Sorg was the executive director of the Consortium and Barbara Truman was the Consortium’s communications specialist and webmaster. The Demonstration Project brought together faculty and staff from the seven institutions on a regular basis to collaborate on identifying common needs and goals for distance learning.

During the year-long project each advisory committee researched and participated in forming and fulfilling distance learning objectives. The Faculty Development Advisory Committee created a survey instrument for assessing the knowledge of, use of, and attitudes toward technology and distance learning. Next, introductory, intermediate and advanced workshops on distance learning were conducted at various institutions within the Consortium. The Learner Support Advisory Committee conducted a survey of student services offered at member institutions and an all-day learner support workshop was held by Sprint. The Survey Course Advisory Committee planned and created a series of video tapes based on the use of technology within Consortium schools.

UCF’s First World Wide Web Course

The World Wide Web and Internet provide hypermedia (point and click) access to instruction which is linked with hypertext. The Web combines photos, graphics, test, audio and video (where available) in an interactive environment. The Internet and the Web have two advantages over other media according to Thomas McManus. The Internet combines media advantages of other media so that the Internet conveys sounds and video
better than books and is more interactive than videotapes and unlike CD-ROM delivery people can be connected cheaply from all over the world. The Web is also a content provider.

The first UCF Web-based distance course was an experiment based on necessity. Steve Sorg was a professor in Vocational Education slated to teach three methods courses in the summer 1996 session. One of the courses was only offered at UCF within the state. Barbara Truman was also finishing up her master's degree in Instructional Technology. Her internship requirements necessitated finding a suitable project to stay on at UCF. Steve Sorg proposed collaborating to put his Vocational Courses online. The paperwork was filed and research began with a review of literature. Apart from the knowledge of the department chair, the college and institution was unaware of the project. Sorg and Truman prepared themselves for designing a Web-based course by attending the distance learning workshops conducted by the Consortium's Distance Learning Demonstration Project. The pair also attended video and teleconferences on distance learning whenever available. A conference was attended to meet actual faculty involved in distance learning. The authors learned that courses inviting debate, discussion, and knowledge-based opinion sharing were best suited for Computer Mediated Communications such as the Web (Ursery, 1995). Sorg's courses for teacher certification met these criteria.

Findings from the Literature Review

Reviewing the literature involved searching the World Wide Web for actual course examples. The World Lecture Hall is a rich source of course Web pages. Most pages located there appeared to be for Web-enhanced classes rather than pure distance classes. In a face to face, Web-enhanced class, existing course materials are put on the Web for students to refer asynchronously. Often, these materials do not appear to be modified in content from their original states. In on-line distance learning this is the worst possible mistake: same materials only in a different format. Web-enhanced classes that have meetings afford opportunities for the faculty member to elaborate on the content; students must interact with each other in order to build learning communities. With e-mail, senders do have the opportunity to see what you think before someone else sees what you said (Maddock, 1995). Without the use of frequent, meaningful e-mail, the course would wind up being little better than a correspondence course.

Advanced organizers were another design feature incorporated into the Web-based first course. Advanced organizers are tools that help stimulate thinking and activate prior knowledge and recall. They help the learner hang new information on their existing schema. One drawback of the Web as a media is the abundant distractions that are available a mouse click away. The ability to discriminate between valuable and junk information is a critical attribute for on-line distance learning students. Judging sensationalism, distortions, persuasion and understand how the technology itself shapes the information it carries (White, 1987). Another deliberate design feature was centralized content links on certain home pages for the subject matter, study helps, general education links and metacognitive links. Embedded links to content were also used in specific page locations as parts of activities and potential resources, but centralized links were used because of the learner characteristics (adult learners) and the lack of prerequisite search skills.
Our on-line resources included study helps and distance learning critical competencies as a teaching strategy. The other courses reviewed in the literature review made very little to no effort to support students with general education references, nor were they frank about letting students know about necessary skills to succeed as distance students. These skills include responsibility for one’s own learning, self-discipline, time management and knowing one’s own learning/personality styles (Sherry, 1996).

Evaluation was another design element built into the first course’s Web site. Feedback along the way during course implementation was important for formative evaluation so that adjustments could be made to activities. One of the greatest dangers in on-line distance courses is that instructors cannot read from students whether the work they are assigning is attainable or that the students are grasping the instruction. In a face-to-face class, students can whisper to one another, react with dismay and check with other students for the reality checks of assignment load. Not so in an on-line distance setting. Students in the first course were able to click on a Web form and fill out the questionnaire regarding the usefulness and difficulty of each activity. The CGI-scripted form sent back an easy to read e-mail message to the instructor when filled out and submitted by the student.

Summative evaluation was also a very important design feature for improving future courses. The university’s traditional instructor course evaluation was used, but it clearly did not apply to this new learning environment so another instrument was created. Students in the first course were required to drive in for the final exam. At that time, students sat down and filled out a pencil and paper evaluation. Sixty-one of the seventy-two students filled out the final evaluations. The data collected was helpful later in designing faculty workshops.

Humanizing Web pages was another design strategy incorporated into the first course pages. On-line course materials reviewed showed a great deal of "professorese" in the style of writing. Our first course reflected instructions re-written to reflect the first person voice. Students were spoken directly to from their professor. Personal photographs were also added to the pages to show the professor working on the computer and talking to the students on the phone. Use of a personal homepage for the professor was also considered very important to give students an identity to connect with so that e-mail messages were more personal. The professor’s photo, hobbies, research interests and work affiliations were all known to the students.

A technology not overlooked in the design of the first on-line course was the facsimile (fax) machine. Students recommended improving distance learning courses by using a fax machine as an additional resource.

Lessons Learned from the First Course
The first course did not employ sophisticated media or software tools. Rather, the course used only the World Wide Web and e-mail. The professor requested that students copy him on course-related e-mail interactions and as a result was inundated with e-mail traffic. The interaction soon broke down and students were asked to be patient. The decision to allow 72 students soon revealed the burden of responding to messages and grading work.

Specific lessons learned were:
1. Make equipment and prerequisite skills clear well in advance.
2. Market the class appropriately to get the right students in the class.
3. Establish protocols and Netiquette for the composition of e-mail messages.
4. Establish expectations for reasonable interaction and response time for grading.
5. Create an e-mail account for the class so that e-mail does not all go to the faculty member’s personal inbox that also has adequate memory for course materials.
6. Use asynchronous computer conferencing to balance the push and pull of interactions.
7. Obtain an e-mail software system that has filtering for sending received mail into specific folders, and that has custom autoresponse for replying to students sending in work.
8. Install virus protection software and scan everything all the time.

The Institution’s Systematic Process for Faculty Development
The first Web-based course was being designed and implemented as the UCF central administration was investigating a systems perspective of thinking for designing new distance learning strategies (Thach & Murphy, 1994). Distance learning needs for students were assessed with data collected from Brevard Community College, one of the Consortium’s member schools. Based on the number of community college students taking telecourses, the direction was taken to develop an on-line Liberal Studies bachelors degree. Another program developed was actually a doctoral track within the Curriculum and Instruction doctoral program for community college faculty. To meet these goals, a budget was set aside to create the Course Development Project. Office space was assigned and a faculty position was created within Academic Affairs for an instructional designer/course developer (Truman) with support from a graduate assistant and student assistant. A faculty coordinator was also assigned (Sorg) to assist in planning, researching and delivering the faculty development workshops.
Lorraine Sherry (1996) states, "The most important factor for successful distance learning is a caring, concerning teacher who is confident, experienced, at ease with the equipment, uses the media creatively, and maintains a high level of interactivity with the students" (p. 5). The faculty selected for UCF's interactive course development were first nominated by their deans for inclusion in the Course Development Project and later chosen by Academic Affairs. An assessment was then conducted to determine skill levels and the state of equipment being used. Compensation was given to faculty for a course release to attend training and develop an on-line course. New multimedia computers were purchased in the cases where antiquated computers were in use.

Interactive Course Development workshops were held in July 1996 and in September-October 1996. During the summer, faculty were expected to attend five, three-hour workshops. Critical technical skills were handled on an individual basis based on need. Distance learning technologies were used and modeled. Eastmond and Ziegahn (1995) describe a good teaching experience as one where students can master new knowledge and skills while examining assumptions and beliefs, where students can engage in invigorating, collaborative research for holistic development. This holistic development also applies to faculty members. Course Development Web pages were created with photographs, both posed and candid shots, of participating faculty. Links were made to all the Web content handouts, computer conferencing forum, Web page generator and forms for supplying feedback (See http://www.oir.ucf.edu/pt).

One of the greatest needs for systematic faculty development in developing Web-based courses is the need for faculty to prepare themselves for their change in role from lecturer to facilitator. Another consideration in the quality of designing a distance course is the faculty member's ability to relate to students. Ross Paul (1995) states:

Faculty members who tend to be the most powerful political group within an institution... may be less sensitive to the personal and skill development needs of part-time, adult students, given that the great majority of them completed their degrees on traditional university campuses on a full-time basis and were successful students who faced far fewer academic problems (p. 54).

Teaching skills for distance learning include: understanding the philosophy of distance learning, dealing with copyright, adapting teaching strategies, designing interactive courseware, identifying learner characteristics, organizing instructional resources for independent study, using telecommunications systems, collaborative planning and decision making, and evaluating student achievement and perceptions (Schlosser & Anderson, 1994).

A formative evaluation was held after a month of running the first eight courses. The evaluation revealed a need for more hands-on activities. The September workshops were expanded and redesigned with an extra one and one-half hours of hands on, computer activities. The subjects of the three-hour workshops were:

1. Orientation to distance education
2. Orientation to distance learning practices and technologies
3. Systematic design process
4. Quality, interaction and assessment and
5. Distance learning course administration.

Creating Web pages was not considered to be critical for creating on-line classes. Rather the focus of the faculty training was on instructional design for creating Web-based, learning environments. The course development process is a team effort consisting of subject matter experts (faculty members), instructional designers, programmers and graphic artists. In addition to the support provided by this course development team, an automatic Web-page generator tool was developed to prevent the faculty from having to learn HTML. The page generator tool uses CGI-scripted forms and Java scripting for interactivity. Faculty involved in the course development project assisted with the course instructional design components incorporated into the Web page templates used with the page generator. A template for each college was designed with all of the course conventions and instructional design components. The Web page generator tool was not expected to be widely adopted by those faculty that preferred to do their own HTML, but the adoption rate was high because of the tool's user-friendliness and time saving feature.

Nearly thirty faculty members participated in the summer and fall Course Development Project. Eight courses were produced in the Fall 1996 term and ten more are being developed for Spring 1997. The College of Arts and Sciences allowed faculty to work in teams for development and conducting the class. One team chose to design their own pages with Pagemill (Macintosh) software. The temptation to get something up on the Web caused these pages to be redone and the course to be simplified. Some faculty chose to take up the design team's offer of assistance such as creating forms for quizzes while others did not. The greatest challenge to the course development process was the existing campus technology infrastructure. The campus computer support was inadequate and the new pressures to support distance learning faculty, much less students, was a tall order. Designing on-line, Web-based courses is a change process that takes time. The success of the Course Development project, despite the obstacles, is leading the campus towards greater networked learning.
Network-focused learning is resulting from the exponential growth of the Internet where student-initiated data gathering and interactive communications make learning potential incomprehensible (Barker & Baker, 1995). They add that network-focused distance learning will one day ellipse the practice of classroom-focused distance learning.

The key to success in distance education is the teacher. Faculty must be master teachers (Barker & Baker, 1995). Instructors must challenge the student to use their higher thinking to research, problem solve and inquire about their own answers (Mizell, 1994). UCF's Course Development Project has lead to rapid interest in distance learning across disciplines and colleges. Systematic faculty development is the key.

Acknowledgments
The authors would like to express their appreciation for the enthusiastic support of Dr. Frank Juge, Vice Provost for Academic Affairs, Mr. Joel Hartman, Vice Provost for Information Technologies and Resources, and the staff of the UCF Office of Instructional Resources.

A UNIVERSITY MODEL FOR PROMOTING TECHNOLOGY INNOVATIONS ACROSS DISCIPLINES

Michael R. Hoadley
University of South Dakota

J. Mark Pike
University of South Dakota

As a result of its reinvestment strategies for the campus, the Center for Instructional Design and Delivery (CIDD) was established at the University of South Dakota in July of 1996. The CIDD is a centralized collaborative model promoting quality instruction and learning, as well as providing educational opportunities for development of innovative instructional methodologies. The primary focus of CIDD is to provide opportunities for faculty to investigate and utilize technologies in innovative ways in traditional classroom settings, distributed learning environments, and distance educational delivery systems. The purpose of CIDD is to help faculty incorporate technology into training/teaching, course/curriculum design, evaluation/research, delivery adaptations and expansion, and faculty development.

CIDD Facility

Currently CIDD is borrowing other facilities around the campus for its training workshops, but that inconvenience has resulted in the development of a plan for a centralized center. The renovation of this facility will provide a location for training and teaching activities, as well as equipment for use and skill development by individual faculty members. Office space and meeting rooms for staff and faculty will be available on the second floor, as well as space for hosting corporate training seminars. Once renovation is completed in July of 1997, the CIDD will also serve as a showcase for the USD campus as part of its recruitment and admission activities.

CIDD Staff

Co-directors of the CIDD represent collaboration between academia and support services on the USD campus. Other currently funded CIDD staff positions include the following:
- Graphics Designer/Multimedia Design and Production Specialist
- Photographer
- Videographer/Digital Video/Audio Production Specialist
- Administrative Assistant/Smart Classrooms Technician
- Electronics Technician
- Senior Secretary
- Four Graduate Assistants

Two positions yet to be hired are the Instructional Coordinator and the Instructional Technologist. The Instructional Coordinator is a staff position and he/she will be responsible for scheduling and conducting training sessions for USD faculty, staff, and students. The Instructional Technologist is a tenure-track faculty position with half-time appointment to CIDD and half-time appointment to the School of Education. Typical faculty duties of instruction, research, and service will be part of his/her responsibilities in the area of instructional design. That person will also be instrumental in the establishment of curricula for the new graduate degree programs in the Division of Technology for Training and Development in the School of Education.

CIDD Faculty

The CIDD model reinforces the idea that faculty members need release time to develop their skills in the rapidly changing field of technology. The CIDD faculty consist of two representatives from each of the academic units on campus (the College of Arts & Sciences, the School of Business, the School of Education, the College of Fine Arts, the School of Law, and the School of Medicine). Currently 12 faculty members have 50% release time (25% funded by CIDD and 25% funded by the individual College or School) to devote their energies and talents to the CIDD activities and the campus initiatives in technology. This sharing of costs for release time is considered an integral part of the CIDD model since it requires a commitment and shared responsibility by both the academic unit and the University.

Expectations

As a result of their assignment to the CIDD, the following expectations (as a minimum) have been placed upon those faculty relative to their duties during the academic year:
Design or redesign at least two courses during the academic year. It is the intent of this project that CIDD faculty keep in mind the need to integrate new and emerging technologies into courses when appropriate. This is extremely important as curricular needs change and new programs are being developed. This specific task provides some focus for the faculty members and provides a direct product for their academic unit.

Serve as a liaison between the CIDD and their academic unit. CIDD faculty are expected to share the information they receive from training workshops and informational meetings with their colleagues. Hopefully this approach helps address some of the public relations needs for a project of this magnitude. Efforts are also being made to promote the idea of CIDD faculty working with their colleagues at other institutions of higher education and the profession.

Assist in the development of basic technology courses appropriate for their academic unit at both the graduate and undergraduate levels. This task is extremely important because of the change in skill levels of incoming freshmen and returning graduate students. Each academic unit is represented in this discussion, with the hope of developing core competencies in technology. CIDD faculty have surveyed the faculty and are currently in the process of making recommendations to the academic units relative to competencies in the areas of word processing, use of presentation software and equipment, and use of the Internet and World Wide Web. Recommendations are also being made to address competencies specific to certain disciplines, such as spreadsheet software for the School of Business or imaging software for the College of Fine Arts. Eventually CIDD faculty will have the responsibility for offering some of the training seminars (credit and non-credit) in technology for students.

Work as a mentor to help three other faculty members redesign his/her courses. As part of the return to their college or school, CIDD faculty are expected to share their newly developed skills and/or facilitate discussions with their colleagues concerning appropriate resources on campus. Each CIDD faculty member has identified colleagues from their academic units responsible for redesign of their curricular offerings, with whom they plan to collaborate during the academic year.

Attend all training sessions offered by the CIDD. Three to four training sessions are offered weekly to CIDD faculty to assist them in their skill development. Sessions are informational and hands-on in their approach to learning. Topics for this year include Multimedia Overview, Networking Overview, Instructional Design Issues, Basics of Photography, Basics of Videography, Web Page Development, Videoconferencing, Web Design Principles, Multimedia Overview, Use of SMART Classrooms, Creating Forms for the Web, Digital Photography, Digital Imaging, Digitizing Audio, Audio Editing, Overview of Using CD-ROMs, Pressing CD-ROMs, Video Editing, Digitizing Video, and Video in Multimedia. Plans are being made to provide additional topics as appropriate. All sessions are repeated at least once each semester and are made available to all faculty on the USD campus.

Assist the CIDD in offering workshops to others around campus. Faculty who have been identified to serve as campus resources are paired with CIDD faculty to provide training to others. Currently twelve training sessions are offered to the campus each semester, with more being planned as the need arises. CIDD faculty will be responsible for coordinating and marketing those sessions. Some of the sessions will also be offered to faculty at other state institutions via videoconferencing.

Make a presentation at a CIDD-sponsored conference. An annual campus-wide conference in April known as IdeaFest will serve as one avenue this academic year for the dissemination of information to the campus faculty, staff, and students relative to research in the field of technology. The presentations will address the conference themes of Undergraduate Research and Diversity. In addition, weekly presentations are made by CIDD faculty during noon forums to highlight new innovations in technology and the direct application of technology to their courses and curricula. Many CIDD faculty have also had presentations accepted at the state, regional, national, and international levels for conferences in their content-specific disciplines. In the future, the plan is for CIDD and the University to sponsor a technology conference for the region.

Provide advice and/or assistance in the design, development, and maintenance of the CIDD home page. A web page has been designed by the CIDD faculty (http://www.usd.edu/cidd/) in order to keep the campus informed of CIDD activities. This activity is a direct result of training provided to CIDD faculty in the area of web page development. CIDD faculty will also be responsible for reviewing and evaluating the effectiveness of that medium for distribution of information.

Assist the CIDD in the pursuit of grant funding. As with any group or organization, receipt of external funding is encouraged. Although the University of South Dakota has decided that this initiative deserves annual funding, not all needs can be met as technology and personnel change. It is also hoped that this type of activity will encourage faculty from different disciplines to work together in the development of proposals in new areas of research and instruction. Currently, several individual CIDD faculty proposals which incorporate the use of technology into their design have been funded by internal and external agencies.

Attend one professional meeting related to the use of technology. Faculty development can not be limited to
local expertise. The CIDD philosophy encourages faculty members to attend technology conferences (not just ones related to their content areas of expertise) and then return to campus to share that knowledge with others through seminars, colloquiums, and general presentations. That information will also be shared through the CIDD home page and other resources available on campus.

CIDD Advisory Board

The CIDD Advisory Board has also been created to represent the interests of faculty, staff, students, and administrators at USD relative to technology-related issues. In particular, this Advisory Board will assist the CIDD in addressing academic and support services for the campus by its monthly review and advisement relative to CIDD-sponsored activities. Advisory Board members have also been asked to serve on numerous committees to deal with policy issues, recommendations for equipment purchases, and renovation of the CIDD facility.

Summary

The University of South Dakota has made a commitment to the use of technology by its faculty, staff, students, and administrators. The Center for Instructional Design and Delivery (CIDD) provides a model for other colleges and universities wishing to meet the technological needs of their campus. By investing in training and development for the users of technology and by promoting the integration of support services, this cooperative approach should reap benefits this year and in the future.

Michael R. Hoadley is a Professor and Co-Director of the Center for Instructional Design and Delivery (CIDD), and Chair of the Division of Technology for Training and Development (TTD), University of South Dakota, 108B School of Education, 414 E. Clark Street, Vermillion, SD 57069. Voice: 605.677.5839, Fax: 605.677.5438. Email: mhoadley@charlie.usd.edu

J. Mark Pike is the Director of the Educational Media Center (EMC) and Co-Director of the Center for Instructional Design and Delivery (CIDD), University of South Dakota, Arts & Sciences Building (North Annex), 414 E. Clark Street, Vermillion, SD 57069. Voice: 605.677.5744, Fax: 6056.677.6518. Email: jpike@sunflowr.usd.edu
In 1996, the authors of this report were funded by the California State University’s (CSU) Chancellor’s Office to train faculty from each of the 22 CSU campuses in a workshop designed to wed innovative pedagogical techniques with new models of distance education. An outcome of that grant was a program entitled Distributed Course Delivery for Problem Based Learning (Hoffman & Ritchie, 1996). This program included video teleconferencing sessions with each of the collaborating universities, a series of newsletters showcasing innovative educational ideas, a series of on-line Internet chats with experts from around the country, and a culminating two-day workshop. Although participant evaluations indicated high praise for both the knowledge and skills gained, we felt there was still something missing—that there was more we could do to help CSU faculty adopt emerging technologies in their teaching and scholarly activities.

In the fall of 1997, the CSU Chancellor’s office published a second round of requests for proposals, again looking for faculty development with an emphasis on pedagogy and distance education. This year we submitted what we believe is an evolutionary step towards a faculty development model that is particularly relevant to technology integration in the CSU system. Rather than bringing faculty from around the state to our campus for training, we proposed conducting an entire institute through a variety of distance delivery methodologies; in essence creating a virtual institute that would assist faculty from around the state in creating on-line materials for their courses. We believe that this proposal synthesizes the best features of training, peer coaching, and modeling, with the power of Internet communications and automated tools and templates to support faculty on-line publishing efforts.

One of the strengths of the proposal is the use of a variety of communications technologies to supplant the time and cost involved in travel, physical accommodations, and instructional facilities of a central site. These technologies not only allow for more effective use of faculty time, but also model the essence of the proposal’s intent which is to implement distance learning technologies capable of making lasting changes in the educational system. We also requested that funds earmarked for Institute participants’ travel expenses be re-allocated to support the connectivity needs of participating faculty, including underwriting the cost of desktop video conferencing and screen sharing capability at each campus, as well as reimbursing faculty to serve as coaches/mentors at each of the 22 campuses. The total cost of these capacity-building expenditures is a fraction of the expenditure required for physical travel.

We also proposed an innovative method of distributing institute materials. Rather than merely maintain the tools, templates, and training materials on a web server at the host university, we proposed to upload and maintain these components on servers at each of the 22 CSU campuses, thereby providing a local course development resource that can be customized and expanded to meet the needs of each campus community.

Taken together, we believe this model is not only a step forward in the creation of programs for California, but is relevant and applicable to other universities or state agencies as they move towards expanding their use of the Internet for course delivery.

Strategies

Few faculty use the Internet for course delivery. Bemoaning this state of affairs ignores the fact that universities hire faculty primarily for their content expertise, not their Internet programming skills. The time and effort required to surmount technical hurdles, such as mastering hypertext markup language (HTML), prevent many faculty from attempting to publish course materials on-line. In the recent past we have not expected faculty to master all the crafts, such as typography, page layout, and offset printing, needed to deliver their print-based course materials; universities and publishers provided these services.

The World Wide Web presents a different situation. For the moment, at least, the Web has removed intermediaries between faculty authors and student readers. Web
publication appears, on the surface, to be merely an extension of word processing (a technical skill itself, which, we should remember, we have come to regard as a “baseline” skill for faculty only in the past decade, if at all). Web publication, however, is in a difficult stage of development. At its best, it is not merely an extension of word processing, but a new, interactive medium of instruction. Taking full advantage of the Web's interactive capabilities requires much more than word processing skills. Yet we often assume that faculty who want to “stay current” can and should become competent Web authors.

Even when faculty are agreeable to and capable of Web publishing, the availability of on-line services to students, availability of existing content in electronic form, and appropriateness of course material and instructional interactions for on-line delivery may prevent a given course from being successful.

Our goal in creating the Institute is to provide faculty with easy-to-implement methods whereby they can rapidly and easily create and manage web-based course materials. The strategies we use center around three components: tools to facilitate rapid creation, development, and management of web-based course materials; techniques to enhance on-line teaching ability and conceptualization of the Internet as an instructional medium by the faculty; and training via the Internet, including a pyramid-type dissemination system, to help distribute the ideas of the Institute throughout the CSU system. We will also purposefully model ways in which faculty can exploit intermediary campus resources, such as faculty development offices, publishers, and campus bookstores, to aid with Web site development and maintenance.

Tools

We realized early in our research that although many faculty believe the Internet is becoming an important means of communicating and delivering information to students, many feel overwhelmed by the rapid evolution of the medium, and fail to envision how they can use it to their advantage. Much of this apprehension is due to the newness of the medium, the skill required to master the programming techniques, the time required to create course materials, and the lack of valid peer examples to set a standard for development.

To help faculty overcome some of these obstacles, we decided to create a series of Web-based and stand-alone tools and templates that, when completed, will provide many of the necessary components of an on-line course. To determine what type of templates would be most needed and feasible to incorporate, we examined professors’ current practices for both on-line and traditional course delivery. Results of this analysis led us to include templates for creating the following components:

- a course syllabus,
- a course schedule,
- course notes,
- WebQuests (Web-based student inquiry activities),
- forms for reflective questioning, and
- on-line testing.

The templates will be available in two formats. First, they will be available on line as forms which prompt users through a series of questions, then automatically create relevant Web pages based upon the submitted information. Faculty can then view and save the document source to obtain the HTML code. For faculty creating their pages on machines not connected to the Internet, the templates will also be available in standalone multimedia programs which also create HTML documents. In either case, as faculty complete the templates, they will have a basic, but fully developed, ready-to-run custom Web site for their course.

Techniques

After developing and implementing the templates described above, the Institute will engage faculty in further explanation and customization of their site as they explore possibilities for both innovative and traditional learning activities. To this end, we are creating a five-module online course, consisting of approximately 10 hours of instruction. The course will provide the techniques and strategies to help faculty develop and manage their own on-line course modules as well as model technologies such as videocassettes, print material, and World Wide Web delivery. On-line resources and instruction for the Institute will include publication of course documents, research, asynchronous forums, synchronous chats, instructional multimedia, e-mail, collaborative design, exchange and critique of electronic documents, and on-line assessment. These will be supplemented with instructional videocassettes and print materials. The course will also model online course management incorporating both innovative and traditional instructional strategies.

Course content will center around five major topics:

Strategies and tactics for on-line teaching and learning. This module will include the following topics: benefits and limitations of on-line learning, identifying course content appropriate for on-line delivery, implementing traditional pedagogies on-line; new possibilities and opportunities for teaching and learning on-line, best practices in on-line instruction and education, and pedagogy for distributed multimedia and distributed learning communities.

Document preparation for on-line courses. Topics in this module will include: using templates specially designed by the Institute for helping professors quickly and easily mount course-related Web sites, using HTML editors; preparing graphics and media files, and converting
existing text (word processing) files for delivery via the World Wide Web.

**On-line student learning activities.** This module will focus on: organizing selected course content around on-line learning activities, best practices in on-line learning, creating activities that are easy to implement and maintain, searching the web for content, activities and other resources, and assessing on-line learning.

**Nourishing an on-line learning community.** Topics in this module will include: facilitating on-line student communication by design and managing on-line forums and chats, and creating and maintaining student document exchanges.

**Management of on-line course resources.** This final module will include: developing and maintaining course-related on-line publications and activities, especially a course Web site, strategies for increasing personal productivity as an author and manager of on-line course resources, developing a plan for gradual improvement of on-line course-related content and activities, and identifying CSU and local campus support for web-based publishing.

The course content is designed to provide faculty with the conceptual understanding and techniques to create, develop, and manage an on-line course. The tools are designed to provide faculty with easy-to-use templates to create many of the required components of an on-line course. The third component of the Institute—training—provides a method for effectively disseminating these tools and techniques throughout the CSU system.

**Training**

The Institute combines the dissemination power of a "train-the-trainers" approach with the instructional effectiveness of coaching and mentoring in a "peer coaching" strategy. Our plan is scheduled to operate in four tiers.

First, we will recruit one participant with at least a base level of experience with on-line course development from each of the 22 campuses to serve as an on-campus mentor or coach. This individual will participate in training through a combination of on-line instruction and coaching via video conferencing and screen-sharing. Each campus coach will in turn spend a total of 15 hours supporting three other faculty on their own campus, one-on-one or in small groups, as they participate in the on-line course. As an incentive, our grant proposal requested a stipend of $1,000, two Internet software packages for screen sharing and web page development, and a desktop video conferencing unit for each of these 22 campus mentors.

The second tier training will begin when the three secondary participants at each campus begin the five on-line modules. The previously-trained campus mentors will provide coaching for these participants: The Institute will provide back-up support for both coaches and participants. Each of these second tier faculty will be responsible for recruiting, training, and a total of 15 hours of coaching for three additional faculty members through the on-line course. We requested a stipend of $500 and an Internet software package for web page development for each of these 66 faculty (three members at each of the 22 campuses).

In the third tier training, the 66 second-tier faculty members will each assist three additional faculty members as they complete the five on-line modules and develop on-line course publications and activities. These nine additional faculty members at each campus (three second-tier faculty each coaching three additional faculty members) will work individually or as a team, as they prefer.

This model optimizes the potential to reach faculty in a significant way throughout the CSU system. The initial mentor, three participants, and nine additional faculty participating at each campus totals 286 faculty who will create on-line materials for students in one or more of their courses by the end of the Institute.

In addition to the 286 faculty directly reached through this initiative, the potential to reach even higher numbers exists. The course material will be uploaded to and maintained on servers at each of the 22 CSU campuses to provide a local course development resource that can be customized and expanded to meet the needs of each campus community. This distribution of the material will allow a fourth tier—an unlimited number of faculty at each campus—to complete the training and use the tools and templates to add value to their courses.

To qualify for their stipends, each coach and original faculty participant team members are responsible for publishing on-line course documents, including a home page for the course, a syllabus, a course schedule, an instructor home page, and on-line learning activities equivalent to one class session. In addition, each faculty must perform their respective coaching activities.

**Assessment**

To evaluate the effectiveness of the proposed approach, we plan to enlist the help of graduate students in our Department of Educational Technology to assess the breadth and depth of impact on course related use of the Internet and World Wide Web. The Institute will develop and maintain a directory of all web sites developed by participants and use this to monitor faculty contributions. Institute staff will monitor each course web site and determine the percentage of participating faculty who actually meet the criteria for successful completion of a course related Web site.

For purposes of this goal, minimum standards for a successful Web site will be:

- course home page,
• instructor home page,
• syllabus,
• schedule,
• student activities (group or individual) for one class session, and
• student interaction site or activity (forum, chat line, or document exchange).

The Institute goal is to ensure that no less than 88 course Web sites (four per campus) are fully established by October, 1997. We expect to see many more sites than this established in some form.

From sites completed by October, 1997, the San Diego State University Center for Learning, Instruction, and Performance Technologies will randomly select 40 for further study to include a qualitative analysis of the content and the degree to which faculty have gone beyond the minimum standards. Going beyond the minimum standards is an important indicator of impact because it serves as a measure of enthusiasm and interest as well as the degree to which faculty are able to adapt the technology to discipline specific content and campus idiosyncrasies.

Benefits

Individual faculty and the CSU system as a whole will receive four major benefits from this Institute.
• Empowerment to publish course materials. The modules and templates will allow professors to quickly develop and post course materials on the World Wide Web for use by CSU students and as examples for other faculty.
• Increased degrees of freedom. Fast updates, changes in course sequences, enhanced collaborations, distance delivery, and enhanced administrative protocols will allow professors to reduce some of the barriers to providing students with the information and support they need to be successful.
• Exploration of new strategies for teaching and learning. Sharing student files for peer assessment and feedback, teaching at a distance, and inquiry activities will enhance the variety of learning strategies implemented in faculty participants’ classrooms.
• Modeling new technologies. The instructional modules will model the use of a variety of technologies including: videotape, Web-based instruction, Internet chats, and video conferencing, thereby providing professors with direct examples of the structure and system of implementing new learning modalities.

Summary

In many locales, private enterprise and distant universities are beginning to make inroads into the delivery of instruction through electronic delivery formats. Local institutions that are slow to respond may find that their traditional clientele are no longer required to settle for the nearest facility, and may instead turn to those institutions that provide the most expedient material.

Our purpose in designing, developing, and delivering the Institute proposed in this article is to provide a catalyst for the development of on-line courses for the CSU system. Whether creating teacher training courses or delivering content in other areas, we believe there is a need to adapt to changing modes of delivery to stay competitive in an expanding market place created through electronic media.

The tools, techniques, and training described in this article will augment CSU capacity building through the proliferation of new modalities of instructional delivery, faculty experimentation with on-line delivery methods, and a demonstration of methods for system-wide support of on-line publishing. These methodologies should help the CSU universities, as well as other interested educational institutions, maintain their competitive edge even in a time of reduced budgets. The Web location for the Institute will be available to participants at the SITE97 conference.

DEVELOPING A TECHNOLOGY-FRIENDLY FACULTY IN HIGHER EDUCATION

Beverly Abbey
Southeastern Oklahoma State University

In response to recommendations from a state external review team and the National Council for Accreditation of Teacher Education (NCATE), a small southwestern university made a decision to bring the Teacher Education faculty and students into the 21st century as rapidly and efficiently as possible. This involved acquiring computers and other technologies, providing professional training for the faculty, and revising courses.

At the beginning of the 1995 Fall semester, the School of Education and Behavioral Sciences was allocated two computer labs: an existing lab with 20 IBM 486’s and a new Education Multimedia Lab of 20 Power Mac 7100’s to be funded in two stages. Although the labs would have open access hours for all members of the university community, priority would be given to teacher education classes and faculty use.

An existing tenure-track faculty position was redefined as a Technology Coordinator. Release time would be provided in order to incorporate faculty training and support and lab management responsibilities. Additionally, this faculty member would work with current faculty to revise and update both instructional technology courses and other education and methods courses.

The three major goals established were to develop a technology literate faculty with training in and access to education-related technologies, to support and promote faculty to integrate technology to enhance instruction and professional productivity, and to prepare pre-service teachers to use educational technology.

The project would affect faculty and staff of the School of Education and Behavioral Sciences and Teacher Education faculty (n = 93) and approximately 1200 students per year.

Model

The project model addressed and was based on three components: use of a systems approach, the theory of diffusion of innovation, and a cyclical orientation.

Systems thinking is a technology of the 1980’s and is a way of looking at the whole system in order to recognize the interrelatedness and interdependence of it parts. Tinkering with one system element affects other elements. The use of this approach provided a means of identifying and addressing impacts of faculty training on other faculty, students, administrators, courses and other schools’ faculty and students. A system analysis and design process was used to provide a procedural structure for the plan.

Anticipated responses to the plan were based on the Rogers’ (1995) theory of diffusion of innovation. An innovation may be a process or a product and resultant changes because of the process or product. Diffusion is the way in which an innovation spreads. Technology diffusion reflects a complex system of interaction and interdependence that depends on the interplay of adopters’ capabilities, opportunities and strategies (Shodjai, 1996). The implementation of the plan would attract the early adopters who would use and incorporate information technology for instructional and professional activities; mid- and late adopters would be addressed in subsequent stages.

The emergence of information technology as a curriculum component (or experience) is a significant innovation in higher education. The events of the past 15 years suggest a steady migration of information technology into instruction and other aspects of the learning experience (Green, 1996).

The model also reflected a cyclical orientation. In order to effectively address technology - use, training or acquisition - it is important, not only to understand but to proceduralize a non-linear format. Information technologies are not static; change has become a permanent aspect of hardware, software, training, and support. The model presents an affirmation of the recurring nature of technology in higher education.

Initial Stages

There were four stages in the first year: computer labs set up and operations, preliminary training needs assessment, beginning training sessions, and pilot collaborative plans to integrate technology into existing courses.

The initial stage required that the labs now available to the School be organized for faculty and student use.
A lab policy and procedures manual was created that specified access and operational procedures, and acceptable ethical practices and policy.

Software was purchased to meet faculty and student needs in five areas:
- To provide student productivity tools,
- To provide faculty productivity tools,
- To provide access to educational software for use by students in curriculum areas,
- To augment existing course content, and
- To create multimedia programs for use by faculty and students.

A newsletter was established to communicate training information, technology and lab updates, current technology news and as a vehicle to illustrate potential instructional tools and techniques.

Concurrently, the faculty was surveyed to identify the most pressing technology and training needs. It was critical to address existing needs of faculty currently committed to the use and integration of technology. Responses to this initial assessment indicated a significant need for training and support in operating systems, word processing and presentation software.

After the labs were effectively functioning and using results from the survey, faculty and staff training sessions were developed. Two basic training sessions were prerequisites for additional training: an overview of computer principles and the labs and introductory word processing. Subsequent to the required modules, training was also offered in other software programs. Sessions were offered at varying times in order to accommodate faculty class schedules.

Lab orientation sessions were also developed. The orientation consisted of an explanation of lab operating procedures, clarification of and signed agreement to abide by the Acceptable Use Policy (AUP), and introduction of lab hardware and software. These sessions were recommended for classes with assignments that required use of the labs. Faculty that did not attend any training sessions but wanted to use the labs for class instruction were also required to attend a lab orientation.

A beginning training manual was produced for each person that attended the training. The manual included reference and support materials for the basic training sessions. Additional material was made available for subsequent training sessions.

The fourth component, collaboration and integration, was piloted during the 1996 Summer semester. One faculty member who had received training worked with the Technology Coordinator to modify existing course content to integrate instructional technology tools. Within the context of an elementary education language arts methods course, a traditional instructional technology task (visuals preservation) and an information technology tool were incorporated. The class received task specific instruction in word processing in order to create a poetry book that included graphic elements.

Evaluation was an on-going component of the project. Informal formative feedback was used to adjust scheduling, session lengths, training class size, and frequency of sessions. A formal summative evaluation was conducted at the end of the spring semester.

First Cycle Summary

Results from the first year indicated a positive acceptance of the program and model. The twenty percent of the faculty that represent early adopters was larger than would be expected from a rural university. Faculty evaluations reflected unanimous support and provided constructive suggestions for modifications. These evaluations from the early adopters were viewed as a needs assessment for that group and suggestions were implemented for the second year.

Plans for the second cycle were based on the model of diffusion of innovation. Early adopters would receive maintenance support in the form of task specific practice sessions and individual review sessions, and identify additional opportunities to integrate technology in direct support of existing curriculum. Advanced training in specific applications would also be made available. Mid-adopters would begin to participate in the training, the application sessions and a new series of less lengthy “how to...” sessions, and identify approaches where technology could be integrated.

Problems

Of course! Problems arise in the best thought out plans. A major area of concern was time - the time for the Technology Coordinator to create appropriate training materials, the time invested by the faculty for the training sessions which affected prep and professional activities, and the time involved in reducing student lab access time for multiple sessions.

Another major problem was the shortage of up-to-date desktop computers for the faculty. Although the labs were equipped with current technology, it was not always convenient for the faculty to use the equipment for personal and professional daily tasks. Newly acquired skills need to be exercised regularly.

Quo Vadis?

What do we do about faculty who do not want to use technology? Is it important that all faculty integrate technology? Does the use or lack of use of technology fall under the aegis of academic freedom? What is the value of authoring specific applications for specific courses? How will integration efforts alter traditional higher education instructional patterns and tasks? Which roles
will change and how? Training occurs in new situations, but distance learning and the Internet represent alternative forms of “old” situations (classrooms and research). Is re-training necessary for effective use of these alternative forms?

Pahl states, “We have met the [computer] revolution and the revolution is us” (Pahl, 1996, p. 342). Like Pahl and Pogo (Trager, 1994a) before him, most of us have finally come to the realization that we have created a monster, in this case technology, which must be tamed and exploited. Because of its great potential, we are allowing technology to change the way we live, communicate and learn. New technologies exist which can support and strengthen democratic ideals and actions throughout society. In preservice teacher education, areas affected by the revolution are: academic freedom, the “new” role of the teacher and the need to create technological equity among groups throughout society. As teacher educators, we have the opportunity to promote transformation and become members of a community of learners that encompasses both students and teachers. Where and how do we begin to retrofit for these changes?

Recently, Seton Hall University had developed the goal of becoming a leader in the use of technology. Faculty, staff, administrators, and students were to play a role in this mission. The University administration recognized that the use of technology for instruction must be accompanied by reform in pedagogy. One challenge that arose was how to initiate this goal without it’s being perceived as a threat to academic freedom. As one initiative to encourage the integration of technology into curriculum, faculty were invited to apply for in-house grants that could assist them to accomplish this task. Curriculum Development Initiative (CDI) grants of up to $25,000 a year for three years were offered to teams of faculty for program redesign that included technology. Recognizing that faculty possessed a wide range of technology skills, the University wisely decided to fund all teams that submitted a grant, received a critique and resubmitted revised proposals. Funded projects included everything from using e-mail to development of sophisticated multimedia packages.

A funded team representing the undergraduate programs in the Educational Studies Department of the College of Education and Human Services (CEHS) is collaborating to effect a redesign effort that included technology. Recognizing that faculty possessed a wide range of technology skills, the University wisely decided to fund all teams that submitted a grant, received a critique and resubmitted revised proposals. Funded projects included everything from using e-mail to development of sophisticated multimedia packages.

Educational Needs Addressed

The United States Department of Labor has released studies showing an increased need for teachers, technology specialists, and health care professionals in the near future. These positions are described as being in high demand and as the only middle management jobs with new openings for job seekers. During fall 1995, the College of Technology Advisory Committee conducted a study to determine the technology needs of students in the college. First, technology objectives were developed and approved by the CEHS faculty association. These objectives fulfill NCATE requirements for both faculty and pre-service teachers. Faculty then completed technology surveys for each course they teach and reported any technology objectives met in their classes as well as the kinds of technology they are currently using. The results were compiled and a curriculum map developed to determine specific needs. We discovered that our students were receiving their technology skills in bits and pieces, with no coordinated plan to
We are also preparing preservice educators who will be curricular changes require our students to produce a can integrate them in the curriculum. The proposed curriculum. School superintendents are resolute about resources for other faculty and students. produced by both faculty and students will become projects, and portfolios are employed as alternatives to technological decisions. Professional presentations, of computer-mediated solutions, present their findings with explore valid pedagogical approaches, and using a variety encounter and investigate real educational problems, variety of learning styles, be project oriented, and allow curriculum. The curriculum is designed to accommodate a learning and assess the effectiveness of a technology-based curriculum. The curriculum is designed to accommodate a variety of learning styles, be project oriented, and allow students to integrate various subject areas. Students encounter and investigate real educational problems, explore valid pedagogical approaches, and using a variety of computer-mediated solutions, present their findings with the knowledge that they can justify and explain their technological decisions. Professional presentations, projects, and portfolios are employed as alternatives to traditional forms of assessment. The research and projects produced by both faculty and students will become resources for other faculty and students.

We believe that our students will be better positioned in the job market after completing a technology integrated curriculum. School superintendents are resolute about hiring new teachers who possess technological skills and can integrate them in the curriculum. The proposed curricular changes require our students to produce a technological portfolio that will showcase their abilities. We are also preparing preservice educators who will be able to use technology reflectively, in ways most likely to support the democratic ideals and values upon which our society was founded. Skill in assessing, evaluating and delivering information and material is critical. Where teachers cannot do so, others will. Apple’s (1982) concept of the de-skilled teacher seems potentially replaced by the superfluous teacher. Preservice candidates must recognize the potential for technology to allow them to use pedagogical practices more likely to engage the learner. In addition, they should be able to guide student analysis of new technology. Preservice students need to reflect on the biases and claims for truth that emerge from information and materials delivered electronically. Critical evaluation of the impact of technology on equity issues such as race, gender, and class is essential. The teacher and the school will have important roles to play in this process. Preservice teachers must be prepared to embrace that role. The desired outcome most important to our profession, however, is that we will instill in both our faculty and students a pedagogical paradigm for creating learning environments which is dynamic and long lasting. Also, one which our graduates will take with them to classrooms all over the United States and promulgate electronically throughout the world.

**Project Activities**

We are accomplishing our goals over a three year period by making profound changes in our curriculum, pedagogy, and modes of achieving learning. We are providing learners, both students and faculty, with experiences using technology as a tool for personal and professional productivity, direct delivery of instruction, and learning activities that can take place anytime, anywhere. As we progress through the three year period, new, more advanced technologies will be added to the programs, and faculty will bring their knowledge and skills to their other courses. Students are being exposed to a wide range of technologies and to their specific application to teaching.

Participating faculty: revise courses to integrate technology use by both faculty and students; produce multimedia presentations to change their modes of teaching; develop student projects that incorporate multimedia; initiate a variety of network-based links with schools all over the world; use a network-based student mentoring program with a public school; use various communication channels to disseminate creative student and faculty projects; and will eventually use distance education and Web-based courses to send enrichment programs and courses to elementary and secondary schools. For next year, we envision the creation of a CEHS Education Information Exchange that employs the College Wide Information System (CWIS), e-mail, the Internet, and distance learning as means to showcase student projects, communicate with students engaged in field experiences, exchange knowledge with teachers around the world, provide a database of curriculum information for students in the undergraduate programs in our college, and provide the activities and motivation for faculty and students to acquire knowledge and skills for integrating computer-based communication tools in the curriculum.

Four faculty from four different programs in the Educational Studies Department enthusiastically volunteered for this project. Participation from these four programs assures that all undergraduate education majors in CEHS will have their technology needs addressed by this project. All of these faculty have made a three-year commitment to devote one-quarter of their work/course
preparation time during the school year and one summer session to this project. Each member of the team is skilled in a specific focal discipline, as well as in curriculum development; each has participated in some technology-related project either in courses they teach or in their research; and each team member has participated in technology workshops on campus. One team member is the project director, who is skilled in instructional design, technology, and curriculum construction.

Recommendations and Conclusions

Prior to the CDI grant, many obstacles impeded faculty from making any real progress in the use of technology. A few early adapters, with computing skills made some inroads, but interested faculty without technology skills often faced frustration. Lack of training for faculty, no rewards or recognition for using technology, no time for preparation of course materials, lack of funds to purchase software, and absence of hardware for production and presentation had been serious impediments to technology reform.

The CDI grants attempted to remedy some of these problems. They provided the following support and incentives: released time, specialized training, support personnel, student assistance, software, hardware, funds to attend conferences, interdisciplinary networking, peer support, team building with a project director, communication with technology support services, and administrative recognition. Each team was allowed to use the supporting funds to accomplish their goals. The CEHS team initiated the project last summer by attending workshops to learn about and explore various technologies currently available. Using this information, we began to implement the following schedule of project activities for this year:

Summer 1996
Redesign of course outlines
Selection and purchase of commercially produced software for courses
Home page authoring and development training for faculty
Multimedia integration and presentation training for faculty

Fall 1996
Development of multimedia packages
Attendance at technology conference/workshops by faculty
Continued faculty training - Internet and use groups
Attendance at technology conference/workshops by faculty
Multimedia authoring and development training for faculty

Spring 1997
Teach revised course one
Develop initial Internet communication links with public schools
Develop student mentoring program with off-site students
Make changes to revised courses
Year one project evaluation

Having completed two-thirds of our activities, we have many suggestions and recommendations for new technology users. Multiple levels of support are needed. Peer support, availability of an in-house project director to resolve immediate problems, professional computing staff assigned to projects, and a room and equipment coordinator sensitive to faculty and project needs greatly contributed to our successes. Meetings with peers to discuss projects, problems, and issues provided encouragement and resolutions for problems when things were not progressing as planned. Classrooms and labs easily accessible to both faculty and students with a nearby help desk are essential. The greatest problems arose from an institutional lack of preparedness to provide the needed resources. The University did not anticipate the increased demand for assistance, equipment, and rooms to accommodate increased faculty and student technology usage. The challenge of new technologies should be in mastering their use within your discipline. There needs to be a match between University goals and the funding and resources that it can provide to accomplish its mission. Failure to do so creates significant negative reactions toward both technology and the institution from faculty and students.

Despite many first semester problems, the CDI project has accomplished its basic goals in the College of Education. New faculty are using technology in their classes. Not only are they using the technology, they have consciously redesigned their program curriculum to include a variety of technologies essential for our students' future success. Our project is a model of current curricular and instructional developments in the preparation of pre-service teachers. We are using the recommended standards (NCATE) for faculty in colleges of education and standards for the training of teachers, and developing innovative curriculum and projects that weave the required technological skills into a remodeled undergraduate curriculum.

Project Significance

The College of Education and Human Services at Seton Hall University is attempting to develop teachers who are reflective practitioners with the depth and breadth of knowledge needed to make informed decisions about learning. Teachers have academic freedom and considerable autonomy about the teaching methods they employ. We want our faculty and students to have the knowledge they need to make curricular choices about technology. Learning is more than a process of transmission. We don't perceive our students as empty vessels passively waiting to be filled. We subscribe to the current educational view that learners are active beings who construct, interpret, and reconstruct rather than simply absorb knowledge (Apple, 1982; Freire, 1987; Giroux, 1988; Goodlad, 1984; Kelly, 1955; etc). As Kelly (1955) says, the learners are scientists who hypothesize about how the world works and
use the new understandings they have gained to reshape the mental constructs they use to make further predictions. Here the learner has more control of the process of knowing, and the teacher, in the words of Giroux (1988), not only promotes academic achievement, but also endeavors to "empower students so they can read the world critically and change it when necessary" (p. xxxix). What better way to support and strengthen democratic ideals in our society? Apple and Beane (1995) cite conditions necessary for a democracy to exist. These include a recognition that democracy is a process requiring creative involvement in the lives of individuals and groups, and an organization of our social institutions to facilitate this process. We commenced our technology saga with Pahl and Pogo, but because of an institutional commitment to academic freedom, active, involved faculty, and a well-planned Curriculum Development Initiative we are ending this chapter on an optimistic note with Oliver Hazard Perry, "We have met the enemy and they are ours" (Trager, 1994b).

We acknowledge Seton Hall University for supporting the Curriculum Development Initiative grants described in this paper.

TEECH Lessons Learned: Strategies for Facilitating Communication in Teacher Enhancement

Joni Falk  
TERC

Gloria Jacobs  
TERC

Jack Lochhead  
TERC

Bridget Mooney  
TERC

TEECH (Teacher Enhancement Electronic Communications Hall) is a three year project, funded by the National Science Foundation. It aims to advance the work of Teacher Enhancement projects by fostering increased collaboration among leaders in teacher development. TEECH endeavors to draw on the strengths of over one thousand principal investigators (PIs) and senior staff of teacher enhancement grants from the National Science Foundation, the U.S., State, and local Departments of Education. Its purpose is to encourage communication, collaboration, joint exploration, and pooling of this community’s collective resources.

TEECH’s first major task was to determine whether its constituents could in fact be considered a community. We needed to understand if they had common backgrounds, common interests, and an agreed upon need to communicate more with each other. We needed to ascertain what would tempt PIs to participate in an electronic community and what would deter them from doing so.

Initial Needs Survey
An initial needs survey (Falk, 1996) was sent out to 465 Principal Investigators (PI) and we received 255 responses, a 57% response rate. Their responses to our survey revealed that PIs of teacher enhancement grants could not be considered as one cohesive community. The only factor that all PIs had in common was that they had obtained funding in order to conduct a teacher enhancement grant. The backgrounds of these PIs spanned a broad spectrum of expertise that included fields as diverse as psychology, geology, discrete math, genetics, neurology, engineering, teachers, principals, administrators, physicists and chemists. What they shared was that in some capacity they were working with teachers in grades K-12 to improve math or science education.

While these Principal Investigators did not share a common background, a common professional vocabulary, or a common theory of teacher change, we hoped that they would use the diversity of their backgrounds to enrich each other. We were encouraged that they identified themselves as being most interested in discussing shared topics of concern such as Teacher Change, Professional Development, Assessment and Educational reform. In fact they rated these topics higher than their specific interest in either math or science or a specific grade level range to which their project was aimed.

In order to effectively begin to facilitate an electronic community it was important to understand how participants were using the Internet. We found that 91% of respondents had access to the Internet. 84% replied that they had used e-mail, 56% had used gopher, 46% had used mailing lists, and 41% had used the World Wide Web.

Respondents were asked to rank the purposes for which they use the Internet. Communication was the most frequently cited purpose (79%). This was followed by browsing and exploring (53%), retrieving information (53%) and posting or publishing was the least frequently cited among PIs at (35%). The results suggested that these PIs were more comfortable retrieving information than they were posting information.

PIs were asked what would tempt them to connect to an electronic community. Their responses revealed that they were interested in three main categories: connecting to other PIs, sharing between projects, and gaining access to information. Some of the reasons expressed for wanting to connect with other PIs included joint proposal writing, seeking individuals with expertise for collaboration, and gaining advice from others on running a project. PIs expressed that projects would benefit by sharing with each other solutions to common problems, tentative findings, and successes and failures. Information that PIs wanted access to included proposal information, material development, resources, and funding information.
PIs also described many factors that would dissuade them from connecting to an electronic community. These included (in order of frequency) time, quality, volume, access, cost, format, technical expertise, organization of the community, equipment, and abuse of communication. Time was stated as the most common stumbling block. Issues of quality that were expressed concerned fear of "long windy conversations" and "exchanges of jargon and phrases." Many were concerned about "receiving excessive e-mail" and "difficulty accessing a network."

**Multiple Strategies to Facilitate Communication**

During its first two years TEECH has developed multiple strategies to meet the needs of this heterogeneous community. These have included listservs moderated by leaders in the field, electronic seminars, on-line lectures given by leaders in the field made available on our Web site through RealAudio and text copies, and a database of PIs and their teacher enhancement projects. While listservs were intended to encourage active communication between PIs, the posting of lectures, in both text and audio formats, was intended to meet the needs of those PIs who wanted to use the site as a resource rather than as a vehicle for communication. We also have made attempts to combine these formats, having a RealAudio discussion with a listserv connected to it.

**Evaluating Participation**

Although our Web site is set up to collect Web site statistics these statistics are often difficult to interpret. While they tell how many "hits" a particular page receives it is not clear how many people this count reflects. What is clear is that more people tend to connect to the TEECH site in order to hear or read lectures than they do to engage in a listserv conversation.

The listservs that TEECH has run have varied in their rates of participation. On average listservs tend to run 8 - 12 weeks before participation begins to drop markedly. Our most successful listserv to date was a discussion entitled "After the Workshop Ends; Difficulties Reflections and Strategies." This listserv had 119 subscribers, and over 250 postings. Slightly more than half of the PIs (64) posted messages to the list while the rest received messages but did not post.

A follow-up survey was sent to the 119 participants of this list and 38 PIs responded. The results indicated that of the respondents 89% found the discussion to be useful, 68% shared parts of the conversation with other colleagues, 24% connected or corresponded with PIs who had posted to the list as a result of their participation, and 91% responded that the discussion was informative or relevant to their project's work. Fifty-five percent of the respondents reported that they had posted to the list; 45% reported not having done so. It is interesting to note that on most questions there was no significant difference between those who had posted to the list and those "silent participants" who had only read the messages. In particular both groups overwhelmingly thought that the discussion was useful (95% of contributors, 82% of non contributors) and relevant to their project's work (86% of contributors, 82% of non contributors). While 67% of those who had posted shared the conversation with their colleagues, a similar 65% of silent participants had done so as well. The only area in which we saw a significant difference between contributors and silent participants was whether they corresponded or collaborated with a PI who had posted to the list. On this question 43% of active participants reported having had such a follow-up communication where as none of the silent participants reported doing so. (p=.002 by Fisher's Exact Test)

**Listserv Dialogue**

Many respondents have written that it has been meaningful to them, both personally and professionally, to participate in a dialogue with other Principal Investigators. Two examples are:

- It is always good to hear that other people are struggling with the same problems. It was interesting to hear the range of solutions to the problems proposed.
- A chance to have informal discussions with peers around the nation in the comfort of my own office! Since having young children, the time I can spend traveling has been radically decreased. I have felt cut out of some of the discussion with national colleagues.

While the tenor of the listserv dialogues has generally been respectful and friendly there was often a competitive edge to the conversation. It sometimes appeared that there was a greater desire to express what a project had done than to learn from, or to collaborate with, others. While the majority of those who participated felt the tenor was positive some expressed a concern that this was not always the case. Two comments that express some reservations follow:

- Was not at first sure whether the tone was coming from the heavy academic orientation of some or whether the lack of sitting face-to-face in a room with other discussants caused some to feel they could be disrespectful of ideas—disembodied ideas.
- Often, PIs talked about their own project without talking about its particular strengths, challenges or weaknesses. There was also some “grandstanding” that wasn’t particularly substantive or reflective.

The pace of the dialogue was often quick. Although e-mail dialogue is asynchronous, so that participants do not have to participate at the same time, the conversation is a
moving target. It is often difficult to jump in the middle, especially when the conversation seems to shift its direction. Some of the difficulty in joining such a conversation is expressed particularly well by a subscriber to one of the TEECH lists who writes why she has not posted.

Why have I not actively participated thus far? I would say that lack of time has been the main reason. I have saved various messages, including your message of two weeks ago, with the intent to respond, but framing a brief thoughtful response takes some time and as time passes it seems that the heat of the opportunity has passed. Perhaps with time I will feel that I can just dash off a quick response or thought, but given the spunky nature of some of the discussion, I'd rather make sure that my words are appropriately chosen.

In this particular case the subscriber says the main reason that she has not participated is “time.” It is not that she has not had the time to read, but that she would like to be careful in composing a response, and by the time she could do that, the conversation would have moved on.

**Lessons Learned**

In reflecting on the listerv dialogue we have decided to make several changes in the future format of TEECH listservs. In developing true communities of practice it is important to nurture a sense of trust, a sense of a common vocabulary, a common goal, and common interests (Gal, 1993). The audience of PIs is very diverse. This group changes each year, when new grants are awarded. The PIs have professional affiliations that are usually much stronger than their affiliation with other PIs of teacher enhancement. Our question at this stage in the project is no longer “are they a community?” but “how can we better facilitate a collaborative community of practice?”

In our last year of TEECH we are determined to focus on smaller sub-communities where there is a clearer sense of a shared background and perspective. The aim will be for people to build on these shared experiences and apply them together to the field of teacher enhancement.

In addition we hope to raise the level of trust of those within the listerv and decrease defensiveness and a desire to grandstand, by increasing familiarity of participants with the other participants on the list. We will do this by having listervs that follow face to face workshops. Photographs of participants, abstracts of their projects and biographical information will be shared to decrease the sense that one is speaking to a group of unknown people. Several listervs will be designed explicitly to sustain communication between people who have already begun working with each other, or have experienced a workshop together.

We have come to appreciate that silent participants in a listerv also gain a great deal from listening to the conversation. We will continue to not only appeal to those who like to post but to find forums for those who prefer to retrieve information and to listen to the dialogue of others.

Last, we have come to realize that “teacher development” is eclectic, ununified, and perhaps just emerging as a field. Professional conferences specifically targeted towards professional development have just begun to emerge within the past two years. While communication between PIs is important, it is equally important to build a core of expertise by gathering lectures and debates of leaders in the field and making them available to a wider audience of those in teacher enhancement. Hence, we will expand our efforts to make TEECH a vehicle for dissemination of key lectures and resources in the field while continuing to encourage communication and collaboration between Principal Investigators.

INTEGRATING TECHNOLOGY INTO ELEMENTARY SCHOOL WATER QUALITY STUDIES

Julia R. Hampton  
Miller Elementary School

Vicki C. Allen  
Miller Elementary School

As the Internet and its related computer technologies enter K-12 classrooms, teachers should be encouraged to use these tools to supplement and expand present curriculum. However, many teachers are not versed in computer technology and unsure how best to develop it. If teachers are given proper staff training and development, computers can be a wonderful addition to the educational environment, unlocking doors and exciting students’ natural curiosity and desire to learn.

In West Virginia approximately 400 teachers are learning about the Internet and its educational potential through the West Virginia K-12 RuralNet Project. This is a National Science Foundation (NSF) funded, three and a half year program of faculty development and training run cooperatively through the state’s two universities. Participants attend a five day workshop designed to teach computer/Internet skills. This is followed by two on-line courses developing teacher awareness and understanding of integrating computer technology into everyday teaching. With the help of this project, we have developed an elementary water quality unit.

Students participate in a project which combines technology, a study of current water conditions, and inter-generational experiences. Computer technology plays a vital role in the students’ water quality unit. The children use HTML lesson plans to begin studying the Ohio River, learning about topics such as flooding and water pollution. They use the Internet as a research tool to learn even more about the River and to contact other RuralNet schools studying water quality. They take a field trip to a local stream, Four Pole Creek, which empties into the Ohio. They examine stream life and collect water samples for water quality experiments. Through one of RuralNet’s partners, The Global Rivers Environmental Educational Network (Project GREEN), students enter their data directly into a water quality database and extract water quality information entered by other students from around the world.

The teachers use a whole language approach emphasizing curriculum in science, social studies, language arts, and writing. The multi-media components include: tape-recorders, a video, Internet access, graphics, text, WordPerfect, and Microsoft’s PowerPoint. Students use technology to learn about the water cycle, water quality, the Ohio River, past flooding, current water problems, and river preservation coalitions. Students use Internet research, e-mail, and personal interviews to get information which they use to make written and oral presentations for parents, guests, and senior citizens. Students use computers to type reports, take notes, and write stories about their experiences. These activities are excellent examples of how computer, and specifically Internet, technology can be added to make learning more interesting and fun for students.

Project Description

In the course of water quality study, students will discuss the importance of water in our everyday life. Using software programs, they study the water cycle and ground water and develop the vocabulary of the hydrologic cycle. The software programs Hydrologic Cycle Version 1.01 by IBM (Haebelin & Kulda, 1986a) and Ground Water Version 1.01 by IBM (Haebelin & Kulda, 1986b) are part of IBM’s Earth Science Series and provide lessons and quizzes for the topics.

Students study macro invertebrate animals using pictures and information in the Field Manual for Water-Quality Monitoring by Mark K. Mitchell and William B. Stapp (1995) that can be ordered from Project Green. A matching card game is played with cards made from photocopied pictures of the macro invertebrates. The rules are similar to the card game Rummy. Rules for playing can be found at the RuralNet pages, http://www.marshall.edu/coe/wvrk12/lp-safe_water.html. After familiarizing themselves with these macro invertebrates and their importance in determining water quality, students take a stream walk to the local creek. Using nets and seine screens, they collect macro invertebrates, identify them, and catalog them in their notebooks. Upon returning to the classroom, the students analyze the stream quality by rating the macro invertebrates using the Macro invertebrate Taxa Groups table found in the Field Manual for Water-Quality Monitoring. They then report their findings to
Students use the lesson plan Microorganisms in our Water at http://www.marshall.edu/coe/wvkr12/ehtml/microorg.htm. This lesson directs students in discovering the variety of microorganisms and how microorganisms can effect water quality. Further analysis of water quality is done by chemical testing of tap water, fountain water, and stream water. Using materials provided by Students Watching Over Our Planet Earth (SWOOPE) called The Tapwater Tour from LaMotte (Johnson, Anger, & Troxel, 1989), students test samples of the three water types for pH, chlorine, iron, copper, and hardness. They then do a water quality report and data comparison.

To increase the students’ awareness of government involvement in water quality, the lesson Who Controls Our Water Quality at http://www.marshall.edu/coe/wvkr12/ehtml/who-cwq.html is used. This lesson has students use the Internet to find out what government agency is responsible for water quality. The students make a class terrarium to demonstrate the water cycle. They review water sources, water vocabulary terms, and the recycling of the earth’s water supply. They explore the meaning of a watershed and call the local water department to get information on sources of water for our community.

As they study the Ohio Valley watershed, students watch the video “A River Called Ohio” (Mitchell, 1995). This recent film gives a history of the Ohio River. Brain-storming activities, prior to the viewing, show their current knowledge of the River. The boys and girls work in teams at the computers and follow RuralNet student lesson plan to find river facts: (http://www.marshall.edu/coe/wvkr12/ehtml/ohio-river.htm). Hyperlinks lead to the Ohio River Valley Water Sanitation Commission’s home page (ORSANCO) and the EPA’s Office of Wetlands, Oceans, and Watersheds. Students record information on a teacher made research worksheet giving the origin of the River, its length, the states it flows through, and its final destination. They also look for the number of people who use it as a source of drinking water and for its economic impact.

Students try to find a map of Ohio Valley Watershed which they can print. At this point the best available one is in not on the Internet, but in the U.S. Environmental Protection Agency’s (1991) manual, Always a River: Supplemental Environmental ED Curriculum on the Ohio River & Water. On a Xerox copy, each student outlines the two rivers which unite to form the Ohio. Then they mark the 15 other rivers that empty into the Ohio. The group gains access to the KidScience Home Page on the Internet, types in their data, and sends it to the Water Sources West Virginia Date Input/Output DataBank. (http://paa.mhpcc.edu/waterWatch/watersources/html/home.shtml)

The class divides into groups and cooperatively creates a bulletin board which depicts the River. They split the River into sections, draw in its tributaries, and depict life along the banks. The emphasis is primarily on our immediate area. To continue their understanding of water quality in the Ohio River, students tour the West Virginia American Water Company Treatment Plant, and learn more about the purification process for drinking water. The drinking water in our area is drawn from the Ohio. Afterwards the class eats a picnic lunch at Harris Riverfront Park and gets a first hand, up-close view of the Ohio.

At another session, a representative from the US Army Corps of Engineers visits to discuss its role in watershed management, and to explain navigational and flood control dams. The representative explains how during the early expansion years of our country, the CORP gradually assumed water management responsibilities.

Using WordPerfect, students practice writing paragraphs and composing letters for e-mail correspondence with keypals who live in other River Cities. Before composing their letters they use Netscape Navigator to access the Miller School home page (http://boe.cabe.k12.wv.us) and link to the Huntington home page to read about the town. They type several defined paragraphs, one describing themselves, another telling something about Huntington, and concluding with their favorite river activity. They also read and discuss excerpts from Wind In the Willows found in The Junior Great Books Program (Great Books Foundation, 1992). They read a play version of Huckleberry Finn. These selections help them as they discuss animal activities and human life along a river.

Students continue Internet research by using search engines to learn about flooding and water pollution. Using the RuralNet lesson plan The Ohio River at http://www.marshall.edu/coe/wvkr12/ehtml/flood.htm, they learn more about flooding and river watchers. They access home pages of schools participating in water studies in other states and countries. They learn about The Ohio River Sweep and group efforts to keep the river clean. Using hyperlinks from the Miller home page, they begin preparation for an oral history project. The boys and girls read an account of a victim’s experience in the Huntington’s 1937 flood. They use additional printed materials and work in teams to complete a 1937 background work sheet. They practice interviewing, then make appointments, and arrange to tape a visit with a 1937 flood survivor. After completing the interviews, students return to class and share parts of their tapes and videos. They listen to them again and take extensive notes using Word Perfect. They begin the process of writing, editing, and revising. Using Alpha Smarts, students work on reports at home where parents can help. In the classroom, they
transfer their work to a WordPerfect document. After they spell check and format their work, the teacher helps edit the story. Final drafts are compiled into a booklet.

Once the stories are written, students make PowerPoint slides to share excerpts from their reports. The scanner is used to add pictures they have found of the 1937 flood. The students invite parents, the person interviewed, and friends to the center. The reports are presented using the computer and a LCD panel. Students give the visitors copies of the finished booklets and show how they used technology in their learning process. In follow up sessions the group goes to the Woodlands Retirement Community for lunch. Using a lap top and the LCD panel the students gives their presentation to a group of the residents. A number of parents join students in a field trip to the Robert C. Byrd Locks and Dam. They tour the museum, eat a picnic lunch, and watch a boat as it enters and exits the locks.

Evaluation

The success of the project is measured by the interest, skills development, and participation of the students. It is gauged by their completed work. They have a portfolio which includes Internet research notes and printouts. The portfolio has a benthic invertebrate analysis, water quality report, and a map with the Ohio River and its tributaries. Their work shows copies of the e-mails they sent and received. The portfolio also has a completed 1937 flood background work sheet. There is a completed summary of their interview responses, a rough draft of their report, an edited manuscript, and a finished report. Students have a tape or a video of the actual essay and some have pictures of the person whom they interviewed. Each student has a booklet of collected oral history stories and completed slides from the PowerPoint presentation.

Success is also measured by the effectiveness of using Alpha Smarts as a writing tool to improve the quantity and quality of writing. When students write at home and transfer the file to the school PC for formatting and spell checking, this allows maximum use of class computer time. This gives students who have no “home computer” an equal opportunity on a writing assignment. It provides a less expensive way to get more “keyboard time.” This is applicable to other learning experiences and beneficial to the entire learning community. Once our academic goals are met, additional successes are determined by the students new awareness of the community in which they live. Their field experiences provide interaction with Ohio River projects, community resources, and senior citizens.

The authors realize that there can be many complications with using the technology of computers and Internet access. Teachers need to be flexible and have alternate plans for times when there are technical failures. Technology can be so beneficial and time-saving on one hand and can be frustrating and time-consuming on the other. This is all part of the learning process for both teachers and students.

This is a class unit which can be duplicated in many places. It can be modified, enhanced, and adapted to fit almost any area of our state, the United States of America, or the world. Some of the ideas came from e-mail messages from peer teachers in the RuralNet program. Others came from Internet research. Since William Smith Miller Elementary is a West Virginia Education designated technology center, there are opportunities to share this project with others.

Faculty Development — 363
In the Fall of 1996, the Double Eagle Elementary School opened its doors to approximately 630 Albuquerque Public Schools (APS) elementary students. Considerable time, energy, and resources had been spent to create a climate at the Double Eagle Elementary School conducive to the incorporation of technology to support learning for these students. Phase One was complete. This phase included the construction of a main building and auditorium. In the main building were three classrooms, a computer lab, and a library-media center. Portable classrooms were in place for the first instructional year. Two computers and a printer for each third, fourth, and fifth grade classroom and 12 computers and four printers for the computer lab had been ordered. Apple IIGS computers had been donated so that two computers and a printer could be placed in each first and second grade classroom.

Phase Two construction began with the opening of school and is scheduled to be complete for the opening of the school's second instructional year (1997-98). This phase includes permanent classrooms and a cafeteria. The DynaComm system will be completely installed, facilitating intranet and internet connectivity for each classroom. Upon completion of Phase Two, this system will provide each classroom with digital, audio, and video connections. The infrastructure existed for school-wide implementation of an educational program that has the power to use technology to support and enhance existing learning opportunities and to push learning vistas in new and creative directions. That infrastructure will expand and be elaborated during the school's second year. The context for remarkable educational potentials and innovations has been established. What remains is to realize these potentials. Toward the goal of realizing these potentials, the Albuquerque Public Schools (APS) and University of New Mexico (UNM) Double Eagle Collaborative was created. This two year collaborative has as its central mandate the goal of promoting staff development and instructional support systems to facilitate the design and implementation of a school-wide, technology-using curriculum.

The APS/UNM Double Eagle Collaborative

The APS/UNM Double Eagle Collaborative established a two year partnership between the Double Eagle Elementary School and UNM's College of Education program in Mathematics, Science, Environmental, and Technology Education (MSET) with particular emphasis on professional development activities and the integration of technology. The gist of the collaboration focuses on multiple layers of staff development activities that include mutual feedback between scholarship, teaching, integration, and application especially as it pertains to: 1) student learning, 2) technology integration, 3) staff development, and 4) classroom management.

Forming the Collaborative

APS and UNM have a long history of successful collaboration. Building on this history, the authors met to discuss a site-specific collaborative during January of 1996. A final proposal resulted from those meetings in early March. Because of the unique nature of this collaborative, the proposal was shared with a wide range of individuals during March, April, and May. Supporting signatures were obtained from the APS Director of District Technology, the APS East Region Assistant Superintendent, the APS Assistant Superintendent of Curriculum and Instruction, the UNM-MSET Coordinator, and the UNM Associate Dean of Research and Graduate Studies. The endorsed proposal was submitted to the Dean of the UNM College of Education and the APS Superintendent. This six month process of conception, sharing, and nurturing culminated in the collaborative's inclusion in the 1996-97 collaborative contract between the two institutions finalized in July, 1996.

Funding the Collaborative

The collaborative is funded by an "exchange of services" agreement between the two institutions. Two classrooms, a second grade and a fourth grade, at the
Double Eagle Elementary School were reserved for the collaborative, and no teachers were hired for those classes. Instead, APS released the equivalent funds to UNM under the contractual agreement. UNM redistributes those funds to support three doctoral fellowships and tuition stipends for preservice and graduate students. UNM assumed responsibility for instruction in the two classrooms and support for school-wide inservice activities. This funding agreement resulted in no additional expenditures for either institution.

Creating a Learning Community

Mecklenburger (1994) sharply challenges traditional academic practices as too often removed from the needs of real communities. The Pew Charitable Trust “Roundtables” present an image of educational reform that is increasingly assailed by charges of irrelevance, technologically resistant, and excessively beholden to research agendas at the expense of teaching and public service (Baker, et al., 1994). In contrast to traditional academic practice, a subset of the growing interest in educational restructuring has shifted to a national conversation about “service learning.” Lynton (1995) affirms the relevance of service learning at all levels of education. Throughout the literature runs the notion that institutions of public education need to forge formal and mutually beneficial relationships with their supporting communities, and that the tradition of academic study isolated from the needs of particular communities is an increasingly unaffordable luxury. Instead, Boyer (1990) offers an image of “complete scholarship” by advocating an institutional balance among four types of scholarship: teaching, discovery, integration and application.

Consistent with Schon’s (1995) notion that practice generates knowledge no less than knowledge informing practice, the APS/UNM Double Eagle Collaborative is aimed at producing significant learning for professional educators from both institutions participating in this partnership, and as a consequence, significant learning for students at the Double Eagle Elementary School. Joint participation by UNM faculty, doctoral students, and preservice students and APS teachers and administrators facilitates the service learning model by bringing together a wide range of academic and professional credentials as well as significant life experiences while simultaneously setting the learning act squarely in the domain of informed practice.

The collaborative is designed to capitalize fully on the creative energy and focused power of two cooperating institutions jointly dedicated to the goal of improving education. By combining a pool of energy and talent, the collaborative seeks to create a learning community with participants assuming a variety of roles and responsibilities.

APS Principal/UNM Faculty. Primary leadership for the work of the collaborative is jointly supported by the school’s Principal and a lead faculty member from UNM (the authors). Shared responsibilities include 1.) selecting, supervising, and evaluating participants based on guidelines established by their respective institution, 2.) jointly planning workshop, inservice, and staff development activities, and 3.) jointly assisting all participants with the planning, development, and implementation of curriculum development and technology integration.

Double Eagle Staff. All classroom staff were selected by the Principal and agreed, as a condition of employment, to participate in the study of technology, curriculum, and the teaching/learning process as framed by the collaborative. In addition to regularly required classroom responsibilities, the Double Eagle Staff assumed responsibility for 1.) working to further their competence in the use of technology as an instructional tool, and 2.) to participate in and continue a commitment to extensive staff development in the use of technology as an integrated instructional tool. Since APS elementary students are released early on Wednesday afternoons, all teachers agreed to participate in workshops for two hours the first and third Wednesdays of each month as well as to work with others within the learning community on a continuing basis.

Double Eagle Interns. Four UNM preservice teacher licensure candidates who had completed all prerequisite course work for the student teaching experience were selected based on a demonstrated interest and emerging expertise in the integration of technology into learning. These Interns’ applications were reviewed by the authors, the candidates were interviewed by each of us individually, and the final four were selected. The four preservice Interns were teamed. One team was assigned to a second grade classroom, and the other team was assigned to a fourth grade classroom. These Interns assumed classroom responsibilities for the entire academic year commensurate with District criteria as well as participation in on-going staff development. Each team took responsibility for the conduct of classroom curriculum and instruction with rigorous and sustained supervision from expert teachers described below as Double Eagle Fellows. Four new Interns will be selected for the Collaborative’s second year.

Double Eagle Fellows. Three doctoral fellows with expertise in elementary education and technology integration were selected and placed 2/3 time (approximately 20 instructional hours) at the Double Eagle. These Fellows were selected for their successful elementary classroom experience, their experience with in-school technology teacher support and training, and their success as doctoral students in the MSET doctoral program. Their responsibilities included support of the two teams of Double Eagle Interns, assisting these Interns with classroom management, curriculum planning, delivery of instruction, and...
creating appropriate learning environments. In addition, the Fellows share responsibility for the conduct of on-site methods courses for the Interns. Second, these Fellows are responsible for working with Double Eagle staff to support their efforts to integrate technology into classroom practice, to assist with the design and implementation of technology using curriculum, to promote the development of technology skills, and to create and maintain the school’s computer lab and primary literacy program. Third, Fellows are taking leadership roles in obtaining, placing, and maintaining technology resources while helping to build staff expertise during the two year duration of the collaborative so that Double Eagle staff can assume those responsibilities at the end of the collaborative. Fellowships were granted for the two year duration of the Collaborative.

**ITS Participants.** One-third of the Double Eagle Staff self-selected to pursue a graduate degree in Integrating Technology in Schools (ITS). These ITS participants met the requirements of the UNM Office of Graduate Studies, criteria established for admission to the MSET Program, and are responsible for their own tuition. The ITS Program (Norton, 1994; Norton & Sprague, 1996) was adapted to offer some parts of the program on-site. These adaptations were designed to assist Double Eagle ITS Participants to assume leadership roles at the school and to play a role in the on-going staff development and curriculum design and implementation work at the school. As their graduate studies advance, these teachers will assume increasing responsibilities for staff development and technology integration in hopes that these activities will continue beyond the two year collaborative.

**Report from the Trenches**

Although our experiences with a school/university collaborative which focuses so intensely on school-wide reform of curriculum and instruction have just begun, we believe the following captures many of our experiences.

**Placing Technology at the Center.** As we embarked on this collaborative, many warned us that we were asking for too much too fast. They cautioned for a slower, more cautious, less demanding agenda of change. Our experiences say otherwise. Perhaps the role of technology has served to facilitate the change process by focusing attention on technology instead of overly targeting more deeply held beliefs about curriculum and instruction. A school-wide commitment to technology has served to divert attention from more threatening issues to a shared, more neutral issue.

**Centrality of Communication.** The principal and faculty member meet often, although generally on an impromptu basis. We make sure that each of us keeps the other posted on plans, activities, concerns, and events. We both attend all events - inservices, faculty meetings, and related committee meetings. The faculty member meets regularly for weekly lunches with the Fellows. At these sessions, we update each other, plan inservices, discuss the Interns’ progress, and talk about curricular activities with the Double Eagle Staff. The faculty member also teaches the courses for the ITS Participants, so is in close contact with them. When concerns are raised by any member of the learning community or communicated through any member, those concerns are addressed. Whenever appropriate, concerns are raised at meetings with the entire community so that they are made public and addressed publicly.

**Centrality of Modeling.** Many of the activities of the collaborative - particularly the bi-monthly inservices and the ITS course work - are abstract. Yet, it is not easy to translate theory into practice, and what seems to work best is to provide models for teachers. Thus, the faculty member and the Fellows have actually written curriculum, designed and/or located materials, and created entire units. We have then approached grade levels asking them to implement, with our support, these units. Faculty and Fellows have modeled teaching strategies, assisted classroom teachers in implementing units, and worked with Double Eagle students. As teachers actually practice and reflect on their practice using insights gained during inservices and graduate work, they are beginning to develop an image of how technology integration might actually be accomplished.

**Providing Resources.** Although classroom computers and printers, as well as lab computers and printers, were ordered from a community business before school started, they have been slow in arriving. The firm commissioned to provide the infrastructure after completion of the physical construction of buildings has also been slow to provide services. We have learned that our urgencies are not always those of the external vendors with which we must work. Additionally, these vendors do not always understand educational learning environments or a vision of technology integration in schools; instead, they come with experiences and perceptions more closely in line with private and governmental needs. We are learning to work with these agencies, to articulate clearly how our needs are different from their expectations, and to act in our dealings with them as business people not educators.

Perhaps our greatest frustration and our greatest victory center on the difficulties with resources. We received a small shipment of classroom computers which were placed in fifth grade classrooms. We were then promised the remaining computers within two weeks, postponed for two more weeks, and finally postponed for three more weeks. Soon, there was a strong undercurrent of frustration throughout the school. Why were there no computers for the other grades? Why were they learning so many new and exciting ways to change teaching and learning only to...
be denied the opportunity to try them? Perhaps it would be better to return to a school-wide lab model and give up classroom integration? The bad news was an atmosphere of frustration and a feeling that the entire project might be on the verge of imploding. The good news was that teachers were learning and were anxious to begin experimenting with new ways of teaching. A school-wide meeting which brought the concerns into the open and clarified exactly what was happening with the vendors seemed to relieve pressures. Luckily, the remaining computers arrived within a week.

Some Thoughts on the Participants. For the Interns, plunging headlong into full time teaching was a shocking experience. No one understands the demands of teaching until they try it. As we near the end of the first semester of the collaborative, the Interns have learned more than they ever expected. The incredible opportunities for situational learning keep them and the Fellows constantly talking, evaluating, and reflecting. The Interns have successfully assumed responsibility for the on-going conduct of classroom instruction. The Fellows find their most important roles with the Interns to center around curriculum planning, modeling instruction and discipline related to specific concerns, and helping Interns deal with situations that arise for which they have no experience.

The hard work and time the Fellows spent with Interns during the first two months of school has resulted in a growing self-sufficiency among the Intern teams. Fellows are increasingly able to spend less time with the Interns and more time with the Double Eagle staff. They are successfully collaborating with Double Eagle staff to design curriculum. Increasingly, teachers approach them with questions not just about hardware problems but to solicit ideas for classroom computer activities to support their curriculum. The Fellows have been able to engage grade level teachers in creating curriculum that successfully integrates classroom technology into the on-going flow of instruction.

The collaborative has been most challenging for the Double Eagle staff. Each of them had agreed, when hired, to participate in the study of technology, curriculum, and the teaching/learning process framed by the collaborative efforts, but none of them had a vision of what that really meant nor the effort it would entail. Most of them had only limited experience with the integration of technology to support curricular goals. Most of their experience with computers had centered around a weekly visit to a school-wide computer lab. Since the work of the collaborative was designed to de-emphasize a computer lab configuration and to emphasize the use of classroom computers as an integral part of instruction, teachers were confronted with the need to know more about computer hardware and software, the need to move from whole group instruction to alternative strategies like committee cycles, and the need to learn alternative ways of planning and presenting curriculum. Most of them had little or no experience with collaborating in curriculum design, and the notion of planning and implementing curriculum across classrooms is new and challenging.

Conclusion
Opening a new school is an exciting, challenging, and frustrating experience. Beginning a new school/university collaborative without precedents for this particular model and with only broad goals and even more broadly defined roles and responsibilities is equally exciting, challenging, and frustrating. Each of us - intern, fellow, staff member, graduate student, principal, and faculty - embarked on this adventure with a strong commitment to a vision that is transformed daily. Each of us brought with us our own experiences and our own expectations. When it came to bridging from a theoretical model to a model of practice and action, none of us really knew what to expect. We had all agreed to become part of a learning community and that is exactly what we have done - learn.

DEVELOPING AN INTERNET ENABLED NETWORK OF PROFESSIONAL DEVELOPMENT SCHOOLS (PDS)

Thérèse Laferrière
Laval University

Since its inception, the Professional Development School (PDS) model has inspired the establishment of a network of associated schools as a constituent part of the four-year integrated education program for future teachers at Laval University, Quebec City, Canada. In the context of a formal liaison between the university and associated schools, the aim is to build a community of educators who would assume responsibility for the orientation, organization, implementation, and evaluation of the preservice and inservice education of teachers. The relation between the university and the associate school is therefore intrinsically structural and pedagogical in ways this paper will describe with a focus on the potential of new technologies, such as, tele-learning, to enhance the PDS model. The network is part of the Tele-Learning Research Network (TL-RN) which is one of Canada’s fourteen National Centres of Excellence (NCE).

Tele-Learning Research Network (TL-RN)

All told, TL-RN is made up of 140 researchers and their partners spread all over Canada, which includes the sub-theme on Educating the Educators devoted to exploring how technology can support learning and growth among professionals engaged in educating a new generation which, at times, is more technically advanced than the professionals themselves.

The aim of the Tele-Learning Research Network sub-theme, Educating the Educators, is to better prepare students for a changing workplace and society. Its organizing principle, Educating a new generation for a network and knowledge driven world, guides the action and reflection of practitioners and researchers as they collaborate in preparing teachers to join with learners in exploring the advances in information and communication technologies which are permeating these global developments.

Tele-learning refers to the professional knowledge which is acquired mainly through a network of technological media defined as complementary or linked to various other networks. In fact, these networks reach far beyond the local school or university but also include among their active members teachers, students, undergraduates and various other experts from a number of schools and universities.

Teachers have to develop the means of participating in the critical and ongoing development and assessment of these new technologies’ potential and consequences for learning, creativity, collaboration, and community. A partnership among universities, governments, schools, and industry is required to bring the nation’s teachers in on this process of educating the educators, in how these new technologies are changing the face of education and the way the world communicates and does business at large.

The research objectives of the tele-learning professional development school (PDS) project include: How can tele-learning tools create functional and collaborative communities of inquiry?; In what ways can tele-learning shrink the gap between sites of learning and sites of practice?; How do the uses of technology for learning change the current practices of participants? The project is testing the limits and gains to establishing virtual professional communities. The main sites are located in Quebec City, Montreal, Toronto, and Vancouver.

School-University Partnership (Quebec City)

Laval University has nearly 4,000 students registered in its four-year integrated teacher education programs. The decision to develop an infrastructure for University/School collaboration in the education of educators followed successful pilot studies, and was made by both university and school representatives. Student teachers now entirely do their field experiences and practica in associated schools. The 23 school districts in the Quebec City Region already signed an agreement with Laval University to this effect. The agreement also includes two other dimensions: professional development activities with associated teachers, and collaborative research. Laval University has assigned one teacher educator to each school during students’ field experiences, and is enlarging its presence in the field. Participating schools are highlighting teacher education as one of their key activities in their school’s basic orientation document, and associated teachers are groomed to work as a team.
On the whole, 35 high schools and 100 elementary schools are involved; that is, one third of all the Region's schools. Such a large participation of the schools and the meaningful collaborations contribute to the mammoth task (Darling-Hammond, 1994). As part of Laval University's priorities, the first years of the network have been generously funded. Having reached its full size, the network of associated schools now calls for continuous support to reach its goal (Holmes Group, 1990 & 1995).

As new equipment is received and pilot studies unfold, the likeliness of having these functions supported by advanced technologies becomes an imperative. But this creates another need in the Region, that is, to develop the technological literacy of its professional educators. Attuned to this growing need, the TL-RN teacher educators at Laval University and their school partners are contributing, during the 1995-1999 period, to the infusion of new technologies at three levels by:

1. concentrating their efforts on the establishment of two fully functioning Tele-Learning Professional Development Schools (TL-PDSs),
2. offering workshops and tutoring to educators that are integrating new technologies in their practices, and
3. providing expertise and online resources to other interested classroom teachers, and school principals.

For instance, a one-day conference held a few weeks ago brought together 350 school principals, teachers, and teacher educators involved in the development of technology infusion plans and their implementation. High school students, teachers, principals, and teacher educators involved in the TL-PDS discussed the challenges and issues related to the five pyramidal layers that they have come to identify as critically important in the integration of new technologies in the classroom. These are:

a. awareness of higher standards for education;
b. access to Internet,
c. exploration of new teaching and learning possibilities,
d. development of new routines (teaching and learning), and
e. project-based classroom management and pedagogy.

The Educating Educators team of the Tele-Learning Research network foresees a radically different teaching environment from the one that prevails today. Each of the four sites (Quebec City, Montreal, Toronto, and Vancouver) is working on becoming Internet enabled. To link the four sites in such a way as to grow as members of a virtual learning community is envisioned.

Changing the Education of Educators

The Educating Educators TL-RN team has found it imperative to put in place research on the constituents of the "new" educational situation which may enhance teacher education. They focus on six constituents for making a success of the project: the telos, the team of teacher educators, the technological area, the nature of the learning process, the human context surrounding the learning process, the evaluation of the tele-learning performance.

The Telos

The term tele-learning points to two different meanings: distance and telos. It is imperative for the researchers to investigate both applications of the term. Whereas the concept of tele-presence applies to a variety of information technologies, the notion of intentionality applies to each person engaged in an individual or collaborative learning project. As hands-on computer technologies provide easier access to a wide proliferation of learning resources, it heightens the necessity of self-determination. What is a learner looking for? What does this learning team want to achieve? Which image of oneself does this learning community hold? These are questions that addresses the telos dimension either at an individual or at a collective level.

The Team of Teacher Educators

The university-based teacher educators hold different perspectives and specialities (e.g., Cognitive Psychology, Educational Technology, English Literature, History of Education, Math Education, Social Psychology). School-based teacher educators also have specialized in different domains. They speak different languages, and the creation of a climate favorable to the exchange of ideas between disciplines and school subject matters was the first challenge. Now the task is to create an intersubjective zone of dialogue, a virtually ideal speech situation in sense, in order to sustain the moments of learning and insight.

The Technology

The use of the technological media made by teacher educators, students, teachers, undergraduates and other persons involved, is of an intensive, diversified and inventive nature (Harasim, 1995). Each category of persons concerned call upon various media to get at some information source, to do some other works and to communicate to others the fruits of the accumulated knowledge and identified zones of inquiry. Texts are exchanged as well as schemes, graphics, and other visual messages. The entire communication process (between students, between schools, between undergraduates already linked to different schools, between undergraduates and teachers or university supervisors and professors, etc.) constitutes a system dominated by complementary knowledge building and common sharing, creating therefore an environment imbued with continuous transformation.

The Nature of the Learning Process

The knowledge building which constitutes the aim of the whole Tele-Learning Program, represents quite a challenge. Rooted in a vision that forging and participating in these new community links is in itself an active engagement in the construction and testing of his or her own knowledge, the actual learning, in general, take shape or form through itineraries or projects which have a certain
The human context surrounding the learning process

The proper learning environment operates on the assumptions that a) each person is to assume the responsibility for his/her own learning development, and b) is expected to receive an important support from peers and teachers and to be part of an elaboration process leading to greater knowledge. The cooperation between the participants is at the center of attention (Sergiovanni, 1994). The scope and complexity of the learning to be mastered encourage this cooperation but it is equally necessary to come up with imaginative and effective techniques to reinforce this cooperation.

Teaching is today more and more a collective activity; in the context of a tele-learning system, the situation is even more striking. Graduates must therefore be in a position to face that situation. The classroom is but one of the sites whence they can operate; it is understood that "to be a teacher" will also increasingly mean to be in a position to intervene with competence at the school level where his/her class is located, and within the school and other social institutions located in the sphere of his/her profession.

The evaluation of the tele-learning performance

The evaluation of learning performances, be it of a diagnostic, formative or summative nature, must be consistent with what was desired as learning benchmarks at a terminal stage of learning. Priority will be given to the understanding of various types of knowledge and the mastering of skills (rather than simple memorization and ability to operate as a "jack of all trades"), the availability of the technical media will be thoroughly exploited and the pursuit of individual itineraries and the implementation of projects of a certain complexity and scope will be traced and a personal appropriation and participation in a community project will also be assessed.

Early results

This very development, in concert with the PDSs and tele-learning systems, has a double impact in the change introduced in the training of future teachers. As a consequence, the identification of the changes which will effectively take place becomes another condition to make a success of the desired learning outcomes. Some of the introduced changes can already be identified and their impact is now being assessed.

The most obvious transformations — and very likely the most important ones — deal with the time factor and the determination of the space (training site) factor. Time is spent by the teacher-in-training in a working team composed of peers or experienced teachers. Supervision includes the works of a student using a computer to produce learning materials which form part of the circulation of ideas. Furthermore, the emphasis being put on project implementation and the cooperation between learners translates into a more flexible teaching schedule. Technical media make it possible to the student, even from his/her home, to have access to extremely voluminous documentation and to take an active participation in group discussions. Finally, the necessity for the future teachers to learn how to solve problems in a team work effort environment, and to discover on-the-spot multiple dimensions of the teaching profession, makes it a quasi-indispensable requirement that a special working place within the associated school be made available for that purpose.

The Educating Educators Team of the Tele-Learning Research Network is determined to take hold of the pedagogical advantage of tele-learning technologies and design and implement information-rich learning environments which will, in turn, lead to a better-educated generation of students conversant with the knowledge- and community-building technologies of the future.

Educators, from preschool to post-secondary, recognize the power of technology as an instructional strategy and content learning area. However, educators are struggling to learn the skills they need to prepare students for a world of technology and information. In response to these monumental teacher training needs, state school boards have passed mandates, offered incentives in funding, and held meetings for the encouragement of computer use by teachers. School district central administrators have designed plans for future technological acquisitions and training hired district personnel to oversee district technology needs, and have offered day-long trainings and after school workshops for teachers. In all this flurry, individual schools have been left behind as passive receivers of these initiatives. Therefore, little growth of technology skills are realized by teachers in many educational settings.

Washburn University’s Educational Technology faculty and students, as well as teachers and students from Indian Hills Elementary School located in Topeka, Kansas, have embarked on a long-term teacher training project. The school’s learning community (including principal, teachers, Parent Teacher Organization [PTO], site council, parents, and local university faculty) were highly involved in the designing, developing, implementing, and monitoring the project. The project began in the Fall of 1995 and is currently in its second year. The project’s objectives include increasing the school’s teachers technology skill acquisition and instructional integration strategies. Conventional teaching and learning roles were redefined throughout the project and often throughout the day.

The project was developed after Indian Hills Elementary Schools determined their teachers were not adequately trained to effectively integrate technology into instruction and instruct using computer-aided studies. The school’s organizations (including site council, PTO, and teachers), joined efforts to formulate a plan which would assist teachers learn better how to use computers which were currently available for instruction. The school’s technology includes a 30-station networked laboratory with an abundance of instructional and multimedia software.

Two facilitators have been contracted through fund-raising efforts from the school’s PTO. The facilitators’ functions were to assist teachers concerning instruction in the computer lab. These facilitators, both parents of Indian Hill students and certified teachers, have had previous experience teaching with technology in a K-6 environment. One facilitator teaches at the local university, Washburn University, in the area of Education Technology.

The facilitators provide instruction to each classroom in the school. Teachers are present to assist with the students as well as guide the instruction’s content; therefore, teachers acquire computer skills along with their students which provides immediate opportunities for teachers to utilize their newfound skills. In addition, the facilitators provide training sessions during non-teaching times regarding specific computer applications.

The Process

The 510 students are scheduled to utilize the Computer Lab at least once a week. Once a week, K-3 graders receive 45 minutes of instruction, while 4-6 graders receive 1 hour. One facilitator assists grades 4-6 and morning kindergarten, while the other assists grades 1-3 and afternoon kindergarten. Each facilitator corroborates with the classroom teacher to design the lessons in alignment with district outcomes. New software available on the IBM network is investigated throughout the project by the facilitators and teachers in order to create developmentally- and subject-appropriate lessons.

Instruction emphasizing document development is augmented to specific classroom learning. For instance, as sixth graders study Africa, the students research a country by accessing information from computer programs and develop an African informational newsletter with text and appropriate graphics (including computer-created drawings). Although document creation is stressed during the
limited time on the computer, other coursewares are also being used to support classroom instruction as time allows.

Teachers can choose to participate in the lessons as a student or they can act as facilitators. The teachers’ level of expertise and comfort guide how they participate in the lesson. For many of the teachers, the lessons are the first time they have had an opportunity to learn the necessary computer skill, while other teachers will choose to inject specific content and instructional directions in the lesson.

Higher Education Collaboration

The facilitator for grades 4-6, teaches educational technology classes to preservice education students. As a requirement of the class, Washburn University students observe and assist in the computer lab. This provides preservice students an opportunity to observe lessons being taught by the project’s facilitators and teachers, as well as numerous opportunities to assist students. The field experience provides a valuable commonality for class discussion. Further, preservice students are able to preview and evaluate educational software at Indian Hills which the university was unable to provide.

Indian Hills Elementary teachers have the option of enrolling in 3 hours of graduate credit for each school year’s efforts in relationship to this project. The learning they obtain during classroom lab time, their endeavors in teaching with technology, and additional trainings are requirements for completion of credit.

Future of the Project

Accepting the faculty and staff’s recommendation, the Site Council, PTO, principal, and university have determined to continue the project indefinitely. As technology, staff, and scope of the project evolves, implementation strategies will change; for instance, in year two, teachers have taken on a greater responsibility for the planning and presenting of lessons, while facilitators are providing technical assistance and expertise as needed.

Each semester university students are able to provide greater levels of expertise as their technology skills are developing. The university is beginning to increase the number and variety of courses offered to the education students, thereby providing more students to become involved in the project.

Indian Hills and the university are also exploring additional ways of sharing resources. In particular, Washburn University will offer selected Educational Technology classes in Indian Hill’s computer lab. Appropriate topics will include sessions on the evaluation and use of educational software. In a “trade-off”, Indian Hills will use one of the university’s computer lab for the development of multimedia projects. This arrangement has benefited both parties, as their teaching resources are limited; additional sharing of resources will be implemented as the resources become available and are deemed appropriate. Indian Hills Elementary will continue to be a field experience site for Washburn University’s education technology classes.

Conclusion

This project exhibits a prime example of the benefit of site-based collaboration. Educational groups within Indian Hills Elementary (including Site Council, Parent Teacher Organization, administration, teachers, staff, students, and community) bonded together to resolve a need in their school. The staff training in technology is being successfully addressed because those closest to the problem are providing the solution.

Because the faculty and staff requested the year-long on-site training, lag time has been reduced between distribution and utilization of information. Participants realized it was no longer feasible to take teachers out of their teaching environment into day-long or after school training sessions, which are enormously expensive and notoriously inefficient in producing change; instead, participants are able to instead link learning to their specific subject area with just-in-time learning.

Graduate and Inservice Education

Section Editors:
John J. Sweeder, La Salle University
Maryanne R. Bednar, La Salle University
Francis J. Ryan, La Salle University

Though usually different in structure, inservice and graduate education may be loosely understood as providing refinement of perspectives and skills gained through teaching experience as well as through earlier undergraduate training. Furthermore, it is the venue for introducing cutting edge theories and practices. Understood in these contexts, the articles in this section describe a wide range of ways that teachers can utilize technology to increase student motivation, to raise understanding and achievement, and to enhance the total learning environment. In addition, some articles, while not specifically centered on formal programs, offer numerous suggestions for teachers in selecting, evaluating, and using technology. Equally important, all of these articles reinforce the reality that technology is an active, dynamic component of the teaching enterprise — it is no longer a debate over whether to use technology in education, but rather when and how to use it with efficiency and sophistication.

Inservice and Graduate Education Programs

Kar-Tin Lee describes the successes and challenges of postgraduate students at the University of Melbourne in Australia as they move through a program that retrains teachers in information technology and that culminates in granting a graduate diploma in Information and Communications Technology Education. The study also examines in detail the level of student involvement in the use of a Bulletin Board System (BBS) as part of their course of study. Similarly, Steven Sorg and Barbara Truman explain the methods used to research, design, develop, and implement the vocational teacher certification course over a six-week period at the University of Central Florida. The article emphasizes how students develop familiarity and confidence using the World Wide Web and e-mail, and it identifies various problems encountered in the assessment process as well as strategies developed for addressing the problems. Gregg Brownell, Jodi Haney, and Les Stemberg present an overview of the development of a Master of Education in Classroom Technology program in the College of Education and Allied Professions at Bowling Green State University. The authors also summarize the results of a needs assessment conducted within the service area of the College. Finally, Lorana Jinkerson explains a new course in learning technologies at the Northern Michigan University as part of its reorganized Master's of Education degree. The upshot of her discussion underscores that fact that course refinements will develop over time because technologies constantly evolve into newer and more effective tools.

Joan Gipe and Joan Lamare examine various ways to integrate technology into teacher education courses. Citing a rich collection of verbatim quotes from undergraduates at the University of New Orleans, the authors show that students effectively incorporate technology into their lessons when provided authentic learning experiences in a supportive environment. Steven Marx presents two similar models for technology instruction. The preservice university-based graduate program includes a unique series of courses which lead to a culminating technology mentorship, while the inservice school-based program identifies teacher needs assessment and teacher technology goals as critical issues.

As the technology field continues to evolve, more and more pressure may be placed upon the basic education media and technology specialist. Professional standards for those who work in these related fields must be reevaluated. Responding to these recommendations, Randal Carlson and John Gooden review the preparation and roles of media specialists and technology specialists in the state of Georgia. They offer suggestions to upgrade current preparation for media specialists and conclude that certification should be required for technology specialists. Barbara Helland, Barbara Summers, Richard Allen, Jill Snyder, Patrick Burns, David Zachmann, and Carl Davis discuss the merits of adventures with supercomputing (AiS), the Department of Energy's K-12 interdisciplinary...
educational pilot program. They highlight the teaching resources developed and various lessons learned as the program, which serves seventy high schools in five states, evolved over five years.

David Bullock and Emily C. de la Cruz examine how electronic resources can be used to expand the forms of expression and performance in today’s classrooms by moving beyond traditional paper and pencil tasks. The article also examines how technology can foster increased collaboration between students and teachers and how electronic resources are prompting a redefinition of teaching and learning. Michelle Cline and Mary Starr argue that a rich sampling of educational hardware is now available for classroom use; however, many teachers, for a variety of reasons, do not use these resources consistently as an integral part of their curriculum. In addressing some of these reasons, the authors describe several types of programs where student mentors work with teachers and other students in fostering the use of computer technology in the classroom.

Carlos Solis focuses on two case studies to demonstrate that one of the most successful vehicles for introducing technology into the classroom is the use of existing teacher-developed curriculum as the cornerstone. He concludes that by making technology a construction tool in curriculum development, teachers are able to see quick results and impact in their classrooms. Aileen Johnson and Gabriela Gonzalez examine how a group of elementary school teachers in Brownsville Texas were, first, introduced to multiple intelligence theory, and second, how this generated a need for new assessment strategies. In particular, the article examines the role of authentic assessment, the content and nature of a multimedia portfolio, and the process for creating student portfolios using HyperStudio software. At Niagara University, John Murphy, Jackie McFarland, Chandra Foote, and Robin Erwin describe how they are collaborating with the Niagara Wheatfield School District in Sanborn, New York on a pilot project to introduce Niagara University graduate education students to hands-on experiences, while bringing authentic assessment and technology into the middle school’s inclusion program. At the University of Exeter in England, Christopher Taylor provides preliminary findings from an inservice project wherein primary grade teachers used robotics to further students’ technology abilities.

**Assessment and Selection of Software**

Increasingly limited resources and downsized budgets force teachers and administrators to consider carefully where, when, and why educational dollars should be spent. Both Sonny Baker and Richard Biehl demonstrate in their respective articles a sensitivity to these realities as they describe criteria for judging software. Baker presents an engaging chronicle in the use of Logo as a basis for recognizing that software products do not necessarily fulfill their claims. Similarly, Biehl expands the notion of quality assurance beyond cost, ease of use, and functional accuracy to include numerous technological and pedagogical issues.

**Technology and the Global Community**

In their respective discussions, Yesha Sivan in Israel, and Kara Nance and Mahla Strohmaier in Alaska, highlight technology’s role in facilitating communication within the ever-expanding, global and virtual communities. Sivan argues that currently there is a lack of ability to analyze the issues of leadership fully within virtual communication. Despite this, he concludes that the juxtaposition of power and knowledge is especially relevant when it comes to leadership within virtual communities where skills like communication, vision sharing, and storytelling are all taking on new forms. Echoing Sivan, Nance and Strohmaier observe that the Information Age has afforded individuals opportunities to become members of a global community, one that presents heterogeneous populations with the capability to interact, and one where, within this interaction, cultural issues become pronounced. Further, the authors recommend that awareness and acknowledgment of differing cultures in the context of an evolving community can facilitate effective communication.

**Windows to Wider Worlds**

As a group, these articles portray a panoramic view of the ways that electronic technologies can and should be used to enhance multiple facets of classroom interaction. They also attest to the creative energy of so many educators who are collaborating within and across institutions to improve teaching and learning and to explore technology’s potential in opening windows to wider worlds within a diverse, global community.

His research interest includes various topics in the philosophy and history of education. E-mail: ryan@lasalle.edu
ENHANCED LEARNING ENVIRONMENT FOR TEACHERS: WHAT NEXT?

Kar-Tin Lee
University of Melbourne

This paper presents the experiences of a group of postgraduate students in the uptake of new technologies whilst undertaking a professional development course in information technology. Since 1990, this department has been conducting a Graduate Diploma in Information and Communications Technology Education course for practising teachers seeking to change their careers. Teachers of varied backgrounds ranging from teachers of English to physical education (some 400 of them) have completed the course to date. They are now actively engaged as information technology teachers within the secondary and primary school systems in the state of Victoria, Australia. This course was one of the first in providing participants with the requisite qualification (as prescribed by teacher accreditation authorities) for this specialist area of teaching.

Purpose and Context of Study
The specific objectives of the study were to: (1) establish the level of student involvement in the use of a Bulletin Board System (BBS) as part of their course of study; (2) identify technical and structural concerns associated with this medium; (3) ascertain learner perceptions and satisfaction in the use of such a medium; and (4) determine the types of resources required to effectively integrate this technology.

Many of the students enrolled in this course lead very hectic lives, and time for study is often limited increasingly by other obligations. Their life circumstances often impose constraints on the ability to access services in the traditional manner. Since this graduate diploma has an information technology focus, it was felt by faculty that students should be encouraged to use electronic means to communicate with lecturers and to perform other related activities. In this way students will be gaining firsthand experience of the medium.

The majority of the students were teachers completing their graduate qualification on a part-time basis. In general they worked full-time during the day and take most of their classes in the evenings, on weekends or during school vacations. These students were commuting to campus and had sandwiched all their courses into one year of full-time or two years of part-time study. This in addition to their life commitments have left them little space to manoeuvre. The trialing of the flexible mode of delivery incorporating computer mediated communications (CMC) was a direct response to the students' demands for more flexible ways of course delivery.

The Department's response was guided by research findings which tell us that the use of computer conferencing can enhance and supplement teaching and learning and provide fertile ground for ongoing learning and professional growth (Harasim, 1990; Honey, 1995; O'Gersh, & Posamentier, (1993); Schrum, 1995; Spitzer & Wedding, 1995; Weir, 1992). A number of studies have suggested that the use of this technology will allow both teachers and learners to interact with each other beyond the confines of the classroom (Casey, 1994; Kazuo, Hamalainen & Whinston, 1995; Waggoner, 1992). Teachers need to be trained to understand the basic components of telecommunications including understanding of the use of the computer, the functions of a modem, telephone and communications software, develop skills in messaging and conferencing and to become active participants on electronic networks (O'Gersh, and Posamentier, 1993). Many educators agree that effective adoption of new technologies in classroom settings requires teachers themselves not only to have the knowledge about the technology but also to have experienced successful models of computer integration in a teaching and learning environment.

One academic member was given the responsibility to set up a bulletin board system (BBS) to facilitate student-to-student and lecturer-to-student interaction. One of seven compulsory units within the course was chosen to trial this new method. Prior to this methodological change, the course had used traditional mail and fax services and telephones which lacked interactivity. The addition of the BBS to the existing combination of media which students
could access immediately created a learning environment which enabled students to connect from home or work at their convenience using microcomputers and modems. However, for the majority of students who have never had the opportunity to use an e-mail system or electronic communications of any form, this proved to be a rather challenging and frustrating learning experience.

Between 1993 - 1995, a bulletin board system (BBS) provided messaging and computer conferencing facilities for students and staff of the Graduate Diploma course. In the unit used for this trial it was compulsory for students to submit their final assignment using the BBS. Students can either connect directly from home or their workplace using a modem or complete the task on-campus using the computer laboratory for access to the BBS. During the semester, assessment tasks were set where students had to upload their findings so that the information would be accessible by other students for analysis and discussion. As one of the choices of their final assessment, students could choose to write an analysis of the information presented on the BBS on a selected topic. This final analysis when submitted would also be made accessible by way of the BBS to the rest of the students in the course.

On average, over the three years there were about 120 students who participated in the use of the BBS. Because these students were enrolled in an information technology course, it was felt that they should explore and explicate a fuller meaning and understanding of using the BBS as a means to enhance learning. It was expected that these students would already possess the necessary technical skills in the use of computers to be able to use the BBS without great difficulty.

Faculty was of the view that being educated in computer information technology is more than an instrumental understanding of how a computer works or is used; it is the development of a broader conceptual framework from which a person is able to understand the issues and implications of the technology. After all, these students are teaching professionals and they would ultimately take their experiences back to their own students whom they have to teach when they complete the course.

As a requirement of the unit, it was compulsory for students to send electronic mail to the lecturer and to transfer assignment work (upload/download files) through the use of the file transfer utility. For those students with a computer and modem connections they were encouraged to connect from home, whilst for those without they had access to the computer laboratory on campus to perform the same tasks. There was no pressure for the students to purchase a modem as facilities were readily available on campus for those who wished to access them.

Students were given a manual on how to connect to the BBS. The electronic file of the manual was also available on the BBS for students to download and then print. The students were given an induction session on how to use the BBS and were provided with the telephone number for the Systems Operator (SYSOP) in case any problems arose. The role of the sysop (who had undertaken this role over and above his lecturing responsibilities in the course) was to help students overcome difficulties in their early attempts to use this electronic means of communication. This person was able to give students some technical help where appropriate.

Method

It was important to discover what experiences might be effective in encouraging students to systematically integrate technology into their private and professional lives. Equally important was the fact that the academics involved were anxiously seeking answers to many questions in order to improve this new medium in the near future.

A survey was developed to collect student responses in November, 1995. A questionnaire containing twelve questions was administered to sixty-six students enrolled in the unit at the time. It consisted of a combination of multiple choice questions, Likert-type questions and open-ended questions. Further information was obtained through informal conversations with students in the course and other colleagues.

The author is hopeful that data obtained from this study will inform researchers and provide strategies to better meet the needs of practising teachers to more effectively prepare them to infuse technology into everyday practice in the classroom.

Findings and Discussion

Within the student population there was substantial variation in the extent to which students used the BBS. Some students, particularly those comfortable with the use of the computer, tended to be very active. Others used the BBS only in a limited way, i.e. they would submit their work online and not continue to engage in the use of the BBS for conferencing purposes or to send messages to the lecturer concerned. The major findings are presented below:

1. A High Level of Awareness of Bulletin Board Systems

Contrary to popular belief, data collected revealed that in the three year period (1993 - 1995) a large percentage (85%) of students in this sample had in fact had some contact with BBSs. They were aware of its existence and in many cases knew of friends who used it. Many teachers were teaching in schools that had a BBS. Only 15 per cent of the respondents were aware of BBSs in the years prior to 1993.
2. A Large Percentage of Students Owned their Own Computers

Eighty-three per cent of these students owned a computer, whilst 36 per cent of them also owned a modem. Of the students who indicated ownership of a modem, seventy per cent of them had high speed modems which were capable of transmitting at speeds of 14400 bps or higher. However, this did not mean that they were actually using the modem as in many cases they were purchased by other members of the family.

3. Reasons for Buying a Modem

This fell into three major categories: (a) to connect to the Internet; (b) to electronically transfer files; and (c) to engage in activities on the BBS. Due to the limited extent of this survey there was insufficient information to gauge exact levels of usage of each of these categories mentioned.

4. Self-perception of Computing Skills Low

Self perception of computing skills at the time of purchasing the modem was fairly low. Twenty-five per cent indicated that they had some skills, with only 15 per cent claiming to be competent users. In contrast when asked what their present level of computing skills were 79 per cent indicated that they either had some skills now, were competent users of computing or were very competent. This is a huge rise in the level of skills perception on the part of the students over a period of three years. It is also indicative of student readiness to adopt new technologies for flexible course delivery.

5. Positive Response to E-mail Access

Response to the provision of E-mail facilities by the Department was positive. When asked to respond to a series of questions in regard to e-mail facilities, a very high percentage (88%) of the students indicated that they would like to have e-mail facilities whilst doing this course. Fifty-one per cent were prepared to pay between ten and twenty dollars to register for e-mail facilities while thirty-one per cent were prepared to pay twenty-five dollars for such a service. Additionally fifty-seven per cent were prepared to pay between ten to twenty-five dollars for telephone bills to connect to such a service with thirty-five per cent indicating their preparedness to pay fifty dollars or more.

6. Demand for Connectivity from Home

Responses to the question “What else would you like to be able to do from home?” are shown below:

<table>
<thead>
<tr>
<th>Items</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Internet access</td>
<td>83</td>
</tr>
<tr>
<td>Access to library/databases from home</td>
<td>82</td>
</tr>
<tr>
<td>Interact with lecturers</td>
<td>77</td>
</tr>
<tr>
<td>Send/receive assignments online</td>
<td>76</td>
</tr>
<tr>
<td>Access to course information</td>
<td>67</td>
</tr>
<tr>
<td>Engage in computer conferencing from home</td>
<td>52</td>
</tr>
<tr>
<td>Engage in peer interaction/group work activity</td>
<td>48</td>
</tr>
<tr>
<td>Student records access</td>
<td>35</td>
</tr>
</tbody>
</table>

This result shows that these students have in fact reached a higher level of competence in the use of new technology. No longer are they requesting for low level usage such as availability of word processing or spreadsheet packages — they are now advanced consumers who are ready to incorporate computer mediated communications into their daily use of the technology.

7. Preparedness to Buy into Technology

Responses to the question: If courses were offered in flexible delivery modes and you did not have a computer and a modem, would you be prepared to:

<table>
<thead>
<tr>
<th>Items</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Items</td>
<td></td>
</tr>
<tr>
<td>Buy them</td>
<td>55</td>
</tr>
<tr>
<td>Lease them</td>
<td>36</td>
</tr>
<tr>
<td>Work at a friend’s place</td>
<td>4</td>
</tr>
<tr>
<td>Go to a study centre with facilities</td>
<td>5</td>
</tr>
</tbody>
</table>

Whilst students indicated the above responses, some ambivalence is evident since thirty-five per cent of those who had selected options as shown above also indicated that they would like to travel to attend conventional classes. This reveals some degree of reluctance in relinquishing the traditional face-to-face attendance mode. This feeling is strengthened by anecdotal accounts which suggest that many students still feel that a combination of both traditional and online modes of delivery would be most beneficial.

8. Problems Identified

The items requiring qualitative responses were analysed and summarised to produce qualitative themes as described and discussed below. The most frequent criticism about the program noted by students was that not enough time was given for familiarisation with the medium. Technical concerns remain the main issue for a large number of students. When asked to reflect on their initial experience of using the BBS, students recalled:

a. having spent numerous hours fiddling with the equipment trying to connect;
b. lack of immediate guidance from anyone;
c. confusion and lack of knowledge on what to do;
d. absence of clear course notes on the technical aspects of BBS connection;
e. having to resort to external help and support e.g. PC Users’ group, friends, - colleagues, computer magazines; and,
f. experiencing great difficulty connecting to the BBS from external locations - lines dropping off all the time.

Much variation was detected in these open-ended responses. As is to be expected these adult learners manifested differences in their preferences and in their approaches to learning with this new medium. Some revealed feelings of great frustration and were quick to shift the blame whilst others were prepared to work through
their problems to achieve mastery regardless of effort and time spent. A great sense of community was present when participants telephoned, faxed or e-mailed each other to find quick solutions to their problems.

9. Student Perceptions

In regard to the question which requested students to provide further comment on whether provision of electronic facilities is useful or necessary, the main theme appears to be that students should be given a choice of selecting the modes of study which they prefer. On the whole there is a very positive response to the use of electronic communications or computer mediated delivery of courses provided that a high level of support is available to alleviate problems such as inadequacies of software and the system’s ease of use. Although students generally agreed that the use of the BBS seemed to emerge as a medium — that if integrated well into the course — can contribute significantly to a better, more student-centred learning climate, their frequent comments indicated high levels of frustration in relation to the technical and structural problems encountered.

Respondents suggested various ways to overcome problems reported above. Specific solutions included: better technical support — online help; clear instructions to guide students through installation of modems and how to connect to the BBS; several hands-on workshops for familiarisation with the medium before students have to do it on their own; standardisation of equipment i.e. faculty to recommend certain brands of modems and communications software with clear instructions for installation; and ensure that downtime was minimal. Students felt that unless these problems are alleviated, the conceptual advantages the medium has to offer will not eventuate.

Assuming that cost, technology and other impediments can be overcome in time, faculty needs to recognise that individual learners regardless of the level of technology provided, will choose to learn differently.

Conclusions and Implications

This report has encapsulated the excitement, positive perceptions of the value of electronic communications and student’s willingness to pay for such services. At the same time, though, student comments reveal fairly high levels of frustration that have accompanied early attempts at making effective use of the BBS. Students realised the benefits of the ability to use electronic communications as it allows them to become actively engaged in a community of people sharing and creating information. These students were excited by the fact that they can draw on new kinds of resources to experience new kinds of learning opportunities, and to work flexibly with materials in shaping educational experiences fitted to their needs. Since it was compulsory within this course that students had to use the BBS, students really did not have a choice in whether to use this technology or not. However, despite the frustrating experience, most of them managed to cope and with the exception of a minority of students, and most are now ready to use e-mail and the Internet.

Responses to questions as indicated above reveal that a taste of this new technology has led students to demand much higher levels of access and more sophisticated use of the technology. Essentially all participating students are of the opinion that the provision for telecommunication on this campus is essential and should be implemented as soon as possible. A fundamental question, however, about the use of electronic communications still needs to be asked — how much value will be realised in practice due to its availability in educational settings. Will these students transfer their skills into their own future classrooms when they complete this course? From the positive responses obtained in this survey there is a strong indication that these students who have had some experience of the BBS will now be better placed to join the electronic communities on the Internet thus forming networks of their own to share their thoughts and ideas and to see this as a continual challenge. What is clear from this survey is that for technology to be integrated properly into the course, students must use this medium in more than one subject within the course. Using the technology in isolation will not prepare these students adequately. More opportunities must be available for students to develop their competence in this area so they can effectively model and demonstrate its use in their own professional activities.

What Next?

At the time of writing, numerous departments within the university have incorporated some form of new information technologies into their teaching. However, it is only when adequate support is provided for the so-called pioneers in the field that more extensive integration of new technologies across the curriculum of the entire department can occur. Very recently, the information generated by this study has been used to support a submission for a grant to develop courses for online delivery. This submission has been successful. The Faculty of Education has committed funds for the development of Web-based materials for delivery of three information technology related postgraduate units online to cater for the department’s students in the second half of 1997. This funding will allow the creation of materials that can be used both now and in the future and will be a resource that will be expanded on as time goes. It will serve as a model for delivery of other course units in future. The success of this project will bring about the existence of a critical mass of interested academics involved actively in a shift in mindset and together the team of pioneers will be a driving force to get faculty to buy into the potential of technology for teaching.

LEARNING ABOUT TEACHING THROUGH THE INTERNET: 
LESSONS LEARNED

Steven E. Sorg
University of Central Florida

Barbara E. Truman
University of Central Florida

Summer term A, 1996, was the time frame for the University of Central Florida's first fully Web-based, distance learning course. It was not a course that had been scrutinized by curriculum committees or that enjoyed the support of media and development resources. Rather it was a little-known experiment undertaken by a faculty subject matter expert and an instructional designer. This paper describes the methods used to research, design, develop and implement the vocational teacher certification course conducted over a six week period using the World Wide Web (WWW) and e-mail. Lessons learned from problems encountered during this experience are shared along with strategies for dealing with the issues.

Background

The WWW and Internet provides hypermedia (point and click) access to instruction which is linked with hypertext. The Web combines photos, graphics, text, some audio and some video in an interactive environment. The Internet, of which the WWW is a part, has two real advantages over other media, according to Thomas McManus. “(The Internet)... combines advantages of other media so that it conveys video and sound better than a book, is more interactive than a videotape and, unlike a CD-ROM, it can link people from around the world cheaply” (McManus, 1995, p. 3). The second advantage is that the Internet is a content provider as well as a delivery system.

E-mail is essential to electronic learning and is responsible for most of the student-professor and student-student interaction. Often, e-mail messages are personal asynchronous messages, but unlike phone conversations one cannot hear inflections of voice. You do have the opportunity to see what you think before someone else sees what you said (Maddox, 1995). E-mail's asynchronous nature also affords a considerable advantage over the telephone by avoiding phone tag. Another benefit is the ability to set up a list to send mail to an entire class with one keystroke (Mizell, 1994).

Assumptions

Several assumptions were made about the learners who might take these courses. Most would be full-time vocational education teachers. As teachers, they would have access to a state-wide free e-mail system, Florida Information Resource Network (FIRN). FIRN provides local dial up in most cities and towns in Florida and also provides an 800 number. Through FIRN they could also request a free ppp connection enabling them to access the WWW at no cost. Students admitted to UCF have access to universal e-mail accounts and free WWW access with local dial up to the university network. We thought that the full-time teachers would likely have access to an Internet connected computer at their schools and some might have home computers as well. Web-based courses, therefore, seemed to be the best way to reach these learners and enable them to have access to the courses that are required for their teacher certification.

Delivery on the World Wide Web

With this in mind, the decision to design and deliver an online, Web-based course was made in December of 1995, five months ahead of delivery. The author, a vocational education professor at the University of Central Florida (UCF), had plans to teach three methods courses (in one) during the first half of the summer term. UCF was the only institution in the state that offered one of the courses. The students who take these courses are vocational education teachers, hired from business and industry to teach in high schools and adult vocational/technical centers throughout the state. These teachers complete this course as one of the four courses required for vocational teacher certification in Florida. During the fall semester, many phone calls were received from teachers around the state who needed this course to complete their certification requirements and maintain their jobs. Some were desperate because they were at the end of their temporary certification period and would lose their jobs if they did not complete their coursework before June 30. Many did not have access to the required courses from universities that are closer to them or they
were not within a reasonable driving distance from a university that offered the required courses.

The author is also the executive director of the Central Florida Consortium of Higher Education, a consortium involving UCF and six feeder community colleges in the region. The Consortium was involved in an $800,000 distance learning demonstration project from the State University System. The coauthor was a communications specialist and webmaster for the Consortium and was also finishing her master's degree in instructional technology. An internship requirement would have forced her to drop her duties on the grant, but the author suggested a collaboration effort to do his Web-based course. Thus, a team effort began that was aided by the experience and knowledge gained from the distance learning demonstration project.

**Research on Distance Learning**

Work began immediately. A literature review was conducted on Web-based instruction, collaborative learning in distance settings, computer mediated communications and distance teaching and learning practices. The Web itself was also searched for articles, faculty homepages and examples of course materials. Fortunately several people who had journal articles published on using the Web for instruction also published their work in their homepages.

Many of the course materials found at that time reflected pages that had poor graphical design. Colors were loud, print was sometimes hard to read because of busy backgrounds and the pages lacked sophistication. The pages appeared to have been done by faculty members without institutional support of media or programming specialists. The course materials also lacked instructional design. Some pages were pure paper conversions of existing class materials written in *professorese* that were probably used in traditional courses rather than distance learning courses. Very few good examples were found on the Web. Lots examples were found on what not to do on course homepages. A literature review was written that described many theoretical practices that are useful for incorporation into the course design. These practices include the facilitation of student to student interaction (Kontos, Mizell, & Hesser, 1995; Schrum, 1995), the use of advance organizers (Olgren, 1995), and techniques of formative and summative evaluation (Murphy, 1995).

Research was thoroughly conducted on the Web for specific applicable content links. The Web is a medium, but it is also a content provider (McManus, 1995). The sites with appropriate content were organized in two ways. General content on vocational education that would be of value to all vocational educators was centrally placed on the author's personal homepage and also on the vocational education program page so that it would be available to students taking any vocational teacher education course.

Course specific content links were placed on appropriate advance organizer and activities/assignments pages.

**Course Design**

Unlike students in a traditional classroom, students here are expected to construct their own knowledge and see perspectives in an online class. Students must be more autonomous, self-motivated and independent, although sometimes they also must work collaboratively in groups. Students must also learn about how they learn to better manage their study time. Their access to study resources is greatly enhanced with links to computer resources and other experts (Collins & Berge, 1995; Zack, 1996).

**Learner Support**

Course design included deliberate elements that were specifically found or not found in the literature review or Web searching. Many of the elements were designed to provide learners with support needed to be successful in an online environment. The first element was a student information form which helped us know the learners. It also helped facilitate the student-student interaction. In distance courses it is absolutely critical that this is initiated by the faculty member. It is not enough to interact with the faculty member and the content, students must interact with each other in order to build learning communities.

Online resources built into the course included study helps and critical competencies for distance learners. Courses found during the Web search made very little to no effort to support students with general education references, nor were they frank about letting students know that they must have certain skills to succeed as distance students. These skills include responsibility for one's own learning, self-discipline, time management and knowing one's own learning/personality styles.

Since we were unsure about the prerequisite skills of the teachers who would be taking this course, we planned to provide technical and academic assistance through e-mail and telephone conversations. The instructional designer/technologist provided the technical assistance and the professor the academic assistance.

Registration on the Web was an idea to which the Office of Continuing Education had to adapt. A person was hired to help create the code for Web-based registration forms. The forms were not made into CGI scripted forms, rather, individuals print out the forms and fax or mail them back with the student's signature.

**Advance Organizers**

Advance organizers were another design feature incorporated into our Web-based course. Advance organizers are tools that help stimulate thinking and activate prior knowledge and recall. They help the learner hang new information on their existing schema. The advance organizer for the course included a course description,
We wanted no ‘orphan’ pages on our site. We included clear titles in the head section of each page because we found that distance learners in an effort to cut down on online time will print course Web pages and work from the printed page before going back online to complete an assignment. The university logo was placed on each page so the learners and others who might find the site would know where they were. Also, navigation links were placed on each page to help students get around the site easily and to connect with the central university homepage.

**Evaluations and Data Collection**

Courses found during our research did not appear to have much built-in evaluation. In an effort to know the learners, we designed a student information sheet that students completed and faxed in as a first course assignment. The instructional designer developed a database from the information obtained from this form and used it as an intervention tool during the course.

We wanted to receive feedback about activities along the way so we could make adjustments. One of the greatest dangers in distance courses is that instructors cannot read from students whether the work they are assigning is attainable. In a face to face class, students can whisper, draw back in fear and dismay and check with other students for the reality checks of assignment load. Not so in a distance setting. CGI scripted forms were created, finally, by the last week of the term. Students were able to click on a Web form and fill out the questionnaire regarding each activity. The form, when submitted, sent an easy to read e-mail message to the instructor.

Summative evaluation was also very important for designing future courses. The university’s traditional instructor course evaluation was used, but it clearly did not apply to this new learning environment so another instrument was created. Students were required to come to campus for the final. At that time they sat down and filled out a pencil and paper evaluation. Sixty one of the seventy two students completed the final evaluations. The data gathered included student demographics, perceptions, and preferences for course delivery.

Qualitative data are also available from the e-mail records and comments provided by students. These data show student learning community development and individual student growth in written communications skills.

**Course Development**

The effort made to design and create the Web-based course was a team effort of two individuals. There was no institutional support because the institution was not adequately aware of what was being done. No safety net existed. The equipment used was also crude. A bumped up 386 computer was used with 120 MB hard drive to create the pages. The media involved were minimal. There were a
few pictures and minimal icons. No supporting print materials were made. A flyer was made describing the course requirements and was mailed to the state vocational/technical center directors and to school district directors of vocational education. About 1800 teachers on FIRN were sent an e-mail copy of the flyers. A month before the class the phone began ringing. It did not stop until a few days before the class.

**Course Implementation**

An optional orientation was conducted on a Saturday during the early afternoon. Thirty five books were ordered but over 75 people showed up. Students brought their spouses who were more technologically advanced. Others brought their children. One student flew in from Pensacola and another stayed overnight in a hotel. The 72 students who registered for the course were instructed to make an e-mail distribution list of all the students in the class from an e-mail directory Web page within the course. The professor wanted to receive a copy of all the mail sent out in the course and instructed students to send a copy of all e-mail communications. Within three weeks he had received about 1200 e-mail messages. No e-mail protocols had been preestablished to instruct students to make sure they sign their name or put in a meaningful subject line. In an effort to head off trouble and be in a position to intervene, the instructional designer created a database from the student information sheets that students faxed back to campus. The database enabled sorting by geographic area, software users, and most importantly, by Internet service provider. The AOL users formed the largest single group and the database helped to get information to them to solve technical problems they encountered.

Students called when they had technical problems and some took the time to write up pointers that could then be distributed to everyone in the class. A few students stopped by to get help in person. One student called the designer on his cell phone after 10:30 at night to troubleshoot what he was doing on his computer. Some students became lost and had to be called to identify the problems they were facing while taking the course.

**Breakdowns**

Several things happened unexpectedly during the delivery of the course. All required intervention or changes in procedure by the professor.

The bookstore had assigned a staff person to take phone requests from distance learners and to take credit card information and ship books in a timely manner. A glitch occurred when that person went on vacation (during the first week of the class) and we found that no one else in the bookstore knew how to handle these requests. One student was three weeks into the five week course before receiving the text.

Most students, especially those who were new to e-mail and the WWW, expected instantaneous responses to their e-mail. Their expectations could not be met and were not practical. Many sent a second e-mail message within a day of their first message asking if it had been received since they had not received an acknowledgment from the professor.

With 72 students enrolled, the professor was overwhelmed with e-mail and assignments to grade. Giving timely feedback became a real problem. E-mail sorting and management systems had to be developed to make course delivery more efficient.

**Course Data**

The final course evaluations revealed that the students were mostly adult learners between the ages of 20-50. They were mostly Caucasian, split almost equally between males and females. School was not the only thing going on in their lives as 87% worked full time. The educational backgrounds revealed a range of education. Three people had general equivalency diplomas and twelve had masters degrees. The teaching specializations covered a range of welders and automechanics to business professionals. Over half the class had good computers, 486s or better, and 62% were accessing the course from home.

Prerequisite skills were sorely lacking. Over half the class had seldom or never used e-mail before taking the course. Almost 75% had seldom or never surfed the Internet. Despite this fact, almost 70% of the students read their e-mail once or more a day. The interaction broke down in the professor’s ability to keep up with the e-mail traffic. Students would have preferred to receive reassure that their papers were received and get them graded in a timely fashion. The instructor could not reply to all the e-mail and grade papers adequately for 72 students. Students reported that the Web pages were clear and almost 75% of the students said the course format met their learning needs. Surprisingly, 76% said they preferred the WWW format rather than the traditional every other Saturday face to face sessions. This was their preference despite their technological tribulations and how students reported not feeling as connected to the instructor as in a face to face course (43%).

**Lessons Learned**

We found that the background research done on distance learning, instructional design, and Web-based instruction was critical to the successful implementation of this course. Also, having a team to develop and implement the course was extremely important. These beliefs were borne out by the acceptance by the students of the course components, format, and style of the course pages. Students said that this form of course delivery met their needs (74+%).
The use of e-mail is invaluable for creating a learning community among students; however, used alone, it can quickly overload a mailbox and overwhelm the faculty member. The ability to auto-sort messages is needed and students should be instructed on netiquette. Many students felt that they should get a response within 24 hours. A more realistic time frame is 48 hours.

Another very hard lesson learned was the importance of backing up files. The professor’s computer got a virus one week before the class and crashed requiring the hard drive to be completely reformatted. At the time, he did not have a home computer. The aggravation that may have been prevented was considerable. The class proceeded on time, but some planned course management was lost forever. During the course of the class, over 1800 e-mail messages were sent in. Ironically, because the institution did not know the significance of this distance course the professor did not have sufficient memory allocated to his e-mail account. While he was away at a distance learning conference, the UNIX web server did an autopurge and ate about 800 files containing evaluation data. Needless to say, some excitement was had restoring those files.

A problem commonly associated with traditional distance education is the lack of opportunities for collaborative work, debate, dialogue, and conversational learning (Kaye, 1989). E-mail creates some of the push, but yet not enough pull. The limitations of e-mail were clearly shown in this Web-based course. The use of asynchronous computer conferencing, especially through the Web browser itself, holds much promise. Computer conferencing, while still limited, has been shown to create learning environments where learners are actively engaged (Mason, 1990; Berge & Collins, 1995; Dawson, 1995). The technological ability of the software program combined with the facilitation of the faculty member allows for the creation of learning environments that foster trust, collaboration and cooperation (Collins & Berge, 1996).

Beginning in the 1980's, computers and technology gained prominence as a viable and necessary part of education at all levels. Through reports such as *A Nation at Risk* (1983), where computer competence was cited as a fourth basic skill, and the Educational Testing Service’s national report on computer competence (Martinez & Mead, 1988), educators increasingly began to see technology as an important part of the schooling experience. Because facility with technology is seen as an important and empowering experience in the world, students are seen as needing competence with technology in preparation for their life after formal education (Marshall & Bannon; 1988, Naron & Estes, 1986; Gilder, 1993). Further, during the 80’s and early 90’s, technology came to be seen as a vehicle for school restructuring and as a way to stimulate the learning experience in a variety of ways, including from a constructivist perspective (Bruder, 1992; O’Brien, 1991; Papert, 1980; Papert, 1993). As these education-based interests grew, teacher educators (through organizations such as the Society for Information Technology and Teacher Education, and the International Society for Technology in Education) became increasingly active in attempting to establish formal means for preparing both inservice and preservice teachers to use technology with students. Most significantly, guidelines in computer education for teachers were developed by the International Society for Technology in Education and adopted by the National Council for Accreditation of Teacher Education (ISTE, 1992; NCATE, 1992, Thomas, 1993).

Within the state of Ohio, the need for both providing access to technology to K-12 students and school personnel and for training teachers has been translated into a major state program, SchoolNet, with current cumulative funding at approximately 500 million dollars. The SchoolNet program provides help to districts in wiring school buildings, teacher training in technology integration, and in purchasing equipment.

In the midst of all this interest and activity regarding technology and education, institutions of higher education must continually ask, “What can higher education add to the mix of opportunities available to teachers to help them become adept at integrating technology into education?” The establishment of the graduate program outlined below is seen as a partial response to this question and as a way to help answer the national, state and regional cry for teachers comfortable with, and knowledgeable about, integrating technology into the classroom.

**Spring ‘95 Northwest Ohio Survey**

As part of designing the program a regional survey was performed within our Northwest Ohio service area. During the spring of 1995, a survey instrument was developed and mailed to 100 randomly selected schools in Northwest Ohio. The intent of the instrument was to gather descriptive data useful in program planning, and also to provide data to the SchoolNet Northwest Ohio Service Providers group in planning regional SchoolNet activities.

Survey packets containing a cover letter to the principal plus six sets of 1) the survey instrument; 2) a cover letter to teachers; and 3) a prepaid return envelope, were sent to the principal of each school. The principal was asked to complete the survey and to also distribute the remaining five packets to teachers in the building. A follow-up mailing was done 10 days after the initial mailing, while a reminder postcard was sent 7 days after the follow-up mailing. The return rate for the project was 61% (n = 366).

**Respondents Inclination Towards Learning About Classroom Technology**

Seventy-seven percent of respondents report that they perceive that teachers in their district have a positive attitude toward classroom technology, while 90% report this as true for administrators (Please note that for this section responses of “Agree” and of “Strongly Agree” have been combined.). However, only 17% report that they perceive teachers in their district as being skilled in using technology and only 14% perceive teachers in their district as being skilled in integrating technology into their
student's learning. Seventy-one percent of the respondents believe that it would be valuable for some teachers in their district to complete a Master's degree in classroom technology, while 70% believe that it would be valuable for some administrators in their district to complete a Master's degree in classroom technology.

As a group, respondents appear very much interested in learning about classroom technologies. While 96% of respondents express an interest in learning about classroom technologies, 70% report an interest in taking courses or workshops in classroom technology to earn graduate credit, while 62% report an interest in taking courses or workshops in classroom technology to earn Continuing Education Units (CEU's). In terms of earning a graduate degree, 26% report an interest in earning a Master of Education degree, while 18.4% report an interest in earning a Master of Education in Classroom Technology. Interestingly, when asked if they are interested in earning a Master of Education in Classroom Technology if they receive support such as tuition waivers, release time from school duties, etc., the percent interested in earning such a degree more than doubles to 38.7%.

It appears obvious that interest in classroom technology runs high in our service area and that both teacher's and administrator's attitudes toward classroom technology are seen as positive. It also seems obvious that respondents believe that teachers in their district are not skilled in using technology and are not prepared to integrate technology into their student's learning. Given all this, respondents recognize the need for qualified people (those with a Master of Education in Classroom Technology) to be available within the district. However, they also recognize that gaining this expertise is time consuming. Although almost one in five express an interest in such a degree, that interest rises to greater than one in three when they are offered the possibility of gaining support in seeking the degree in the form of tuition waivers, release time and so on.

One way that higher education can assist in bringing more technology integration to the schools is by educating the leaders in classroom technology within a given district. These leaders will be individuals with the relevant technical skills (to the extent outlined in this program) who have an in-depth understanding of the research and pedagogical content necessary to be successful in this area. They will be individuals who can make a real difference in both the lives of teachers and students in their district.

Respondents Specific Desires Regarding Topics in Classroom Technology

While it was not possible to build a user profile based on interaction with demographic data gathered, since there were no significant interactions, it is possible to present descriptive information regarding desired education, attitude towards technology, interest in classroom technology, and format of training desired. Table 1, Column A shows topics desired regarding classroom technology for the top ten topics by percentage of respondents answering either 4 (Some Need) or 5 (Strong Need). Table 1, Column B shows topics desired regarding classroom technology for the top ten topics by percentage of respondents answering 5 (Strong Need) only. Please note that the topics derived from the survey are strongly represented in the Master's program presented in this document. These topics reflect not only the expressed needs of the teachers surveyed, but also the recommendations of various groups (cited earlier) and the perceptions of those currently engaged in classroom technology education both regionally and nationally.

The Program

Given the data derived from national reports, etc., the following program was designed. Please note that the location of this program in the Department of Educational Curriculum and Instruction (EDCI) is by careful choice. The application of technology in education must have as a major concern decisions made about education — decisions made about what is taught and how it is taught. Pedagogical decisions must drive any adoption of technology in education. Technology must not drive pedagogical decisions. For this primary reason, the program presented here is located in EDCI, the primary teacher education unit in our College and the unit responsible for issues regarding what is taught (the curriculum) and how it is taught (instruction). Also, for technology to be successful in the schools it has to be seen by teachers as integral to education — not as a separate add-on. Please note that the program below builds upon the recommendation of the ISTE report, (ISTE, 1992) and subsequent NCATE guidelines (NCATE, 1992).

Master of Education in Classroom Technology

The Master of Education in Classroom Technology is intended to educate leaders in the area of classroom technology. These individuals will be capable of working within their local Community of Practice and within the regional, state and local areas of which they are a part to support and develop the integration of technology into the learning experiences available through schools and the community at large.

While this program develops specific technical skills, the theme of the program is the continual development of the integration of technology into the school setting from a curriculum and instruction perspective. The relationship between choices made about how technology is used in learning settings and the effect of those choices on what is learned (and how it is learned) is seen as one of the major themes of the program. Two other major themes are: 1) the educator as change agent; and 2) the exploration and

Application of concepts and practices that will allow the teacher to use technology with students in active (as opposed to passive) learning settings. Specifics of the program follow.

Courses for the Master’s of Education in Classroom Technology: (33 semester hours). Note: This is a version of the EDCI Plan A option. In this specialization, students will complete EDCI 638 - Seminar on Classroom Technology and Learning, which includes a significant paper based on a project completed during the course. Students may also opt for a version of EDCI Plan C option and complete a Master’s Thesis as specified in the Graduate Handbook. In that case, students will take a minimum of 33 semester hours, will not take EDCI 638 - Seminar on Classroom Technology and Learning, and will instead take EDCI 699 - Thesis Research, for a maximum of 12 hours.

Please note that this program comprises a required core of 21 semester hours with 12 semester hours of suggested additional classroom technology courses. In consultation with the program advisor, other relevant courses may be substituted for up to the full 12 semester hours of these suggested courses. Depending on a student's background and goals, relevant graduate courses may be substituted from units including, but not limited to, the College of Technology, Computer Science, the College of Music, and other courses offered in the College of Education and Allied Professions. Substitutions must be approved in writing by the program coordinator prior to the student beginning the course. A listing of required and suggested courses follows.

Required Core:
- EDCI 631 Survey of Computers in Education (3)
- EDCI 632 Classroom Technology Planning in Education (3)
- EDCI 633 Hypermedia for Educators I (3)
- EDCI 611 The Curriculum (3)
- EDFI 641 Statistics in Education (3)
- EDFI 642 Research in Education (3)
- EDCI 638 Seminar on Classroom Technology and Learning (3)

Suggested:
- EDCI 634 Hypermedia for Educators II (3)
- EDCI 635 Classroom Technology, Problem Solving, and the Curriculum (3)
- EDCI 636 Networks for Learning (3)
- EDCI 637 Distance Learning and Education (3)

Course Descriptions

Required:
- EDCI 631 - Survey of Computers in Education (3) On demand. Survey of computers in education with hands-on experience. Introduction to word processing, spreadsheets, data bases, computer assisted instruction, the Internet and e-mail. Methods of incorporating the computer in various subject matter areas. Introduction to pedagogical issues regarding classroom technology.
- EDCI 632 - Classroom Technology Planning in Education (3) On demand. Introduction to creating, implementing and evaluating technology plans. Consideration of curriculum, instruction, hardware, software, wiring, personnel, training and funding issues. Concepts and skills for configuring computer systems and local area networks; relationship of local area networks to wide area networks; wiring issues.
- EDCI 633 - Hypermedia for Educators I (3) On demand. Introduction to Hypermedia including the creation of Hypermedia based materials for both presentation...
purposes and student interactive use. Introduction to instructional design principles. Prerequisite: EDCI 631 - Survey of Computers in Education.

EDCI 638 - Seminar on Classroom Technology and Learning (3) On demand. Investigation of relevant topics and readings in technology and education. Preparation and presentation of a piece of research in technology and education. Prerequisites: EDFI 641 - Statistics in Education, EDFI 642 - Research in Education, EDCI 633 - Hypermedia for Educators I, and an additional six semester hours in classroom technology or other approved technology-related courses.

EDCI 611 - The Curriculum (3) - Sources of curriculum: foundational bases for contemporary curriculum; forces that shape design and development of curriculum; and factors relating to implementing, modifying, and evaluating curriculum.

EDFI 641 - Statistics in Education (3) - Statistics as a tool in education and research, descriptive statistics, transformation of scores, sampling and probability, linear correlation and regression, introduction to statistical inference, and basic tests of significance.

EDFI 642 - Research in Education (3) - Identification and evaluation of research problems, research designs, use of library resources, data gathering, and writing research reports. Prereq: EDFI 641.

Suggested:

EDCI 634 - Hypermedia for Educators II (3) On demand. Continuation of Hypermedia I including in-depth coverage of scripting, use of digital cameras, camcorders, and videodisks in creating multimedia materials, and further development and application of instructional design principles. Prerequisite: EDCI 633 - Hypermedia for Educators I.

EDCI 635 - Classroom Technology, Problem Solving, and the Curriculum (3) On demand. Investigation of technology as a means to teach problem solving in the curriculum. Coverage of Logo and extensions of Logo, as well as other software to develop problem solving skills. Emphasis on a constructivist approach to using technology to develop students' problem solving abilities. Prerequisite: EDCI 633 - Hypermedia for Educators I.

EDCI 636 - Networks for Learning (3) On demand. Intensive investigation of and experiences with tools to access, and resources available on, the Internet. Creation of Web pages. Applications across the curriculum. Investigation of relevant issues regarding privacy, censorship, commercialism and proprietary rights. Prerequisite: EDCI 631 - Survey of Computers in Education.

EDCI 637 - Distance Learning and Education (3) On demand. Introduction to the theory and practice of distance education. Experience with teaching in a distance learning environment. Comparison of distance learning to other forms of education.

Currently, the program is offered to part-time students (the population identified with the greatest need for the program) in a format that can be completed in thirty months. Students start by taking two courses during a six-week summer session and progress through the program as a cohort. Students then take one course in each of the fall and spring semesters, continue through another summer, fall, and spring cycle, and then finish with a summer, fall cycle to complete all eleven courses. (Students may deviate from this cycle if they substitute an approved course for one of the four suggested courses.) The suggested sequence encompassing all courses listed above follows.

EDCI 631 Survey of Computers in Education (3)
EDCI 632 Classroom Technology Planning in Education (3)
EDCI 633 Hypermedia for Educators I (3)
EDCI 634 Hypermedia for Educators II (3)
EDCI 611 The Curriculum (3)
EDCI 635 Classroom Technology, Problem Solving, and the Curriculum (3)
EDCI 636 Networks for Learning (3)
EDFI 641 Statistics in Education (3)
EDFI 642 Research in Education (3)
EDCI 637 Distance Learning and Education (3)
EDCI 638 Seminar on Classroom Technology and Learning (3)

Conclusion

This program was officially approved in October, 1996. So great is the need for this degree specialization that a group of 24 students started the program in the summer of 1996, fully aware that the degree at that time was a proposed program and was still working its way through the approval process. Students have reported a very favorable reaction to the program to date.

In a later report, we will detail specific collaborative activities (including a summer internship project) and ongoing evaluation activities, all aimed at both maintaining and enhancing the usefulness of the program. The timeliness and high quality of the degree specialization outlined above demonstrates another way that institutions of higher education can contribute to the further development of the integration of technology into the schools. By affording the opportunity for practitioners to gain both in-depth technology skills and a deeper understanding of how technology and pedagogy can interact to the benefit of students, both formal and informal leaders will be available in the schools and will help students gain from purposeful interaction with technology.

390 — Technology and Teacher Education Annual — 1997
From 1870 to 1970, classrooms didn’t change much. From 1970 to 1995, classrooms have changed in many ways. However, from 1995 to 2015, the change will be even more dramatic. By 2015, few students will actually travel to school. Many will stay home and access the classroom from their home media center. Textbooks will not exist in the form we have known them - they will now be on CD-ROMs. Science experiments will all be interactive on computers allowing students to truly experiment rather than just follow a “recipe” for a procedure. Handwriting will be all but obsolete. Libraries will no longer store large, heavy books but will have all information on databases ready to be accessed from anywhere in the world. Keyboards will change because voice-activated writing will be the norm. Since we will spend so much time sitting at the computer, we will have to have exercise equipment at our fingertips so that we can walk a treadmill while we wait for the Internet to download a file. Lunch breaks will be eliminated in favor of exercise, and food will be taken while we work. The food will be non-fat and manmade to reduce our intake of fats and cholesterol. Teachers won’t have to do playground duty, but take their turn in the computer lab assisting students from hundreds of miles away, solving their distance retrieval problems. I won’t be teaching then - technology will have outdistanced my education - but I will visit my grandchildren’s classroom via my home media center to advise the students of how school was BT (before technology).

Learning Technologies: A New Course With New Directions

As part of the reorganization of the Master’s of Education Degree at Northern Michigan University, a new course has been developed and made a requirement of all Master’s candidates. This new course, ED 583 Learning Technologies, will be the focus of this paper. The class has not been offered yet, but will be beginning in the summer semester 1997. This course is intended to prepare teachers to meet the challenges of a technology-infused learning environment.

Learning technologies can open intellectual doors, empower learners, enliven instruction, and even change what and why specific content is taught. This course is designed to foster creative and divergent thinking regarding the application of learning technologies to the processes of teaching and learning. The intent is to discuss and analyze how newer learning technologies are changing the teaching / learning environment. Emphasis will be upon the effects with as well as the effects of learning technologies. Change theory in relation to teaching and learning with educational technologies will be taken into account as well as the concept of learning technologies as ‘partners in cognition’ and distributed intelligence (Thornburg, 1992).

Course Research Base

Traditionally, human cognition has been seen as existing solely “inside” a person’s head, and studies on cognition have by and large disregarded the social and physical surroundings in which cognition takes place. Recently, however, research in cognition has forced us to reexamine our preconceptions. Aspects of research that will be used in this course concern the concept of human cognition that is distributed among individuals, knowledge that is socially constructed, and information that is processed between individuals and the tools (technologies) provided by the culture.

Change theory in society, and in education, relates directly to the diffusion of innovations including learning technologies in school settings. As Thornburg (1992) states, “The only thing constant is change.” Change in the non-school world has been increasing at an astounding pace, partially due to technological advances. Many of these advances are communication advances, ways in which information is disseminated, manipulated, and stored. Effective communication is a necessary base for
education and schools are essentially communication facilities. Therefore, research in this broad area will be addressed in the course.

Much discussion about teaching and learning with technologies has focused on the question of how technologies can be used to facilitate education. However, technology relates to education in other ways. Teaching and learning take place in a sociocultural context, the nature of which is determined as much by technology as by anything else. To the extent that the purposes of education are determined by the context in which it occurs, technology, by virtue of its role as an agent of social change, is a force in shaping them. Technology also affects the content of education, because among the objectives of education is that of making understandable the world in which we live, and we live in a technological world.

Finally, learning technologies, both the actual physical devices and the processes whereby they are incorporated, have always been a part of teaching and learning. How, and to what extent, these technologies have and will continue to effect teaching and learning will be the overall framework for the course discussions of distributed cognitions and change as described above.

Course Goals
The primary goal of the course is to stimulate, challenge, and confront the student’s preexisting knowledge, attitudes, and behaviors about how learning technologies interact with, reshape, and support student learning styles and preferences, the teacher’s teaching style and preferences, the social environment of the classroom, and the instructional design and content of the instruction. Underlying goals include extending the students’ knowledge of the teaching and learning possibilities of educational technologies for enhancing and supporting student and teacher cognition. In addition, students will recognize the implications of educational technologies for teaching and learning now and in the future, as well as understand the diffusion of innovation in education.

Course Objectives
Upon completion of the course, the student will be able to:
1. articulate both the pros and cons of utilizing a variety of learning technologies in teaching and learning,
2. evaluate research on teaching and learning with learning technologies,
3. project the appropriate use of learning technologies into current and future teaching and learning situations,
4. make research-informed decisions when adopting learning technologies in their classrooms,
5. plan for and be open to continual change in the teaching / learning setting,
6. examine and situate learning technologies for enhanced student cognition, and
7. analyze learning technologies for ways teaching and learning may be done differently.

Course Content Outline
The course content is intended to reflect new learning technologies in relation to traditional, contemporary, and emerging issues in education. These include but are not limited to cooperative learning, interdisciplinary and thematic instruction, and multiple intelligence theory.

Instructional Approach
Teaching strategies will include, but not be limited to, the following: readings, presentations, whole class and small group discussions and debates, written assignments, and electronic communications. The following two scenarios suggest the direction of the course.

Scenario A: Reflections. Looking back over your own life as both a student and a teacher, describe what a student does and what a teacher does. What does the classroom look like? What adjectives do you think of when you hear the word school, classroom, student, teacher, school work, learning, teaching, technology?

Scenario B: The Principal Story. This is a story which you will discuss. I am your principal. You are all third through sixth grade teachers. We are meeting to inform you of a death of a citizen, Mr. Smith, in our school district. As you know, Mr. Smith was very wealthy, had no family, and was a little eccentric. Well, he has left all of his estate to our school district with one stipulation - we can only spend his money on technology and technology related items. That means we cannot buy more books or desks, hire more teachers, or build more rooms. We can, however, buy new furniture to hold the technology, hire new teachers to help us learn to use the technology, etc. In other words, everything we do with his money must somehow be related to utilizing technology.

There will be enough to put a computer on each teacher’s and student’s desk, as well as one for each of you to take home. In addition there will be a loan-home computer for each family in the district who has a child in school so that you may give homework to be completed on the computer. Families who do not currently have telephone lines into their homes will have them paid for so the students can access the homework line and the Internet. There will be an abundance of technology to work with both in school and at home for both the teachers and the students. Third grade teachers will no longer teach cursive writing. Instead, everything that your students have done in the past with cursive writing will now be done with keyboarding and word processing. Fourth, fifth, and sixth grade teachers will do likewise.

What are your thoughts, comments, concerns, feelings, etc. about this scenario? Or you can get broader in your thoughts - that is, look at all sorts of changes in the current
curriculum as we move into using more technology in classrooms at all grade levels and in all subject areas. What are you concerns? What are your dreams? What do you think we can do away with in the current curriculum? How do you see what students learn and what the teacher teaches will change as we get more technology in schools? How does using technology for teaching and learning change what is necessary to learn? How does the delivery of information change in the classroom?

A Work in Progress
Further course refinements will occur both prior to as well as during the semester. More changes should occur once the course has been taught. True to the course goals ED 583 should continually evolve over time, never quite finished as technologies constantly evolve into newer and more effective tools.

Lorana A. Jinkerson is Assistant Professor of Educational Technology, Department of Education, Northern Michigan University, Marquette, MI 49855. Voice: 906-227-2159, Fax: 906-227-1385 E-mail: ljinkers@nmu.edu
The need to incorporate technology into our teacher preparation courses has become so self-evident that we are now faced with the question of how to accomplish this goal. The need for technology-using teachers is beginning to receive more attention in accreditation standards, in state certification programs, and in reforming and upgrading teacher education efforts. But according to Teachers and Technology: Making the Connection, the report by the Office of Technology Assessment (1995), state policies and leadership vary widely, as does the implementation in colleges of education. Additionally, there has been virtually no connection between reforms in colleges of education and reforms in the K-12 schools, nor are there many incentives to make those linkages. Our research attempted to address some of these findings, specifically regarding technology and teacher preparation and modeling by teacher educators.

**Description of the Project**

During the summer semester (1996), the course instructor and coauthor of this research decided to expand technology usage in her section of a corrective reading course. This course is the final required reading course for elementary preservice teachers before they begin student teaching. Part of the requirements for this course involves each university student tutoring one K-12 reluctant reader, referred to in our program as a client. The whole language philosophy guides the literacy activities. Prior to this summer, technology was incorporated into this one section by using several CD-ROMs with only one computer-on-a-cart rolled into the classroom for each class, but more integration of technology was needed. With the assistance of the coauthor, a doctoral student interested in helping faculty integrate technology into teacher education courses, we developed ideas for authentic uses of technology.

**Review of Literature**

Reviewing the literature, it was apparent that a number of considerations should guide our design. In the theoretical framework of Bruner (1960, 1966), learning is an active process in which learners construct new ideas or concepts based upon their current and/or their prior knowledge. The learner selects and transforms information, constructs hypotheses, and makes decisions, relying on a cognitive structure to do so. We recognized that most of the students had taken, or were taking, a general introduction to technology course whereby they learned productivity tools, for example, word processing, spreadsheet, and database management, some graphics, some exposure to e-mail and an introduction to the Internet.

Additionally, we wanted to use technology that was not only nonthreatening, but that had proven effectiveness. Johnson (1996) described the success she had in incorporating e-mail into a reading methods class. She felt that the combination of real life application and effective instructional practice increased the likelihood that these preservice teachers will use the technology in the future. Brovey (1996) also indicated how his use of e-mail and e-journals provided preservice teachers with purposeful computer-based experiences and led to more responsiveness between his students and him.

Matthew (1996) pointed out the effectiveness of using CD-ROM storybooks to enhance the literacy experience of young children and the lessons learned by the preservice teachers while observing the youngsters interact with the multimedia. Land (1996) demonstrated the efficacy of integrating the Internet into his education course. His home page organizes web resources into categories that are appropriate for his students.

Both Dertouzos (1991) and McKenzie (1994) have shown the importance of availability and accessibility to successful employment of computer technology. The location and the number of machines per person are critical factors affecting usage. Until the advent of the graphical user interface browsers, the man-machine interface of the Internet was anything but user friendly. Busy students and teachers will find struggling with unreliable hardware or difficult to use software unrewarding, and will consequently refrain from using it. Because we did not have a state-of-the-art Netscape lab to use until the end of the 1996 spring semester, this research could not have been carried out before the summer semester.
Since usage of e-mail, e-journals, interactive multimedia CD-ROMs, and the Internet, have been found effective before, we decided to use a combination of these technological applications in our program. We felt that a combination of all of these approaches would give the students additional tools to use with their teaching strategies. For example, in order to show the usefulness and application to instruction of e-mail, both authors e-mailed the university students regularly, and in fact, we even e-mailed messages to the clients. The clients were also given a choice of having an e-mail pen pal in another state. Although not required to use e-journals, the university students were encouraged to do so.

Participants

The class was composed of twenty female students, nineteen undergraduates, and one graduate student working on elementary education certification. Eighteen students were majoring in elementary education, one was in middle school, and one was a special needs preservice teacher. Nine students were 18-25 years; six were 26-35 years, and five were 36-50 years. Three identified themselves as African-American, thirteen as Caucasian, and one as Spanish-American. Although three students left this field blank, they appeared to be Caucasian, bringing that total to sixteen.

Research Setting

The course was conducted in three separate buildings, the College of Education (COE), the University Computer Center (UCC), and the Learning Resource Center (LRC). The corrective reading course is designed to teach students how to implement various strategies for assessing and teaching reading, and to provide university students practical experience in tutoring a client. During the summer, the course met twice weekly for about three hours per day for six weeks including the tutoring experience. Both before and after the students tutor their clients, there are discussions about strategies to help their clients become better readers.

The students met their clients for a total of fifteen contact hours spread over five weeks, meeting twice weekly for an hour and a half each day. For two hours per day during the first week of class, the university students met, without clients, in a twenty station IBM Netscape lab in the UCC. This training was for introducing basic e-mail and Internet. In addition to showing the students how to use this technology, a further purpose was to get them thinking about how they could integrate this technology into their teaching. Although no effort was made to directly teach technical vocabulary, equipment and software were named as they were used. An integral part of the lab is the LCD panel that allows the students to see on a large screen what commands to enter into the computer, and what the results of those commands look like. The CD-ROM software that the students used with their clients was installed on six multimedia pentium computers in the LRC.

During the five weeks that the undergraduates worked with their clients, they were given the opportunity to use the twenty station lab for a half-hour each class period. This meant that the clients had an opportunity to use this technology for at least one hour per week or for five hours for the session. Students were not required to use the lab, since science, writing, art, and math centers were set up in their regular classroom. The undergraduates made use of the technology as their comfort level increased, and as the needs and interests of their clients required it.

Data Sources

A survey was given on the first day of class to assess the students' levels of technology familiarity, usage, and their general attitudes toward technology. This survey was readministered on the last day of class to allow for pre-post statistical analyses. In addition, students' e-mail dialogue with the instructors and their weekly entries in a technology journal provided narrative data that would be used to document changes in knowledge and attitudes regarding technology.

Results and Discussion

Although twelve of the twenty students indicated they had computers at home, only ten had modems, and most used computers only to do word processing. By the end of the semester, their computer usage included finding lesson ideas on the Internet, conducting online database searches, using CD-ROMs in their lesson plans, and regular and continued use of e-mail. One interesting observation was an increase in the language of technology that occurred within e-mail dialogue, journal entries, and during informal conversations with other students and the instructors. Another observation revealed their initial e-mail to be full of typographical errors and strange letter and word spacings. By the end of the semester, as students became facile with the editing feature, much of their e-mail looked as if it were done with a word processor.

Examination of the pre-post survey items indicate positive changes in familiarity and usage for computer LCD projection panels, CD-ROMs, modems, local area networks, wide area networks, computers in the classroom, database searches, New Orleans Freenet, Internet, Netscape, and e-mail.

In Their Own Voices

The most meaningful way to indicate the changes in attitudes toward technology by the students is to examine their own statements. Students were required to keep weekly anecdotal notes of their tutoring session, including their reflections about technology usage. Additionally, they wrote a technology reflection included as part of their final portfolio. The following are excerpts from these documents categorized into three sub headings which are: client
changes, student attitudes — beginning/ending, and increased student technology knowledge.

Client Changes. The following is a good illustration of the positive effects integrating technology into lesson plans had on the writing process for one student's client. The client was a very reluctant writer at the beginning of the semester. The following is from the tutor's anecdotal notes:

I am amazed at the willingness to write that M. expresses now that she is typing her book rather than writing by hand. She obviously prefers the keyboard to pencil and paper and I can't say that I blame her. Another thrill for her is seeing how nice her book pages look when they are printed with the laser printer. She says it looks like a real book and of course I tell her that it is a real book.

In her final reflection about her client, the student had this to say about the client's self confidence as a direct result of this course:

M.'s family purchased a computer this summer. She felt comfortable enough to show her family how to browse the Internet sites. What a confidence builder that must have been for the youngest family member to be able to show the way! ... Hopefully, her home computer will be a source of writing pleasure.

The following indicates a remarkable change in the attitude of one client toward computers. In her anecdotal notes about technology, for the week of June 6, 1996, this student noted about her client, "O. hates the computer! I tried to find info about the sanddollar with him through Netscape, but he didn't want to look at the computer. He didn't even want to read e-mail." Continuing, for the week of June 23, 1996, she said, "O. loved working with Seaside Adventure [1995]. He did not take his eyes off the screen. He laughed and danced like never before." By the end of the course, she stated, "O. has advanced so much on the computer. He works it all by himself - taking complete control of it. He can even control the mouse." This is an excellent example of why we need to try different computer applications. Although O. did not respond to the Internet, his attitude toward computers completely changed when he found software that met his needs.

The following excerpt from another student's anecdotal notes displays the progress made by one of the clients that was typical of clients who came to the class with little or no computer skills. For the week of June 18, 1996, she wrote, "After using the computer in the UCC, she demonstrated very little knowledge of the mouse and keyboard." For the week of June 20, 1996, she wrote, "L. was amazed that we could receive mail through the computer. L. wrote a letter inquiring about a pen pal. She enjoyed typing on the keyboard." The student concluded her anecdotal records with this comment, I have included the letter to B. [her pen pal] that L. has typed and sent through e-mail. The reply that L. typed and sent to Joan [coauthor of this research] is also included [in her submittal with her portfolio], to demonstrate that L. has gained knowledge of writing, typing, and sending a letter/reply through e-mail.

Student Attitudes — Beginning/Ending. Some students entered the course expecting it to be taught in the usual fashion, and were upset in the beginning when they found out they were going to be using computers. The following, from a student's final technology reflection, demonstrates her initial attitude:

I was very frightened at first, when we began talking about using the computer in our lessons with the students. ... I must admit that I was frustrated and felt overwhelmed at times, however with more time I know that I will get more comfortable with the computer. ... I feel that as a teacher I should have access to and knowledge of how the Internet works.... I feel grateful to have this opportunity to get training and learn how the Internet works and the many uses there are for teachers.

The following, taken from a final reflection, is a wonderful illustration of how some students felt at the beginning of the class: the fear of failing, the fear of looking foolish in front of a child, and the change that occurred over the semester.

I have resisted the computer ever since it was first introduced to me, simply because it seemed too difficult. ... At the beginning of this semester I was completely freaked about having to use the computer every class period, and to make matters worse I had to have a 9 year old student with me. I was sure that I would make a total fool of myself, not to mention the fact that I would be completely embarrassed to let a child see that I did not know what I was doing....

I have learned more about the computer this semester than I ever thought possible. ... Oh what fun I have had, learning about this overwhelming piece of equipment that I have abhorred all these years. ... I cannot wait until I can go buy my very own computer, with Windows!! Internet, here I come!!

Increased Student Technology Knowledge. The enthusiasm for using technology that the students gained by watching the effect of technology usage with their clients can be seen in this excerpt from a student's final reflection:
This summer has given me a new perspective about using the Internet in my classroom. I had heard about the Internet but this was the first time I had used it. I found it to be very helpful with gathering information for lessons and catching my student's interest in learning about new things. ... The ideas and lesson plans available are great, having the students write back and forth to other students is just amazing. The student becomes so involved in writing and reading on the Internet it is just great. As for the CD-ROMs I have worked on the computer in the LRC lab, I found them to be very informative and interesting not only to the student but myself as well.

The following is representative of how students felt about themselves as they mastered the technology, used the Internet from their home computer, and realized that they could learn from their clients

One of the areas that I have truly grown in this semester is in the area of technology. ... I have Kermit [the only telecommunications software program supported by the UCC] up and running and have been using e-mail, surfing Lynx [the only browser that UNO students have access to from home] to surf through Yahoo, and ERIC. I now have a better understanding about using CD-ROMs. I am now pretty good at e-mail .... I am really pleased that I finally got "hooked up" [to the VAX from home]. ... I feel that is quite an accomplishment. I have learned a lot about computer technology from both my teachers in this course and from my client, S. So it is important to realize that our students are not the only ones who do the learning. I feel I am off to a good start and am looking forward to the future.

The above was a typical example of how proud the students felt when they were able to use the Internet from their home computer.

Although students are required to take a computer literacy course early in their curriculum, many of the students were still only in the word processing stage of computer literacy. Since they had no authentic uses for some of what they learned, many forgot what they had learned. This can be seen in the following, and again it is tied into the client's learning also:

This was the first semester that I had so much time and availability to use the computers. I am very grateful for the experience. I learned more this semester than I did when I took Computer Literacy 1000. ... I also believe this was a good experience for my student. ... She especially enjoyed the CD-ROMs.

I got my greatest joy out of receiving and responding to the little notes from Dr. Gipe and Joan Lamare. Every semester that I had an account I was never able to access the e-mail again and so my notes all went unread. But this semester was different.

As for the pen pal, that was very exciting. ... it was quite exciting to communicate via the computer. I feel like I have made great strides towards becoming computer literate and will continue to do so in the future.

Challenges

We would be remiss if we were to leave the impression that all proceeded smoothly. The major obstacle to overcome was the logistics of conducting this course, especially since there was no Netscape lab in the College of Education building. Because of this we had to conduct the technology part of the course in two other locations, away from the regular classroom located in the COE building, the University Computer Center and the Learning Resource Center. Consequently, for the technology component, there were times when the class met in the UCC and times when it met in the LRC. If there had been a Netscape lab in the COE building that also ran the CD-ROM software, the students and clients would have had more time with the technology, and less travel and interruption time.

Since this was the first time the course was conducted with an emphasis on technology, there were some course delivery problems; for example, we gave out too many handouts at first, and didn't allow enough instructional time before the students had their clients. Because of switching locations so frequently, some students forgot to bring their earphones when we met in the LRC. Even though the LRC had multimedia computers, there were no speakers, since it was an open lab and the computers were used mostly for word processing.

Conclusion

Although we anticipated a positive change process, it was fascinating to observe it. Some of the students were intimidated by computers originally, but, by the end of the course, most of these students were making full use of all of the technology. Many students indicated they will use technology available to them during their student teaching experience. We attribute this willingness to use technology, as well as an increased technology vocabulary, to the fact that students had authentic experiences using technology.

In conclusion, we would like to present the voices of two students, taken from their final reflections. The first student wrote about her own personal growth and development as a result of this course. The second student reflected on the impact that this technology had on her and her client. The first student wrote:
During the course of the summer I have grown tremendously with my computer knowledge. I have grown comfortable with the Internet, e-mail, and CD-ROMs. At first I was very hesitant to accept why I was being forced to learn the computer and why I was being forced to use it with my student, much less in my classroom. My whole outlook is why I was being forced to use it with my student, why I was being forced to learn the computer and CD-ROMs. At first I was very hesitant to accept grown comfortable with the Internet, e-mail, and tremendously with my computer knowledge. I have During the course of the summer I have grown them in my classroom given I have the resources to that I could use it on computers other than at UNO. mail system. I feel very confident with the system behind my knowledge and enjoyment with the e-mail system. I feel very confident with the system that I could use it on computers other than at UNO. The e-mail part of the computer is such an advance in technology that I don't know how we survived without being able to communicate through a screen and keyboard. My student was the real driving force towards computers versus that of a child. During different attitudes/reactions that I as an adult have The most important aspect that I learned was the My first thought about CD-ROMs was “Why didn't I find out about these sooner?” I will definitely use them in my classroom given I have the resources to do so. They are so easy to use and the children enjoy them. Lots of learning and teaching can be done with CD-ROMs. ... To sum up my experience on the computer — FANTASTIC AND ENJOYABLE, not to mention enlightening.

The second student reflected: The important aspect that I learned was the different attitudes/reactions that I as an adult have towards computers versus that of a child. During the sessions I struggled with using the computer because I felt so computer ignorant. I knew that the computer was benefiting B., but I felt so dumb because I did not know what I was doing. ... B. had no problem using the computer. She loved the CD-ROM programs. She especially liked reading the new information on various sea creatures. This was beneficial to me because I was able to observe some of her reading strategies.

This is the first class that has allowed me to experience computer technology with a student. I think this is extremely significant ... computer knowledge is essential. Therefore I think it was very important for me to have had this experience because I was able to explore the use of educational computer programs. ... Through watching B. this summer I can see the impact the computers have in relation to student learning. Computers allow learning to be challenging and at the same time fun.

In as much as this was only one class, this project has shown that undergraduates can effectively incorporate technology into their lessons when provided authentic learning experiences in a supportive environment.

Traditional technology inservice instruction has fallen under much criticism lately, much of it justified. Fifteen years after microcomputers began entering the schools, America's schools have become a technology-free zone" (Rhodes, 1996, p. 45). One of the main reasons for this is the lack or inadequacy of teacher training in technology. Technology training for teachers has had several major shortcomings: short and infrequent training; lack of follow-up; lack of classroom access to necessary tools; outdated instructional designs; and many others. However, better organized and ongoing inservice instruction could become an effective tool for getting teachers to start using technology with their students.

CPDT

My experience working for the University of Texas at El Paso (UTEP) under a Texas Education Agency Center for Professional Development and Technology (CPDT) grant pointed to a style of inservice that could prove truly effective. This grant provided computer hardware for schools and one semester of training to support the use of technology by teachers and students. In the three years of the CPDT grant, 17 schools received 24 computers each, along with scanners, printers, and in some cases digital cameras and LCD projection panels.

The grant also funded three technology specialists, including the author for six months, who were responsible for initial setup of equipment, technical support, and teacher training. This support lasted for one semester after the schools received their equipment. In all, seventeen schools participated in the grant, for a total of 408 computers placed in classrooms through the course of the grant. A typical setup in a school put three computers per classroom, with a Stylewriter printer, scanner, and in some cases a QuickTake camera. This was considered a minimum setup to support innovative uses of technology in the classroom.

A Model for Effective Inservice Instruction

The following is a framework for inservice instruction, which can be easily replicated in any school or district where technology is being underutilized, or not used at all.

I started with a needs assessment, determining what teachers knew about technology and what they wanted to learn. In seeing this type of survey used, both in my experiences in my two CPDT schools and in other schools, one common response is that teachers who don’t use computers don’t know what they want. The key here is to find out who’s interested in learning, then tailoring the training to suit them. After looking at the surveys, I set up a series of monthly training sessions after school. This was organized in concert with the principals and on a volunteer basis. Classes lasting from one to one and one-half hours took place immediately at the end of the school day.

I set up two different programs: one school was already very technologically rich, and while some people still needed basic training, there was a desire for some more advanced classes; the other school was relatively technology poor, and I provided a set of courses on the basics. Based on teacher responses to the survey, the focus of the first training sessions in both schools was on Macintosh basics and ClarisWorks.

One key to any success I had in getting teachers to attend these sessions was the success of the first session. In both schools I used a variation of a math activity called M & M Math. This is a fun spreadsheet activity that many teachers are already familiar with, includes giving out candy at the end of a long school day, and teaches something they can go back and use immediately in the classroom. Also, Texas standardized test for elementary students requires the students to make and analyze spreadsheets and graphs starting in the fourth grade, so it related directly to their curriculum. But the most important fact may be that the teachers had fun using the computer, and this led to many returnees at later sessions. Other ClarisWorks sessions involved learning the graphics tools, and a session on making and using databases in the classroom.

At the technology rich school, some teachers were interested in more advanced programs and activities. This school is also a microsociety school, students in grades 4 to 6 work for a company or official body. This led to student and teacher interest in programs that would help their companies. The companies were already keeping their
accounts in spreadsheets, but the computers we provided also included Quicken 5.0. I held a Quicken training session for teachers, and went back the next semester to provide one for the (student) financial officers of four companies. Several teachers also wanted a session on PageMaker, attended by about six. While these sessions were not as widely attended as the more basic ones, they reached a group of teachers already more amenable to innovative uses of technology in the school.

Based on my experiences, I would offer the following outline for an effective inservice program in technology. It is intended to be flexible. I only mention specific pieces of software when I have used and seen them used effectively in the classroom. All sessions are almost 100% hands on.

All sessions must be taught with an emphasis on curriculum, and should include handouts with lesson plans, articles and activities to help teachers immediately integrate the content of the sessions into curriculum.

Graduate Level Programs in IT

The previous section described my work with CPDT and suggests resulting from that experience and others. This section will deal with instructional technology courses offered at the university level, and will offer a framework for a course of study designed to produce teachers who use technology effectively and innovatively in the classroom and who become technology leaders in their schools.

I have taught instructional or educational technology classes at New Mexico State University (NMSU) in Las Cruces and at UTEP. At NMSU I was responsible for designing and implementing the curriculum for several sections of the undergraduate and graduate educational technology course required of everyone in the teacher education program. This included selecting, or in most cases creating, the printed course materials. These classes were frustrating because there was no follow-up to see if these students actually became technology-using teachers.

Based on evaluations, the vast majority of the students found the courses helpful, and seemed motivated to use technology in the classroom, but without following their progress in the schools there is no good way of evaluating the effectiveness of these courses. My current job at UTEP provides a welcome solution to this problem.

Challenge Grant

The College of Education at UTEP in partnership with the Socorro Independent School District received a federal Challenge Grant in educational technology. This grant has five parts: staff development; connectivity; e-mail mentors; parent centers; and evaluation. I am one of the four instructors hired or given release time to work on the staff development component. Within this section of the grant, courses are offered for inservice teachers leading to endorsements or Masters degrees in instructional technology.

All participants in the program take the same four educational technology courses in consecutive semesters. Those seeking a Masters take an additional four education courses, and have a two semester practicum in technology mentoring. For endorsement students, the mentoring is part of their coursework. The mentoring portion is designed to use the grant teachers to begin the infusion of technology throughout the participating schools. Each teacher in the program is required to mentor three other teachers in instructional technology. The program is designed to create classroom teachers who are innovative users of technology in the classroom, and who are technology leaders in their schools.

Participants enter the program in cohorts of approximately twenty; two cohorts started in January 1996 and are finishing their third technology course while a third cohort was started in the fall of 1996. The cohorts are team taught by the four professors hired under the grant, two technology specialists and two curriculum specialists. The effectiveness of the team teaching is difficult to judge at this stage for several reasons. First, the initial curriculum specialist did not come on board until midway through the second course. Second, one of the technology specialists left after the second semester and was replaced by the author. Finally, the second curriculum specialist wasn't approved until this fall, and because of scheduling problems is concentrating on helping the teachers in the classrooms. With the new cohort, which hasn't had to deal with this turmoil in staffing, the team teaching model seems to be working very well, though upcoming evaluations will of course tell us more.

As we see what is actually possible in our classrooms, our vision of the technology courses changes. The structure of the program provides a unique opportunity to build a series of four technology classes, each connected to the other, to create expert technology-using teachers. However, it is also an unusual model, the same group of people, the
same professors, for four consecutive classes. While teaching many of the basics will probably remain the same, the shape of later courses could take on a more innovative look.

The first technology course actually looks much like the inservice model provided above. The main difference, of course, is time; classes meet three hours once a week for sixteen weeks. This time allows for an in depth study of all aspects of the curriculum; there is time for basic instruction, group and individual projects, and a clear focus on integrating the subject matter into the classroom. The first two cohorts, now finishing their third semester, are writing web pages, creating curriculum projects in Digital Chisel and HyperStudio, using telecommunications in a variety of ways, and beginning the process of mentoring in their schools.

One trend that may already be appearing is the growing technological literacy of teachers entering the new cohorts. The group entering this past fall clearly has a higher initial level of technological literacy than the first two cohorts. They will probably be doing advanced multimedia authoring and designing web pages in their second semester. This will provide the opportunity for some innovative approaches to curriculum that could help ensure the integration of technology into the classrooms of cohort participants.

By the third or fourth semester, instruction could take place mostly in the field, with perhaps monthly class meetings to discuss progress, activities, and future plans. This would put the faculty out in the schools, observing and assisting in the integration of technology into the classrooms. Site visits are one way of being sure our students are translating instruction into their classrooms, and would provide a valuable assistant to teachers wanting to try innovative projects, but justifiably nervous of taking on such projects alone.

The following table suggests a possible course of study modeled on the Challenge Grant example.

Lessons Learned

From my experiences at both universities, I have determined a few essentials for successful training. A one to one student computer ratio is essential for all students to learn the basics. Some things just need to be done individually, and without that capability, some students fall behind. At both universities, I have taught with more than one student to a computer, and this was the most common complaint of all students.

There needs to be adequate projection ability, preferably with the lights on. A weak projection panel or room that can't be darkened make it difficult, if not impossible, to effectively demonstrate new activities to the class. Basic troubleshooting skills are also important, so that a simple freeze doesn't bring everything to a halt. One of the reasons for keeping the curriculum flexible is to allow adjustment to the changing needs and abilities of the participating teachers.

Conclusions & Recommendations

University Instruction

The next several years will begin to tell whether the model of graduate instructional technology classes being tried under the Challenge Grant will be effective. One problem we have faced early is schools not having the technologies in place to support work done in the lab at UTEP. A commitment from participants' schools to make the necessary technology available should be considered. Educational technology programs should consider having laptop and/or desktop computers available on a limited basis for checkout for those teachers who do lack access at their schools.

Inservice Instruction

To effectively implement technology on a widespread basis, every school needs a technology coordinator. This
person should have a background in education and technology, not just computer science or engineering as has happened in the past. The tech coordinator should have main responsibility for teacher training, tech support, and instruction (Pearson, 1994). They should not be responsible for maintaining and running a lab or a schoolwide network, though they probably will be.

Inservices need to be on a regular basis, and ongoing throughout the year, preferably at least monthly. Classes should be an hour to one and one-half hours in length, especially if held after a regular school day. Parts of the plan outlined above could easily fit into staff development days if available. As in the university program, instruction needs to be immediately useful and usable in the classroom.

The ideal combination is a technology coordinator in each school and a college or university nearby capable of offering several classes or even formal programs in instructional technology. This will be a slow process, so it.

HELPING TEACHERS USE TECHNOLOGY: REDEFINING THE SUPPORT ROLES

Randal D. Carlson
Georgia Southern University

John S. Gooden
Georgia Southern University

Without question, the amount of technology in our schools is expanding rapidly (Bluhm, 1988). But with this expansion comes new requirements for training users and installing and maintenance of the equipment (Odvard & Kinnaman, 1994). At the same time, schools are being squeezed for funds to support new mandates and to expand the technology base (Halstead, 1992). An initial look at the personnel who may be charged with the responsibility of supporting these new technologies produces several likely candidates — the technology specialist, the media specialist, teachers, students, and outsource providers. Can school districts support the new wave of technology that is coming into our schools with the current support structure? Is personnel training planned and supported systematically? This paper addresses these questions by contrasting the expanding and changing roles of the two major support providers, the technology specialist and the media specialist, who seek to better support the new technology boom that we see in our schools.

The technology specialist and the media specialist are not the only sources of technology support for today’s schools. Other sources of support may be important in some instances, but may not be as widely used. Teachers and students have traditionally been sources of expertise in special circumstances, especially those requiring knowledge of local facilities, requirements, or abilities, but they are limited in the amount of time that they can provide in order to support others who need help with technology. Teachers with a strong interest in technology may be given a reduced load so that they could provide technical support to the faculty; however, these occurrences are rare. Outsourcing of support and training, while currently rare in schools, is becoming fashionable throughout American business and industry and may be the wave of the future.

With the introduction of computers and multimedia technology to the schools, the need for technology specialists, a position which has been evolving over a period of years in Georgia, is greater than ever. But the nature of the duties depend greatly on the school district — its structure, management style, and vision. The state of Georgia provides some, but not full funding for the position. There are few limitations on the use of those funds and there is no certification requirement for the position.

The media specialist, however, has a long and rich history of function in the school. Beginning in the early 1900s as a librarian, the media specialist has evolved through audiovisual skills coordinator roles to what today is a three tiered responsibility. According to Information Power (ALA & AECT, 1988), the media specialist is charged with promoting reading, viewing, and listening by young adults; providing information skills; and helping teachers in the design, implementation and evaluation of instruction. In addition, the media specialist is trained in Schools of Education nationwide to perform those three tasks and is certified by states to hold school positions.

Methodology

In an attempt to contrast the support roles for technology growth, a team of researchers visited schools in rural southeastern Georgia. These visits were part of a larger study in Georgia under the auspices of The Council for School Performance designed to investigate the effect of Georgia’s lottery on technology in the schools statewide (Dolan, Jones, & Henry, 1996). The Council selected 21 schools from 14 counties in the southeast region to participate in this study. The schools were highly rural in nature reflecting the character of this region. Only one school was located in an urban setting. The schools consisted of four high schools, six middle or junior high schools, and eleven primary or elementary schools. Included in the twenty-one were four “Model Technology Schools.” These schools had been given supplemental state funding through a competitive grant process for the acquisition of new technology.

The Superintendent of each school system was initially contacted by the Council and asked to participate in the study. The level of cooperation from the schools was remarkable, despite extremely heavy workloads and other visitations and testing scheduled for February and March 1996 — the site visit time. Each school was eager to
participate and provided excellent support for the visits. Each building principal was asked to identify a visit coordinator which was usually the media specialist or technology specialist.

A typical site visit was extended over two day period. The visit began with an orientation to the building and principal, media specialist, and technology specialist interviews. Administrative matters were reconciled on that day and observations of technology used in classrooms, special purpose laboratories, and the media center were begun. On the second day, the researcher and a graduate assistant conducted student and teacher focus groups. The second day also served as an opportunity to clarify responses from the first day’s interviews and to complete the observations. Interview and focus group data were recorded, transcribed, and analyzed using a qualitative data management program. The coding of data focused on, among other categories, perceived and actual technology support supplied by media and technology specialists.

Discussion
Media Specialist

The media center, sometimes still referred to as the “library,” has become the “technology hub” of each building because of the services provided there and because the media center is most frequently the site within a school where new technology is first introduced. Therefore, media specialists are expected to keep up with the constantly changing technologies that affect how the media center/library functions. The role of the media specialist has evolved into one of the primary supporters of various forms of technology. However, the level of support given by media specialists to teachers in the area of multimedia technology varies according to training, comfort level, and interest of the media specialist.

Media specialists seem to see the bulk of the change when it comes to new technology. Due in large part to recent statewide educational funding initiatives, every library in the state is automated. New equipment and software required that all books be entered into a database and new procedures developed for accountability of volumes. Additionally new data resources, principally CD-ROM technologies, World Wide Web (WWW), and the Internet environments make searching for information a complex, multifaceted skill. Information search and retrieval strategies had to be addressed with students, faculty, and staff. These technology-related requirements significantly affected the media specialists’ workload.

New equipment exacted a time toll, too. Media specialists were quick to reveal the additional burden that technology could put on an already busy person. The following comments indicate the frustration felt by some of the media specialists:

“I feel I need more training on IBM’s. I had Macs here in the past. I need to learn to use so many things - there is a learning curve. I need to know how to use the IBM’s so I can use it to help others...[It is difficult not] having the time to keep up.”

“...started this 32 years ago; now everything is different.”

“I got my masters in 1982. We didn’t have any computers then -- even at Georgia Southern.”

“[I recently] got my masters and everything was done on computers; ...had a multimedia presentation course.”

The media specialists were at the forefront of the technology wave. The media center was typically the first place in the school to be equipped with the new technology. Teachers who frequently were intimidated by the technology, and students who are not, now look to the media specialist as a primary source of expertise. The technology training that the media specialists receive varied according to district, personal interest, and state and local mandates. There seemed to be a great gap between media specialists who were trained and certified a decade ago and those who were more recently certified. Media specialists were encouraged to update their skills with some limited formal training and help from the Regional Educational Services Agencies (RESA), a state funded agency designed to assist schools in a variety of education-related issues. But, there appears to be no systematic program of professional updating of skills. These skills could be and sometimes were updated by local college or university courses or inservice training, but this was inconsistent from person to person and district to district. Media specialists have to be able to pass those skills on to teachers and students so that these skills may be applied in teaching and learning situations.

Technology Specialist

The level and kinds of support provided by the technology specialist depends on the district’s size, how technology is organized and staffed, and the availability and workload of the technology specialist. The organization and staffing for technology varies greatly from one system to another. In most school systems, technology support is the responsibility of a single individual who is assigned to the central office and provides services to all buildings. This individual is usually available to a particular building once or twice each week and provides on-call services. There are some systems, however, where there is a central office administrator who has system responsibility for technology and has a staff of several technology specialists.
assigned to multiple buildings to provide daily and on-call services.

Therefore, unlike the media specialist who spends time at just one school, the typical technology specialist divides time among several schools and functions as part of the central administration for the school system with duties that usually call for working with teachers from all grades at several locations. The technology specialist is the one who advises the administrative staff and school board on technology related issues and is a member of most school technology committees. In addition, the technology specialist takes the lead in matters concerning technology planning, frequently installs new technology when it arrives at the school, trains teachers on how to use new equipment and software, and assists teachers with the integration of multimedia technology into the curriculum.

Because there is no statewide certification or qualification standards for this position, it is not surprising that technology specialists have very different preparations for their jobs and a very different foci when it comes to deciding what should emphasized. Technology specialists, as a group, were highly credentialed and motivated to help the faculty use technology for teaching and learning. Most had an Educational specialist degree, which is a terminal degree beyond the Master's degree. They do not see their primary role as one of direct interaction with students. They see their impact on student learning through improved teaching methods and multimedia integration. Technical training for the position was almost always informal - learned in previous positions in business, industry, or education; or through personal interest.

Three different types of technology specialist preparation became apparent. The first is the super-media specialist. This person had been a media specialist, frequently for a number of years, and became interested in new technologies as they were developed. This individual has minimal formal training in technology selection and use above that required for the media specialist. This technology specialist views the position as a coordinator - a medium in which information and expertise is shared throughout the school district. One technology specialist summarizes it best: "...10 years as a media specialist ... was the only applicant ... was interested in technology, and was active in the schools." The super-media specialist concentrates on "people skills and technology knowledge."

A second group of technology specialists sees their role as a technologist. They typically have received their training in technology in business or industry. They may have various degrees and professional certifications, but likely are not media specialists or trained in math/science. They view themselves as "primarily a support person through hardware training and repair." They see themselves as "hands-on person(s) ...(with) solid technical backgrounds."

A third group of technology specialists concentrates on instructional and curricular matters. These technology specialists are more likely to have degrees in curriculum (usually mathematics or science) and have come directly from the classroom due to a personal interest in technology. They view themselves as needing to "be available for staff development or demonstrations in the classroom." They "work with teachers on problem solving strategies," "work with teachers on instructional strategies," "check lesson plans," and "do actual teacher evaluations."

All technology specialists combine the traits of the three aforementioned types, but in varying degrees. Large systems were able to hire a number of technology specialists who had varying interests and talents. This is clearly an ideal situation, but limited funds prohibits this in most systems in southeast Georgia. In fact, the technology specialist position, in most school systems, was only made possible because of lottery funds. This addition was continuously applauded by teachers, principals, and media specialists.

Table 1 provides a comparison of the technology specialist with the media specialist on a number of important support and training issues.

Summary and Recommendations

The data showed that teachers receive primary technology support from the technology specialist and the media specialist, although in some buildings, teachers received support at various levels from their colleagues and students. But, almost every school relied on external, state agencies for support in technical areas and especially for training in complex technology uses.

Media centers were automated throughout the region, and were the "hub" of the schools' technology programs. The media specialist, because of physical presence, was looked to for support in many schools. This individual was forced to assume this quasi-role as technology person, sometimes with little or no training. This may detract from other duties. The lack of adequate preservice, postgraduate, and inservice technology training impacts the ability of
schools to fully integrate technology into the curriculum. Because, there is no state certification requirement for technology specialists, they possessed varying skills, capabilities, and interests. This uneven preparation resulted in unequal technology leadership across the region. Schools with strong technology programs had concerned and involved leadership from the technology specialist, principal or superintendent, and probably all three.

Schools in southeast Georgia have markedly increased the exposure of their students to technology in the past three years. However, the effectiveness of this exposure has varied according to access, infrastructure, funding (federal, state and local), teacher training and support, and leadership. Technology training has not been shown to be a priority for local school districts when measured by either funding levels or results. One issue that needs to be addressed in order to improve teacher training and support is certification of the technology leaders in the schools. States should review the certification requirements for media specialists so that they reflect the knowledge and skills necessary to run a technology enhanced media center and should require certification of technology specialists. In addition, technology skills and curriculum integration should be an integral and meaningful part of teacher preparation programs at both preservice and postgraduate levels. The State Department of Education, educational service agencies, and local colleges and universities should provide technical and curricular support to schools districts trying to implement technology integration. Media and technology specialists can make a difference in the schools, but a system-wide change program must be instituted to provide the full effect that technology can make in education.

During the first three years of the Adventures in Supercomputing pilot, the number of schools wishing to participate in the AiS program far exceeded the resources available to accommodate all that applied. Rather than choosing the best and brightest for the AiS program, the selection of AiS schools was based on diversity of the target population of students and teachers, and the anticipation that a school's participation in AiS would effectively infuse new technology into that school.

Each school in the program received a dedicated digital connection to the Internet, computing time and space on a central compute server, technical support through consultants in each state, four Macintosh computers with appropriate software tools, and a color printer. Key components of the AiS program are the summer institutes and follow-up workshops in which teachers receive training in 1. computer networking, 2. computer programming (Fortran 90, C, and C++), 3. computer graphics and scientific visualization, 4. mathematical modeling, 5. project development, 6. implementation of the AiS curriculum, and 7. system administration.

As noted above, the AiS curriculum was structured to introduce students to computational science, in which supercomputers are used to run simulations that rely upon mathematical and physical models.

As part of the AiS curriculum, students engage in extended projects which require them to pose hypotheses, devise methods and procedures for solving problems and draw upon a wide variety of resources including hardcopy and electronic sources, computer simulations, and human experts. Each year, institutions in the five AiS states have hosted a statewide exposition where students present their projects to other students and teachers.

An integrated curriculum is a very important component of the AiS approach. Students discover the relationship between math and science as they use computation as a tool to investigate science-related questions of interest to them. Their reports and presentations foster the development of excellent communicative skills. Students and teachers have responded very positively to this approach of an integrated curriculum.

In a letter stating support for the Adventures in Supercomputing program in Iowa, Principal Lindsey Beecher cited the following benefits of the program: 1. spurring technical growth in the district, 2. giving disadvantaged students motivation through experiences with ground breaking technology, 3. changing the curriculum in many courses - greater emphasis on students creating their own knowledge, 4. giving technological knowledge to staff enabling better utilization of technology, 5. exposing students and staff to a wealth of information not previously possible, and 6. expanded opportunities for students to interact with their community by enhancing communications.

During 1994, the Center for Children and Technology (CCT) completed their initial assessment of the AiS program (Honey, McMillan, Tsikalas & Grimaldi, 1995). The assessment focused on the second-year AiS schools because teachers in these schools had one year of experience using the curriculum and technology. The evaluation of the AiS program was designed to assess student learning as evidenced in the final project presentations,
and systematically to examine variations in learning based on a range of demographic and contextual data. Two central findings emerged from CCT’s assessment. First, a substantial number (51%) of AiS students fell into an Integrated Knowledge Cluster, demonstrating mastery of their computational areas of inquiry; this was the highest of the three clusters categorized by CCT. Second, there was no evidence of a gap in achievement based either on gender or race.

The assessment conducted by CCT in 1994-1995 extended their previous evaluation of the program and indicated that the program reached a diverse group of students, ethnically and socio-economically, and included many girls (Honey, McMillan, Tsikalas & Light, 1996). Another indicator of success of AiS was the amount of new technology introduced into the schools as a result of AiS program - the schools and teachers in the program have leveraged DOE’s initial investment to raise three times that amount in new equipment, grants and in-kind contributions!

Over the past five years, the Adventures in Supercomputing pilot program has evolved to encompass an interdisciplinary approach to project-based curriculum using the techniques of computational science. In order to examine the success of the AiS program, it is necessary to understand how the state coordinators adapted the rapid changes in technology and applied the assessment results to shape the program. This can be illustrated by studying the evolution of the program components as the program matured.

Program Components

Classroom Environment

The Adventures in Supercomputing program is a derivative of an earlier pioneering program developed by Dr. John Ziebarth in Alabama (Ziebarth & Carruth, 1992). Ziebarth and his coworkers were successful in attracting students to computational science by using a supercomputer as an attractor. In that early program, students accessed the supercomputer via a dumb terminal. As an extension to Ziebarth’s program, the AiS state coordinators defined a classroom environment that mimics the computing environment at a Department of Energy laboratory where K-12 students and teachers use a 56kbs Internet connection and personal workstations (four Macintosh computers) to access shared central computers. This represents an evolution from dumb terminals to smart terminals and enables students and teachers to post-process their model results locally, using graphics packages such as Spyglass Transform. The scientific visualization component is an essential feature which allows the students to interpret the results of their computer simulations. As a result, excellent projects have been produced by students. In addition to providing computing facilities for students and teachers in the AiS program, the computing resources at the laboratories or universities also support network services such as e-mail accounts, World Wide Web servers and listservs.

The design of the AiS pilot program was such that participating AiS schools relied heavily on local DOE laboratory or a local university for such computing and networking resources. Early in the development of AiS, we recognized that this model would work in the pilot stage, but would not scale as increasing number of schools joined the AiS program. During the past year of the pilot program, the AiS coordinators redesigned the classroom computing environment to encourage schools to assume the responsibility for networking costs and to introduce multitasking, multi-user workstations into the participating schools. These workstations empower teachers and students by moving more of the key advanced technologies to their local environment, thus reducing their dependence on a central site. Since cost, ease of maintenance, and compatibility are important issues in the schools, the workstations are actually high level PCs running Linux with Fortran 90 and C compilers.

An important feature of having a Linux (Unix) workstation on site is the ability to provide network services locally. This includes WWW servers and pages, e-mail, disk caching of important web pages, and netnews. The provision of these services locally enhances performance by providing a much higher stream rate (10 Mbps) and greatly relieves network traffic, allowing the Wide Area Network to be used to maximum advantage for other purposes.

Teacher Training

The first AiS summer institute was held in 1992. Training modules for the teachers concentrated on the rudiments of computational science: Unix commands, Fortran programming, scientific visualization via Spyglass Transform and network tools. In the pre-World Wide Web world of 1992, teachers could only retrieve information available on the Internet by using such network programs as ftp, gopher, and WAIS. At the first institute, very little time was devoted to preparing teachers to integrate AiS into the classroom. Teachers were required to develop course outlines, but project development was only discussed briefly. During the first year of the AiS program, the Research Institute for Studies in Education at Iowa State University conducted an initial assessment of the AiS pilot program (Fulton & Sweeney, 1993). One of their recommendations highlighted the lack of consistent guidelines for the program: “Teachers expressed high management concerns as measured by the Stages of Concerns Questionnaire. These concerns did not diminish from pretest to post-test. The lack of specific program expectations might be one explanation for this lack of change...”(p. 19)

The results of the AiS assessment conducted by the Center for Children and Technology in 1993-1994, which focused on AiS teachers from the first institute, further
emphasized the students’ and teachers’ lack of understanding of the computational science project components. The foundation for CCT’s assessment was the videotaping and scoring of a subset of student computational science projects. Assurance that the coders of the videotapes understand the AiS goals and objectives as they make judgments of students’ performance is essential. For that reason, coders are selected from the AiS teacher pool. The scoring scheme for the videotapes is based on an earlier videotape coding scheme developed at CCT (Hawkins, Bennett & Collins, unpublished). The scoring rubric involves five dimensions, each of which are scored on a scale from 1 to 5, where 1 represents poor work and 5 represents outstanding work. The five scoring dimensions used are:

Understanding: To what extent do students demonstrate knowledge in their area of inquiry?

Critical thinking: To what extent are students able to reflect about the challenges and problems they encountered in their project and the larger implications of their work?

Clarity of presentation: To what extent are students able to effectively communicate their ideas to others?

Teamwork: To what extent do students work collaboratively on substantive aspects of the project?

Technical competence: To what extent are students able to apply programming skills to analyze or investigate their areas of interest?

As mentioned above, based on the five dimensions of scoring, the 1993-1994 videotaped presentations manifested three distinct clusters. The three clusters were characterized as follows:

Integrated knowledge: Students in this category were successful in applying computational techniques to a well-defined set of questions and were successful in combining a substantive body of knowledge about their project subject area with a real understanding of the methods of inquiry they used to investigate their problem. They exhibited high scores across all five dimensions, but their understanding score was particularly high. Over half (51%) of the students videotaped were in this category.

Procedural knowledge: Students in this category had average to above-average scores which were relatively consistent across the dimensions except for a distinct drop in the technical competence dimension. These students basically fulfilled project requirements, but displayed little ability to reflect upon or explain the implications of their work. For example, students in this cluster had a difficult time explaining how the mathematical model they used helped them address or solve their problem. One third of the students were in this category.

Fragmented knowledge: Students in this cluster had average to below-average scores which varied the most across the dimensions and this was the only cluster that had an understanding score that was lower than the critical thinking score. These students were unable to develop a well-defined problem that could be translated to a computational model. Consequently, the students in this cluster were not able to gain a substantive understanding of either the content or the mathematical and programming components for their project. The mean scores in this group exhibited more spread than those in the other two groups.

Based on the recommendations of the assessments by RISE and CCT, the coordinators involved experienced AiS teachers in redesigning and teaching the third summer institute. During that summer institute, computational science modules (programming, network resources, and scientific visualization) were introduced in the context of project development. Modules on team building, mathematical modeling and exemplary AiS computational science projects were also introduced. More importantly, current and new teachers in the AiS pilot program were required to develop a number of computational science mini-projects during the two week institute.

Results of refocusing the 1994 Summer Institute and the teachers’ growing experience with the AiS curriculum were apparent in CCT’s assessment conducted in 1994-1995. The videotaped results were again grouped into clusters. However, the clusters did not exhibit the same characteristics as in the 1993-1994 assessment. The profiles of the three 1994-1995 clusters were almost identical across the five scoring dimensions which is contrasted with the 1993-1994 clusters where the clusters exhibited different profiles and scoring levels. Students in the 1994-1995 study had consistent scores across understanding, critical thinking, and clarity, relatively higher teamwork scores, and slightly lower technical scores. The 1994-1995 clusters differed from each other in the level of the mean scores that they include: the High cluster (37% of students) reflects above average to outstanding scores; the Middle cluster (35% of students) reflects scores midway between average and above average scores, and the Low cluster (27% of the students) includes average to slightly below average scores. As CCT states in their 1994-1995 report:

This change in the character of the clusters, coupled with a decrease in the number of other significant variables, suggests that teachers and students in AiS are gaining a clearer and more substantive understanding of what constitutes a successful AiS computational science project. As teachers continue to become more familiar with the curriculum and adapt it to their strengths and interests, and as the course becomes a familiar part of the available
curricula in participating schools, teachers will continue to build, based on experience and growing expertise, a more fully developed understanding of the elements that are necessary to good computational science research. (p. 74)

The summer institutes for the past two years of the program have continued to support project development and assessment rubrics for the classroom. Since no new schools have been added since 1994, the teachers continue to gain more experience with the AiS curriculum and with emerging technological tools.

Curriculum

In 1992, researchers at Oak Ridge National Laboratory began work on a graduate level electronic Computational Science textbook (http://csep1.phy.ornl.gov/csep.html). Researchers at Ames Laboratory in 1994 began a complementary project, focused upon developing an archive of interactive undergraduate computational science curriculum modules (http://uces.ameslab.gov). In 1995, AiS coordinators formally packaged their summer institutes as a set of materials that support and enhance high school computational science education, available via the World Wide Web (http://ais.cs.sandia.gov/AiS/textbook/textbook.html). This AiS textbook articulates a curriculum that encourages students to work in teams and develop logical thinking skills, and, as well as a curriculum which emphasizes oral and written communication skills, is learner-centered and presents a multi-disciplinary approach to solving real-world problems. Like the later summer institutes, the AiS textbook presents the computational science curriculum in the context of project development, team building, and mathematical modeling. The authors of the textbook have created a supplementary online teachers’ manual that contains a set of lesson plans which also meet mathematical and science standard objectives. The textbook is currently being tested by the AiS teachers in the five states.

Conclusions

The AiS pilot project was designed prior to the introduction of the World Wide Web. At that time very few schools had phones in the classroom and even fewer schools had connections to the Internet. AiS schools received a direct, digital Internet connection, networked machines, and access to central computing resources at the host institutions. Today, states are developing and implementing technology plans to connect their schools to the Internet, and correspondingly, schools districts are struggling to provide technology in the classroom. Over the past five years, the AiS program has addressed many of the problems facing school administrators today and can serve as one example of integrating technology into the K-12 schools. The great success of the program is evident in the understanding the students have manifested through the integrated approach to learning and is encapsulated in the saying of R. W. Hamming, “The purpose of computing is insight, not numbers.”

GOING ELECTRONIC: MODELING A PAPER"LESS" CLASSROOM

David J. Bullock
Portland State University

Emily C. de la Cruz
Portland State University

Integrating media and technology use into statewide educational programs is a priority in the State of Oregon. The School of Education at Portland State University (PSU) is actively participating in this endeavor by providing preservice and in-service programs with increased emphasis on the integration of media and technology. As Oregon’s only urban university, our mission addresses the importance of learning across the lifespan as a means of meeting our communities’ educational needs. Toward that end, this paper will address the following key issues as related to teacher preparation in the State of Oregon:

• How can electronic resources be used to expand the forms of expression and performance in today’s classrooms by moving beyond traditional paper-and-pencil tasks?
• How can electronic resources facilitate a redefinition of teaching and learning in classrooms?
• How can technology facilitate a shift toward more collaboration between students and teachers?
• What does research say about the impact new technologies have on teaching and learning?

Rationale

There has been a long history within technology in teacher education supporting the notion of integrating technology into the curriculum (Copeland & de la Cruz, 1991; Daugherty & Boser, 1993) with varying degrees of success. Despite increased training in the uses of technology, teachers face numerous barriers when putting their ideas into practice within the social and cultural contexts of their schools.

One of the benefits promoted by early advocates of technology was the efficiency of electronic data transmission and communication. Lancaster (1985) and Swan (1993) revisited the prediction that we would become a ‘paperless’ society. Clearly, that prediction has not come to fruition. Why not? When considering the concept of “paperless,” one must consider the importance of changing the way we think about communication. Mainstream American culture highly values and privileges the written word - more specifically, the printed written word (Keller-Cohen, 1996). Despite the increasing variety of means to access information and communicate with one another, the symbolic importance of print in American culture has not diminished.

Such cultural privilege is also reflected in many traditional schooling practices: standardized tests which focus on verbal and analytical skills; textbooks as main sources of knowledge; and reliance on written work, e.g., essays, papers, and written exams as means for evaluating student achievement. By acknowledging such regard for the printed word and placing it central to the teaching and learning process, other forms of expression are minimized and even excluded. In doing so, we then privilege those students who can successfully demonstrate their knowledge through reading, interpreting, and creating printed text. This places a growing proportion of our population, whose strengths lie in other forms of communication and expression, at the margins of teaching and learning in schools.

The teacher preparation program described in this paper attempts to broaden definitions of teaching and learning to include multiple forms of expression. By diversifying the repertoire of instructional resources in a paper"less" classroom to include visual, electronic, audio, and multimedia, we hope to accomplish a number of goals: the student-teacher dialectic is downplayed, and both students and teachers become learners; learning becomes an active, learner-centered process; learners will have access to a repertoire of resources which are representative of a wider range of human endeavors beyond their own spheres of experience; and learners will have increased opportunities to demonstrate their knowledge and expertise in a variety of ways.

One of the goals of our graduate teacher education program is to identify ways in which students can authentically engage in activities using technology in their roles as students, prospective teachers, and practicing professionals. Following Hansen’s (1993) model for technology teacher education curriculum, we have based our program on three elements: (1) purpose (experiential learning, personal...
development, technological enlightenment); (2) content
(professional knowledge, curriculum development compet-
tence, pedagogical knowledge and skill, technological
foundations); and (3) process (planned reflection, class-
room instruction, individualized and group learning, tech-
technological method).

Background

The Graduate Teacher Education Program (GTEP) at
Portland State University involves students working
together as a cohort throughout their five year program.
Each cohort is guided by a team of faculty and focused on a
specific theme. Among the cohorts started in the fall of
1996 is a secondary group (Teaching and Technology
cohort) focused on the uses of technology in teaching. As
we’ve developed the program for this group we have placed
an emphasis on using electronic resources. We realize that
it is unrealistic to expect students in our program to be
completely electronic. We have provided opportunities to
experience teaching and learning which incorporate the use
of electronic media in conjunction with traditional instruc-
tional resources. We are moving in the direction of using a
wider variety of resources, while decreasing our depend-
ence on paper/print resources—a paper-less classroom.

The Teaching and Technology Cohort has been
fortunate to participate in a US West and National Educa-
tion Association (NEA) sponsored grant called Oregon US
West/NEA Teacher Network (Teachnet). Pairs of our
preservice students have formed teams with teachers
working in schools throughout Oregon. All communication
has been electronic, using web pages and electronic mail
e-mail). Team members have been asked to share informa-
tion about themselves and their educational programs, then
explore the Internet and share their findings. Discussions
have been guided by a series of assignments posted on a
web page for all to access (http://otn.uoregon.edu). Similar
teams exist at each of Oregon’s state colleges and universi-
ties. One unexpected benefit of this program has been that
the teams link cohort members living in a metropolitan
setting with practicing teachers working in rural Oregon.
This has given our students a much broader perspective of
teaching in general.

Program Components and Modeling

Most students’ initial exposure to the use of technology
in teaching and learning is through an integrated Instruc-
tion and Technology course, taught by a team of faculty (for
more details, see de la Cruz & Bullock, 1996). During this
course, students are introduced to many of the technologies
they will encounter in schools, as well as some which are
still on the horizon. They learn how to use these technolo-
gies to both create and present media. An emphasis is
placed on appropriate uses of media and technology as they
enrich contemporary models of teaching and learning
which focus on the family, community, and workplace as
places of learning (O’Neil, 1995). In addition, students
learn the fundamentals of developing instructional units,
designing lessons, and creating assessment tools. During
this course, students collaborate to develop their first term
projects (e.g. work samples, community studies) and
present them using appropriate technology.

Students learn to communicate via electronic mail,
participate in listservs, access newsgroups, and create web
pages to enhance communication and collaboration. These
forms of communication continue throughout the program.
By nature, they allow us to limit the amount of paper used
in class. Assignments, syllabi, schedules, and readings may
be accessed and shared electronically.

The Instruction and Technology course is only one part
of our overall effort to integrate technology throughout our
curriculum. The program’s Teaching and Learning class
takes advantage of a new hall on campus with state-of-the-
art technologies. Other content area courses draw attention
to appropriate software, software evaluation, and designing
instruction which includes media and technology.

We have used with a variety of electronic resources over
the past few years, and found some to be very effective in
increasing the amount of communication between cohort
members and faculty. For one of our first experiments, we
had students save assignments into their own personal
folders on the School of Education network server. Faculty
could then access the assignments from their offices. They
could also leave additional assignments in special folders
for students to copy or review. Students immediately
learned how to work with a computer network, and how to
save their documents in a format their instructors could
open and read. Since the network is only accessible from
School of Education offices and labs, access was limited.

Our next step was to use e-mail for some of the same
purposes. Students sent their assignments, daily journals,
and questions to faculty via e-mail. This allowed students
and faculty who had computers at home more flexibility
with regard to when they worked on or responded to
assignments. Faculty also found that the amount of
communication with students increased, and comments
about assignments tended to be more detailed. At the same
time, the need for “paper” assignments decreased signifi-
cantly. E-mail has also been the primary source of commu-
ication between students working on the Teachnet project
and their “teacher partners” in the field.

The more we used e-mail, the more possibility we saw
for increasing communication. Our next step involved
setting up two listservs. One is used by all GTEP cohort
students, while the other is for the cohort working specifi-
cally with the Teachnet project. Both listservs are used by
students and faculty in a variety of ways: cohort business,
information sharing, planning student get-togethers,
seeking advice, general announcements. Preliminary data
suggests that the amount of communication between
students, as well as students and faculty, has increased. We are just beginning to evaluate the quality of the communication to see if it has helped to increase "connectedness" and learning.

One of our newest endeavors in going electronic has been the use of web publishing to share course information and assignments. Students in our Instruction and Technology class can access the class syllabus, schedule, and list of assignments via the Internet. We’ve even included links to some Internet sites as starting points for research. Students in the Teachnet project have taken this a step further by setting up a cohort web page with links to their own personal pages and other useful Internet sites (http://131.252.56.87/TandT/TandT.html). We are already getting feedback from students suggesting that they like the ability to access class information electronically when they need to, and many are enjoying the opportunity to “publish” information about themselves on the web. Some are already planning to make a web page version of their resume available to potential employers.

In addition to “networked” electronic communication, students are using multimedia applications such as Microsoft Powerpoint and The Digital Chisel (Pierian Springs) to create presentations rather than written papers for class assignments. Students were introduced to these applications when faculty used them for presentations in various classes. Subsequently, students attended workshop sessions on each application, and have begun using them for their own presentations (we’ve even had one group of students create presentations for faculty who are unfamiliar with the software). We’ve established a working relationship with Pierian Springs Software, a local company, and plan to try out a new “electronic portfolio” template they are developing. In addition, we’ve purchased a CD recorder so that students can eventually create their own CD which includes various versions of their portfolios, resumes and work samples.

**Implications for the Future**

In establishing program goals which expand the effective use of technology in education, multiple forms of expression and performance are being perceived as critical elements of effective practices in teaching and learning. These opportunities for learning have contributed to an overall decrease in the amount of “paper” needed for communication and assignments. They have also allowed us to increase communication, incorporate multimedia elements into presentations, and set up links to resources beyond the School of Education. The Teachnet project, in particular, has encouraged an increased awareness of the resources available on the web, and talk between preservice teachers and teachers in the field. The opportunities for sharing and learning from each other have been enormous.

The potential for a broader definition of technology in teacher education seems compelling when examining preliminary data from this cohort experience. We are continuing efforts to incorporate state-of-the art technology into the curriculum. Future enhancements include desktop video conferencing, expanded web page development and access, and more discipline-specific applications in methods courses. We hope to eventually institute many of these components at a programmatic level, so that all preservice teachers going through this program will benefit from such experiences.

Moving toward a paper “less” classroom motivates students to effectively use technology and provides increased opportunities for collegial interaction and collaboration. This encourages students to seek out curriculum material from a broader variety of resources. By modeling a paper “less” classroom as part of students’ teacher education program in the ways described above, the program provides support for student teachers as they experiment with expanded visions of teaching and learning.

There are a variety of exciting and stimulating educational technology materials available for classroom use. Access to the Internet provides a host of opportunities for exploration and resources on an endless variety of topics for students and teachers. Software tools are being developed and implemented that enable members of an educational community to manipulate and display data and think about concepts at a higher level (Becker, 1994; Marcinkiewicz, 1994). However, all of these technological resources are only as good as the classroom teacher. Given the nation’s interest in improving education for students, the lack of attention to teachers is ironic, for at the center of effective use of instructional technologies by students are those who oversee the daily activities of the classroom—the teachers. Educational technologies are not self-implementing, they do not replace the teacher. (Office of Technology Assessment (OTA), 1995, p. 1)

Numerous studies have been conducted and a variety of articles have been written describing the amount of technology available in the classrooms and what teachers are doing, or not doing, with this technology (Becker, 1994; Marcinkiewicz, 1994a). Most of these reports make similar recommendations on improving the situation by providing more equipment, more teacher training and support, and more time for teachers to implement the technology into their curriculum. Few recommendations address specific methods of implementation. Most remedies include spending more money or restructuring schools, solutions that may not be practical (Becker, 1994; Marcinkiewicz, 1994a).

This paper proposes a solution to the problems classroom teachers face in dealing with the technology available to them. The solution involves the element of the educational system in which teachers have the most knowledge and experience — the students. Student mentors collaborate with teachers as technological support in the classroom. Questions that can be asked about technology are: What kinds of technology are available in the classroom? Amidst all this technology, where does the classroom teacher fit? Is the classroom teacher using the technology that is available? What kinds of support do classroom teachers need? What can be done to provide the necessary support?

**Availability and Use of Technology**

Supply of computers is high, but teacher demand is low. Despite the amount of technology available, teachers are ultimately responsible for its use in the schools. Simply having more technology does not in itself persuade teachers to use it. Often these teachers are inadequately prepared for implementation. Only five percent of U.S. teachers met the majority-of-standards criterion on a national survey that sets the criteria for exemplary use of computers by classroom teachers (Becker, 1994). Marcinkiewicz (1994b) surveyed 170 teachers and found, although half the teachers surveyed used computers, only eight percent used computers as an integral part of their curriculum and 48.5% felt they were expendable.

There are numerous reasons cited for lack of computer use by teachers: anxiety due to lack of self-competence and efficacy, discomfort with lack of familiarity about technology, lack of good software for computers, lack of access to or wasteful spending for equipment and materials, no single best choice of media for all instructional needs, lack of support personnel, and fear of change (Becker, 1994; Chin & Hortin, 1993; Ely, 1993; Hannafin & Savenye, 1993; Marcinkiewicz, 1994b; OTA, 1995; Swan & Mitrani, 1993).

The implications of the use of technology for improving the preparation of novice teachers or enhancing the continuing professional development of inservice teachers are rarely considered. When teachers’ needs are discussed, the focus is often on providing short-term, one-shot training to familiarize teachers with a specific application or general computer literacy (OTA, 1995).

On a national scale, one would have to conclude that computer-based instruction in the U.S. schools and universities has had minimal impact. However, where deliberate efforts have been made by individual teachers or entire institutions, one would have to say that, in those
circumstances, the teachers and learners will never be the same again. They have gained new skills, new perceptions of how to learn, increased motivation, and renewed enthusiasm for teaching and learning (Ely, 1993, p. 55).

Exemplary Use of Technology

A study conducted by Marcinkiewicz (1994) suggests that the adoption of computer use may occur incrementally or hierarchically as described by instructional transformation. Instructional transformation, a theory by Hooper and Reiber (1995), describes a teacher's use of computers in terms of five progressive levels:

1. **familiarization**: the teacher becomes familiar with the computer;
2. **utilization**: teacher begins to use computers during instruction;
3. **integration**: the computer becomes critical to instruction in the classroom (at this level the teacher is aware of changes in his/her role in the classroom);
4. **reorientation**: due to that awareness, the teacher restructures instructional activities to enhance computer-teacher-students interactions, and,
5. **evolution**: there is constant evaluation and tuning of the implementation of technology in classroom instruction by the classroom teacher (Marcinkiewicz, 1994).

Exemplary computer-using teachers would be functioning at the integration level or higher. Along with the level of computer use, there are many other elements that are essential in developing exemplary computer-using teachers. Educators who have high levels of self-competence and efficacy are more likely to be exemplary computer-using teachers. Innovativeness is another factor that contributes to a teacher's level of computer use. Exemplary computer-using teachers adopt innovation as a way to keep current with and have access to increasing amounts of technological information (Marcinkiewicz, 1994a, b).

There were some variables found in exemplary teachers' backgrounds compared to other teachers. Exemplary computer-using teachers spent twice as many hours personally working on computers at school than did other computer-using teachers. These teachers also had more formal training in using and teaching with computers. They reported having training in more areas than did other users (Becker, 1994).

In classrooms, exemplary practitioners directly address curricular goals by having students use a wide variety of software, including simulations, programming languages, spreadsheets, database programs, writing tools, and electronic bulletin-board communications software (Becker, 1994). Becker found four characteristics of teaching environments that seem to be conducive to promoting exemplary use of computers:

- the existence of a social network of computer-using teachers at the same school;
- sustained use of computers at the school for sequential activities, that is, where computers are used to accomplish a goal other than learning, for example, writing and publishing, industrial arts, or business applications;
- organized support for computer-using teachers in the form of staff development activities and a full-time staff member in the role of computer coordinator, and
- acknowledgment of the resource requirements for effectively using computers, for example, smaller class sizes and funds for software acquisition (p. 303).

**Student Mentor Program Descriptions**

What means are available to support the transition of non-computer-using teachers to teachers who integrate computers in the classroom? Some schools are utilizing the technological knowledge of their students. These students are technology mentors to teachers and other students in the school. Two examples of successful technology mentor programs are described below. Following the examples is a list of ways in which the use of students as technology mentors can assist teachers in becoming exemplary computer-users.

**Example #1.** A team of researchers at the University of Michigan have been conducting research at a local high school through a grant from the National Science Foundation. The researchers and teachers have created a technology rich, investigative-based, science program (Huebel-Drake, Mouradian, Stem, & Finkel, 1995) This paper focuses on the support teachers and students have received as the amount of technology equipment has increased and the use of the technology in the classroom instruction has evolved over the past three years. The technological support provided to meet the teachers' needs is an integral part of the implementation of this program.

The first year of the program, there were 18 AppleTalk computers being utilized by the students and staff. There were 21 ninth grade students in the pilot science program. Support was provided by one graduate student who had a dual role of technician and researcher.

The second year, there were 70 computers utilizing Ethernet connections. In addition to work in school, students in the science program were allowed to borrow the computers to use at home. As the amount and use of technology, along with the number of participating students increased, the support needed for the classroom teachers increased. At this point in the program, the role of the researcher became separate from the technician role, and a graduate student was hired to be the technician in the school for approximately 30 hours a week. Two high school students who were interested in technology became interns to the technician.

The third year of the program involved all incoming freshmen. At this time, there were 110 computers distributed in three rooms. The majority of the computers were
was provided by the same two students who were interns with the graduate student the previous year of the program. Those two students were paid to work for two weeks before school started to make sure the computers were repaired and ready to go. During the school year, the student technicians continued to be paid for a few hours a week.

The student technicians’ responsibilities included: keeping 100+ powerbooks loaded and running smoothly, managing the file server, accounts and connectivity, fixing problems with the network, answering questions and troubleshooting during class sessions, and providing support for teachers. In addition, they trained several new volunteer interns. The goal of the new interns was to become future technicians for the program.

Along with the training received from the technician at the university, the students’ technical knowledge derived from prior experiences. One technician’s knowledge had been fostered by playing with PET computers in second grade, curiosity with Apple IIs computers in fifth grade, taking a BASIC class at a local hands-on museum, and messing around with computers on a daily basis.

Example #2. Last year, after coming to the realization his students possessed skills teachers needed, a high school teacher started an after school training class with 10 student volunteers. The students were instructed on a variety of skills and techniques that might be useful for elementary teachers such as creating web pages, building tables, and using hypermedia programs. The goal was to assist the teacher as he/she worked with the students in the classroom.

The students were placed in elementary schools in small groups of two or three, visiting their school once a week during the time they were scheduled for their technology class at the high school and sometimes after school. The original plan was to start in one teacher’s class and then move throughout the building assisting the entire staff. Unfortunately, there was a scheduling problem at the school so the students spent their entire training experience with one class. The student mentors were trying to work with the teachers during the school day. Although it was not the intended goal, the high school students became tutors to the elementary students as well as mentors to the teacher. All individuals involved, students and teachers, profited from the experience.

For example, one group of technology mentors comprised of three females, were placed in a second grade classroom and worked with the students using Hyperstudio (1995). The mentors brought a laptop computer with them and used two other computers that were available in the school. They worked with small groups of about eight second graders. The end goal was to make a class portfolio that included the second graders’ voices, photos, information about each individual, and the events that were taking place in the classroom throughout the year.

The technology mentors enjoyed the time they spent working with the students in the classroom. They were amazed at how much the second graders already knew about the computers and how the software worked. According to the technology mentors, they learned just as much from the students as the students learned from them.

Even though the mentors enjoyed their experience working with the students, they reported that they felt frustrated by their lack of work time with the teacher. The teacher did not possess as much knowledge nor did she feel as comfortable using the computers as did her students. The support given by the mentors was advantageous to the classroom teacher in that the second graders were able to create an end product (Hyperstudio document). However, the classroom teacher did not acquire the technological skills necessary to reproduce this type of product independently.

Benefits for all. Interviews with the participating classroom teachers and student mentors contributed to devising a list of benefits for all participants (teachers, students, and mentors) in the case studies described above. The teachers found the mentors to be helpful in the classroom; there were more hands to help students, they lent credibility and value to the lessons, and provided immediate assistance with technology problems. The teachers became familiar with technology, appreciated the kind, gentle, patient instruction, and gained awareness of and respect for the vast amount of knowledge held by the mentors.

The classroom teachers also noted the students in their classrooms benefited from positive interactions through this cross-age and peer tutoring environment. The students found the lessons to be more credible because the activities became self directed, they gained power over the computers, and they received instruction from teachers (mentors) who had a different perspective and who were gentler, more sympathetic, and “cooler”.

The mentors felt they also reaped rewards from this opportunity in many ways: they felt helpful, boosted their self-esteem, provided an opportunity for practical application of skills, looked great on the resume, and helped with communication and assimilation in to an adult world.

Technology Mentors: Support for Classroom Teachers

Teachers spend the majority of their working lives out of sight of other adults. If they are to successfully incorporate a new and complex resource like computer software into their teaching practice, they must have access to other people from whom they can learn. These resources could be either experts who have already mastered the resource or a community of teachers-learners who pool their efforts and
share their exploratory findings (Becker, 1994). Technology mentors in the classroom provide teachers with experts who have mastered many of the skills teachers need. As these mentors move from one classroom to another, they create a community of knowledgeable teachers and students which increases the pool of learners twenty fold. Technology mentors assist in creating environments that are computer active and rich in resources, on-site support, and motivation for teachers.

**Computer Active Environments.** Schools are considered to be exemplary when there is a greater number of computer using teachers (Becker, 1993). This will happen if student mentors work with teachers and student in the classroom. Even if the teacher is not directly involved in the mentoring process, technology mentors promote the type of environment needed for exemplary use of computers. The classroom students become empowered, bringing the classroom teacher along with them.

**Resource-rich Environment.** Exemplary teachers practice in a resource-rich environment. Technology mentors assist in providing a resource-rich environment. Becker (1994) also found that exemplary computer using teachers had lower class sizes. Even though the number of students in the class do not decrease, the presence of technology mentors in the classroom increases the teacher-to-student ratio.

**On-site Support.** Exemplary teachers work in schools that invest heavily in staff development and on-site staff support for computer-using teachers, often by providing a full-time staff member designated as a computer coordinator (Becker, 1994). This type of support does not meet the needs of classroom teachers because one person cannot supply the needed daily personal support. Technology mentors, available on a daily or weekly basis, supply the necessary personal support for the teacher.

**Motivation.** As mentioned earlier, the adoption of computer use may occur incrementally or hierarchically as described by instructional transformation. Student mentors help this developmental process occur at a faster rate by providing a greater amount of personal support and instruction for the classroom teacher that is specifically tailored to meet the teacher's needs. Self-competence contributes to a teacher's pursuit or avoidance of computer use. Innovativeness (one's willingness to change) contributes to the level of computer use. Marcinkiewicz (1994) suggests as technology continues to change and expand, it will be increasingly necessary to help teachers adopt innovation as a way to keep current with and have access to increasing amounts of information. Technology mentors will be able to support teachers in their quest to be innovative. Teachers who have had technology mentors in their classrooms commented that the mentors know the "latest" in technology and are adept at how to use it. The teachers also used technology, such as Hyperstudio, that they would have otherwise avoided without support from the mentors.

**Conclusion**

In order to integrate computers into their current programs, practicing teachers will have to work beyond their current professional expectations. They will need to be highly motivated to see a reason or need for using technology. Self competence is highly related to achievement and learning situations. This suggests that if teachers are expected to integrate computers into their teaching, computer integration needs to be considered as achievement and teachers should be cast as learners. Practicing teachers assume the role of learners only when they participate in extra education, such as inservice or other staff development programs (Marcinkiewicz, 1993). Teachers become learners on a continual basis when they participate in the technology mentor/teacher program. Staff development in this manner would be progressive in nature. As the technology mentor/teacher relationship unfolds, the mentoring can accommodate planning time with the teacher. The teacher is the curriculum expert, and the student is the technology expert. The teacher can share what the expectations are for the students in the classroom, and the mentor can give suggestions for innovative use of technology.

TEACHER PROFESSIONAL DEVELOPMENT: TWO CASE STUDIES OF CURRICULUM-DRIVEN TRAINING

Carlos R. Solís
Rice University

At schools, educational software and hardware find their way into classrooms through school-budgeted acquisitions, grants, donations and parents’ efforts. This surge in educational technology has spurred the need for training strategies that will effectively develop teacher’s abilities to incorporate these technologies into curriculum. Thus, in many instances what schools lack is not so much basic hardware, but teacher training (OTA, 1995). The Office of Technology Assessment concludes that among the most urgent policy changes is the provision of high-quality preparation of staff (p. 42, 1995). More specifically, Teachers and Technology: Making the Connection (OTA, 1995) reports:

One of the most clear findings of the OTA case studies ...is that even very highly motivated teachers require substantial amounts of time—often over a three to five year period—before they feel fully versatile with a complicated new technology and are able to expand technology tools to fit their particular teaching goals. (p. 41)

What are the optimum methods for providing the current teaching workforce with the needed intellectual framework and specific technical skill sets to keep pace with the infusion of technology hardware and software in K-12 classrooms? McCraw, et al. (1995) have suggested that one of the most successful ways in which to integrate technology and curriculum is through thematic units. Papert (1993) proposed that people learn more effectively when they are involved in construction processes that are related to objectives that are meaningful in their lives.

In our work with teachers through the Center for Technology in Teaching and Learning at Rice University, one of the most successful vehicles for introducing technology is the use of existing teacher-developed curriculum as the cornerstone. Weaving together technology with teachers’ curriculum-driven needs offers opportunities for “just-in-time learning” that often produces short-term and long-term results, while enabling teachers to attack the technology learning curve in a less-threatening atmosphere.

The Context

The two case studies presented are anchored in experiences with a technology-rich K-8 school attempting to absorb and manage change on a massive scale. In the fall of 1994, The Rice School/La Escuela Rice in Houston, Texas opened its doors to 1300 students. One of the school’s distinguishing features was the generous gift from Compaq Computer Corporation of 1100 workstations and six servers over a three year period. This hardware was coupled with the donation from Southerwestern Bell of a fiber optic connection directly to Rice University for Internet access. The school’s technology infrastructure was designed to allow each station to connect to up to six servers. Furthermore, the design of the network allows students, teachers and staff members to have personal disk space. Deploying this amount of technology in this building required effort and planning, but the bigger effort was to make the system a useful teaching tool and to provide teachers with the capability to work and dream independently with these technologies. The purposes of the programs described below were several:

1. to develop and effective model for integrate technology into curriculum;
2. to stimulate teachers to embrace technology solutions when appropriate, and
3. to become proficient in their execution.

When The Rice School/La Escuela Rice opened in 1994 it had set three main goals in the development of its educational programs: a) to provide children with a multi-age educational system, b) to provide children with an education that would allow them to function in a bilingual society, and c) to provide children with a technologically rich environment that would promote new ways of learning and collaboration between students and teachers. The teacher population was recruited with these goals in mind. Given that it was impossible to select teachers with experience and training in all of these areas, the resulting population was composed of individuals who run the gamut of having no exposure to computers to individuals that have used them extensively.
Between the opening of the school in 1994 and the middle of 1996, technology training was competing with numerous other demands for professional development such as multi-age grouping techniques and dual language learning. The initial technology training focused on meeting the teachers need for "personal and administrative uses" of computing for activities such as electronic mail within the school, word processing, and grade book reporting and the basics of the operating system (at that time, Windows 3.1). Every week sessions were offered and individuals self-selected the training they felt appropriate for their needs.

This "cafeteria-menu" approach to training programs met with very limited success for at least two reasons. First, the priority level for the training was low both from an administrative and teacher viewpoint, with the classes being frequently canceled in order to have teachers attend other school functions. This stemmed from the numerous demands of starting a new school with ambitious goals and competing priorities for teacher time. Second, the training was not tied to particular instructional goals, rather to a more general notion of computer proficiency.

In the Spring of 1996, an alternative to this style of training and with the slight diminishment of other competing demands for teacher time, the Center for Technology in Teaching Learning initiated two different approaches to professional development in technology.

Both programs stressed voluntary participation, intensive contact with CTTL technology specialists, and validation by the school administration of the time and effort needed by the teachers participating in these programs.

Curriculum Driven Approaches

Galileo's Web. Galileo's Web was supported by CTTL to explore the possibility of adapting and incorporating world wide web-based educational resources that were designed for higher education into middle school education. This project included a middle school elective course, entitled Special Projects, that was taught throughout the spring of 1996. Over 120 students were enrolled in the course which was collaboratively taught by a teacher who specializes in gifted and talented education and the author. The students were a multi-age group of sixth through eighth graders.

The learning and exploration were centered on Galileo Galilei's life. Both the teacher and the students used a web site created under the direction of Dr. Albert van Helden in the History Department at Rice University for one of his courses. The Galileo Project [http://www.rice.edu/Galileo] was the starting point for exploration. It was created in an effort to provide users with a hypertext information source about Galileo and the science of his time. This resource has been used successfully and is continually updated for undergraduate education at Rice University.

Prior to beginning the semester, the teacher was approached by members of the Center for Technology concerning her willingness to develop a prototype course and experiment with technology. The teacher had autonomy to work with the technology support group and was free to experiment. With a background in and strong track record in interdisciplinary teaching, she welcomed the opportunity to enrich her course with technology, but was apprehensive about her lack of computer knowledge. Assured that she would receive personalized training and that she could progress at a her own comfort level, she accepted the challenge.

The teacher laid down a curricular plan for the whole semester. This plan included themes and activities that would be carried out in a traditional classroom. The initial units were executed and enhanced with technology. All of the student created projects were developed and executed with off the shelf technologies such as word processors, drawing programs, graphical VRML tools, web browsers. In addition, students created multimedia libraries for personal use by harvesting objects off the world wide web. Time was allocated in class for cooperative learning groups, to plan and execute projects, for student-teacher consultations and for independent pursuits. Added to the mix were visits to the class by Dr. van Helden and Dr. Patricia Reif, a Rice University professor of space physics and astronomy. Information gathering combined world wide web browsing with access to related books and video resources which the teacher brought into the classroom.

In the initial stages, the teacher required a great deal of support and individual training. The author worked closely with her and projects were done as a "team" effort. Within six weeks, the teacher was completing projects on her own and taking a leadership role in the instruction and support of technology used in her projects. And by the end of the semester, the teacher felt strongly that technology she had "pushed beyond the 'dark ages' of instruction without technology." The class projects and lesson plans can be viewed at http://www.rice.edu/armadillo/Rice/Galileo

Project Constellation. Based upon the small, but successful experiences in Galileo's Web, there was thought about how to scale-up the technology infusion process to reach a greater number of teachers and students at the same school. What were the successful characteristics of the working relationship that could be applied to more teachers. Upon reflection, there seemed to be a number of positive elements deserving of replication:

1. The teachers should begin with a curriculum plan that they wanted to teach.
2. Technology support should be offered on a one-to-one basis, in addition to more general training that could be offered in group sessions.
3. Technology support needed to begin by "guided practice" with the technologist facing the same classroom environment as the teacher.

4. The teachers should be encouraged to move at their own pace in experimentation.

5. Reflection and evaluation should be an on-going process to keep the project on course, given the increased numbers of persons involved.

6. There had to be buy-in from the school administration with full acknowledgment that technology training time would not be usurped for competing purposes.

In the fall of 1996, eighteen 18 teachers were recruited through a self-nomination process for a semester long "technology support program" named Project Constellation (http://cherokee.cs.rice.edu/Constellation). The project derived its name from Chiron, the mythological centaur, teacher of the gods, and the Centaur constellation. This name was chosen as part of the idea that teachers trained in this group should become guiding lights for students and other teachers. The final selection of participants was left to the instructional technologist. The main criteria for selection were previous experience with computers and grade level they taught. An attempt was made to recruit a cross section of the teachers and areas that they teach. The development of Galileo's Web had a positive impact on this program since it was used as a prototyping system to then develop Project Constellation. Furthermore, Galileo's Web became a very visible project at the Rice School/La Escuela Rice and exemplified for others the kinds of achievement and developments that are possible with this kind of training.

Participants in Project Constellation had from six to twenty-five networked computer stations in their classrooms, depending on the ages of their students. Classrooms from kindergarten through second grade had four computer stations and classrooms in the eight grade had one computer station per student.

Training and support. Training and support for this program came in several ways. The CTTL instructional technologist met all the recruited teachers for two hours every week for project development. The group sessions also included three Saturday sessions of six hours. Group training sessions included project based software instruction, cooperative project development, teacher lead discussions of articles on teaching with computers, and group sharing of success formulas and frustrations.

The program focused on construction targeted at curricular needs. Product rather than technological details was at the center of this program. The approach was similar to the one proposed by Resnick (1996) in his proposal of distributed constructionism. Participants worked with software that enabled them to create with materials and activities with minimal acquisition of new skills. Their worked was shared with others in the group and with their students. In the process of sharing and teaching, participants reengineered their work and learned from each other. For example, in the process of learning how to use and produce web based instructional materials, teachers used 'What You See Is What You Get' editors that allowed to quickly construct resources and concentrate on content rather than on mastering technological feats. Support materials that facilitated construction, such as web based graphics libraries and basic templates, were created for the teachers to minimize repetitive labor with no learning value. Teachers could discuss constructions through the establishment of web based threaded discussion groups and listservs.

Teachers in Project Constellation also had access to the instructional technologist during one and half hour sessions once a week. These sessions were reserved for one on one training and project discussion. Every participant in this project had a regularly scheduled session and both the instructional technologist and the teacher respected this time.

Understanding the common time and resource constraint facing today's teachers, CTTL provided them with slip accounts, electronic mail accounts and web space. These allowed them to explore the Internet from home and communicate with each other and the instructional technologist using laptops provided by the school.

Project Constellation benefited not just from the experiences derived from Galileo's Web, but from itself. Since training takes place in two rounds of 18 teachers each, experiences and lessons learned from the first round can be applied to the second. Also, the achievements of participants in the first round serve as a showcase that attracts others to the second round.

Impact on the teachers and the school. Project Constellation impacted teaching and technology at The Rice School/La Escuela Rice at several levels. It allowed teachers to construct and create units using computers and the world wide web "in close correlation with themes and topics that [were] being studied in the classroom". During the course of the program participants became reflective about the role that computers play in the classroom and moved from the "learning about computers" mind set to a "using computers to learn" attitude. In this process teachers saw technology in their classroom as "tools that enable children to learn". Some of them expressed the "need to improve placement of computers in the classroom" as they became part of their daily activities.

Participation in this project also brought about teacher involvement in the technology decision making structure of the school. While in 1995 teachers rarely attended sessions of the committee that oversees technology at the school, 1996 brought an active participation in this committee. Project participants also served to attract students in the middle school recruitment efforts as their work in Project Constellation became a very visible project at the Rice School/La Escuela Rice and exemplified for others the kinds of achievement and developments that are possible with this kind of training.
Constellations was showcased in an effort to attract new applicants.

Teachers and students collaborated in project development and construction. For example, in the QuiltingABC project (http://www.rice.edu/armadillo/Rice/QuiltingABC) three K-2 teachers worked with their students in the production of an electronic quilt. This quilt, a shared unit that is accessible through the World Wide Web, contains digital art squares created by the children and electronically “sewed” together by the teachers. Each square links to a more detailed rendition of that section as well as to a scanned self portrait and autobiographical notes created by the author of the square. This project was part of a unit on communities which explores the role of quilts in American culture. It included readings, exposure to quilts that were meaningful to the children’s teachers and mathematical exercises based on quilt patterns.

Examples of developed activities include the Quilt Project for a kindergarten through second graders and the Colonies Project. The Quilt Project was based on the role of quilts as part of a community study. Teachers stressed the importance of the quilting traditions on American culture. Quilts were brought into the classroom, children designed quilt squares following mathematical principles and worked on paper quilts. At the same time, they developed an electronic quilt (http://www.rice.edu/armadillo/Rice/Quilt) with digital drawings which were electronically “sewed” together and linked to scanned self portraits and biographical notes.

At the other end of the student age spectrum, eighth grade teachers developed the Colonies Project (http://www.rice.edu/armadillo/Rice/Colonies). The object of the Colonies Project was to have teams of students develop imaginary colonies which included maps, clothing, monetary systems, simple machines and means of communication. This project was developed by three teachers in this group and implemented by a team of five. The teachers used the world wide web to deliver problems and information on how to create a colony. The web was also used to allow the transmission of sample work by student teams and to provide students with means of electronic contact with the teachers leading the project.

Establishment of the Working Relationships

The development of both projects involved the participation of administrators, researchers, instructional technology specialists, network administrators and teachers from CTTL and The Rice School/La Escuela Rice.

The initial agreements were reached between CTTL directors, CTTL staff that would be involved in program development, and the school principal. A contract that outlined the responsibilities of both institutions was put together and signed. CTTL provided training, materials and Internet access from home for the participating teachers. The Rice School/La Escuela Rice blocked out time for teacher development, provide teachers with laptops to allow them to access the Internet from home through CTTL sponsored slip accounts. Teachers with perfect attendance to training sessions also received a day off.

The CTTL instructional technologist defined clear and solid working relationships with the participants. At the beginning of the programs he explained to the participants what would be expected from them and what he would provide in their partnership. Project participants agreed to keep electronic journals for a year and to allow the instructional technologist to document their work in the classroom as well as their classroom environment. Participants also agreed to complete questionnaires as needed by the instructional technologist. The relationship between instructional technologist and teachers in both programs had a common thread: the establishment of a strong and trusting partnership in learning. In both cases, the teachers had access to the instructional technologist outside the training environment, and in both cases the instructional technologist worked with the teachers at a tutoring level. The instructional technologist, while being a member of the CTTL staff did not keep an office at the Rice University. Instead he was deployed at The Rice School/La Escuela Rice full time. He helped the teachers at many levels, including hardware troubleshooting, serving as a voice for teachers in school policy discussions that involved technology and education, by researching electronic classroom materials that would support ongoing activities and by setting up and creating applications that were useful to teachers.

Trouble Spots

The implementation of these programs face several challenges. On one hand, teachers are attempting to change the way they teach and learn while trying to meet state requirements for essential elements that are not always compatible with innovation. Furthermore, all these activities were carried out on an already heavily loaded schedule making thoughtful reflection, practice and exploration difficult for them. Second, these programs were carried out in an environment where the administrative sections of the school are the product of a traditional educational systems with little exposure to information technology. Problems encountered here were often related to specific infrastructure commitments needed for both programs’ foundations. It would appear to be necessary, after reviewing these two programs, to devote time and develop programs aimed at bringing school administrators to the forefront of educational technology. It is important that administrators understand the true meaning of their commitments to educational technology programs. In future projects progress and results could be improved by establishing regular meeting times, progress reports and working sessions with school administrators, in the same fashion that teachers were guided in their development.
It was also difficult to keep participants active in journal keeping. Journals, which were supposed to serve as a tool to document change in attitudes toward technology were kept used on an irregular basis and in general were used more as a vehicle for complaining about other school officials. Therefore journal requirements were removed halfway through the program and regular administration of questionnaires was used instead.

What Makes the Difference

The most important aspects in the success of these programs were the development of an instructional system that made learning about technology meaningful for the professional goals of the participants in learner centered environments (Norman & Spohrer, 1996). By making technology a construction tool in curriculum development teachers were able to see quick results and impact in their classrooms. “Project Constellation was my first opportunity to use resources available through the Internet to actually develop activities which I could use in my classroom with my children immediately”. Equally important was the fact that teachers knew that the CTTL information technologist would be present at the school for support and consultation, as well as for individualized training. “I realize that the individual sessions that we receive are so valuable”. The participants also regarded the individualized training sessions as an important aspect of their learning. Finally, providing participants with the ability to access Internet services from home helped them work, explore and learn better than they had been able to do before, when they only had access to computers at school. Teachers’ schedules at schools are often time overloaded. They need to be provided with the opportunity to learn after hours, without expecting them to own a home computer or to have to pay for Internet services. The CTTL sponsored accounts and laptops provided by the school were key elements to facilitate this effort.

Russell Elementary School, site of the multimedia portfolio project described in this paper, is a Professional Development School that is collaborating with the Lower Valley Center for Professional Development in a Texas Education Agency funded project. A major initiative undertaken by the campus this year has involved all teachers in training in multiple intelligence theory and classroom applications. As teachers learned more about this theory, they realized that they must also adopt a new evaluation process to enable students to demonstrate the ways in which they were using the different intelligences in their learning. This paper will describe the role of authentic assessment as a tool for evaluation, the content and nature of a multimedia portfolio, and the process for creating student portfolios using HyperStudio software.

With the increased emphasis on alternative forms of assessment to complement pencil and paper tests and standardized assessment tools, teachers are currently exploring ways to allow students to document their accomplishments and growth. Assessment based on multiple samples of student work generated in meaningful contexts is of vital importance as a tool for evaluating student learning, communicating that information to parents, and involving students as partners in the evaluation process. These new multi-faceted modes of assessment assume even greater importance in classrooms that are implementing a curriculum designed to foster learning by engaging students' multiple intelligences. When students demonstrate their learning using one, or more, of the seven intelligences identified by Gardner (1983, 1991), traditional forms of testing and assessment are no longer appropriate.

During the fall semester, all elementary teachers were given training in Gardner’s theory of multiple intelligences and in learning to identify each of the seven intelligences (verbal, logical-mathematical, spatial, bodily-kinesthetic, musical, intrapersonal, or interpersonal) and assess their students' multiple intelligences. In this way, we are able to build on children’s stronger intelligences and to provide instructional activities that address each intelligence, thereby allowing all children to learn in the way that is most effective for them. However, the multiple intelligence approach to teaching and learning requires us to implement assessment procedures that are multifaceted and based on student products, portfolios, video or musical productions, exhibitions, panels, and samples of problem-solving. Portfolios seem to provide the most effective way for students to document their learning and growth. In fact, we are particularly impressed by the value of portfolios in involving students in reflecting on their own learning and growth, in selecting the products, works-in-process, and other samples of materials that document their ability to use the different intelligences as a means of learning. As a tool for authentic assessment, portfolios possess certain distinct advantages. They provide for ongoing evaluation offering a more clear perspective of student progress and treat each student as a unique human being. By concentrating on the abilities of each student, on what s/he can do, and on what s/he is accomplishing. Students also become reflective learners by selecting items to include in their portfolios and in explaining why these items are important and what learnings they demonstrate.

The decision to use HyperStudio software to create students’ multimedia portfolios was based on its user-friendly features that allow children to continuously document their learning activities and progress. HyperStudio portfolios are more than just a collection of papers for them and their parents to shuffle through; they can incorporate sounds, graphics, narrations, still photographs of projects, scanned images of selected work, writing samples, and works-in-progress into this electronic record. The portfolio becomes a living document that belongs to the student who makes decisions about which work best demonstrates growth and progress toward self-selected goals. Even more important, in the context of multiple intelligences, students can select works in which they demonstrate effective incorporation of a specific intelli-
gence in their learning processes. By allowing students to reflect on work they have completed, they view themselves as successful contributors. Students set personal goals and help develop a standard for excellence, seeing themselves as valued members of the class. Participation also helps develop responsibility as students are continuously involved in updating and editing their own portfolios. Finally, at year's end, HyperStudio allows the portfolio to be copied to videotape and taken home.

These portfolios are highly personalized representations of student-selected work, achievement, performance and personal interests. Although student-selected content varies widely among the children in the classroom, some unifying structure was provided by the teacher. Obviously, students also needed to have familiarity with computers and possess some prerequisite computer skills in order to be able to use HyperStudio for the production of their own portfolios.

**Prerequisite Computer Skills**

Before using HyperStudio, children need certain competencies in using the computer as a productivity tool. During the early fall, children have become familiar with Claris Works word processing, learned disk management procedures (such as: saving/opening files on their own disks), become accomplished at accessing CD-ROMs for information and pictures to incorporate into reports, and developed competence in scanning graphic images into files. Students are comfortable using pull-down menus and know how to enhance their work with audio narrations using the Macintosh built-in microphone or sound clips and how to use story boards to plan the sequence of screens for their presentations. They have also had many opportunities in using the KidPix2's clip art, paint and transition tools to create and illustrate their original writings.

Training in HyperStudio merely required the acquisition of a new set of vocabulary and skills. Using the HyperStudio Tutorial and Addy, the guide dog, children learned the terminology and conventions that are essential to creating products with HyperStudio (Gross, 1995). One important learning is the understanding of the concept of stacks and branching using buttons that is a different model from the usual linear page-after-page book model. Students also learn to use the Bibliography Template to categorize and describe the cards in their stack that represent each type of presentation, i.e. text, graphics, sound, video, and animation. The elements of design become important as children learn how to select backgrounds, borders, animation options, and text and button styles to complement their projects. Since these third-grade students were already comfortable with computers, they quickly learned to use the basic features of HyperStudio. In fact, some more technically adept students even learned to use hypertext links to tie together cards in their portfolio stack.

**Portfolio Development and Content**

Students used teacher-developed guidelines for portfolio content, for organizing and sequencing its content, and for using self-evaluative criteria to create oral or written descriptions accompanying their selected products (or works-in-progress). Each portfolio began with an introductory autobiographical sketch that set the stage for the selected content of each portfolio. Each autobiography includes personal background, place of birth, information about the student's family, personal interests/hobbies, and reflections on their preferred, or stronger, intelligences.

The Teele Inventory of Multiple Intelligences (1992) was administered to each student, and after the responses were scored, teachers discussed the characteristics associated with each intelligence and how people demonstrate the intelligences in their everyday life and in school activities. (Armstrong, 1995, p. 26-31). Children learned about the importance of each intelligence in their success in school and become skilled in identifying times they are using the different intelligences. They also learned that all human beings favor certain intelligences and that other intelligences are rarely used (dormant). These understandings were important to the children as they began to select samples to represent their effective use of at least four different intelligences for inclusion in their HyperStudio Portfolio.

After several class discussions about portfolios and examination of portfolios created by other classes, students were encouraged to identify examples from the portfolios that reflected the use of a student's linguistic/verbal intelligence. With the teacher's guidance, they then generated a list of reasons why that particular item was a good way of showing how the student had used his/her verbal intelligence. Finally, they dictated a short description as to why they thought this work was a good sample to illustrate the student's verbal intelligence using the following stems:

I chose this work because ...
I think it shows how I use my verbal intelligence because ...

One thing I learned about myself when I did this "piece of writing" (description of selected example) is that ...

Children then worked in groups to select a different example to reflect musical, spatial, or logical-mathematical intelligence and created a description to justify their selection using the given stems.

In order to help students understand how they might observe themselves or others demonstrate their bodily/kinesthetic, interpersonal and intrapersonal intelligences, they suggested actions and activities that children do at school, on the playground, or in other community settings that would be good examples of using one of the three intelligences. Following the discussion, students were
asked to choose a classmate and write a few sentences
describing a time when they observed him/her using a
bodily/kinesthetic, interpersonal or intrapersonal intelli-
gence. These short “MI biographies” were read aloud and
became models for short “MI biographies” that were
written for each child portfolio by at least one classmate.
Children then selected the “MI biography they wanted to
include, which in some cases was saved as a sound clip
read by the author, and in other cases was typed, or
scanned, into the HyperStudio stack.

Guidelines provided by the teacher helped the students
with ideas about what to put into their MI Portfolios.
Students were given the following suggestions as to what
types of samples might be included to represent, or
describe, each intelligence:

1. Verbal-Linguistic Intelligence: preliminary drafts of
writing projects, best samples of writing, written
descriptions of investigations, poems, jokes, journal
excerpts, audiotapes of reading or storytelling, or
samples of word puzzles solved.
2. Logical-Mathematical Intelligence: best samples of
math papers, rough notes from computations/problem
solving processes, final write-ups of science lab
experiments, samples of logic puzzles or brainteasers
created/solved, or samples of graphic organizers.
3. Spatial Intelligence: photos of projects, diagrams, flow
charts, sketches, mind maps of thinking, and samples or
photos of collages, drawings, paintings.
4. Musical Intelligence: lyrics, raps, songs, rhymes written
by student, audiotapes of musical performances
5. Bodily-kinesthetic Intelligence: samples of projects
actually made, photos of hands-on projects, photos or
written descriptions of pantomimes, charades, imper-
sonations, videos of physical exercises or games, or
illustrations using body language/gestures.
6. Interpersonal Intelligence: descriptions or photos of
ways in which student interacted with others, letters to/
from others, photos/write-ups of cooperative learning
projects.
7. Intrapersonal Intelligence: descriptions of feelings,
personal ideas, goals, and objectives, responses to
interest inventories, notes of self-reflections about work
or learning.

These suggestions seemed to provide enough direction
for students that they were able to make reasoned choices
as to what they wanted to include in their portfolio (or write
about for an MI biography for a classmate). In order to
encourage student’s critical evaluation of the materials they
might include, a maximum stack size of 20 cards was
imposed on their work. They were further limited by the
memory available on the Macintoshes that were in the
classroom. These restrictions helped to guide students
during the design process. When they were given their 20

large index cards that served as their storyboards, they used
them to provide a visual schema of what they wanted to
include, how they wished to organize the stack, and how
cards would be linked together. Obviously, a great deal of
shuffling and modifying went on as they began to create
their portfolio stack, but the results were gratifying not only
for teacher and students. Through their involvement in the
Multimedia Portfolio Project, the students’ self-esteem
grew, and they were thrilled with visible evidence of their
knowledge, abilities and growth in using each of their
different intelligences.

Conclusions

HyperStudio portfolios have met the teachers’ need for
manageable and portable portfolios. The project served
many valuable purposes for students as they: 1) became
more reflective and strategic in the use of the different
 intelligences to enhance their learning; 2) learned to be
selective in choosing items to include; 3) used evaluative
rubrics and criteria to justify the inclusion of the selected
items; 4) developed their organizational and written
communication skills; and 5) experienced the joy of
sharing their accomplishments with their peers and
families.

An important benefit to these students is that the
portfolio structure designed by the teachers promotes the
development of critical thinking, organizational and
written and oral communication skills. Children also
experience a real sense of ownership in their portfolios
while learning to evaluate their strengths and weaknesses
and to describe their products in terms of their growth and
increased competence. Teachers and students alike have
found multimedia software to be a valuable tool that allows
students to keep a year long visual record of products
demonstrating their knowledge and proficiency in various
areas.

As schools move toward forms of authentic assessment
across the curriculum and grade levels, multimedia
portfolios provide an effective medium for students to
identify specific ways in which they are demonstrating their
learnings and growth through their activities and products.
These products can then be placed in other formats such as
computer files or videotapes and shared with parents and
others as permanent, portable records that can accompany
them throughout their school careers. Teachers found that
portfolios foster student reflection and encourage better
home-school communications when parents have tangible
records of their children’s accomplishments.

Acknowledgement

Activities described in this paper were funded under a
Texas Education Agency grant to the Lower Valley Center
for Professional Development and Technology.

The Potential and Problems of District-Funded Technology Inservice

Nancy M. Wentworth  
Brigham Young University

The United States has been involved in a massive effort to increase the use of computers into curriculum and instruction (Office of Technology Assessment, 1988). Several recent studies (Strudler, Quinn, McKinney, & Jones, 1995; Willis, Willis, Austin, & Colón, 1995) show that one of the problems with integrating technology into any curricula is the teacher in the classroom. There are a number of reasons for this: computer illiteracy, computer phobia, disinterest, lack of equipment, or other problems. Teacher inservice can help teachers overcome computer illiteracy and phobia, but may not always help teachers integrate computers into their curriculum. Inservice programs that include a full-time, site-based training program, focusing on the individual needs of the teachers have a better chance of achieving the desired outcome of technology and curriculum integration (Pappillion & Cellitti, 1996).

This study reports on a collaborative effort between a university teacher education program and a public junior high school in a program to integrate technology into the school curriculum. The university-public school partnership had defined inquiry and professional development as two of its primary functions, so they were jointly committed to helping teachers develop new curriculum that integrated technology into the curriculum (O'Neil, 1992; Broughy, 1992). Participants had discussed the importance of defining problems for students to solve as a part of the inquiry process. They also agreed that the problems needed to be authentic and real-world in nature. Learning had been discussed as an ongoing process of construction, generation, and creation of meaning enhanced by interaction with other learners in cooperative and interdependent efforts. The validity of learning should be constantly tested against and internal sense of reality and worth. Good teaching and leading is a creative process, demanding the constant injection of new information, new perspectives and new energy. Assessment should downplay paper and pencil, short answer as well as norm referenced tests that compare students to each other in favor of authentic performance, reflecting how knowledge is tested in adult work and civic settings. Portfolios of students' best work should be jointly created by students and teachers (Wiggins, 1992).

Research Design

The focus of this research project was a district funded inservice program aimed at developing curriculum that integrates technology into instruction that includes the problem solving process. An earlier project began in a school with only one teacher being mentored by a university professor. The professor spent time helping a classroom teacher learn to use computer programs that were available at the school. The teachers and students were introduced to a spreadsheet program as a tool in data collection and analysis problems. The students were then placed in groups of four and asked to design and complete a problem that would require the collection and analysis of data. The professor worked with both the students and the teacher to select the problem and analyze the data (Wentworth, 1996).

Because of this work, a grant was awarded to the school to inservice all teachers in the use of computer technology as a part of problem solving in the classroom. The professor, as part of a larger program of teacher education, was also involved in the supervision of student teachers in this particular school. The teacher education program was changing this same year to include university course work for the student teachers to be done at the school. The professor spent at least two full days a week in the school working with student teachers and with classroom teachers on the development of their integrated curriculum. Having the student teachers in some of the classrooms allowed teachers freedom to develop lesson ideas and help in the computer lab with other teachers who did not have student teachers in their classrooms. Along with the integration of technology in the classroom, the teachers were placed in teams to integrate across subject areas. As teachers produced lessons that integrated in this way they provided them to the district.
Both the teachers and students kept research logs of the projects from conception through final report. The researcher kept an account of the types of problems designed by the teachers, the discussion about the data required to answer the question, the use of technology to solve the problem, and the final analysis and representation of the data. Throughout the project, the researcher interviewed the teacher and students about their work asking questions to get at their problem solving and their views about the use of technology as part of the problem solving process: how did they select the data to collect, how did the technology aid in the analysis of the data, what conclusions were drawn from the results. The researcher also keep a journal of frustrations and successes experienced by the teachers and students.

**Results**

Initial problems arose with the district-funded project that had not occurred with the mentoring of only one teacher. The district office did not fund the project for software because a large company was going to donate it to all schools in the district. This was a different software package than the teacher had learned and used previously. However the university professor was familiar with it. Four months into the school year the software was still not available, and the school learned that it was not to be donated, but would need to be purchased. Software was not licensed on all machines initially so work could not begin as early as had been hoped. The new computer lab was not wired on schedule which also delayed the inservice. Some teachers were unwilling to participate in the project because it was not required by the district or principal. However, once the initial inservice took place most teachers were excited to begin designing curriculum that would include the technology they had seen.

In spite of the many problems beginning the project, several lesson plans were created and implemented by the teachers. The university professor and the school teacher had learned from their experience that defining the problem presented to the students was a key element to successful integration projects. Teachers were encouraged to think of a specific question to ask students. This helped focus the data collection, investigation, and analysis. The inservice was done with groups of teachers by departments that would naturally have similar content.

This was not a complete integration process. It was felt that more complete integration would come after teachers had become familiar with the software and exposure to inquiry learning. Two examples of a questions to ask students to begin the projects were:

1. You were very interested in the weight lifting at the Atlanta Olympics. You thought about the size and weight of the participants and the amount of weight they lifted. How would you determine which weight class lifted the highest weight as compared with their body size? Which person would you declare as the “strongest man on earth” based on this?

2. You are interested in how the Olympic games will effect the area of Salt Lake City in the year 2002. What areas of change do you expect to find? What data will you collect before the games? What data will you collect after the games? What predictions will you make based on the information you can collect about the Olympic games in Atlanta?

Question 1 integrates both mathematics and physical education. Question 2 integrates social studies and mathematics. Teachers collected data on these questions and then began to define questions for their students as examples. As the teachers implemented these in their classrooms, the students began to ask their own questions. The teachers were excited to see students engaging in inquiry in this way.

**Conclusions**

District funding made possible on-site inservice program for all interested teachers. Teachers worked on the same software and began together, so they supported each other across the learning curve. Teachers were able to consider integration of their content areas as they included technology in their curriculum. Having a university professor at the school helped the teachers initially try the technology. They worked together with the students to learn the software, and then to determine how it could enhance the curriculum. As the year progressed, the professor spent less time teaching how to use the technology and began to help teacher rethink instruction and content. New types of problems were considered because the technology could help students investigate and seek out answers. Having a teacher at the school who had been through the process was a great benefit as well. She was able to help other teachers when the professor was not at the school. She supported their ideas, and helped them prepare work that integrated content areas.

Both students and teachers enjoyed experimenting with the technology. They worked together to define questions that had significance for the content of the curriculum. The questions were complex and interesting, requiring many days to complete. Teachers and students worked several days defining the problem and deciding on the data required to answer the question defined by the problem. Teachers and students felt like co-investigators and learners. The teachers began to feel confident in their abilities to use the technology. The began to trust the students to learn specific content as they defined their own problems.

Niagara University, Lewiston, NY, and the Niagara Wheatfield School District, Sanborn, NY, are collaborating on a pilot project to introduce Niagara University graduate education students to a hands-on experience in a real world work environment while bringing authentic assessment and technology into the school district’s Edward Town Middle School Inclusion program. Faculty specialists in authentic assessment from the School of Education at Niagara University are assisting five middle school teachers in building authentic assessment into their classroom curriculum. During the 1996-97 school year, a succession of five person teams of graduate students will work alongside the middle school faculty. A portion of the middle school student activities will be placed on electronic portfolios.

Problem and Issue

Much of the instructional scheme and curriculum used by the middle school faculty was designed for a pre-technology era and needs extensive rewriting to meet twenty-first century New York State Education Department standards. Niagara Wheatfield sought outside assistance from Niagara University to provide the expertise for curriculum renovation — specifically, the incorporation of authentic assessment. Niagara University graduate education students sought a real world work experience to develop their pedagogical skills.

Purpose of Project

The project provides a dual constructivist learning environment — for the graduate education students as well as for middle school students and their teachers. The project provides for the professional preparation of graduate education students by hands-on training at a technologically rich school site. The overall project goal is to seek dramatic improvements in instructional methods other than lecture, recitation, and seat work using the graduate students as a catalyst for change. The goal for the graduate students is their construction of knowledge about a new approach to accountability — authentic assessment, and the use of technology in the approach. Authentic assessment techniques will produce student portfolios (for the middle school students and the graduate students) which will be developed and stored using computer and CD-ROM technology.

Review of Literature

In their collaboration, Niagara Wheatfield and Niagara University have surveyed and continue to survey a wide range of expertise. Below are selections of the most representative works. Since Niagara Wheatfield and Niagara University are seeking innovation, the lesson learned by General Motors at the GM Hamtramck plant provides a sobering starting point. Simply, there is no magic bullet. General motors tried to use automation, a technology fix, to bypass other production and organizational problems (Murnane & Levy, 1996). The plan ended in disaster with production down and organizational problems unsolved. The lesson for the Niagara team — use the study to approach all the factors: the on-site location, the new technology, the philosophical approach, and the ongoing organizational environment.

The Niagara partners want the Niagara graduate education interns to control their own learning in a real world work environment. The philosophical approach to the project is Constructivism with Columbia University providing suggested models to make constructivist activities effective. Importantly, the Columbia authors sensitize the team to the fact that the graduate students will be handling complex ideas whose mastery will require a significant degree of practical experience (Reibel, 1996).

The Niagara team is looking for strong models of teacher training in a constructivist, technology rich environment, especially sites where a partnership supported...
an extensive ongoing investment. The answer may be ACOT, Apple Classroom of Tomorrow. In the mid 1980's, Apple Computer Corporation responded to a question of what happens to students and teachers when they have access to technology whenever they need it. Apple initiated a program of selected Apple partner school sites (the ACOT sites) and created ACOT teacher development centers. Apple assembled teams of university researchers, Apple personnel, and teachers to evaluate the program activities. Over the next ten years, the ACOT project produced evidence of the advantages of a constructivist learning environment and models of new teaching strategies (Apple Computer, 1995). Researchers looked for support for constructivism where technology was considered a knowledge building tool. They found that participants' progress evolved through developmental stages: Entry, Adoption, Adaptation, Appropriation, and Invention. At each stage, the dynamics of constructivist learning called for different kinds and levels of emotional support, collaboration, technical assistance, and instructional sharing from colleagues (Sandholtz, Ringstaff, & Dwyer, 1991).

Finally, the Niagara team focuses on evaluation. If individuals are to be charged with the responsibility of their own learning, charge them with the responsibility for carefully collecting and selecting work they feel best represents their growth according to set standards. Constructivism leads to authentic assessment. Technology provides a perfect vehicle for capturing and storing the selections (Whitby, 1995). The literature suggests that constructivism can guide portfolio development. Teachers, graduate interns, and middle school students must explore the possibilities of portfolio construction while gaining an idea of what a portfolio may be. The work of Arter and Spandel provides a perfect vehicle for capturing and storing the selections (Sandholtz, Ringstaff, & Dwyer, 1991).

### Design and Purpose of Study

This case study is a preliminary effort to record the activities of the participants. The next stage will be building hypotheses and conducting experimental research comparing the professional progress of graduate education students participating in the project with that of graduate education students not participating in the project. By professional progress it is meant the knowledge and hands-on skills of integrating authentic assessment and technology into a middle school Inclusion environment.

This study is designed to be a work in progress. It will provide an opportunity to observe activities, gather data and determine facts and variables. Since this study takes place in an environment subject to drastic change, we seek an opportunity to determine as many variables, independent and dependent, as possible. This study may turn out to be a troubleshooting guide.

### Data Gathering

The case study will observe graduate students moving from theory to application and from old methods to new. Not all data gathering methods have been finalized. The following grid in Table 1, designed by Apple Corporation’s ACOT teams (Apple Computer, 1995), will be adapted to guide data collection on observations and interviews of graduate students and the five middle school teachers, and classroom activities. It matches seven focal areas against how activities or behavior inside an area match traditional instruction modes (teacher centered — accenting learning of facts) or newer construction approaches (learner centered — stressing inquiry and learner invention). Since it is expected that the participants, including the graduate students, will vacillate between old and new approaches, it allows observers to catch such vacillations in time to provide support (Dwyer, Ringstaff, & Sandholtz, 1991).

</tr>
</tbody>
</table>

By collecting data over an extended period of time, the study can utilize the Apple ACOT developmental stages to capture data on the evolution of beliefs about learning and teaching and the consequences of these changes on classroom practices as shown in Table 2. (Sandholtz, Ringstaff, & Dwyer, 1991).

<tr>
<td>Appropriation</td>
<td>New instructional patterns and questioning of old patterns</td>
</tr>
<tr>
<td>Invention</td>
<td>Pedagogy approached developed by teacher</td>
</tr>
</tbody>
</table>

### Evaluation

The graduate students will be evaluated through the following criteria:

1. Third party observations of their progression through technology skill stages as outlined by the ACOT developmental stages: Entry, Adoption, Adaptation, Appropriation, and Invention.
2. Their own personal electronic portfolios reflecting (a) their best efforts in showing knowledge of models of teaching strategies and new ideas, and (b) their assistance in the production of student portfolios reflecting the middle school students’ best efforts.

Conclusions
This case study will not lead to identifying a specific cause-effect or independent-dependent variable relationship. No conclusions about causes and effects will be made. It will permit gathering observations and facts that will help direct attention to independent and dependent variables for a future experimental study. This case study will provide background for decisions on improving facilities and equipment at the site, classroom setups, participant preparation, scheduling, data gathering schemes, communication among participants, and support of faculty.

A MODEL OF STAFF DEVELOPMENT USING CONTROL TECHNOLOGY

Christopher Taylor
University of Exeter

The author, a Lecturer in Education at the University of Exeter, was asked by a group of teachers in a local primary school to support work they were doing to better address technology issues. The purpose of the research was twofold: to develop a model to change practice in a school, and to enable the teachers involved to incorporate the use of Information Technology into their teaching by using a form of Control Technology. A secondary advantage from the project was the opportunity for the author to develop ideas in Design and Technology, which is his teaching commitment, and to work intensively with groups of children in school as a part of a program known as “Recent and Relevant,” whereby tutors in the institutions involved in the initial training of teachers work in schools to keep up-to-date.

Definitions and Clarification

In Britain, the term technology is used in a number of different ways in the context of education. Information Technology (IT) is the use of electronic, microprocessor or computer-based technology. Design Technology (D&T) refers to the process of designing, making and evaluating artifacts. Both of these subjects have foundation subject status and are statutory parts of the English National Curriculum (HMSO, 1995, IT in the National Curriculum). Control Technology (CT) refers to the use of a computer or microprocessor to control machines, models or events, (such as a simple robot) generally by means of the use of switches and sensors. Both D&T and IT have been previously identified as areas of weakness in British schools by the Office for Standards in Education. “The most disappointing feature at KS2, however, is the frequent lack of progress beyond KS1 levels of attainment... Pupils are often not confident with control, which is often absent after KS1” (HMSO 1995, IT, A Review of Inspection Findings). “The D&T subject knowledge and experience of teachers needs to be more extended, especially for those teaching Years 5 and 6” (HMSO 1995, D&T, A Review of Inspection Findings).

CT Project

The primary school project was cross-curricular in nature and provided opportunities for children to work cooperatively while using math to solve problems and constructing circuits. The initial ideas for the project were based on a curriculum pack developed by Cornwall Local Education Authority (LEA). However, this included few opportunities for the use of IT. The school’s initial proposal was that the children would construct lighthouses and the researcher would help them to interface their models to a computer, and program them to flash when it was dark. As four classes were involved, spanning an age range of three years, it was proposed that the idea of lighthouses be broadened to also include road safety, with the idea that the Year 4 children work with programmable floor robots, the Year 5 children construct lighthouses, and the Year 6 children also work on road safety but construct their own traffic lights and motorised buggies rather than using a floor robot. To assist this project, the school was loaned a buffer box and software, an ideas pack on Control Technology (NCET, 1989), and a floor robot for the length of the project. This would enable the classes to fulfil the Controlling strand of the National Curriculum to “create, test, modify and store sequences of instructions to control events” (HMSO 1995, IT in the National Curriculum).

The traffic lights and lighthouses were interfaced to the computer (an Acorn BBC Master, similar to an Apple II) using a Buffer Box made by Deltronics. This buffer box would protect the computer from damage and also act as a 6 volt power supply. A piece of software called Contact was to be used, which permits the computer to access eight output ports and eight input ports. This was closely related to Logo in terms of language and structure; however, the school had not used Logo previously. Although all this technology was rather old and obsolescent in terms of design, the BBC computer was well equipped for control work, by virtue of having a number of built-in interfaces and readily available, simple software. This work also did not require large amounts of computer memory, fast processors or sophisticated windows-based software. The floor robot to be used with the Year 4 class was called PIP (Programmable Interactive Plaything) from a firm called
Swallow Systems and functioned much like a floor turtle except that it had its own built-in computer which allowed it to be programmed with a subset of Logo. A rechargeable battery meant that it could be recharged overnight and it was sufficiently robust to function effectively in a classroom environment.

**Procedures**

The researcher received an outline of what the school wished to gain from the project, and how it was to be undertaken. He then negotiated with a team of four teachers who covered Years 4, 5, and 6. Using a form of assisted self-development, he agreed to give support to the teachers by participating with them in the planning process, and by providing them with a limited amount of classroom support (i.e., working with one group of children from each class). Resource materials for the children were also provided. The teachers were encouraged to observe the targeted small groups and participate as the children tried out the researcher’s ideas for themselves. The teachers were then encouraged to extend these opportunities to the rest of the class.

The total time given to the school was approximately twenty hours. Data was collected by means of direct observation. In addition, copies of children’s work were collected. The researcher kept a notebook of observations as the project continued. The teachers involved were interviewed towards the end of the project to see if they perceived any change in practice.

**Preliminary Findings**

At the time of writing, the research has been completed in the school, but the data gathered has not yet been fully analysed. Observations suggest a high degree of motivation amongst both teachers and pupils. The floor robot has been a particular success, with the children in the class using it to extend their knowledge of angles and estimation of distances. They programmed the robot to move round the roads, waiting at Stop and Give Way signs. The children in two classes with the Year 5 and 6 pupils have undertaken more involved model making, constructing motorised vehicles with remote controls, and their teachers have found the time and energy to extend the introductory sessions so that bare chassis could be decorated to make cars. Traffic lights have been constructed and interfaced to the computer, with the children programming them to work in the correct sequence and to change when a switch is pressed. One class constructed lighthouses with two electric circuits so the lights flash and there is a sound signal (a buzzer) to warn of fog. One group got as far as interfacing their lighthouse to the computer, programmed it to flash, then added a light sensor so that the light flashed when it was dark and went out in the daylight. There was no sensor suitable for detecting fog, so an intermittent buzz was programmed and manual switch was used to activate the program.

The teachers indicated that they felt they had gained considerably from the project, and there had been noticeable learning gains among the children involved, particularly in the areas of problem solving, constructing circuits, craft skills (using tools etc.), and sequential thinking. Pragmatic constraints (staff illness, lack of time, and the need to rehearse for a Christmas production) limited the amount of follow up that was possible, and prevented the teachers from continuing the activities with all groups of the classes. This is now planned for next term. One teacher, working with the floor robot, has been able to continue the activity with the whole class, largely because this activity demanded less in terms of supervision, and now feels much more confident of its use with children. In the other classes, there is a determination to carry on with the work as soon as the timetable permits. There is a commitment to buy more Control Technology equipment and copies of Logo for each of the classroom computers. The staff now feels confident in the use of Control Technology, recognises its links to the whole curriculum, and are ready to take on the use of Control Technology as a school wide activity.

Ready availability of resources is one issue that has come out of the work. Without materials being readily available, it is difficult to manage D&T activities. Glue guns and glue sticks had to be found from classes, tools had to be acquired, wheels had to be found and the children had to bring in some materials from home. The author had to supply flashing light bulbs for the lighthouses, motors for the cars and 6 volt bulbs for the traffic lights. There was no budget in the school for IT for this year, so the school was working with a borrowed buffer box and software, hoping to buy their own equipment in the following year. Timing was not totally successful. Since it was Christmas term, there was timetable disruption in the last three weeks, greatly restricting time available for development by the class teachers. In order to prevent this in the future, a less ambitious plan, perhaps working with only two or three classes at a time might be better; however, the teachers felt that it was necessary for a critical mass to be involved in order for the initiatives to be developed.

One issue, noted by three of the teachers and the author, was one of a gender difference. It was noted that the girls seemed to have a different approach and attitude to the activities than the boys. They had less self confidence, seemed to listen to advice more carefully and were more persistent. In contrast, the boys seemed to have much more confidence and were better at managing the tools, but were less careful in following their designs and were more liable to produce ideas that would not work. The orthodox way of designing, making, evaluating, and improving seemed short-circuited. This is an area where more research is...
required. It might be that different teaching strategies could be employed to overcome these difficulties.

With regard to the model of assisted self development, this model was clearly successful. Its success depends on the motivation of the teachers concerned, and a feeling of a sense of ownership of the activity. It is one area of the curriculum where teachers can be quickly alienated and de-skilled. "It is important for colleagues to be supported in using Information Technology to improve the quality of their teaching, rather than simply adding it on top of an already over crowded course" (Davis, 1992). Traditionally, British schools have had access to advisory teachers who would work in schools to develop aspects of the curriculum, usually employed by LEA's. However, the devolution of financial control to school has marginalised such roles, and many LEA's have reduced or closed down their advisory sections. As yet, private consultants have not filled that vacuum left by the removal of LEA advisory services.

Conclusion

This project demanded a large input of time from the author, although there was no cost involved to the school, except for teaching materials. Such a project can probably only take place successfully where there is an "animateur" who has time to give, in this case the time was made by the need to research. One must be aware of the problem of the "Hero-Innovator" who will "Assault the organisational fortress and institute changes in himself and others at a stroke" (Open University, 1985). In this case, the author was well known to the staff of the school and was participating at their invitation. The project became a successful partnership activity between the school and the university. It would not have been possible for the school to buy in a consultant for that period of time. However, the university lecturer at a school of education, with a contractual requirement to research and publish, is in an excellent position to undertake such activities. They give to the school in terms of their time and expertise; the school gives them the context for the research.

Seymour Papert made far-reaching predictions for Logo when it was first introduced as a commercial product for school use around 1980. The claims for Logo's impact on cognitive development and learning effectiveness influenced school district buyers to invest in Logo as a central component of the elementary school technology toolbox. Over the years, the overall experience with Logo in the classroom has been mixed, and although Logo-related products still profess many advocates, Logo didn’t live up to the proclamations of educational transformation made at its introduction.

Today, the developers of proliferating classroom technologies also declare expansive cognitive, social, and learning advantages for their wares. Because independent research almost never deals with the specifics of “which” of these new products to choose within a genre of expanding possibilities and provides few answers to the seemingly simple questions of when, where, why, and how to use the new technologies in the classroom, decision makers still rely mostly on the claims of the manufacturers or distributors when choosing to purchase one product over another. Not surprisingly, not all the products perform as promised. In this regard, the chronicle of the early Logo experience exposes the need for a more teacher-influenced approach to choosing technology products for use in the classroom.

Early Logo Research Exemplifies the Problem

The initial questions regarding the use of Logo focused on the impact of the technology on learning and cognitive processes: 1) How will the use of this technology affect the learning process? 2) How does the use of the technology affect cognitive processing in students who use it? 3) Does education with the new technology require different levels of cognitive processing from other educational experiences?

When Logo was introduced, Papert made very specific claims in answer to these questions that implied he knew the answers. Specifically, his assertions, derived from his relationship and studies with Piaget, were based on his constructivist view of learning and a few early Logo studies (most with older children) at MIT (Papert, Watt, diSessa, & Weir, 1979; Reinhold, 1986).

Logo was introduced to the larger educational community in 1980 with strong and specific theoretically-based pronouncements of its ability to enhance the independent construction of knowledge, improve higher-level thinking, and expand the generalizable skills of young children. The research on Logo to that point provided very little practical evidence to support the breadth of such claims. Even so, in Mindstorms, Papert (1980) eloquently described how Logo could develop a child’s intellectual structures and how the computer could be used to expand the human mind. Teachers and administrators believed him.

Almost immediately after Logo was released to the schools, controversy ensued over the efficacy of Logo as a learning environment. Since that time, almost no specific computer-based product has received as much attention, research, and commentary as Logo.

Early Acceptance of Logo

Because of Papert’s stature and the broad and growing acceptance of constructivist principles over the last fifteen years, the adoption of Logo far exceeded the research-derived foundation for its use. Soon after Logo’s general release, concern evolved for the apparent absence of a well-defined empirical framework regarding the implications of Logo usage. Many researchers became concerned with the largely unsubstantiated claims concerning the benefits of Logo and computer programming on young children’s cognition. This resulted in critical analysis of the design and the application of the technology to achieve specific classroom objectives. The few representative studies discussed below frame the issues of contention during the first few years of Logo’s general implementation in classrooms.

Cognitive Development and Logo

Clements and Gullo (1984), for example, researched the benefits of Logo programming compared to drill and practice forms of computer-aid instruction (CAI). Their study of eighteen 6 year-old children randomly divided into
a Logo and a CAI group were assessed using a pretest/posttest research design over a 12 week period. Posttesting revealed that the programming group scored significantly higher on a measure of reflectivity and on two measures of divergent thinking, whereas the CAI group showed no significant pre- to posttest differences. The programming group outperformed the CIA group on measures of metacognitive ability and ability to describe directions, but no differences were found on measures of cognitive development.

The study extended the work of others in demonstrating that programming with Logo could increase some aspects of problem-solving ability and perhaps affect cognitive style, but the early Logo research offered little evidence to support claims of general cognitive development.

Contact Time and Logo

The question of contact time with Logo also held early research interest. How much time was really required to master Logo and benefit from its use? Gourman and Bourne (1983) reported that third-grade children who used Logo for one hour a week performed significantly better on a test of rule learning than did children with half the programming experience per week. Today, the question of optimum contact requirements remains salient and unresolved in the employment of Logo and other technology innovations.

Student Preferences

Other research revolved around the variable impact of Logo on children from different backgrounds and with differing learning preferences. Papert (1980) assumed that all children would function well in Logo environments. However, research by Vaidya (1985), revealed three distinct categories of Logo learners: 1) those who are sophisticated Logo learners; 2) those who function well in Logo environments with support and direction from the Logo teachers; and 3) those who do not function well in the Logo environment.

The research conclusions were based on a very small sample (n=14) studied over a period of eight months, but at face value this type of analysis seems necessary to answer the question of different learning preferences and cognitive implications and the role of teacher intervention regarding Logo.

The Role of Teachers and Adult Mediators

The role of teacher or adult mediator also was questioned by Logo researchers. A number of studies concluded that mastery of programming concepts is not a guaranteed outcome of prolonged exposure to Logo and required carefully designed teacher intervention (Carmichael, Burnett, Higginson, Moore, & Pollard, 1986). Other studies found that young children without “appropriate” adult mediation may not discover the “powerful ideas” that Papert associated with using Logo (i.e., Kull, 1985; Clements, 1985).

Implications of the Early Logo Research

In total, the body of early Logo research was extensive, but not conclusive in any area. The research offered conflicting formal results in response to almost every salient question about the use of Logo in the classroom. The research efforts also lacked the consistent operational definitions, populations, and/or longitudinal design to definitively answer substantive questions about the impact of the Logo experience. Many arguments surrounding the disparate experiences with Logo focused on the method of research as opposed to teachers and children in classrooms. The conflicting research claims mirrored the informal case studies (admittedly legitimate qualitative research) and teacher reports of failures and successes with Logo. It seems that for every strong advocate there was an equally vocal skeptic.

Logo was abandoned by some teachers in favor of new or more traditional experiences. In other classrooms, Logo continued to be enthusiastically employed. Even today, the question of Logo’s impact on learning remains controversial. As many results could be used to refute as to substantiate the claims made for the importance of the program in supporting specific educational benefits.

How Does This Relate to Today’s Technologies?

In spite of the ongoing controversy, the results of using Logo technology are perfectly clear, if you know how to read the research. It doesn’t matter if you live in the qualitative camp, the controlled camp, or somewhere in between. It all comes down to these facts: Logo did not revolutionize elementary education, but it did get computers in front of kids. Trained teachers and access to computers are prerequisite to employing any technology with success. With the training and access issues put aside, teachers who continue to employ Logo with positive results can tell you why they use Logo. They like the tool, the kids like to use the tool, and they believe the tool offers advantages over other activities they could be doing in the classroom. Teachers who dislike using Logo can tell you why as well: They prefer doing other things or using other products that help the kids learn similar computer skills.

Today, Logo is just one of many tools to use to program, explore alternatives, and debug operations. Some people prefer to teach these skills with Logo-related tools; some with Visual Basic; some with Hyperstudio or Digital Chisel; some with felt boards, crayons, blocks, and paper.

The Real Justification for Using Technology in the Classroom

The real reasons to use (or not use) Logo in the classroom may have had nothing to do with the original
questions researchers asked about the technology. Yes, the research questions regarding efficacy may be important to guide in the design of appropriate technology-enhanced educational experiences—but teachers face a more immediate, practical dilemma.

Teachers want to know what kids think and what other teachers have done with the technology. Teachers, just as they did in 1980 when confronted with Logo, continue to ask very basic questions: Will the use of the technology enhance the learning experience from the students’ point of view? Will my students prefer using the technology as opposed to another tool to learn the same concepts? How can I choose the best technology among seemingly similar products? What does the research have to say that can help me in choosing and implementing the technology effectively? Is using this tool the best use of my time and the district’s resources?

Research has not traditionally addressed these types of questions. Instead, for 25 years, researchers have focused on questions of the efficacy of computer-based treatments compared to non-computer ones. The research results regarding the efficacy of technology usage are so ambiguous and politically driven, as they were in the early days of Logo, as to confuse rather than support educators in their search for the best technology investments. Even so, the research has been consistent. The research almost never shows the computer and related media as detrimental to results gathered through traditional learning measures (i.e., achievement tests). Instead, computer technology is measured as neutral or perhaps a bit more positive in its impact on traditional assessments of learning (Roblyer, 1996). After realizing that the scores can’t definitively justify the use of technology in the classroom, then what?

Kaestle (1993) identified the root of the issue: “...the most common complaint leveled against [researchers] is the lack of connection between their research and teachers’ practice” (p.23). Those who control the budgets want justification for their decisions. Teachers want techniques and methods that work once the technology arrives. Given these priorities, the questions of efficacy and improvement in learning are not always relevant when making product selections.

Is It Relevant?

Perhaps the most important justification for using a technology in the classroom is the relevance of technology. Technology is a major component of the real future where today’s children will live. To prosper in that future, today’s children must use and be proficient in using all types of technology. They must be able to move quickly from one form of technology to another, receptive to new and ever expanding capabilities. Even if computers and other technologies don’t teach better—when selected and employed by trained teachers (and trained is the operative word in this context) the technologies can support an adaptive learning environment that is relevant to the world that children will live in for the rest of their lives.

In a relevant world, the right questions to ask regarding technology products in the classroom would include these questions first, and the questions of efficacy later: 1. Do we use the relevant technologies in the classroom that parallel the technologies being used in business, commerce, and academic research? 2. Are the technologies being integrated into the classroom experience in natural ways that encourage students to choose among tools that make the experience personal and relevant? 3. Do our students have the same access and opportunities to use the range of technologies available to other students in other schools? 4. Are we using the technologies we already have to maximum advantage? 5. Do our teachers embrace computer and information technologies and understand the priorities in making students technologically literate so they can prosper in the 21st century?

Since students will need to use technology in order to prosper in their adult lives, the employment of technology in the schools is necessary for reasons of social equity, societal relevance, and global competitiveness. In this context, trained teachers should not only use technology, but be able to filter out the self-serving claims from valid educational results and use their own experience with technologies to assess the best products for their classrooms.

Empowering Teachers to Choose for Themselves

The practical, relevant decision to use a specific technology product must be based on the experience of using a particular product in the classroom with specific teachers in specific, describable social contexts. For teachers to be empowered to make such informed choices about the technologies they use and the ways they will use them, five things must happen:

1. Teachers must embrace computers as one of the standard tools of their trade. People can’t make informed decisions about technology if they don’t use it. Teachers must employ computers in their own work and embrace them—just as computers are being employed in every other discipline in the modern world. This means that the educators who train teachers in colleges and universities must also model and demand the use of technology in courses at all levels. An often optional one-unit course in computer literacy can no longer suffice as adequate training for teachers who must prepare children for a future filled with technology.

2. Every teacher and student in America must have on-demand access to a standard desktop computer for research, writing, computing, Internet access, and
3. Research reports on new technologies must be independent and timely. The report-to-journal process is too slow for making product decisions. Research results must also appear in easy-to-digest formats that suggest practical implications to teachers who must design lesson plans and establish objectives for their daily activities. Most teachers don't read the referred journals in education and don't have time to interpret how complex studies may relate to practice. Perhaps one of the major educational technology associations should act as a clearinghouse for the dissemination and practical interpretation of (pre-published) research results. The World Wide Web and teacher-focused conferences would be logical venues for disseminating the compilations.

In this vein, the fledgling movement to publish the action-oriented observations (whether qualitative or quantitative) of trained teacher-researchers should be encouraged and funded. Teachers should be rewarded to talk about what they like and dislike about specific products and practices. Teachers need to share their experiences as legitimate research with the rest of the educational community.

4. Technology-savvy teachers must be involved in the decisions to buy and use technology—and in the design of new technologies as well. Product developers must provide more teachers with advance copies of technologies to try before those who hold the purse strings choose and dictate the technologies available to a specific school. When teachers aren't involved and committed to a new technology product, even if the technology may have good applications, the products often end up on dusty storage shelves next to the mimeograph machine and the Apple IIs.

5. The experience of teachers and students should count as much in the reputation of a technology as the research claims of the developers. When felt boards were introduced to display stories and messages, no one questioned the justification of the tool. Teachers knew the felt boards helped the students remain engaged. The colors and shapes appealed to the children. How did the teachers know this? They observed their students moving the shapes and telling stories with passion—not always with more passion than they would have told the stories without the felt board, but in general the teachers "saw" the tool as useful, fun, and adaptive.

Teachers who found felt boards useful believed in them and had ideas for using them. The individual training, preferences, and experiences of teachers had a lot to do with making the felt boards useful. Teachers also shared their ideas about using felt boards in the lunch room and in meetings. No elementary school teacher with a felt board was without a box of forms, shapes, and project ideas.

Computers, the Internet and the World Wide Web are a lot like felt boards in many ways—in the right hands the opportunities are limitless. In the hands of those with lesser imagination or inadequate training, they are only shapes on a desk or pictures on a screen. The trained hands, imagination, and shared experiences of the teachers make a difference.

**Moving Toward Informed, Teacher-Centered Decisions**

With the five requirements of teacher skill, computer access, readily available research, teacher-centered decisions, and experientially-motivated practice in place, technology-enhanced educational practice will be able to move away from faddish expenditures based on largely overstated claims to fact-based choices made by informed educators with specific classroom requirements.

Recent introductions of interactive, multimedia programs and other technologies, exhibit patterns of employment by classroom teachers (or school districts) similar to the adoption of Logo in the early 1980s: The conjecture of theorists overshadows research-justified claims, widespread implementation precedes understanding.
of the impact of the technology, and opinion overshadows demonstrable results about the long-term benefits (or drawbacks) for the classroom, children, and/or teachers. But in practice, none of the general claims for the media really matter. The things that matter are the employment of relevant technology in real-world applications and the use of programs and tools that motivate kids to employ those technologies, as they'll be required to in the "real" world. In these terms, using Logo mattered, so it was worth employing even if it didn't deliver on its other claims.

Teachers must be empowered to draw their own conclusions regarding the best of the products to use in their classrooms. Yet, in no way should this conclusion suggest a moratorium on research regarding media, technology and learning by those in other educational and research roles. Controlled research and independent observations are still imperative to understanding the relationships between the capabilities of a technology and possibilities in practice. The questions of efficacy are legitimate—they just aren't practical when specific products are at question. If someone proves that a media definitively increases learning potential and efficacy in all settings—that's a different discussion. Whether you favor Clark's (1994) claim that media will never influence learning or Kozma's (1994) view that it does, the underlying justification for using technology in the classroom would remain the same: Students need access and experience with relevant technologies because technologies are instrumental to their success in the future.

Software Quality Assurance (SQA) looks beyond the basic functionality of pieces of software to consider the myriad details that affect software’s efficacy in classroom and teaching practice. Traditional factors such as cost, ease of use, and functional accuracy expand quickly to include a variety of technological and pedagogical factors. The most functional, least expensive software isn’t always the best choice. The best choice is the software that can be integrated into the teaching environment to meet the goals for which it was originally desired (Richie, 1994). The role of SQA is to assure that processes are in place to do this. Software quality is a complex discipline. It entails multiple interdependent activities with the goal of improving and assuring the efficacy of software use.

SQA is a professional discipline that concentrates on the processes necessary to design, build, install, and use quality software for effectively meeting the requirements of the purchasers and users of that software. SQA is concerned with the process of acquiring and evaluating software.

Software Quality Control (SQC) is an applied discipline that involves comparing software products and services against predetermined standards in order to determine the likely effectiveness of the software based upon its compliance to a group of measurable factors that have been embedded in those standards. SQC is concerned with the product acquired through the assured process.

Quality Management Infrastructure

In evaluating software, SQC works to assure that software meets organizational standards. Compliance to standards only assures software efficacy if those standards are the right ones. SQA works continuously to assure that the standards to which software is held are the correct and most effective standards. This requires an understanding of a quality management infrastructure involving mission, policy, standard, and procedure that, when properly implemented, allows for reliable and effective quality control.

Software Mission Statement

The quality levels associated with individual pieces of software are largely a function of how well the software delivers against the mission established for that software. Establishing a mission statement for software requires asking why one would use software in education. Such planning is easiest in the context of a school or district that is already working to define its organizational mission.

Those districts conducting such broad strategic planning will find it easier and more comfortable to discuss the narrower perspective of educational software.

Mission statement creation for educational software should be conducted in layers. Just as the mission statement for a school will be a superset of any particular mission adopted by a program or academic department, each school or district should create a single overriding mission statement for educational software across the entire organization. The cross-organizational scope of such a mission statement will require it to remain broad.

Each software activity within the school can then begin by adopting a specific mission statement for each area of software. Differences in mission will appear for different pieces of software, but each must remain consistent with the overriding software mission statement already adopted. Examples of such broad mission statements for education software might include:

1. We use educational software to augment and extend the capabilities of each teacher.
2. We use educational software to increase the efficiency of each classroom.
3. We use educational software to extend the content resources available to each student.
4. We use educational software to personalize each student’s learning environment.

Many would choose to adopt an all-of-these attitude for the role of educational software in a school or classroom. Such a generalizing approach only delays the qualifications and prioritization that must then be developed specifically each time a particular software purchase is considered or debated. A final mission statement should not only be a
Software Policy Statements

In the educational setting, SQA works to identify the quality factors necessary to assure the effectiveness of software in the school and classroom. Policy statements are then created that embody the organization’s values related to each quality factor (Lebow, 1995). The factors considered must move beyond simple technical concerns over software utility, although a prerequisite to the success of any software is that it be able to operate in its intended environment (Hezel, 1990). Or having established and agreed to a set of software mission statements, stakeholders turn toward identifying the traits or factors that quality software should exhibit if it is to be expected to fulfill its mission (Lathrop & Goodson, 1983). As with the mission statement this discussion happens at multiple levels of detail; general traits that educational software is expected to exhibit, and specific traits that should be exhibited by software in particular classroom situations (Raizen, Sellwood, Todd, & Vickers, 1995).

An effective SQA process will identify and prioritize those factors that are considered essential to the success of software in particular school or classroom settings (Sewell, 1990). Teachers in classroom settings will practice SQC using only the core prioritized factors as criteria. Adding such factors to teachers’ classroom toolkits enhances their confidence in discussing and participating in complex software discussions which affect their classrooms.

Once planners have decided which factors to include in the software quality discussion, policy statements are written for each one. Policy statements define the organization’s values with respect to quality factors without getting into the specifics of their implementation or assessment. By writing a policy statement for each quality factor, stakeholders can be sure that a common meaning is associated with each factor by everyone, thus eliminating problems later when differences in expectations surface around the semantics of the definitions and meanings associated with the mission and policy.

Some example policy statements for software factors might include:

1. Students should never be able to access, update, or destroy information or data of other students with whom they are not engaged in collaborative projects or activities.
2. Software should be able to run on the broadest possible range of hardware and communications capabilities available at the school, including those likely to be adopted in the near future.
3. Software interfaces should tailor the timing and content of any presentation of material, based either on student self-identification of themselves as being at certain achievement levels, or on software assessment of the level of a student’s interaction against predefined achievement levels.

Software Standards & Guidelines

Standards and guidelines are written in order to clarify how policy directives will be met in the actual classroom. Examples of standards and guidelines might include:

1. Students will save files only to diskette or to their own personal network directory.
2. Students will not copy software files to external devices such as diskette or magnetic tape.
3. Software documentation must include references to non-software support resources.
4. Software vendors must clearly communicate age and developmental levels of expected users.
5. User passwords are a preferred way of assuring students identify themselves correctly to the software that they use.
6. All software should be compatible with Microsoft Windows 95 or Windows NT.
7. Software that can be installed as a network version should be so installed.

Software Procedures

Few software packages will meet all desired standards or possess all desired traits. It is not possible for stand alone software to meet all classroom needs. Such expectations are only met by how we choose to use that software day-to-day (Niederhauser & Stoddart, 1994).

Procedures are statements of how shortcomings in software can be mitigated by the ways we train, operate, and manage the software in each classroom. By describing how to use the software, we define the broader system that includes the software, the user of the software, and the infrastructure that is in place to support the software and user. It is this broader system against which quality compliance is measured by quality control.

Procedures explain how standards compliance is to be assured in any context where the software itself doesn’t guarantee compliance through its implementation. Few standards can be effectively enforced without some procedural support.

Examples of procedures that enhance software capabilities might include:

1. Awareness training on security and authorization needs of the school.
2. Independently developed documentation when vendor documentation isn’t adequate.
3. Reflective journals by all students after using educational software.
Software Quality Factors

The development of effective standards and procedures helps assure that a sound process is in place for obtaining software compliance to the direction of the organization. Policy statements describe that direction and cumulatively support the organization achieving its mission for educational software (Winn, 1988). Since many teachers and schools struggle in knowing where to start as they set educational software policy, the following list of twenty technical and pedagogical factors might prove helpful.

Technical Factors

Technological factors to be considered are those that determine whether or not a piece of software can be practically used in the classroom at all. These include reliability, ease of operation, controllability, flexibility, portability, and any other considerations that might actually prevent the software from being successfully implemented. Each teacher, school, or district will need to identify the significant few that are important to them (Pelton, 1993).

1. Correctness. Extent to which software and its use satisfy stated requirements. All requirements must be shown to be clear, complete, unambiguous, measurable, and testable. All design features must be shown to conform to the requirements. A high level of correctness assures that all functions do what they're supposed to do.

2. Access Control and Authorization. Extent to which the use of software processing requires permission in order to be carried out. All relevant authorization rules must be defined as requirements and the design of the software must include a method for implementing those rules. Reconstruction requirements must be defined and an audit trail designed to meet those requirements must be designed and implemented.

3. Integrity and Reliability. Extent to which software activity must be accurate. File integrity requirements must be defined and mapped to the controls that are designed. Integrity assures that all system functions are secure from unauthorized access. Assures that a high degree of confidence can be assigned to all functions when they are used or needed.

4. Continuity of Processing. Extent to which processing must be able to continue. The impact of any possible failures must be defined during requirements and appropriate contingency plans developed during analysis and design.

5. Service Levels. Extent to which service schedules can be met by the software. Regardless of its ease of use, the software must support appropriate service levels. Software that takes a long time to set up for each student is too limiting in the classroom.

6. Ease of Operation and Use. Effort required to learn, operate, and use the software. With the variety of software available today, one need not settle for software that isn't easy for students to use and operate.

7. Portability. Extent to which software can operate in multiple environments. It is important to consider the long-term when discussing the flexibility and portability of software. The extent to which the software can operate on various new or emerging hardware platforms in a classroom is important. With technology changing as fast as it is, one must guard against software that becomes obsolete quickly because it doesn’t port, or transfer, across revising platforms.

8. Performance Efficiency. Assures that all functions make the best use of available resources and the system is able to perform within its specified limits. High system efficiency implies both high software efficiency and high software usability. Software usability directly affects operator effectiveness and efficiency; and the system operator is a key factor in the measure of overall system efficiency.

9. Flexibility. Assures that all functions can be changed when needed. High system flexibility implies modular system components and generality of component functions. The need for flexible software also emphasizes verification of changes. Flexibility also requires high integrity in instances where modification of functions or data could possibly compromise security.

10. Expandability. Assures that the capability and performance of all functions can be expanded or upgraded. High system expandability implies generality and modularity of components and functions, and implies spare system capacity. The emphasis is on high system flexibility to incorporate enhancements and new functions, and high verifiability to test changes. For limited-capacity environments, efficiency would also be emphasized.

Pedagogical Factors

Pedagogical factors are those that determine whether or not the software will achieve its educational purpose once implemented. These include alignment with learning theories, cognitive schema and mental models, motivation, theories of instruction, and any other educational concerns that might affect the usefulness of the software in the teaching process (Collins, 1993). Again, each teacher, school, or district must determine the core significant set of factors that are important to assuring the success of software in their own circumstances (Tennyson, 1993; Townsend & Townsend, 1993).

1. Meaningful Learning. The information offered or required by the software should be potentially meaningful to students. It should offer students meaningful activities involving information and not just rote activities designed to maximize the capabilities of the software. Students should be required to make inferences while using the
software, potentially creating groups of concepts, or differentiating discreteness within a range of information.

2. Personalization of Instruction. The software should offer some level of personalization in the way it interacts with each student. The software should be tailored such that students can pace themselves through the software, not just in speed, but in depth and breadth of materials available. The software should offer students constant and immediate feedback on their performance.

3. Behavioral Aspects. The software should go beyond facts and figures and specify behaviors and actions that are expected of students. The criteria for successful completion should be displayed by the software, and students should be offered a wide range of opportunities to model appropriate behavior.

4. Long-term Memory Emphasis. The instruction offered by the software should present or encourage multiple representations of the materials to be learned. Students should be offered a maximum of retrieval opportunities and heuristics, and they should be challenged to use or develop strategies for using these retrieval paths. The software should help to minimize counteracting distractions through an immediate and involved user interface.

5. Organization of Instruction. The software should offer information in such a way as to emphasize distinctive features of areas of study, and should provide opportunities for students to compare and contrast various materials and presentations. Heavy emphasis should be placed on representational elaboration and alternative representations, both initiated by the student and initiated by the software.

6. Metacognition. The software should promote each student’s awareness of thinking and the self-regulatory behavior that accompanies such awareness. Software presentation should include memory strategy cues that are age appropriate to the student user. A balance of general and domain-specific presentation strategies should be used as part of any feedback to students. Users should be encouraged to use active skills and strategies in their interaction with the software.

7. Availability of Organizers. Presentation of information by the software should facilitate linkages to student current knowledge and prior experience by highlighting related or analogous information. Possible anchoring ideas for students should be triggered by continuous discrimination of new and repeated information in the domain context that can then be noted by student users. Software should work to stabilize and clarify anchoring ideas in order to facilitate their use in later sessions, particularly for software that is used periodically for short periods of time.

8. Support of Schemas. Information presented by software should support student knowledge by stimulating schemas they may already hold by either triggering existing schemas in order to create expectations of content that might be forthcoming, or by promoting alternate schema development by presenting information contrary to student expectations. Information should be presented in a form, and at a pace, such that schema discordance does not preclude a successful use of the software.

9. Diversity of Knowledge. Software should present information in ways that are age appropriate. Preferably, software interfaces should be available that help model physical or empirical knowledge using perceptual qualities of information being presented while also offering generalized information to encourage students to develop more intuitive logical-mathematical knowledge. Feedback within the software interface should emphasize one or the other of these presentation approaches based upon actual results achieved by the student user.

10. Stages of Development. Software presentation of information to student users should be capable of adjusting to the developmental stages of the students expected to use the software. Particularly important for software intended to be used across multiple grades, information presented should be tailored to the expected cognitive strengths of student users, while allowing further development through continued interaction with the software.

Conclusion

Quality is neither assured by having a mission statement for educational software, nor by having a list of policies in place. Rather, a thoughtful process of defining a mission statement and set of policy statements increases organizational confidence in both the mission and the policies. Likewise, clear standards that help define what is meant by the policy statements, as well as supporting procedures to assure that compliance to the standards is reasonable, help to assure that the day-to-day educational software activities in the classroom will support the mission for which that software is intended.

Many teachers will find themselves applying this SQA model in reverse. Rather than attempting to identify and purchase a quality piece of education software, they will find themselves confronted by an existing piece of software that they’ve been given or have inherited. Their desire will be to make the best of what they have got. In those circumstances, this SQA model can be used to diagnose the discomfort. Teachers should think through an abbreviated version of this planning process in order to determine if their problems with the software are incorrect procedures, inappropriate standards, misaligned policy, or the wrong mission. Problems with standards and procedures are easier to fix. If the software supports the wrong mission, it might best be abandoned.

SQA works to make quality compliance more likely. Nothing can guarantee that educational software in use will
meet the needs of all. But effective quality planning, at the classroom level, in the school, and across the district, helps assure that a best effort is put into making educational software effective whenever and whenever it is used.

PATTERNS OF LEADERSHIP IN VIRTUAL PROFESSIONAL COMMUNITIES

Yesha Y. Sivan
Tel Aviv University

Since the 1970s Computer Mediated Communication (CMC) have been used sporadically in education (Harasim, 1989; Rice 1992). Concepts like remote learning, copyrights control, lurking, MUDing (Multi User Dungeon), and other CMC terminology have appeared in the literature. While Rice (1992) says that “there is little theoretical or empirical research in this area” he, with others, published a few hundred papers about CMC. Such pre-1995 research dealt mostly with text-based systems that were used by computer users. The “text-ness” and the “computer-ness” of CMC have changed dramatically with the emergence of the Internet. As of 1996, even novice users can use CMC with relatively easy-to-use Graphical User Interfaces (GUIs). Three factors have led to the demise of “text-ness” and “computer-ness” of CMC.

Factor 1 - The deployment of the Point to Point Protocol (PPP) (PPP FAQ, 1996) which enable personal computers, often at the homes of users, to be linked as equal members to the net. This equality means that my home PC is equal to an IBM main frame when it comes to the Internet. Sure, the IBM may deal with more mail, and serves more files, but my own “little” computer can send and receive mail, send and receive files (e.g., FTP), and even be accessed from anywhere (e.g., Telnet).

Factor 2 - The development of the World Wide Web (WWW) which allows the publication of multimedia content. With any commonly available text editor one could write documents that would look almost the same by various browsers all over the world. With a little more effort one could add pictures, create links, and even deal with sounds and loading of files. The web became an easy way to publish content and a universal way to read content (with the dissemination of free or almost free browsers).

Factor 3 - A new improved cost/speed ratio of modems. In early 1996 the cost of 14.4 modems dropped below the $100 line. Currently (December, 1996) the cost of 28.8 baud modems became so marginal that many PC makers are embedding the modem board as part of the basic computer.

The combination of these three factors created the initial boom of the Internet, a boom that has changed the field of CMC. Let me therefore humbly argue that the value of pre-1995 research mostly stemmed from suggesting concepts and issues. Yet now we must take a fresh look at the relations between these concepts and the real world. CMC terms like, remote learning, copyrights control, lurking takes a different meaning when 75 million Internet users are involved.

The Lamda Community Project

The new networking technologies or the “Internet” as they are globally known, create a unique opportunity for building virtual professional communities. The uniqueness of the Internet stems from its social component. It is the first time we have a global many-to-many technology that facilitates media of all sorts (not just audio as in the telephone).

The Lamda community project was created to “use the Internet to support science and technology education” as part of the Israeli national program to “advance science and technology education in Israel.” (“Tomorrow 98” or in its Hebrew name “MAHAR 98”). The funding was channeled through the Science and Technology Education Center which is located in the Tel Aviv University School of Education.

The research questions of the project revolve around the nature of professional virtual communities. More specifically we are looking at user-network interaction, site design, authoring of content on the net, the building of subcommunities, and project based learning. The issue of leadership, as this paper will show, emerged as one of the critical issues during the last year of operation.

During the first year, 1994, we conducted a general overview of network technologies, and their potential educational use both in Israel and in the world. This initial examination revealed what we then called “a messy situation.” It appeared that beyond the usual challenges of “large scale changes in K-12 education” (Sivan, 1995) educational research and practice lacked a clear understanding regarding the role of CMC in such a change.
In the second year, 1995, the first 50 members of the community joined-in and the first web site was created. The initial design of initiating members and site building was constructed (See Figure 1.). Once we developed the basic graphical language of houses, roads, tours, etc. we had to develop few iconic means to represent various aspects of the community. The city metaphor gives us a wealth of such means (i.e., special zones, the Junk Yard). Table 1. includes the main centers in the site. (For a complete description of the various centers see Lamda English Site Tour, 1995).

1996 became the year of initial deployment. On the one hand steady growth in membership and on the other hand a steady build-up of the Lambda community Site. Today (December 1996) we have about 200 members and 9000 pages in our site. Among other things the Lambda site includes a dual-mail-web discussion center; a weekly news; an automatic front page; an automatic translation of MS-word files to web mini-sites (for project based learning); general feedback mechanism; and, of course, various content centers in the area of science and technology education.

**Lambda Community as a Test Case for Virtual Professional Communities**

The Lambda community was designed as a “self-evolving system.” As such system, we try to foster an iterative interactive process among three factors: the members, the material on the Lambda community site, and the technological systems supporting the community.

This iterative interactive process is similar to the process of establishing a new city whereby there is interaction among the residents of the city, the physical structure (streets, zones etc.) and the various systems in charge of constructing the city (road contractors etc.) Unlike cities, which basically have a regular structure, there is no standard or known structure for virtual communities.

Our initial research on virtual communities (which was based mostly on typical Internet communities) identified four major dimensions of the relations between the community and its members (see Tables 2 and 3). In all four we have decided to veer from the typical Internet mode and to select a somewhat different approach (to be later called a “market-driven” approach).

The origin of our market driven approach can be traced to the classical dimensions of a community (Hazan, 1988; Shapira & Shavit 1995.). (See Table 4.)

450 — Technology and Teacher Education Annual — 1997
If we follow these dimensions we can see that the simplest way to achieve a sustainable community is to base it on a market driven approach. We do not claim that professional virtual communities should always behave in this market driven way. We simply selected an approach that would match the look and feel of a professional community. This selection seems problematic to typical veteran Internet users, especially to those from the academia who were used to the freeness of the net. In the name of “free access to all” we are often perceived as elitists. While this was not the original goal, this very approach proved to be a selling point. Apparently, in the eyes of non-Internet users this approach seems natural. This market driven approach have special meaning when it comes to leadership within the community because we actually pay our leaders!

Leadership in the Context of the Lamda Project

In January 1996 we presented an initial vision for the community. In this vision (which was presented as a “starting point to be updated as the community develops,” we defined the community as a meeting grounds for members. In the opening memo to new members we listed these examples:

- A teacher in Dimona (south of Israel) discusses the question of how can family members help in science teaching with a teacher from Ramat Hasharon (part of the Tel Aviv metropolitan);
- A group of students in Ma’agan Michael exchange information with students in Japan on the effect of salt on the quality of Sushi and Carp;
- Teachers who are interested in creating a teaching program on the subject of Alchemy from a historiosophic point of view consult one another;
- Teacher confer with regional science supervisor on improving the salaries of science teachers;
- A group of teachers in the South send their feedback regarding a new simulation program to the Logal company located in the North;
- Natural science teachers contact the Mabat project regarding their new booklet “The Average River and Its Future”;
- The Rehes publishing house consults the users of the book “What is the matter of people - new age biology” on teaching methodologies used in this book;
- Teachers discuss the concept of pay-per-success

At that time we also coined the term “community entrepreneurs.” These entrepreneurs would join forces with us (the team) and other members to develop the community and establish it. Again, in the opening message to new members, we demonstrated the meaning of “community entrepreneurs” by suggesting that entrepreneurs can:

- Lead discussion groups (e.g. on the advantages and disadvantages of “science for the gifted” programs);
- Initiate training courses for teaching staff at schools (e.g. a basic course on network uses);

Figure 2 - Hourly Summary of use in June 1996.

- Initiate network-based teaching materials (e.g. types of flora throughout the country);
- Publish monthly newsletters (e.g. on the subject of the science of matter);
- Manage a reaction team (that will provide scientific background for news events);
- Initiate educational programs (e.g. surrounding the Israel Chemical Company Ltd.);
- Translate material on the sciences and science teaching from English to Hebrew.

At the time we did not use the term leaders. Partly by ignorance, partly by design, we felt the term entrepreneurs matched better the needs of the community. As we will later report the issue of leadership became a major factor in the development of the community. While we have no conclusive results we are convinced that we need a better understanding of leadership within virtual professional community

Research Methods

Three types of data feed the research: use data; on-line reflection; and focus groups. They are described next:

Use Data

The web allows real-time capturing of member’s behavior. Since all members must log on to the site we are able to know who used which service. For example (see

BEST COPY AVAILABLE

Graduate and Inservice — 451
we can see that there is a decline in use at around 8:00 pm (possibly due to family time). The numeric data allows us to analyze patterns of use (e.g., novice vs. expert use of the site; the appeal of various services, etc.). Further cross analysis (e.g., kind of member vs. kind of service) allows us to fine tune and adjust the services.

The charts above in Figure 3 lists the total numbers of hits per month (upper-left); the total number of hits per day (upper-right) and the distribution of total hits per the hours of the day (bottom).

The charts above in Figure 3 lists the total numbers of hits per month (upper-left); the total number of hits per day (upper-right) and the distribution of total hits per the hours of the day (bottom).

**On-line Reflection**

Beyond the quantitative data that we get from the system there is also the automatic capturing of discussions. The main fora for discussion is called the “Discussorium.” The Discussorium combines both the capturing of the data (into web pages) and the links to members via e-mail. The qualitative data is stored for future reference and study. A typical discussion page (See Figure 4) includes a list of messages. Let's follow line number 12 (marked with the arrow on the right). The line includes an icon for attached files (a Netscape .htm file in this case), the subject, the author, and the date and time of the original message (A click on the subject will lead to the message itself. A click on the author name will open a reply mail window).

**Focus Groups**

Few times a year we have open house meetings where we meet with members to explore the state of the community. Because valuable data and ideas are generated at these times, the meetings are logged and transcribed for further study.

**Results: Patterns of Leadership in Virtual Professional Communities**

The continuous stream of data coupled with the need to answer daily needs led to many insights of potential interest to builders of professional virtual communities. Of those insights, we believe that our understandings regarding the patterns of leadership in virtual professional communities are critical to the long term sustainability of such communities.

The original vision of the community was presented in January 1996. Since then it was not developed or reformulated. The theory was left aside and daily actions began. By December 1996, we had about 200 members and over 9000 pages.

**Types of Projects Initiated by the Leaders**

Leadership within the community manifests itself in many ways. During the year we captured these leadership acts under the title of projects. We have divided these projects into four groups which as listed in Table 5.

452 — Technology and Teacher Education Annual — 1997
Preliminary Observations about Leadership in Virtual Communities

Here are some preliminary observations concerning those leaders:

- Leaders can learn new things quickly. They are not afraid to ask and demand resources from the team.
- Leaders appear in various ways. They contribute to mailing lists; they organize various new centers; and they bring-in new members.
- Leaders can be divided roughly into two groups: those who want to advance themselves and those who want to advance the community. In the Lamda community these types blend. Furthermore, we have found ourselves pushing for the self-advancing type.
- The idea of professional teachers who advance themselves does not come naturally to teachers. We succeed more with new (and young) teachers than with the veteran (and old) ones.
- At times, leaders in our community lack basic skills of organization and management.
- Longer term leaders are hard to find, shorter term leaders come more easily.
- Leadership takes time; and since teachers chronically lack time they are often prevented from becoming leaders.
- Leadership qualities of content is relatively easy (collecting data and presenting it); leadership of processes is more difficult.
- Virtual communities allow some people to become leaders, and prevent others from becoming one. The virtual world changes the needed entry qualities of leaders.
- Leadership in a virtual community calls for a different mix of leadership qualities.

Discussion

We must admit that currently we lack in our ability to fully analyze the issues of leadership within virtual communities 1) because the current leadership theory has not yet developed the concepts when it comes to the virtual world; and 2) because the current state of our Lamda community is not yet representative. Let me elaborate on this two claims here.

Leadership science deals with political (including wartime) leadership, idea-based leadership, and corporate leadership. While much can be borrowed from the this research we lack basic experience in virtual leaders. Leadership patterns, at least in the past, took years to develop, and we simply did not have enough years in the virtual world. The virtual world has not yet matured to the level where patterns of leadership have emerged (for a sample of CMC leadership see Perkins & Newman, 1996).

Beyond this general problem we also have a more local problem. Despite our genuine efforts we were unable to simulate real world virtual communities. Due to technical difficulties of installing new members, those with previous experience were able to fully participate in the community. For example, one of our first leaders was Mrs. Z a very prolific teacher who started up two mini-projects. To our surprise, when her system stopped working she did not push us to re-install her. While she may have dropped even if all the technology performed flawlessly, we will never know if she fulfilled her full potential as a leader in the virtual world.

Of the 40 proposed and implemented projects, four reached the level of paid projects. Apparently it takes longer for a project to justify a "paid project" status (paid status was given to projects that had real value for the community). We may see a surge of "paid projects" early in 1997 when some current mini-projects mature.

Another problem that revealed itself was the basic lack of project management skills. Apparently many members wanted to initiate projects that did not materialize due to lack of experience in managing projects. On the other hand, when we supplied the structure or when the person came with management skills the project took off more easily.

Although these two problems (the lack of leadership theory in virtual communities, and the immature state of our own community) prevents us from suggesting general lessons we can examine the seeds of leadership within virtual communities. In that sense the Lamda community presents a unique opportunity. We will therefore pay special attention in forthcoming year to examining these emerging patterns of leadership.

In conclusion, from the four classical dimensions of communities presented earlier (See Hazan, 1988; Shapira and Shavit 1995), the concept of “power” seems to be tightly linked with leadership. Alvin Toffler (1990) begins his book Powershift, by observing that “despite the bad odor that clings to the very notion of power... power itself is neither good nor bad.” Since it is “an inescapable aspect of every human relationship,” he determines that to “a greater degree than most imagine, we are the products of power” (p.3). Interestingly, he defines power as “purposeful power over people,” and concludes that, “in its most naked form, power involves the use of violence, wealth, and knowledge... to make people perform in a given way” (p. 14) (argument made by Penner, 1996).

I find the juxtaposition of power and knowledge to be especially relevant when it comes to leadership within virtual communities where skills like communication, vision sharing, and story telling all take a new form.

The research was partly funded by the Ministry of Education and by the Tel Aviv University Science And Technology Education Center (SATEC). Special thanks to Prof. David Chen who head the Science and technology Center and to the team at the Learning Network Laboratory that runs the Lamda community.
As political and ideological barriers all over the world have lessened, and in many cases disappeared, opportunities for collaborative research among scientists, researchers, and educators have grown, necessitating technological advancements to support these cooperative efforts. Although some of the technologies have long been available, only recently have the political climate and associated costs made certain classes of technology realizable for many members of the global community. The most applicable of these technologies fall under the category of computer-mediated communication (CMC).

Applications of CMC recognized by the majority of the global community include electronic mail (e-mail) and the currently evolving computer conferencing systems. All of these CMC capabilities provide opportunities for expansion of educational audiences. Teachers can share their experiences with new student groups and facilitate interaction between heterogeneous student populations. As in the physical classroom, the teacher in the virtual classroom should monitor and control student interactions to ensure a balance in each individual’s dual needs for freedom of expression and protection during their educational experiences (Nance & Strohmaier, 1994). Before the individual types of CMC and the effect that each has on the virtual classroom can be presented, particularly with respect to the impact on cross-cultural communication in an educational setting, clear definitions of culture and community must be delineated.

Culture

According to Webster’s Dictionary (Guralnik, 1986, p. 345) culture refers to “the ideas, customs, skills, arts, etc. of a given people in a given period.” This general definition is presented after five other definitions that do not pertain to human beings. Although this definition is outdated, a vagueness persists in defining the concept of culture. There are many different perspectives on the term “culture.” One way of viewing the concept of culture is as everything human made (e.g., Herskovits, 1955). Geertz (1973) discussed culture as a system of shared meanings, contributing a metaphor for culture quite appropriate for CMC:

The problem of cultural analysis is as much a matter of determining independencies as interconnections, gulfs as well as bridges. The appropriate image, if one must have images, of cultural organization, is neither the spider web nor the pile of sand. It is rather more the octopus, whose tentacles are in large part separately integrated, neurally quite poorly connected with one another and with what in the octopus passes for a brain and yet who nonetheless manages to get around and to preserve himself [or herself], for a while anyway, as a viable, if somewhat ungainly entity. (Geertz, 1966, pp. 67)

Gudykunst (1991, p. 44) defines culture in a basic way that is easily applicable to CMC: culture refers “to the system of knowledge that is shared by a large group of people. The ‘borders’ between cultures usually, but not always, coincide with political boundaries between countries.” The foundation of Gudykunst’s definition comes from Keesing’s (1974) long, but understandable definition:

Culture, conceived as a system of competence shared in its broad design and deeper principles, and varying between individuals in its specificities, is then not all of what an individual knows and thinks and feels about his [or her] world. It is his [or her] theory of what his [or her] fellows know, believe, and mean, his [or her] theory of the code being followed, the game being played, in the society into which he [or she] was born....It is this theory to which a native actor refers in interpreting the unfamiliar or the ambiguous, in interacting with strangers, and in other settings peripheral to the familiarity of mundane everyday life space; and with which he [or she] creates the stage on which the games of life are played. (p. 89)

In essence the actor’s — or interactant’s — cultural foundation is interwoven in his or her perception. Perception “refers to how an individual views input based on past experience and knowledge. This perception allows the individual to incorporate stimuli, both common and new, to allow for an appropriate response” (Nance & Strohmaier, 1995, p. 609). To what extent is this process conscious to the interactant? Keesing (1974) elaborates:

But note that the actor’s ‘theory’ of his [or her] culture, like his [or her] theory of his [or her] language may be in large measure unconscious.
Actors follow rules of which they are not consciously aware, and assume a world to be 'out there' that they have in fact created with culturally shaped and shaded patterns of mind. We can recognize that not every individual shares precisely the same theory of the cultural code, that not every individual knows all the sectors of the culture...even though no one native actor knows all the culture, and each has a variant of the code. Culture in this view is ordered not simply as a collection of symbols fitted together by the analyst but as a system of knowledge, shaped and constrained by the way the human brain acquires, organizes, and processes information and creates 'internal models of reality.' (p. 89)

With the basic conceptualization of culture in hand, how does this affect the global community? "The flow of humans across national and cultural boundaries is more active than ever before... Among them...business men and women...researchers... [and] students.... In this worldwide context of cross-cultural [interaction], the concept 'adaptation' takes on a special social and academic significance" (Kim & Gudykunst, 1988, p. 7). Cross-cultural adaptation refers to becoming compatible, assimilated, or adjusted to a new cultural environment. It becomes ever obvious that cross-cultural adaptation is no longer a luxury, but rather a necessity for a successful participant in the global virtual community.

Community

Community does not imply that the parts should all be the same, but rather that the different parts have a common goal or purpose. Nance (1996, p. 431) states that in the global community, "as with any other community, the majority of community members desire safety and security." When dealing with a heterogeneous population it is important to acknowledge individual differences as well as the common ground or goal of the group itself. By addressing these, and other salient needs of the interactants, the value of diversity is maintained while continuing to focus on the common goal rather than hidden agendas, thereby increasing the effectiveness of the output. "Important issues need to be addressed in order to balance each individual's dual needs for freedom of expression and protection in the cyberspace" (Nance & Strohmaier, 1994, p. 115).

As teachers and mentors, we shape the future by our choices of what to present to those in our sphere of influence, as well as our attitudes when we present those materials. Our presentations of our personal perspectives influence the evolving perceptions of those we encounter, both students and peers. Increasing our understanding of cultural diversity and applying these concepts to our own interactions can result in improved comprehension and tolerance — ultimately enabling and contributing to the unity in community. "Unity implies the oneness of that which is made up of diverse elements or individuals" (Guralnik, 1986, p. 1553). Unity in a community is impossible without effective communication.

Communication

Communication can be viewed as existing on a continuum based on the comprehension by the receiver of the message being sent. Computer-mediated communication is no different. By viewing the Internet as the communication facilitator, the communication effort can be assigned a location on the continuum based on two separate input criteria. The location could be evaluated based on the degree to which the communication facilitator contributes to effective communication. There are a number of unique communication technologies available, each of which would be assigned its own place on the continuum.

One characteristic of an Internet communication technology, which provides a means of measuring the effectiveness of communication, is whether the device facilitates synchronous communication, asynchronous communication, or both. Synchronous communication requires that both parties are available for communication at the same time. This is not to imply that synchronous communication can only involve two parties, but examples are simplified if synchronous communication is investigated as communication between two parties. This definition can be expanded when the number of participants is investigated, as it relates to the continuum.

Synchronous communication is ideal in some situations and extremely detrimental in others. Consider the generally synchronous tool which most commonly facilitates synchronous communication over distance in the current world: the telephone. When considering this example of synchronous communication, most individuals can readily identify the associated advantages and disadvantages, as most individuals have experienced both at some point in their lifetimes. Advantages associated with a telephone include immediacy of dialog, pitch, vocal tonality, verbal rate, and pausing among others. Disadvantages are quite varied, and include: omission of visual nonverbal cues, required accommodations for time zone differences; ensuring both parties be simultaneously ready for synchronous communication; dealing with no warning that synchronous communication is needed — often resulting in trial and error (phone tag); as well as the technological occurrences of echoes and odd lag time based on technological discrepancies.

Expanding on the basic examples of the telephone, one can add asynchronous components by introducing the concept of an answering machine, answering service, or voice mail system. These technologies allow synchronicity when both parties are available and have an asynchronous component which, if it doesn’t allow complete delivery of
the opportunity to learn about other cultures. The obvious traditional asynchronous e-mail model minimally facilitates than by our method of delivery and associated actions, the their student peers. If the example is extended further students are the “many.” This context has the same issues context then the instructor is generally the “one” and the classroom is extended by using e-mail in a one-to-many include others beyond the two of them. If the virtual classroom is extended by using e-mail in a one-to-many context then the instructor is generally the “one” and the students are the “many.” This context has the same issues for the virtual classroom as the one-to-one situation, due to the lack of awareness and input of the students regarding their student peers. If the example is extended further – each individual “broadcasts” all messages – then there truly is a virtual classroom, but in a limited sense. Since many cultural differences are less evidenced by our written words than by our method of delivery and associated actions, the traditional asynchronous e-mail model minimally facilitates the opportunity to learn about other cultures. The obvious exception are courses in which culture is a topic.

Synchronous environments, such as current computer conferencing systems, can have either audio or audiovisual capabilities in a one-to-one, one-to-many, or many-to-many context. In the audio-only context, the students have the advantage of the audio cues. The cues in this category include all aspects of vocal communication such as tone, pitch, rate, pausing, and silence. However the visual cues are absent from the interaction. In the audiovisual context where the visual is in real-time condensed mode, there are also the advantages of the audio cues for the interactants. The visual mode gives the interactants certain visual cues, however these cues require some training to accurately decode. As the visual mode is compressed, one will see periodic snapshots of visual interaction.

Even when the video is compressed, the audio is generally not compressed. The nature of the human ability to decode the two sets of cues will intuitively allow the interpretation of the two inputs together although the timing will not correspond exactly. This situation will prove difficult for the teacher or student in trying to decide which set of cues to work from when determining turn-taking behavior. The final scenario involves both audio and visual cues in real-time. This is the ideal situation as both audio and visual nonverbal cues are available for interpre-
tation by the interactants. Unfortunately, the technologies which support this final and ideal situation are extremely expensive at this time. Thus most virtual classrooms require the adjustment to the virtual environment created by the technology being used as well as to cross-cultural variables.

**Conclusion**

The Information Age and the associated global community provide many exciting opportunities for people everywhere. Collaborations are possible between individuals who will never meet. Conditions which had previously restricted the individual’s sphere of influence no longer exist. Successful interaction between the many subcultures in the global community can be accomplished through increased awareness. Perhaps the global classroom can be facilitated through the development of a “general protocol for cross-cultural interaction which provides a reasonably homogeneous environment for interaction between heterogeneous cultures” as proposed by Nance and Strohmaier (1994, p. 118). Or perhaps, we, as teachers and mentors, can facilitate improved communication by educating the global community with regard to cultural diversity.

As technology is increasingly being integrated into various curriculums, the need for strong instructional design is increasing as well. Currently, there are many computer programs and World Wide Web sites that provide information, but is this information presented in an instructionally sound manner? The authors in this section address these types of instructional design issues.

To begin this section, Heath discusses the traditional approach to instructional design and its incompatibility with the concept of flexible learning that is required for distance education and online learning. The dynamic and unpredictable nature of learning is recognized in non-linear development models.

According to Ahern, Burleson, and Martindale, there are more consumers of information on the internet than there are producers. To create good instructional software for the internet, the producers need to incorporate useful instructional design practices. Next, Salis and Masili describe hypermedia in an internet environment for distance education applications. They are developing a markup language and a browser that will aid in explicitly showing navigation strategies.

Gillan and Fuller use the web as a means for children to work with businesses. Together, they explore the development of web pages. This project integrates technology into the Social Studies classroom while emphasizing learning through group activities in school, community, and business partnerships. Houghton focuses on communities as well. He discusses CROP, Communities Resolving Our Problems, a website that purpose is to teach people across communities by integrating desktop and online resources. Three main modules are discussed, each of which represent a different type of educational model.

Sadok, Kelner, Marques, and Lima explore authoring paradigms. They discuss video and audio media as a means of communicating information, going beyond the mind on to further human dimensions such as feelings and emotions. Boger-Mehall and Mehall present the strengths of using technology, mainly multimedia and hypermedia, to teach surgical intuition and problem solving.

Adams and Jansen present a paperless classroom implementation that uses technology to support appropriate models of learning in various instructional situations. How technology enhances learning is emphasized. Finally, Shimizu and Yamashita explore the application of fuzzy reasoning to the educational evaluation of calligraphy.

Stephanie Boger-Mehall is a doctoral candidate in the Department of Curriculum and Instruction specializing in Instructional Technology in the College of Education at the University of Houston. E-mail: srmehall@uh.edu

Caroline M. Crawford is a doctoral student in the Department of Curriculum and Instruction specializing in Curriculum Theory in the College of Education at the University of Houston. E-mail: caroline@bayou.uh.edu
Over the past two decades educational course designers have used a cognitive or a systems approach for designing and developing courses. But course developers are now finding that the traditional systems approach to instructional design is not compatible with the concept of flexible learning required for distance education and online learning. Consequently, the systems approach is being challenged by constructivist theories and models which recognize that social context, roles and relationships are central to learning (Jones, Kirkup, & Kirkwood, 1993). Non-linear development models also recognize that learning is dynamic and unpredictable and that learners can and do make their own decisions about learning tasks (Thorpe, 1995).

As a whole, instructional design models have evolved through three phases over the past three decades and some experts agree that the field is now experiencing a fourth generation of change (Tennyson, 1995). First generation models were based on behaviorist concepts like those which guided the development of instruction through teaching machines. Rapid growth in educational technology, together with the introduction of systems theory, led to second generation ISD models which saw the addition of phases for analysis, needs assessment, and formative evaluation. The third generation experienced was characterized by a proliferation of mature models (Anglin, 1995) and provided more and varied interpretations of ISD. Second and third generation ISD models are basically refinements of first generation ISD models and approach learning from a positivist point of view. However, fourth generation ISD rejects the behaviorist point of view and embraces contemporary interpretivist and constructivist approaches of how people learn and what it means to learn (Anglin, 1995).

The systems concept was one foundation for systematic instructional design models — the most well-known model being the Instructional Systems Design (ISD) model of Dick and Carey (1990). Using the ISD model, the procedure for designing, developing, and validating instruction progresses through predetermined steps in a systematic fashion. The goal is to begin with well-defined needs, goals, and learning objectives so that the “correct” knowledge can be transferred to learners effectively and efficiently (Dick, 1995). Experts play a critical role in ISD and the roles of end-users are minimized. A major activity for the instructional designer is to correctly classify learners, skills, hierarchies, and tasks with the underlying assumption that design can take place out of the context of the learning environment and with limited input from learners.

The use of instructional objectives is the essence of systematic design models. Instructional objectives define behaviorally what is to be taught, how it is to be taught, and the criteria for determining whether instruction has been achieved. Without a doubt, when Mager’s (1962) method of writing and using instructional objectives is combined with Tyler’s (1949) concept of objectives-based instruction, and with Bloom’s (1956) Taxonomy of Learning; a sophisticated objective-analysis format for development is created (Popham, 1993). Even novice designers have been known to embark on creating an instructional package by simply following all of the steps and rules of this approach. The ISD model is an example of this combination.

The systematic design model was introduced into educational settings with the intention of improving “traditional” instruction in several ways. For example: active learning, not passive learning, should take place. Performance objectives, not teacher objectives, should
Among the earliest authors who bridged the gap between psychology and educational practice were Glaser (1962) who coined the term instructional system, Mager (1962) who created a system for writing instructional objectives, and Gagne (1965) who elaborated on the analysis of instructional objectives and related classes of objectives.

However, in its attempt to offer a solution to instructional design problems, the systems approach generated a set of its own problems and accompanying critics. Ironically, models based on information processing theory and systems theory are now called "traditional" design models. Jonassen (1991) criticizes systematic models as a "top-down" behaviorist and subject-matter-expert approach to education. Instead, he champions constructivist instructional approaches (Jonassen, 1994). Wedman and Tessmer (1993) comment that systematic models are too linear and time-consuming to be practical in the "real world" and Rowland (1992) states that systematic models do not reflect the ways that instructional design experts really work when designing learning materials.

From the learner's point of view, the weakness of the systems approach for instructional design becomes apparent: learning may not always be linear. It may require the learner to spontaneously adopt a different approach for learning the task at hand. Some critics complain that linear instruction is often boring and lacking creativity although proponents try to refute that charge (Dick, 1995).

From the designer's point of view, instructional design cannot always be based on careful and logical decomposition of the knowledge and skills to be learned (Carroll, 1992). "One size fits all" does not work successfully for instructional purposes. Development does not occur in a linear fashion; some steps require several visits and some may follow a different order or be completely eliminated. Too many instructional objectives with too much detail may follow a different order or be completely eliminated. Too many instructional objectives with too much detail can be counterproductive, especially if they are created early in the development process (Willis, 1995).

Reigeluth (1996) recommends taking a more global view because our larger "super systems" have changed radically and no longer support the underlying assumptions of systems thinking and linear process models. Private, public, and non-profit sectors of our society are being transformed from the industrial age to an information age. This means that industrial-age concepts such as standardization, top-down organization, centralized control, conformity, and compliance are being replaced with customization, teams, diversity, initiative, and personal autonomy with accountability.

### Constructivist Design Models

New concepts and approaches to cognitive processes are emerging today from a new paradigm - called Constructivism - where learning is regarded as a constructive process and the learner is building an internal representation of knowledge (Perkins, 1992). Constructivism has its roots in twentieth century psychology and philosophy and the developmental perspectives of Piaget (1954), Bruner (1966), and Vygotsky (1978). Knowledge and understanding are not acquired passively but rather in an active manner through personal experience or experiential activities. As Perkins (1992) explains: "The key concept of Constructivism is that a human is 'active' - not just responding to stimuli, as in the behaviorist rubric, but engaging, grappling, and seeking to make sense of things" (p. 49). The application of a constructivist agenda recognizes that most, if not all, knowledge domains are complex and ill-structured in a number of ways and mastery requires a significant degree of practical experience. Knowledge and skill are intimately bound up with each other, and knowing and knowing how are seen as significantly interdependent (Spiro, 1992).

Consequently, Reigeluth (1996) thinks that the underlying instructional theories for instructional design must change. Approaches to instruction must support construction of learning through problem-based learning, project-based learning, team-based learning, simulations, and use of technology resources. Learning must shift from passive to active learning and from de-contextualized tasks to authentic learning tasks. Design activities of analysis, synthesis, evaluation, and change can no longer occur in a linear fashion. Instead, these activities must occur in a series of decisions which take place in an iterative series of cycles.

Hannafin (1992) expresses concern regarding the ability of traditional ISD (Instructional Systems Design) models to accommodate design of learning which takes place with the support of emerging technologies. "Emerging technologies" can be explained as those that go beyond single-use applications of video, audio and computers to include more sophisticated combinations and complex applications of artificial intelligence, expert systems, hypermedia, Internet and WWW access, and advanced computer and telecommunications. Emerging technologies provide a rich set of resources that progressively broaden, rather than narrow, learning themes and therefore require an alternative design model.

### Alternative Design Models

An effective Computer Mediated Communication (CMC) course design calls for a collaborative and group-oriented approach. Course topics best suited for the CMC medium are those that invite discussion, emerging objectives, opinion-sharing, reflection, and debate (Berge &
Collins, 1995b). Use of new technologies, CMC activities and online classrooms necessitate an alternative, nonlinear instructional design model. Berge and Collins (1995c) recommend a “facilitation” model which is derived from a humanistic framework and posits that adult students are best capable of defining their own learning needs, objectives, strategies, resources, and means of evaluation.

The facilitation model of course development encourages adults to be more self-directing throughout the instructional process; capitalizes on their experiences, strengths, and interests; and enables them to apply whatever knowledge and skills while they learn to their own problem solving or developmental tasks. Successful course design offers objectives, resources, strategies, timelines, products, and assessments that are flexibly negotiated between faculty and students. (Berge & Collins, 1995c, p. 61)

The R2D2 model (Willis, 1995) is another non-linear instructional design model which can be used successfully for the development of CMC courses and activities. The R2D2 model promotes recursive, non-linear, organic and developmental planning, and reflection and collaboration among experts and participants. Like the “facilitation” model, objectives emerge from design and development in the R2D2 model with an emphasis on learning in meaningful contexts. Formative evaluation with subjective data is considered of prime importance. One of the key attributes of a non-linear model such as the R2D2 model is that different pieces of development can occur simultaneously. Design and development activities are accomplished as a cross-functional team effort with the different project members contributing to emerging decisions, solutions, and alternatives. Although activities of a non-linear model cannot be captured on a flow chart, it is incorrect to assume that there is a lack of form and structure guiding the process. Willis captures the essence of these activities through the three focal points of the R2D2 design model — Define, Design/Develop, and Disseminate. The overarching principles are Recursion and Reflection which take place throughout the development process.

Gayeski (1995) also recognizes that instructional design should be an iterative process, not a linear one. Projects are never really done. Design becomes a collaborative process with input from a variety of constituencies, including prospective learners. Instead of a single instructional designer who works with a subject-matter expert, project teams carry out development projects. These project teams can work over greater distances of time and space with enhanced electronic communication tools. This approach corrects one of the major weaknesses of a traditional linear ID model, in which various phases are often accomplished independently from each other. In this context, individual developers will know how changes by other groups affect their contribution to the total project.

Emerging technologies will continue to challenge instructors to create meaningful learning activities. As a result, alternative design models will take on a more important role.

The World Wide Web’s (WWW) ability to deliver entertainment, provide information, and conduct commerce holds a particular fascination for the public. Everyone from individuals to corporations and major newspapers to universities have a homepage that provides information, entertainment or a product for sale to anyone who is "surfing" the Internet.

The World Wide Web is more than a simple curiosity but represents a fundamental shift in the way the world interacts. Historically separate industries of television, cable, telephone and computers are merging rapidly into single web industries.

Education is not immune from this rapid technological shift. The Internet represents a tremendous opportunity to redefine our notions of computer-based instruction, distance education and even teaching itself. The established fields of courseware and multimedia design are time consuming, mechanistic processes. The Web, however, has the promise of providing highly targeted individualized instruction for all students with a fraction of the development time and cost. The possibilities are endless but the transformation of the Internet into a truly capable delivery vehicle for education is not without problems.

The Problem

A major problem is that traffic on the Internet represents more consumers than producers of information. Teachers using the Internet for instruction must use whatever is currently available from a myriad of information providers. This can be frustrating because there appears to be little awareness of good instructional design or methodology displayed on the World Wide Web. The active design of home pages is more for information and not for educational or instructional purposes.

Consequently, for this study we assumed that good instructional software could be developed for the Internet by incorporating useful instructional design practices in conjunction with typical courseware authoring development techniques using readily available tools (Grabowski & Droms, 1994). Because Hypertext Markup Language (HTML) is the current Lingua Franca of the Internet we were also interested in how well HTML would behave as an authoring language and whether it could be used to deliver instructionally sound Internet applications. The results of this investigation indicate three major design factors that designers and teachers should consider when using HTML and the Internet as an instructional design and delivery vehicle: connectivity, architecture, management.

Authoring

Given the complexity of programming a computer, authoring programs are designed to allow non-programmers such as teachers the opportunity to create instructional software using a simple palette of instructions and commands. In the late seventies to early eighties, developers could choose from either an authoring language or an authoring system. Later, as operating systems became more graphic, scripting environments were invented to deal with the advanced complexity.

Authoring Languages and Systems

Authoring languages are based entirely on a formal programming languages such as Pascal or C. By reducing the number of available instructions and restricting the development of code to accepted instructional patterns simplified the language and the development of courseware. For example, PILOT (Programmed Inquiry, Learning or Teaching) was designed to create computer-based tutorials based on the concept of the frame (Conlon, 1984). Using a simple set of commands, an author could easily build a sequence of content screens while managing how the user would interact with the lesson. Authoring languages, although designed for a narrow application, were still enough of a programming language to allow the developer a great deal of freedom in the actual implementation of the courseware.

In contrast, authoring systems relied on highly structured instructional strategies. A content expert using an authoring system would simply answer a series of questions presented on the screen in order to build an instructional application (Miheim, 1994, p. v). The reduced time to build an application at times outweighed the restrictions in design.
Scripting Environments

In the late 1980's microcomputers such as the Apple Macintosh developed the graphic user interface (GUI) which allowed for non-linear, event driven software. Developers had to create applications in an environment that made it very difficult to program. Consequently scripting environments were developed that bridged the gap between higher level and authoring languages. Further these environments allowed the developer the opportunity to choose the level of complexity. Scripting environments fit nicely between an authoring language and a formal high-level programming language.

HyperCard was the first attempt to allow non-programmers to develop Macintosh-like applications that would conform to the GUI interface. HyperCard allowed the developer to choose between 5 levels of complexity ranging from simple browsing to full scripting capabilities. For example a developer using HyperCard could create a card reminiscent of PILOT to construct content frames. At the other extreme, HyperCard also provides the developer with a complete scripting language called HyperTalk.

HyperText Markup Language

HyperText Markup Language is not an authoring language nor is it a scripting environment, instead it is simply tokenized text. HTML provides a standardized way of transmitting information over the Internet by incorporating embedded commands or tokens in text files that can be recognized by applications called browsers. When a browser such as Netscape or Mosaic logs on to the Internet it downloads a simple text file. If the text file is encrypted with tokens that the browser recognizes, then the file will be displayed on the screen according to the design of the developer. Even though it resembles an authoring language using the frame concept, there is no underlying programming language controlling the interaction. Instead the developer must rely on the inherent capabilities of the user’s browser. Nonetheless, HTML allows for the easy development of cross-platform applications currently not possible with traditional authoring applications.

Instructional Design

The goal of any instruction is to overcome a deficiency in skill or knowledge. A careful understanding of the instructional goal provides the designer with clear guidelines in terms of content organization, as well as determining the content sequence and pacing. Without a clear understanding of the goal state, instruction becomes muddled and unproductive. Consequently, we developed our lessons using sound instructional design practices.

The Study

Participants

The participants were fourteen advanced graduate students in a Summer Special Topics course in Instructional Technology. These fourteen students included: nine doctoral and one masters student in Instructional Technology, one masters student in Interdisciplinary Studies and 3 masters’ students in Museum Science. In addition, three students who were taking the course over a distance from the primary location.

Materials

For each lesson, the audience, task and outcome were identified. Furthermore, the content organization was determined and finally the implementation plan was decided.

Each individual lesson corresponded to traditional instructional design methodology. Issues of scope, sequence, and pacing guided our lesson design. Consequently, it was recommended that each lesson implement the following plan:

- Open with a splash screen (orienting technique)
- Use a typical frame design that adhered to appropriate sequence and pacing
- Implement guided practice
- Provide for simple evaluation

Standard HTML was chosen as the authoring environment. Furthermore, we did not use an HTML editor to produce the lessons because there is no industry standard HTML editor available to classroom teachers.

Procedure. The course was delivered using various Internet protocols such as e-mail, ftp, telnet, and http over a period of four weeks. The first two weeks included basic instruction in HTML along with a refresher course in instructional design. Each member of the class had two weeks to develop an individual lesson that corresponded to the delivery plan. The final week was spent in uploading and evaluating each individual lesson.

Results

In general, we found that HTML can be used to quickly create lessons that correspond to simple computer-aided instruction (CAI) (Hannafin & Peck, 1988). Consider Figure 1 in which the author used a mix of graphics and text to both capture the students’ attention while also providing an orientation to the content of the lesson. Notice the use of a HTML link to simulate a button that links the next screen in the sequence.
We wanted to know if we could develop lessons in appropriate chunks, which would in HyperCard be represented as a single card. The underlying HTML code for Figure 1 was a single text file (see Figure 2) that the Netscape used to display the splash screen information.

The goal was to be able to easily modify the individual screens and provide for a convenient way to reorder the sequence and pace if the instruction warranted it.

<TITLE>Problem Solving in Intermediate Algebra</TITLE>
</HEAD>

<H1>Problem Solving</H1>

This lesson is designed to provide you with an exciting, new approach to solving stated problems in Intermediate Algebra. Through the course of this lesson, you will see a structured set of steps that will allow you to solve general stated problems.

The average time spent working through this lesson is 15 minutes.

Let's begin...

</BODY>
</HTML>
```

Figure 2. HTML source code.

**Practice**

Problem: Donny's Donuts rents a standard car at a daily rate of $41.95 plus 12¢ per mile. A traveler is allowed $50 for car rental. If the traveler needs the car for only one day, how many miles can the person travel on the $50 budget?

Figure 3. HTML source text.

Instead of a single application file that includes text and graphics such as in HyperCard, HTML requires separate files for both text and graphics. For this investigation it was decided that, like individual cards in a HyperCard stack, each content screen would be constructed in a series of individual text files that would then be linked together. These links would act as buttons and would be normally indicated both by a different color than the main text as well as underlined (Figure 3). When the user clicked on the link, it would change color to indicated that this link was visited. This displays some of the limitations of HTML as an authoring language because the author must manage each link without the help of the application.

**Design Implications**

In developing Web-based instruction, we identified three major factors that educators must consider when using for the Internet for instruction: connectivity, architecture, and management.

**Connectivity** is a major problem for network-based instruction. Traditional authoring was designed for specific delivery platforms. In the Internet, the actual machine that the software will be delivered on is unknown, which can cause different display problems for the instructional designer. One result of this study noted is which platform the HTML is developed on and whether it does make a difference. However, a more pressing problem is the lack of easy and affordable access to the Internet. Slow connect times, incompatible browsers, or a lack of suitable hardware can cause problems for students and reduce the impact of the network-based courseware.

**Network architecture** is also a problem. Authoring systems typically developed and delivered the instruction using the same platform. Networks change this development cycle into a client/server relationship. This essentially removes one of the core features of authoring which permitted a content expert to control how a lesson would be delivered as well as how individual users interact with the software.

The Internet is a server-based system, which means that the content of a lesson resides on a remote computer from the one that is actually delivering the lesson. Due to the variety of different platforms and browsers it is difficult to provide true student interaction. One way to overcome this limitation is to provide a server-based solution through a language called Common Gateway Interface (CGI). In the future, this may be resolved with applications that support Java; however, simple but effective interaction can be built into the design as this study has demonstrated.

**Management** issues are also a very important consideration. Issues such as what type of server (Macintosh, Unix, PC) are crucial for longterm development and management. The type of server can make trivial issues such as file names a huge problem and require a large time commitment.

Other issues such as who provides the Domain Name Service will require teachers and educators to come to grips with the nature of other issues such as firewalls, file names, etc.

The managing of specific development issues can also be very time consuming. Even though HTML and the Internet work well in cross platform situations, questions such as which version of HTML to use, which graphic
format or the conversion of files from one format to another requires careful attention.

Conclusion
The Internet has a lot of potential to deliver quality, effective instruction but in reality is in its infancy. Over the next few years many of these issues will become moot with the development of new tools and technology. Currently, there is a tremendous interest in Java a programming language developed by Sun Microsystems to create applications for delivery over the Internet. Other technologies and even authoring environments will surely follow. Nonetheless, the results of this study simply underscore the fact that sound instructional design will always mean better instructional applications regardless of the tools used to produce instruction or the medium used to deliver instruction.

In the past few years we have been experimenting with using hypermedia in a World Wide Web environment for distance learning applications. The courseware was essentially composed of 3D representations and textual nodes interconnected at several strategic points. Most of the students reported positively on the organization of the inherent nodes of the 3D model and appreciated the utilization of referential and bi-directional links. Despite the positive results of this first experimentation, we have identified, through the analysis of students' comments and tracking issues, a common lack of intentional activation of conceptual nodes. In this paper we discuss this problem and propose solutions at the level of the visualization of a didactic component's network, in order to provide a potential guidance for students. Our solutions are based on visualizing, before selection, the nature of the reachable components and the semantic model, showing more explicitly navigation strategies. We are currently developing a markup language (AOML) and a browser (Büxis) to support these concepts. Besides various information-filtering features, the language supports differentiating the access to the same data set from different paths. The browser provides navigation and information retrieval features and manages contents visualization and fruition, through several site views, compass functions and tracking functions. Our system offers a basis for carrying out studies and comparisons on the way students utilize pedagogical resources, as well as for evaluating the recall of knowledge processing.

Iperler is an integrated system for telelearning developed at CRS4. It combines a World Wide Web browser, a 3D viewer and a synchronous collaborative tool (Salis, Scateni, Leone & Vandamme, 1995; Salis & Scateni, 1995; Salis, Leone & Benevento, 1996). Iperler presents hyperlinks from both the 3D viewer and the hypertext browser.

Experimentation with an Iperler prototype has been carried out with a small group of students from the School of Medicine at the University of Cagliari. The analysis of quantitative and qualitative data related to the bi-directional access to visual and verbal representations highlights some interesting points to be considered for future development (Salis, Scateni, Leone, & Vandamme, 1995). For the present purpose, we refer to the qualitative analysis. The following points are worth noting:

1. Most of the students who have used Iperler reported positively on the way inherent nodes of the 3D model are structured, so that it seems to enhance the progressive research of details.

2. For the same reasons, most students appreciate the use of referential nodes that link visual and textual attributes using a direct method for reaching a specific modality of knowledge presentation.

3. One of the main complaints reported by the students has been their lack of confidence that they have covered all the information. This result makes clear that since students are worried about the so called didactic contract that exists between the tutor and themselves, they do not utilize the most important property of a hyperdocument; in fact, the interactive hypernodes permit does not seem to lead students to a personal construction of a conceptual network. This problem is crucial from the constructivist learning theoretical point of view, which is granted from a significant number of cognitive psychologists. The linking mechanism is viewed as the most significant transformation of conventional learning material, but it could have no effective impact if it does not assure learners a helpful cognitive strategy.
Problem

Students are not accustomed to the non-linear approach which hypertext provides. Indeed, it is the first obstacle of student performance with hypermedia navigational tools. Not surprisingly, it has been found that knowledge of the subject matter relates to an ability to navigate in a non-linear way through the information space (Ohlsson, 1992). The hypermedia integration in the teaching practice has suffered from lack of guidance and structure in the instructional sequence.

It is true that hypertext technology has emerged to help the recognition of the idea of non-linear-thought capabilities as a great advantage for the construction of conceptual relationships. It is also recognized that knowledge construction does not necessarily derive from a linear process or from an ordered addition of an idea’s parcels. A problem arises as soon as we base the construction of hypermedia for learning on the fusion of these two assumptions: by stating (implicitly) that, as the construction of knowledge is not linear and as the main feature of hypertext technology is the non-linear access, an interactive conceptual network becomes a pedagogical solution. Duchatel (1992) reports: “Hypertext based systems do not teach, but, instead, provide the student with an excellent opportunity to learn on their own accord, as they possess minimal structural knowledge of content.” Moreover, studies processed by Messing (1990), have shown that students tend to adopt a linear pattern of hypertext review similar to that taken with a book. We suppose that by applying this strategy, students think they may increase the didactic contract and do not consider other strategies which might get them lost in an implicit knowledge structure.

We consider that a novice user does not have any reason to spend time in understanding how and why isolated concepts have been connected in a certain way. The interest in such a question might be mentioned by an expert in the knowledge domain, but is not to be expected from a novice before reaching a consolidation stage of knowledge processing. Learners go through the nodes doubting that selective activation of nodes is useful. One reason is probably due to the lack of clear advice about each nodes’ composition. A second reason is given by the fact that when learners reach a node they do not have the possibility to evaluate what another selection would show them.

The observation of how most hypernodes are reachable emphasizes that learners should assume a conceptual network of knowledge similar to that acquired by an expert in order to perform the navigation through information. We think that the cognitive overhead often discussed in the literature may issue from this problem, rather than from an inappropriate interface. If the interface presents unclear navigational tools, learners would have to face the problem of disorientation, which is a different one. Disorientation cannot be directly associated with the construction of meaning, since increasing the time spent following alternative paths could resolve the problem of covering content.

According to these considerations, we propose the study and development of a flexible mechanism for the free selection of interconnected nodes that avoids the loss of the conceptual map defined by the document’s author caused by conventional hypermedia navigation techniques.

Cognitive Approach System for Navigation Control

A Cognitive Approach System (CAS) for the control of navigation should provide the following capabilities:
1. display of the concept mapping from which the user may activate a conceptual node;
2. continuous presentation of the current node and of at least two sublevels;
3. tracking functionality, showing if a node has already been visited or has never been seen;
4. distinguishing subcomponents of a node which belong to the visual or to the verbal representational systems, in order to let users select the preferred knowledge representation form when more than one is available.

When selecting a specific medium for presentation, users should be informed about all referential links available in other formats presenting the contents of the same conceptual node.

Most of the web hypermedia systems include a navigational tool for the structure of the documents rather than for the knowledge nodes. Users may eventually be guided in using the system (commands, help, index, menu, etc.). The guidance through the structure does not solve the exploration problem for learning goals achievement.

A solution to this problem resides in the construction of a didactic tool which may support the navigation over and through the knowledge corpus. User orientation will be supported by a control panel on the screen where the concept map of topics is continuously presented. In this approach, parts of the concept map are tracked according to the location of the nodes users move in. The tracking mechanism produces a systematic update of the control panel window. Thus, the control panel may be seen as an advanced organizer for learning strategies and as a path monitor as well, in that it helps users to anticipate the nature of the content they are going to explore.

Referential Framework

Barker (1993) has individuated the three most common types of navigational tools normally implemented into hypermedia systems:
1. the trial-and-error mechanism simply involves jumping from one node to another. In this case, the user does not base his decision on a semantic link’s nature at all.
2. a second type of navigational tool is based on semantic web links priorities, as decided by the designer. Normally, the designer arranges web links in a thematic manner, which could help users avoiding getting lost. Exploration may be limited with this approach.

3. finally, a concept map tool can be used to indicate the type of material available and also the nature of links between nodes.

The concept map function is seriously limited when implemented within World Wide Web hypermedia. The limitation is essentially caused by the lack of a tracking system over the knowledge corpus, and by the impossibility to keep users informed about the status of their exploration. Furthermore, once users decide to reach a modality-specific presentation (visual or verbal), they follow subsequent links which could also be explored through another medium. Other strategies that allow the exploration of the components of a node are parallel semantic web connections that the designer thinks users should access on their own at any time along the hypermedia consultation.

The notion of parallel exploration could expand the role of the utilization of multimedia on the Web; if we want to profit of multimedia advantages a differentiated approach with respect to learning style, multimedia components must be selected by learners themselves. As symbolic systems for knowledge presentation, visual and verbal environments call for a different perception activity the users should be able to carry out according to their preferences. Because of the way we process information, these systems can be used independently or simultaneously.

Among a number of relevant studies of conceptual representation, the dual coding theory proposed by Paivio (1990) has retained our attention. The author stresses the important relation that exists between the visual and the verbal system of mental representation. It seems that this relation exists along all the phases of the learning process.

This process starts with the reception of the external input which solicits the visual system or the verbal system according to the nature of the input. As one proceeds through the coding/recoding phases, Paivio hypothesizes that the activity may happen from one of these systems independently from the source of the input. This should be due to the important influence of prior human experience which matured with a given topic. The same independence is detected at the final step, when the output or the response is generated. Rieber discusses this double coding mechanism in terms of memory effects: “. . . information encoded in both verbal and visual forms with strong and flexible links between the codes should enhance retention, retrieval and transfer” (Rieber, 1994). Such cognitive assumptions let us think of the existence of an interrelation between systems during information processing.

We start from with the cognitive assumption that human cognition may deal simultaneously with verbal and imagery codes during the knowledge coding or recoding phases. This assumption helps us define a framework that could offer a useful interface for the dual coding approach. Believing that the interconnection between modality-specific knowledge presentations should work with more correspondence to the manner human cognition works, we are developing a CAS interface facility in order to empower users with a greater control on how they orient their learning approach.

**CAS Implementation Components**

We have already developed a first version of a CAS interface facility, implemented using several existing software components, such as HTML and VRML browsers, image viewers, and sound players. The system’s core, however, is constituted by our own data organization and navigation layers.

**Data-Organization Layer**

The special requirements of CAS for data organization has demanded the creation of a new markup language, i.e. a new SGML document type (Sperberg-McQueen & Burnard, Eds., 1994), that we named Approach Oriented Markup Language (AOML). The language allows the definition of approaches through which to access an information base, thus making it possible to access the same data set from different paths. Elements also contain a keyword hierarchy to allow standard or affinity queries, as well as attributes that provide static or dynamic filtering for discriminating contents following user’s needs.

The differentiation in the dual coding theory’s systems are implemented by AOML at the node level. In an AOML document each node is a finite conceptual element and contains all representations needed for digestion. Subcomponents cannot be addressed separately, but are just classified by their belonging to verbal or visual system. User can, through this property, choose to use contents of one of the two systems or both.

**Points of View**

To fulfill aforementioned needs we have coded a Points of View (POV) system, that supports, besides various information-filtering features, distinctions between the two cognitive systems. For example, after setting a POV concerning verbal data, the user navigates in that system, until he decides to examine a parallel path or to activate both verbal and nonverbal representations, or until the author proposes a POV’s change. In any case, through the visualization techniques that we will detail later, users always know what kind of media will be used to represent nodes, which contents are already examined and what else could still be used. It is also possible to filter all the node hierarchy in order to extract (and then visualize) only visual or verbal contents.
Information-Access Layer

The information-access layer is constituted by the Buxis navigator, implemented in the Java language, mainly to relieve users from software maintenance and to give independence from a particular HTML or VRML browser.

For the time being, the tool allows navigation and retrieval of information, delegating contents visualization and fruition to other existing software, controlled using a master/slave paradigm, in a manner which is transparent to the user. Future revisions could be integrated in a single software object, in order to reach maximum interface homogeneity and simplistic installation.

Site Views

Buxis offers several site views, different by detail level and features, that can be used simultaneously, providing thus a range of advanced navigation and orientation features.

Level one, the highest-level, is the Bird's Eye View. It provides an overview of the site's graph, zooming if necessary to see more in detail some portions (i.e. arguments) of the graph, without getting into dual coding elements.

The Neighbor View, instead, involves both immediate static and dynamic (i.e. based on keywords or affinity search) arcs of the current node, in order to provide the simplest representation of all available links between conceptual nodes, without overloading users with complex nodes from physically distant nodes; furthermore, at this level nodes show if they comprise verbal, non verbal or both types of elements, as well as what kind of elements have already been visited.

Such map views cooperate with the Focus Node View, that gives maximum control on the current node (Card, 1996). This high-detail view shows different icons and comments for every element in the node, highlights if it belongs to the verbal or to the non verbal level, and gives all of its tracking information.

Orientation Aids

Buxis allows navigation through its views and follows the user when changing node using another browser (or viewer), providing a feedback and a Compass function that helps orientation.

A Graphical History Map gives another navigation landmark (Gershon, 1996). It allows the user to jump back of one or more visited nodes or sub-elements that are graphically represented by their icons.

Tracking Functions

A Track Function indicates if a node has been visited, the time of the last visit, and what kind (and what number) of subcomponents have not yet been activated.

A complementary feature is the Path Receipt which is displayed on the different views, or in a textual representation, the space-time route that users follow during exploration in order to fulfill tutor and user's knowledge control needs.

Conclusions

AOML is already refined and stable; the navigator is currently in a prototypical state. We have released the first working version last June and we are, at this moment, developing the advanced visual features. In order to implement CAS in the Iperler structure, we will proceed to the validation of a first version of the tool in the framework of a definite verification study. Given the nature of our approach, we will verify and validate the system by using a control group. Thus, the validation phase will allow us to assess the effect of CAS application through the recall method as well as through the analysis of data drawn from open questionnaires.

Acknowledgments

We like to thank Enrico Gobbetti for his valuable comments on drafts of this paper.

Research and development described in this paper have been carried out with the financial contribution of Sardinia Regional Authorities.

WEB MARKETING AS FREE ENTERPRISE EDUCATION

Robert Gillan
Northwestern State University of Louisiana

Frank Fuller
Northwestern State University of Louisiana

Public school students often develop World Wide Web design skills that seem remarkable to older, technically less-sophisticated people. The traditional values of age and seasoned experience seem at times to contradict the apparently youth-controlled worlds of the Internet, Web page design, and the alternative systems of advertising and marketing that the Web allows. Though the truth of such an inverse relationship between age and success is far from proven, small business people, especially those working in business that do not have a pronounced technology component, can feel quickly lost in a world where every national competitor shows a URL at the bottom of each television or magazine ad.

Schools alert for business partners and campus adopters can find a source for rich cooperation in this anomaly. Middle school and secondary school students, as the youngest of young Internet designers, engage with small business partners in an expertise-sharing activity that imparts to the students a new appreciation for the demands of free enterprise and provides a local outlet, as well as an enhanced appreciation, for student projects. Students help businesses designing Web-based pages for marketing and community service. In exchange, businesses, Internet Service Providers and Chambers of Commerce provide free-enterprise and occupational exploration opportunities for students and their teachers.

The primary tool for this program is the HTML-based Web page. Each teacher or teaching team tailors relevant information to extend specific curriculum goals in ways that support other class activities. Working with relevant demographics, business/marketing surveys, governmental information, maps, pictures, and other records that have a unique relevance to the school’s supporting community, further enhances required research skill.

The exploration vehicle for this innovative teaching partnership is a Northwestern State University Educational Technology Program project called MainStreet on the Web. This two-year grant, recently funded by LEQSF, addresses the following curriculum goals:
1. The project develops a model for technology integration within social studies/free enterprise curricula.
2. The project applies computer literacy skills and introduces programming design and multimedia application.
3. The project imparts relevance to state and local studies of the broader curriculum through the search for facts, marketing studies, demographics, maps, local industries, and natural resources.
4. The project incorporates the creation of schemata through designing and researching a variety of kinds of information through HTML documents and systems.
5. The project emphasizes cooperative learning through group activities involving school, community, and business partnerships.

The World Wide Web provides a system for linking each classroom with the greatest imaginable system of resources. While the global scope of those resources permits classrooms to transcend the geographical and cultural limits of their communities, MainStreet on the Web has as its primary objective a more modest ambition. Students are linked, not with infinite resources, but with the system of cultural and business activities that occur just outside the school house door. MainStreet on the Web encourages students to see familiar and local enterprises in the same context as the worldwide resources of the Web. There, they have the chance to engage in constructive investigation of local resources, both in terms generated by their own understanding and in relation to other, possibly more sophisticated, Web-based information and marketing pages. They help their local businesses develop an initial presence on the Web and, at the same time, learn from those businesses what they hold dear, have to offer, and most want to describe in their marketing presentations.

Two central players in this program, apart from schools and their adopters, are the local Chamber of Commerce and local Internet Service Providers (ISPs). The Chamber provides a standardized set of links identifying general,
governmental, cultural, and commercial resources common to many of the concerned businesses. Chamber members can provide valuable assistance in making school-with-business connections, as well as providing a framework for Web-based marketing for both the City and many of its public agencies. The development teams can encourage ISPs to provide connections for Web developers as well as special rate for new business partners. This partnership increases interest and Web utilization which repays the ISP.

There are additional benefits in this program beyond experience for students and a set of preliminary marketing tools for business persons. Business participants learn to appreciate and work with school technology personnel, both young people and professionals. Students gain valuable insight into the relationship of their current skills and their applicability to the workplace, in addition to understanding the nature of computing within a broad spectrum of the entrepreneurial system, especially within businesses not commonly thought of as technological industries.

Free enterprise classes and Web Development Teams from local schools are not, of course, going to provide Web marketing documents of professional or enduring quality. The purpose of this program is not to underwrite business marketing campaigns but rather to introduce small businesses to the Web, to introduce students to the world of business, and to introduce schools and businesses alike to each other — their skilled and committed fellow citizens of different generations and, often, surprisingly common purposes.

A prototype of this program can be found at the URL http://www.tec.nsula.edu/mainstreet.htm along with project materials which outline the development, management, and instructional considerations necessary to insure an educationally sound collaboration among participants. The files include curriculum enrichment ideas for computer literacy, free enterprise, economics, social studies, and retail marketing.

CROP: Communities Resolving Our Problems - Community Design for 21st Century Learning

Robert S. Houghton
Western Carolina University

In brief, CROP is a feature-rich and instructionally focused web site currently in operation on the Internet. The basic idea of the CROP site is to teach each other across communities, and through integrating desktop and online resources, to more effectively teach ourselves. In design, the CROP web pages consist of three main modules (SUP, LEAP, and THINK), each of which represents a different kind of educational model. These three main modules will be discussed in greater detail.

CROP promotes constructivist principles, engagement through situated learning, authentic problems, distributed professional development and learning, higher order thinking, problem solving skill development, just-in-time training, collaboration and team building, and technology integration for classrooms and communities. An easy-to-search database format provides data for on-going course improvement and long term qualitative research into the nature of questioning. CROP is also a process of value to any content area at almost any age, but adds special value to reading, writing, and social studies activities. Beyond the classroom, CROP integrates larger communities along the lines of specific problems. It also constructs social capital and provides a new kind of social history; a public record of a community's on-going work towards solutions to problems. Along the way, CROP provides a bridge from classrooms in technology transition to a twenty-first century learning community.

A Module: SUP - Problem Survey and Threaded Interaction

This module emphasizes social interaction. It promotes communication through a running survey of problems as well as contributions to those problems. As educators we know the value of authentic problems. Authentic problems engage us in specific situations, giving concrete application to our teaching. It is not that these are so hard for teachers to create, but creating them every day for every lesson is certainly a major challenge. It is a bit ironic that public schools that need real problems for their instruction are surrounded by communities awash with real-world problems, with Still Unsolved Problems (SUP). Until the Age of the Internet, we have lacked a constant means of communication between those actively engaged in the classroom and those in the home, business, government and other systems that surround our educational community. We can increase this rate of interaction through the use of the Internet which gives us a historic opportunity to do so. This opportunity has important implications for our culture in general and education in particular.

At its most basic level, this module is a database linked by form pages. These form pages allow the user to add records to the database and to search the database. When displayed, the full database records simultaneously provide a form that attaches contributions for the discussion to the thread of thought on a particular topic.

For now, preservice and inservice teachers in various courses and workshop participants are encouraged to use these form pages to enter problems; any problem on any subject. In time, as we train our local community members to use the Net (slang usage for Internet), they will also be encouraged to share in community problems. As the number of users increases, a critical mass can be achieved where every question will be likely to have an interested contributor. Further, the questions are of interest in their own right. What percentage of the questions match different parts of Bloom's taxonomy? How does this change within a particular community or classroom that is participating? The questions become both a running poll of community needs and a running history of communities problems, whether the community is a classroom or stretches to communities beyond the school building.

That databases provide excellent reporting functions raises interesting political and sociological implications. During the next debate on school financing, a school district might be able to report that several thousand community based questions were actually answered by classroom students. Interaction builds social capital as well as educational capital. Schools might also be
reporting increased student interest in community development and community service. Knowing the problem goes a long way towards generating the interest to solve it.

To be successful, the database must have a wide range of problems for a very wide range of children and adults. When this database grows large enough, those looking for problems to solve, will find extensive lists of problems on any topic. They will find real people with actual problems that could use problem-solving help. In theory, with a database of sufficient size, any teacher nearing the end of any unit could search for still unanswered problems relevant to their instructional activity.

Currently, though, the database is not rich with problems. This process of filling the database works most effectively as a team of people interested in the same area share with each other their problems and contributions: a team of employees, a classroom full of students, a region of student teachers, a group of administrators, etc. Others who are not part of our team can begin to make contributions as well. Because we are sharing our problems in a public forum. As teams and groups begin to cross-talk, many new directions are possible.

A further limitation on the growth of CROP is the state of technology diffusion. Your classroom and work situation may be in transition from no or limited technology access to something greater. You need a way to participate now without computer technology and then migrate to more sophisticated uses as your resources grow. The SUP process can be carried out with cards, tagboard and the school building library. This process will parallel important aspects of a computer-rich environment.

A Module: LEAP - A Taxonomy of Tools

LEAP stands for Look, Evoke, Assess and Perform (or Publish). Each represents a different stage of the problem solving cycle. This module is a structured toolbox in which the structure is a process for solving problems. It provides scaffolding to assist the problem-solver towards integrating a wide array of technologies and applications at different stages of the problem-solving process. Increasingly, it teaches users how to use its tools. Links to these resources are made directly from the World Wide Web (Web) pages. This module tackles another long standing issue for our field of education, providing a conceptual model for integrating technology and curriculum (Taylor, 1980).

Because a wide range of computer tools is suggested by links to these tools at each LEAP stage, LEAP widens the view of the computer-mediated tools that should be in use. In so doing, the model also builds on the wide range of cross-curricular thinking processes involving discovery learning and critical, reflective and evaluative thinking. It further complements prior work across many content areas (Germann, 1991; Peters, 1987; Clarke, 1990; Gipe & Richards, 1992). Consequently, the model has application for the learners/students, preservice and inservice teachers and administrators; this group will hereafter be called the thinkers.

![Figure 1. Simplified LEAP model.](image)

An Overview of the Simple Model

In this model, the learner looks for and collects data, constantly cycling through decisions based on relevance and interest. The quantity of data streaming through our computer networks has been likened to a firehose operating at capacity, but a firehose surrounded by the needy who are holding out small and specialized cups. To throttle this deluge and move just the needed information to the problem at hand makes management a critical skill for the learner at this stage of the thinking cycle. Further, the tremendous range of “information highway” options through our computer networks (e.g., the Internet) along with the numerous high capacity local workstation tools (e.g., the full Compton’s Encyclopedia with multimedia on CD-ROM) make for both complex and sometimes costly decisions (costly in terms of time and access charges).

These thinkers use the found information of the previous stage to evoke a response. That is, the composer must create with sufficient skills to stimulate a response from others. Without a response, the effectiveness of the communication cannot be known. The greater the communication skill, the greater the ability to put the new found information of the Look phase in a context readily understood by the creator or by the listener(s). To date, primarily just one computer tool, the word processor, has been heavily promoted for composing thought. However, not only is the text manipulated by the word processor (just one of many means of computer mediated expression like paint, digital video editing, and music, but it is no stronger than other equally available tools for efficiently and playfully mapping and guiding developing thought through the use of outliners, draw programs or spreadsheets.

The learner must next pause to assess progress. Assessment runs from low level spelling and grammar checking to reflective discussions among members of online work groups of projects underway. This stage requires emphasis on value judgment. Evaluation skills must cover the wide range of potential means of expression noted in the previous stage, from word processor programs to spreadsheet programs to multimedia. This
assessment is formative in nature. That is, the goal of assessment at this stage is to have an impact on a creation still in development.

Last in this cycle, the thinkers perform or publish their creations. Publishing implies far more than submission for a grade in a classroom. It calls for the targeting of an audience most similar to the focus of the author or creator. Publishing is sharing among peers, among those with genuine interest in a topic. Further, I use the term synonymously with perform. I intend for this stage to appeal equally to those whose means of sharing does not necessarily involve the simple frame of a page or a video screen, such as a choreographer, a conductor or a gymnast. The emerging information highway gives thinkers an instantaneous neighborhood and global reach for their effort. Yet, publishing is not really last in the cycle. Publishing often serves as the incentive to begin the cycle again, a recycling stimulated by feedback on the performance or publication. Inherent to the publishing stage is a more summative assessment of achievement.

A Deeper View of the Model

![Complex LEAP model](image-url)

The concept of a cycle facilitates description within the linear nature of an essay on paper and aids initial instruction for students. However, it disguises the nonlinear nature of the process in the real-world. The model should support non-sequential interaction between any two or more stages of the model. In a more realistic model above, the arrows go both ways and to all stages, not just the next stage.

An Overview of the Complex Model

The implication for the more experienced thinker is simple. There is no correct place to start. There is no mandated next stage. The time spent at any one stage varies with the experience of the thinker and the needs of the project at hand. Yet it is my hunch that when the project is finished and the communication has been "published", thinkers will find that the better the balance among the time spent at each stage, the higher the quality of their work.

LEAP is an extension of the work of those developing thinking process skills in many curriculum areas (Kelvin & Leonard, 1992; Pelletier, 1992; Manzo, et al, 1992; O’Loughlin, 1992; Pruett, 1993; Reschke, 1991). LEAP and the larger CROP model can easily scale to communities of many different sizes, taking advantage of the global reach of today’s computer networks (Hunter, 1992; Anderson, 1993).

Not!

A balanced discussion of new technologies must also consider actions not performed by the computers of today or of the foreseeable future. Humans, not computers, choose problems and purposes. That is, somehow a selection must be made among all the vast things at which one might view at the look stage. Our selections are based on human intentions, on problems and purposes as thinkers see them. Only when these decisions are made can computers amplify human intelligence. At each LEAP stage the most substantive actions of that stage are not taken by computer technologies, but by the value laden actions of human beings. Consequently, these actions taken at the local computer highlight aspects of thought that are unique to humankind. I pass for now a more extended discussion of the question of whether technologies can ever can fulfill them or whether it should. It is my bias that the computer cannot perform these value laden roles, but if it could, it should not; however, connecting our value systems with these wide reaching computer capabilities is essential in allowing the technology to provide the greatest possible magnification for the role of human intelligence, for the ethical direction of technology, and for the even more critical role of intelligent teaching. The importance of this issue requires educators to consider carefully the degree to which our system of education emphasizes instruction in ethics. Without a significant ethical base, increasing human power to think (through the enhanced ability to deal with information) merely empowers a two-edged sword to cut in both random and negative directions.

LEAP provides an educational framework for integrating new technologies with the critical and creative processes of finding, inventing and sharing solutions to real world problems. In the nonlinear environment in which we live, our inventiveness and our ethics, not just our forecasting skills, may yet keep the human race alive.

A Module: THINK - A Reference Room

Where the SUP module is a polling booth and chat room and the LEAP module is a workbench, the THINK branch is a specialized reference room. THINK serves as a growing reference room of resources and links to study higher order thinking skills, to explore issues in the practice of problem solving and to follow links to other thinking agendas including ethical, creative and critical thinking. As Bloom’s taxonomy and the thinking skills agenda is reasonably well known, it is perhaps more useful.
to consider why the Bloom initiative has been so difficult to achieve.

Bloom laments that years after the publication of the taxonomy of thinking, it is still not well used and worse, that the quality of thinking activity is little different in American classrooms than it was forty years ago. So, where do we go from here? I believe that Bloom and others have not gone far enough, but by this I do not mean go further in analytical divisions of thinking. Neither Bloom’s work (Bloom, 1956; Jonassen, Hannun, & Tessman, 1989) nor Marzano’s revision (1988) of it used by some states (e.g., North Carolina’s educational system) connects sufficiently with real-world problem solving. Bloom’s taxonomy is not a strategy but an analytical listing of the elements. For example, when your tire goes flat or when you need to advise your state legislator on an issue Bloom’s taxonomy does not readily come to mind, even though when finished we can analyze our process and see that at different times we used the different levels of thinking skills. One might say that Bloom’s thinking stopped short of his stages of application, synthesis and evaluation. Bloom has given us a set of tools, some bricks and boards, but not given us the design for how this becomes a house. CROP is so designed to provide the house whose blueprints reference the higher order thinking skill agenda that was given such momentum by Bloom and others.

Conclusion

Today, then, not only do we need instructional designs to apply Bloom’s taxonomy in a meaningful way, but we need models that incorporate power tools into our models of thinking. The previously discussed LEAP model represents steps in this direction. LEAP provides scaffolding to assist the problem solver with integrating a wide array of technologies and applications at different stages of the problem solving process. SUP provides engagement with authentic problems to solve and contributions to the problem solving process. CROP provides engagement with authentic problems to solve and contributions to make. In turn, the Internet provides the vehicle to deliver these new forms for extending and transforming the practice of learning and teaching. Our instructional designs are no longer bound by our physical architectures. Those interested in experimenting with the expansion of this form of learning into the twenty-first century are encouraged to contact the author.

The wide-spread use of multimedia tools often involves people from different walks of life including education specialists, designers, publishers, marketing personnel, sales personnel, and film producers. The integration of various media has proven to be a powerful means to facilitate communications and persuade users. It is the dynamics of video media and audio media that makes information absorbing go beyond the mind, carrying new human dimensions such as emotions and feelings. As most multimedia users are not computer literates, we look at how easy it is for them to produce multimedia presentations under current multimedia authoring tools by analyzing the stages, components and complexity of the authoring process itself.

Authoring

Authoring refers to the process of creating anything in any area of human knowledge, generally through the help of specialized tools. We use the name multimedia authoring when referring to the process of creating multimedia presentations using computer hardware running authoring software which deals with texts, images, audio, etc.

Authoring Paradigms - A Quick Review

Authoring should be a systematic and a well structured process. There are very few techniques specifically designed for the authoring of hypermedia documents. Currently there is no completely “point-and-click” authoring system; some knowledge of algorithm design, heuristic thinking and a basic understanding of how programs work is required (Siglar, 1995).

A number of authoring paradigms can be distinguished depending on the authoring technique used. Usually a combination of one or more of the following paradigms is found: time and flow based iconic representation such as Authorware; card based such as Apple’s HyperCard; frame paradigm; script-based systems such Hypertalk used in Apple’s HyperCard and Toolbook from Asymetrix; structure editing systems as described in the paper Rossan, Hardman, & Butlerman, 1993; object direct timing relations paradigm used in (Ryichi & Kaneko, 1990; Fujikawa, 1991); the cast score scripting paradigm; collection based as in HM-Card (Maurer, Andrews, & Scherbakov, 1994). Whereas time- and flow-based authoring is intuitive and best suited for rapid development, it does not capitalize on the inherent modularity of the presentation.

The use of index-card structure makes the card scripting paradigm less attractive because of its low performance and long learning curve. Therefore, the script paradigm offers a strong interactivity with the environment and better flexibility.

Some of the paradigms are biased towards specific applications. A case in point is the cast score paradigm which has better handling of interactive presentations and animations where synchronization is of prime importance.

Structured systems, (see Rossan, Hardman, & Butlerman, 1993), define where and when objects are presented on the screen or on audio channels. Structure-based authoring is far from being intuitive and requires a greater learning curve than the time- and flow-based one, for example.

The Authoring Model

The Active Context-Based Authoring Model (ACAM) is a distributed multimedia generic authoring model. It defines four main modules for presentation, authoring, hypermedia and distribution support. The full model is described by Kelner, Djamel, Sadok, and Ricardo (1996). The authoring module is the object of study in this paper. It is divided into two main parts: authoring in the large and authoring in the small.
Authoring in the Large and Authoring in the Small

A major drawback identified in existing authoring systems is that they deal with the authoring of multimedia information and ignore the conceptual phase of a project design.

This work considers project authoring as an important part that is essential to the authoring process. Many authoring applications require a macro vision enabling them to provide a big picture of the subject being presented. At the project level, a graph with application links can be used to show the way these components are related to each other. This mechanism was first used in the HDM model (Garzotto, Paolini, & Schwabe, 1991; Garzotto, Paolini, & Schwabe, 1993; Lucena, Rossi, Schwabe, & Cowan, 1995).

Authoring in the small refers to the process of instantiating the types/classes/concepts/structures defined during the previous stage.

ACAM’s Authoring Methodology

A methodology for this development work, with stages representing the natural and intuitive course of an authoring process, was established. Starting with a generic model, successive refinements are applied until it results in the author’s target application.

The methodology consists of the four stages:
- Conceptual Modeling - an open authoring stage allows the modeling of real world situations. It defines relations among topics/subjects/themes;
- Navigational Modeling - defines the navigational aspects through the promotion/election of parts of the topics/subjects/themes to the status of nodes;
- Presentation Modeling - the presentation interface and user interaction aspects are defined; and
- Instantiation - multimedia data is created and associated with the elements of the presentation according to the pre-established author’s model as defined in the previous stages.

ACAM’s Authoring Paradigm

The discussion has shown that different paradigms have different strengths and that there is no single one that outperforms all the others for all considered applications.

The Proposed Paradigm

In order to support the above requirements, the ACAM user interface adopts a balanced combination of the following paradigms: time line and flow icon based paradigm to allow direct manipulation of multimedia objects and links; in order to facilitate the understanding of complex applications, ACAM adopts the idea of context, supported by the collection paradigm, and found in systems such as in HM-CARD. Contexts modularize presentations into manageable hierarchical objects and avoid overwhelming the author with information; run-time execution information can also be stored in the objects themselves, independently of the time line as adopted in the direct timing relation paradigm; support for structure editing and automatic derivation of synchronization information; a script language is used to provide better interworking with other applications.

An Analysis of the Authoring Process

To implement the four ACAM’s modeling parts, namely, conceptual, navigational, presentation and instantiation, the proposed paradigm defines six stages that an author may execute sequentially or in a cyclic way. These are:
- application parametrization: defines parameters controlling the application. Examples of these maybe the levels of users, the application purpose, users’ age, presentation language, etc.
- definition of blocks, sub-blocks and relations: here the application is structured in information blocks and sub-blocks (see Figure 1). The way these are inter-linked is also defined here; therefore, the system may derive from here the navigational model. The way a block is going to interact with another one, through the use of a selection button or after a given time has elapsed, is defined later together with the information that makes up a block. A user may select a block and define its graphics, context and synchronization information separately from other blocks, therefore guarantying their reuse and extendibility.

**Figure 1. Project Authoring.**

- definition of media objects: involves the creation of multimedia objects using the menu option “Object” (see Figure 1). Objects will be subsequently associated to their respective blocks (see Figure 2). Created
objects are then added to the system's object library. Library objects may be real ones (such as sound, text, image, or video files) or significant names that will be instantiated later on.

Figure 2. Creating Presentation Frames and Objects.

- **defining the graphics information for a block**: when clicking on the node, the author can select the option "Diagramation" and a window containing graphical tools is provided. These graphical tools, except the sound icon, are used to define the frame location and size (see Figure 2);
- **assigning objects to blocks**: the objects of each block will be retrieved from the “Object Icon Palette” and dragged to the frame which the object must be associated. The window where this task is carried out simply covers the previous information ensuring that the structural scheme remains visible during the whole process (see Figure 2);
- **definition of the flow and object synchronization of a block**: using this option the author may define temporal relationships among the objects of a block, through the use of a time-scale flow line, in order for these relations to be as visible as possible (see Figure 3);

Figure 3. Object Synchronization.

Conclusions

In this paper we have presented an authoring paradigm that, unlike existing ones, focuses on the author as well as the final authoring application or product. We have shown, through a comparison of some of the existing paradigms, that there is no overall best paradigm but that a suitable combination of these may produce better results. Core to this paradigm are the initial stages identified, namely the parametrization and project design phases. The proposed paradigm combines the use of icons, the time line and structured authoring.

The pace of medicine in today's society has quickened. With the explosion of medical information, medical education has struggled to keep pace. In addition, the changing health care environment means faculty have less time for bedside teaching and demonstrating physical diagnosis. Overall, this has left medical students alone trying to bridge the gap between learning core medical knowledge and using that knowledge to care for patients. In addition, advancements in medical technologies such as CT and MRI imaging have taken much of the mystery out of making diagnoses. Many times these machines will make the diagnosis for you (Whitman & Lawrence, 1991). However, "[r]adiologic or ultrasonic examinations, CT, and the vast array of laboratory tests available to all of us today will not compensate for a poor or incomplete history and physical examination" (Silen, 1991, p. 7). Over-reliance on technological aid has led to decrease in the quality of problem solving skills among younger physicians. The ever widening gap between learning and using information indicates that the need to teach problem solving is greater than ever.

Traditionally, the hypothetico-deductive method is taught to medical students. This is the diagnostic process of focusing on one or more evolving diagnostic hypotheses. The hypothesis can fall into several forms: a state, a clinical disorder, a syndrome, or a specific disease entity. Usually, the doctor will begin this process simply from the patient's age, sex, race, and presenting complaints. Additional hypotheses emerge as new findings are discovered (Abernathy & Hamm, 1995). This model obviously works well because it is what most doctors use. However, this approach is ill-suited to some fields, notably surgery. In trauma, emergencies, and operative situations, there is rarely time to reflect and formulate formal hypotheses. Therefore, experienced surgeons have developed problem solving skills and intuition to cope with these situations.

Whitman and Lawrence (1991) discuss five reasons problem solving should be taught. First, patients do not present with a disease, they present with symptoms. Physicians must apply factual knowledge by moving from symptoms and physical findings to a diagnosis. Problem solving enables the student to transition from data gathering to data interpretation. Second, due to today's hectic medical teaching pace, there is a decrease in contact between students and teachers. This places the burden of learning to interpret information on the student. Third, students who use problem solving and systematic approaches to diagnosis save time and money by using fewer tests and arriving at a correct diagnosis more rapidly. Fourth, there are some medical diagnoses that only can be made through problem solving. For example, there are no tests that will tell a doctor that a patient has acute appendicitis. One must weight the factors for and against and arrive at a conclusion. Finally, in operating rooms and emergency situations, surgeons must continue to rely on their problem solving abilities because information is changing rapidly and many times a decision must be made before all the facts are gathered. "Problem solving when taken to its highest level becomes superb judgement" (Whitman & Lawrence, 1991, p. 97) or intuition. Surgeons must develop problem solving skills which will later evolve into intuition.

The material that is taught to medical students, especially in surgery, is increasingly complex and ill-structured. Typical instructional methods which teach isolated medical facts, will fail to accomplish important educational objectives in part because of the oversimplification of the material presented. This oversimplification results in the inability to transfer knowledge across to new and varied domains (Boger-Mehall, 1996). Since one cannot learn every fact for every situation, the new surgeon must be taught problem solving skills that will allow him or her to think with flexibility and apply their knowledge across many situations.

The most common method of teaching problem solving is through the use of patient scenarios or "scripts."
Recently, The New England Journal of Medicine started featuring “Clinical Problem Solving” which uses thinking aloud scenarios to highlight the thought processes involved in making medical decisions. This “script” or “hypothetical patient” approach to teaching medical thinking gaining popularity.

The mind of a master surgeon has been compared to that of a master chess player. It is thought that both have a kind of “intuition” that allow them to determine the next move. According to Abernathy and Hamm (1995) “Intuition” often means that part of thinking which cannot be explained...[I]n general, intuition refers to remarkable mental performances that move rapidly yet unaccountably to correct conclusions” (p. 23). On a practical level, intuition is the ability to recognize the whole from the sum of its parts.

A 28-year-old man with a stab wound to the left chest in the midaxillary line, 6th intercostal space. His vital signs are pulse 120, blood pressure 120/80...A left chest tube produces 400 cc of blood. Diagnostic peritoneal lavage (DPL) shows 3,000 red cells per cc... While you are preparing the patient for laparotomy, another 1,000 cc of blood comes out of the chest tube. You take him to the operating room, and first you explore the chest, finding an actively bleeding deep laceration of the left lower lung...Oversewing doesn’t work. It is still bleeding. (Abernathy & Hamm, 1994, p. 39).

Situations in real life are not black and white as they are presented in many texts. In the scenario above, it is the “intuitive” application of knowledge to the given situation that enables the surgeon to help the patient. For any problem there is not a universally right or wrong approach, rather each problem is patient specific. Often there are several coexisting problems, and in some cases, time doesn’t permit the gathering of all the facts before a decision must be made. Thus, the development of problem solving skills and intuition best enables surgeons to apply their knowledge to an array of problems in changing and varied situations.

The goal of curriculums that teach surgical problem solving and intuition is for the students to gain the characteristics that master surgeons possess. These surgeons are clear thinkers that are not distracted by false leads. They can link their present situations to past experiences quickly and accurately. They know what questions to ask and how to prioritize their actions. Three ingredients necessary to create a master surgeon are: (1) surgical practice, (2) intellectual curiosity, and (3) an ability to look back on cases objectively (Abernathy & Hamm, 1995). Teaching surgical problem solving and the use of scripts promote the aquisition of these necessary ingredients.

Unlike problem solving, intuition cannot be directly taught. The instructor must provide opportunities for the student to acquire this skill. The script approach allows students to examine the thought processes of master surgeons “as they consider problems and make decisions about them” (Abernathy & Hamm, 1995, p. 11). Abernathy and Hamm (1995) discuss the potential benefits of using scripts to teach surgical intuition. As a student reads a script, it provides a framework on which to hang additional textbook information. While an actual patient is always the best teacher, the use of scripts allows the student to experience a wider variety of patient situations than one could ever encounter in real life. This provides the students with “experience” upon which they can draw for future patient encounters. Scripts also allow exploration of the risks and benefits of different decisions and how they impact the patient’s outcome with impunity for poor decisions. They may also be used by cognitive scientists to better understand how expertise is acquired (p. 11).

Utilizing the script approach to teach medical students will give them the opportunity to think flexibly and intuitively. According to cognitive flexibility theory, the way students are taught has a significant influence on the type of cognitive structures they create. The manner in which students store and structure knowledge acquired determines to a great extent how flexible they will be when using that knowledge (Boger-Mehall, 1996). Cognitive flexibility “…includes the ability to represent knowledge from different conceptual and case perspectives and then, when the knowledge must also be used, the ability to construct from those different conceptual and case representations a knowledge ensemble tailored to the needs of the understanding or problem-solving situation at hand” (Spiro, Feltovich, Jacobson, Coulson, 1991, p. 24). Flexible instructional methods (i.e. problem based learning) help students learn the contours and complexity of the material they are studying, and it helps them work with that content from several different perspectives (Spiro, Feltovich, Jacobson, & Coulson, 1992). The flexibility of the students’ knowledge structures allows them to apply their knowledge to novel and varied situations.

Although the content of the scenarios must be created by experts in the surgical field to create the best learning environment, the method of instruction is crucial to cognitive flexibility theory and the development of intuition. Scripts must provide multiple presentations of the same information, and there should be many concrete examples of the uses of a given concept(Dick, 1991). In addition, scripts should provide opportunities to utilize the same information for different purposes.

Through the development of problem solving and intuition, higher order thinking skills are acquired. These skills are nonalgorithmic and complex (ill-structured). The path which surgeons take is neither visible nor specified in advance. Higher order thinking skills lead to multiple solutions, each with benefits and costs. Many operative situations will require the application analysis of multiple
criteria, sometimes conflicting with each other. A surgeon with higher order thinking skills can derive meaning and direction in situations where there is apparent disorder. Overall, this level of thinking requires effort. There is considerable work involved in making these kinds of judgements and elaborations (Abernathy & Hamm, 1995).

With advances in technology in today's society, traditional medical education can be enhanced to teach skills that aren't learned during lectures. Lecture is a teaching format that is ideal for well-structured domains such as anatomy and biochemistry. These do not require the flexibility that ill-structured domains like clinical medicine does. Traditional systems such as textbooks and lectures lack the flexibility needed. Each case in medicine is different requiring doctors to be cognitively flexible. With appropriate supporting material, the computer is a well suited tool to teach in a flexible method. It provides the variability needed to present ill-structured material and to help students explore more than one perspective on a topic or issue. Technology provides a nonlinear, multidimensional medium in which complex subject matter can be taught. The power of technology supports a flexible approach that uses multimedia and hypertext systems.

Advantages of computer instruction include for students to work independent of faculty thereby requiring less faculty time commitment. Students can also return to the program for additional studying if desired. The logistics of coordinating students and faculty into class meetings is alleviated, and there is no limit as to the number of students who can utilize the program. Self-contained programs can be exported to other schools via CD-ROM or World Wide Web. Some new technologies allow the student to utilize the program from home or other remote sites.

Using technology to teach surgical problem solving and intuition is gaining interest in several medical schools across the United States. Computer programs can be used to teach problem solving skills and to encourage the student to integrate and process information instead of memorizing.

UNIVERSITIES are usually successful in creating, gathering, and imparting knowledge. They are less successful in applying that knowledge to instruction. Academic researchers recognize the valuable addition of technology to communication, efficiency, and decision making, but whiteboard and paper remain the primary teaching materials in most classrooms. There have been efforts in the academic community to move from a paper-based classroom to a paperless classroom. Unfortunately, these efforts have usually been isolated and generally have not tailored technology to support various student learning styles. This paper presents a paperless classroom implementation that uses technology to support the model of learning appropriate to a particular learning situation. The focus is not on the technology but how the technology enhances learning.

**Goal**

The Department of Electrical Engineering and Computer Science of the United States Military Academy (USMA) is in the sixth year of an on-going project to use technology to enhance learning. The goal is to use information and educational technology to make the transition from a lecture-based, paper-centered learning environment to a discussion-based, paperless one. Lectures and texts are linear in nature, while learning has long been recognized as a non-linear sequence of events. By reforming and reorganizing the way learning material is presented, the paperless classroom enables students to be more efficient in their learning. Applying the paperless classroom concept facilities an active learning environment that uses distributed resources to contribute current information to the student.

The current learning environment is for the most part instructor driven using in-class resources. Students attend lectures where topics are developed and discussed and then depart the classroom to hopefully practice or review concepts through readings and homework. In the cases where there is audio or video employed to demonstrate a concept, there is usually little linkage between the mediums. The paperless classroom desires to change to multimedia and hypermedia, linking media and concepts to cater more effectively to students’ learning styles and academic desires.

**Background**

**Problem**

Despite the proliferation of computer networks and information technology into the classroom, instructors and students still use paper as the primary means of assigning and submitting graded requirements.

**Solution**

With computer networks, such as local area networks (LAN) or the World Wide Web (WWW), instructors assign, assess, return, and discuss student projects without ever using a piece of paper. This not only saves the cost associated with paper products but also gives the students the ability to display a broader range of information in multiple media. This effort is primarily a pedagogical step towards identifying and implementing student-created multimedia in a current technical course.

**Previous Work**

There is a wealth of research on the positive effects of technology in the classroom (Leidner, 1995). Studies on the introduction of video clips into classroom instruction show that video clips are motivational for students. It has been shown that instructor consoles contribute to both perceived and actual information structures. Classrooms with both instructor workstations and videodisks improve student attitudes about the instructor and the course. Several institutions have reported positive results from the use of electronic mail (email). Overall, the body of literature convincingly illustrates that new technology positively influences student attitudes toward the quality of the instructor and course organization. Several institutions besides the USMA have attempted to institute paperless classroom concepts (Brown, 1994; Lane, 1995; Shneiderman, Alvi, Norman, & Borkowski, 1995); however, none of these efforts have been as broad or as enduring as the efforts at the USMA.
The evolution of a paperless classroom began over six years ago in CS383, Computer Systems. Previously, assignments were handed out in printed form. Lectures were delivered using overhead slides, and students read and annotated printed text books. In 1990, the Academy purchased large screen monitors for all computer classrooms, enabling instructors to deliver material through presentation graphics. At the same time, the Academy network was established, allowing students after-hours access to the instructors' slide show materials. Instructors embedded multiple media items into the slide shows to accentuate or expand on certain concepts. The course was well on its way to becoming an all-compassing multimedia in the classroom, but was still tied to a text course resource.

When the Academy network reached the student rooms, the course began to make serious inroads in the pursuit of the paperless classroom. Students were emailed assignments and given access to shared directories on classroom servers, making it easier for students to ask specific questions or submit class assignments. Multi-user dimensions (MUD) were created and used for student interaction. Other interactive forums were list serves and electronic bulletin boards. They are all used with varying success.

In 1994, course media elements and slide shows were incorporated into a system of Web pages that allowed students a nonlinear access to the course material. A learning style assessment was added to help students approach the massive amount of material contained in the WWW course resource. A hypertext reading file gave students a new way of pursuing a topic through the reading assignments (Carver & Howard, 1995). For the last two years, efforts have been dedicated to expanding the media coverage throughout the lesson material. Throughout these technological innovations, the overriding focus was enhancing the learning environment for the students. Technology that distracted from or did not add to this focus was discarded.

Requirements Planning

Before beginning the odyssey of purchasing and implementing vast amounts of information technology, it is useful to articulate actual requirements. Based on experiences at USMA, the following questions can help ensure that all participants of the budget and planning process are clear on the intent and execution of the transition plan.

Where Are We Teaching?

In this step, instructors should focus on the physical locations of the student and the instructor. If the instruction is delivered in the classroom, one should focus on information presentation. If the student uses the course resource outside of class or in a distance learning situation, connectivity and supporting referential materials are important. If using the resource as an integrated tutorial or help system in the work place, structuring the information to answer specific questions is the dominant design theme.

What Are We Going To Teach?

Multimedia is not the goal. The information technology integration process must focus on using multimedia or hypermedia as the means to the end. The goal should always be making learning more efficient. By considering how applicable particular technology is to the target subject, an instructor can assess and articulate where and how technology will affect the lesson. Experience shows that at the beginning of the transformation lesson content will be the same as it was in the older style class. Later, instructors discover they can cover more material in less time due the power of the multimedia and hypermedia presentation.

Who Are We Going To Teach?

Just as text books are selected so that they are at a meaningful and realistic level for their students, technology used in a paperless classroom should not overwhelm the course material nor scare the students away. Before purchasing any technology, instructors should survey their courses to determine the degree of computer literacy and the overall level of comfort with technology. Experience shows that younger students seem to adapt easily to on-line systems, while older students have difficulty reading large amounts of text from a computer screen.

How Are We Teaching?

Technology should allow lecture based courses to migrate easily into discussion-based ones. The key is to create active learning environments. Instructors should consider how they have organized their courses and then find ways to implement new tools. For example, large lecture courses could benefit from having notes, slide shows, or recorded lectures placed on the campus network for student reference.

Learning Environment Tasks

Deliver Instructional Material

Perhaps because professors, instructors, and lecturers perform the task of delivering instructional material on an almost daily basis, this area has seen most of the advances in recent years. Starting with notes written on a chalk board, instructors have progressed to view-graphs and presentation graphics slide shows.

The next step is the use of multimedia to enhance the information content of the presentation. This can be done in several ways. The first is to use several separate media sources and have the instructor switch the presentation between them. For example, he might show a slide show, then switch to a video cassette by turning off the projector and turning on the VCR and TV. This solution has the elegance of simplicity but is hindered by the fact that not all faculty are comfortable with the technology involved in
operating and maintaining all the different media devices. A more advanced technique would be to embed the multimedia objects into the slide show and have the instructor select them when they are appropriate to the presentation. The use of embedded graphics has been implemented using Hypertext Markup Language (HTML) and the WWW. Using web pages that link to multimedia files, the instructors use the web browser to select and play the various media files. So far, maintenance has not been an issue due to the wide variety of media formats available through most web browsers.

Another benefit to delivering instructional material electronically is that students can tailor the way they receive the information by their learning style (Carver, Howard, & LeVelle, 1996). In CS383, students take a learning style assessment that adapts the lesson interface through the material based on their individual learning style. Used for three semesters now, this assessment tool is implemented using the Felder Learning Model. While this has been successful in a robust multimedia course such as CS383, further work is being carried on to validate the benefits of an adaptable interface to an on-line course reference.

The future of delivering instructional material lies in reaching students outside the traditional classroom environment. This is not only crucial to the student living in a remote area (Farinetti & Malnati, 1996) but is also important to schools with limited enrollment in some courses (McShane & Shaw, 1996) one way to accomplish this is to record video or audio tapes of classroom lectures and mail them directly to students or place them on a Web site or networked computer. While this does enable the instructor to deliver material, experience (Hubbard, 1996) as shown that students quickly become bored with the "talking heads" and are frustrated by their inability to ask questions.

Delivering instructional material can also be achieved with video teleconferencing (VTC) systems. While the cost of these systems range from hundreds to thousands of dollars, their implementation is the same. One instructor sends video and audio signals to students at another location. The students can interact with the instructor by using the system on their end of the conversation. At this time, VTC has been used primarily for guest lecturers.

**Interact with Students**

Once the basic instructional material has been presented to the students, they will often respond with questions or comments that help them gain a better understanding of the material. Traditionally this has been done in lecture classrooms, through office hours, and laboratory sections. The common thread to all three methods is giving the student contact with an instructor as well as instigating conversation among the students as a class. In large courses or situations when the student cannot conveniently travel to the instructor's location, this is typically the first area of education to suffer.

One method for generating student interaction is to use electronic mail (email) to pose queries, answer questions, and pass along assignments and assistance. A more open forum can also be generated by a mailing list, such as a USENET news forum, list serv, or bulletin board system. In these applications, one student's question is passed to all users that are subscribed to the list, allowing many people to comment and keep up with a discussion. Another method that uses computer connectivity to foster interaction is the use of Multi-user Dimensions (MUDs) to enable students to interact with instructor. At both Georgia Institute of Technology and the USMA, faculty members hold virtual office hours by logging in to the MUD at specified times. Students can pose questions on certain topics in theme rooms, where the question is available to anyone entering the room (Dieberger, 1996).

One of the more innovative means of interacting between students is with a game. The CS383 course uses the action-adventure game DOOM to pose multiple choice review questions to the students (Carver & Gregory, 1996). The goal is to place the students in a familiar environment (a computer game) and then encourage studying through a competitive application (answer the question correctly or your game character dies.) This has been extremely successful and, with a free editor available through the WWW, been maintained to keep pace with the course.

**Assign, Receive, and Evaluate Assignments**

To increase comprehension of the material, most courses assign projects and papers that force students to demonstrate an understanding of certain concepts. Assignments are given out in CS383 through links on web pages, files on networked drives, and email to students. They search library resources using automated databases, browse the WWW using search engines, and request material from information services like ERIC and Lexis. These are all available to most instructors, but experience has shown that students must be encouraged to use them. Project requirements to include a multimedia component or hypertext link to outside sources are the first step in showing the student that information is available through sources other than the text book (Adams, 1996).

When the project is due in a paper-based classroom, students print out their paper or project and hand a folder to the instructor. This is not only inefficient and costly but it also denies anyone else the benefit of student research. One simple method of electronic student submission is to create a shared directory on a networked computer and require students to place their submissions there. The instructor can access them at anytime and the projects are available for later use. Care must be taken, however, to prevent the spread of computer viruses and electronic
copying between students. Passwords, permissions, and logs have been useful but not totally effective.

The most elegant method for receiving and evaluating assignments is to have students create Web pages and submit their projects as HTML files. This has been done successfully at Brown University (Landow, 1996) and USMA. Not only does it allow student research to be available, it is also a vehicle toward expanding projects beyond linear text. Students are able to include graphic, video, and audio components in their projects that were not previously available. The drawback is that electronic submission requires projects to be graded online. Qualitative evidence in CS383 has shown that it is no more difficult than reading printed papers.

Assess Understanding and Assimilation

Finally, every course has an evaluation or assessment component. As with the other categories of classroom tasks today, this is mostly done through printed examinations and possibly scanned answer forms. This method has several widely recognized drawbacks:

1. Tests are costly to create in terms of instructor time. Usually, multiple editions of a test must be created to allow fairness between separate sections of a course.
2. Written examinations are costly in terms of time spent evaluating the student responses. Although electronic grading is useful, its restriction of multiple choice tests is too confining for most instructors.
3. Consistency of evaluations can vary because of the time pressures placed on graders. An answer that earned a B at dinner time might earn an F at 3:00 AM!

Automated Testing can alleviate these issues. Quizzes can be given through scripts and test programs (Carver, Ressler, & Biehler, 1995) or games (Carver & Gregory, 1996). The advantage to these methods is that a computer can create an almost endless number of different multiple choice and short answer tests with little effort and grade them all consistently. In the case of CS383, the Student Response System can give tests that adapt to the user’s demonstrated level of knowledge (Carver & Ring, 1996). The drawback to these methods is one of student validation. Passwords and user names are not stringent enough to prevent students from getting other people to take tests for them. There is also the question of time constraints. Both of these issues are addressed by having the student take the exam in a computer lab at a specified time. In this way, a proctor can verify the student’s identity and ensure that the test is completed in a set amount of time.

The Value Added

Whenever educators and technologists begin discussing ways to introduce technology into a classroom environment, the question of value added or return on time invested immediately surfaces. While it has been shown that students enjoy and are challenged by learning in a paperless classroom, CS383 has also shown that instructors can teach more efficiently. Preliminary or reference information typified by objectives on the lower end of Bloom’s Taxonomy can be delivered outside class through electronic means. This frees the instructor’s time to enable higher level concepts to be discussed and exercised during limited lecture or interaction time (Howard & Lane, 1996).

Another, perhaps more tangible, benefit is that studies have shown that students who learned via online multimedia retain the information as long as or longer than with only text (Howard & Carver, 1990). Information retrieval is also more efficient, if certain structural methodologies are applied when creating the electronic course material (Adams & Carver, 1996).

Challenges

Each step along the path to a paperless classroom has requirements for integration and maintenance issues that must be resolved in order for the technology to continue to be beneficial. At a minimum, instructors must have the knowledge to place material on networked computers or create multimedia resources for their courses. Following this, of course, is the requirement for students to be able to access the material from their dorm rooms, classrooms, or study areas. This investment into connectivity and network infrastructure is not trivial in the short run, but it shows substantial returns in the long term.

Initial decisions to implement a certain piece of equipment or technology must be made after consideration for both integration with current equipment and expansion in the future. Most institutions have adopted an open systems approach rather than tying themselves to a particular operating system or platform. Normally, their funding does not allow for replacement of equipment within the projected eighteen month obsolescence cycle.

Funding is the most contentious of all the issues raised in this paper. It is undeniably difficult to find funds to initially purchase equipment or software. Additionally, one must budget for proper staffing to ensure maintenance. There needs to be a sustained flow of funds. Another budget planning item is upgrading and eventually replacing equipment. Depending on the technology, this period varies between one and five years.

Conclusion

There are varieties of opportunities for using technology to implement the paperless classroom. Technology is the means to increasing learning efficiency. One can use technology to better display information, increase access to information, improve information sharing, and organize better class presentations. Technology is not a panacea for educational problems, but by combining technology with applicable learning models, the overall quality of education is enhanced. Students raised in an age of technology
demand student-centered and led learning. Educators must discover and develop how to implement new technologies into the learning environments and focus efforts on facilitating learning—not implementing “multimedia toys.”

EDUCATIONAL EVALUATION OF CALLIGRAPHY: APPLYING FUZZY REASONING

Seiichi Shimizu
Kawamo PR.

Hajime Yamashita
School Waseda University

Recently, the computer-assisted instruction (CAI) system and multimedia system have been developed, but the fuzziness exists when we decide our educational evaluation; especially, in the case of sensitive evaluation such as calligraphy, art and so on. The authors would solve such a problem by applying fuzzy reasoning.

In this paper, we would not only discuss the analysis method, but also illustrate its practical effectiveness with the case study concerning calligraphy education in primary school.

Introduction

Although computer and the other educational technologies have been developed in the last ten years, the fuzziness concerning many educational evaluation decisions exist. Compared to the evaluation of Mathematics and English, the evaluation of calligraphy and art, what we call artistic subjects, are affected by the teacher's subjectivity. Especially in the educational evaluation of these artistic subjects, it is most difficult to evaluate students' works objectively. When teachers evaluate them they are driven into a difficult situation, because they should mainly evaluate the sensitive aspect of the students' works; however, the fuzziness of these sensitive aspects prompt teachers to shy away from objective evaluation.

In order to solve such problems, we have developed an evaluation method for calligraphy education through the application of fuzzy reasoning.

We would firstly explain our new analysis method and present its practical effectiveness for the students' works in calligraphy evaluation.

Analysis Method

We propose the process of calligraphy evaluation applying fuzzy reasoning which is shown in Figure 1. Generally, the student's works in calligraphy education could be evaluated by two aspects; one aspect is technical, and another aspect is sensitive.

Next we explain the process of evaluation methods while applying fuzzy reasoning:
1. construction of evaluation tree;
2. preparation of evaluation standard and reasoning rules;
3. establishment of evaluation membership function;
4. analysis of works and execution of fuzzy reasoning; and,
5. evaluation of result by fuzzy reasoning.

Let the technical variable be \( x \) and the sensitive variable be \( y \), then the evaluation function \( z \) of a work could be defined by the following:
\[ z = D(x, y) \]

Moreover, the technical aspect could be evaluated by its sub-aspects such as the formatting, the balance, etc. And the sensitive aspect could be evaluated by its sub-aspects such as the vividness, the dynamics, etc.

Let the formatting variable be \( x_1 \) and the balance variable be \( x_2 \) and let the vividness variable be \( y_1 \) and the dynamics variable be \( y_2 \), then the evaluation functions for \( x \) (technique) and \( y \) (sensitivity) could be respectively defined by the following:
\[ x = D_1(x_1, x_2) \]
\[ y = D_2(y_1, y_2) \]

According to these analyses, we could construct an evaluation tree which is shown in Figure 2.

The value of each function \( D_1 \), \( D_2 \) could be measured by several ways, but we would evaluate them applying fuzzy reasoning proposed by Mamdani (1974).
Let the evaluation value of x and y be by three levels, H (high), M (middle) and L (low), and the evaluation value of z be by five levels, A (excellent), B (very good), C (good), D (fair) and E (poor) then we have the nine reasoning rules which is shown in Figure 3.

Figure 3. Reasoning Rule.

If we define the membership functions for the evaluation of x, y, and z, then we could evaluate each work of students calligraphy. We decide most suitable membership function which are based on expert teacher’s knowledge. These membership functions are the most popular triangle type proposed by Mamudani (1974).

Case Study

We would present a case study of the calligraphy evaluation which has been experimented at fifth grade in primary school. The student’s work is shown in Figure 4, which we would evaluate according to the fuzzy reasoning mentioned above. The calligraphy looks fairly well-formed and nicely balanced, so we could decide that x is H (fairly high) in aspect of the technical evaluation; on the other hand, it looks neither so vivid nor dynamical, so we could decide that y is M (middle) in aspect of the sensitive evaluation. Therefore, we could have the function $z = D(H, M)$ and evaluate the calligraphy. When the fuzzy reasoning is executed, we get the final results. By the defuzzification, we have the gravity-centre z. We have $z = D(H, M)B$; then, this calligraphy could be evaluated B which implies fairly good.

In this way, we could evaluate the calligraphy works by applying the fuzzy reasoning. We are integrating the observant opinion of veteran teachers for this analysis and they say the same.

The analysis method is not only effective for such evaluation, but also useful for educational training of the novice teachers. If the novice teachers evaluate students works by this method, they could obtain similar evaluations as the expert teachers.

Conclusion

We have discussed a new evaluation method for calligraphy education by applying fuzzy reasoning and have illustrated its practical effectiveness with a case study in primary school. The evaluation method is useful for calligraphy education; and, moreover, it could be also used for educational training of the novice teacher.

Finally, the authors are grateful to Prof. L.Zadeh of University of California for this research.

With the dissolution of the old USSR and the further fragmentation of countries across the globe it appears at times that we are all swirling out of control and growing farther apart. At times the world seems to be fragmenting with chunks growing further and further apart but, simultaneously, it feels as if the world has grown smaller, more friendly with bigger, broader, and brighter with friendships around the world. We've all been on a journey of discovery, ours, an incredible trip from Greenville, North Carolina eight years ago to 1997 in Orlando, Florida, USA. Part of what makes it such a fascinating trip, and a reassuring one, is this International section of the Annual. As you read the accounts of teacher educators from around the world notice the number of articles coauthored by educators in different countries and reflect on the continuum we are part of.

The path of technology infusion is very similar for each of us; perhaps it is a collection of paths that crisscross, weave in and out, present differing vistas and different difficulties, and, for some, even dangers, but still there are the same barriers, the same epiphanies, the same successes. Each year editing this section I am reminded of the beliefs, the ideas, and the concepts that bring us all together: the education of our future through the education of teachers who can use technology to break down barriers to learning and construct realities from dream castles spun on the Web, sided with shining CDs, and windowed with the Internet and CuSeeMe, giving views of the world we never dreamed of but views our children and grandchildren will live in. Let this section stand as symbol of the interconnectedness of humanity and of the path we are all on.

Sections Decisions
Every year it becomes more difficult to decide the placement of papers into discrete sections. More and more we encounter proposals that seem to fall into one category only to have the papers fit better in another. It would seem the simple thing to do to place the paper in the more appropriate stack, but in reality it is quite difficult so we tend to let papers stay with their original editors. There are 20 or 30 other papers we would have liked to appropriate for this section for they really provide us with additional international views; however, every paper in this section could be rightly be claimed by other section editors as well. Papers in this section cover telecommunications, preservice education, graduate education, distance learning, special needs — the list goes on.

We attempted a Venn diagram of our papers and section topics, but it began to resemble an explosion in a bicycle wheel factory so we gave up and were forced to get to the business of editing and arranging.

Several years ago readers of the Annual traveled via articles from the West to the East; it seems fitting that the trip be reversed this year. Start with the global overview provided by the Chisholm, Irwin, and Carey article. Their initial analysis of perceptions and attitudes towards computers across continents is the first stage of developing a crosscultural research tool to explore learning and computer use.

Asia
After that initial review we land in Malaysia. Keng-Soon Soo describes the positive results of using interactive video in ESL classes. Going north across the South China Sea we explore two projects in Taiwan, the Republic of China. The first, described by How-gao Hsu, Dar-chin Rau, Yen-dann Lin, and Shih-shion Liou, review the results of the Faculty Cultivation Code of 1994. They report on the three research methods used to gather data and formulate ways of improving the educational practice component, i.e. practicum or student teaching, of teacher education. The second paper, also from this group of authors, focuses on training art teachers in the integration of computer multimedia for use in primary schools' fine art and craft classes.

Almost due north from Taiwan rests the largest city in mainland China, Shanghai. Authors Weiguo Feng, Yi Lu, Yuren Wu, and Maochang Que, from two Shanghai
universities, describe the rising need for more foreign language speakers and, thus, more teachers of foreign language. They explore existing technologies that are available to students and teachers, both in schools and at home. They also discuss the projects sponsored by the Audio-Visual Educational Committee, a subcommittee of the National Committee of Education, to increase the use of technology in teaching.

The second Shanghai article, by Chen Xin with American coauthors Julie Bao and JoAnn Lan, tells of an interesting method of IT dissemination — through a testing program delivered by the Shanghai Television University. The incredible numbers taught and tested would be a daunting task in any situation, but is a Herculean task in this period of Shanghai's rapid growth.

Shanghai makes an excellent gateway into mainland China. The next authors, Zhang and Bao are at the Universities of Maryland and Shippensburg respectively, but their article reviews China 5000, a virtual learning center, on the WWW, with China related materials. This is a major resource for IT in Chinese studies.

Southern Europe and Western Russia

Leaving China and moving west we pick up signals from a distance learning system in Patras, Greece. Bouras, Lampsas and Spirakis describe Open and Distance Learning (ODL) as learning from telematics. The TRENDS project uses ODL techniques for the development of inservice and distance learning. Leaving Greece we cross the beautiful Ionian Sea to Italy, where three authors from the University of Calabria, Frega, Grego, and Volpentesta, work with Meeus of Le Réseau, Belgium, to develop telematic services for training those with reduced mobility. This project is part of an employment initiative of the European Union and involves many regions of Spain, Germany, Austria, Belgium, and Italy.

Retreating from Western Europe across the Black Sea we stop at Rostov-on-Don where Kramarov, Rozina, & Mezhevikin report on the initial steps they have taken to involve students, faculty, and inservice teachers in IT. They focus on using the Internet for research and professional development. While still in Russia we head north-northwest to Saint Petersburg where Zhengin of the Herzen State Pedagogical University, with Mims of State University of West Georgia (USA, not formerly part of the USSR), describe how political changes have led to new education paradigms. The new paradigms affect three aspects of the educational process: content, structure, and technology, with technology becoming a priority.

Northern Europe and the United Kingdom

Leaving Russia, again heading due west, we encounter Helsinki where the University of Helsinki has linked a large urban school with a small school in northwest Finnish Lapland to provide a virtual classroom where students in both locations participate and learn. This project is described from different perspectives in two separate articles, one by Jukka Husu, the other by Heikki Kynäslahti.

Turning south we enter Germany and arrive at the University of Bonn where Cremers, Lüssem, and Sunderkamp have developed a WWW-supported course on graph theory for teachers. The initial part of the course is modularized into learning units, with each unit having a number of components and ending in an automatically generated test which provides immediate feedback. In the second stage students work in small groups to develop greater understanding of the concepts. In the third phase all students work together to create a common hypertext document.

From Germany we cross the North Sea to Scotland arriving via a number of web sites identified by Walker, Curran, and Hattler (Chatham College, Pittsburgh, USA) who prepare their students electronically for a junior interim abroad. Their use of technology enabled others who could not make the trip to share is some of the learning.

At the other end of this British Isle we hear from Brunner and his partner in New Jersey, US, about their Internet exploration. Exciting aspects of this paper are their use of video-conferencing and their review of the experiences in two voices. Also of interest are their issues to be addressed which begins with the social and moral aspects.

Africa

Before we hear further west we turn south and visit the continent of Africa. At almost the southmost point sits Port Elizabeth where Greyling and Calitz examine the new challenges for Information Technology departments. South Africa has a growing need for a computer literate workforce and meeting that need begins in the schools; however, students have great difficulties passing the IT courses. The authors examine the possible causes and look at proposed solutions. A key element seems to be the language difficulties such as when the instructor does not speak the first language of the student, or a language has no equivalent word for some technical part and/or no equivalent concept.

South America and Mexico

Once again headed west we leave Africa for the New World. Recife, Brazil is the easternmost point of South America. Jurema, Lima, and Filho with their colleague Dalmau in Oregon report on how the prepare educators to face the challenge of instructional technology. They point out that "the challenge facing educators today is not just to use computers at school, but to use computer education and informatics to mediate improved social and learning relations in schools." In addition they identify a number of foundational premises for developing a program based on
the pedagogy of informatics that includes the very interdisciplinary nature of IT, the need for learners to be active participants, and the idea of a new cultural resource being created when students and teachers work cooperatively.

Our final paper takes north west from Brazil to Mexico City where Vallejo, Espinosa, Brito, and Tames discuss the development of a department to aid faculty who wish to create educational technology materials for their courses as well as to direct IT projects that enhance students learning. The department brought together an interdisciplinary group that has overcome a number of difficulties to develop a new virtual university.

A Guiding Memory

This year the annual is dedicated to the memory of Brent Robinson. For many reasons the size of this section and the Annual in general is due in part to his fine efforts as Vice President in charge of international affairs. He has been our conscience, reminding us Americans that the World does not see things through our eyes nor perceive things through our experiences. At times I think he viewed us somewhat like well-intentioned puppies who still needed house breaking; we are a young and brash nation. In any event Brent kept us humble, sometimes amused, sometimes irritated, always challenged to become better neighbors. I fervently hope that we may continue to grow in that wisdom and that in some way this section, dedicated to sharing papers from around the world, may add to that growth.

Acknowledgements

A special thanks to Linlin 'Irene' Chen, a UH doctoral student who helped us edit several of the papers in this section.

Dee Anna Willis is coordinator of the graduate and undergraduate introductory courses in instructional technology for teachers in the Department of Curriculum and Instruction, College of Education, University of Houston. Her research interests include technology diffusion in teacher education, site-based teacher education, and the use of IT in initial teacher certification.

Tracy Morrow is a doctoral IT student in Department of Curriculum and Instruction, College of Education, University of Houston. She is interested in instructional technology in business as well as in teacher education.
PERCEPTIONS AND ATTITUDES TOWARD COMPUTERS ACROSS CONTINENTS

Inézs Márquez Chisholm
Arizona State U, West

Leslie Irwin
Arizona State U, West

Jane M. Carey
Arizona State U, West

Through American schools have more computers than schools in other countries and a much higher ratio of computers to students (Anderson, Beebe, Lundmark, Magnan, & Palmer, 1994), the presence of hardware does not guarantee equitable access to technology for all students (Arias, 1990; Dunkel, 1990). Lamentably, “the poorer, non-Anglo-American, limited English proficient students have least access to computer use in schools” (DeVillar & Faltis, 1991, p. 112). Even when schools with large low socio-economic and minority population have computers, frequently there is limited availability of varied technologies, a disproportionate use of drill-and-practice applications, and defective, inoperative, or outdated hardware. Moreover, these students are not likely to have computers at home. Consequently, to meet the diverse needs of our multicultural population, teachers must have both computer and cultural competency. Cultural competency hinges upon cross-cultural knowledge and understanding of preferences, attitudes, and perceptions of technology.

Similarly, university study-abroad programs, faculty exchange programs, and international business studies require an understanding of computer training preferences among various cultural and international groups. As we learn more about ourselves and our global neighbors, we become more effective partners in the technological world. Also, evidence shows cross-cultural differences in educational traditions as well as social and cultural philosophy (Yoder, Shaw, Siyakwazi, & Ylin-renko, 1993). These differences likely correspond to differences in teaching and learning preferences, so awareness of international differences in attitudes and perceptions toward computers may provide insight into the challenges of becoming a computer literate society.

Computers are a cultural artifact; as such, they reflect the cultural, perceptual, and cognitive perspective of their creators. The resulting computer culture is individualistic, analytical, and sequential (Chisholm, 1993). However, this computer culture may not be compatible with other cultural groups and their preferred ways of interacting, organizing, learning, working, and thinking. Moreover, the introduction of computers, especially into non-Western and Third World countries, will likely induce changes in interpersonal behavior, communication, and education (Darr & Goodman, 1993). The computer, as a tool, organizes knowledge, reshapes work and learning environments, and expands information access. In the same way, social, cultural, and political factors define how computers are perceived, used, dispersed, and experienced. Thus, the computer culture generates changes in the recipient native culture and, in turn, the native culture influences how computers are learned, used, and perceived.

Developing countries face a dichotomous dilemma of need and accessibility. There is a necessity for computer literacy to participate in the global exchange of information, trade, and the benefits of computer technology in education. On the other hand, the introduction of computer technology is viewed as a massive financial burden and a socio-cultural intrusion on traditional societies with fragile economies, high illiteracy, few skilled workers, high unemployment, malnutrition, and even starvation (Hawkridge, 1990). Though these countries have imported computers from more technologically developed nations, access to computers is still limited. Both logistical or problems of infrastructure (such as the lack of electricity and telephone lines in some areas) and resource problems (such as the small numbers of trained people to maintain the hardware) limit access. Further, humans tend to naturally resist change. Attitudes and perceptions of computers in these countries, therefore, may be ambiguous at best.

Research suggests that negative attitudes and unfavorable perceptions of computers adversely affect computer literacy (Chen, 1986; Dambrot, Watkins-Malek, Silling, Marshall, & Garver, 1985; Lillard, 1985; Loyd & Gressard, 1984; Marcoulides, 1988). While positive attitudes increase the likelihood of achievement, negative attitudes decrease the attainment of competence (Lloyd &
technology, rather than passively be absorbed or demolished. In short, the indigenous culture should shape technology education stemming from a multicultural perspective. In a survey of adolescents from Victoria, British Columbia, and Shanghai, People's Republic of China, they found Chinese students had significantly more positive attitudes toward computers than the British Columbia students. Consequently, the authors seek answers to the following questions:

1. Do preferred ways of learning about computers differ significantly across cultures and countries?
2. Do attitudes towards computer technology differ significantly across cultures and countries?
3. Do attitudes towards computer technology differ significantly across ethnicity?
4. Do perceptions of usefulness of computer technology differ significantly across cultures?
5. Do perceptions of usefulness of computer technology differ significantly across ethnicity?
6. Is increased access to computers related to more positive attitudes toward computer technology?
Methodology

For the purposes of this study, the researchers define computer attitudes as a learned predisposition to respond in a consistently positive or negative manner towards computers. This definition is derived from Fishbein (1972). Attitudes consist of three components: cognitive, affective, and conative (Assael, 1987). The cognitive component consists of a person’s beliefs, which can be informational and valuative about an object. The affective component represents the person’s overall evaluation of computers. The conative aspect is a tendency to act toward the computer in a positive or negative manner. Computer perceptions are an awareness and discernment of computers based on personal opinion, knowledge, and experience. Perceptions are ways of finding out, both through sensing (fact finding) and also through intuition (finding meanings and relationships) (Briggs Myers, 1976). Computer access in this study refers to the extent to which computers, as well as varied applications, are available to an individual. The instrument used for data collection hence reflects these definitions.

Instrumentation

The authors developed a four-part questionnaire addressing computer training preferences, computer attitudes and perceptions, and computer access. The first section gathers demographic information such as age and college major. The second section asks fourteen questions about computer access and training. The third section, a four-point Likert with twenty-seven questions, investigates attitudes and perceptions toward computers. The final section, a four-point Likert scale with thirty-six questions, explores training preferences and perceptions of computer technology.

A graduate student from mainland China with six years of experience teaching English as a Second Language translated the questionnaire into Mandarin, and a native Spanish-speaking university professor in Bilingual Education translated the questionnaire into Spanish. Foreign language faculty then translated the items back into English. This process ensured the accuracy of the translations.

The pilot questionnaire is now being administered to American college students majoring in business and education at a metropolitan university in the Southwest. Results of this pilot will help refine the instrument and provide reliability and validity data.

Procedure

The researchers are sending copies of the questionnaire to collaborating faculty at urban universities in the targeted countries. Instructions included with the questionnaire contain specific instructions for achieving uniformity in its administration. A cover letter to the participants assures them of their anonymity. The collaborating faculty will administer the researcher-developed questionnaire to one hundred freshmen education and business students at each participating institution. The researchers will also obtain data at two community colleges. These community colleges are located in a large metropolitan city of the Southwest. One of the two colleges has a large minority student population; the second has a large majority population. Faculty will collect and return the completed questionnaires. In addition, the collaborating faculty and the researchers maintain continual communication via electronic mail. This rapid and direct form of communication facilitates articulation and provides expeditious responses to queries.

Summary

This paper describes a study in progress. It includes a review of the literature, purpose and research questions, methodology, instrumentation, and procedure. By the SITE conference presentation of this paper, a pilot study will have been conducted and corresponding data analyzed.

The researchers speculate that computer perceptions and attitudes among freshmen university students in developing countries are similar to those found in the United States during the late 1970’s and early 1980’s when personal computers were not widely used in this country. The researchers also believe that there may be more congruency between freshman students from a minority-rich community college and the samples from developing countries than between that same community college and the community college sample from a majority community. It may be that access to computers and previous experience with computers may be more important to attitudes and perceptions about computers than the state of development of the country in which the students reside.

The researchers are interested in the relationship between computer culture and native cultures. It may be possible to discover links between attitudes and/or perceptions and training effectiveness suggesting better training within specific cultures and across cultures. Knowledge of computer training preferences and other data generated from the research will assist in the development of international business programs, international exchange programs, and secondary education. The findings will also provided useful information on culturally compatible instructional approaches for developing computer skills among students of different cultural and national backgrounds.

COST-EFFECTIVE ESL INSTRUCTION WITH INTERACTIVE VIDEO: THE MCALL PROJECT

Keng-Soon Soo
Universiti Malaysia Sarawak

Like other Asian universities, Universiti Malaysia Sarawak (UNIMAS) must grapple with the problem of improving students' level of English proficiency. Over 80% of undergraduates are required to take courses in English proficiency. Other Malaysian universities are leaning toward a 'no-exemption' proficiency English policy, meaning every student must take English proficiency courses. To compete in the global economy, Malaysians must be able to use the recognized international language, English, at a level of proficiency acceptable not just to themselves but also to the international community (Soo, 1995). This represents an enormous challenge in terms of human, monetary, and physical resources. It would be nearly impossible for conventional English proficiency programs to meet this challenge. Soo and Ngeow (1995) proposed a new multimedia computer-aided language learning (MCALL) program to cost-effectively overcome the bottlenecks of conventional English proficiency programs. They demonstrated that from a cost-effectiveness perspective, such a program compared well with conventional teacher-taught classes (see a revised version of the cost-effectiveness comparison in Table 1).

The enormous savings made possible by the MCALL program makes it very attractive to institutions with the organizational flexibility and the technical expertise to implement it. However, the most important question remains: Are MCALL classes as effective as conventional classes?

The MCALL Program

The MCALL program was designed to provide a learning environment based on the following constructs:

1. Adopting an Internationally Recognized Benchmark of English Proficiency

No evaluation process is perfect, and standardized tests have been heavily criticized for many inadequacies. However, stakeholders such as administrators and employers want to know how well students are doing in their courses. Where the professed objective of a program is an internationally recognized level of proficiency, an internationally recognized evaluation tool, such as the Institutional TOEFL, is preferable. A widely used test simplifies comparing student achievement across institutions and even boundaries and is one of the simplest ways to demonstrate the effectiveness of any proficiency program.

2. Returning Control of the Learning Process to the Learners

Students expect teachers to teach them the English language as if they are empty 'sponges' waiting for teachers to fill with knowledge. Unfortunately, hard-working and well-meaning teachers have tried their best with little success to transmit lexical items, grammatical structures, and communication strategies into the blank minds sitting passively in front of them (Rogoff, 1994). In many instances, vocabulary and grammatical rules are internalized, but when it comes time to communicate, the language produced violates even the most basic rules of grammar and is often inappropriate to the context.

Recent learning theories suggest that learning is an active process of constructing meaning rather than acquiring knowledge. Following this line of thinking, instruction should be a process of supporting the process of construction and not merely transmitting knowledge (Duffy & Cunningham, 1995). This construction process requires learners to individually construct their own understanding by interacting in authentic situations. Because learners are central to this process, they must have ownership not only of the learning process but of the problem itself. Therefore, students should be given autonomy in setting up their personal learning objectives and take responsibility for their own learning (Mar-Molinero & Wright, 1993).

3. Redefining Teachers' Roles

In this new paradigm, teachers are no longer transmitters of knowledge but are coaches, mentors, and managers of the learning environment to aid their students in constructing knowledge. Scaffolding, or supporting, learners is a very demanding job. In addition to being...
subject experts, teachers must be experts in learning psychology as well.

Although learners have ownership of the problem, teachers ensure that the problem is authentic and sufficiently challenging and that learners do not go off the proverbial cliff in their attempts to solve the problem. In some ways, computers can help, but teachers must acquire a measure of technical expertise as well. In short, in this new learning environment we need a "super" teacher acting primarily as a "resource provider and mentor, with students as apprentices who gradually advance themselves...to gain an increasing measure of skill and independence over time" (Pennington, 1996).

4. Utilizing Digital Multimedia Language Learning Courseware on a Massive Scale

Although conventional CALL research has a history of at least thirty years, effective application into education has been scant. This may be due to the limited capabilities of the early, heavily text-based CALL. In comparison, multimedia is a far more powerful medium than traditional CALL, but comparing the two should be done as cautiously as comparing the computers of today with those of a decade ago. In this paper, multimedia is defined as a hypertext format consisting of a combination of video and audio instructional materials on a common platform to create a data-rich, intellectually stimulating learning environment allowing constructive higher-order learning. Rather than the all-too-common rote drills that actually constrain learning to low-order learning, the multimedia mind-tool should promote the conceptual understanding stemming from successful construction of knowledge resulting from puzzling and reflecting on one's new experiences in the light of one's prior knowledge (Jonassen, 1996).

As multimedia technology has only recently matured and its application into language learning is far from advanced, its effects must be researched. The effectiveness of multimedia CALL compared to that of human teachers is in question because language is largely creative and skill-based. The computer itself, devoid of creativity and intelligence, cannot adequately "teach" creative and intelligent learners the use of a creative skill (Jonassen, 1996). However, certain types of computer activities such as authentic simulations of language tasks are well suited for higher-order learning. To create a realistic learning environment, often there is no better tool than well-designed and well-managed multimedia courseware.

Method

To test the effectiveness of the learning environment, from July 5 to October 26, 1995, UNIMAS set up an MCALL Laboratory (Soo & Ngeow, 1995) to compare the effectiveness of MCALL classes with conventional teacher-taught classes. Learner achievement was used as the basis for comparison. Unfortunately, because of technical difficulties with the laboratory, the MCALL component of the experiment did not begin until August 9. In other words, the conventional classes had a five-week headstart over the MCALL students, who had no language lessons during this period.

Sample

The student population consisted of first-year undergraduates who were enrolled in their first semester of college. The students were from a heterogeneous population since, in Malaysia, enrollment in universities is controlled by a central body ensuring that each university has a representative mix of ethnic groups and SES. The students averaged 21 years in age and 11 years of English proficiency instruction in school.

Instrumentation

Upon entry into the UNIMAS experiment, all participating students took a placement test, the Institutional TOEFL. Students scoring 550 or more were exempted from taking any proficiency courses and, therefore, did not participate in the experiment. At the end of the experiment, the students sat for a parallel test. The Institutional TOEFL was chosen as both the pre- and post-test because of its high reliability and validity.

Assignment to Experimental and Control Groups

Participating students were first randomly assigned to ten English classes. Six of these were randomly chosen to serve as the experimental group. Students in these classes would learn English in the new learning environment outlined in the MCALL program. Besides using the computer, the experimental group could also use a workbook that came with the courseware. In the remaining four classes (the comparison group), students were taught in conventional teacher-taught classes. These classes used a grammar text and other supplementary teaching aids such as newspapers and audio tapes in their lessons.

*Groups of 3 students to 1 computer lowers cost per student. Alternatively, with the same number of students, equipment requirements can be scaled down three times.
Negotiation of Goals
Consultations were held between each MCALL student and the researchers to determine their achievement goals. These goals referred to their target scores at the end of the experiment. Considering the students’ goals, the researcher offered suggestions as to the amount of learning time the individual student should spend in the MCALL laboratory so that the student could achieve his goals. Formal commitments stating the minimum amount of lab time were made between the researchers and each student.

Assignment of Student-Mentor
In the experimental group, five to eight students were assigned to a senior who served as their mentor. Mentors monitored the students’ learning progress and attendance records as well as acted as the liaison between the MCALL teacher-manager and the students. The student-mentor also did basic housekeeping tasks to staff the MCALL laboratory. However, they did not provide any teaching to the students.

Extraneous Factors
The main objective of this research compared the effectiveness of the MCALL program to conventional teacher-taught classes. However, the outcome may be skewed by some extraneous factors.

Race. Few studies have examined the effects of race in relation to instructional methods. Scott (1995) found no relationship between race and posttest scores of students. Strohsahl (1994), however, found that non-white male students performed better than non-white female students and better than both white female and white male students on language achievement. In light of this, race was included as a factor analyzing results.

Gender. In introducing new instructional methods, especially those based on technology, the possibility of differential effects on the achievement of male and female students cannot be ignored. Clariana and Schultz (1993) found a significant interaction between gender and achievement in mathematics computer-based instruction (CBI) but not in language arts CBI. Roy (1993) found no difference between males and females learning with CBI at all grade levels. However, Strohsahl (1994) found that male students outscored female students in language achievement when CBI was used. In view of the mixed trend and to ensure educational equity, gender is also included in the analysis.

Analysis
Instructional Methods
Using a repeated measures design (SPF-p.q), the performance of the experimental and control groups was compared using instructional method as the independent variable and the pre- and post-test scores as dependent variables. The post-test scores were significantly different from the pre-test scores \[F(1,185) = 133.20, p = 0.0001\]. The 39.17 point increase for MCALL students was significantly different from the 26.28 point increase achieved by the students in conventional classes at \[F(1,185) = 5.25, p = 0.0231\]. Obviously, the MCALL program is significantly more effective than the teacher-taught classes (see Table 2).

To analyze if this significant difference could have been caused by race or gender, two models using a common repeated measures design (SPFpr.q) were used. Race and gender were the independent variables, and the dependent variables were once again the pre- and post-test scores.

Race
